of the daily logarithmic rentabilities distributions, within each evolution subperiod and on its whole, the results were the values comprised in table one.

By watching the average values presented in the mentioned table, there is also a confirmation of the delimitation in numbers of the two subperiods of adjustments/decreases (*a* and *e*) reported to those of accumulation/increase (*b*,*c* and *d*), also differentiated according to the intensity of the previous by gap evaluated tendencies. A decrease of the volatility of the stock market is also confirmed, it is being quantified by the evolution of standard deviation values associated to daily rentabilities, but also through the reduction of the amplitude between extreme rentabilities (maximum-minimum). At the same time, it is being observed that, in the case of market decrease subperiods (*a* and *e*) an intensification of the daily average volatility can be recorded, resulted according to the documented realities in case of most stock exchanges.

If we look at the average value and the standard deviation associated to the daily rentabilities of the five subperiods from the evolution of the BET index as estimates of return series and risk, we can analyze the evolution of the risk-return series relation, by using figure number 2.

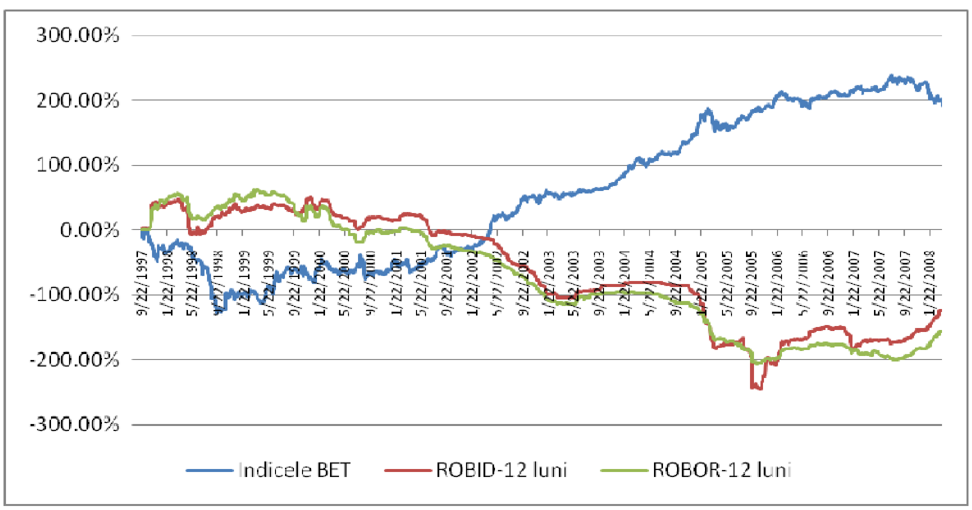
As one can notice, there is an inverse relation between the two, the subperiods *a* and *e*, which have generated significant negative rentabilities, *b* recorded the highest volatility, while in the case of the subperiods *c* and *d*, the average positive rentabilities were accompanied by small volatility values. Apparently contradictory, the inverse relation between the two concepts can be explained by dint of reasonings associated to the evaluation model of equilibrium assets (CAPM): the increase of the market risk leads to the increase of expected return series and indirectly to the fall of share prices, for shares which were overvalued.

The relation between the stock market and the interest rate level in the economy

As it resulted from the conclusions of empirical studies which investigated the relation between the stock market and macroeconomic variables, the evolution of the interest rates in economy represents a potential candidate for the role of causing factor. In this respect, we have chosen to analyze the evolution of the daily interbank interest rates in Romania, in the period between the 19th of September, 1997 and the 21st of March, 2008, on available maturities: a week (1W), a month (1M), three months (3M), six months (6M), nine months (9M) and a year (12M), both for passive rates (ROBID or P) and for active ones (ROBOR or A).

In order to be able to analyze the possible relation to the evolutions of the Romanian stock market, we will successively transform the initial chronological series of the interest rates in series of percental modifications. By estimating the correlation between the evolution of the rentabilities recorded by the BET index and the evolutions of interbank interest rates on different maturities we could notice the absence of any significant correlation. The explanation for the small degree of correlation of the two variables can consist of the fact that the relation between the two phenomena is not manifest on the level of daily data, but on longer time horizons or that the relation is, nevertheless, also manifest on the level of daily data, but in a lagging manner. Due to this reason, we have represented in figure number 3 the evolution of cumulated return series, associated to the BET index and to the ROBID and ROBOR rates, with a 1 year

Figure 3: Evolution of the cumulated return associated with the BET index and the interbank interest rates ROBID and ROBOR with a maturity of 12 months



Source: Author's own manipulations.

maturity, in order to be able to compare on the level of the entire analyzed period the possible connections between the three variables.

From the above graphic representation one can clearly see the manifestation of an inverse relation between

Table 3: Estimațiile parametrilor regresiei liniare dintre rentabilitățile zilnice ale indicelui BET și modificările relative succesive ale ratelor interbancare ale dobânzii active

	A1W	A1M	A3M	A6M	A9M	A12M
a (intercept)	0.0010	0.0010	0.0010	0.0010	0.0010	0.0010
t-stat	2.8600	2.8600	2.8500	2.8200	2.7700	2.8300

R^2	0.0000	0.0000	0.0000	0.0003	0.0009	0.0008

Source: Author's own manipulations.

the ascending evolution of the Romanian stock market and the evolution of interbank interest rates during the entire analyzed period (19th of September, 1997 - 21st of March, 2008), the graphics of the two phenomena appearing like a double mirror image. Thus, we can assert that the result obtained in the case of the other stock markets is being confirmed, that means a negative correlation of the stock market with interest rates in the economy, with the mention that this relation is not significant on the daily evolution level.

Although such a representation is extremely suggestive, stock exchange investors with a shorter investment horizon cannot use it in order to formulate forecasts based on this relation between the stock exchange and the interest rates. In order to do this, statistical modellising of these connections take place, their performance being tested.

In the following, we will analyze the utility of modellising a regression on daily data regressions level between the two variables, starting from the premise of a linear relation. Tables no. 2 and 3 contain the estimates of the regression parameters modelled between the series of daily rentabilities of the BET index and the series of relative successive modifications of the active and passive interest rates.

Table 2: Estimates of the parameters associated with the linear regression between the daily return series of the BET index and the subsequent daily changes of the passive interbank interest rate

	P1W	P1M	P3M	P6M	P9M	P12M
a (intercept)	0.0010	0.0010	0.0010	0.0010	0.0010	0.0010
t-stat	2.8500	2.8700	2.8800	2.8800	2.8800	2.8700
ß (panta)	0.0014	0.0075	0.0142	0.0105	0.0090	0.0089
t-stat	0.3400	0.6900	0.7700	0.5400	0.3800	0.6100
R^2	0.0000	0.0002	0.0002	0.0001	0.0000	0.0001

Source: Author's own manipulations.

Thus, it is being confirmed that, both in the case of passive, as well as in the case of active interests, very little of the daily variations associated to the BET index are applied, the most significant influences being exerted by A9M (0,09%) and A12M (0,08%). At the same time, it is being confirmed that, between the index and passive rates there is a direct relation, while in the case of active rates, excepting A1W, an inverse relation is being recorded.

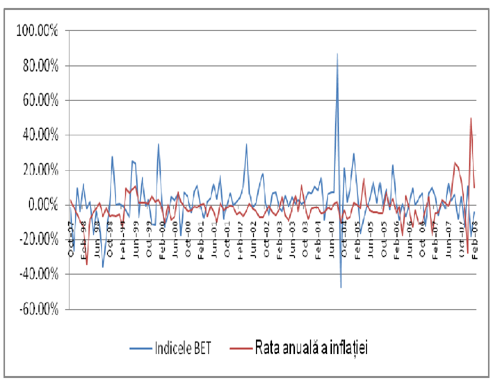
On the other hand, by repeted attempts, it is being observed that, when we estimate the rentabilities of the index according to the lagged series of the interest rates, the 8 period lag is being frequently remarked as having a superiour explaining power. For instance, in the case A12m(-8), the result for the gap parameter of the regression is an estimate of -0,0409, this time, a significant value (t-stat = -2,51), which leads to a coefficient of determination R^2=0,27%.

The relation between the stock market, the inflation rate and the unemployment rate

Within this section, we will analyze the relation between the monthly rentabilities of the BET index and the monthly percentual modifications of the annualized inflation rate (in the period between between September 1997 – February 2008, sample of 125 monthly observations) and of the unemployment rate (in the period between February 2002 – February 2008, sample of 73 monthly observations). In figure no. 4, we have represented the monthly percentual evolution of the BET index, compared to the monthly variations of the annualized inflation rate. As one can notice, there is no significant correlation between the two and, moreover, there are periods in which the high volatility, associated to a variable, cannot be found in the volatility of the other one (in the period August-September 2004, in the case of the BET index, respectively by the end of the year 2007 and the beginning of the year 2008 in what inflation is concerned).

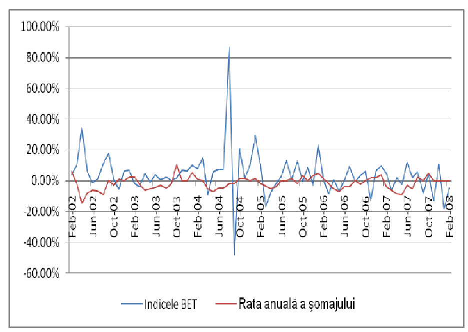
As a confirmation, the estimate of a liniar regression between the BET indexand the inflation rate, analyzed on monthly data ($R_{BET}=a+b*\Delta^{\%}Rate_{of\ inflation}$) does not lead to significant results: a=0.0245 (t-stat=1.92), b=-0.0677 (t-stat=-0.46) şi R^2=0,17%. By extending the analysis on the lagged series of the two variables, after successive attempts, we noticed the fact that a larger part of the variation of the BET index is explained by the modifications of the inflation rate 14 months ago, there being an inverse relation between the two. By estimating the parameters of the regression, in this case we obtained the following values: a=0.0343 (t-stat=1.81), b=-0.4222 (t-stat=-2.04) şi R^2=2.80%.

Figure 4: Monthly percentage changes of the BET Index and the annualized inflation rate



Source: Author's own manipulations.

Figure 5: Monthly percentage changes of the BET Index and the annualized unemployment rate



Source: Author's own manipulations.

A likely situation can be found also in the case of the relation of the stock market with the unemployment rate. The comparative evolution of the variations of the two variables is being presented in figure no. 5. The estimation of a linear regression between the BET index and the unemployment rate on monthly data ($R_{BET}=a+b*\Delta^{\%}Rate_{of\ unemployment}$) does not lead, either, to the obtaining of a significant relation. Thus, in the case of the two parameters, the following values can be found: a=0.0413 (t-stat=2.25), b=0.0093 (t-stat=0.022) and R^2=0,17%. Again, trying some models by using lagged series leads to a bettering of the significance of the relation, for the unemployment rate, lagging by 10 months with regard to the rentabilities of the BET index the following parameters being obtained: a=0.0522 (t-stat=2,69), b=1,1286 (2,57) and R^2=8,33%. As a result, in this situation, there is a direct realtion between the two phenomena, the parameters of the linear regression being significant from the statistical point of view.

Also, the fact that the evolutions of volatility associated to the stock market cannot be found, not even lagged, in the case of the evolution of the unemployment rate, balances the scale even more in favour of the lack of a significant relation between the two variables.

By taking into account the manifestation of a first degree self-correlation within the framework of the rentabilities of the BET index, we have estimated the parameters of a model AR(1) (in this case, the BETSOM(-1) variable). to which we have added as an exogenous variable the monthly unemployment rate variation, with a 10 month lag (SOM(-10)). Table no. 9 presents the results of the estimate of this regression. In the case of this regression, the value of the adjusted determination coefficient R^2 can be remarked (19,87%), which is by far superiour to all other regressions, which means that approximately a

fifth of the monthly variations of the BET index are being explained by the two exogenous variables: the series of the monthly variations of the BET index, with a one-month lag, respectively the series of monthly variations of the unemployment rate, with a ten-month lag.

Conclusions

As we could see, from the three analyzed macroeconomic variables, only the inflation rate and the unemployment rate have lead to the estimation of significant relations to the variations of the stock market. Thus, between the monthly variations of the BET index at a given time and the monthly variation of the annualized inflation rate 14 months ago, an inverse relation can be observed, which results from most of empirical studies conducted in this direction. In the case of unemployment rate, the relation between the two variables is a direct one, the reduction of the unemployment rate leading to the reduction of the return series of the BET index. Apparently paradoxical, this relation can be explained by the fact that, on a stock market with a long-time growth tendency, the continuous shrinking of the unemployment rate is associated with the possibility of the over-heating of the economy and with an emergence of inflationist pressures. In any case, the two macroeconomic variables account only for 2,8%, respectively 8,33% from the variations of the BET index, significantly reducing their influence upon stock market evolution.

BANKS

THE ANALYSIS OF THE CREDIT RISKS IN THE BANKING ACTIVITY

Apetri Anişoara Niculina

University "Stefan cel Mare" Suceava, Faculty of Economic Studies and Public Administration, Universitații Street , nr.13, Suceava 720229 , Romania, e-mail: anisoarad@seap.usv.ro, Telephone: 0330-101130, 0230-522978 interior: 314

Abstract: We could say that banking risk is a phenomenon which appears during the banking operations and which induces negative effects to those activities by the deterioration of the business' quality, the elimination of profit and even losses are registered. In this paper I shall present in short the way in which the financial and nonfinancial analysis is made in the Romanian banking system, as instruments of quantification of the credits risks and as a way of managing it.

Whatever the level of the taken risks the loss can be minimized if the creditation operation are organized and managed in a professional way.

Keywords: the crdit risk, the financial performance, the SWOT analyses, asset classification.

The banking risk can be provoked inside the bank by clients or by the external competitive medium. The conditions which lead to the emergence of the banking risks are determined by the manifestation of a complex of factors which depend on:

- the general evolution of the economy;
- changes connected to the structure of the bank;
- the political and economical conditions.

The analysis of the banking risks implies, first of all, the complete onset of the main categories of inner risks like: the lending risk, the liquidation risk, the credit solvency risk, the interest rate risk, the currency risk. The analysis of the inner banking risks is completed by the evaluation of the external risks, like those associated with the delivery process of goods and services (technological risk, product risk) or with the business medium (the competition risk, the settlement risk) on which the banks have a limited control.

There are a lot of banking risks and they are multidimensional and they have to be grouped and defined as well as possible in prospects of meaning, pursuing and controlling them. The management of risks and the management of the assets and passives which address first of all, to the quantifiable risks as:

- the financial risks connected to the variation of the rate of interest, the risks connected to the insurance of liquidities and the risks of losses in funds operations;
- the credit risk which expresses the losses caused by the impossibility of the clients to acquit the obligations to the bank, this being considered to be a commercial risk emerging from choosing the friends and clients.

The bank has a purpose the quantification of risk, using international known methods, procedures and techniques, taking into consideration the main elements like:

- The client's financial performance;
- The structure of the assets or of the made investments;
- The quality and structure of the refund source;
- The quality and structure of the guaranties.

The quantification analysis of the risk of the credit has as a purpose the knowledge about the client's evolution in the past periods and the prognosis about his future performances, so that we could make a prognostic on his viability.

The analysis of the quality and the classification of the credit portfolio are made considering the evolution of the lent person's financial performances, as well as his debt service and his ability to honour his debts in time.

The framing of the economical agents in one of the five categories of the financial performance marked from A to E is made on the basis of the financial analysis of the data provided by the accountant documents solicited from the bank's client's. This thing allows the assignment of a scoring to the quantificable criteria, which then corroborate with the analysis results of the unquantifiable criteria, that is to say the nonfinancial analysis. Following the analysis of the financial performance according to the main liquidity indicators, solvency, capitalization and the debts service, the credits are classified: standard credits, under observation, under standard, questionable and loss. The main used method of nonfinancial analysis in the SWOT method (strenghts, weaknesses, opportunities and threats).

Following the classification of the credits in order to limit the risks in the crediting activity and the keep to minimum level of solvency, the banks constitute peculiar victuals of risk besides the general reserve of the credit risk. This is made by the application of a percent on the balance on current account of the given credits. They also have recourse to the cession of the risks by striking assurances with specialized institution in order to cover the risk of loss to the credits portfolio.

When giving credits, the banks take care that the solicitors present credibility for their payment at the dead line. All banks analyze the reliability of their clients and ask the guarantee of the credits in the conditions established by the credit laws. For limiting the credit risk, the central bank can establish the following rules:

- limitation of the credit for one debtor.
- limitation of large credits
- provision making

The Romanian norms establish that the credits given by a bank to one sole debtor cannot pass 20% of their own funds. Moreover, there are restrained the credits given to persons that have special relations to the bank. For instance, the amount of credits that can be given by a bank to their stock holders is of minimum 20% of its own funds.

According to the careful norms of BNR the total amount of the big credits given to the debtors cannot overpass 8 times the level of the company's own funds. The big credits can be given only upon a decision taken in unanimity by the Committee of Directors, and the amount must be communicated by BNR.

The credit risk can be defined as the interest risk, the credit or both not being paid back at falling due or partially reimbursed. The incapacity to reimburse the credit can come from some internal factors of the company, as:

- quality and morality of management;
- the company's incapacity to adapt to the market;
- the time in which the debentures from the beneficiaries can determine financial blockages and therefore production troubles in the company's activity.

The credit risk management implies:

Preventing the risk that has 2 aspects: dividing the risk that has as objective the dissipation of risks so that the law of probabilities reduces the possibility of some losses and the constitution of some guarantees that must be seen as a subsidiary insurance, the decision to give the credit being taken according to the possibility of credit reimbursement that results from the analysis on the business that the bank is crediting.

The measurement of the risk is done in 2 stages. The first one is the establishment of some maximum limits of the risk assets compared to the own funds of the bank by recalculating the solvability rate (COOK norm). The second step is the measurement of the risks to which the bank is exposed by the periodical evaluation of the credit portfolio. The measurement of the credit risk in order to constitute the risk provisions imposes the evaluation of the financial performances of all bank clients based on their balances.

a) The duty service (client's capacity to fulfill their duties at falling due). This might be:

- good - if the rates and interests are paid on falling due with a delay of maximum 7 days
- poor, if rates and interests are paid on falling due with a delay of up to 30 days
- inadequate - if rates and interests are paid on falling due with a delay of more than 30 days

b) The financial performance (evaluated based on some criteria established by each bank). The financial performance reflects the economic potential of an economic entity obtained after the analysis of an assembly of economical and financial indicators (cash, solvability indicators, benefit mini indicators, activity indicators) calculated based on the data from the annual financial situations, through which one appreciates the client's financial reliability. Besides the financial standing indicators analysis, the qualitative factors are also used for the appreciation of the financial performances: the company's management quality, marketing policy - competence, market position, distribution and other aspects related to the credit history and the stock holder quality.

The performance is calculated based on some points by giving them for each analyzed aspect, calculating an average of the quantity component and one for the quality component.

After the evaluation of the financial performances of the clients, the credits will be enclosed in one of the following categories:

- A category or Standard credits
- B category or In observation
- C category or Substandard
- D category or Doubtful
- E category or Loss

For individuals, the classification of the portfolio of credits is done according to the duty services.

c) Initiating the legal procedure

3. The actual management of the risk lies in the use of some techniques as the revision of credits through which the bank can lesser or eliminate the losses or can save the credit.

The revision of credits, besides reducing the losses, allows the solving of some other problems as:

- ensure the uniform application of the credit documents
- verifies if the credit politics, bank's norms and bank norms are respected
- the information of the bank management about the credit portfolio situation.

Another salvation technique is the debenture sale by bank of a trusty bank that takes care of the debenture forfeiture, transforming them in money for a commission.

Credit risk is the most common cause of bank failures, causing virtually all regulatory environments to prescribe minimum standards for credit risk management. The basis of sound credit risk management is the identification of existing and potential risk inehrent in landing activities. Specific credit risk management measures typically include three kinds of policies:

- policies to limit or reduce credit risk;
- Policies of asset classification;
- Policies of loss provisioning, or the making of allowances at a level adequate to absorbed anticipate loss not only on the loan portfolio, but also on all other assets that are subject to losses.

Policies to limit or reduce credit risk. Bank regulators have traditionally paid close attention to risk concentration to banks. A regulator's objectives in credit risk management is to prevent banks from relying excessively on a large borrower or group of borrowers, but not to dictate to whom banks may or may not llend.Modern prudential regulations usually stipulates theta bank not make investments, grant large loans, or extend other credit facilities to any entities in excess of an amount that represents a prescribed percentage of the bank's capital and reserves.

Most cou8ntries impose a single-customer exposure. The Basel Committee on Banking Supervision has recommended a maximum of 25 percent, with intention to reducing it as soon as this is practical.

Lending to connected parties is a particularly dangerous form of credit risk exposure. Related parties typically include a bank's parent, major shareholders, subsidiaries, affiliate companies, directors and executive officers. Most regulator establish limits for aggregate lending to related parties, typically stipulated that total lending to related parties cannot exceed a certain percentage of tier 1 or total of qualifying capital. A prudent banking practice wood requires all loans to related parties to be approved by the board.

Asset classification is a key risk management tool, a process whereby an asset is assigned a credit risk grade, which is determined by the likelihood that debt obligations will be serviced and debt liquidated according to contract terms. Assets are classified of the time of the origination and than reviewed and reclassified is necessary a few times per year.

Assets classified as “pass” or “watch” are typically reviewed twice per year, while critical assets are reviewed at least each quarter.

Standard rules for asset classification that are currently used in the most developed countries, according to the international standards, are:

Standard or pass. Loans and other assets that are fully secured by cash or cash substitutes are usually classified as standard regardless of arrears or other adverse credit factors.

In some advanced banking systems, banks use more than one rating level for assets in the pass category. The objective of such at practice is to improve the quality of portfolio analysis and trend analysis to be able to better differentiate among credits of different types, and to improve the understanding of the relationship between profitability and the rating level.

Banks engaged in international lending face additional risks, the most important of which are country, or sovereign, and transfer risks. The former encompass the entire spectrum of risk posed by the macroeconomic, political and social environment of a country that may affect the performance of borrowers. Transfer risks are the difficulties that a borrower might have in obtaining the foreign exchange needed to service a bank’s loan.

Specially mentioned or watch. In this categories are includes:

- Credit given through on inadequate loan agreement, a lack of control over collateral, or without proper documentation.
- Loans to borrowers operating under economic or market conditions that may negatively affect the borrower.
- Borrowers with of adverse trend in their operations or an unbalanced position in the balance sheet.

Substandard. This classification indicates well – defined credit weaknesses that jeopardize debit service capacity , in particular when the primary source of repayment are insufficient and the bank must look to secondary sources for repayment, such as collateral, the sell of the fixed asset, refinancing, or fresh capital.

*Doubtful.*Such *a*ssts have the same weaknesses as substandard assets, but their collection in full is questionable on the basis of existing facts. Nonperforming assets that are at least 180 days past due are also classified as doubtful, unless they are sufficiently secured.

Loss. This classification does not mean that an asset has absolutely no recovery or salvage value, but rather that it is neither practical nor desirable to defer the process of writing it of, even through partial recovery may possible in the future.

Loan Loss Provisioning Policy

Assets classification provides a bases for determining an adequate level of provisions for possible loan losses.. Such provisions, together with general loss reserves that are normally counted as tier 2 capital and are not and are not assigned to specific assets, form the basis for establishing a bank’s capacity to absorb losses. The established level of mandatory provision is normally determined by certain statistics. In countries where the legal framework for debit recovery is highly developed, such as the United States, studies have demonstrated that approximately 10 percent of substandard assets eventually deteriorate into loss. An analysis of adequacy of the overall allowance for losses should include the following aspects:

- A survey of the bank’s existing provisioning policy;
- An overview of asset classification procedures and the review process, including the time allotted for review;
- Any current factors that are likely to cause losses associated with a bank’s portfolio and that differ from historical experience of loss;
- Trend analyses which service highlight any increases in overdue loans and the impact of such increases;

- An opinion of the adequacy of the current policy and. On the basis of the loans reviewed extrapolation of additional provisions necessary to bring the bank's total loan-loss provision to a level in line with International Accounting Standards (IAS).

At present, the risks represent an ever more increased role in the bank management activity, and without a corresponding identification and prevention policy applied to them the bank can be exposed to certain situation of an utmost gravity.

Any economical activity involves a risk, but in the case of the banks, the dictum "risk is my job" fits like a glove because, indeed, what could be more risky than to collect money available from the market and to lend it to various clients-physical and juridical persons- for long periods of time, being mainly based on promises and provisions regarding the business/audited project and less on the collaterals (non-cash) which are either insufficient., or very hard or even impossible to be recovered.

The quantification of the risk and the company uncertainty, as well as the determination of the influences that they have over the economical phenomena, represent a permanent problem for the decision factors which coordinate the activity in companies.

Abstract : The Directive 2006-43-CE regarding the statutary audit of the annual accounts and the funded consolidated accounts gets the power of an actual law from the moment of its inclusion in the national legislation, respectively for Romania from the end of June 2008. The banks will be between the economic entities of public importance compelled to respect this norm. The article presents some of the obligations of the bank sistem and the audit firms starting with the second half of 2008. At present we may say that our country is setting its time for adhesion to international accounting procedures by a convergence process. Bank appreisal in a competitive and volatile market environment is a complex process wich normally centers around the analysis of particular aspects, including risk profile and management, financial statements, portofolio structure and quality policies and practicies, human resources, and information capacity.

Keywords: Directive, Statuary Audit, Audit Committee, Internal Control, Financial Statements

The Directive 2006-43-CE regarding the statuary audit of the annual accounts and the funded consolidated accounts has been published in the Official Journal nr. L 157-87 from 09.06.2006 of the European Union and it gets the power of an actual law from the moment of its inclusion in the national legislation.

The Directive 2006-43-CE replaces the Directive 84-253-CEE regarding the authorization of the persons responsible for the legal control of the accounting documents. The responsibility for transforming the directive into a law belongs to the Government through the Department of Economy and Finances, the deadline for the transformation being the end of June 2008 in Romania.

There is already a current law project regarding the transformation of the Directive concerning the statuary audit. The project can be consulted on the site of the Department of Economy and Finances (www.mfinante.ro), conform to the procedure of decisional transparency. According to the Directive 2006-43-CEE the banks are considered to be entities of public interest.

In Romania, the public interest entities are defined by the article 33 of the Accounting Law nr 82-1991, republished, modified and upgraded by the Law nr. 259-2007, such as:

- Credit institutions;
- Non-banking financial institutions, defined according to the legal regulations, inscribed in the General Register;
- Assurance, Reassurance and Assurance-Reassurance societies;
- Authorized entities, regulated and overseen by the Committee of Supervision Of the Private Pensions System;
- Societies of Financial Investments ;
- The juridical persons that are part of a group of societies and they enter the perimeter of consolidation by a mother-company that applies the International Standards of Financial Reporting.

The motivations for including special stipulations in case of public interest entities:

- They have a great visibility on the market;
- They present a special importance from the economical point of view;

- In the case of banks, we consider that the motivations for the inclusion of special stipulations can be extended, without limiting to:
- The high degree of exposure to a very large scale of risk;
- The enhanced sensitivity of bank's actives and passives to the circumstantial factor;
- The rapidity of receiving and dissemination of negative signals in the economy.

The member states must assure themselves that the statuary auditors and the audit firms that make the audit for the public interest entities will publish on their website, in the next three months from the closing of the financial year, an annual report concerning transparency including at least the following:

- A description of the legal structure and of the shareholders;
- A description of the network and of the legal and structural agreements of the network, when the audit firm belongs to a network;
- A description of the audit firm's leadership;
- A description of the internal systems of quality control of the audit firm and a declaration of the administrative or management structure regarding the efficiency of its functioning;
- A notification of the moment in time when the last check of quality was done, as the Directive requires;
- A list of the public interest entities for which statuary audits have been done in the last year by the audit firm;
- A declaration about the policies of the audit firm concerning the independence which confirms as well that an internal check of the way in which independence was respected has been done;
- A declaration about the policy the audit firm follows regarding the continuous professional training of the statuary auditors, respecting as well the Directive's stipulations;
- Financial information that prove the importance of the audit firm, such as the total business figures divided into fees from the statuary audit of annual and consolidated accounts and fees received from other assurance services, services of financial consulting and other non audit services.
- Information regarding the base for the partners' remuneration;

The report regarding the transparency will be signed by the statuary auditor or the audit firm, whatever the case. Directive -43-CEE has the compulsory special stipulation that every public interest entity should have an audit committee. It is left to the member states latitude the competence of this committee:

- The non-executive members of the administrative structure and-or
- Members of the structure supervising the audit entity and-or
- Members elected by the general assembly of the shareholders of the entity under audit.
- Another condition of the Directive refers to the Audit Committee's structure so at least one member of the Audit Committee must be independent and have competence in the accounting and-or audit domain. The Council of Administration has the final responsibility for the bank's activity and it has to answer to the structures of bank regulation and supervision, to shareholders, to depositors and to the public society. The Councils of Administration are compelled to chose a strategy, based on adequate policies, starting from the observation that liberalization and volatility of financial markets, the greater competition and the diversification expose the banks to new risks and challenges which bring the necessity to of continuous innovation of the manner of administrating and activity and its afferent risk in order to maintain competition. [223]

The responsibilities of the Audit Committee mentioned in *The Directive concerning the statuary audit* are:

- To survey the process of financial reporting;

[223] H. van Greuning, S. Brajovic Bratanovic, Analiza si Managementul riscului bancar, Casa de Editura Irecson, Bucuresti, 2003, p.12.

- To survey the efficacy of systems of internal control, internal audit, when necessary, and of risk management inside the society;
- To survey the statuary audit of the annual, individual and consolidated financial statements;
- To verify and survey the independence of the statuary auditor or the audit firm and especially, the carrying out of supplementary services for the entity under audit process.

As far as the survey of the reporting process is concerned, the audit committee expects the statuary auditor to have the possibility of expressing an opinion upon the financial statements, therefore making sure that the bank adheres to specific format and terminology mentioned by the law, by the authorities for regulation and supervision, by the professional structure in this domain and by the practical activity of credit institution.

Another obligation of the audit committee is to survey the adjustments brought to the financial statements of the branches and offices from abroad that are included in consolidated financial statements of the bank in order to be put in conformity with the financial frame of reporting on the basis of which the bank reports in the native country. The foreign banks that have entered the Romanian can bring about some clashes of opinions on the accounting principles currently applied and the possibility of applying the reporting frame from the native country and the Romanian financial reporting frame. If the financial statements are in concordance with only one of the reporting frames, the auditor is compelled to state an opinion about the conformity with this frame, respectively the non-conformity with the other financial reporting frame.

Regarding the survey of internal control, the bank's audit committees are familiar with the COSO (the Committee of Sponsoring Organizations of the Tradeway Commission)[224], which considered by a large number of professional structures and credit institution to be a real standard for the evaluation of internal control, and it is based on five component parts :

1. control environment;
2. risk evaluation
3. control activities
4. survey and learning process
5. information and communication.

The International Audit Standard ISA 315 Understanding the entity and its environment and evaluation of the risk of significant distortion, states for the financial auditor that internal control targets the following parts:

- control environment;
- the process of evaluating the risk by the entity;
- informational system, including the linked activities, which are relevant for the financial reporting and communication;
- control activities;
- surveying the control processes.

The five components parts of the COSO model are quite close to the sense International Audit Standard ISA 315 Understanding the entity and its environment and evaluation of the risk of significant distortion [225], and their aim is a the existence of a good communication between the Audit Committee and the statuary auditor in order to achieve a correct evaluation of the internal control, starting from the common base of understanding the place and the role of the control in the bank management.

The Audit Committee surveys the statuary audit of the annual, individual and consolidated financial statements, its objective being the new approach oriented towards the identification and treating the domains of risk instead the traditional manner of approaching the balance and the profit-loss account.

Verifying and surveying the independence of the statuary auditor or of the audit firm, is of great importance for the banks, the proposal for the appointment of an auditor from an audit firm, made by the administrative or supervision structure, depends on the recommendation of the Audit Committee.

---

[224] www.coso.org.ro
[225] Audit Financiar 2006 – Standarde – Codul Etic, Editura Irecson, Bucuresti, 2007, p. 131.

The statuary auditor-audit firm reports to the audit committee:

- about the important problems that are reflected in the statuary audit;
- about the significant clashes of opinions on the internal control regarding the financial reporting process.

A special compulsory stipulation referring to the independence of statuary auditors that audit public interest entities is that the Member States must assure themselves the statuary auditors or the audit firms auditing public interest entities:

- confirm annually in writing to the Audit Committee aspects concerning their independence from public interest entities;
- inform annually Audit Committee about the supplementary services made for the public interest entity;
- discuss with the Audit Committee about the threats to their independence and the protection measures made to diminish those threats.

The statuary auditor the key partner that makes the statuary audit on behalf of the audit firm is not allowed to have an important leading job in the entity under audit before the pass of at least two years from the date of the resignation from the auditor job or the key partner in the audit mission. The member states assure themselves the statuary auditors or the key partners responsible for the statuary audit are replaced periodically, in their auditing mission, after seven years at most from their appointment and they are allowed to participate again to the entity's audit process after a period of at least two years.

The survey of assuring quality like it is stated by the Directive must be made at least every three years for the statuary auditors or audit firm that make statuary audits for the public interest entities. As far as the banks are concerned the auditors will take into account The international declaration regarding the practical activity of audit 1006, created by the International Committee for Practical Activity in Audit of the International Federation of Accountants which has included surveyors on behalf of the Basel Committee on matters of bank supervision, the only objective of this declaration is to offer practical assistance to auditors and to promote a good practice in applying the International Audit Standards in the audit of the bank's financial statements [226], based on the characteristics that make banks different from other commercial societies:

- Banks have for safekeeping a larger amount of currency elements, including cash money and negotiable titles; their security must be permanently assured. The liquidity of this element induces a high degree of risk expressed in an enhanced vulnerability of the bank in front of fraud and theft.
- Banks often starts transaction in a primary jurisdiction, and they are developed, administrated and finalized in other jurisdictions.
- Banks operate in conditions meant to maintain a very law report between permanent capitals and total actives, that determining a higher vulnerability in front of negative economical situation with consequences on the risk of liquidity and therefore on the risk of bankruptcy.
- The bank actives may suffer rapid changes of value, sometimes being difficult even to evaluate actives; a small decrease of the actives' value can have a significant effect on the banks' solvability.
- Banks obtain important funds from short-term deposits, which can become really volatile in certain conditions, a loss of public trust having then catastrophic effects.
- Banks have responsibilities like the trust of their clients regarding the actives; that is why operational procedures and internal controls are needed in order to make sure those actives are treated in conformity with the contract's conditions and terms.
- Banks are involved in a large number and variety of transactions for the surveying of which are necessary complex systems of accounting and internal control, the IT technology being irreplaceable.

[226] Audit Financiar 2006 – Standarde – Codul Etic, editura Irecson, Bucuresti, 2007, p. 748.

- For a better coverage of the territory, banks operate through networks of branches and departments divided on geographical criteria, which implies a decentralization of authority and a dispersion of the functions of accounting and control, with the normal difficulties of maintaining a certain standard ; the situation is more complicated when the network exceeds the national boundaries and enters different jurisdiction.
- The possibility of the client to initiate and carry out transaction without the bank's employees help has increased by the use of ATM or e-banking.
- Banks accept and take upon quite frequently important commitments without an initial transfer of funds to be reflected in the active or passive balance which makes the evidence of extra balance accounts more important for the banks than for other common commercial societies.
- The bank activity is regulated and supervised by authorities, and the requirements of regulation can influence the accounting principles a bank follows, the conformity with the requirements of regulation and authorization
- The relations the audit firm through its representatives can have with the bank from the position of the client can affect the independence of auditor in a considerable manner when facilities are received, other than those offered to common clients.
- Banks have almost exclusive access to systems of compensating and payment of checks, fund transfers etc.
- Banks are connected to national and international systems of payment, being therefore vulnerable to the systemic risk in the countries where they operate.
- Banks must establish adequate procedures of evaluation and administration of risks, having work methods and instructions similar to those of the European Union. The convergence in the accounting domain will be continued by the transposition of the Directive 2006-43-CE in the national legislation. The Romanian Bank system has succeeded in a high degree to be compatible with the European bank system, the proof being the presences on the market of foreign capital banks that are already respect the international procedures. We appreciate there is sufficient experience so the banks and the financial auditors may successfully assimilate the Directive 2006-43-CE.

FINANCIAL INTEGRATION OF NEW EU MEMBER STATES AND FOREIGN BANKS

Baicu Claudia

„Spiru Haret" University, Faculty of Marketing and International Business, Splaiul Independenței, nr. 313, Bucharest, Sector 6, 0040 21 3169793, baicuclaudia@yahoo.com

Starting from the idea that foreign banks which have invested in Central and Eastern Europe have an important role in raising the financial integration of the banking systems from the region with banking systems from Western Europe, this paper has two parts closely connected. The first part emphasises the main factors which determined Western banks to extend their activity to the Eastern part of the continent. The second part refers to the implications that foreign banks have on Central and Eastern Europe, positive aspects as well negative aspects being underlined.

Key words: foreign banks, banking systems in Central and Eastern Europe, European financial integration, European Union

1. Introduction

The reorganisation, beginning with the 90's, of the banking systems in Central and Eastern Europe[227] (CEE) and the tendency to globalise the banking activity have created the premises that foreign banks to have an important participation within the banking sector of these countries. A characteristic of the foreign banks involvement in CEE countries is represented by the prevalent presence of the foreign banks which come from the first European Union (EU) member states (before 2004 enlargement).

The causes which determined the foreign banks to adopt such a decision are multiple and vary from the desire to service their clients which have invested in the region to privatization of state-owned banks and the growing potential presented by the banking systems in these countries. Last but not least, the historical and cultural ties between CEE countries and the countries from Western Europe should be mentioned.

After closing the transition period during which the Eastern-European banking systems were, mainly, reorganised and privatized, nowadays, together with the accession process, one could notice the more and more powerful integration with the developped European banking systems. Besides some other factors which have contributed to the financial integration of the new European Union member states an important role was played by foreign banks. Excepting the capital infusion, foreign banks have realised an important transfer of know-how in many domains of banking activity. All these have had positive effects on the efficiency of the local banking systems but also have substantially contributed to the alignment of the banking systems in the host-country to the techniques and practices used in the mature banking systems in the home-country.

2. The determinants of foreign bank participation in new EU member states

In time, the specialty literature has emphasised a series of factors which influence the decision of a bank to make investments abroad. Later on, a synthesis of these factors has been made and their analisis on the specific case of Central and Eastern Europe, as destination market of foreign banks.

2.1 „Follow the clients" motivation

The traditional factor which explains what drives foreign bank participation is represented by the banks' desire to service their clients, nonfinancial firms, which have invested abroad („follow the client" motive). Once arrived on the destination market, the firms need a bank to provide services they ask. Consequently, the banks from home-countries follow their clients which invest abroad, intensifying their activity and maintaining the relationships developped in the home-country. This finding adds new meanings when the financial and banking system from the host-country is not developped. One should underline the fact that also the clients are interested to maintain the relationship began with the bank in the home-country

[227] For the purpose of this paper, Central and Eastern Europe is defined as the following EU member states: the Czech Republic, Estonia, Hungary, Latvia, Lithuania, Poland, Slovakia, Slovenia, Bulgaria, and Romania.

because, knowing their history, it can offer credits and facilities more rapidly and more conveniently than a local bank.

After 1990, CEE countries have began an important and ample process of reorganisation and liberalisation of the economy whose effect was, amongst other, raising of the direct foreign investments made on their territory and the intensification of the commercial exchanges with Western Europe. The development of the economical integration of the Western and Eastern countries of the continent was stimulated also by the geographical proximity and by the historical ties and transformations that the Eastern countries have experienced once the accession negotiations to European Union have begun. Under these circumstances, initially, the decision of the foreign banks from Western Europe to extend towards CEE was a normal consequence of extending the activity of its own clients towards the Eastern Europe. In the first phases of transition towards the market economy, this attitude of the foreign banks was necessary also due to the fact that the CEE banking systems were not developped enough.

2.2.The legal conditions

An important factor for a bank to take the decision to extend its activity abroad is represented by the regulations in use on the destination market and the treatment applied to foreign banks. For a long time, the CEE banking systems were closed, and the foreign banks did not have the permission to operate in the region. Once the reorganisation process begun, the restrictions concerning the activity of the foreign banks on the territory of these countries were eliminated, and the process of deregulation which, initially, had taken place in developped countries, was extended towards developing countries, including ex-communist countries.

Goldberg and Saunders (1981) underlines the fact that foreign banks tend to extend their activity especially in countries in which the credit activity is expected to grow and in which important normative liberalization processes take place. Thus, in CEE countries both conditions could be fulfilled, the banking legislation was under an important process of harmonisation with regulations from European Union, and the banking credit had an enormous development potential.

Even the attitude of the national authorities towards foreign banks was different from one country to another or from one stage to another, however, presently, as previously mentioned, the foreign bank participation in these countries is very big. A relevant example regarding the treatment applied to foreign banks is represented by the model applied in Poland. In the first phase of transition towards a market economy (1990-1992), the policy regarding foreign banks entry was quite liberal. Beginning with 1993, the Polish authorities imposed some restrictions. In order to operate on the Polish territory, foreign banks were obliged to invest in already existing banks. As, during that period, many of the Polish banks were in a difficult situation, the foreign banks were not very interested in making such investments.

Cooperation in the banking sector was promoted through a series of twinning agreements between local state-owned banks and foreign banks from Western Europe. These agreements promoted the development of the institutional connections between Polish and Occidental banks, which were even able to participate with Polish banks' capital. Also, technical assistance programmes were perfected in order to disseminate in the Polish banking system the knowledge and experience of the foreign banks. However, the involvement of the foreign banks was not realised as much as it was desired. The first state-owned bank was privatized in 1993, and the process of privatization and consolidation of the Polish banking system accelerated in 1997, when the banking legislation was modified, as to correspond to European Union requirements. The accession negotiations to European Union began in November 1998. The Polish government delayed total opening of the banking sector until 1999, when, according to the agreements with European Union it had to open to foreign competition.

The differences between countries concerning the regulations of the banking activity were another cause which, for a period of time, drives foreign banks participations. The existence of these differences determined the banks from many countries to invest in those foreign markets in which the regulations and the control of the banking activities were less severe than in the home-country. This is the case, for example, of the banks from the USA, which, immediately after the World War II, had to extend their activity abroad in order to evade the restrictions imposed by the American authorities.

Presently, under the circumstances of globalisation of the financial markets, respectively the harmonisation of the banking regulations at international level, the importance of this factor for justifying the foreign bank participation is diminishing. These appreciations are valid also for the foreign banks which invested in CEE, as the accession negotiations to European Union have imposed adopting the *acquis communitaire*, the banking legislation in CEE countries being alligned to legislation in European Union. In this sense, Cull and Peria (2007) mention that a factor which can determine foreign bank participation refers to institutional and regulatory similarities between home and host-country.

2.3. Particularities and opportunities specific for the CEE markets

Focarelli and Pozzolo (2000) underlines that the most important factors which influence foreign banks to choose the destination market are the opportunities they represent, respectively the countries with higher expected rate of economic growth are preferred, and the banks from these countries are less efficient.

The same observation is emphasised by Claessens, Demirgüç-Kunt and Huizinga (1998), which underlines that a reason for which foreign banks extend their activity in developped countries is in order to follow their clients, while, in the case of the developing countries, the foreign banks, which are more profitable than local banks, extend their activity willing to exploit the competitive advantages resulted from a bigger efficiency.

The mentioned conclusions are valid also for the specific case of CEE countries as destination markets for foreign banks. The restructuring process of CEE economy has created the premises that, in this region, the rate of economic growth to be bigger than in other countries.

At the beginning of the transition towards the market economy, the CEE banking sector has suffered fundamental changes. The monobank system was eliminated and the banking system on two levels was established. A part of the new commercial banks were carved out of the old central banks from which they took the commercial functions. Also, some other private local banks were authorised to function. But the lack of experience of the new banks together with a reduced capitalisation were one of the major causes which made them be not so efficient as the banks from developped banking systems. Under these circumstances, the foreign banks could take advantage of the experience they had and obtain supplementary profit.

Later, the majority of state-owned banks were reorganised and recapitalised, so that the consolidation of the privatization process represented another opportunity for the foreign banks. This happens as in their home-countries, the foreign banks were confronted with a harsh competition and limited possibilities to raise traditional banking activities. Also, in the Central and Eastern Europe, the credit market presented a huge growth potential.

The specific factors which have transformed the CEE banking market into prioritary destinations for the banks in Western Europe include economical, historical and cultural ties which have existed in time, between the two regions. This explains, at least partially, the interest manifested towards the Central and Eastern Europe by the Austrian banks, as „descendants" of their predecessors from the Austro-Hungarian Empire, or of the Greek banks to invest in the Balkans. Similar observations regarding the importance of economical and cultural connections between the home-country and the host-country are underlined by Cull and Peria (2007), too.

3. Implications of international investments on new EU member states banking systems

The entry liberalisation of foreign banks in CEE has some **positive effects** on banking systems in the region.

The general accepted oppinion is that, by capital infusion or the know-how they brought, the foreign banks have an important role in modernising the CEE banking systems, in raising the competition and its efficiency, with beneficial implications on the quantity and quality of the services offered, and also on costs. Lastly, those who take advantage of these transformations are the local consummers of products and banking services.

By introducing some new products and services, the modern usage and occidental management methods, and some innovative techniques, such as assessing and monitorising credits or the personeel training, the foreign banks contribute to diversification and improvement the products and services within the destination banking systems and also contribute to strenghtening the banking management. All these lead to raising the integration process of the CEE banking systems with developped European banking systems.

Also, in the first phases of transition, the foreign banks, having an advanced technology, have had the opportunity to offer their clients high quality services compared with local banks. In this context, the local banks were motivated to make important investments regarding technological developement, which resulted in raising the quality of the services offered.

The foreign institutions which have bought shares in state-owned banks have facilitated capital obtaining from the international financial market, which resulted in improving their credit capacity. Also, the foreign banks which invested in CEE due to the fact that they are, generally, important banks, had the possibility to finance themselves from international markets with more reduced costs than local small banks, less known at international level. At the same time foreign banks can obtain cheaper capitals from their home-countries. Indirectly, this is reflected in offering the clients credits with lower interest, with positive effects on economical developement of the host-country.

At the same time, as the foreign banks are, generally, better capitalized than local banks, can more easily satisfy the minimum capital requirements imposed by the regulations in use, as part of the prudential supervision policy envisaged by the national supervision authorities.

Another associated advantage of the foreign banks in the region is represented by the possibility of developement financial markets from the host-country. This advantage is more obvious in the case of foreign banks which did not take over local banks and, consequently, do not have an extended territorial network, which could allow them to obtain deposits. In these conditions, in order to finance their activity, they can use the host-country interbanking market, contributing to intensifying the connections with other banks, to raising the operations volume on this market, implicitly its level of developement.

Even if it is well known the fact that one of the main reasons for which banks invest abroad is to follow their clients from the home-country which extended their activity abroad, though, the reverse can be valid. Thus, the investments of the foreign banks in CEE may attract clients from their home-countries, which feel safer to work with a known bank, which they trust.

Although the host-countries are aware of the role that foreign banks can play in modernising and developement the national banking system, in some cases, and, especially phases, foreign investments were treated with **some reserves**.

The host-country authorities manifested some reserves regarding foreign banks due to the possibility to lose national control on banking systems and raising their fragility. As foreign participation has an important weight, the massive and quick withdrawal of foreign banks from the CEE market could determine the destabilization of the local banking systems. Also, the stability of the CEE banking systems will depend on the stability of the banking systems from countries which invested in CEE, respectively the situation of their parent banks.

Many times, restricting the activity of foreign banks in CEE was motivated by the necessity to protect local banks, which are not developped enough in order to compete with important foreign banks, with international reputation.

Another concern manifested by authorities in CEE countries refers to the possibility that foreign banks could serve the most profitable market share, respectively the best local clients and the big multinational companies, leaving the local banks clients with the biggest risks. At the same time, one may add the fear that foreign banks will attract the most qualified personeel from the local banks.

Another reason of concern is represented by the fact that foreign banks which invested in Central and Eastern Europe could transfer some of the activities to the central headquarters from the home-countries.

Also, we should mention the fact that, generally, the supervision of a foreign bank is more difficult to make than the supervision of a local bank, sometimes, the supervision authorities having difficulties in assessing the risk of the parent bank.

4. Conclusions

An obvious characteristic of the international banking after 1990 was extending the operation of the foreign banks towards CEE, as at the moment the foreign participation in the banking sector of these countries is very important. The banks from Western Europe hold the biggest part from the foreign banking capital in the Central and Eastern Europe.

This orientation was determined by the changes produced in CEE and by the possibility to obtain important profits, as a consequence of the growth potential presented by the CEE banking systems. The phenomenon is due mainly to the privatization process of the state-owned banks. The foreign banks' interest for this part of Europe was also due to the fact that in their home-countries the possibilities to develop traditional banking activity were limited. Last but not least, the foreign banks have made investments in the Central and Eastern Europe countries to serve their clients which invested on these markets.

Besides the positive effects which they have on CEE countries, the foreign banks from Weastern Europe have an important role in raising the financial integration between the Eastern and the Western part of the continent.

Real assets, represented by residential properties, hold about half of the tangible capital in developed countries. Consequently, mortgage market, which assigns the market for financing real assets, is a key component of the financial market. Because of this importance, the mortgage market's efficiency is considered to be a key factor of the financial market's efficiency. In particulary, a weak functionning of the former is believed „to pollute" other components of financial market. The article is meant to emphasize, for the euro area, those institutional caracteristics that maintain the national mortgage markets' heterogeneity. In this way, we have identified the presence of heterogeneity both in terms of mortgage products features (essential from the viewpoint of mortgage market integration) and of consumers preferences (influenced mainly by demographic factors). Also, we question about the possible implications of mortgage market's expansion to the monetary policy and financial stability.

Key words: mortgage products, mortgage debt, institutional heterogeneity, financial integration

1. Basic caracteristics and institutions of mortgage market

The mortgage market represents a particular type of credit market, specialised in lending activities collateralised with real assets. Although mortgage products cover a great variety of forms, some of them close to the consumer credit, there is an important difference between the two products in terms of maturity, sureties and financing techniques. The caracteristics of this market arise from the utilization of real assets as a guarantee:

- real assets are durable
- their evaluation isn't accurate. Each property and location are unique, therefore it is extremely difficult to compare similar mortgage products.
- in most countries residential mortgage is limited to the property itself, not being accepted other assets.
- mortgage collateral is at the core of mortgage lenders' activity. European Mortgage Federation introduced the term of „collateral's efficiency", which is determined by a series of actions: the constitution and registration of the guarantee, the ranking of the surety, its repossession.

The mortgage market consists in two major segments: the residential market, financing the real estate ownership, and the non-residential market, which finance other types of real assets. The first component has a special importance because dwellings represent the only significat households' real asset. That's why governments adopt special measures having as purpose the good functioning of residential mortgage market.

The non-residential mortgage market gathers, generally, the caracteristics of the residential one, but it distinguishes by three main aspects:

- real non-residential properties have a bigger value than the residential ones, and therefore create needs for substantial mortgage loans.
- non-residential mortgages are much more risky than residential ones because the demand for commercial or business spaces is more volatile than that for dwellings.
- the meeting between borrowers and lenders needs in this special field of mortgage market includes a great variety of special elements.

The most recent statistical study published by European Mortgage Federation (Hypostat 2006) revealed a growth in the volume of residential mortgage loans in the EU 27 of 11.1% in 2006 compared to the precedent year. A detailed evolution for the main european countries is presented in table 1.

TABLE 1: Mortgage market in EU countries (2006)

Country	Value of Mortgage Debt, € million	Growth in Mortgage Debt	Residential Debt to GDP Ratio	Per Capita Mortgage Debt, € thousand
Belgium	114,105	12.9%	36.3%	10.9
Bulgaria	1,745	73.5%	7.0%	0.2
Czech Republic	8,055	33.9%	7.1%	0.8
Denmark	221,970	13.4%	100.8%	40.9
Germany	1,183,834	1.8%	51.3%	14.4
Greece	57,145	25.8%	29.3%	5.1
Spain	571,746	20.2%	58.6%	13.1
France	577,800	14.7%	32.2%	9.2
Italy	276,102	13.3%	18.7%	4.7
Hungary	10,215	11.0%	11.4%	1.0
Netherlands	525,874	7.9%	98.4%	32.2
Austria	60,669	12.7%	23.5%	7.3
Poland	22,514	53.7%	8.3%	0.6
Portugal	91,895	15.7%	59.2%	8.7
Romania	2,276	57.2%	2.3%	0.1
Slovenia	1,956	43.0%	6.6%	1.0
Slovakia	4,209	36.7%	9.6%	0.8
Sweden	173,499	9.1%	56.7%	19.2
UK	1,583,372	11.9%	83.1%	26.2
EU27	**5,713,615**	**11.1%**	**49.0%**	**11.6**

Source: European Mortgage Federation

We have observed that countries in south-eastern Europe have a lower mortgage debt to GDP ratio, and therefore a less developed mortgage market. The main reason consists in the delay of the restructuring their banking systems, in the lateness implementation of economic and institutional reforms. In this context, the lack of an official institution having as purpose the accurate and timely evaluation of non-financial assets' price, the absence of explicit regulations concerning the property right, the securitisations, the possibility of refinancing and the additional costs justify the low level of mortgage loans.

On the other hand, there are several countries (Denmark, United Kingdom, Netherlands, Sweden, Switzerland) caracterised by a significant ratio of mortgage debt to GDP. This evolution had been determined, firstly, by the predominance of mortgage banks in the banking system. Also, demographic expansion, caused both by the natality growth and by the increasing number of immigrants, maintained the high dinamics of dwellings demand.

The high level of mortgage debt to GDP ratio suggests, however, a large level of loan-to-value ratio, which implies a large degree of borrower's indebtness and, consequently, longer terms for the repayment of debt. To a similar conclusion reached Tsatsaronis, Zhu (2004) too, which have identified two groups of countries in the euro area: one including the countries with weak, undeveloped and strong regulated mortgage markets, caracterised by a low ratio of mortgage debt to GDP, and a second one, of countries having a liberalised, deregulated mortgage market and a high level of the ratio mentioned above.

In our opinion, the main leading factors of the dinamics observed on the credit market, and particularly on the mortgage one, are: the performances concerning the economic growth, a close monitoring of inflation rate, as a premise for financial stability, the predominance of bank based financial systems, the increase of households income and the existence of favourable expectations concerning the maintainance of this trend, the boosting of the building activity on the basis of the excess in dwellings demand. Further, low interest rates and the development of mortgage market by introducing new, innovative products, contributed to a rise in customers interest and access on this market. Nevertheless, on the background of recent evolutions on the international financial market, of the increases in the key interest rate adopted by ECB and other central banks in member states and of a surplus in dwellings supply relative to the demand in some european states, one can foresaw a small shrink of mortgage market activity.

A great variety of institutions acts on the mortgage market, namely deposit taking institutions or mortgage banks and non-deposit taking institutions. Mortgage banks are credit institutions which finance the investments in real assets, having as financing source the issuance of mortgage bonds. Deposit taking institutions include commercial banks, savings banks and represent the main mortgage market institutions in most countries. The major advantage of this institutions results from the access to cheaper financial ressources and the deposit insurance. It is also the source of the main drawback, namely the duration differences between assets and liabilities. Thus, the ressources obtained from households are caracterised by short-term maturities, meanwhile the mortgages with fixed interest rate have long-term maturities, which implies a significant exposure to liquidity and interest rate risk. One solution consists in opening a credit line at international financial institutions or at a parent-institution, or the recourse to alternative financing sources (covered bonds, mortgage baked securities).

Another possible disadvantage of deposit taking institutions is their inability in achieving a high level of geographic diversification. This aspect is of particular importance especially in US, because most banks are of small dimension, with a limited territorial covering, therefore the most mortgage loans proceed from the own market share. On the other hand, banks reach at a significant degree of sectorial diversification, because loans are offered to a great variety of investors and customers.

The main distinction between deposit taking institutions and mortgage banks consists in their access to financing sources, which emphasizes the direct link of mortgage banks with capital market. Countries that frequently appeal to the financing of mortgage loans by issuing bonds are: Denmark, Sweden, Germany and France. Concerning the mortgage collateral holding, there are different practices. The final owner can be the mortgage institution, which issues bonds and uses the ressources obtained for buying the mortgage from the initial owner, or the mortgage bank will issue an instrument of debt and will use these funds for giving loans, the borrower keeping the mortgage collateral in his balance sheet.

Mortgage loans involve a high risk exposure, especially in countries with an unsound, weak mortgage market. Also, vulnerability to macroeconomic shocks is more accentuated on those markets caracterised by an intense banking activity but a small degree of banking products diversification and sophistication, mainly of the credits portfolio, which implies an inadequated risk dispersion on type of borrowers, activity areas and geographic regions.

2. Cross-country heterogeneity on mortgage market

In the euro area the mortgage market isn't homogeneous, integrated, but rather is caracterised by distinct features and products from one country to another, term the market's size, reflected by mortgage debt to GDP ratio, legal regulations, institutional caracteristics or tradition.

An important element of the dicrepancy between national mortgage markets is represented by the product's specific features. Consequently, European Mortgage Federation (2008) has grouped mortgage loans into three categories:

- mortgage loans granted for housing purposes, secured on real estate property;
- mortgage loans granted for consumption purposes, named also equity withdrawal;
- housing loans, which consist in loans secured by a personal guarantee or unsecured, granted for housing purposes.

Among the countries members of EU, Great Britain holds the most and diversified mortgage products (flexible rates, high Loan To Value ratio, buy-to-let, lifetime, subprime). Generally, countries with marketbased financial systems, for which the capital market rends long term financing, as an alternative to customers' deposits, and diminishes the mismatch between assets and liabilities maturity, are caracterised by an active role of mortgage market, and, implicitly, are exposed on a greater extend to the process of liberalisation and deregulation.

European Mortgage Federation (2006) revealed the predominance of variable interest rates in countries having as main financing source the customers' deposits, meanwhile the countries with an active mortgage bond market employ frequently a fixed interest rate for the mortgage loans. In table 2 we have synthetised the most relevant institutional caracteristics of mortgage markets, for a representative sample of EU countries, in order to catch their degree of development and flexibility.

TABLE 2: Institutional caracteristics of the mortgage market

Country	Representative interest rate	Type of mortgage loans provided	House prices	Organisations which compute and publish house prices indices
Belgium	fixed	Mortgage and housing loans	n/a	Private consultancy
Denmark	fixed	Mortgage, equity release and housing loans, secured on residential property	Transaction price	Mortgage association
Germany	fixed	Mortgage, equity release and housing loans, secured and not secured on residential property	Values quantified by experts	Central bank of Germany
Greece	variable	Mortgage, equity release and housing loans, secured and not secured on residential property	Transaction price	Central bank of Greece
Spain	variable	Mortgage and housing loans, equity release loans	Official valuations	Ministry of Housing
France	fixed	Mortgage, equity release and housing loans, secured and not secured on residential property	Transaction price	Chambre de Notaires de Paris, National Statistics Office
Romania	variable	Mortgage, equity release and housing loans, secured and not secured on residential property	Transaction price	No house index
Sweden	variable	Mortgage, equity release and housing loans, secured on residential property	n/a	Statistics institute
UK	variable	Mortgage, equity release and housing loans, secured on residential property	Transaction price	Department of communities and local government

**informations were collected from European Mortgage Federation*

Correlating the informations from tables 1 and 2, we can statuate that cross-country heterogeneity is persistent in all the considered indicators. From this point of view, the empirical studies focusing on mortgage market are difficult to realise and interpret, because heterogeneity means the absence of a unitary approach of the concept of mortgage loan, discrepancies in the process of evaluation of house prices, in computing the house price index, in the frequency of its publication (monthly in Great Britain and Holland, quarterly in Sweden, Ireland, France, Spain, Greece, Denmark, Belgium, semi-annually for the euro zone index and annually in Germany), the geographical representativity of the index (reflects house price changes nationally in Belgium, France, Holland, Ireland, Sweden and UK, or only for representative cities in Germany, Denmark, Greece, Spain). Further, some countries don't keep a distinct statistical evidence for mortgage loans, but only for the entire amount of consumers' loans, don't have official institutions to evaluate real assets or don't compute a house price index.

Several studies had analised the influence exerted by institutional caracteristics of national mortgage markets on house prices, on consumption and on the monetary policy. In this context, the empirical research revealed the existence of a correlation between house price and private consumption, which varies significantly between countries. A strong correlation was reported for US, UK, Canada and Holland, meanwhile France, Germany and Italy registered an insignificant statistical value.

According to Egert, Mihaljek (2007), the leading factors of the house price dinamics for countries in centre and eastern Europe are: income, real interest rate, the growth of mortgage debt, demographic factors. Debelle (2004), Terrones and Otrok (2004), Calza, Monacelli, Stracca (2006) tried to underline the leading factors of house prices growth and the potential implications on monetary policy and financial stability.

Calza, Monacelli, Stracca (2006) had identified the presence of a significant correlation between private consumption and house price in countries having a developed and diversified mortgage market. After conducting a VAR analysis on the effects of monetary policy shocks on consumption and house prices, the authors revealed the presence of heterogeneity both in the duration and severity of effects. Moreover, the shock' s amplitude is positively correlated with the development indicators specific to mortgage markets, such as: mortgage loan to GDP ratio, loan-to-value ratio, the existence of equity release products.

OECD (2004) ascertained that the monetary policy's impact on mortgage interest rates varies significantly from one country to another. One explication is given by institutional factors, namely: the preponderence of a certain interest rate regime, refinancing costs, the senzitivity of mortgage market to the changes in house demand.

3. Perspectives of the european mortgage market. The emergency of new mortgage products.

An important step towards the harmonization of the european mortgage market took place at the end of 2007, when European Commission adopted the White Paper on the integration of EU mortgage credit markets. The act statuates the necessity of eliminating the legal and administrative barriers which bound the supply of mortgage loans in the euro area, consecrating the term "supply driven integration". Further, a special attention is paid to the consumer's protection, to the standardization of precontractual clauses and to promoting new products. Analysing the regulatory changes in member states' legislation, we have synthetized several types of innovative mortgage products:

- Securitisation, a mortgage operation whose aim is to improve the structure and performance of mortgage market. This technique consists in gathering in a mortgage pool a great number of individual mortgages, and in issuing an instrument of debt. Each investor in mortgage titles receives a share of the net cash flow with which has contributed to the pool. Contrary to the success registered in US, securitisation is a negligible factor in most european countries.
- Rechargeable mortgage allows the reuse of a mortgage loan's collateral as a guarantee for a new loan. It is extremely important to include in the mortgage contract the recharging clause.
- Reverse (lifetime) mortgage aims to provide a complementary funding source to elder or retired people, which own a dwelling. The originator rends a mortgage loan to elder customers, lagged in time, according to their specific needs, taking over the property as a collateral. The particularity of this mortgage product consists in the fact that the borrower doesn't pay-back the loan. The contract ends after one year from the borrower's decease. There are two possibilities: borrower's heirs repay the loan and receive the property right on the dwelling, or the originator will execute the guarantee. This type of contract was introduced in UK, Spain, Hungary and is very popular in US.
- Life annuity is a product conceived to increase the income of retired people, which consists in the payment, by the originator, of a monthly annuity for the customer's lifelong, in exchange of the property right on customer's dwelling. The contract ends at the customer's decease, when the originator becomes the new owner of the dwelling. This mortgage product registered a particular success in Hungary, and was introduced too in Belgium, Spain, Italy, Ireland and UK.

– <u>Equity withdrawal (equity release loan)</u>, as a particular type of the clasic mortgage loan, is more intensely emploied in US, UK, Australia, Denmark and Netherlands, countries caracterised by the amplitude and flexibility of the mortgage market. It represents an alternative to consumer credit, because it provides liquidities without a pre-established destination, the guarantee being represented by the borrower's house. Therefore, the bigger the increase in house prices, the bigger the value of collateral, and implicitly, the amount that can be obtained as a loan.

The non-uniform implementation of mortgage products in the euro area, followed by distinct contractual clauses (financing at a variable or fixed rate, the possibility of refinancing, the method for computing the annual effective global rate) accentuate the degree of the european mortgage market segmentation, and, implicitly, the response to a change in monetary policy.

Conclusions

Although the harmonization of the regulatory framework is a difficult, long lasting process, we believe that the european mortgage market integration will bring three main benefits. The authorities will benefit from a more efficient transmission of the monetary policy signals into the entire euro area, favouring the increase in the degree of resistance to financial shocks and the financial stability of the integrated markets. Households will have access to diversified mortgage products, to a more transparent legal framework, in which the consumers protection has a key role. Last, but not least, the lenders will take advantage in terms of management and portfolio diversification, risk dispersion, the possibility of achieving scale economies, and therefore, an improvement in the activity's efficiency.

THE NECESSITY OF OPERATIONAL RISK MANAGEMENT AND QUANTIFICATION

Beginning with the fact that performant strategies of the financial institutions have programmes and management procedures for the banking risks, which have as main objective to minimize the probability of risk generation and the bank's potential exposure, this paper wants to present the operational risk management and quantification methods. Also it presents the modality of minimum capital requirement for the operational risk. Therefore, the first part presents the conceptual approach of the operational risks through the point of view of the financial institutions exposed to this type of risk. The second part describes the management and evaluation methods for the operational risk. The final part of this article presents the approach assumed by a financial institution with a precise purpose: the quantification of the minimum capital requirements of the operational risk.

Key words: Operational risk, operational risk profile, standard approach, gross income, administrative general expenses

Operational risk conceptual approach

In the last period of time the changes that took place on the financial market, because of the development of new activities and implementation of new products, generate new types of risks, more complex and bigger. A recent category is represented by the relative operational risk, for which the Basel Committee elaborated standards and regulations. In this way it was recognized the impact of this risk for the activity of the credit institution.

The past experiences indicated that in the case in which the financial institution has not an adequate risk management, it is exposed to jeopardis which can transform into important losses. These losses can generate even the cessation of the institution activity.

The Basel Committee considers the operational risk a distinct category, as the credit risk or the market risk. It defines the operational risks as „the risk of direct or indirect loss resulting from inadequate or failed internal processes, people and systems or from external events". It also takes into consideration the legal risk, but excludes categorical the strategic and reputational risks.

According to Merrill Lynch, this definition does not explain clearly how should be interpreted the nature and the measure of the indirect losses. This determines the financial institutions to have their own definitions, but this will create unsubstantiality. Because of the fact the Basel Committee wanted to underline only the minimum standards for all the financial institutions, as well as the non-existence of a concrete definition of this risk, in practice were adopted the list of risk categories and the analyse of each one. The separation was made in order to cover all the possible operational risks and to concentrate the most significant causes of the loss severity met day by day.

The specialized literature presents the opinions of more authors regarding the operational risk area. Therefore in 2001, The PNC Financial Services Group recommended a more concise definition for the operational risk, a definition that should be based more on direct losses and which exclude categorical the business risk, the strategic risk and the reputational risk: „the operational risk is the risk of the income direct loss, which results from internal events connected to inadequate personal, important errors or ilegal behaviour because of the errors or the systems and processes inadequation, or from external events where the risks are not cover by the credit, market or interest rate risk ”. Thus the operational risk can be interpreted as a vulnerability of the financial institution, that can be reduced or eliminated though an increased control.

The important increase of the operational risk is due to organisational, infrastructure, business environment or improvment changes. These changes were materialezed in: the development of the technology, the increase of the attention to the transparency, the increase of the electronic commerce, the increase of the operations for the natural person and small economic agents, deregulation, the incompatibility of the systems, the increase use of the authomatic technologies, globalization, the increase use of the external sources and the complicated technologies to reduce the credit and market risks. All these determined a healthy management of the operational risk and the inclusion in the internal process of a bank. Thus, the financial institutions considers that this risk appears in the departments called „Operations” and are concretized into potential losses generated by errors and controls, systems and processes omissions. That is why it is not necessary to have a special department for the operational risk. Also, the risk management is made by a global risk committee. But there are some institutions that consider the operational risk as the risk that not harmonise with the credit or market risks and which incorporates all the risks, except the credit risk and the market risk, in order to take into consideration all the potential influences over the profit and losses account. This thing brought some problems and thus the financial institutions decided to limit themselves to things that can be measured easily.

For a banking-financial institution we can mention a series of main operational risk factors, as: internal fraud, external fraud, employment practices, the job safety, clients, products and business practices, bank’s products and operation practices, the technic infrastructure deficiency, activity disturbances and system defections. For a good management of the operational risk there are six steps that have to be followed: identification of the risk type, identification of the risk factors, the exposure to the risk rank evaluation, the risks estimation, the loss and profile estimation and source explanation, the comparison of the risk with the profitability of each risk type, being complusory to know the potential loss or the causes that generated this type of risk.

The operational risk management and evaluation

In the last period of time more and more authors were interested by the operational risks, especially because of the fact that operational risk can appear not only for banks. Until now, most of the banks considered operational risk through the past events. Therefore, because they hadn’t an operational risk management they pointed out more the effects and less the causes. But recently, the Basel Committee proposed the responsabilities share between the risk management and the operational risk management. For an adequate operational risk management it has to be respected the second pillar of the Basel Agreement. This pillar follows the set up of the capital minimum level, the minimum funds used to cover the unexpected loss that can appear unexpectedly during the activity of a financial institution.

For the operational risk management are followed the next elements:

- the analyse of the operational risk profile. This point starts from the identification of all operational risk types to which the institution is exposed. This identification follows: the portfolio composition of the institution and the characteristics of each entity; the methods and the producs used for the issurance(design, processes); the competition; the market structure; the business environment; sources for clients; distribution channels; human resources management; the transaction complexity and volume; the behavior and the attitude to risk;
- the assignement of the operational risk type accepted or rejected by the institution;
- the methods of identification, evaluation, monitoring and control of the operational risk. These evidence the processes, the systems and the people involved in the activities and generate information that in the past were given by the internal control department: operational loss that took place in the past, events that could have generated losses, but were avoided, evaluation of the essential risk; the characteristics of the insurance operations; the control strictness that provides the efficient quantification of the operational risk and the identification of the diminuation solutions of this risk: autoevaluation, sensitivity tests, limit

scenarios; other souces that generate operational risk: clients dissatisfaction, employees migration, a high number of operation, incapacity of the system, high degree of manual intervention in the IT system, external loss and operational risk exposure report; changes suffered by the business environment.

as an option we can describe the manner operational risk is incorporated in the methodology of determination of the necessary capital to control this risk.

Taking into consideration the fact that this risk is a new risk on the market, today there are a few institutions that make an adequate management of this type of risk. Therefore, the affirmation that there is a optimum solution, is false, because we can follow at the most the components of the operational risk: operational risk instruments. These changes from one institution to another and include: the estimation of the necessary capital to cover the operational risk, the scenarios against the exposure, the adjustment of the statistic distribution, the connection cause-effect, the distribution into risk category; a data base to create all that we mention before. The data base has information regarding the transactions, the events, control and reference points, exceptions, variants, process maps; reports regarding management. These reports are different and can have information as broken interfaces, confirmation lack, incomplete transactions, correlations, trends, capital at risk.

Taking into account the data limited character and the lack of flexible informational system, the quantification of this type of risk is very difficult to be made and sometimes even impossible. Therefore the financial institutions are in the situation of spending a lot of money with the specialised employees, technological process or specialised institution in this area.

During the time, there were a lot of opinions regarding this type of risk, but the most important quantification methods of the operational risk and constitution of the mandatory reserves to cover the risk, are the one presented by the Basel Committee: Basic Indicator Approach, Standard Approach and Advanced Approach: Scorecard Approach, Internal Evaluation Approach and Loss Distribution Approach.

The implementation of the Basel Agreement II in Romania involves both the development of the rating agencies and the statistics data basis and econometric methods to substantiate the internal models of the bank. The preference of the Romanian banks for the models that determine the capital requirements for the operational risks was in 2007 81% for the Basic Indicator Approach and 1% for the Advanced Approach. According to a study made by the National Bank of Romania for the 2008 are the next anticipations: 68,75% of the financial institutions are going to use Basic Indicator Approach in order to evaluate the operational risk and only 3,12% are going to use advanced models. This trend is due to some factors as the capital value, which is bigger that the legal one, non-existence of the stimulus to make the institutions to reduce the capital value through advance approaches, high expences for the implementation and use of the internal evaluation approaches of the operational risk.

Any sensitive method that measures the need of capital for the operational risk follows the estimation of real loss, potential on a probability basis for each business line or at the level of the all bank, as:

- the evaluation of the risk on the basis of a correlation between the risk and an indicator, the case of Basic Indicator Approach, Standard Approach and Internal Evaluation Approach;
- the risk evaluation on the basis of loss distribution, the case of Loss Distribution Approach;
- the risk measurement on the basis of the scenarios made by the experts

The advantages of the quantification of the operational risk are:

- the banks can identify the operational loss to which they are exposed and for which they don't have the necessary experience, for exemple: the low impact of the events, the high number of the events with high frequencies;
- it promotes a frame to model extreme events: the analise of the scenarios with low frequencies, the high impact of the events; for exemple: the business stop;
- potential high pay-off for banks: it helps to incorporate the risk reduction quantification in the process of making a decision regarding a private investment; the banks that administrate and measure this risk can reduce their costs and they are less sensitive to the systemic problems.

The quantification of the minimum capital requirements of the operational risk

In order to apply the II Pillar of the Basel Agreement, regarding the minimum requirements to cover the operational risk, the financial institution X, we can not mention the name, used from 2007 the Standard

Approach, although its group uses an internal model. The group uses an internal model because it has not hystorical data in order to make proper scenarios or to measure some relevant indexes to determine loss liquidation. It proposes 2 years until the group would use the advanced approach.

The Standard Approach supposes the organisation of the financial institution into eight standard business lines, that use as a common index, as a substitute for the bank general exposure to the operational risk, the gross income. Also the Basel Committee recommends the use of this index. But this index was criticized in a recent german study: the increased of the gross income supposes an increase of the capital needed to cover the operational risk and therefore we have a decrease of the bank income and this is oposite to the bank strategy; this method is not sensitive because there is no strong correlation between the income level and the operational risk exposure; the institutions can not influence the capital requirements through a prudential management or a reduced operational risk; we have a negative correlation between losses and the capital need; a reduced capital is needed in case of more loses; the capital need is not adjusted to the real value of the operational risk and this generates a non-efficient risk control and an incentive management. As an alternative for the gross income, the majority of the ZKA[228] Association recomends the use of the „General administrative expenses" index, because it can used by all the banks, no matter the business lines and can produce distortions in the case of the banks organised in a different way.

Though the Standard Approach presents some limits:

the results are not connected directly to loss data

the operational risk profile varies from one event to another even in the same business line.

Therefore, in the case of the Standard Approach, the capital requirements are determined as a product between the relevant index for each business line and a percentage comprised between 12 and 18. In the case we have for one of the three financial exercices a negative requirement, this will be equalised with the positive requirements from the other business lines, from the same financial exercise. In the case in which the total capital requirement is negative, in the formula used to determine the capital need for the financial institution, it will be considered zero. So, we can conclude that the capital need can be determined as:

$$\text{Capital}_{SA} = \frac{\sum_{t=1}^{3}(\max[\sum_{i=1}^{8}\beta_i \cdot Ir_i ,0])}{3}$$

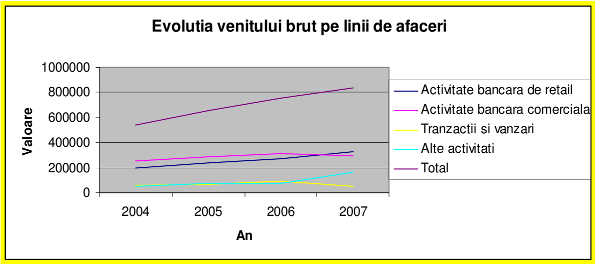
For the analysed financial institution, the relevant index is called „gross income". Also, in the group view this index represents the sum of the values from the profit and loss account. These values are results from interests, incomes from shares and other income bonds, commission results, financial operation result and other operation incomes.

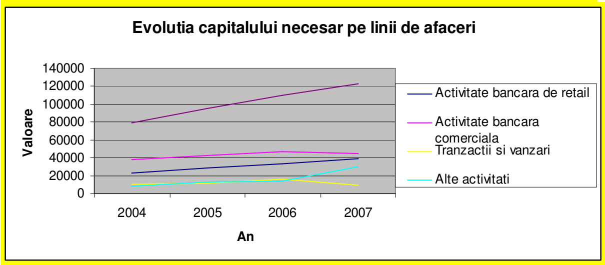
For the loss analyse, the financial institution considered as main business lines: corporations financing, payments and discounts, retail brokerage(although there is not the case from our country, because the company has such activities the institution included them as a business line, but for the capital need formula it was considered zero), tranzactions and sales, retail activity, commercial activity, agent services and assets management. These operations were made taking into consideration specific norms and policies, part of the internal procedures.

For all the business lines, the financial institution used as relevant index „the gross income". According to Basel Committee, this index is a transparent index, present in all the financial reports and used to make easily calculations and national and international comparisons. Also, it is easily audited and reflects very good the operational risk sensitivity.

---

[228] Zentralerkreditausschuss (2001) „Comments of the Zentraler Kreditausschuss on the Basel Committee's Consultative Document of 16 January 2001 on a New Capital Adequacy Framework for Banks ("Basel II")" Berlin

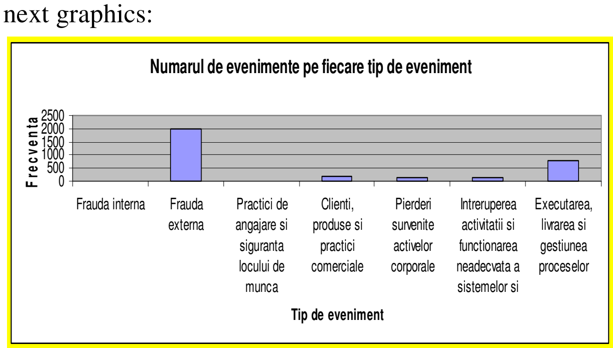


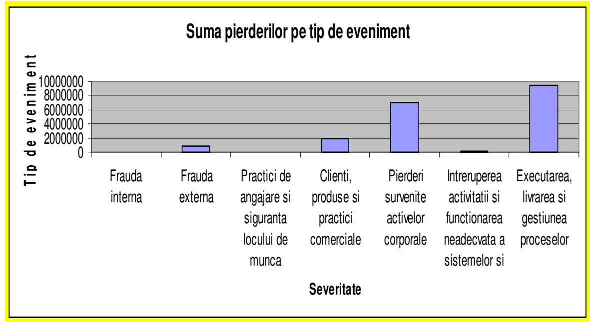


Source: personal process

For some business lines we can observe high values. These values reflects the gross income dimension and the intensity of the institution activity for all the activity sectors. Also they offer to other departments involved, information regarding the potential loss that can appear and the necessary value to cover the operational risk loss for all the business lines. Analysing the graphic, we can conclude that the most risky business lines are the commercial and the retail banking activity and they are due to trading and processing errors that can appear during the time. The most are connected to the open account operation, as follow: the wrong introduction of the general data; incomplete documentation; the signature absence; errors in the pay office: non checked signatures, the issue of discordant documents in the case of foreign exchange; errors at the payment: un-authorized payments, the payments delay, the wrong choice of the currency in the payment process, the payment orders transmission delay, the multiple transmission of the same order, the incorrect introduction of data in the system, the loss of checks, compensation of the false debit instruments; errors in the foreign exchange process: disrespect of the foreign regulations; IT errors: the incorrect data transfer, nonfunctioning of the systems; frauds in the credit process: the acceptance of the incomplete files, the information distorsion, the use of false IDs; errors regarding complaints: the delay of the reports for other authorized departments, the delay of the complainets responses.

The losses generated by the operational risk are identified and connected in accordance with the international standards for the seven events types, as: internal fraud, external fraud, employment practices and the safety of the working place, the clients, the products and the commercial practices; the tangible assets loss, the activity rupture and the unadequate systems functionment and the process execution, the delivery and management. Therefore, on the basis of the information generated by the back office department, internal audit, IT and risk management department, the Operational Risk Department can present the loss situation for each event that can cause demages for the financial institution. The events status is presented in the next graphics:

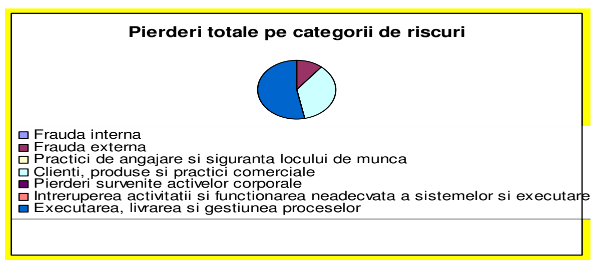


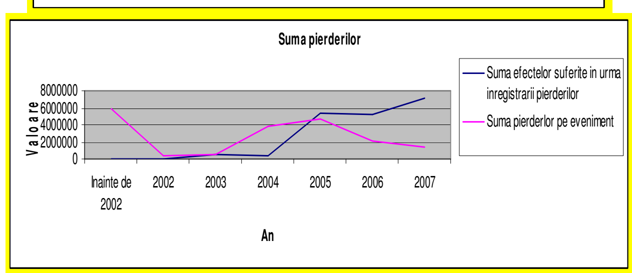


Source: personal process

As we can see the most frecquent losses are generated by the external frauds, especially the cards frauds, as: unproper protection systems, „chargeback" situations, thefts, duplicating. On the second place we have the losses generated by the bad execution, delivery and management of the processes that appeared in the transactions.

From the point of view of the events severity the first place is taken by the events generated by the execution, delivery and management of the processes caused by: incorrect communications, disfunction of the models or systems, the incorrect safe-keeping of the data base; introduction, operating, keeping and updating errors; not keeping the deadlines; processes externalisation; the documentation missing; losses; processes externalisation followed by the clients category, commercial products and practices, that includes losses because of the: unproper products, neglect, low preparation or unprofesionalism, agressive sale of the products, disrespect of the behaviour rules, confidential information un-proper use and incorrect analyse of clients need.





Source: personal process

As we can see from these graphics, the non-existence of the internal frauds and the employment safety can be explained by an efficient management of the financial institution.

The key indicators can identify at the right moment the appearence of a loss generator event if they are used at the proper time. The Administration Council decided to make a very strict control of all the departments exposed to the identification of the operational risk and make a report for the Operational Risk Department of the financial institution, which was responsible with the trainings for all the other departments, in order to identify and report corectly this type of risk. The implementation of this type of risk needs a very high cost in order to adopt the risk policy, to train the employees and to adopt the informational system. Also there were analysed the trends of the loss events and the effects of these losses for the institution; The Operational Risk Department monitored the risk profile and the material exposures to losses, based on key indicators. These indicators prevent the risk increase, through the identification of un-expected events signals and allow a transparent scheme of the operational risk, using some criteria: the analyse of the operational risk events, of the external data, of the internal audit reports, others experience.

In conclusion the dinamic approach of the capital need for the operational risk demonstrates the frequency increase of the events that generate this type of risk. This idea is supported both by the Basic Indicator Approach and the Standard Approach.

STABILITY OF THE EXCHANGE MARKET IN ROMANIA, IN THE PERSPECTIVE OF JOINING THE ERM II

Bărglăzan Diana

Politehnica University of Timişoara, Faculty of Management in Production and Transportation, 1, B-dul M. Viteazu, SPM building, 2nd floor, 217, diana.barglazan@mpt.upt.ro, 0256-404055

Romania joined the European Union last year and now it is preparing to join the ERM II. The paper is investigating the recent evolution of the exchange rate leu/euro and its compatibility with a future participation to the ERM II. The findings show that while the exchange rate evolution was not very smoothly in the last few years, the stability of the exchange market was high enough and Romania does not seem to encounter any problems concerning a future participation to the ERM II. The forecasts for the next years confirm the maturity of our exchange market and its capacity of maintaining the exchange rate sufficiently stable so that Romania might achieve its objectives in terms of euro adoption.

Keywords: stability, exchange rate, ERM II

1. Introduction

From the 1st January 2007 Romania is a member of the European Union. Not yet a full member, since full membership is granted only to the countries having adopted the euro. Accomplishing the convergence criteria and joining the Euro Area is the next step in the European integration process of our country. Before adopting the euro, Romania must spend at least two years in the ERM II (European Exchange Rate Mechanism II), keeping its exchange rate towards the euro stable, inside a band of ±15%. As many other countries from Central Europe, Romania decided to wait and join the ERM II only when it counts on accomplishing all the convergence criteria in the next 2 years.

Table no. 1 – Objectives of the Central and European countries concerning the ERM II and the euro adoption (as expressed in 2004)

Country	Objectives concerning ERM II participation	Objective set for euro adoption
Estonia	Rapid entry, maintaining the fixed exchange regime (fluctuation band zero)	2007
Latvia	Maintaining a narrow fluctuation band, of ±1%	2008
Lithuania	Rapid entry, maintaining the fixed exchange regime (fluctuation band zero)	2007
Poland	The shortest possible duration (2 years), with a standard fluctuation band (±15%)	2008-2009
Czech Republic	The shortest possible duration (2 years), with a standard fluctuation band (±15%)	2009 – 2010
Slovakia	The shortest possible duration (2 years); possible start in 2005	2008
Slovenia	Rapid entry (end of 2004)	2007
Hungary	Rapid entry, followed by a participation of a duration depending on the pace of convergence criteria accomplishment	2008

Source: Călin (2004), p. 68

The ERM II is the successor of the ERM (Exchange Rate Mechanism) established in 1978 in order to limit the fluctuations of the exchange rate movements between the currencies of the Western European countries. The ERM II is a fixed and adjustable exchange rate system, involving the risk of speculative attacks. Naturally (and especially after the crises experienced by the Western countries participating to the

ERM in 1992), countries try to avoid such vulnerable exchange rate arrangements. But participation to the ERM II is required, because it is considered that a successful participation proves the durability of the nominal convergence reached by the members of the EU (and before being accepted as a new member in the Euro Area, a country should be put to the test, so that a nominal convergence forced and superficial is detected before jeopardizing the stability of all the countries from the Euro Area).

The rest of the paper is organised as follows: the second section is presenting the opposite views of the communitarian institutions and new member states, and the arguments used by each side; the third part is presenting the evolution of the exchange rate between the Romanian (new) leu and the euro; the forth section assesses the compatibility of the evolution of the exchange rate in Romania with the requirements of the ERM II, evaluating the stability of the exchange rate of the leu towards the euro; finally, the last section contains the conclusions.

2. ERM II – accelerator of real convergence or unnecessary purgatory?

There is no consensus between the communitarian institutions and the representatives from the new member states, concerning the ERM II. Yet the fact remains that participating to the ERM II for two years is a mandatory condition for the countries wanting to enter the Euro Area. But while the communitarian institutions are encouraging early entrance in the ERM II and a long stay inside the mechanism, the national authorities from those countries have opting for the shortest possible stay: 2 years (see table 1).

For their part, the communitarian institutions agree that the real and nominal convergence obtained by the EU member states adopting the euro must be durable. They argue that the ERM II is offering the participant countries a flexible, yet stable exchange rate arrangement, ideal for achieving nominal convergence (price stability) while allowing the exchange rate to adjust to the movements of the equilibrium exchange rate determined by the real convergence and the Balassa-Samuelson effect.

Although a soft peg, the ERM II is not considered a threat for the financial stability of the participating member states, since the extended fluctuation band ($\pm$15%) is large enough to discourage speculative attacks (it was tested on the EMR after 1993 and no currency was pushed outside the fluctuation limits by speculative attacks). Moreover, the ERM II is endowed with a short term financing facility allowing the countries attacked to find support and supplementary means for fighting the speculative attacks. There are even some economists from the new member states supporting this strategy (Orlowski, 2002; Jankovics, 2002; Backé and Wójcik, 2002). And the experiences of the current members of the Euro Area seems to prove that participation to the ERM II is safe and does not imply a high risk of speculative attacks.

So far, everything sounds very logical, but then, why are all the new member states afraid to stay too long in the ERM II?

Well, it remains a soft peg imposing the national authority to defend a certain exchange rate towards to euro, and such an exchange rate arrangement can engender severe crises, because exchange crises appear always in the countries trying hard to defend a fixed exchange regime (Aubin C., Norel Ph., 2000: p.268).

Many economists suggested that, for the Central and Eastern European countries, the best strategy would be to join as soon as possible the Euro Area (Csajbok and Csermely, 2002; Buiter and Grafe, 2001; Coricelli, Jazbec and Masten, 2003). Also, outstanding economists from outside Europe recommended the new EU members to spend as little time as possible inside the ERM II – P. Kenen (see IMF, 2004).

Some economists even proposed the unilateral adoption of the euro in the Central and Eastern European countries, even before the accession to the EU (Begg, 2001; Buiter and Grafe, 2001; Balcerowicz, 2002; von Hagen and Zhou, 2003) – this strategy was declared from the start as unacceptable by the communitarian institutions. Under no circumstances participation to ERM II can be avoided, since the communitarian institutions insist on the necessity of equal treatment of old and new member states and on the idea of using the exact same set of convergence criteria.

In June 2004, the first countries from Central and Eastern Europe joined the ERM II: Slovenia, Estonia and Lithuania. In May 2005 other three countries joined the ERM II: Malta, Cyprus and Latvia. Slovakia fallowed in November 2005. There were no problems – Slovenia, Cyprus and Malta successfully finished their stay in the ERM II and adopted the euro. The countries counting on a latter adoption of the euro have not entered yet into the ERM II (Czech Republic, Poland, Hungary, Romania, and Bulgaria).

3. The evolution of the exchange rate between the Romanian leu and the euro

The exchange policy of Romania is, since 1991, the exchange rate managed float. The National Bank of Romania monitored closely the evolution of the exchange rate. First, the US dollar was used as a reference currency. After the euro was launched, the US dollar was replaced by a currency basket made by the US dollar and the euro. Gradually, the part of the euro increased in this basket. Finally, the reference currency remained the euro.

Although the legislation did not impose the NBR to focus on the evolution of the exchange rate, it chose to do so. The BNR allowed a real appreciation of maximum 2 – 2,5% per year, against the currency basket used (made by the euro and the US dollar).

Before 2004, while the annual inflation rates were well above 10%, the analysis of the real exchange rate is definitely preferable to one of the nominal exchange rate. For the period 1999-2004 the real exchange rate (RER) of the Romanian leu against the euro and its trend (determined by means of a Hodrick-Prescott filter) is analysed and presented in figure 1.

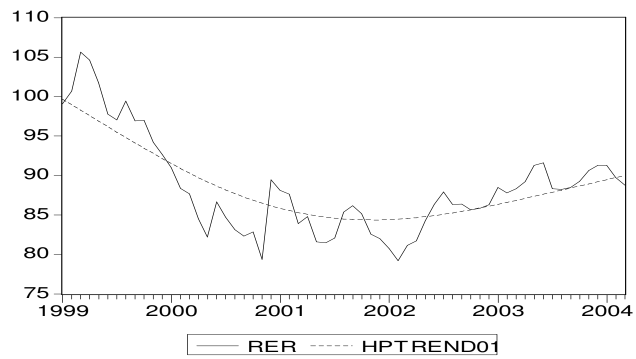

Figure 1 – The trend of the evolution of the real exchange rate

Source: Călin, 2004: p.267

The graphic clearly shows that after an evident real appreciation experienced in the first part of the period (January 1999 – beginning of 2001), the trend changed.

In October 2004, the NBR decided to reduce the frequency of its interventions on the exchange market. Its interventions became fewer, but more massive and less predictable. In only a few months, the nominal exchange rate of the Romanian leu against the euro passed from 41.127 lei/euro (October 2004) to 38.494 lei/euro (December 2004) – an appreciation of 6,84%. In March 2005, the exchange rate was 36.422 lei/euro – meaning a nominal appreciation of 13% for a five months period. If we consider also the inflation differential between Romania and the Euro or the USA – around 7% at that time) we can have a clearer image of the size of the real appreciation of the Romanian leu.

This evolution came as a shock to most Romanians (population and companies). After 15 years of depreciation, for the first time, the Romanian leu strongly appreciated in nominal terms against strong currencies as the euro and the US dollar. Apparently, the strong appreciation of the national currency was not desired by the NBR and may be, not even anticipated by it. Nevertheless, the NBR held to its decision, and after several months of strong appreciation, the exchange rate stabilised. Its level in January 2006 (3,6445 RON/EUR) was very close to the level from February 2005 (3,6765 RON/EUR). The market seemed to have found its equilibrium.

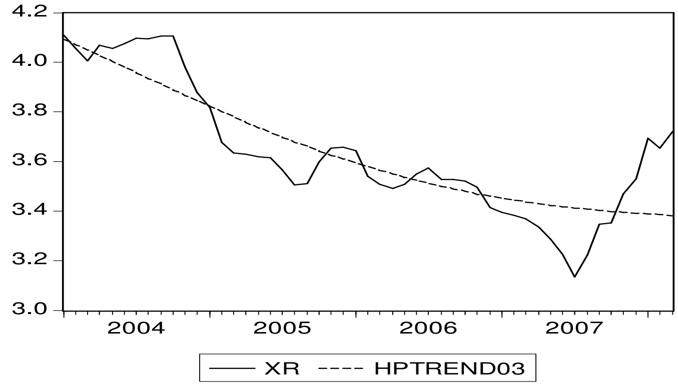

Figure 2 – The trend of the evolution of the nominal exchange rate (January 2004 – March 2008)

Starting with February 2006, the Romanian leu showed a clear tendency of appreciation, but in a completely different rhythm (passing to 3,1337 RON/EUR in July 2007 – an appreciation of 14,75% over a period of 18 months).

In the last few months, in the context of an increase in the level of the inflation rate (at over 8%), the nominal exchange rate started to depreciate (passing from 3,1337 RON/EUR in July 2007 to 3,7218 RON/EUR in March 2008). This seems to be a short-term deviation from the trend- as it can be seen in the figure 2, the trend did not change. Still, it represents a depreciation by 18,75% in only 9 months.

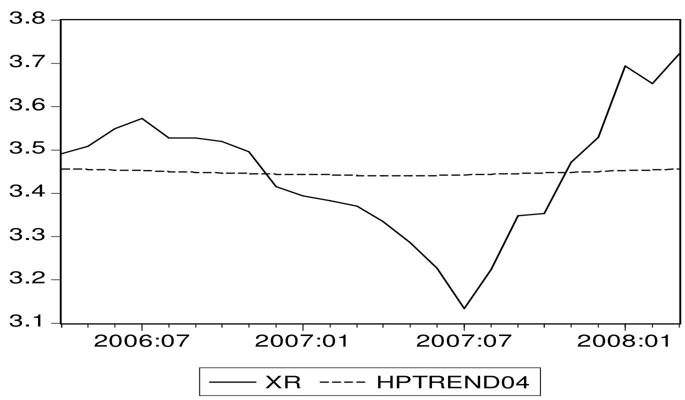
We could say that the exchange rate between the leu and the euro is now stable. In the end, the level of the exchange rate nowadays (April 2008) is around 3,6 RON/EUR, very close to the level from January 2006 or February 2005. But is a depreciation of over 18% in just a few months compatible with the ERM II?

4. Stability of the exchange rate

The ERM II allows fluctuations inside a band of ±15%, a band established around a central rate. If we should have chosen a central parity for the leu, it would have been, most probably, somewhere around 3,5 RON/EUR (most forecasts made in the last few years are estimating the exchange rate RON/EUR between 3,4 and 3,65 RON/EUR for the period 2007-2013).

Let us consider the last 2 years: April 2006-March 2008. The evolution of the exchange rate is presented in figure 3. If we look at the trend, the stability is obvious.

For our data sample, the mean is 3.446571, and the median is 3.4809. The maximum level reached by the exchange rate in the last 24 months is 3,7218 RON/EUR in March 2008, while the minimum value is 3,1337 RON/EUR in July 2007.



In table 2 we present the maximum deviation of the exchange rate between the Romanian leu and the euro, assuming various central parities.

Table 2 – Compatibility of the exchange rate evolution with the ERM II

Central parity	Maximum depreciation	Maximum appreciation	Compatible with ERM II
3,2	**16.3%**	2%	NU
3,3	12,78%	5%	DA
3,4	9,46%	7,83%	DA
3,5	6,33%	10,46%	DA
3,6	3,38%	12,95%	DA
3,7	0,59%	**15,3%**	NU

Considering the fluctuation band accepted in the ERM II as ±15%, the evolution of the exchange rate between the leu and the euro can be considered as stable (and compatible to the ERM II) for any central parity between 3,2363 and 3,6867 RON/EUR.

5. Conclusion

The Romanian exchange rate market reached a high level of maturity. By the time the NBR decided to dramatically cut the frequency of its intervention, the market was already able to function well without many interventions.

For years it has been said that in Romania the main problem concerning the convergence criteria is the inflation rate and that once the inflation is under control, the criteria concerning the interest rate and the exchange rate would be easily accomplished. This seems to be true for the exchange rate – with annual inflation rates expressed with a single digit, the exchange rate is already stable enough as to fluctuate within a band of ±10% around a central parity of 3,4 RON/EUR. Certainly, this does not mean that the participation to the ERM II is risk-free (on the contrary – so far, since the NBR was not forced to defend a certain level of the exchange rate, the incentives to speculative was lower; after joining the ERM II, that incentive will increase). But it proves that Romania will soon be able to participate to the ERM II and to accomplish the convergence criteria concerning the exchange rate, if that participation is handled with competence and caution.

PROVISIONS SYSTEM – METHOD FOR PREVENTING CREDIT RISK IN BANKS

Bâce Grigore

Babeş – Bolyai University, Cluj-Napoca, 0264598583, email: grigore.bace@bnro.ro

Abstract. In the paper the author shows the modalities of preventing credit risk in financial institutions, based on provisions method.

Key words: provisions, protection at risk, credits classify

1. Introduction

The risk of non reimbursed credits represents a serious threat as far as the banks' possibility of paying bank deposits is concerned. For this purpose, the regulation of The Central Bank of Romania no. 5/2002 regarding the classification of credits and placements, as well as the formation, regulation and use of provisions specific to credit risk. The methodological norms no. 12/2002, both completed by Regulation no.7/2002, state that banks, for the purpose of protecting the deposits of individual and legal entities, have to limit credit risk and try as much as possible to obtain their receivables from debtors.

As a result, banks classify credits in:[229]

- standard;
- under supervision (only for the credits given to clients belonging to the non banking system;
- below standard (only for credits given to clients belonging to the non banking system;
- doubtful (only for credits given to clients belonging to the non banking system;
- Loss.

The classification of credits and placements is made by the simultaneous use of the following criteria:

- debt service;
- financial performance;
- Initiation of juridical procedures.

The evaluation of the financial performance of a company, outside the sector of credit institutions, will lead to its framing into one of the five categories of financial performance (A-E). This evaluation will be made according to internal norms, based on the score attributed to quantitative and qualitative factors.

The quantitative factors mainly refer to the following indicators:

- liquidity;
- solvability;
- risk;
- Profitability.

The qualitative factors that banks take into account when analyzing the credit, refer to aspects concerning:

- the administration method of the analyzed company;
- the equality of the shareholders; structure;
- received collaterals (others then those accepted with the reduction of the exposal towards the debtor);
- the market context in which the company performs its activity.

The financial indicators are calculated based on the data included in the financial statements of the company, dawn up according to the regulations issued by the Ministry of Public Finances or by foreign

[229] *The regulation of the Central Bank of Romania no. 5 from 22.07.2002 regarding the classification of credits and placements, as well as the formation, regulation and use of provisions specific to credit risk.*

authorities with similar role. The category of financial performance is determined, and helps the category chooses, in the month following the month when the banks had access to the respective reporting.

In the case in which banks are not able to evaluate the financial performance of a client from the non banking sector, it will go directly to category E.

The frequency, with which the financial performance of a company is determined, coincides with frequency with which financial statements are made.

The analysis and classification of the credit portfolio has as purpose the evaluation of the financial performances of the credit requester and their debts service.

The framing of the requesters into categories A, B, C, D, and E is made after the analysis of their financial performance, as shows below:

- **A Category** – their financial performances are very good and they afford to reimburse in due time the interest and the rate and their financial performance are likely to remain very high.
- **B Category** – good and very good financial performance, but they are not maintained at the same level for an extended period of time.
- **C Category** – adequate financial performance, but with an explicit tendency of decrease.
- **D Category** – low financial performance and an explicit cyclic tendency on short period of time.
- **E Category** – the financial performance show losses and there are clear perspectives that neither rates, or would interest be paid.

The debts service of the credit requester is divided into five intervals:

- 0-15 days;
- 16-30 days;
- 31-60 days;
- 61- 90 days;
- Minimum 90 days.

By correlating the data referring to financial performance with the data referring to the debts service, there is obtained credit classification.

<table>

</table>

Table 1 - The Rating Credits System

Under these circumstances:

- **Standards credits** are those which do not imply deficiencies and risks that might endanger the administration of the debts as stipulated in the credit contract.

- **Credits under supervision** are the credits given to clients with very good economic results, but which, during short periods of time, met difficulties in reimbursing the due rates and the corresponding interest.
- **The below standards credit** presents deficiencies and risks that endanger the liquidation of the debts being insufficiently protected by the net value of the capital and/or the payment capacity of the credit beneficiary. These credits are characterized by the real possibility that the bank should partly overtake some losses as a result of the impossibility in recovering the entire loan, unless the credit's deficiencies are corrected.
- **Doubtful credits** are those loans that the reimbursement or the liquidation of which, based on the existing circumstances, values and collaterals, is uncertain. These assets are those which are unprotected or little protected by the accomplishable value of their collaterals.
- **Loss credits** are those credits that can no longer be repaid to the bank, a fact that causes their recording as assets to be un-guaranteed.

2. Forming risk provisions

The same regulation included the rules regarding the formation of provisions for the expected losses from the crediting activity.

Thus, for determining the required provisioning for credit risk corresponding to a credit or placement, there are covered the following stages:

1. determining the calculation basis for provisions for credit risk:[230]

a) by deducting from the exposal of the bank the collaterals accepted to be taken into account according to the methodological norms of The Central Bank of Romania no. 12/2002, in the case of a credit classified as "standard", "under supervisions", "below standard" and "loss", in circumstances in which there are no juridical procedures and all the amounts corresponding to that credit record a debt service of no more then 90 days.

b) by taking into account the entire exposal, irrespective of collaterals, in the case of a credit classified as "loss", in the circumstance in which there were started juridical procedures or when at least one of the amounts pf the respective credit record a debt service over 90 days, as well as in the case of a placement, irrespective of the corresponding classification category.

2. Applying the provisioning coefficient to the calculation basis obtained; the correspondence between the classification categories and the provisioning coefficients.

The provisioning coefficients are:

- 0 for "standard" category;
- 0.05 for "under supervision" category;
- 0.2 for "below standard" category
- 0.5 for "doubtful" category;
- 1 for "loss".

The formation of credit risk provisions refers to their creation and will be made by including as expense the amount representing the provisions requires.

The regularization of credit risk provisions refers to the change of their existing level in order to recreate the balance between the existing level and that so the requirement and it will be made by including in expenses of the sum representing the difference between the level existing in balance of credit risk provisions and the level of the requirement.

The use of credit risk provisions refer to the annulment of credit risk provisions in the event of credit risk and it will be made by the reversal on income of the sum representing the level existing in balance of credit risk provisions and the placements taken out of the balance sheet.

---

[230] *The methodological norm of The Central Bank of Romania no. 12 from 22/07/2002 for the application of The Regulation of The Central Bank of Romania no.5/2002 concerning the classification of credits and placements as well as the formation, regulation and use of rpovisions specific to credit risk.*

Banks form and/or regulate on a monthly basis their credit risk provisions corresponding to the credits and placements appearing in the balance at the end of the respective month, by including as expense and/or by reversal on the incomes of the month for which the reporting is made, irrespective of the financial result of the period.

Up to 30.06.2007 considered as extra balance sheet the sums corresponding to a credit or placement in the following circumstances:

1. at least one of the respective sums record a debt service over 360 days;
2. there was given an executor function to:
3. the credit contract, as well as collateral contracts, if the case;
4. the final court decision regarding the credit contract, as well as the collateral contracts, if the case;
5. there was started the procedure of forced execution in the case of individual or legal entities; the court decided to declare bankruptcy;
6. the court decided to declare bankruptcy

3. The solvability indicator

According to the methodological norm of BNR no. 12/2003 concerning the supervision of solvability and large exposal of credit institutions, the banks are forced to calculate the solvability indicator and to maintain it at a minimum level of 12%. This solvability indicator represents the transposable into Romanian legislation of Basel I Agreement concerning capital adequacy, with the mention the minimum value recommended by this agreement for the solvability indicator is 8%.

The solvability indicator expresses own funds (as defined in the norms of The Central Bank of Romania regulating the own funds of the credit institutions) as percentage from the total assets and extra balance sheet elements, net of provisions, adjusted according to the risk.

Credit institutions report to The Central Bank of Romania on a quarterly basis the solvability indicators calculated on individual basis, and, quarterly, the solvability indicators calculated on consolidated basis.

In the calculation of the solvability indicators, assets and extra balance sheet elements are evaluated according to the accounting regulations harmonized with Directive no. 86/635/CEE and with The International Accounting Standards applicable to credit institutions.

The own funds, as defined in the norms of The Central Bank of Romania regulating the own funds of credit institutions; represent the numerator of the solvability indicator. The numerator of the solvability indicator is represented by assets and extra balance sheet elements, adjusted according to the risk.

The risk degree ascribed to assets is expressed by a percentage, while the balance sheet value of each asset is multiplied by the adequate percent in order to obtain a value adjusted according to the risk. In the case of extra balance sheet elements, expressly enumerated by these norms, there is performed a two staged calculation.

In the case of extra balance sheet elements, the potential costs for replacing contracts, in the case in which the counterparty does not pay its obligations, is calculated by applying the method described in annex II to Norms no.12/2003. These costs are multiplied by the amounts corresponding to the counterparty, excepting the amounts of 100%, which are replaced with 50% in order to obtain values adjusted according to the risk. The sum of the amounts according to risk of assets and extra balance sheet elements represents the numerator of the solvability indicator.

In the case in which the asset elements and the extra balance sheet elements enjoy a lower weight due to the existence of direct, express, irrevocable and unconditioned collaterals or to the collateral acceptable in the opinion of The Central Bank of Romania, the smaller weight will be applied only to the parts guaranteed or entirely covered by collateral.

Credit institutions are obliged to permanently maintain the solvability indicator calculated above on a level of at least 12% and, in the case in which the indicator decreases below 12%, the respective credit institutions have to adopt adequate measures in order to re-establish, as soon as possible, the minimum level of this indicator.

BASEL II CREDIT RISK MANAGEMENT AGREEMENT

Bâce Grigore

Babeş–Bolyai University, Cluj-Napoca, email: grigore.bace@bnro.ro, telephone no 0264598583,

Abstract. In the paper the author show the modalities of financing the companies taking into account Basel II Agreement.

Key words: capital adequacy, currency mismatch, haircut

1. The necessity of improving Basel I Agreement

In July 1988, The Basel Banking Supervision Committee issued a set of recommendations referring to the introduction of a minimum level of capital for international active banks in order to facilitate the fair competition between them (foe example, the Japanese banks has a much lower capital then non Japanese banks with the same credit risk).

The proposals of Basel Committee were not imperative, but an expression of good practice. In the European Union there were introduced though the Capital Adequacy Directive.[231]

According to the agreements, the basic capital of a bank has to be maintained at least 8% from the banks' exposal, and to the different exposal categories there were given a percent from 0 to 100, while to loan for companies a percent of 8%, irrespective of the credit's quality.

The main deficiency of this agreement was the fact that the percents used – 0, 20, 50 and 100% - was given on a simplistic basis. For example, a bank had to form the same capital irrespective if it gave a guaranteed credit to an AAA rating company or an un-guaranteed credit to a BBB rating company. Thus, a bank could administer these norms in the sense that exposal from high quality credits could be sold and credits could be given to debtors of inferior quality, but with a better yield. But, at that time the agreement was considered as a good compromise, since the technology of risk management was not developed enough to enable finer tuned capital request, and the banking industry required minimum capital requests harmonized for fighting the decline in banks' capital.

From that moment on, the process of allocating capital as compared to given credits became more sophisticated and many banks developed their own rating systems. Many banks went forward and used the series of historical data referring to the losses in the crediting activity in order to estimate the average and variation of losses for every type (measures) of credit and, thus, there were estimated the probability distributions of losses. These estimations could have been used for the whole management of credit portfolio, so that the bank would maintain a target rating of its credit portfolio.

In 1999, the Basel Committee decided to rectify the capital adequacy regime in order to adapt it to the changes in the process of risk management used by banks and that would offer them more freedom in credit risk management. In this sense, in 1999 and 2003, there were made public two consultative agreement projects and in July 2004 there was published the final version of the agreement.

The new agreement acknowledges the progresses made in credit risk management and brings incentives for enabling banks to use sophisticated models of risk management. Moreover, it is allowed the use of credit risk derivatives for covering the positions generated by crediting.

The agreement is structured on three pillars:

---

[231] 393L0006 (Capital Adequacy Directive) – Council Directive 93/6/EEC of 15 March 1993 on the capital adequacy of investment firms and credit institutions (Annex V), modificată de 398L0031 – Directive 98/31/EC of the European Parliament and of the Council of 22 June 1998 amending Council Directive 93/6/EEC on the capital adequacy of investment firms and credit institutions şi de 398L0033 – Directive 98/33/EC of the European Parliament and of the Council of 22 June 1998 amending Article 12 of Council Directive 77/780/EEC on the taking up and pursuit of the business of credit institutions, Articles 2, 5, 6, 7, 8 of and Annexes II and III to Council Directive 89/647/EEC on a solvency ratio for credit institutions and Article 2 of and Annex II to Council Directive 93/6/EEC on the capital adequacy of investment firms and credit institutions.

- Pillar 1: minimum requirements of capital – the quantitative approach of prudential requirements;
- Pillar 2: supervision of the process of capital adequacy;
- Pillar 3: market discipline – requirements of more detailed reporting of the supervision institution and the population.

In order to calculate the required capital, Basel II agreement suggests three different approaches:

1. Standard approach, similar to that proposed by Basel I, uses more refined percents. This approach also enables the use of derived financial instruments for limiting credit risk and decreasing capital requests.
2. Foundation internal rating based (IRB) approach, which allows the bank to use its own rating system, including the use of own calculation regarding the probabilities of entering payment default (PD), but the losses recorded when the counterpart enters loss given default (LGD) are provided by the supervision authority.
3. The advanced IRB approach, where banks calculate their capital requirements basing on their own models, validated by the supervision authority, including PD and LGD probabilities.

The main advantages introduced by the new capital agreement are:

- Take intro account the specificity of each credit institution and the risk profile it presents;
- Leads to the development of the rating agencies market;
- Ensures the diversification of the models referring to risk evaluation and the determination of the capital requirements in the context of the evolution from a simplified approach to advanced approaches;
- Implies the formation of human resources in order to due efficiently the procedures of evaluating rating agencies, the unfolding of the supervision process according to the requirements of the second Pillar and validation of the internal models of the credit institution;
- Stimulate the market transparency and discipline.

The main advantage of the new prudential requirements is that they imply the allocation of additional financial and human resources, cost that, on intermediary term, and will be compensated by the decrease of capital requirements.

2. Standard approach

In the standard approach, the percents are given according to the type of credited state/institution and according to their rating.

The most important categories of debtors are:

- States, including central banks;
- Local authorities;
- Multilateral development banks;
- Banks;
- Corporations.

Debtor	**Capital requirements**					
	AAA la AA-	**A+ la A-**	**BBB+ la BBB-**	**BB+ la B-**	**Sub B-**	**Fără rating**
States	0%	20%	50%	100%	150%	100%
Banks Option 1 (a)	20%	50%	100%	100%	150%	100%
Option 2 (b), (c)	20% (20%)	50% (20%)	50% (20%)	100% (50%)	150% (150%)	50% (20%)

				BB+ la BB-	Sub BB-	
Corporations	20%	50%	100%	150%	150%	100%

Table 1 - The Rating System

a) percents are based on the rating of the state where banks have their headquarters
b) prevents are determined according to the rating of the bank;
c) Between brackets there are indicated the percents for short term (less then 3 months) credits.

In order to expose the retail credit (considered as such by the supervision authority), the risk percent is 75%. According to Basel II, on order to be classified as retail, the exposal has to meet the following conditions:

- to be over a individual entity or small business;
- to be generated by a certain bank product, for example credit cards or consumption credit;
- should not be over 0.2% from the retail portfolio acknowledged as such by the supervision authority;
- should not be over 1 million euro for any counterparty;
- these principles have been included in REF 14/2006

For the exposal on mortgage credits, capital requirement is 35%, substantially lower then 50% of Basel I.

The standard approach is largely based on the external ratings given by rating agencies (external credit assessment institutions, ECAI), acknowledged by national supervision institutions.

The eligibility criteria for rating assessment companies are:

- Objectivity: The methodology for rating determining has to be rigorous, systematic and validated on historical experience. Moreover, ratings have to be permanently re-evaluated and to answer to the changes of the financial standing of the debtor. Before being recognized by the supervisor, the methodology of determining the rating for every market segment, including their testing, has to be applied for at least 1 year, preferably 3 years.
- Independence: The external agency of rating should be independent and not subjected to political or economic pressure that might influence rating. The process of determining the rating should be free of the constraints that might appear in circumstances in which the composition of the administration council or of the shareholders' structure may be accused of creating conflicts of interests.
- Disclosure/ international access: Individual rating should be available both to national and international users. Moreover, the general methodology of rating assessment should be publicly available.
- Disclosure: The rating institution should make available the following information: the methodologies of rating assessment, including the definition of PD, current ratios of PD for each rating category and the probabilities of transition from one rating category to another.
- Resources: The rating institution should have enough resources for giving high quality ratings. These resources should enable the constant contact with the superior and operational levels of the units the rating of which is evaluated, in order to add value to the given rating. The evaluations should be based on methodologies that combine quantitative and qualitative approaches.
- Credibility: To a certain extent, credibility is derived from the above criteria. Moreover, the dependence of the independent users (investors, insurance societies, trade partners) of the ratings provided represents a proof of the credit institutions' credibility. Credibility also is influenced by the existence of internal procedures preventing the inadequate use of confidential data.

Basel II acknowledges credit risk reduction techniques through collateralization, collaterals and credit risk derivatives.

As far as the collateral is concerned, there are allowed two modalities of approach. The simplest approach is similar to Basel I approach, according to which the credit risk percent is replaced with the collateral's risk percent, which can not be smaller then 20%. The other, more advanced, approach, for protecting the bank against the volatility of the collateral's price, is based on the adjustment of the collateral's market price by applying haircuts, either provided by supervisor (basing on quantitative and/or qualitative criteria, or internally calculated. Then, the adjusted market value of the collateral is deducted from the gross value of the credit, thus obtaining the adjusted exposal, and then multiplied by the corresponding risk percent.

Thus, for a collateralized transaction, the exposal after risk mitigation procedure is calculated as follows:

$$E^{*} = \max\{0, [E \cdot (1 + He) - C \cdot (1 - Hc - Hfx)]\}$$

where:

E^{*} is the value of the exposal after risk mitigation procedure;

E – current value of the exposal;

He – the *haircut* applied to the respective exposal;

C – current value of received collateral;

Hc – the *haircut* applied the respective collateral;

Hfx – the *haircut* applied for *currency mismatch* due to the expressed in different circulating mediums of the exposal and the collateral.

When the collateral is formed from a basket of assets, the haircut applied the the asset basket is $H = \sum_{i} a_i H_i$, where a_i represents the percent of the asset (measured in circulating mediums) in the basket and H_i represents the haircut applied to the respective asset (Regulation of BNR no 19/2006).

The acceptable collateral according to both approaches represents:

- Money or deposits;
- Financial securities with at least BB- rating issued by the government or public authorities;
- Financial securities issued with corporation of at least BBB- rating;
- Shares or bonds belonging to a principal index;
- Gold.

Moreover, the advanced approach accepts shares that do not belong to a principal index, but are tranzactioned on a principal market, bonds without rating issued by bank institutions, collective and mutual funds investment securities.

In order to use these types of collateral, a bank has to meet standards referring to:

- the legal certainty of the documents used;
- the requirement that the assets used for risk mitigation should have a reduced correlation with the credits the risk of which is reduced by them;
- the solidity of the management policies of the collateral.

The proposals referring to warrants and balance sheet netting enlarge the area of eligible warrants or of suppliers of derived contracts on credit risk, through the acknowledgement of the protection for credit risk provided by the government or other banks with lower risk percentage then the debtor's and other units with A- or better rating. This latter category included the protection provided by the mother-company, subsidiaries or affiliates of the debtor, when they have a lower risk percentage then the debtor.

As for the collateral, in the case of the compensation there are determined haircuts. Thus, the exposal obtained after the use of a master netting agreement is:

$$E^{*} = \max\{0, [(\sum(E) - \sum(C)) + \sum(Es + Hs) + \sum(Efx \cdot Hfx)]\}$$

where

E^* is the value of the exposal after risk mitigation procedure;

E – current value of the exposal;

He – the *haircut* applied to the respective exposal;

C –value of received collateral;

Es – absolute value of the net position in a financial security;

Hs – *haircut* applied *Es*;

Efx – absolute value of the net position in a circulating medium different from the *settlement currency*;

Hfx – *haircut* applied for reducing *currency mismatch*.

As an alternative to the standard approach and the estimation of own percentages for the collateral (advanced approach), banks may use value-at-risk (VaR) models for reflecting the volatility of the exposal and the collateral for the *repo* contracts covered by netting contracts.

The use of VaR models is allowed only for the banks with internal models of market risk acknowledged by the supervision authority according to the Market Risk Amendment. Those banks that did not receive this authorization may request separately (from Market Risk Amendment) the supervision authority to acknowledge the above models of market risk for *repo* transactions. These models will be authorized only if the bank is able to prove the quality of the model used though data referring to the testing of its results for a period of time of at least 1 year.[232]

In this context, the exposal for the banks using internal models of market risk is:

$$E^* = \max \{0, [(\sum(E) - \sum(C)) + \text{multiplicator} \times \text{results VaR}]\}$$

In the calculation of capital requirements, banks will use the result of VaR model (VaR value) corresponding to the previous working day.

As far as the derived contracts and guarantess are concerned, the operational requirements to be completed are:

- they have to be a direct receivable over the protection seller and have to refer to the specific exposal (or the group of exposals) , so that the protection should be clearly defined and solid;
- the contract should be irrevocable; the contract should have no clause stating that the protection seller may, unilateraly, renounce the ensuring of credit risk protection or to increase the cost of protection in the case in which the quality of the credit deteriorates;
- the contract should be unconstrained;
- the contract should have no clause that would allow the protection seller to delay the payment of damages in the case of the credit event.

If protection is in another circulating medium, its value should be reduced by applying a haircut:

$$G_A = G \cdot (1 - H_{FX}),$$

where:

G – nominal value of credit risk protection;

H_{FX} – *haircut* applied;

G_A – effective value of collateral.

In the case in which there are maturity differences between the instrument providing credit risk protection and the credit instrument, the value of the credit risk protection will be adjusted as follows:

$$\mathbf{Pa = P \times \frac{t - 0.25}{T - 0.25}},$$

where:

Pa = value of credit risk protection adjusted for maturity differences;

[232] The supervision institution rates these models according to the errors generted in the green, yellow and red area and, according to the area to which the model belongs, it gives a multiplier for VaR value.

P = value of credit risk protection adjusted for any *haircut*s;

t = min (T, residual maturity of protection contract) expressed in years;

T = min (5, residual maturity of credit risk exposal) expressed in years.

3. Internal rating approach

This method anables banks to determine their capital requirements for different exposals, using their own estimations for a part or all the components of risk. They include:

- the probability of default;
- loss suffered by the bank (as percentage from the value of the exposal) in the case of loss given default;
- exposal in the moment of exposure to default, EAD;
- effective maturity of the credit instrument, M.

The use of an own methodology in estimating these credit risk components is the object of the supervision authority's approval and, in certain circumstances, banks will have to use, for one or several risk components, values provided by the supervision authority.

THE IMPACT OF EUROPEAN INTEGRATION ON THE PAYMENT SYSTEM

The introduction of euro in 2002 led to the creation of a single "domestic" market for cash retail payments in euro. In order to create a single market for cashless payments as well, the European banking community, ahead by European Council Payments, has launched the Single European Payments Area project (SEPA) in 2002. The project designed new payment schemes for credit transfer and direct debit, as well as a card payments framework. SEPA credit transfer scheme was officially launched on 28 January 2008. The whole project is expected to be implemented by the end of 2010. In this paper we refer to the necessity of introduction of this ambitious project, to the essential features of its components and to its overall economic impact. We also discus the challenges of Romanian payment system generated by the implementation of SEPA.

Keywords: payment system, Single European Payments Area, Romanian payment system

Introduction

Over the last two decades payment and settlement system have gained an increasing importance in the most countries as a result of a growth in the volume and the value of transactions resulted from money and foreign exchange markets, in particular, and from financial markets in general.

Generally, a payments system is made of three major components:

- RTGS system settles large-value payments on one to one basis.
- Clearing House settles low-value payments through clearing system on net basis.
- Securities settlement system – settles transaction with securities.

Given the fact that payment system represents the main channel through which central bank implements monetary policy, it has a vital importance to the economy, especially in what concerns well functioning of financial system and assurance of financial stability.

1. Payment System in Euro zone

Since the payment system plays a vital role both in terms of financial stability and facilitation of transactions among customers, European Central Bank and the Eurosystem give an important attention to the smooth functioning of the payment system in the euro area.

1.1. Components of Payment System in Euro zone

The payments in euro area are settled through the following components:

- TARGET (Trans-European Automated Real-time Gross settlement Express Transfer system) settles large-value euro payments. It was created by interconnecting national RTGS systems and the ECB payment mechanism in January 1999. Today TARGET is the largest payment system in the world (Godeffroy J. M., p.1).
- The Correspondent Central Banking Model allows Eurosystem counterparties to use their eligible marketable assets issued in other euro area countries as collateral in order to get a credit from their home central bank.

- EBA (Euro Banking Association) Clearing is a private provider of both high-value and low-value clearing and settlement services to banking community in the European Union through three systems: EURO 1, STEP 1 and STEP 2 (the only retail payment system).

1.2. Payment instruments in euro area

The most used cashless payment instruments within euro area are credit transfer, direct debit and cards (www.ecb.int).

Credit transfer is a payment instruction initiated by the payer, being sent to the payer's bank, which moves the funds to the beneficiary's bank, possibly through some intermediaries. Credit transfers are the most used instrument, representing around one-third of cashless payments.

Direct debit is a payment initiated by the payee through its bank, after the agreement between the payee and the payer. Direct debits are used both for returning payments with a pre-authorised agreement and for one-off payments where the payer authorises the individual payments. The payments through direct debits represent around one-quarter for all cashless euro payments.

Cards are issued by a credit institutions or card company. They can be debit cards or credit cards. Debit card allows the cardholder to charge purchases directly and individually to an account. Credit card allows the cardholder to make purchases within a certain credit limit. Card payments represent less than one-third of cashless payments.

2. SEPA – Single European Payments Area

2.1. Creating of SEPA

In spite of the introduction of euro in 2002, the payment systems of member countries adopters of single currency were not equipped to handle it as differences between national and cross-border payments continue to exist. Since then a "domestic" market for cash retail payments in euro was created, but not for cashless. Although large-value payments, procedures, instruments and services have been harmonized until today, this performance was not achieved in the case of retail payments. To pass these deficiencies, the European Payment Council (EPC), the decision-making and coordination body of the European banking industry in the domain of payment, launched the SEPA project in 2002. It represents a programme which aims to create a single domestic payments market in euro, where, the costumers could make cashless payments in euro zone as easily, efficiently and safely as in their domestic countries, from a single account anywhere in the euro zone using a single set of payments instruments (Schmiedel H., p. 5).

European banking community is now implementing common standards and procedures for credit transfers, direct debits and payment cards to eliminate the differences between domestic and cross-border payments in euro. Creation of SEPA between 2008 and 2010 may be compared to the transition process from national currency to a single common currency (Schaefer G. K., p. 3).

SEPA is implementing in three stages (ECB 2006, p.14):

1. The design stage began in 2004, engaging the plan of the new credit transfer and direct debit scheme and the framework for cards, clearing and settlement infrastructure.
2. The implementation stage last between the mid-2006 and end-2007, consisting in preparation for the adoption of the new SEPA instruments, standards and infrastructure.
3. The migration stage started in January 2008, being characterised by the coexistence of the national payment schemes with the new SEPA schemes.

2.2. Components of SEPA

SEPA takes into consideration the following aspect (ECB 2006, p.19-26):

1. SEPA instruments

SEPA introduced two new payment schemes for credit transfer and direct debit as well as a card payments framework. These instruments will gradually replace the current national instruments.

a) SEPA credit transfer is an interbank payment scheme which defines a universal set of regulations and procedures for credit transfer denominated in euro. In this scheme any customer can be reached. The whole amount is credited to the payee's account, without a limit on the value of the payment. The duration of settlement is maxim three business days.

b) SEPA direct debit is an interbank payment scheme which defines a universal set of regulations and procedures for direct debits denominated in euro. Under the SEPA there are two different models for direct debits: 1) debtor gives the mandate directly to the creditor and 2) debtor gives the mandate directly to its bank. In this scheme direct debits can be made to any receiver. The duration of settlement is maxim five business days for the first payment and two business days for returning payments. SEPA also develops a business-to-business direct debit scheme.

c) SEPA card framework sets out a set of high-level principles regarding of card payments, developed by EPC. Under this framework cardholders will be able to pay with a single card all over the euro area, being limited only by brand acceptance by merchants. Card payments will be made in a common and reliable way. Payment card processors can complete with each other and provide their services within euro zone, building a more competitive, consistent and cost-efficient card market.

2. SEPA infrastructures

The SEPA clearing and settlement framework refers to the principles according which infrastructure providers will sustain the SEPA instrument schemes. This framework also ensures the separation of scheme and structure. SEPA aims to build an infrastructure which allows all euro payments to be made, received, and settled directly or indirectly and to assure full transparency in terms of infrastructure providers' services and prices.

3. Standardization

In order to permit automated processing of all payments denominated in euro, the EPC has adopted a common approach of standards regarding business requirements, logical data elements and payment messages. These standards are obligatory in the bank-to-bank field and suggested in the customer-to-bank field.

4. Legal framework

The legal framework for SEPA instruments was set up taking into account three main issues:

- The right to provide payment services to the public
- Transparency and information requirements
- The rights and obligations of users and providers of payment services.

2.3. The impact of SEPA

The SEPA project is comparable to the switch to the euro from the point of view of its aspiration, dimension and complexity. Thus it represents the rational main further step towards faster European integration. The implementation of SEPA will get several positive economic effects and opportunities, but also challenges (Schmiedel H., p. 5):

- Costumers, both citizens and companies will benefit by the ease, safety and simplification of making payments in euro using a single bank account. Also, SEPA will stimulate the competition among banks in order to provide innovative services and new, added value products to their costumers.
- Within SEPA, the payment cards will became the favourite instrument, replacing the cheques and cash payments. The costumers will be able to use a single card for all euro payments, which will led to an increase in usage of cards. Moreover, the increasing competition among acquirers and card scheme should drive down costs and fees.
- The overall impact of SEPA on banking community differs depending on its stages. Over time the benefits and challenges of SEPA are influenced by two contradictory effects: first, the increasing in banking industry competition due to the elimination of the barriers across national countries and, second, the assurance of cost savings in payment processing and growth of business opportunities.

In the short term, the coexistence of SEPA and national retail payment schemes is supposed to generate higher cost and a limited impact on the banks' income. The industry and consultancy studies focused on the impact of SEPA show that the initial investment costs of banks at European aggregate average level are range between 5.2 bullion euro and 7.7 bullion of euro, as it is presented in table below (Schmiedel H., p. 9).

Study	Estimated SEPA investments in EUR billion	
	Low	High
Accenture/PSE Consulting (2006)	3	>8
Boston Consulting Group (2006)	0.5	5
Eurogroup/FBF (2007)	9.1	12
Iflex-solutions/Financial Insights (2006)	5.4	5.4
TowerGroup (2005)	8	8
Average	5.2	>7.7

Table 1 Overview of selected SEPA impact studies

In the longer run, when SEPA schemes will replace national schemes, the banks' costs are expected to diminish due to automation, possible economies of scale and scope and innovations (e.g. electronic invoicing). The banks' income will also be influenced by the increasing of competition. Furthermore, the banks' approach will have a significantly impact on costs and incomes. Banks that introduce supplementary automated services will be able to produce new business opportunities (Schmiedel H., p. 20).

The cost of the new system could be significantly diminished by extending the implementation stage because SEPA could be better fit into the technological innovation cycles of national payment systems. Thus, SEPA will have the possibility to become a welfare enhancing project, through the cost reduction for cross-border transactions and higher efficiency due to the increased cross-border competition in banking industry (Schaefer G. K., p. 25).

2.4. Implementation of SEPA

SEPA includes all the member countries of euro zone, together with the other members of European Union, and Island, Liechtenstein, Norway and Switzerland.

On 28 January 2008 the European banking community formally launched SEPA credit transfer. This represented the first step in a migration process during which costumers will move from existing national electronic payment systems to the new SEPA instruments. During the migration period customers will be able to use SEPA schemes parallel with the national instruments. Since the initial points are different across euro zone, most of the migration work will take place at the national level.

The next important step will be the introduction of SEPA direct debit by the end of 2009, whose implementation was delayed for juridical and technical reasons. This scheme will require to be improved by further options in order to offer appropriate solutions for diverse consumer requests.

This will be followed by implementation of SEPA card framework, which came into effect on 1 January. This will generate wide changes on European card markets. The objective of SEPA project with regard to card is to support the expansion of this instrument from both supply (banks) and demand (cardholders, merchants) points of view, with no difference between national and cross-border card payments. A new European card scheme is expected to emerge, harmonizing card payments in euro area (Tumpel-Gugerell G., p.2).

By the end of 2010 all infrastructures should be able to process SEPA payment instruments and public administrations, companies and citizens will use exclusively the SEPA instruments.

3. Romanian Payment System

3.1. Introduction of Electronic Payment System

Romania's joining of European Union required the implementation of an electronic payment system, similar with the systems used by the member countries. In this purpose, a large project was lunched in 2001, co-financed by the EU (through PHARE) funds in amount of EUR 8.04 million and by domestic banking system (through TRANSFOND) in amount of EUR 8.4 million (NBR, Annual Report 2005, p. 63). The implementation of the new Electronic Payment System (EPS) was the widest project coordinated by the National Bank of Romania (NBR). The EPS is compatible with the payment systems in the EU regarding the functionality and conformity with international standards and practices in the field. The EPS, gradually implemented in 2005, is managed by the NBR and services related to technical operation are provided by TRANSFOND (National Society for Funds Transfer and Settlement), which was set up in 2001, being a joint-stock company, held by NBR (33.3%) and 25 credit institutions (66.67%).

3.2. Components of Electronic Payment System

Romanian EPS comprises three components (BNR, Annual Report 2005, p. 65-73):

1) ReGIS system (the Romanian electronic Gross Interbank Settlement system)

ReGIS, launched on 8 April 2005, represents the real-time gross settlement system, ensuring the settlement of large-value (above 50,000 RON) and urgent payments in domestic currency realised by credit institutions, on its own behalf and account or on customers' account as well as of payments in domestic currency arising directly from or made for the settlement of net positions initiated by the net settlement systems and the settlement of operations performed with financial instruments. ReGIS ensures the connection to the TARGET.

2) SENT system (the System for Electronic Net Settlement run by TRANSFOND)

SENT, launched on 13 May 2005, represents the automated clearing house, ensuring the clearing of low-value payments (for instance, credit transfer and direct debit smaller than 50,000 RON) among credit institutions and between them and State Treasury and the computation and transmission of multilateral net positions of the participants for final settlement in ReGIS. Presently, the clearing sessions take place three times on day. The clearing of order payments accepted by SENT requires the insurance by collateral under the form of funds and/or government securities deposited in the ReGIS or SaFIR systems.

3) SaFIR system (Settlement and Financial Instruments Registration)

SaFIR, launched on 3 October 2005, represents the depository and settlement system of operations with government securities and certificates of deposit issued by NBR. SaFIR is a real-time gross settlement system, which organizes and manages the registration and transfer of property rights on these financial instruments, and settles the transactions related to them.

In the architecture of the Romanian payment system there still functions a system of paper-base clearing of payments related to debit payment instruments (cheques, bills of exchange and promissory notes), which will be replaced in the future by an electronic system operates through SENT. EPS also includes a back-up and recovery system, whose aim is to assure the permanent operation of the payment system in the situation of unforeseen events.

3.3. Impact of SEPA on the Romanian payment system

Conclusions

The adoption of euro as single European currency will be finished only when the SEPA will entirely become a reality, allowing the customers to make cashless payments across euro area, using a single bank account and a single set of instruments, as easily, efficiently and safety as in their national payment systems today. The implementation of SEPA will get several economic benefits and opportunities for customers and merchants, but also challenges. From the view of banks, initial stages of SEPA requires substantial changes and the positive effects can appear mainly for those banks that launch new technological products and provide innovative services. The implementation of SEPA in Romania needs for the support of the regulating local authorities and also for massive investments in the banking system.

Fifteen Romanian banks have already joined SEPA and have engaged to respect the SEPA standards as far as credit transfer operations in Euro are concerned. Other Romanian financial institutions must fulfil the adhering process by the end of December 2010.

LABOUR FORCE AN IMPORTANT FACTOR IN A BANK SYSTEM

Breje Cristina Emilia

University of Oradea, Faculty of Economics Scienties, Univesity Street No. 1, cristinab_or@yahoo.com, Tel: 0359-450392

This work belongs to a more ample paper: "Evolutions and tendencies of the human resources in the Romanian banking system after 1990" and presents the results of the first stage of the research: documentary analyse.

Introduction

Human resource is complex, it can't be easily measured and to be efficient it requires, from the organization, a permanent supporting and developing effort. It also has:

- an active role within the framework of the economic process;
- it communicates with the medium where it works;
- it offers an unlimited potential profit.

Analyses

The manpower of the banking system is a priceless active, it has a very important role in a bank's success, performance and competitiveness. The banking system manpower is very important in the promotion the products and of the services of the bank where she/he works. Among the indicators aggregated by the performance the most important are:

- the clients' satisfaction;
- the profit
- the efficiency
- the staff turnover

The real profit growth is the most important factor which determines the bank's share increase. The real profit development is realized only through a lasting increase, increase which is mainly influenced by the growth of the loyal clients base. Loyal clients may constitute an important, oral and unwarranted selling force. But to increase the number of the loyal and contented clients the banks need employees who involve themselves[233]. The employees who involve in their activity influence the profit either indirectly through the productivity increase or directly through turnover decrease. Each bank has to assure itself that its staff is in good relation with the clients, because the success depends on the hired staff. Each employee of the bank interacts both with inner clients (colleagues, superiors) and with external clients[234], on the employee's attitude and behavior also depends the image and the reputation of the bank. There is a strong connection between the quality of the services offered to the colleagues and the quality of services offered to the clients. The way in which colleagues help one another to solve different problems makes an impression on the offered services. On the service quality received by the inner clients depends the service quality extended to the external clients. There is a proportional report between the number of the services used by the client and the productivity of the bank.

A study realized by BNR underlines that one of the most important competitive advantage of a bank is represented by the qualified staff. The competent employees, who like what they do, who feel good in the staff they work with, tend to be more productive, try to know better their clients and their clients' desires. The benefits resulted from the clients reward represents the key to the drawing of the new clients.

In this moment the banking market is concentrated around five banks, which hold more than 60% of the market share[235]. The Romanian capital of banks has significantly decreased (52,2% in 1998 in regard to 6%

[233] Marcus Buckingham, Curt Coffman-Manager against the stream-Editura Allfa 2007
[234] Iuliana Cetină, Emanuel Odobescu, Banking Marketing Strategies, Editura Economică, 2007
[235]Yearly Reports BNR

in 2006), while the foreigner grew from 24,3% in 1998 to 54,7% in 2006). Last year, the banks from Romania accomplished a cumulated net profit of 2,74 billions lei, more with 24,5% comparative to the result obtained in 2006 according to the information reported by the credit institution to BNR. Over 50% of the net profit realized by the banking system belongs to BRD – Groupe Societe Generale and to Banca Comerciala Romana (Romanian Commercial Bank).

The net profit for each wage-earner has grown with 10,5%, from 38.000 lei/employee at the end of 2006 to 42.000 lei/employee at the end of the last year, taking into account that the staff from the banking system has been supplemented with 7.565 employees, to 65.655 employees.

Once with the buying-out of the banking system, foreign experienced managers have been named to manage the banking institution from our country, to develop the business according to the new business lines from the modern banking. But the most important leading positions of the banks are occupied by Romanian bankers. That's why it is very important to know how to train that persons from these key positions, what has to be done not to lose them and how to get an important position. It is very useful both for the universities and for the banks from the banking system to know the tendencies of the human resources, the favorite staff qualities in the banking system, the working conditions, how to form those indispensable specialists, how to prevent the human resource migration in order to succeed to keep and to motivate the staff.

The establishment of the correct politics, the determination of the necessary abilities, finding the applicants, the elaboration of some registration forms, the recruitment and the interview of human resource has a very important role in order to have "the right man in the right place" [236].

A bank employees are its most important clients. In our days there is a crisis of human resources in the banking system due to the fact that this field is developing now[237]. At the end of September 2007, in the banking system there were over 62.000 employees, with 17% more than at the end of the same month of the last year. Many banks have announced to extend in 2008. BCR aims, for 2008, to reach to a network of 700 units, form over 550 in the present, and UniCredit Tiriac has planned to open other 70 new branches. Raiffeisen Banks wants to open 250 units until the end of 2008. Volksbank Romania plans to extend its network of branch offices till it gets to 200 units in 2008, from the 135 units estimated for the end of 2007 and to increase at least twice and a half the number of franchises, from the 90 of this kind of agencies at the end of this year[238].

Competent persons are needed in banks, persons who posed the pluralism of knowledge, abilities and behavior necessary for the banking system. Financial-banking or economical studies are not compulsory to hire in a bank as long as you can adapt and as long as you are competent. Concerning the persons with experience, they are coming either through internal promotion or from other banks, the fluctuation in the banking system is on average of 25-30%, as results from the specialty reviews. In the most cases, the lack of specialists from the financial-banking field is recorded in the case of middle and top management positions. If in the administrative field, of entry-level, of human resources or of IT, the vacant positions are easier to cover, there are specialty and technical positions, such as the ones from the operations, sales and the department manager, which are more difficult to cover if there aren't specialized people. A well-known phenomenon in the subsidiaries and the branch offices in the small towns, where relationships between people are warmer, is that the branch office manager goes together with a part of the team and more than that it is possible to go together with the clients. A departure from one bank to another brings to the employee an increase of the wage with 30%, and, if the position needs relocation, the percentage in almost always bigger.

The banks declare different rates of fluctuation of the staff: BT – 12% in 2007, Raiffeisen Bank – 0,7% in 2006, BRD – 3,5% in 2007, RBL – 11% in 2006[239]. The staff fluctuation implies certain costs for the banks such as: direct costs for the staff substitution, costs related to the lost of the key persons in organization, costs related to the lost of the relationship with the clients and of the acquaintances.

To assure the staff, the banks have found many methods in order to attract the possible employees. So, the banks have implied, more and more in the last years, in collaboration with different institutions of higher education in the field, trying to attract, from the university years, the precious persons and the ones with potential. The banks have to identify their staff qualities and then to install them in a position which offers

[237] Financial Week, A new crises on the working market: we don't have any bankers, Art. published in 15.01.2007
[238] http://www.ghiseulbancar.ro/articole/54/8619/Romanian_banks_extended_very_much_in_2007_si.htm
[239] www.wall-street.ro

them the possibility to develop these abilities. The banks have to assure their staff: mentoring programs, carrier management, the company values reconfirmation, training and team building.

Generally, the feeling of affiliation towards the employer is direct proportionally with the satisfaction of the activity which the employee develops and with the reward system offered by the company. But if the banks don't pay too much attention to their employees, if they don't motivate their employees then they risk to lose the best employees, they risk to suffer due to the lack of the staff and to increase the operational risk. Motivation can be made through financial methods:

- direct rewards which include: wages, benefits, prizes, participation to the profit, commissions, the possibility of buying shares from the bank where they work, etc. The remuneration policy of the banks takes into account, besides the wage, performance bonus and other premiums, granted depending on the bank performances (yearly, after the publication of the results for the ended financial year) or depending on the individual performance of an employee (the participation to an important project, the attraction of a strategical client, special results) or, if there is the case, there are decided certain promotions[240].
- indirect rewards are the help offered to the staff during the labour contract, but even afterwards, in certain conditions and can include compulsory legal rewards such as indemnities for holidays, unemployment support; rewards regarding the pension such as inheritance pensions, smart money, additional pensions, etc; different assurances; the charge for the free time, for instance some free days with the occasion of some events in the family; special easements for employees; other indirect rewards such as the deflations to the commissions for operations, discounts for the credits interests and errands, free confectionery products, Christmas parties, different championships, etc.

Non-financial motivation is more and more used:

- merits public recognition;
- respect from their chief;
- promotion conditions.

But the solution isn't the wage increase, the most important factor is the satisfaction at the workplace.

The main reasons which determine the employees to direct to another workplace are[241]:

- the lack of a professional evolution vista;
- the lack of correlation between the results and the wage interest;
- the lack of the results appreciation;
- the appearance of an opportunity in another company;
- the wage interest;
- the relationship with the chief;
- the team atmosphere;
- the work volume is too high.

Proposals for a bank with content employees:

- communication with the employees
- resistance to change diminution
- the creation of a medium perceived as being just
- organizational culture evaluation
- changings observation
- employees reallocation

Abstract: In this study we try to underline the main challenges and perspectives for financial stability and financial surveillance. Our investigations regard the European environment issues. We make some consideration about the advantage and disadvantage of financial integrated supervision in relation with sectorial one. Also, we talk about the controversies concerning the central bank involvement in surveillance process and financial crises management. In the end, we highlight the National Bank of Romania preoccupations for financial stability in the European integration perspective.

Key words: financial stability, European integration, central bank, reform, challenges, perspectives, regulation, financial surveillance

Introduction

The transformations in the economic environment lead to a continuous accommodation in what concerns the assurance of financial stability. A series of actual phenomenon constitutes the main challenges for the public authorities. Among the most important ones, without an hierarchisation, are:

- the development and diversification of financial markets, its actors and products offered, connected with the financial innovation;
- the globalisation and the (European) integration process;
- the inflation menace and the fight against it;
- the universalization versus specialisation in the banking activity, connected with the development of giant multinational financial groups.

The financial innovation has as consequence the development and diversification of financial markets, its actors its products and services offered. This trend is doubled by a contradictory process, of universalization and specialization in the financial – banking activity. In a continuously changing market, the financial institutions must restructure themselves in order to remain competitive.

Financial supervision and financial stability

The number of financial conglomerates in World Top 500 of financial institutions increased from 42% to 60% only between 1995-2000[242]. Such a trend called for a specific response also from the surveillance institutions point of view – the increasing number of national consolidated financial supervision agencies.

The first consolidate financial supervision agency was created in Singapore in 1982 and after that in Norway, in 1986, soon other Northern European Countries adopting this system. The same system was adopted also in other countries, including Australia, Japan or Korea, but from the globally 29 such agencies registered in 2004, more than half were in Europe[243].

As a theoretical issue, the institutional model for financial supervision attracted the attention and generated controversies, generated by the rapid transformations in the contemporary financial systems, the new

[242] De Nicoló, Gianni; Bartholomew, Philip F.; Zaman, Jahanara; Zephirin, M. G. – Bank Consolidation, Internationalization and Conglomeration: Trends and Implications for Financial Risk, IMF Working Paper 03/158, 2003

challenges (such as globalization, financial innovation, the development of multinational financial groups) and the more severe consequences due to financial contagion.

According to Čihák and Podpiera, the general framework for regulation and supervision in the financial sector is structured as follows: macro-prudential supervision, micro-prudential supervision, consumer protection and policies concerning the competition. In most of the countries, the macro-prudential supervision is realized by the central bank and the problems concerning the competition remain to separate supervision agencies. A consolidated/integrated supervision agency is in charge with the micro-prudential supervision of at least three segments of the financial sector: banking, insurance and capital market.

Figure no. 1. The general structure of the framework for regulation and supervision in the financial sector

The consolidated supervision has several *advantages*:

- in the context of financial conglomerates, it is more efficient, being able to evaluate the risk of the financial group for the ensemble;
- the coordination and the exchange of information is more efficient in one institution, comparing with the situation of several agencies, forced to cooperate;
- the competitional neutrality between financial-banking products on different financial sectors in a unitary regulation approach, and also the flexibility and the rapidness in response when appears a new product or financial service (especially on emergent markets) and the possibility to evaluate the general impact, not only at sectorial level;
- the cost reduction, the infrastructure, the staff, the administrative and management structure being common, there are substantial savings, comparing with the functioning on independent agencies. Also, the participants in the financial market register some cost savings as consequence of reporting to a sole institution;
- enhanced responsibility, the guilt for an failure could not be shared or transferred to another institution, responsible for a certain financial sector supervision;
- the transparency, due to a better understanding for the public and financial institutions of the supervision activity realized by a sole institution.

Of course, under some circumstances, the financial (integrated) surveillance has some *disadvantages*:

- if the objectives that must be followed by this institution are not very well established and transmitted to the public, could appear deficiencies in the surveillance activity;
- an possible inflexible and bureaucratic organization of the financial surveillance institution, that could make more difficult an efficient supervision activity;
- the risk of political involvement or group interests' involvement in the supervision activity.

Beside the dilemma financial integrated supervision versus sectorial supervision, there is also the controversy about the involvement of the central bank in the surveillance process. If there is an unanimous opinion about the need for the central bank to be involved in the activity supervision at macro-prudential level, about the need to involve also in supervision at micro level, there are different opinions.

The issue about the most adequate supervision model must be approached connected to each particular situation. Thus, in an economy with a less developed financial market or oriented more toward the financing through banks (a bank-based economy), the model with the supervision activity concentrated at the central bank is appropriate. For the economies with developed and specialized financial markets, where functioning financial conglomerates, the integrated financial supervision seems to be a better solution, when it is settled an independent agency that collaborates with the central bank, which reserves only the role of macro-prudential stability.

European integration, financial integration and financial stability

The liberalisation of financial services supposes also a huge process of deregulation, which sometimes needs new regulations that concern the financial system of the European Union as a whole. Such regulations, with the view to realise a financial harmonisation in the member states, concretised in a series of Directives, with profound impact on the functioning of the European financial markets and the increasing competition.

Willem Duisenberg, ex-president of the European central Bank, considered that the European banking supervision should face two challenges: the internationalization of the financial activity and the geographical split of the jurisdiction on the monetary policy implementation and the activity of the banking supervision[244].

The success of the European financial integration can be insured only through the cooperation of the member states, that must prove flexibility in adapting to the transformations suffered as result of the integration, both on economical-financial and political level[245]. The national central banks must face the challenge of the potential conflict between the implementation of monetary policy as well as insuring the financial stability.

The financial stability is strictly correlated with the evolution of the assets on the market. It is well known that in the case of the financial crisis the price of securities and real estate assets register significant fluctuations and can be the cause of those crisis. The measures of monetary policy target the fight against inflation, having as indicator the evolution of consumer prices.

The evolution of economies in the last few years lead to the conclusion that between the monetary policy measures and the securities prices on the financial market and the real estate assets prices there is a double determination relationship.

Nowadays, taking into account the recent evolutions on the main world financial markets and the contagion phenomenon, the problem of financial stability became a priority worldwide. The sub-prime mortgage crisis in United States showed us the fragility of the international financial system, the possible failures in financial supervision and the important losses that can occur.

Anna Schwartz, exponent of US monetarism, says that "There never would have been a sub-prime mortgage crisis if the Fed had been alert. This is something Alan Greenspan must answer for" and

[244] Duisenberg, Willem – The Future of Banking Supervision and The Integration of Financial Markets, Working Paper presented at the conference organised by Euro Group entitled „Improving integration of financial markets in Europe", Turin, 22 May 2000

[245] Stoica, Ovidiu; Căpraru, Bogdan – Impactul integrării europene asupra supravegherii bancare, volumul Conferinței internaționale "Racordarea sistemului financiar la exigentele integrării europene", Editura ASEM Chişinău, 2004, pp. 37–40

highlights that the central bank is itself the chief cause of the credit bubble, and now seems stunned as the consequences of its own actions engulf the financial system.

In the United Kingdom, the Financial Services Authority admitted failures in its supervision of Northern Rock Bank, but said it should continue to have responsibility for regulating the banking system and it would be overhauling its procedures as a result of the weaknesses identified. The FSA recognized "a lack of adequate oversight and review" in the case of Northern Rock, and few regulators were assigned to monitor the bank, which ran into trouble in September 2007.

The International Monetary Fund said at the beginning of April 2008 that the worldwide losses stemming from the US sub-prime mortgage crisis could hit 945 billion dollars as the impact spreads in the global economy, reevaluating it from about 800 billion dollars (500 billions EUR), the estimations in late February. Only in March 2008, the Bundesanstalt für Finanzdienstleistungsaufsicht (BaFin), the German Federal Financial Supervisory Authority estimated the losses from the sub-prime crises worldwide at about 600 billion euros, among them 10% in Germany.

Apparently, the Romanian banking system was not affected by the sub-prime crisis, at least not directly. However, the increasing refinancing costs on the interbank market and doubts about the real price for real estate assets were the first signs of the crisis we conscience.

In the last period we can observe a real preoccupation for National Bank of Romanian (NBR) regarding the evolution of real estate assets prices. Also, our central bank has implemented some measures against the bank and clients large exposure to the loans in foreign currencies.

In December 2006, NBR has adopted new banking regulations, assuring the transposition into the national legislation of the EU Directives. So, Government Emergency Ordinance No. 99/2006 on credit institutions and capital adequacy, which, apart from the transposition in principle of provisions of Directives No. 48/2006 and 49/2006, also revises the provisions specific to various categories of credit institutions (banks, credit co-operatives, savings and loan banks for housing, mortgage loan banks and electronic money institutions). Given the applicable unitary prudential regime, according to the Community legislation, credit institutions and investment firms, this Ordinance addresses, in a separate section, issues related to the enforcement of legal provisions on financial investment companies under the supervision of the National Securities Commission. Also, Government Emergency Ordinance No. 98/2006 on supplementary supervision of credit institutions, insurance and/or reinsurance undertakings, financial investment companies and investment management companies in a financial conglomerate ensures the transposition of Directive No. 2002/87/EC and governs the regulation of supplementary supervision of regulated entities that belong to groups carrying out inter-sectoral financial activities (financial conglomerates), with a view to ensuring financial stability and protection of depositors, the insured parties and investors.

Conclusion

The success of the European financial integration can be insured only through the cooperation of the member states, which must prove flexibility in facing the two challenges: the internationalization of the financial activity and the geographical split of the jurisdiction on the monetary policy implementation and the activity of the banking supervision

In the last years, the national central banks must face the challenge of the potential conflict between the implementation of monetary policy as well as insuring the financial stability. Because between the monetary policy measures and the securities prices on the financial market and the real estate assets prices there is a double determination relationship, we consider that the preoccupation of central banks must be focused much more on these prices and interfere whenever it is necessary.

Also, we think that the issue about the most adequate supervision model must be approached connected to each particular situation. For the moment we consider that regarding Romanian financial system the model with the supervision activity concentrated at the central bank is much appropriate.

Abstract: The double role of the banks, independent economically entities, having as objective the maximisation of the profit, in the condition of minimizing the risks, on one hand, and of elements of the banking system, coordinated by the central bank, having as objective the implementing of it's monetary policy, on the other hand, involves a new dimension of the risk, meaning that the policies carried out by the banks in order to achieve their personal object of activity, may be contradictory with the monetary political measures assessed by the central bank, at a certain moment.

KEYWORDS: banking risk, financial decision, solvability, liquidity, crediting risk, the indicators;

1. The banking risks

The appearance of the banking risks is established by the manifestation of a complexity of factors, which are referring to: the general evolution of the economy, changes in the organisation of the bank, financial decisions, the economic and politic conditions. *The general evolution of the economy* induces modifications of the macro-economical indicators with an impact upon the banking activity. Definitely, a high rate of inflation indicates certain economic lack of balance that severely affects the results of the banking activity on a short term and implicitly causes a medium and long term increment to all categories of banking risk. The dependence of the real instalments of the interest by the inflation rate and the implications that the interest is having upon the level of the resources and investments of a bank that's operating in a competing environment, as well as upon the bank profits, induces the existence of a direct proportional relation between the level of the inflation and the level of the banking risks.

The problems in organising a bank is a matter of management, and the organisational solutions solved by the bank's management are close related to the quality of the leaders. An inefficient systematisation is definitely a management error which influences badly the whole ensemble of the bank's activity. In a developing banking system, as it is the one in our country, one of the major deficiencies is the lack of the experienced managers, as well as the operative stuff, generally picked from the non-banking economy. The training of the stuff and the specializing in the peculiar area of the banking activities are the components of an efficient long term bank policy. The risks resulting from the problems related to human resources are attenuated by the realistic policy carried out in this area.

The taking of a financial decision undergoes certain risks, the sources of which are residing in the non-banking and/or banking economical environment, as well as from the inside of the bank, in the last case being involved the human factor. Paraphrasing Albert Camus, the bank managers can't make a decision without the risk of loosing something.

The existing and future *political and economical conditions* of the country have effects upon the service of public duties. The inter-conditioning between the economical and the political generates, on a long term, positive or negative tendencies that leave a certain imprint upon the image of the country in the world. The quantifying of the country risks is performed by taking into account these tendencies, affecting in this way the external banking operations. In a concrete way, the external financing activities, performed through banks or through the credit lines sustained by the foreign banks, through an autonomous bank, are conditioned as far as the interest terms, the securities or the reimbursement conditions are concerned, by the risks evaluated by the financing persons, taking into account, in the first place, the country risk and only then the bank risk – established through the assessment of the patrimony and through the calculation of the indicators for the economic-financial output.

2. Quantification of the banking risks

During the analysis of the banking risks, a special importance is given to their quantification, according to a system of specific indicators, allowing the statistic and dynamic evaluation of the risks, by reporting to the international standards or to the personal historical experience of the bank. The measuring of the risks is directly related to the one of the incomes (because, for obtaining profit, a bank has to overtake certain risks). As a consequence, the risk indicators are more relevant in a general evaluation context of the profitability of the bank and of its compatibility on the market, the final objective of the banking management also consisting in maximising the incomes of the shareholders, adjusted with the influence of risks.

3. The indicators for measuring banking risks

The specialised literature approaches the theme of the indicators for measuring banking risks, proposing different associated variables, usually, to the main risk categories. In the practice of the Romanian banks, there were confirmed, for the quantification of the internal risks, the following traditional indicators:

1. The indicators of the crediting risk;
2. The indicators of the liquidity risk;
3. The indicators of the solvability risk;
4. The indicators of the interest rate risk;
5. The indicators of the currency exchange rate risk.

1. Almost all the banks, at a smaller or higher level, overtake ***the crediting risk***, what supposes the necessity of the attemptive analysis of the way in which the quality of the credits portfolio evolves in time, with a special impact upon the profitability, the adequacy of the capital and upon the general trust in the respective bank. As a consequence, two reference indicators for the estimation of the crediting risks are established according to the percentage of the weak quality which delays or do not allow the accomplishment of the anticipated incomes, respectively:

- the volume of the overdue credits/total credits *100
- the volume of the non-performed credits/total credits *100

Of course, the optimal is represented by the minimal values of the two indicators, tending towards zero, in the first case, and in the second one, the overdue credits, but especially the non-performent ones, blocking the activity and the financial results of the bank. Other indicators of the crediting risks use in the calculus formula of the reserves also the commissions constituted by the banks for covering the eventual losses, such as:

- reserves for credits losses/total credits *100, report expressing synthetically, the managerial expectations concerning the evolution of the quality of the loans portfolio;
- commissions for credits losses/net losses *100, report reflecting the prudence level adopted by the bank in its crediting policy;
- gross profit/commissions for credits losses *100, respectively the cost for covering the crediting risk overtaken by the bank.

The potential measuring indicators of the risk that may signalise in advance the variations of the incomes of the bank are: the geographical concentration and on economical sectors of credits, the accelerated growth rhythm of the volume of credits, the increased profitableness of certain categories of credits.

2. Because of the informational limits of the cash-flow system, the banking analysts use a series of indicators for measuring ***the liquidity.*** Obviously, the more cash or banking assets the bank disposes, the bitterer its ability to face the requests for withdrawing the deposits, as well as the eventual delays in reimbursing the credits. The commercial banks normally keep between 20 and 30% from deposits in the form of liquid funds. The main indicators calculated by the treasury and analysed for assessing the liquidity are:

- global liquidity reflecting the possibility of the patrimonial active elements to be transformed on short term in liquidities, for satisfying the exigible payment obligations;

- the immediate liquidity (treasury), reflecting the possibility of the patrimonial elements of the treasury (cash, account current of BNR) to face the short term debts;
- the liquidity in accordance with the total of the deposits, reflecting the possibility of the patrimonial active elements to face the debts representing the total of the deposits and of the loans.

The treasury also establishes the exposure of the bank in accordance with the current deposits and total deposits (respectively the report between these ones), expressing the evolution tendency of the deposits on term, in comparison with the ones of the current availabilities with influence upon the stability of the resources and the level of costs.

Other indicators calculated for estimating the liquidity risks are:

- The position of the liquidity, indicator derived from the practice of the treasury management, calculated on days, weeks and months, and the optimisation of which consists in the balancing of the liquid assets with the immediate passives. In case of a negative position, the liquid assets are insufficient for fully paying the obligations, the bank having to appeal to urgent financing sources, such as: loans on interbanking market, loans from the central bank or the liquidation of certain portfolio assets before term. If the position of the liquidity is positive, the exceeding of liquidity (over the admissible limit) is placed on short term in the deposits on the interbanking market.
- The net passives, respectively the difference between assets and passives, classified in accordance with the due term, indicator calculated for signalising the period for the maximal need of liquidity. The simple net passives (successive) are established on each period, as a difference between the assets and the passives with the same deadline. The cumulated net passives are established as difference between the cumulated passives and assets, corresponding to each period of time;
- The liquidity parameter, representing the report between the sum of the passives and the sum of the assets, both pondered with the average number of days or with the current number of the respective due term group. If the liquidity parameter is:

=1, then, the bank does not have to make deadline transformation;

< 1, the bank makes the transformation from short time passives in long time assets, in the conditions of an increase curve of the interest;

>1, the bank transforms the long time passives in short time assets, resulting the liquidity risk.

- The liquidity rate expresses the evolution of the indebting degree of the bank towards the monetary market. This is calculated periodically, in accordance with the due term of the loan operations, in the view of the formula: new contracted loans/overdue loans in the same period *100. A supra-unitary rate indicates the decrease of the liquidity because of the increase of the indebting degree, the relation being inversed in case of a sub-unitary rate;
- The report total credits/total deposits reflects the proportion between the resources attracted from the depositors, loaned to other clients. The biggest part of the credits is liquid.

The traditional measures of the liquidity risk generally tend to concentrate upon the liquidity of the assets in the balance sheets. In this context, we consider that it would be useful the introduction in practice of the indicators more directed towards the relationing of the actual flows or cash potential with the needs. For example, the weight of the volatile resources may suggest the liquidity needs of the bank and the percentage used by this one from its crediting reserves.

3. The adequacy of the capital – ***the solvability*** – permanently constituted an essential preoccupation of the banking management and of the regulations in the profile, because of its signification concerning the solidity of the bank and the safety of the deposits. More than that, the adequacy of the capital has also an important competitive dimension, the banks being capitalised, being more attractive for the resources, either from deposits, of from loans, in favourable conditions.

4. ***The risk of the interest rate*** is measured, in a traditional way, either through report between the assets and the passives sensible to interest, or through the difference between these ones. One of the problems raised by such a practice refers to the difficulty in selecting the due term to be used as a criterion for sensibility, the preoccupation that the reinvestment of the modification of the rates may rapidly and quantifiably influence the sensibility to interest and the failure in appreciating the value sensibility to the modification of the rates. The more advanced indicators of the interest rate risk include the measuring of the gap, on different due terms, the dynamic measuring of the gap according to certain reinvestment estimations and rates, the measuring of the duration for the assets of the bank, the passives and the elements not included in the balance sheets.

- The risk of the interest rate, established as a report between the productive assets and the interest carrying passives (the standard level being 1);
- The absolute difference of the banking interest expressed through the net incomes between the interests reflects the ability of the bank to cover the expenses with the interest benefited at the deposits, certified by the deposit etc from the incomes obtained by cashing in the interests at the afforded credits. The interest difference has to established in a way in which it may assure the sustaining of the banking duty (the difference between other banking expenses and other banking incomes), as well as the obtaining of a satisfying profit.
- The gross percentage difference of the banking interest, resulting from the reporting of the absolute difference to the productive assets *100. Correlated with the level of the active/passive interests, practiced by the bank, but also with the volume accomplished by credits/deposits. A standard level of this indicator is comprised in the interval 3-10%.
- The net percentage difference of the banking interest is calculated as a report between the average level of the active interest rate and the average level of the passive interest rate *100.

The management of the financial risks affords a special attention to the interest rate risks, related with the currency exchange one, on short term, when there are parity conditions. In practice, the banks use simulations for analysing their exposure to the interest rate risks, determining the impact of certain modifications in the interest rates on different categories of due terms, upon the profitability and the market value.

5. *the currency risk* is framed by the specialists in the category of the market risks, being established by the variations of the currency exchange rates, the deficits of the payment balances, the liquidities penury on an international plan. This risk is amplified for each participant to the development of an external payment transaction. The measurement of this type of risk is accomplished according to the position of the commercial banks, which establish an operation ceiling, in accordance with their own standing. The bank with debts upon its payment engagements, in a certain type of currency, takes a long position if there is a high probability for that currency to enter an appreciation process. On the contrary, the bank takes a short position, because of the economical context in which they act, the Romanian banks prefer the long positions, irrespectively of the currency exchange rate.

The indicators of the currency risk calculated by the commercial banks are:

- *the individual currency position* is established on each currency that is going to be administered;
- *the global currency position,* representing the net balance of the debts in estimates in comparison with the passives in estimates, both transformed in the reference currency for being compared; this indicator offers a general image upon the currency exposure of the bank.

The indicators used for the quantification of the different categories of risks generally respond to certain informational needs in the analysis and management process of the banking risks.

THE HIGHER CREDIT RYTHM REPRESENTS: FINANCIAL DEVELOPMENT OR ANXIETY REASONS ?

Ciobanu (Sireteanu) Elena

„Alexandru Ioan Cuza" University of Iaşi, Faculty of Economics and Business Administration, Doctoral School of Economics, Suceava, Street Bistriţei no.5, Blok B2, S. A, Ap. 9, elenasireteanu@yahoo.com, 0742093120

Abstract: The present paper analyses, the causes of nongovernmental credit rapid expansion in Romania, to quantify its implications over financial macroeconomic stability and to identify the solutions of which the authorities dispose, for the counteraction of negative effects concerning this phenomenon.

Financial transitioning is based mainly on the financial deepening and is well conducted with a priority in the moment of refueling the turbulences on the extern markets.

Key words: rapid credit growth, financial and macroeconomic stability, credit risk, prudential supervisory

Introduction

Through the past years, the Eastern and Central European countries, respectively Romania, have registered a rapid growth of the nongovernmental credit. The credit rapid expansion, determined serious preoccupations regarding the analysis of the causes and effects related to this event especially when there have been pointed out financial turbulences on the extern markets..

Related to the countries from the ex-communism sector, the most important component of the financial market is represented by the banking sector, which assures the financial sources for the economy, mainly after the elimination of restrictions on capital accounts[246].

Numerous serious and trustworthy working papers[247] warn us that a boom credit may conduct to major macroeconomic unbalances and to worst situations in the banking sector, also to macroeconomic and financial crises.

Thus, the authorities must maintain an equilibrium between the macroeconomic stability and the financial one and the credit expansion . If this evolution is determined by a financial development or if it represents a dangerous expansion for the economy.

In the first situation, the growth of the credit cannot affect, the macroeconomic evolutions being mostly compensated through the growth for currency request. The credit expansion is mainly determined by the growth for credit request, which happens as a result of the optimistic anticipations regarding the income dynamic and taking into consideration the process of integration in the Euro – zone.

Also, the growth of the credit offers is determined by the presence on the Romanian banking market and on the Central and Eastern European banking sector of foreign banks and institutions, which are interested in accomplishing important market ratings by promoting attractive packages.

Incoming capitals have big advantages for the banking sector. The presence of this foreign operators on the banking market, determines a more pleasant and stable financial environment, a bettering of the corporate governance and for the capacity of managening the risks.

It can be explained that the credit expansion partially represents an amplification of the process of financial intermediation, based on the convergence process of catching up, which exists between the ex-communist countries and the western countries, related to the level of development of the financial superstructures.[248]

However, the credit growth has numerous negative effects which can affect the normal functioning of the economy. It is reasonable to consider, that the credit rapid expansion can outcome the bank's capacity to

[246] The banks own 85 percent of all the financial actives, according to Backe, Egert and Zumer (2006)

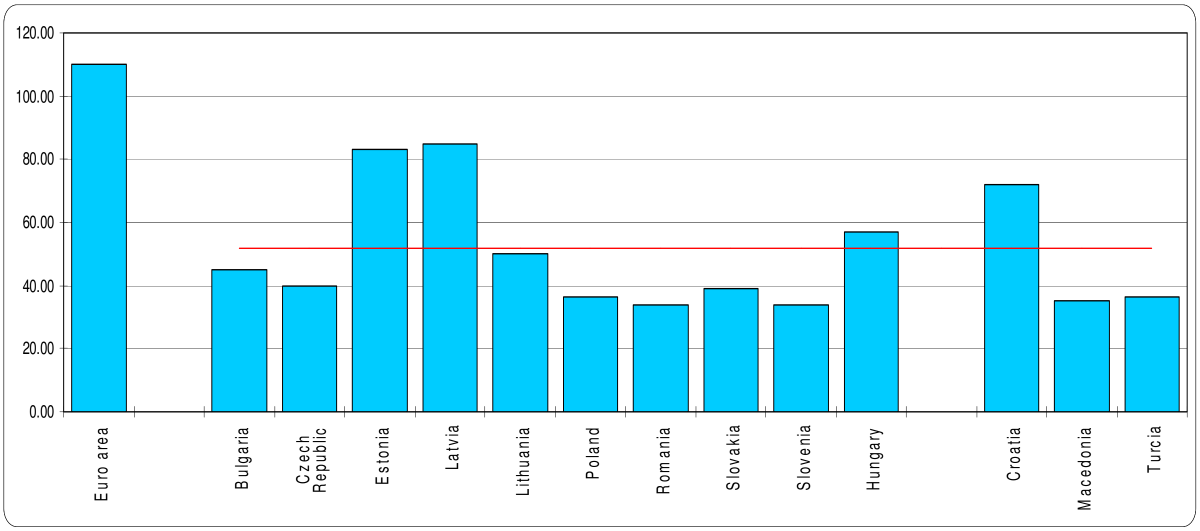
[247] Kaminsky, G, Saul Lizondo and Carmen Reinhart, "*Leading Indicators of Currency Criss*", IMF, Staff Paper vol.45, No.1, Neagu F, A.Mărgărit, M. Copaciu, I. Răcaru, R.Mircea, A. Andrassy, *Non government credit in Romania: perspectives and implications,* Study Books NBR, No.15, 2006

[248] *Assessing and Managing Rapid Credit Growth and the Role of Supervisory and Prudential Policies*, IMF Working Paper 05/151/2005, p.10

evaluate the risks, which can lead to a growth in information asymmetry, resulting a higher level of repayment. All in all, in this zone, the model which banks use to make business hasn't developed from the basic type "initiate and hold" in the balance sheet, to a more sophisticated type, "initiate and distribute", outside the balance sheet, and the region hasn't been confronted with the problem of "frenetic security".

The Evolution of nongovernmental credit

The higher credit rhythm has been determined, mainly by the reforming process in the banking sector, which is in a continuous competition, by the bettering of the macroeconomic frame and by request growth in total dischargement of capital account. This was a condition for joining the EU and also for maintaining the interest differences positive. However, the financial intermediation degree in most of the countries from Central Eastern Europe, compared to the countries in the Euro Zone, has a very low level, under 50%, as it is displayed in figure 1:



Source: FMI – IFS, BNR

Figure 1 The weight of nongovernmental credit in GDP

At macroeconomic level, the growth of rapid expansion of the credit, stimulates the aggregate request, which generates inflationist pressures which also contribute to the extern unbalances. These extern unbalances have been accentuated in the Baltic states, Bulgaria and Romania and also in countries which have registered the most rapid credit growth in the past 5 years.

The rapid credit growth in countries from Central and Eastern Europe may be justified by the initial low levels of financial intermediation**.**

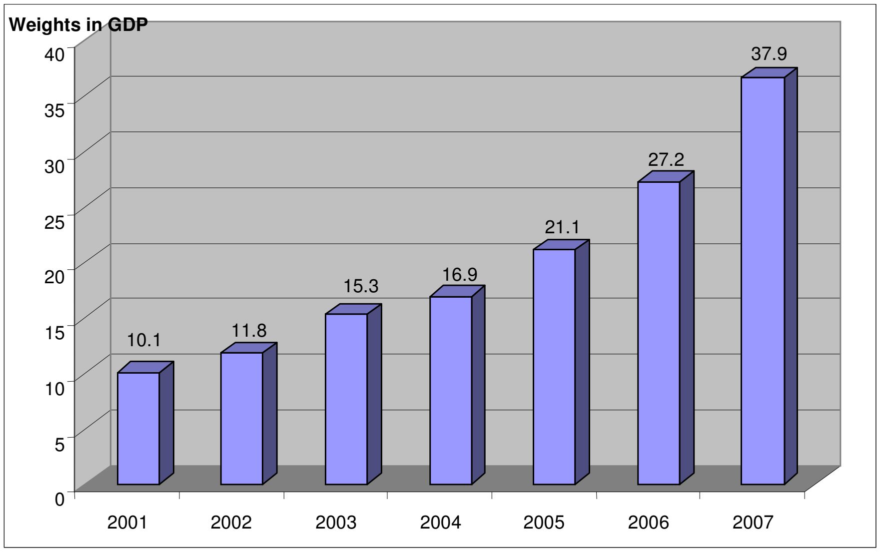
The economic literature confirms the fact that the alert credit expansion shows alarming signals regarding the appearance of financial riots, but without outlining a real depression. So, the standard limit of growth warming and also the annual growth of financial intermediation rhythm with five GDP points on a five year plan (Dominique – Kunt and Detragiache, 1997) represents the possibility for a potential financial crisis. This limits have been outcome at the Baltic levels of the countries: Slovenia, Bulgaria and Croatia.

Thus, the structure of credit dynamic presents supplementary risks related to financial stability, besides the risks that devolve from the normal credit expansion. Consequently, the household credit growth has outcome the investment credit growth in this region. This shows that the risks are prevalent associated, to the population segment, which presents a high rate of obligement.

Another aspect is based on the high rate of obligement for the foreign currency credit, which comes from the real and nominal tendencies of appreciations, and from the available funds in foreign currency because of the capital, incomings. All those could lead to the appearance of currency risk, also keeping in mind the depth of extern unbalances.

Financial intermediation has grown substantially through the last years, in Romania has reached 37,9% of GDP in 2007, getting really close to the Poland's level, taking into consideration the conditions of national currency depreciations and the maintenance of a high inflation.

The weight of population credits has reached the same level with credit granted to no financial firms.



Source: NBR; ISN

Figure 2 –Financial intermediation in Romania

Rapid expansion, in Romania, was determined by numerous factors:

1. Better business conditions, the economy entered the upward faze of economic cycle, the consuming proclivity has grown and also the population's residential investments;
2. The banking system was reshaped and sold to investitors, bettering the corporative governance, generating a cruel competition between the credit institutions;
3. Positive anticipations regarding the evolution of incomes and business cycle.

If the credit level has an upward rhythm, the Romanian's savings are at the lowest level in Europe (20%), this fact is backed by the low weight of savings in GDP (14%). Until the end of 2007 there had been a really low level of interest from the Romanian banking system in attracting the population's savings, because these were mostly financed from the exterior only in 2008 this offered to the population better efficiencies , up to the level 10,5% (April).

The analysis of credit growth

The economic literature[249] presents many causes for the appearance of expansion phenomenon:

a) the process of economic growth, which most of the time requires a rapid credit growth and also a development of the financial deepening;
b) the faze of investment growth and firm's production expanses, using bank loans with the "accelerator" concept;
c) financial liberalizations which means inadequate reactions from the market participants and also the manifestation of some risks. The change of attitude, meaning anticipating the future, becomes pessimistic, the prices for pledged goods and financial assets decrease, in this way the debtors are in impossibility of payment for the loans and the respective interest;
d) the reduction for financing requests regarding the public sector, determined by consolidation of the fiscal position;
e) the implementation of a macroeconomic stabilization program through fixing the exchange rate, in the case of emerge ting countries with a fixed currency rate;
f) the liberalization of capital account determines ready money excess.

249 *Are Credit Booms in Emerging Markets a Concern?,* World Economic Outlook, Chapter IV, IMF, 2004

It is really hard to make a clear distinction between the cases of healthy financial development and those of dangerous credit expansion.

In this sense, there have been used more methods of credit growth level determination with relative results, in practice. In this way, the studies' results[250] conducted at The National Bank of Romania level related to, the credit dynamic and also to the associated risks conclude in Romania's case, that the credit portfolio is of good quality and on a short term prognosis there haven't been identified risk factors that can affect the portfolio. But there is a slight increasing tendency of growth for credit risk, if the credit activity maintains very high. These tendencies need a constant information monitoring activity. This activity refers to the credit[251] volumes and structures on specific debtor types, on economy sectors, the crediting conditions, the bank's exposure risks, the prudential measurements that these use the national currency exposure level or foreign currency. This process also needs some special macroeconomic data: the inflation rate, the economic growth, the real account, difference, the unemployment rate, the resistance level at some vulnerability tests and also some quality information, the level of national legal frame harmonisation with the international standards, the level of financial system trust.

The mentioned studies show, that a rapid foreign currency credit growth in the population segment, especially those for household use, may have some negative effects on macroeconomic stability, because this determines the growth of the aggregate request compared to production resulting, the increase of inflation, the current account deficit and also the depreciation of the national currency.

The inappropriate evolution, on a long term period regarding the payment balance in Romania's case (in 2007, the extern deficit represented 14% of GDD), has increased the national currency exchange rate vulnerability, taking into consideration that our country, needs extern investments to finance the extern deficit.

Temperation measurements for credit dynamic

The higher credit rhythm determines the authorities to conduct monetary policy measurements and prudential measurements to stop a potential expansionist credit process and for stimulating the financial development.

Monetary policy measurements

At the decisive moment regarding a monetary and prudential adequate policy, the authorities will take into consideration the macroeconomic and structural factors, respectively the existence of macroeconomic unbalances, the solidity and the financial system structure, the financial debtors situation and the quality of the prudential supervision process.

Regarding the Central and Eastern European Countries, where the liberalisation of the capital movements is almost complete, appear some difficulties using the monetary policy measurements.

The increase of interest rate conducted to discourage the credit process, determines incoming important capitals, which[252] lead to the increase of monetary flow.

Consequently applying combinations of monetary policy instruments and of currency exchange rates (management floating) lead to the excessive increase of foreign currency credit. This determined NBR to change to a more flexible exchange rate, in this way they would stop the mentioned effects.

In the process of curbing the credit expansion, the authorities have adapted administrative measurements also. Thus in many ways, NBR increased the minimum reserves, for the passives in lei and also for those in foreign currency[253].

Prudential supervisory measurements

The prudential supervision of the banking system represents a complex process which is being realised from the authorisation, through the closing of that activity.

---

[250] *Financial stability report*, 2006, NBR, p. 108-114

[251] Cerna Silviu, *The rapid credit growth: dangers or solutions*, Rev. Oeconomica, No. 3/2006

[252] According to the NBR report dated 26 March 2008, the interest rate for monetary policy was 9,5%

[253] Now, Romania has the highest level of interest rate for foreign currency deposits 40% and for lei it is of 20%.

The prudential supervision measurements are necessary in the case of credit expansion, and mostly when the financial stability is in dangerous or when it is necessary to harmonise the national laws with the international ones.

In this way NBR adopted a series of normative legislative papers to temperate the increasing record rhythm of 74% for the foreign currency[254] credit.

At the present, NBR and also the other banks are preoccupied with the implementation of the European request regarding the New Capital Agreement, which will have as a result the strengthening of the risk management capacity and to assure financial stability. Simultaneously the laws adopted at the beginning of 2006, permitted NBR to exert the supervisory process upon the financial nonbanking intermediaries, regarding the suitable capitals.

Conclusions

The high increasing credit rhythm, in Romania's case, can be explained partially through the process of "financial deepening", and also by the amplification of financial intermediation process, justified by the very low initial levels.

The authorities must fallow the maintaining of equilibrium between the macroeconomic stability and the credit expansion, which can become very dangerous. In this way it is necessary to improve the supervisory systems.

The measurements ordered by the monetary authority will not have the wished results, if it won't have the necessary support from the fiscal authority.

To maintain the turbulences on the extern financial markets claims for a reevaluation of the entire regulations frame, so in this way the risks from financial innovation can be supervised.

PARTICULARITIES OF THE ROMANIAN BANKING SYSTEM IN THE EUROPEAN BANKING SYSTEM

Ciurlău Loredana

Universitatea "Constantin Brâncuşi" din Tg-Jiu, Facultatea de Ştiinţe Economice, Tg-Jiu, str. Victoriei, bl. 198, sc. 4, ap. 16, jud. Gorj, Email: lciurlau@yahoo.com***, Tel: 0724115905***

Rezumat: the integration in the European Union does not involve only the economical sector, even if it is the most important, but also a redressing of the other components of the social life, assured by the constant increase of the GIP, of the stopping of the inflation and the reduction of the depreciation of the national currency.

Romania must have a solid bank system, whose action directions must direct to the finalisation of the privatisation process, the harmonisation of the national legislation with the communitarian legislation, the institution of some prudential regulation adequate to the economic environment and the selection of the most dynamic orientation on the market in the competition domain.

Key words: rating system, bank capital regulation, Operational risk; Basel II; capital requirement.

The process of integration of the Romanian bank system in the European bank system began quite late comparatively to the other candidate countries, given the presence in the Romanian landscape of some important banks in the European Union, such as ING Barings and ABN Amro and continued with the privatisation of BRD, the Bancpost and Bank Agricola privatisation, to these summing the apparition of some important banks of the region in the Romanian bank system.

An important premises of the integration in the Romanian bank system of the European Union is represented by the intensification of the economical activities with European partners, remarking thus an increase in the volume of the exports and imports with European partners, the increase of the weight in the exterior commerce of Romania and the economical flux to and from the European Union and the increase of the level and the weight of the European capital subscribed to the Romanian society, including the bank sector.

It is observed a consolidation of the position of the banks with foreign capital, which become majority in the Romanian bank system from the point of view of the activity volume and the social capital.

	Number of banks	
	30.09.2006	30.09.2007
1. Banks with integral or majority state capital	2	2
2. banks with majority private capital (including Creditcoop and the branches of the foreign banks)	36	39

The participations of the foreign capital in accordance to the origin country

Source: The National Bank of Romania

As for the bank system, the European integration process supposed the harmonisation of the autochthonous legislation with the requirements of the European Union and the adopting of some institutional measures which aim for the enforcement of the administrative capacity of the national Bank of Romania of supervision and modernisation of the payments system, their realisation pursuing the increase of the competitiveness and the stability of the bank sector and of the capacity of the bank to assure an efficient financial intermediation.

The enforcement of the supervision capacity represents one of the major preoccupations of the National Bank of Romania, through which we pursue the increase of the competitiveness, of the stability and the credibility of the bank sectors, and also of the capacity of the banks to assure an efficient financial intermediation.

The transition to the supervision based upon risks represented a necessity of the process of monitoring of the bank system, focusing on the alignment of the best international practices in the field for the identification and the compensation of these risks.

At the level of the bank sector, the main challenge is represented by the implementation of the Basel II agreement, which allows a better evaluation of the risks exposure, introducing the operational risk and the market risk, the risk exposures being evaluated according to some methods based on historical observations.

The new capital agreement gave the credit institutions a much larger flexibility in the risks administration.

Many banks did not wish to apply for 2007 the stipulations of the Basel II Accord, but from 2008 we will preponderantly pass to the standard approach. Some of the autochthonous banks, especially those which belong to some European bank groups, expressed their intention to pass as fast as possible even to the internal models regarding the determination of the capital requirements, fact motivated by the need of the Unitarian approach of the risks at the level of the entire group they belong to.

Basel II started however to be practiced in many countries of the world, including in the E.U. from the end of 2006. "The migration from Basel I to Basel II represents the most important event in the history of the bank supervision", declared the NBR Governor Mugur Isărescu.

The implementation of these requirements supposes increased efforts both from the Central Bank, and also from the credit institutions, which must allocate increased resources in this regard. To a certain extent, the demarche is made easier in Romania by the fact that almost the entire banks systems is held by banks from the Occident, which have already passed this test and, hence, they will be able to facilitate the transition of the subsidiaries to the new capital requirements. And in certain cases the mother-banks will be able to supply even their own internal methods of risks evaluation.

The new capital accord is based on three pillars: minimum capital requirements, the bank supervision and transparency.

As for the first pillar, next the banks must reach a solvability rate greater than 8%. This indicator is calculated as report between the own capital of the credit institution and the taken risk. What changed drastically is the way the banks administrate the risk. If before the financial institutions considered only the credit risk and the market risk, from now on they will have to quantify the operational risk too. Beside this aspect, the way the first two risks are evaluated changed fundamentally.

The credit risk is evaluated through some fix weights, established for the main loans categories. In exchange, Basel II will give the banks the possibility to choose between one of the three available variants: the standard-method, the internal basic models and the advanced models.

The standard-method is the simplest one and it is similar to the one used by banks, with the specification that the weights are stable and much better detailed. A special attention is paid to the loans for the population which receive smaller risk weights. The same treatment could be extended at the level of IMMs also if certain requirements are respected.

The method of the internal models reflects the best the innovative aspect of the new capital accord, being available in two versions: a basic one and an advanced one. The internal models are differentiated from the standard method through the fact that the weights through which they evaluate the risk of each asset are no longer the same for the entire bank sector, but they are individually established, by each institution on its own. The advantage is, in this case, that the risk is evaluated much more correctly and the overdimensioning situations of the capital requirements are eliminated. Thus, the banks should constitute fewer reserves, so hat they will have more money for the crediting.

In order to analyse these methods, however, the banks must fulfil certain criteria, through which they can prove to the supervision authority that their own evaluations are correct and complete. Also, the supervision activity is based upon new principles, which underline the necessity that the banks evaluate by themselves the necessary of capital in report to the assumed risk. In exchange, the role of the supervision authorities is to analyse and take the necessary measures in report to these individual evaluations. The analysis of the Central bank will force this way the credit institutions to develop more solid methods of risks evaluation. In the context of the unique market, the application of the new accord will stimulate the cooperation between the supervision authorities from different state members, in the case of the monitoring of the international groups.

Through the promoted policy, N.B.R. created a sector made of more and more powerful banks capable to assure a financial intermediation on efficiency criteria, where the private bank segment becomes preponderant.

The risk exposure of the bank system can be pointed out also through the evolution of the main financial and bank prudence indicators, presented in table no. 3.

Indicators	Dec. 2006	Dec. 2007
Capital risk		

The solvability rate (> 12%) Own capital rate (own capital / total active)	18,1 8,6	12,7 6,8
The credit risk Due and doubtful credits (net value) / total credits (net value) Due and doubtful debts (net value)/Total active (net value) Due and doubtful debts (net value) / own capital (from the prudential reporting of the own funds) Credit risk rate* General risk rate	 0,2 0,1 2,8 53,0	 0,2 0,2 4,0 57,0
C. The liquidity risk The Liquidity indicator (actual liquidity/necessary liquidity)	 2,3	 2,1
D. Profitability ROA (Net profit /Total active) ROE (Net profit /Own capitals)	 1,3 10,2	 1,1 10,4

The evolution of the bank prudence indicators

* unadjusted exposure, afferent to the credits and the interests classified in the doubtful and loss categories/ Total credits and classified interests, exclusively elements outside the balance sheet

Source: the National Bank of Romania "Monthly Bulletin" December 2007

According to the criteria established by N.B.R. within the bank *rating* system, in December 2007, noticeable modifications were produced at the level of the assets held by the banks classified in rating 2 and 3. the weight of the balance assets of the banks contained in rating 3 increase 11,5 percents as compared to the same period of the previous year, disfavoring the *rating* 2 ones, whose weight reduced by 11,9 percents. As in the previous periods, the requirements imposed by the maximum *rating* were fulfilled by none of the existing credit institutions. By analyzing the evolution of the main prudentiality indicators during 2007, the weight of the due and doubtful credits remained unchanged, while their weight in total active increased by 0,1 percents as compared to December 2006. The weight of the due and doubtful debts in the own capital registered an increase by 1,1 percents, up to the level of 2,6 %. The rate of the credit risk increased by 1,2 percents (up to 4%), while the general risk rate increased by 4 percents (up to 57%). As for the profitability indicators, the ROA level diminished by 0,2 percents (reaching 1,1%), and the ROE one increased by 0,2 percents (up to 10,4%). The integration of the Romanian bank sector in the E.U, will generate an increased competition among the different credit institutions, which will lead to the increase of these institutions' efficiency, to the diminishing of the costs and their intermediation margins, to the diversification of the financial instruments supply, to the reduction of the financial risks, to the intensification of the bank intermediation process.

Abstract: In January 2007, Romania became a member of the European Union and the National Bank of Romania a member of The European System of Central Banks (ESCB). This event was a confirmation of the success of Romanian reforms, but, at the same time, it was the beginning of a new stage in the process of accomplishing the nominal and real convergence conditions, set in the Maastricht Treaty. In this study we have explored some considerations about the NBR's reform performances before and after the EU accession and, also, we have discussed about the main challenges and perspectives for the Romanian central bank in the new economic environment imposed by the integration process.

Key words: European integration, central bank, reform, challenges, perspectives

Introduction

In this study we have tried to highlight the main challenges that the National Bank of Romania (NBR) would have to overcome in the EU integration process. In January 2007, Romania became a member of the European Union along with Bulgaria. In this context, the NBR has to continue its reforms and work towards accomplishing the nominal and real convergence conditions, in the perspectives of the Euro adoption.

For the beginning we will explore some consideration about the NBR's reform performances before and after EU accession. In this direction, we will calculate the Grili, Masciandaro and Tabellini - GMT (1991) central bank independence index and the coefficent of correlation between interest rates and inflation in the Romanian economy. Also, we will analyze the level of nominal and real convergence indicators accomplished in the last two years, emphasizing the NBR's contributions. After that, we will talk about the challenges and perspectives for the Romanian central bank in the near future.

Central banking in Romania before accession to EU

The perspective of accession of our country to European Union was a very influent factor regarding structural reforms of the Romanian economy and banking system. In this context, the National bank of Romania has had a very important role in the process of nominal and real convergence imposed by the new economic environment conditions.

The efforts of the National Bank of Romania to adjust to the European integration conditions were in the same direction with the transition to a market economy. The economic development got to a point were it was a real benefit for the accession process, and, at the same time, those reforms imposed by the EU accession process were a very welcomed stimulant for achieving a high degree of functionality for the Romanian economy.

In line with the objectives of European Union accession of Romania, the adjustment of the National Bank of Romania's policies to integration requirements has been related to the following aspects: harmonization of banking legislation; adoption of a proper monetary regime for achieving price stability as mentioned by the Maastricht Treaty convergence conditions; restructuring of the national banking system in the direction of strengthening financial stability; coordination of monetary policies with fiscal ones; modernization of national payment settlement system; participation of NBR to negotiations of the European acquis' chapters.

The National Bank of Romania's role after the accession to EU: challenges and perspectives

As a predictable scenario[255] of the Euro adoption and accommodation to the single monetary policy, we could consider the following stages (some of them have been already achieved): adoption of Euro as a reference currency (3rd of March 2003); liberalization of the capital account (April 2005); denomination of the national currency (1st of July 2005); implementation of inflation targeting regime (July 2005); introduction of M3 monetary aggregate (January 2007); entrance in ERM II for at least two years before the Euro adoption.

In the perspectives of this reform continuance, the main objectives and transformation of our central bank consider the following: participation of NBR in the ECB/Eurosystem; improvement of surveillance of the Romanian banking system; implementation of Basel II principles; elaboration and implementation of the convergence program; an adequate monetary policy conducted in accordance with the fundamental objective of price stability; coordination of banking regulations with the acquis of the European Union.

On January 1st, 2007 the National Bank of Romania became a member of the Eurosystem/ESCB and the Governor became a member of the ECB General Council. Since this moment, NBR has been fully represented in all working structures of The European System of Central Banks (General Council, dedicated committees, working groups), participating in the decision process regarding regulation in European Union, which implies four working tiers (Lamfallussy procedure). The main benefits of this process include the faster pace of decision-making due to the delegation of powers regarding technical regulations to dedicated Committees and the possibility to achieve, over time, convergence in the field of supervisory practices at the level of competent authorities in the EU[256].

In the next years, the NBR has to accomplish the convergence criteria for adopting the Euro. Hence, it has to elaborate and implement a coherent convergence program that addresses the starting point and the time spent (maximum 2 years) in ERM II. There can be two big problems: early entry might extend the stay in ERM II and, also, late entry might weaken the rationale for fast-paced reform. Officials estimate the entrance in ERM II for 2012 and the effective entrance in the Euro zone for 2014.

Before entering the ERM II, Romania has to fulfill nominal convergence criteria and be successful in real convergence. Thus, the NBR has to consolidate a low inflation trend, establish the domestic market for long-term capital and interest rate convergence, and accomplish a sustainable exchange rate. Also, it must be continuing the structural reforms[257].

Here are Romania's economic performances in the perspective of nominal and real convergence.

Nominal Convergence Indicators	***Maastricht Criteria***	***Romania***	
		2006	***2007***
Inflation rate *(percent, annual average)*	*<1.5 pp above the three best performing Member States* ***2.8 percent*****	***6,56***	***4,84***

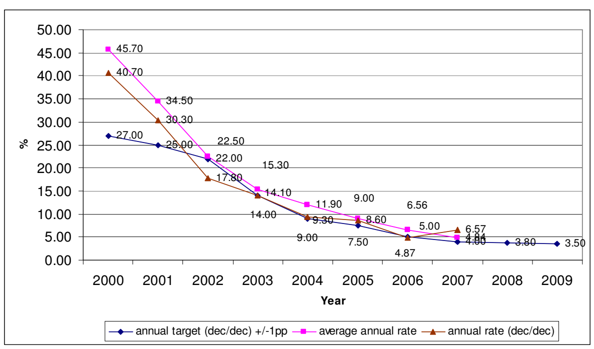
Table no. 1. Real and nominal convergence indicators for Romania in 2006-2007

As we can see, the nominal criteria are still partially achieved, with monetary criteria being the weakest. So far, the National Bank of Romania has achieved high performances regarding the levels of inflation. Beginning year 2000, inflation rates have been dropping sustainable from 45,7%, and, since 2004, the levels of inflation rate have achieved one digit value. Even if in 2007 the annual rate has increased, the average annual rate has dropped 1,72%, confirming a deflationist trend.

Although the National Bank of Romania has achieved good levels of inflation rates in the last years, the gap between the European levels of inflation and the Romanian ones are still large. Only in the perspective of the year 2009 Romania has programmed an inflation rate target comparable with inflation rates in occidental European countries.



Source: www.bnr.ro

Figure no. 1. The evolution of inflation rates in 2000-2008

Calculating the correlation coefficient between monthly inflation rates and the main interest rates for different periods of time, we can observe a higher correlation, as we move toward year 2007, the year of our accession to EU (it gets positive value, closer to 1). This situation denotes a good functionality of interest rates formation mechanism, confirming the efficiency of the interest rate as a monetary policy instrument in the context of Romanian disinflation.

average active interest rates for non-bank clients – monthly inflation rates	
Jan 1994 – Dec 2006	0<0,5396<1
Jan 1998 – Dec 2006	0<0,7632<1

Jan 2000 – Dec 2006	0<0,7790<1
reference interest rate – monthly inflation rates	
Jan 1998 – Dec 2006	0<0,6938<1
Jan 2000 – Dec 2006	0<0,7170<1
Jan 2000 – Jul 2007	0<0,7412<1
average passive interest rates for non-bank clients – monthly inflation rates	
Jan 1994 – Dec 1999	0<0,4804<1
Jan 1994 – Dec 2006	0<0,6038<1
Jan 1998 – Dec 2006	0<0,7673<1
Jan 2000 – Dec 2006	0<0,7782<1

Table no. 2. The correlation coefficient between monthly inflation rates and the main interest rates of economy for different periods of time

The monetary policy strategy of inflation targeting will be kept until the ERM II entrance, because cohabitation between inflation targeting and an explicit exchange rate target is not appropriate. For the moment, it is the best choice that can be made in order to gradually achieve nominal and real convergence, in accordance with the fundamental objective of price stability. Also, the NBR would have to implement a performing communication strategy with the public, in order to be transparent and proactive.

Since January 1st, 2007, the NBR has reconsidered the structure of monetary aggregates in compliance with the ECB methodology and classification of financial instruments by institutional sector according to ESA 95. This change gave rise to influences between monetary aggregate components and between their counterparts. We can observe that the definition of M2 mirrors the interest in analyzing and monitoring a monetary aggregate which, apart from cash, includes *highly liquid* deposits as well.

Another important change in the monetary aggregates' structure is the introduction of M3 - broad monetary aggregate, which comprises *M2* plus marketable instruments issued by monetary and financial institutions. Money market instruments, in particular *money market fund shares and units* and *borrowings from repurchase agreements*, are included in this monetary aggregate (their highly-liquid nature makes these instruments be substitutes for deposits).

Calculating the degree of the National Bank of Romania's independence with Grili, Masciandaro and Tabellini – GMT (1991) central bank autonomy index on December 2007 we have obtained a score of 12 out of a maximum score of 15. This score suggests good central bank independence degree for NBR.

Political independence

No	Criteria	Scor	Value	Details

The overall "economic autonomy" index (Political independence+ Economic independence)			12	

Table no. 3. Grili, Masciandaro and Tabellini index – GMT (1991) calculated for NBR, December 2007

Regarding the real convergence, indicators reveal a great gap between Romanian values and EU15 ones, even when compared to some central and eastern European countries. Thus, in 2006 the Romanian level of GDP per number of inhabitants in PPS represented 33,5% of the EU15 average, 47,3% of the Czech Republic one, 57,5% of the Hungarian one, and 70,9% of the Polish one. Even so, the Romanian economy has developed very rapidly – in 1999, the starting year of negotiations with EU, the level of GDP per number of inhabitants in PPS was 23,2% of EU15 average, at that time.

Starting since the late of year 2006, the NBR has adopted some regulations regarding the harmonization of Romanian financial-banking legislation with the European one, as an action of adaptation to the new conditions of the European economic environment. In this direction, in January 2008, the Single European Payment Area (SEPA) came into force in the entire EU, and in Romania, as well. This is an important measure of modernizing our payment settlement system and connecting with the ones in other European countries. That has implied an adaptation of the banking infrastructure to the new conditions and better payments services for clients.

In this context, we think that the main challenges and preoccupations for the NBR in the next years will be the following: threats of capital movements that can influence currency evolutions; maintaining of a deflationist trend and achieving inflation targets; a growth in balance of payments deficits; winning the market-maker position for the banking system; the contagious effects of the American subprime credit crunch; wages pressure; a quick harmonization of our financial-banking legislation with the future Directives of EU; a growing competition in the banking system due to the single market passport and an increase of the capacity of the central bank in banking and payment settlements supervision; greater central bank independence; efforts for rising the NBR's communication strategies' efficiency.

Conclusions

The European economic environment will have a major influence on the National Bank of Romania's institutional reform. At the same time, the NBR will still be one of the most active institutions in the restructuring of our economy in the perspective of European integration. Its main objectives will be focused on its contribution in achieving nominal and real convergence and adoption of the Euro at the right time. In this direction, the NBR will be confronted with many challenges and thus it must adopt the proper policies for every situation.

JOB SATISFACTION

Corneanu Bogdan Ionut

Univeristatea Lucian Blaga din Sibiu, Facultatea de Ştiinţe Economice, Sibiu, Calea Dumbrăvii 17

Email: b_corneanu@yahoo.com, Telefon: 0722357272

We live in a highly competitive world, were the success of any organization depends on its human resource. In this way banks are no exceptions. A hard working, loyal, happy employee is no doubt a genuine asset of any organization, including banks. It is important to manage human resource effectively and find out whether its employees are satisfied and so they will be committed in their work, projecting a positive image of the organization, and determining its performance.

Keywords: job, banks, satisfaction

The concept of job satisfaction, though of considerably recent origin, is closely linked to motivation in the workplace and is a causal factor in improved performance in the workplace. These issues are again linked to job characteristics, which primarily describe the inherent features of a job, which can again motivate or de-motivate workers.

The worth of employees in the running of organizations has been analyzed and debated by management experts, sociologists and psychologists in depth and detail. A number of theories, most of them the result of painstaking and detailed research, are in use to explain human psychology in the workplace, the stressors and de stressors of a working environment, and the reasons behind employee performance, or for that matter, the lack of it.

For all practical purposes, employee satisfaction is essential for corporate success and all famous leaders of corporate enterprise apparently were also exceptional leaders of men. Low attribute rates in companies is an indication of stable and employee friendly HR policy and a barometer of corporate well being. The onset of higher employee turnover brings with it indications of difficult times ahead and is considered as a serious competitive disadvantage by business and financial analysts.

The issue of job characteristics and employee satisfaction has been looked at from a number of perspectives. One view, which is followed by many, is the importance of money. A number of employers feel that in today's multiple opportunity, flexi choice, work from home environment, money is the basic reason for a person to take up a job, furthermore that people work only for money. Companies that pay more usually get the most applications be it at college graduation time for new entrants to the work force, or later on for mid career shifts for middle and senior people.

There are again many management experts and HRD specialists who feel that the theory of money being the only real choice in an employment choice in a free market situation has many serious limitations and indeed is deeply flawed. These experts feel that while money is an important factor in the contemplation of an employment decision there are a number of other factors, which also influence such choices.

The truth is far more complex and while the cynical continue to believe in the overwhelming supremacy of money, in its power to buy happiness and satisfaction, be it in personal life or the workplace, a number of management thinkers, social scientists and corporate managers feel otherwise, advocating and using distinctly different HR philosophies and policies.

These include the understanding of need hierarchies like Abraham Maslow's theory of needs and Clayton Alderfer's ERG theory of motivation, the thinking of Herzeberger and McClelland and the various theories of goal setting and motivational processes. A number of organizations base their HR practices upon an understanding of these various theories and their adaptation to the business environment. Another variable which has come to occupy a permanent factor in HR policy making is employee reaction to the comparatively new practice of having to spend a significant part of working time in front of laptops and computer screens, be it any job profile, such is the pervasiveness of information technology in all areas of corporate life.

It is an undeniable fact that the future of business enterprise depends upon the satisfaction level of its workforce. Dissatisfied workforces cause immediate problems only to their particular businesses.

However, if these problems are left inadequately attended they have a tendency to spiral out including other businesses, industries and regions harming relationships, productivity, profits and finally also the creation of national wealth.

Employee satisfaction is thought to be one of the primary requirements of a well run organization and considered an imperative by all corporate managements. The last five years of globalisation, the rise of the Chinese economy as the world's cheapest manufacturing destination, the gradual pervasiveness of the internet and the emergence of outsourcing on a global scale have shaken up years of corporate practices in both manufacturing and service sectors of the economy.

The challenges faced by HR departments have accordingly increased manifold as businesses try to adjust and to and use the new economic realities to their advantage. In the UK the shift from manufacturing to service has resulted in the a huge change in the nature of skills required and available and the country has made rapid progress to becoming a high end service economy, home to top class skills in many service areas, notably finance, investments and banking. The shift in the nature of jobs has also led to a change in job characteristics and in the functional tools used for carrying out jobs. The various characteristics of particular jobs play a major role in providing job satisfaction to the worker. It has always been accepted that job satisfaction leads to the generation of company loyalty and lower satisfaction levels lead to attrition and higher turnover.

It can thus well be that job satisfaction levels could be an area where improvement of conditions could result in benefits for the national economy.

The following issues are thus significant in definition of the problem:

- Organisational growth needs an exposition of dissatisfiers in the workplace
- Placement of right personnel in appropriate positions is necessary for optimising performance
- Dissatisfied employees are unlikely to perform well at their jobs
- Communication between management and employees, articulation of job characteristics that improve motivation and implementation of measures to introduce necessary job characteristics will help in increasing employee performance

The appropriate way to conduct this specific research assignment would be to start with the framing of a set of research questions that would determine the general direction of this research effort. The research questions are now defined as follows.

- Do job characteristics have any bearing on the job satisfaction levels experienced by workers?
- Does job satisfaction result in better corporate performance?
- What are the reasons that result in job satisfaction in the corporate workplace?
- What could be the stressors and de-motivators, both external and internal which, when perceived as job characteristics could lead to lower levels of job satisfaction?
- What could be possible motivators that could result in increased levels of job satisfaction?
- Has the ubiquitous and ever increasing presence of IT and the internet changed the job characteristics and the levels of job satisfaction in the workplace?
- Is harassment in the workplace a cause of dissatisfaction and demotivation?
- Have recent international developments in business and economics affected levels of job satisfaction in the UK?
- Is the situation regarding satisfaction at the workplace worrying in the national context?

Job satisfaction is an extensive subject and detailed work has been carried out in the area.

Job satisfaction, its causal factors and its effect upon organisational health are all part of the various factors under study for this assignment. Job satisfaction for an individual can be influenced by a number of factors that include first the job itself, the salary, the promotion policy of the company, the attitudes of the co workers, the physical and mental stress levels involved, the working conditions, the interest and challenge levels. These various factors are just indicative of the many factors that contribute or take away from job satisfaction. Sometimes, even changing the colour of the furniture fabric can lead to higher levels of job satisfaction. While job satisfaction is not quite the same as motivation the two are closely linked and many times motivating actions also increase satisfaction levels. Most organisations periodically measure job satisfaction among employees through mainly quantitative techniques using rating scales.

We view job satisfaction as emerging from a variety of factors, including characteristics of the organizational environment, specific features of the job, and the personal characteristics of the worker. Higher job satisfaction has been linked with employees who are able to exercise autonomy and with those who have a higher level of job involvement Women have been found to report significantly higher job satisfaction than men although this gender gap appears to be narrowing . Some researchers have noted that older workers tend to have a higher level of job satisfaction, although a number of studies have shown that the age variable might be more a proxy for experience . Older workers also tend to be situated in higher-level positions, which might be more fulfilling than the less exciting entry-level positions of those just entering the work The researcher intends to commence the literature review of the subject issue with a discussion on current thinking on motivation and job satisfaction and then move to allied topics like the use of IT in work places, the problems associated with bullying in the workplace and how tweaking of job characteristics can increase motivation in the workplace, in order to get a firmer handle on the many perplexing variables.

Working in the banking system is not easy but it can bring you enormous satisfaction if you commit yourself to what you do, if you are responsible and hard working.

In the banking system job satisfaction is linked to jobs requirements:

- Bank experience or customer care experience would be a plus
- Enthusiastic person, always willing to help and solve customer's issues
- Problem solving and attention to details
- Fast learner
- Very good communication skills and listening skills
- Selling skills
- Team player, adaptability, ability to work under pressure
- Good knowledge of English is a must, especially verbal and computer skills

And responsibilities:

- Providing information to potential individual consumer and corporate customers regarding product and service features, pricing, delivery, contractual conditions. The employee develops qualified leads by selling the company image; he/she encourages individuals to visit a branch or contacts the company sales executive about the potential customer.
- Providing immediate information to the queries raised by bank customers on: account balance, statements of account, products' procedures;
- Phone Banking Representative is responsible to smoothly transfer of service to the Account Administration department, in case of queries that need further investigations and/or special attention. Phone banking Representative must ensure that all service requests (received by prior established channels) are properly handled and solved within the time lines agreed.
- Processes customer complaints in a courteous and professional manner in order to resolve any issues within his/her control. Knowledge of the relevant information and facts and an understanding of the issues are required by the employee to deal with the complaint promptly and within established guidelines. More complex complaints are passed on to Customer Service Unit Officer.
- Working with customers who wish to terminate their contract with the company. This requires the employee to understand the customer's position and develop ways to retain the customer's account and interest in the company. This reactive form of selling requires the employee to compare competitive products, services, and prices and to appeal to the customer's original reasons for wanting a bank product.
- Keeping track of the reasons for which customer interacted with him. This information is necessary to increase customer satisfaction by better understanding each customer’s needs in future interactions, by customizing approach to each customer, and by identifying general or

specific reasons for customers' requests and complaints. In order to do this, proper identification of the customers' requests and accuracy of interaction coding are required.

- Keeping strict confidentiality of all operations and discussions with clients.

The clients must be satisfied with being offered the best services, they will have greater profitability and therefore they will use more bank services. Our strategy must be the best and profitability comes no doubt. The client is satisfied, we are optimistic and we view positively the outcomes.

Every business enterprise wishes to continuously improve the job satisfaction levels of employees as much as possible within their particular constraint and resource allowance. As can be seen from the number of theories, illustrations and conditions, most of which are extremely fluid, there appear to be numerous motivator and demotivators that can improve or reduce satisfaction levels and thereby hurt both motivation and performance.

The measures listed below, culled from all the information available with the researcher from a review of existing literature distils and concentrates current expert and management thinking on improvement of job satisfaction.

- A proper salary and reward system that is beneficial to employees, eminently fair, impartial towards gender or ethnicity and which promises rewards, in terms of money and career progression is the first and foremost requirement for ensuring job satisfaction in the workplace.
- The provision of a workplace which is co operative and where employees are cherished and wanted is essential for job satisfaction. This requirement is omnibus in many ways and includes the prevention of harassment, involvement of employees in real goal setting, planning, and problem solving, showing respect for diverse ideas and opinions, giving and taking honest and constructive feedback, arranging for mentoring facilities, and sharing as much information as possible with employees
- An atmosphere at work that continuously works towards employee progression and advancement, in skills and responsibilities, by way of using the full range of employee knowledge and skills by providing opportunities for challenging assignments, considering reassignments so that employee strengths align with position requirements, providing meaningful work with restructuring of positions if necessary and possible, providing public recognition of efforts and achievements, giving employees additional responsibilities and the freedom to take action, explaining why assignments are important to the accomplishment, providing opportunities to learn new things and supporting developmental assignments and on-the-job training.

THE NEW TECHNOLOGIES EXTENSION IN BANKING: THE CASE OF E BANKING IN THE ROMANIAN PRACTICE

Danciu Victor

Academy of Economic Studies. Bucharest Romania

Abstract: The new technologies in the banking services are part of rapid changes in the way of life and thinking. The banks are aware these new changes are fundamental for their performance improvement. The banks of Romania have rapidly growing and developing e-banking services, especially the Internet information and home and mobile banking. The sites of banks provide specific information, particularly on credit. Moreover, these are some other sites, which are dedicated to credit information. The future of e-banking, services in the Romanian practice depends on how much the banks understand the part these services play in attracting and keeping customers and the easiness of Internet, home, office and mobile access.

Key words: e/banking; Internet banking; home/office banking; mobile banking; Romanian banking system.

1. Drivers and reasons for e-banking

We see the change coming rapidly not only in technology, but also in society, in the economy in the way we live or we think. Banks should go on and meet all these changes, trying to make profits, but never forget the very essence of their existence: Their Customers. The banks presence in the on-line environment is a prerequisite for meeting the customers' expectations and adding value to the banking services.

The banks are aware that on-line activities are fundamental for their performance improvement. Therefore, for well-grounded reasons, they are set to use more and more the on-line banking. No bank wants to be left behind when it comes to the e-banking revolution (Sheshunoff, A., 2000, p. 51). With the development now moving at "the speed of the Internet", falling to far behind may make it effectively impossible, or at least very difficult, to catch up with the competitors. Most banks with websites are already providing or implementing full service e banking to their customers. These banks fully understand that the e banking is the corner stone of an effective customer relationship management. Bank customers are becoming increasingly more interested in having on-line access to their bank. The speed of on-line banking services is selecting the customers. If they are not willing to wait, the customers move their business to a competitor bank. Therefore, the banks could implement the on-line banking as an offensive tool, instead as a defensive one (Eliopoulos G., 2000, p. 125). At the beginning, the implementation of the Internet banking was driven by the desire to hold on the current customers. The objective of attracting new customers was a secondary concern. Banks are setting up websites because their competitors are doing the same. The passage to the relationship marketing philosophy, which has as basic principle the interactivity, forces the banks to consider the new opportunities on-line banking provide to reach customers and to avoid the limitations associated with a traditional strategy.

The translation from the traditional strategy to the new on line strategy is a progressive one. It is like a journey which begins with a strategy for driving traffic to the site, keeps on increasing actual utilization of on-line services, offering a broad array of e-commerce services and ultimately establishing a web based loyalty management program.

On line banking works best when is implemented as a part of a bank's overall customer relationship management strategy to retain the bank's more profitable customers, to sell them more services, and to attract profitable new customers.

The banks could offer Internet services in two ways (Ghencea S., 2007, p. 146). First, they could create sites and the Internet banking become a new channel. Second d, it could set up a Virtual Bank, Internet Only, without human presence. The virtual bank could completely play its revolutionary part if the banks are focusing on segregation the market into target groups, in order to hold the groups which are compatible with virtual services, change the infrastructure to support the new vision, identify and fulfill the value desired by customer and knowledge warehouse. From the standpoint of the customer, the virtual bank has to perform services anywhere, anytime and in any way, into a "one-touch" system.

2. On-line banking, a result of an improved architecture of the Romanian banking system

The architecture of the Romanian banking system has two levels. The National Bank of Romania (NBR) as a central bank is the core of the whole banking system. The commercial banks work according to the legislation, and under supervision of the NBR.

Romania commenced fairly late with the reforming up its banking system. Cleaning up the banking sector in the transition period of the country was a costly and time-consuming process. As NBR adopted a more decisive attitude with regard of supervising banks, enacting stricter legal requirements and taking more restrictive approach to monetary policy in the late 1990s, the Romanian banking sector began to restructure. After weathering the financial and banking crisis in the late 1990s, and subsequently initiating the process of bank restructuring, the sector began to consolidate. Supported by economic stability that has been firm since year 2000, the sector emarked to a steady growth path.

The Romania's banking market has as main characteristic an oligopolitic structure with respect of market share. The five largest banks commanded a market share of 62 % in 2006, as data in Table 1 show.

Table 1. **Top 10 of Romanian banks after, market share (%)**

Nr. crt.	Bank	2006	2004
1	Blanca Comercială Română (BCR)	26,2	26,1
2	Banca Română pentru Dezvoltare – Group Société Génerale (BRD-GSG)	16,3	13,0
3	Raiffeisen Bank	8,0	9,2
4	Unicredit Tiriac	6,8	4,63
5	Banca Transilvania	4,7	2,9
6	Banc Post	4,5	4,6
7	ING Bank	4,2	5,62
8	Alpha Bank	4,1	3,18
9	Casa de Economii si Consemnatiuni (C.E.C.)	4,1	5,9
10	ABN Amro Bank Romania	3,1	4,97

The on-line operations are growing in the Romanian banking system, even if both the banks and the customers are modestly using the e-banking services. Since about tree quarters of the bills are cash paid, the main distribution channel of the Romanian banks is the branch, (Toma A., 2007, *Biz, nr. 137, 1-15 martie, 2007, p.50.*

The Internet banking services are requested only by 7% of Romanians, comparing with 84% in Finland, the country in first place in EU by the end of year 2007 (7 Plus, February, 11, p.8).

The multiplication of the distribution channels and an increase of promotion and information importance are becoming stronger trends. They are confirmed by dynamic of e banking. In February 2007, 27 of 37 banks of Romania have implemented a e-banking system. Among them, 26 or 63,4% provide Internet banking, 13 banks had home banking and only 3 banks offered mobile banking (Table 2).

Table 2. e banking in the banks of Romanian Top 10 (February 2007)

Nr. Crt.	Bank	Internet Banking	Home Banking	Mobile Banking
1	BCR	Multicash BCR	Multicash BCR	-

Source: http://www.banking.ro/e *banking php*

BRD-SCG only offers two Internet banking services. Some smaller banks such as ABN Amro and ING have two Internet banking services, too. All the Top 10 banks, but CEC, provide home banking services. CEC is the only state owned bank, and it provided not e-banking services at that time. Only two Top 10 banks, BRD and Raiffeisen and one smaller, Romexterra respectively provide mobile banking.

1. e-banking in the practice of Romanian banking system

The banking institutions of Romania are using the Internet from the year 2000. They are directed toward e banking, mainly at the beginning levels. The most offered service is Internet banking providing information.

At this first level, the banks present their products and services, and use Internet as a promotional channel. The transactional level of e banking is supposed to perform the complete range of banking operations, and it is a little less present into the practiced of Romanian banks. These banking operations have some risks, since they imply a connexion between the external user and the informatics system of the bank. Therefore, the data protection by such operations is needed. Internet banking and home banking are mainly involved in payment operations.

There are some present and future drivers, which are motivating the banks of Romania to emphasize e-banking services. A greater pressure for most of the banks seems to have the stronger competition and the struggle for attracting customers, mainly individuals. Under these circumstances, the banks have to stress more the promotion and marketing their products and services using e banking.

Beyond the competitive reasons, the rise of the number of Internet users in Romania is a strong driver for a greater use of e banking. There are about 6 million Internet users in Romania, and it could become good space for banking operations, which could support the materialization of many banking transactions (R. Bărbuceanu, 2008, p.). As a result, the banks are following their customers even here, offering them information, which they could obtain from the personnel of the bank, face to face or at call centers. (A. Drăgan, V. Toma, Biz, nr. 139,2 / 15 April, 2007, p. 40).

The banks are also strongly motivated by the advantages of e banking. The concept of e banking was only recently a main concern of the bank of Romania. The main reasons of such an attitude are the lack of a proper banking culture and the limited number of target customers for on-line services. At present, the banking customer has greater expectations, is more careful with the cost and conditions of banking offers, and has less time to go to the banking premises. More over, the stronger competition urge advantages for the customer's benefits. The Internet provides many and various advantages for the banking customers.

At random, the first of them is the interactive on-line relationship. The customers could interact with the bank, could get information in real time, could applicate for certain products and services and update the information without going to the bank. In their turn, the banks could quickly at low cost for production and spreading inform their customers and capture the public attention. The banks get a better visibility, could update more rapid the information, and could obtain a quick feedback from the customers. Moreover, the banks could more clearly segmenting the market, get better targeted products and services, the required investment for such an approach being smaller. The promotion campaigns on Internet are easier to evaluate and more effective. Last but not least, the Internet makes easier the distribution, and in this way the bank is getting an alternative channel. This new channel is an important support for the negotiations, transactions and delivery process.

As an important plus, the Internet allows many banks to have the same chances. The web site of a bank reflects and even become its public image. The difference between a good, stately site and a poor and ineffective site means a sum of thousand dollars. Therefore, the smaller banks could afford an equal or superior Internet site, comparing to one of a large bank.

2. Internet as an information channel in the Romanian banking system

Who wish specific information has at disposal the sites of banks and some other sites, which are specialized in delivering information about credit. Most of banks display detailed information about credits types, interest and commission included, on their sites.

The interested people could also make applications for credit, which afterwards arrive at the call-centers.

The Romanian economic magazines Capital performed an analysis in 13 banks of Romania. Among them, there are the five of Top 10 banks in the banking market hierarchy, BCR, BRD, Raiffeisen, Unicredit Tiriac, Banca Transilvania respectively, and some other smaller banks such as Alpha Bank, Ing, Volksbank, OTP (R. Barbuceanu, 2008, p. 33). Table 3 shows a relative hierarchy of the studied banks after the range of information, which is available on their sites at the end of year 2007. The data of the Table 3 show that all large banks are in the frontline of the use of Internet. The most advanced banks seem to be BRD and Banca Transilvania, and they are followed by some smaller banks such as Volksbank, Banc Post, OTP.

Table 3. Information available on the sites of banks of Romania

Banks	Interest	Commission	Rates	Applications on line
BRD	Yes	Yes	Yes	Yes
Banca Transilvania	Yes	Yes	Yes	Yes
Volksbank	Yes	Yes	Yes	Yes
Banc Post	Yes	Yes	Yes	Yes
OTP	Yes	Yes	Yes	Yes
Credite Europe Bank	Yes	Yes	Yes	Yes
Banca Romaneasca	Yes	Yes	Yes	Yes
Raiffeisen	Yes	Yes	Yes	No
ING Bank	Yes	Yes	No	Yes
BCR	Yes	No	Yes	Yes, no real estate
Alpha Bank	Yes	No	No	Yes
Unicredit	Yes	Yes	-	No
CEC	Yes	No	Yes	No

Source: Capital, 17 January 2008, p. 33.

The sites of the banks have also information about shareholders, and some banks are including chapters such as the section about professional career, too. BRD is a bank, which emphasize the section human resources. This section has more chapters, human resources policy, areas of bank practices, respectively and a chapter for young people who have evolution potential for management positions. The Banca Transilvania's site makes with an other site connection, which is dedicated to the members of B.T. Club.

This site has tree chapters, training, consulting and networking respectively (Banks sites and A. Dragan, V. Toma, 2007, pp. 48-49).

3. Sites dedicated to credit information

The sites dedicated to credit information have been launch in the year 2005. Despite they are niche site, they have rapidly advanced, having even about 30.000 visitors a week. The market share and the notoriousness are the drivers, which stimulate the internauts searching the bank's name, so that the actual banks hierarchy in the Romanian banking market is observed.

These web sites, among them being Conso.ro,Finzoom.ro and Vreau Credit.ro, allow the visitors getting information about the cheapest credit, no matter its type or currency.

By filling a blank with the requested amount and the number of partial payments, one could see the list of credits and the banks, which could offer it. The detailed conditions of the bank's offer are also available, so one could estimate the total cost of every offer by bank.

In a large measure, the initiatives of the Romanian banks for increasing their presence in the virtual space by means of a good web site are due to the global trends in the banking industry. Romania is following these trends and local banks should know the customer profile, and comply with their marketing strategies. Thus, strategic objective of the bank is focusing on the way its site is organized.

Within the countries where there are well-developed banking services and a proper customer culture, the banks have more diversified information on banking operations range. On the sites of some banks are available comparisons between their products, on-line consulting services about financial planning and direct contacts between the bank personnel and the on-line users. All these facilities are progressively added to the on-line information of the banks of Romania.

In order to join these international practices, the Romanian banks should fully understand the part Internet play in attracting customers and, especially, in loyalty of the customers. At the some time, the on-line services evolution and presence of the banks of Romania in e-banking will depend on the easiness of the Internet, home and mobile banking access, on the shorter time of the banking customers, and on the facilities these customers will receive.

INSURANCE BROKERAGE IN ROMANIA

Dănulețiu Dan-Constantin

“1 Decembrie 1918” University of Alba Iulia, Faculty of Sciences, Alba Iulia, Nicolae Iorga street, no. 11-13, dan.danuletiu@gmail.com

Dănulețiu Adina-Elena

“1 Decembrie 1918” University of Alba Iulia, Faculty of Sciences, Alba Iulia, Nicolae Iorga street, no. 11-13, adina.danuletiu@gmail.com

The paper highlights the importance of brokerage on insurance market and shows the evolution of this kind of activity in Romania. A few aspects concerning brokerage activity are taken into consideration, stressing on Romania’s EU accession impact on brokerage as well as on the essential issues allowing a quantitative analysis of insurance brokerage in Romania. The paper lets the reader see a couple of opportunities as well as a couple of constraints brought by Romania’s EU accession to the Romanian brokerage market and the elements momentary braking the development of this activity to its full potential. It also suggests possibilities to support the growth of insurance brokerage.

Keywords: insurance intermediary, insurance broker, insurance agent

Distribution of insurance is handled in a number of ways. The most common is through the use of insurance intermediaries. Insurance intermediaries facilitate the placement and purchase of insurance, and provide services to insurance companies and consumers that complement the insurance placement process. We should emphasize on the intermediary not being and not having to become a party in the insurance contract (2).

Traditionally, insurance intermediaries have been categorized as either insurance agents or insurance brokers. The distinction between the two categories relates to the manner in which they function in the market. Insurance agents are, in general, licensed to conduct business on behalf of insurance companies. Agents represent the insurer in the insurance process and usually operate under the terms of an agency agreement with the insurer. The insurance broker is a specialized intermediary whose main activity consists in offering services based on a reasonable standard of experience and professional abilities. Brokers assist clients in the choice of their insurance by presenting them alternatives in terms of insurers and products. Acting as "agent" for the buyer, brokers usually work with multiple companies to place coverage for their clients. The broker offers advice and he normally signs the insurance contract as the insured’s agent, but he usually gets a part of the fee to by the insurance company (1). A broker acting on consolidating insurance markets is more often asked to inform and protect the client during the process of insurance contracts negotiation. Brokers act for the insured’s interests by actually placing the risks to an insurer.

As far as the presence of insurance intermediation companies in Romania is concerned, the regulations concerning Romanian insurance market was initially extremely vague and insurance intermediation was provided according to Law no. 47/1991 by entrepreneurs – individuals or companies – whose legal status rather blurred. The endorsement of Insurance and Reinsurance Activity Surveillance Office (OSAAR) authorized the setting up of intermediation agencies and it didn’t settle any barriers to the main activity of the companies. According to Law no. 47/1991 the companies acting as intermediation agencies were allowed to get involved in other activities beside insurances. This feature only made the intermediation activity more difficult to be surveyed by that time and it made some of the important objectives of the insurance field almost impossible to be fulfilled. The above mentioned objectives refer to: the difference between brokers and insurance mediators, share holders’ structure, information concerning the mediators’ experience within the field of insurances, registering the intermediation activities to the book accounts, the OSAAR’s gathering of financial papers, intermediation activities analyses and control and so on. Later on, insurance intermediation has been better and clearer regulated by Law No 32/ 2000 and, as consequence, the brokers interested in continuing their activity had to request and get a license from Insurance Surveillance Commission (CSA) according to the law.

A few changes have been made to the law during Romania’s EU accession process and now it stipulates that the insurance intermediation activities are those preliminary activities necessary in order to sign the insurance-reinsurance contracts and in order to provide assistance in drawing up and managing contracts, especially when damages are involved. When the above-mentioned activities are carried out by an insurer/re-insurer or by one of their employees acting under the insurer's / re-insurer's responsibility, one should not consider them intermediation activities.

Law No 32 /2000 stipulates that insurance agents and brokers are insurance intermediaries. A legal entity may act as an insurance and/or reinsurance broker if Insurance Surveillance Commission (CSA) authorizes it. In order to be authorized by the Insurance Surveillance Commission, the petitioner will bring to the CSA the papers proving it will act under certain conditions:

- it is a legal entity whose name necessarily includes one of the expressions "insurance broker", "insurance/reinsurance broker" or "reinsurance broker";
- it has a paid up registered share capital with a value exceeding a certain limit settled on by CSA regulations;
- it signed a third party liability contract valid through the whole European Community territory and the states within the European Economic Space;
- it only activates as an insurance and/or reinsurance broker;
- it hasn't previously been the subject of bankruptcy nor of a bankruptcy and/or legal reorganization by the date of authorization request;
- shareholders, main shareholders and stakeholders have a clean criminal record as far as patrimony related crimes or crimes defined by financial and fiscal law are concerned;
- its executive manager complies with the requests of the CSA standards concerning education and work experience;
- its name is not putting public opinion on the wrong track.
- An insurance/reinsurance broker is limited by the following restrictions:
- it can't be a main shareholder or stakeholder of a insurer/re-insurer;
- it can't be a shareholder or manager of an insurance and/or reinsurance broker;
- it can't activate by means of insurance agents.

Insurance/reinsurance brokers may collect insurance premium, pay for the damages using the currency stipulated by the insurance/reinsurance contract and issue the insurance/reinsurance papers in the name of their insurer/reinsurer.

Authorized insurance/reinsurance intermediaries may carry out intermediation activities in Romania or in any member state, under the condition of previously informing the CSA.

Emergency Governmental Decision no. 210/2005 altering the law no. 32/2000 has articulated and defined the brokerage assistants and the brokerage mandate. Meanwhile a couple of arrangements have been made in order to stimulate a better intermediation activity. Some of these arrangements referred to:

- requiring an integrated education and training system;
- laying down the compulsoriness of providing a minimal information set to the clients;
- setting up special bank accounts for insurance premiums or damages and protecting these sums against creditors;
- stating the broker's insolvency when the broker does not bring the insurance premiums to the insurer within 30 days later than the date settled by contract terms and the possibility that CSA initiate the procedure of bankruptcy and legal reorganization;
- accomplishing professional training standards of the broker's employees;
- the existence of a Journal of brokerage assistants;
- arrangements made in order to avoid the existence of more brokerage mandates issued by the same client for the same objective;
- the procedure of requesting mutual understanding or of brokerage mandate reversion at client's initiative.

Another opportunity for developing brokerage businesses has occurred due to Emergency Governmental Decision no. 87/2006 which granted the right of insurance / reinsurance brokers to intermediate facultative pensions, according to the specific law in force.

The National Union of Consultancy and Insurance Intermediation Companies in Romania (UNISCAR) was set up by a group of 12 consultancy and insurance intermediation companies as a non-profit organization in September 2000 and this was another essential element for the development of Romanian insurance brokerage. The main purpose of the Union was to support its members to get the public recognition of the insurance consultants' and mediators' activity.

The objectives of the Union refer to:

a) working together with insurance companies and the authority surveying insurance activity to prepare technical and legal basis within the insurance field;
b) drawing up the working standard, deontological norms and trying to reach a higher level of quality for the services provided by its members;
c) supporting its members in the education and training their employees;
d) supporting the legitimate interests of its members against third parties, including state institutions and mass-media;
e) developing national and international connections with similar organizations and organisms.

Broker's Ethical Code has been drawn up by UNISCAR in 2001, stating the professional standards and the principles any broker member of the Union has to comply with in his interaction with clients, insurers and other mediators. Another document drawn up by the Union was the Cooperation Protocol between UNISCAR and the National Union of Insurance Reinsurance Companies. The Protocol defines the minimal principles based on which brokers and insurers affiliated to these professional associations will cooperate and it aims to a better collaboration between the two professional categories on the insurance market for clients' benefit. Supporting professional training of insurance intermediaries is another concern of UNISCAR

As far as the importance of insurance brokerage at EU level is concerned, the European Directive concerning insurance intermediation, which came into force on 15 January 2005, highlights this. The fundamental objectives of this directive refer to enabling insurance intermediaries to operate freely throughout the European Union and to enhance the consumer protection. It set up principle of single license based upon notification, but general good requirements and extra information requirements in host country remain applicable.

A quantitative evaluation of Romanian insurance brokerage market is considered below. Thus, the insurance brokers' number evolution between 2001 and 2007 is shown in table no. 1.

Table no.1.

Insurance brokers' number in Romania between 2001 and 2007

Year	2001	2002	2003	2004	2005	2006	2007
Number of brokers	87	150	204	266	317	344	397
UNSICAR's members	18	23	24	28	41	47	73

Source: 2002-2006 Insurance Surveillance Commission's reports; Media Xprimm 2008

A significant decrease in the broker's number due to Law 32/2000 application has to be noticed. When Law 32/2000 came into force there were 817 active so-called brokers, but after the law being put into force, the number of brokers has severely reduced to 87. As their presence on the market was important, the brokers' number increased during 2001 and 2007, meaning a four times growth compared to the first year after the law enforcement. UNISCAR has now 73 members, meaning less than 20% of the total number of active brokers on the market, but they concentrate almost 67% of the incomes registered on the brokerage market in 2007. In the perspective of the share of intermediated insurance premiums, the situation is quite similar as UNISCAR brokers registering premiums intermediation evaluated at more than 66% of insurance brokerage.

As an effect of Romania's EU accession, a significant number of brokers from European Economic Area (EEA) made public their intention to activate on Romanian market, based on the freedom of establishment right or on the freedom to provide services on the unique license principle. A brief presentation of these brokers according to their origin country and number is made in the table no. 2.

Table no.2

Number of brokers from European Economic Area intending to activate in Romania

No.	Country of origin	Freedom of providing services principle	Freedom of establishment principle
1	Austria	4	
2	Belgia	11	
3	Bulgaria	2	
4	Cipru	1	
5	Danemarca	1

23	Ungaria	7	1
Total		537	2

Source: author's calculus based on the data from www.csa-isc.ro

There's an important number of intermediaries from European Economic Area (EES) interested in providing their intermediation services on the Romanian brokerage market, most of them being British (378 brokers out of 537), German (43 brokers) or French (32 brokers).

Romania's EU accession brought a number of opportunities for Romanian brokers, such as: settling a healthy business climate leading to a wider insurance cover, a wider market to activate on, the possibility to accentuate the brokers' role as a consequence of EU brokers' representation, simultaneously with offer diversification. As far as brokers are concerned they are expected not to request, negotiate and sign insurance contracts only, but also to provide other services such as risk evaluation, risk management, control and damage management.

On the other hand, a market concentration trend is expected as well as the emergence of specialized brokers, as an effect of market segmentation. An accentuated competition on the market due to EEA competitors is also expected.

The importance of brokerage on commercial insurance market is highlighted by the paid insurance premiums and the brokers' insurance market share in table no 3.

Table no 3

Brokers' insurance market share

from the perspective of intermediated gross insurance premiums

Year	Gross insurance premiums intermediated (lei)	Nominal growth (%)	Real growth (%)	Gross insurance premiums intermediated (mil. euro)	Nominal growth (%)	Share of direct insurances
2002	172433300	-	-	49,38	-	10,3
2003	288713301	67,43	46,74	70,22	42,20	10,8
2004	665660448	130,56	110,94	167,8	138,96	19,1
2005	855389230	28,50	18,32	232,63	38,64	19,4
2006	1233580000	44,21	37,51	350	50,45	21,5
2007*	2100000000	70,24	59,75	640	82,86	29

** estimated values*

Source: author's calculus based on the data from 2002-2006 Insurance Surveillance Commission's reports; Media Xprimm 2008

An analysis of the data in table 3 points to the significant growth of Romanian brokerage, showing that the number of insurance brokers has permanently increased. The same conclusion originates in the growth of values of insurance premium paid up due to brokers comparing to the values of insurance premium paid up due to insurers from 10.3% in 2002 to about 29% in 2007.

Brokers' involvement on private pensions market has been even more significant, as shown by table 4

Table no. 4

Private pensions intermediated by brokers

No.	Specification	Clients' number / percent
1	Clients due to brokers/ mediators	1.265.657
2	Clients validated after four months of direct selling	3.991.032
3	Brokers' and mediators' share	31,7%

Source: www.csspp.ro

One of three insured persons having bought a private pension has signed his / her contract due to an insurance broker, as shown above.

There are also some problems that curb the development of the brokerage activity in Romania. Thus, in Insurance Surveillance Commission (CSA) point of view, the main problems derive from a poor communication between the Commission and certain brokers, especially when registering changes of headquarters or point of sales to Trade Registry with no CSA notification and endorsement is involved. Other problems are related to a delayed presentation of their financial papers to CSA or to lack of contracts concerning professional third party liability.

Some insurers are also complaining of poor quality intermediation services especially for those services for which they granted special mandates according to Law 32/2000 (article 35) such as: collecting insurance premiums, paying for the damages in insurers' name, using the currency stipulated by the insurance / reinsurance contract, according to the legal regulations in force, and issuing insurance or reinsurance papers in the insurer's or re-insurer's name.

On the other hand, most of the brokers' complaints concern the insurers' hostile attitude determined by their former bad experience with other intermediaries as well as forcing the modification of their existing collaboration contracts and bringing the contracts to even terms for all brokers, under the threat of ceasing the contract if the new contractual terms are not agreed. Other complaints refer to: not validating the brokerage mandate when regularizing damages to be paid based on an insurance contract that have not been intermediated by a broker, insurers breaking their paying damages terms, and a poor professional training of the insurers' representatives in branches, distorted, delayed and even discontinued communication between brokers' and insurers' decision makers. There's also a long period of time between the moment a new insurance product is brought gets to the insurer's portfolio and the moment it is introduced to the broker.

We consider that by solving the above-mentioned problems, the Romanian brokerage market may double within the next three years as in brokers' perspectives.

A NEW CRISIS OF HUMAN RESOURCES MANAGEMENT IN THE ROMANIAN BANKING SYSTEM

Due to the fast market growth and due to the stiff competition, lately we have been experiencing a great demand for banking activity experts. Beginning with the demand and offer game, the migration of skilled manpower from one bank to another is quite high and each employer in the banking system would like to be able to implement a human resources management that would allow them to stabilize the manpower, to obtaining loyalty of the best employees, to reduce new staff training costs. The foreign agents of the banks claim that Romania is not the only one who is going through such a crisis, which will last at least two or three more years.

Crisis, human resources management, banking system

The number of banks in Romania (50%) continues to be low compared with the number of banks established in the European Union Member States (150%), consequently the banking system may still continue to develop, while Romania continues to be an interesting market for the main operators in Europa. But the Romanian banking system continues to have as salient feature a high level of bureaucracy compared with the western countries is we refer to the high number of employees operating in indirect activities (approximately 10% of the bank staff in Romania provide services other than actual operations carried out to the benefit of the client).

As far as the banking concentration level is concerned, Romania ranks low having a number of 4900 inhabitants / banking establishment, compared with the average corresponding to the European Union states that amounts to 2297 inhabitants / banking establishment. The savings level also features poor results; it amounts to 17.5 euros / month, compared with Czech Republic – 21 euros / month, Poland – 27 euros, Slovenia – 36 euros.

Human resources management acquired a special international importance as human resources are deemed to be the greatest asset of a company. Human resources are unique from the point of view of their growth and development potential and of their ability of knowing and exceeding their own limits.

Due to the fast market growth and due to the stiff competition, lately we have been experiencing a great demand for banking activity experts. Beginning with the demand and offer game, the migration of skilled manpower from one bank to another is quite high and each employer in the banking system would like to be able to implement a human resources management that would allow them to stabilize the manpower, to obtaining loyalty of the best employees, to reduce new staff training costs.

The problems encountered by the banks as far as human resources management is concerned focus on the following coordinates:

- Development and retention – the financial and banking sector is a dynamic field, displaying an accelerated growth, leading to the modification of skilled staff expectations;
- Motivation – compensation and motivation are essential components of human resources management system and these must be real and competitive;
- Geographical location – as territorially distributed human resources must be managed, the issue of data fragmentation, of centralized management and of management costs occurs;

- Efficient training – the need of training emerges along with the increase and complexity of the market and of products provided; it is necessary that this training be carried out as efficiently as possible, incurring costs as low as possible;
- Cost control – within an environment that is increasingly competitional, where profit is increasingly difficult to yield, and the margin of asset interest and liabilities interest is more and more reduced, thus the issue of rendering processes carried out more efficient and of using in an optimal way the manpower emerges;
- Reporting – the majority of ad hoc reporting requests refers to human resources; more often than not human resources departments operating inside banks must meet the requests coming both from the inside and from the outside;
- Legislative amendments – in the human resources field, legislative amendments entail a need for immediate adaptation carried out with minimum costs.

The actual crisis is encountered at the management level, since very few banks undertake human resources planning activities. The recruitment is usually carried out at the very last moment, either when an employee is leaving or when extension may no longer be supported by current employees.

Nowadays the Romanian banking system is confronted with a human resources crisis; each extension within territory entails the drawing of human resources and the banks are compelled to employ staff included in the junior category, who do not have professional experience, consequently banks are exposed to operational risk, as this has lately become reality that is characteristic to the Romanian banking system, under pressure of competition of investors in Romania, the majority of banking groups with foreign capital that controls the Romanian banks and under pressure of competition for increasing the market share.

Joining the European Union may entail a short-term deepening of the staff crisis in the banking system affecting Romania, since a large number of graduates could be interested in job outside Romania, attracted by the possibility of gaining high salaries. The crisis may also be generated by European companies penetrating the Romanian market; wishing to develop, they will recruit experts; moreover, outside banks might open subsidiaries in various cities, employing the staff operating there.

The domestic banking system is witness to a genuine migration process of the staff from one bank to another. The highly trained staff has become a rare asset of banks, which compete in order to employ the best professionals. The main cause of this human resources management is connected to bank expansion. Staff migration from one bank to another and the leave of experts to other activity sector have led to the occurrence of a human resource crisis in the banking sector.

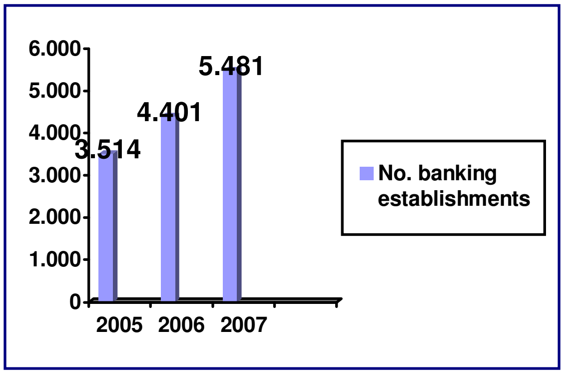
The banking market has become more and more of a paid work field. This is the natural consequence of demand, which exceeds the available experts offer. Unfortunately, a set of competences below the standard level is sold for a price high above the average and this happens more and more often.

Although the largest salaries received by top management are paid by banks or establishments operating in the financial field, Romania is confronted with a lack of staff in the financial and banking field, lack that has deepened following the adhesion, on account of economic climate and of absence of strategies intended to attract young persons on the labour market. Generally, the lack of experts in the financial and banking field is noticed in the case of middle and top management positions. If for the entry-level administrative, human resources or IT field it is easier to cover vacancies, there are highly specialized and technical positions, such as the operation, sales or department management positions that are difficult to cover if there are no specialized employees. The massive staff fluctuation and the preference of many experts for freelancing (persons working on their account, providing services to companies, without being employed) result in the sharp deepening of lack of staff operating in the field.

The managers of the banking establishments complain about the fact that they have to hire unskilled persons, which affects the efficiency of the services. This staff related crisis prevents the development of the medium and small-sized banks during the next period. The banking establishments in Romania have the fewest employees compared with the other countries in the European Union, if in our country there are approximately 100 employees in a bank, in Poland the average of the employees in a banking establishment is over 200 persons. From the point of view of the active efficiency of the employee, unfortunately we find ourselves in the same situation. We have a quarter of what Slovenia has, a third of what Hungary has, approximately 70% of Poland`s, 1/3 of Slovakia`s and a quarter of the Czech Republic`s. In the future the training system of every bank will differentiate; the banks will focus on the standardization of the sales processes, trying to open small establishments to sell standard products and where the operational risk will be reduced.

At present, there are 41 banks operating in Romania, the field market being divided into over 5 400 establishments. According to the statistics, in this field there are over 65 000 persons working, in the last year having been recorded an increase of approximately 10% of the number of employees. A significant increase was recorded at the salary level, the average of the salaries in the banking system being 1000 €. The reason of this salary boost is related directly to the lack of specialists.

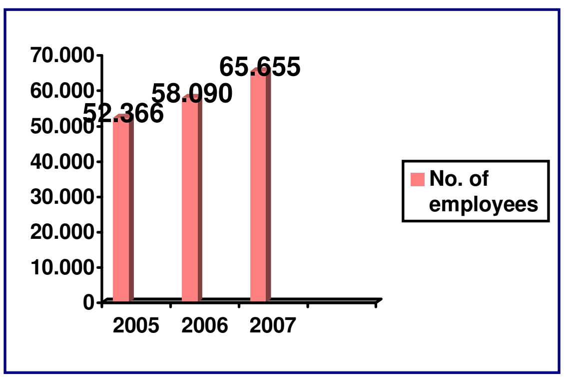
The Romanian banks have continued in 2007 the accelerated process of extension of the subsidiary networks. The number of the banking establishments in Romania was at the end of December 2007, of 5 481, with 1080 more than at the end of the previous year.



The evolution of the banking establishments in Romania

In 2006 the rate of development of the banks was almost to 1000 new agencies and subsidiaries. According to the data supplied by the specialists from BankingNews, from the most important retail banks in Romania, the rate of extension will remain at the same level in 2008 as well. Thus, the objectives established by the banks indicate the emergence of over 900 establishments in the course of this year.

As far as the situation of the employees from the banking system are concerned here too it was registered an increase, thus from a number of 52 366 employees registered at the end of 2005, by the end of 2007 it came to a number of 65 655 bank clerks.



The number of employees from the Romanian banking system

In the competition for the best clerks between the banks, only the one who offers the best salary packaging wins. The consequences of the workers deficit, as well as of the treble of the salaries in this field are directly visible in the profit of the bank in Romania, which in the last year has decreased with 0.33%.

However, for a worker who does not earn very much from the beginning in a banking establishment, the starting salary for the entry-level jobs is under 300 €. This is why the young persons have changed their options, giving up the idea of finding a job in a bank, some of them preferring to work in the insurance field, where the salary is much bigger and where they can gain experience faster.

The banks need specialists both in retail banking and in the corporate area. Companies focus both on universities and on other fields, because the universities cannot cope anymore. The banks count on the ability of the young persons to quickly adapt and take on the responsibility to train them for the specialties they need. The solution for the intercession of the staff deficit could be the achievement of efficient training programmes.

Due to the fast market growth and due to the stiff competition, lately we have been experiencing a great demand for banking activity experts. Beginning with the demand and offer game, the migration of skilled manpower from one bank to another is quite high and each employer in the banking system would like to be able to implement a human resources management that would allow them to stabilize the manpower, to obtaining loyalty of the best employees, to reduce new staff training costs. All these are possible today, by means of the Oracle Management solution of the Human Resources and Oracle iLearning solution.

For Oracle, the banking sector was and will be a strategic direction, both globally and on the Romanian market, taking into consideration that 17 of the first 20 banks in the world, according to some statistics of Banker Magazine, work with Oracle technology, and all of the first ten banks in Romania also use Oracle technology.

The solution of human resources and Oracle remuneration manages the employees of BCR (Romanian Commercial Bank), BNR (National Bank of Romania), LIBRA BANK, RAIFFEISEN, etc. Oracle Management of The Human Resources answers to all the challenges and covers the whole variety of processes related to the management of human resources: multidimensional centralized management, management of salaries, management of qualifications and competences, management of the process of evaluation, recruitment and hiring process, the complete analysis of manpower, in addition it is offered a complete and personalized solution of mixed training which allows the provision of courses to the internal employee (the employees of the bank), as well as to the external employee (to the clients, for example, the training for the use of the internet banking solution).

At present, Oracle covers with top solutions the whole range of operation of a bank. For example, the solution of calculation and analysis of the bank`s profitability, which is number one in the world, calculates the profitability on any dimension requested by the management: client, bank products, cost center, sales person. The solution is extremely valuable to the top management of the banks in the context of the more and more difficult attainment of profit against the background of a stiff competition on the market.

The strategic function of the IT element in banks becomes more important as we take part in the globalization and standardization process in the international banking system. The creed of the Oracle specialists is that of granting the banking establishments a competitive advantage.

The foreign agents of the banks claim that Romania is not the only one who is going through such a crisis, which will last at least two or three more years. As it can be seen, this year too, the banks are going to invest important resources in the extension of the networks, under the circumstances in which the number of banks in Romania is reduced, and the domestic banking market is developing. Thus, due to the expansion in the retail banking, next year the banks are expected to hire at least 10 000 persons, reaching a total of 80 000 employees in the system.

Abstract: In this article we aim at drawing up a concise presentation of the electronic payment system in our country combined with assessments of this system aligned to the European Union's from the point of view of functionalities as well as respecting European and international standards and practices in the field. Interbank real time settlement system in Romania is structured in order to be compatible with similar infrastructures in the European Union member states, Single Euro Payments Area. Payments handling will be simplified as all incoming and outgoing payments will use the same format.By providing new payment instruments and common interoperable infrastructures, SEPA will bring about further European integration and market efficiency.

Key words: interbank payments, electronic system, Eurosystem, efficiency

1. Introduction

Since the establishment of the European Economic Community in 1958, the movement towards a more integrated European financial market has been marked by several events, the most visible of which were undoubtedly the launch of the euro in 1999 and the cash changeover in the euro area countries in 2002 in particular. Less visible, but also of great importance, was the establishment of the central banks' large-value payment system, known as TARGET (Trans-European Automated Real-time Gross settlement Express Transfer), on 1 January 1999.

The introduction of the euro as the single currency of the countries of the euro area will be completed only when the Single Euro Payments Area - SEPA - permits to individuals and corporations to make cashless payments throughout the euro area from a single payment account anywhere in the euro area using a single set of payment instruments as easily, efficiently and safely as they can make them today at the national level.

In Romania, the first steps in view of implementing this system were taken starting with the year 2005 by gradual operationalization of its three components: gross basis settlement, net basis settlement and settlement of government securities operations. As a result, implementing an infrastructure of payments and settlements compatible with similar infrastructures in the European Union member states contributes to the Romanian system alignment to the Community requirements in the field.

2. The Single Euro Payments Area

The Single Euro Payments Area - SEPA – implies that customers can make payments throughout the whole euro area as efficiently and safely as in the national context today and, at the end of the process of implementation of it, euro area customers will have the possibility of using one payment account and one set of standardised instruments. SEPA consists of the single currency, a single set of euro payment instruments – credit transfers, direct debits and card payments – an efficient processing infrastructures for euro payments, common technical standards, common business practices, a harmonised legal basis and ongoing development of new customer-oriented services.

On the world level, with 2.3 trillion euros settled every day, the European Union system -TARGET - represents one of the three largest wholesale payment systems, alongside Fedwire in the United States and Continuous Linked Settlement (CLS), the international system for settling foreign exchange transactions.

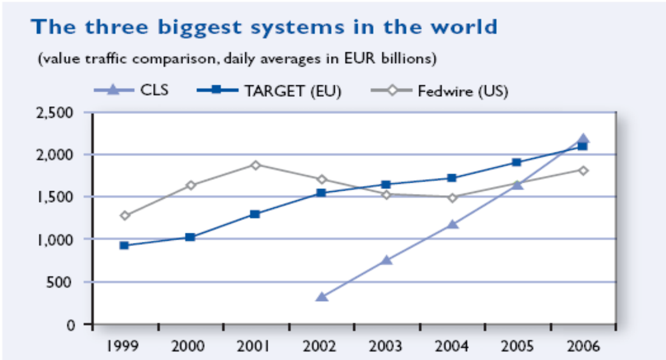

Figure 1. The three biggest systems in the world

Source: European Central Bank, A Single Currency – An Integrated Market Infrastructure, pag. 8

For the ending of the year 2007 (November 2007) and beginning of the 2008 (May 2008) it was projected a better variant of TARGET system called TARGET2 which replaces the current decentralised technical infrastructure. Also, it is created the CCBM2 project, which provides a single set of procedures for all eligible collateral used on both a domestic and a cross-border basis (proposed to be launched in March 2007).

Regarding the payment instruments, it has developed two schemes:

- SEPA Credit Transfer – programmed to start in January 2008;
- SEPA Direct Debit – roll-out starts in November 2009;
- SEPA Card Payments – for January 2008, which permits cardholders to be able to pay with one card throughout the euro area and there will no longer be cards for national use only. The point-of-sale terminals will be standardised and merchants will be able to accept a wide range of cards with a single terminal. There are currently more than 350 million cards in circulation in the euro area, which are used to make more than 12 billion payment transactions and 6 billion cash withdrawal transactions per year (ECB, The Eurosystem's view of a "SEPA for cards", November 2006, p. 1);
- SEPA Clearing and Settlement Infrastructures – also for January 2008.

By the end of 2010, the infrastructures must be able to reach all euro area banks and process euro payments made with the three SEPA payment instruments, respectively credit transfer, direct debit and card payments.

Around 50% of Europe's banks expect implementing the SEPA Direct Debit scheme to be highly complex, a higher proportion than for implementing SEPA Credit Transfers. In several nations, the SEPA Direct Debit scheme is significantly different from existing national. Banks inside the Euro-zone expect 62% of their investment in Automated Clearing House – ACH - payments and 64% of their cards expenditure to be SEPA-related, whereas banks outside the Euro-zone expect the proportion of their payments spend on SEPA to be 35% for ACH payments and 42% for cards (Accenture, The European Payments Revolution, Accenture European Survey 2006, p. 5).

3. Electronic System of Interbank Payments in Romania

The payment system in Romania experienced significant structural changes in 2005 by completing the process of implementing the electronic payment system and gradual operationalization of its three components, that is (NBR, Annual Report 2006, Chapter 4, Payment system, p. 67):

- RTGS system, Real Time Gross Settlement system, a real time gross settlement system that entered into force on April 8, 2005;
- ACH, Automated Clearing House, managed by TRANSFOND SA – an automated clearing house that became effective on May 13, 2005;
- GSRS, Government Securities Registration and Settlement system, registration and settlement system of government securities operations that entered into force on October 3, 2005.

3.1. Interbank Discount System on Gross Basis

In Romania, gross basis settlement system – RTGS – is a real time gross settlement system ensuring the exchange of payment instructions between participants and final (definite) settlement of interbank funds transfers on a continuous, transaction by transaction basis, as well as final (definite) settlement of net positions resulted from net basis settlement systems and funds transfers afferent to financial instruments based operations (RTGS system regulations 3rd version of October 10, 2006, NBR, p. 5).

This system represents *the first component of the Romanian electronic payment system*, entered into force on April 8, 2005 (according to Regulation no 1 of February 23, 2005 on payment systems ensuring funds clearing, published in the Official Monitor no 265/March 31, 2005, annulled by Regulation no 9 of September 23, 2005 on modifying and completion of the National Bank of Romania Regulation no 1/2005 on payment systems ensuring funds clearing, published in the Official Monitor no. 881/Sep. 30, 2005), ensuring high-value settlements (over 50.000 RON) and urgent interbank payments by payment order as well as great value and urgent payments between credit institutions and State Treasury initiated by payment orders for the Treasury. At the same time, RTGS system accepts and processes the instructions from NBR authorized clearing houses or from systems ensuring transaction settlement by means of financial instruments for participants' net or gross positions settlement.

In view of fulfilling safety, security and availability conditions used internationally in projecting RTGS system in Romania there have been implemented *Straight Through Processing* - STP – systems in order to ensure efficiency increase through cutting down on operational risks and settlement time.

For the year 2006, the daily average of the number of transactions processed through RTGS increased with 41% comparative with the year 2005, but, in the same time, the daily average of payments amount processed through RTGS decreased with 19% given the results from previous year, mainly because of reduction NBR interventions on the monetary and currency markets, as we can see in Table 1.

Year	**No of transactions**		**Payments Amount (mil. RON)**		**Average value of transaction (mil. RON)**
	Total	**Daily average**	**Total**	**Daily average**	
2005	1,100,668	4,325	2,408,448	9,370	2.19
2006	1,548,371	6,096	1,927,346	7,588	1.24
Variation	+ 41	+ 41	- 20	-19	- 43

Table 1. Evolution of payments through RTGS in Romania

Source: NBR, Annual Report 2006, p. 71

Payment transactions performed by financial institution in the own name, but on the clients accounts (with messages SWIFT MT103) are higher (81.19% of total system number of transactions), but total amount of its was relatively reduced (only 22.47% of all amount payments from the system). At the same time, the number of transactions performed by financial institutions in the own name and account (with messages SWIFT MT202) was relatively low, but these payments had a significant value (Table 2). Regarding payment transactions which involve direct credit or debit transfer, their volume was down, because these correspond some operations with low frequency, as takings by NBR of commissions, direct debit and credit transfer on the transfer participants accounts in relation with the central bank, operations performed by NBR in the name of participants in case of emergency, when participants are in impossibiity to connect to, and to do themselves the operations.

Payments	**MT103* (%)**	**MT202** (%)**	**Transfer direct (%)**
Total number	88.19	8.13	3.68
Total Amount	22.47	50.03	18.5

Table 2. The structure of the payments through RTGS in Romania, year 2006

Source: NBR, Annual Report 2006, p. 72

**MT103 represents transactions performed by financial institution in the own name, on the clients accounts*

*** MT202 represents transactions performed by financial institutions in the own name and account*

In the year 2006, the average availability of the RTGS system, respectively the access of participants to using of system without any occurrence on the time of its functioning, was 99.89%, taking part in tolerances established by NBR for the services quality level.

RTGS system was conceived in such a manner so as, along with the European Union accession, to make possible connecting to the platform of high-value payments settlements in the euro zone – TARGET ensuring the process of cross border payments in euro as well as changing the settlement currency from the actual national currency into euro.

3.2. Interbank Multilateral Net Settlement System

In Romania, since 1995, there has been the Interbank Clearing House belonging to the National Bank of Romania. This entity allowed passing over from an intermediary settlement system (on a bilateral net basis) of interbank payments to a settlement system through multilateral clearing after a cessation of more than 50 years. Starting with the year 2001, multilateral clearing of interbank payments has been taken over by another operator - TransFonD – a trade company created by the banking community that carries out its activity as a BNR authorized agent.

The net settlement Electronic System managed by TransFonD Ltd – ACH system – represents the second component of the electronic payment system in Romania that entered into force on May 13, 2005 (BNR Regulation no. 1 of February 3, 2005 on payment systems ensuring funds clearing and Regulation no3/23.02.2005 on direct debiting made through automated clearing house, Official Monitor no. 265/31.03.2005). *ACH* is an electronic system of multilateral payments clearing ensuring the exchange of payment instructions between participants, calculates participants 'net positions through multilateral clearing and initiates, in RTGS system, a settlement of a net settlement instruction (ACH system regulations, version 5 TransFonD, July 7, 2005, pg. 7).

The administrator and operator of ACH system is TransFonD too, ensuring clearing small value payments (respectively transfer-credit type and direct debit under 50.000 RON) between credit institutions (except for institutions issuing electronic currency) and between these and State Treasury, respectively calculating participants' multilateral net positions in the system and transmitting these positions to final settlement in RTGS system.

Payment instructions of transfer-credit type are initiated by participants to ACH system under packages form (folders) representing groups of payments instructions of the same type, with a single initiator participant, a single addressee participant and a single settlement date sent and processed within ACH system framework. Just like the RTGS system, ACH settlement system implies *a single national circuit* at the level of bank units' headquarters participating at the settlement through TransFonD headquarters.

Within the electronic system of interbank payments in Romania, in order to prevent net settlement risk, it is implemented a unilateral guarantee procedure with blocked funds in the system reserve and with guarantee eligible assets, in principle, interbank deposits and government securities, that is compulsory for all credit institutions participating.

4. Conclusion

The efficiency of interbank real time settlement system is appreciated through operational performances and facilities that it offers by liquidity supplying in a definite time (a bank day), the mechanism of waiting at queue as well as real time monitoring its own liquidities during the day.

In Romania, RTGS system can process and deduct a number of at least 30,000 day payment instructions and may ensure processing without interrupting payment instructions during the peak hours of a working day of at least 40% of the daily volume during an hour interval (RTGS system rules, ver. 3 of October 1, 2006, NBR, pg. 73). ACH system has certain specific characteristics such as great volume of processed instructions – between 150,000 and 300,000 instructions per day (TransFonD Annual Report 2005, p. 14) – but of small value, as well as the fact that there are many clearing sessions on the same day, each session being followed by obligations settlement between participating members in the RTGS system. Thus, just like the RTGS system, ACH system may ensure normal processing during peak hours of at least 40% of the daily operations volume in an hour interval.

Another criterion in assessing the system efficiency consists of the commissioning policy set out by NBR in its quality of system manager that may apply commissions' deduction on each type of instruction according to the volume of instructions processed and deducted in RTGS. Likewise, along with the system that is in operation, the commissions level was reduced by 25% compared to the one practiced until that moment in the system of great value payments on paper support.

The main *advantages that credit institutions clients benefit from as a result of implementing the electronic payment system* are the improvement of payment services quality by reducing the period from the moment of issuing the payment invoice and receiving funds of the payment beneficiary, the increase of funds circulating flow, efficiency increase, their safe transmission as well as cut down in costs afferent to payment operations. Moreover, perspectives foresee also implementing a model that would ensure electronic processing of small value payments afferent to instruments of written debit payment (checks, bills of exchange, promissory notes). This represents the last component of the classic payment system in operation. Thus, starting with May 13, 2005, the clearing system managed by NBR ensures only processing and clearing debit payment instruments on paper.

Interbank real time settlement system in Romania is structured in order to be compatible with similar infrastructures in the European Union member states, Single Euro Payments Area. Payments handling will be simplified as all incoming and outgoing payments will use the same format. By providing new payment instruments and common interoperable infrastructures, SEPA will bring about fur ther European integration and market efficiency. This consolidation of infrastructures will spur competition and banks can then negotiate better clearing prices.

The research performed confirms that the SEPA programme will result in enormous change both for banks and the wider European payments industry. On the negative side, banks initially anticipate the main impact to be the high cost of compliance. Many banks also predict that the collateral damage from SEPA implementation will include a substantial reduction in ACH and card revenues (Accenture, "The European Payments Revolution", Accenture European Survey 2006, p. 36). However, on the positive side, banks will have access to an increased supply of competitive payment processors (both card and ACH), which will enable some to defer part of the cost of compliance. The larger, pan-European banks will also have access to open markets and the ability to introduce new products which would not have been possible under the current restrictive domestic scheme regimes.

Abstract. This paper is focused on the relationship between e – money and free banking percepts. The discussion details how e – money helps to address three main aspects of the free banking debate: the lender of last resort function, currency backing and multiplicity of currencies. In this article we have focus on possible implication for the future central banking, rather than predicting radical change to the current monetary policy framework. If the incumbent central banks could be let to behave in a way, which would make their currencies as attractive as those, produced by the private sector, the benefits of the free banking system may be attained even without displacing current institution or currencies.

Keywords: free banking, account based electronic payment systems, e-money, currency backing, multiplicity of currencies.

1. Free Banking – definitions and characterizations

The location of monetary policy in central banks is a recent development in the history of finance. Central banks became monetary policy makers only as the gold standard was replaced by fiat money, which was controlled by governments. There are alternatives to central banking as practised today, like currency boards, full convertibility (under a commodity standard) and free banking. White (1995) defines free banking as "a monetary system without a central bank, under which the issuing of currency and deposit money is left to legally unrestricted private banks," a definition representative of a general consensus in the free banking literature - see, for example, Dowd (1993).

White points out that, as a monetary regime, free banking consists of two main elements – unregulated issue of transferable bank liabilities and unmanipulated supply of base money or basic cash. There is no government role in regard to the quantity of money produced inside or outside the banking industry, and outside money free of central bank control is desirable. Money issue is not seen as a device of governments to achieve their goals, but operates as the means for individuals to pursue their own purposes. That said, White (1995) does not reject the idea of a clearing house at the centre of the financial system when without a central bank; his view is that this should be a market mechanism designed to eliminate imperfections within the financial system.

As envisaged by Dowd and others, free banking is regarded as the multiple issue of currencies by competing banks, whose notes, however, are interchangeable and redeemable against a "community-recognised commodity", while option clauses protect against "sudden excessive demands for liquidity". This last is an arrangement that obviates the need for a lender of last resort, since free banking is a system in which monetary and financial stability are guaranteed by market determination of the preferred currencies and interest rates. Dowd (1996) has underlined the basic requirements for successful free banking based on private money. One of them was the emergence of a clearing system. Another was the use of option-clauses - auto-control mechanisms used in cases of 'fire-sales' to defend against bank-runs. The final one was the development of a private lender of last resort within the financial sector to help individual institutions that were solvent but facing a liquidity crisis. In an earlier study, Dowd defined the distinctive features of a free banking system as:

- multiple note issuers who would guarantee to redeem their notes in a commodity
- recognised as valuable;
- a regular note exchange between note issuers;

- the insertion of option clauses into the convertibility contracts to protect the note issuers against sudden excessive demands for liquidity (Dowd, 1993).

Free banking as an alternative to central banking was discussed by Capie, Goodhart, Fischer, and Schnadt (1994). Although they described today's free banking proposals as a "somewhat fringe academic exercise without much support from financial practitioners," they emphasised that free banking ought not to be discounted as an alternative to central banks and currency boards for the operation of monetary systems. They pointed out that the preference of governments for central banking stems from national pride and seigniorage interests, while the financial community in general and commercial banks in particular support the central banking option for two reasons of their own. First, commercial banks economise systemic non-interest bearing reserves by offering a safety-net. As a result they are able to reduce individual bank capital requirements when providing leadership in joint exercises like establishing payments and settlement systems. Second, commercial banks enjoy an influence on central bank decisions through the dynamics of the relationships between controllers and controlled, supervisors and supervised. (This influence may not, however, extend to the full theory of capture, which argues that commercial banks capture central banks and thus approve their operations.)

It can be identified four problems associated with free banking theory:

- it may lead to extra transaction costs;
- some additional bank reserves of real assets may be needed;
- there may be possible minor inefficiencies connected with multiple note issue;
- it seems indeterminate how the system as a whole behaves since free banking theory relies on the law of flux. (the theory of reflux is explain on the situation where a note issuing bank will lose/gain reserves at the clearing if it expands faster/slower than other competing note issuing banks).

They then summarised four responses of free banking advocates to the argument that free banking may lead to bank runs and contagious panics. The first is the denial of the likelihood of such events in a free, competitive system. The second is the argument that an implicit central bank safety net or a deposit insurance scheme invites moral hazard (absent in free banking), while intrusive regulation to minimise moral hazard leads to further distortion and misallocation of resources. The third is that free banking decreases susceptibility to instability through its adoption of self-regulatory mechanisms like option clauses, clearing houses, and narrow banking. The fourth is the denial of any sizeable externalities and social losses in excess of internalised private losses in the case of banking failures. Such possible externalities were not found to be potentially greater in banking than in other industries.

2. Electronic money

Electronic money has different shapes. Up till very recently, electronisation of the payment systems has been based on improvements in account-based systems, their reach (domain) and their speed. Account-based systems record all the transactions and authorise them centrally, whereas non-account-based systems circulate e-tokens through telecommunication networks or on smart cards and may allow transactions without central authorisation. Account-based e-money systems are really very little different from the debit card of credit card networks of EFT systems currently in use. Token-based e money, "e-cash", on the other hand, is radically different in the sense that it introduces an electronic form of currency.

The formal definition of e-money offered by the European Central Bank is as follows: "an electronic store of monetary value on a technical device that may be widely used for making payments to undertakings other than the issuer without necessarily involving bank accounts in the transaction, but acting as a prepaid bearer instrument" (ECB 1998, p.7). This definition highlights some important aspects of e-money:

1. The fact that it stores monetary value on a technical device with a capacity to be used widely for making payments.
2. Its role as a prepaid bearer instrument, excluding account-based electronic payment instruments such as credit and debit cards and EFT payments.
3. Its use to cover payments to undertakings other than the issuer, essential to differentiating e-money products from single purpose prepaid cards like telephone cards.
4. Its ability to by-pass bank accounts or any other financial service providers' authorisation.

Because it does not specify the type of technical device used, such a definition serves as a useful starting point and is well suited to a development that is in an emerging state, the full technical potential of which remains unclear. In particular, the above definition includes card-based schemes, which can be used in conventional retail commerce, as well as various types of "cyber money" which are designed to circulate in the Internet. The definition is unsatisfactory, however, in two respects: Firstly, it may overemphasise the technical distinction between account-based and token-based systems, which have ultimately similar effects. Secondly, it does not distinguish clearly enough two quite distinct kinds of e-money issuance strategies: the conventional strategy of a new electronic payments medium and the more radical one of electronic issue of alternative, competing currencies (not based on conventional, government-organised monies).

We might call the two different kinds of e-money "representative" and "independent" e-money, respectively. As long as it is representative of legal tender under a given monetary policy framework, 'e-cash' is a form and extension of cash generally, an addition to coinage, notes, cheques and debit and credit cards, etc. In this respect, e-money is clearly nominal in its effects - such as increasing velocity - and may be regarded as neutral in terms of systemic change. It has important implications for the current monetary framework, in that it makes for easier payments, revolutionizes monetary base management, and enriches currency choice through making it easier to use several currencies and/or to switch between them. It would reduce the demand for conventional central bank money. But, e-money as a mere representation of a given currency may have no different effect on monetary policy frameworks than what has already been caused by advanced payment systems, which have decreased the proportion of currency in circulation to total money stock especially in the last couple of decades.

However, the impact of e-money would seem to be most significant when it comes to the electronic issue of non-bank money, that is, money issued without reference to banking reserves. If e-money is introduced as independent money, not a representation of any conventional currency, it may have the potential to revolutionise the competition among monetary policy frameworks. This impact may well be different for developed and developing countries: For developed countries, it may provoke 'currency competition' among core currencies like Dollar and Euro, or perhaps between these traditional currencies and new, privately issued monies (if the performance of the incumbent central banks is seen as unsatisfactory by money users). For developing countries, it may facilitate and speed up currency substitution to dollarisation and/or Euroisation.

3. Electronic Money and Free Banking

The direct or indirect relationship between e-money and free banking has been addressed quite often recently. For example, Browne and Cronin (1996) pointed out that laissez-faire banking could emerge endogenously over time in response to technological improvements in information and financial products. As a result, regulation of the banking industry after e-money could prove unjustified because of the system's likely inherent stability and efficiency. White (1995) argues that the technology gives an opportunity to issue private bank notes as smart card balances, which are transferable without bank involvement. He adds that digital payment technology has begun to foreshadow a world in which central bank currency is obsolete - replaced, perhaps, by privately issued currency in the form of balances written to smart cards or downloaded to personal computers and transferred by means of electronic wallets or over the internet. He also investigates the potential of e-money to make small denomination currencies interest-bearing for the first time in the history, and concludes that, when combined with anonymity e-money would facilitate the public's turning away from government-based notes and coins.

If we now turn our attention to the relation between e-money and free banking, it seems to us that e-money has very significant, even synergetic, effects. Not only does e-money foster a clearer understanding of the nature and workings of money, and thus of its 'proper' management with its influence on banking and finance that has been analysed in the earlier section, but its electronic issue may provide a technical means to bring free banking into play. Provided the electronic issue of money does not become subject to excessive regulation or outlawing1, it may enrich currency choice through a process of substitution that has been supported by the e-money based financial service provision. Chief influences of electronisation which suggest such a scenario are the following:

- because bits and bytes are more easily re-defined than banknotes and coins, it may be easier to revise or change currency representation, leading, in the case of countries, to easier entry and exit to monetary unions, and facilitating intercurrency switching by end-users and, therefore, private money issue. This view may be supported by the long planned currency conversion in the Euro area with conventional banknotes and coins;

- thanks to the opportunities for transparency afforded by Internet applications, money can be backed as easily by commodities as by indices, or both. It does not mean to turn back to commodity backed currencies but the monetary institutions may not take the risk of inflating their currencies because of these opportunities that has been available with the advent of e-money technologies;
- the increasing use of distribution channels such as the Internet, digital TV and mobile phones, may enable 'good money' to reach end-users more easily. Conversely, end-users that have need of a reliable medium of exchange may find it easier to reach better alternatives;
- ease of access to e-money may speed up the formation of a critical mass, the moment when people generally become willing to accept the new proposed unit of account because they become convinced that it now enjoys widespread recognition and appropriate worldwide liquidity and systemic support. This potential of e-money allows institutions to challenge mismanaged currencies with stronger proposals.

Insofar as free banking considers that sound money not only delivers price stability but also financial stability, it may now be only a matter of time before free banking *challenges* central banking in practical fact with the advent of e-money. Such a development would be influenced by the manner in which free banking addresses three key questions which e-money serves to emphasise:

1. The role of the lender of last resort

Under present monetary policy framework, the misbehaviour of one financial institution can have disastrous consequences for the financial system as a whole with regards the risk for a total collapse of the money stock. In order to prevent contagious risk, central banks are given the sole right to issue money without limit and for as long as it takes, provided the situation is in extremis and the danger is systemic. The lender of last resort is a costly arrangement and there is always a risk for socialisation of private losses. On the other hand, free banking leaves it to the market to 'discipline' bad money and it does not entertain the need for a lender of last resort. It is believed that the system will never fall into a systemic risk because the invisible hand of market mechanism forces every individual financial institution to be ready against bankruns. It is also believed that weakened and unfeasible institutions will be replaced by the competitors before they create any systemic risk. If the danger still persist, Dowd and others envisage 'option clauses', whereby in extreme circumstances banks can exercise compensatory delays to withdrawals. This is a concept of prudence – appealing to the depositor to avoid rash investment and precipitate action.

E-money serves to reinforce free banking by providing it with a powerful instrument for its realisation and it may decrease the need for a lender of last resort for at least two reasons. The first one is because option clauses becomes very easy to arrange, manage and realise, thanks not only to the electronification of money but also electronic finance, electronic distribution channels and electronic relationship management. E-money serves to decrease the costs of making and performing on option clauses and all manners of contracts between issuers and users. Secondly, it creates new frameworks to analyse individual defenders of the integrity of money so as to take individual decisions, which in the end, eliminates systemic structuring within the financial service provision. It allows individual institutions to develop personalised relations with the end users so as to be ready to convince them on the quality of their service in case of a fall of a financial institution. Lender of last resort function is not to save individual institutions and unless one failure does not effect other members of the financial system, there will be no need for it in the first place. With increased end-user awareness supported by e-money, no economic entity will question the overall stability of the system when they can easily reach to the data that can convince them about the integrity of money that they rely on.

2. Currency backing

If one is clear that a lender of last resort is not envisaged by free banking because it is not necessary, one can turn one's attention to two related topics – the cover of money (backing of currency) and a multiplicity of currencies (currency competition). The unit of account function of money generally has two aspects. On the one hand, for money to enjoy general acceptance, the unit of account needs to be widely recognised, otherwise circulation will be impeded and people will not wish to use it. Thus, for example, the US dollar enjoys far greater global acceptance than the Russian rouble. In crisis moments, however, the unit of account in itself is not enough. Money's ability to act as a medium of exchange becomes a matter of its backing or its cover. Until 1973, gold provided the anchor for all currencies, even though technically it was held at a remove. Since then, foreign currency reserves (that is to say, other units of account) have played an increasing role. To give an example, the backing for US dollar is the power of US economy to keep the value of dollar against other currencies strong enough to eliminate any loss of the value for end-users. Liquid money and capital markets and strong fiscal structure with budget surpluses further sustain the cover of the US dollar.

It is important to consider the question of cover in the context of our overall approach (Figure 1). It may be no accident that much of 20th century monetary history centres on a debate about cover and the quest for a replacement to the gold standard of equivalent effect but without the disadvantages of gold. It was during the beginning of the 20th century that central banks (in the negative sense) came to the fore, printing bad money seemingly without constraint. The ultimate cover of such money is, of course, future tax revenue, which is an indirect reference to future profitability. Tax cover and fiat finance may disguise but cannot change the basic economic fact that the cover of money entails a spectrum between potential values and created values, future profitability and existing assets, or a mixture of the two. Where we are on the spectrum depends largely on economic conditions.

Figure 1 Spectrum of cover

This image is neither new nor radical. In terms of our analytical framework, the spectrum of cover suggests that 'cash', or money as a medium of exchange, is related to the finite things that one can buy. Insofar as money is not backed by consumable goods, it cannot but be a potential (and in crisis moments, actual) call on future profits. This is the true match for money as store of value. This image is important because it is ordering, on the one hand, yet admits to a wide variety of backings, on the other. One cannot say, for example, that gold is good and assignats are bad. Indeed, free banking experience embraces both. The point is that the backing has to be appropriate and adequate.

3. The Multiplicity of Currencies

The prospect of unregulated currencies implies multiple currencies or currency competition, giving rise to the question of how these would work. The fungibility of cover is supported by the clearinghouse system, which does not arbitrate over what the 'right' cover should be, but leaves this to the market. After free banking theory, multiple currencies do not proliferate, but are subject to rationalisation. In their ultimate expression of self-administered banking (home banking, etc.), one can envisage one currency per person. This is wholly impracticable, however, since trade and division of labour even between two people requires a common element, a universal language enabling communication. It is said that multiple currencies imply a worldwide bank, but surely this, too, requires a common language. However many names we give to our separate currencies, they need to be linked. To be sure, these linkages do not need to be determined, as under the gold standard, from gold (or some other backing) via a primary currency or numeraire, thence to all others. Rather, the independently determined currencies will coalesce in an implied reciprocator ('best basket'), a shared unit of account one level up, so to speak. Parities may not all be 1:1, but parities will be needed and they will need to be based on floating, so that market forces can be allowed to work to discover the best denominator. Put another way, the actual parties to any transaction are free to determine the parity that suits them.

Insofar as this scenario takes us beyond national economic considerations and the world economy at large becomes our primary frame of reference, here we touch again upon free banking's recognition of the need, at least as advocated by Hayek, to denationalise money. This, as is readily conceded, leads to a shrinking number of currencies – the logic of which may be the universalisation of finance. Global financial markets and electronic finance in particular do not respect national monetary jurisdictions, so that their impact must be to promote homogeneity in the fields of monetary policy and supervision, and the denationalisation of money. Indeed, for this purpose, there could hardly be a more effective means than e-money.

The denationalisation of currencies gives rise to a further consideration, however. To denominate money in a national motif is to mask the fact that what really matters is (a) its interchangeability with other currencies and (b) their mutual convertibility into real rather than fiat or, perhaps better put, sound rather than unsound, cover. In this respect, e-money easily extends the reach of good money with the best cover to the end holder, functioning successfully both as a medium of exchange and as a store of value. Every holder of money also gets to choose from among currencies that are independent of local availability constraints. The multiplicity of currencies in this regard makes more than one unit of account available as the common denominator in trade at both local and international levels with the right to choose the currency that is most preferred. This practice is limited at the moment on the level of currency substitution but e-money extends the reach of good money and increases the level of competition among national and international, which helps to save individually strong money with sustainable integrity.

Conclusions

For two main reasons, e-money may lead to a new era for free banking type practices. Firstly, innovation in payment technology is reducing the fixed costs of banking business. Being cheaper than printing, distributing and retrieving banknotes through banking systems, the creation of digital strings of money is likely to reduce the cost of maintaining a payment system infrastructure for the economy as a whole. This may attract more economic entities to provide financial services as the natural barriers to entry to the banking sector become less effective. Secondly, as the computing power of new generations of computers increases, risk management and data processing with huge amounts of entries might become risk-free and less costly to process. It may then be possible that the information monopoly of banks relating to financial services may deteriorate, giving further opportunities for non-banks to supply financial services to customers. Such a development may decrease the special treatment of banks over against other firms, so that the argument about the private positions of banks in an economy may become even harder to defend.

Abstract : During its evolution, the French banking system registered the passing from a bank under the absolute control of the state to a bank that meets the customers' needs. In this work, we try to emphasize the switch from the extreme specialization of the banking activities which characterized the universal bank during the period precursory to WWII, as the modern bank is in a continuous adaptation to the market's needs.

Keywords : specialization, resettlement, universal bank.

1. Banking specialization – Characteristic of the French post-war banking system

A dominant characteristic of the French post-war banking system is the strict specialization. The reorganizing of the French banking system , inherent to the WWII, oriented itself to the promotion of the state control of the banking system.Therefore, through the banking law issued on the 2nd of December 1945, the nationalization of the Bank of France (created by Napoleon Bonaparte in 1800) has been decided , as well as the nationalization of the deposit banks that dominated the French banking market : Credit Lyonnais, Societe Generale, The National Bank for Commerce and Industry respectively Comptoir d'Escompte de Paris.The nationalized banks devoted themselves to the collecting of the short term savings, supported the emissions of the treasury and actively participated in the financing of the rebuilding and the modernization of the French economy. Actually, at the root of the decision of nationalizing from the French banking system was the necessity of a rapid restoration of the French economy, respectively of the French banking system affected by war.

By the same law, the banks are classified as :

- business banks – banks which can have industry shares , but cannot collect deposits from the population, respectively call accounts
- deposit banks - may collect deposits from the population, but are not allowed to have industry shares

Through the same law are established the limits between the deposit banks and the business banks which avoided nationalization and which could carry long term commitments.

The specialized banking dominated the French financing system until the beginning of the eighties, even if it proved to create more problems than the one it resolved. Beneficent for the French economy immediately after the war, it became a brake in the way of financing the industry. This was the reason for which the sixties are the years when the resettlement process, respectively of giving up the strict banking specialization started.

The first stage of the resettlement of the French banking system was constituted by the de-specialization initiated with the "Debre-Haberer" reforms between 1966-1969, reforms which led to the changes of the legal framework of the French banking system. These reforms followed three main targets :

- the attenuation of the restraints linked to banking specialization ;
- the stimulation of the competition between the banks, by granting the right to open new offices depending on their strategies to all the banks ;
- the improvement of the techniques of managing the banking risk.

Besides, by promoting these reforms inside the structure of the French banking system, a modification of the classification manner of the banks of the system appeared. Therefore the deposit banks (which are said to be specialized in short term riskless operations) and business banks (which have industry shares and mobilize firm resources or personal resources) keep up, but on the market also appear the so called medium and long term credit banks, which base their credit operations on the savings they attracted. This classification was based on the duration of the operation which these crediting institution were able to carry out. The purpose was the framing of the credit banking activities in a well defined category, respectively achieving the control of the monetary creation and orientation of the savings in the context of keeping the inflation under control and satisfying the investments needs.

Giving up the strict specialization aims at the modality of resources constitution and their distribution (allocation) as well, bringing into being an important step, we could say even decisive, towards the “bank does it all”(banque a tout faire), namely what we call „universal bank”.

Until the beginning of the eighties, there was a strict delimitation between the financial intermediate carried out by banks, respectively the one effected on the stock market , plus a delimitation of the intermediate inside the banking system. This way, there could be observed a special legislation for the mutual banks, different from the one for the deposit of business banks, as well as there was a distinct law for the savings banks. In spite of the fragmentation of juridical nature the French banking system had a fast evolution. The structural harmonization, respectively a sole juridical framework for all the French credit institutions was created by the Banking Law from the 24^{th} of January 1984. Only the Treasury, the Bank of France, the Savings House the and the financial services of the Mail Post remained outside of the applying field of this law. According to this law, the credit institutions are classified as follows :

- banks members of the French Banking Association – called certificated or listed banks because they appeared on a special list. In this category entered all the banks emerged before 1984;
- mutual banks – popular banks, cooperative credit associations;
- other credit institutions – Saving Houses, Credit Houses;
- other financial institutions – mutual funds, specialized financial institutions.

As a matter of fact, this law eliminated the division between business banks and deposit banks.

2. The diminution of the involvement of the State in the banking activity

Simultaneously with the promulgation of the Banking Law in 1984, the French banking environment became more unitary, even if some of its institutions still had particularities. Besides, the progressive liberality and modernization of the capital market in the mid-eighties favored the increasing competition generated by the emergence and development of the non-banking societies (OPCVM and insurance companies), respectively of the intermediating societies on the stock market field. The possibility of emiting negotiable debt titles starting with 1985 offered new financing forms, leading to the broadening of the financing mechanism available to those interested.

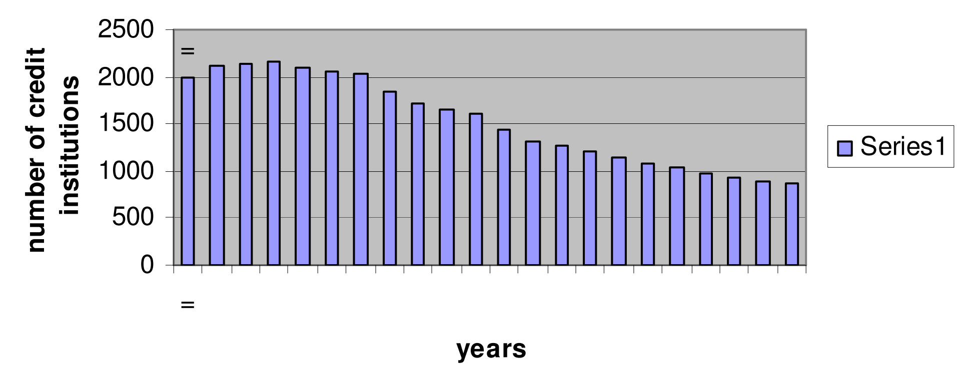
If we follow the evolution of the number of active crediting institutions in the French banking system, we notice the decrease of their number as a result resorganizing of the shareholding.This decreasing resulted either as a consequence of the activity ceasing of the credit institutions left without development perspectives because of the harsh competition, or as a result of their restructure by mergers or aquisitions, or after the reorganizations of the banking system.If in 1998 there were 2106 credit institutions, in 2005 their number had decreased to 874.

Table 1: Evolution of the number of the credit institutions in the French banking system, with the exception of the state of Monaco

Year	84	85	86	87	88	89	90	91	92	93	94	95	96	97	98	99	00	01	02	03	04	05
Credit institutions	2001	2109	2144	2152	2106	2063	2027	1837	1713	1649	1608	1445	1309	1273	1209	1143	1085	1034	974	925	893	874

Source: www.banque-france/statistics.

Figure 1:Evolution of the number of the credit institutions in the French banking system, with the exception of the state of Monaco



From the point of view of the crediting activities, we have observed that the share of the first 20 institutions passed from 65,1% in 1988 to 78,4 in 2006 and together the first five French banking groups cover more than 64% of the given credits and more than 75% of the constituted deposits.We see the concentration of the banking activities at the level of banking groups, the trend on the French banking market being similar to the world-wide manifested tendencies.Overall it has been stated that the first ten world banking groups control more than 85% of the banking activities in France.

During the past fifteen years, the structure of the French banking system underwent a permanent transformation process, this mainly taking place in the shareholding structure.It has been recorded a decrease of the State involvment in the banking activity, the number of banks where the State has shares diminishing visibly. In fact, this is the effect of the repeated privatization waves which started in the mid-eighties, more precisely between 1986-1987, followed by another wave in the mid-nineties (1993).These privatizations led to the exiting of the majority of the crediting institutions from the public sector.

3. The Diversification in the French Banking System

The recomposing of the French banking landscape at the end of the nineties had as a common denominator the merger and aquisition operations which, even if led to the diminution of the number of credit institutions in the French banking system, didn't induce a decrease of the banking offer.We may say that the effect was one of mantaining and even multiplication of the banking offer, the mergers and aquisitions leading to the increment of the power od the new banks emerged „overnight".It is a phenomenon we started to face at the level of the Romanian banking system, but in our case we are only at its beginning.

Table2:Number of mergers and aquisitions made in France between 1996 and 2003

Year	Mergers		Aquisitions	
	Number of mergers	Number of involved institutions	Number of aquisitions	Number of involved institutions
1996	29	67	37	115
1997	24	51	28	110
1998	26	57	34	149

1999	39	90	22	115
2000	32	70	29	98
2001	28	63	22	63
2002	32	69	18	43
2003	24	51	15	54

Source: Banking Board, www.banque-france.fr

Thus, after these operations which led to the reorganization of the French banking system, nowadays the French baking market is being dominated by eight groups : BNP – Paribas, Credit Agricole, Societe Generale, Credit Lyonnais, CCF –HSBC, Banques Populaires, Caisses d'Epargne, Credit Mutuel – CIC. The constancy of the number of offices spred all over France, respectively the modernization of the services and products offered to the customers is one of the base characteristics of the contemporary French banking system.

Another characteristic is the diversification of the French banking activities, respectively the development of their activities at international level. This penetration on the international market was a normal response to the increasing competition. It is not a new phenomenon. The wish to expand the banking activities abroad goes a long way back, we can already speak of a thirty years old history. There were years when the French banks systematically tried to conquer the Middle East, South-Eastern Asia, North America and not last the other European countries. An element which favoured the expansion of French banks in Europe was the process of European integration, process which is in full development.

4. Conclusions

The French banking system from the beginning of the XXIst century is completely different from the one which worked in the sixties. Its structure has been profoundly modified, the range of activities it unfolds is more wide and the administration of the banking risks doesn't look at all like the one used years ago.

The French banks, the big French banking groups penetrated on the Asian, American and European credit markets, the internationalization of business having a high rank on their agenda.From this point of view, the French banking system follows the globalization trend which nowadays leads the entire financial world.

The French credit institutions became very attentive at the way of administration of costs, the main characteristic being the development and improvement of the monitoring and administration methods of the performances of their activity and even more of the risks it faces.The implementation of the provisions of the Basel Agreement confirms the care of these institutions for the improvement of their performance.

In conclusion, the French banking system is being characterized by dynamics, a continuous diversification of the performed activities, which makes it a role-model for the entire international banking community.

INTERNAL RATING MODELS FOR CREDIT RISK EVALUATION AND SUPPORT INSTRUMENTS

Ganea Tudor

The « Titu Maiorescu » University, The Faculty of Economic Studies, Bucuresti, bd. N. Titulescu, 39-49, bl. 12, sc. A, et 5, ap. 25, sector 1, doruganea@yahoo.com, 0722612561

Ciobanasu Marilena

This article approaches the necessity of designing internal models of rating, in order to evaluate and manage credit risk. The authors address in equal measure the credit institutions, the Romanian legal entities, the Romanian branches of the credit institutions from third-party states, their potential customers, whether individual persons or legal entities, as well as the whole academic community in the finance-banking field. The internal rating models can be used to calculate the risk weight value of exposures, in order to determine the minimum capital requirements for credit risk, in accordance to government ordinance no. 99/2006, supplemented and modified by the Law no. 227/ 04.07.2007. By means of the internal rating models, we could achieve the following goals: pertinent evaluation of debtor characteristics; use of the computer system in risk evaluation within the decisional process of credit approval, internal allocation of capital and corporate governance of the credit institution.

Key-words: Internal rating models, risk management, corporate governance, credit risk, IT instruments

The elaboration of this article has been determined by three important evolutions.

Firstly, the Basel Committee on Banking Supervision, followed by the European Comission, has introduced, under the title of Basel II, a series of standards regarding the estimation of essential banking indicators: *PD* (probability of default), *LGD* (loss given default) and *EAD* (exposure at default).

Secondly, the Government Ordinance no. 99 was passed in 2006, followed and modified by the Law 227/ 04.07.2007 and accompanied by a series of new regulations, more specifically, the new banking legislation, applicable to credit institutions, as of the date of Romanian E.U. adherence on January 1st, 2007. This new legislation allows the integration of the Basel II requirements with the Romanian finance-banking legal framework.

Last but not least, the Romanian banks have become ever more interested in creating and improving methods and procedures of risk evaluation, while implementing the Basel II requirements.

We consider that designing an information system necessary throughout the process of credit-approving by the credit institutions represents a timely initiative. The role of this system is to assess and evaluate the loan candidates' characteristics. The information system will allow establishing a set of variables which will, in turn, provide a comprehensive image of the potential debtor's status, as well as designing an aggregate system, capable of outlining the candidate's position in comparison with the other debtors. That set of variables will differ in function of the type of candidate: individual person or legal entity.

The information system will provide a financial diagnosis and a risk rating score for the applicant, so that the bank could limit the risks assumed during the crediting process and direct the applicant to the best credit option according to the set of variables that characterize that particular person.

In the case of legal entities, their current and estimated economic and financial status will be assessed. One method proposed by this project will consist in determining, by means of specialized IT instruments, the economic and financial indicators and a client rating, by processing data taken from the clients' accounting documents. In this respect, the information system can be used to reach a decision in credit approval, in the financial analysis related to the crediting activity, in increasing caution when making payments and in optimizing investment and selling banking products.

Individual persons will be analyzed based on a series of social, economic and demographic criteria, the project aiming to create an assessment scoring-function for this category of applicants.

Thus, banks can diminish credit risk according to the approach based on internal models of rating, and can also offer counselling to prospective credit applicants in choosing the best suited financing offer. Therefore, an easy connection can be developed between the credit institutions and their clients, based on the centralization of information concerning the offer or the demand in an interactive database.

Supposing that the present article might evolve into a scientific research project, it would comprise the following stages:

The first stage is represented by the **Market Research,** by means of specific instruments: establishing samples on groups of beneficiaries, drawing up surveys, conducting interviews, as means of research, centralizing and processing collected data.

We propose as the second stage the **Adjustment of the Information System**, comprising drafting models for shaping data structures, desinging the data base and designing a module capable to allow the on-line choice of the best suited credit offer.

We would continue by **filling in the database**, then testing its functioning.

A distinctive and major stage would be the **design of on-line counselling modules**, followed by **the promotion of the designed product**, by implementing the website/portal into the market, respectively, its upload on the internet, by designing the interface for the web – website/portal, by holding conferences in order to endorse the final product, by promoting the product on the level of credit institutions, Romanian bank association, World bank and by publishing results in form of articles in various specialty magazines.

The project's result will materialize in an information system which will play a double role: on the one hand, it will allow for a pertinent information of prospective credit beneficiaries about existing options at any given time, and on the other hand, it will build a model of evaluation for each client. This model will be used by the credit institution to screen its own clientele, or it will serve as a self evaluation tool for each visitor of the website, regarding his/her own capacity to repay a potential credit.

The advantages of the information system in analyzing the opportunity of bank crediting address especially the time issue, in that the time needed to take the granting decision, to delegate competencies to persons who have the quality of experts, to bring to a common denominator the documentation resulted from the analysys. Also, another goal will be the development of research in bank crediting activity and even the professional improvement of the bank's personnel.

There are a series of limitations in designing such an expert system, respectively, of the evaluation model: the necessity to obtain accurate information regarding past client activity in a 2-4 years time-frame; the necessity to manually or automatically process the information in creating a knowledge database, and limitations of economic nature (changes in legislation, shifting of the demand-supply balance, competitional influences, etc.).

The emergence of new players in the financial-banking market and, implicitly, the strong competitive character of this activity sector, second to the substantial growth of the financing need, impose on the banking instiutions a need to constantly improve the services on offer, doubled by the need to optimize associated costs. From this perspective, the project generates an economic impact by means of:

1. The analysis of the risk profile of credit applicants that will considerably diminish the incumbed costs for all beneficiaries (credit institutions as well as clients);
2. Diminishing of credit risk, improving the efficiency of credit institutions' activity and profit growth for those institutions;
3. Decrease of time and costs for credit applicants by an educated choice of offers.

We can also highlight some elements showing the project's social impact*:*

1. The project will help improve the confidence and trust of the general population in credit institutions, as well as the security of their operations;
2. Financial education of potential credit beneficiaries.

The validation of internal models by the authorized supervisor represents an essential condition if a credit institution intends to use another approach than the standardized one in determining the capital requirements.

While building the internal rating models, we must „have strict stress testing procedures at our disposal”[258].

Generally speaking, stress testing can be described as an useful tool in the the process of assessing the possible effects of extraordinary, but plausible events, which can affect the evolution of an institution.

The effective use of stress-testing methodologies is extended nowadays not only to the commercial banks, but also to the regulatory authorities and to the Central Banks. At present, all these institutions are combining stress-testing with their own macro-economic models.

Stress-testing is implemented at country level in order to assess the strength of the financial system to unfavourable economic evolutions. This type of analysis is set up in conformity with the Financial System Assessment Programme (FSAP) deployed by the International Monetary Fund (IMF). According to the Central-European Bank, the FSAP is implemented in the following countries: Ireland (2000), Finland (2001), Luxembourg (2002), Germany (2003), Austria and Netherlands (2004), Belgium, Greece, Italy, Portugal, Spain and again Ireland (2006).

In our opinion, stress-testing should be extended to a larger geographical area. We appreciate this direction to be important in the context of the increasingly powerful integration of the EU members, both on the economic and the financial level. We can only guess that such testing is essential in order to assess as accurately as possible the effects of changes the Basel II has brought to the EU credit institutions since January 2007. We mainly have in view the banks adopting the Internal Rating-Based approach.

Conclusions

At present, the Romanian banking system is in a incipient stage from the point of view of using the internal rating models. These models represent a major objective for the appropriate banking risk management. In Romania, rating companies operating with such information tools will have to be put into place. Apart from their practical usefulness, the authors of this article also envisage the possibility of extending the proposed studies to national and international research projects, as wells as to materials which can be exploited in the further education of the banking experts.

The financial system of our country is going through a process of continual consolidation and development, based on an entire array of opportunities and meeting multiple challenges in equal measure. One of the most important challenges stems from the implementation of the Basel II standard, which has an influence both on the functioning of the credit institutions and on the National Bank, as a monitoring body. Although many bank customers are fully aware of the fact that saving, investing and anticipating future evolutions have an essential impact on their life quality and financial security, they do not posess, in most cases, the necessary knowledge and information to effectively manage these elements. The main scope of the present article is trying to make the academic environment aware of the necessity of creating and providing for free all the instruments the public requires in order to effectively manage their own financial resources.

Key-words: web portal, education and financial assistance, banking products and services

The population is exposed to higher and higher financial risks, without always being aware of their existence. While in other coutries from Europe, extensive public information campaigns were launched several years ago, in our country, no such basic financial education programmes have been initiated yet on a social scale. Even if the financial product and service providers are private organizations, we estimate that ensuring the population a minimal financial training would have as a result not only an educated customer pool for these organizations, but also a greater succes in avoiding unwanted situations generated by the risk of non-reimbursement related to the financial obligations assumed by individual customers. These risks can negatively influence the credit institutions' indicators, the indicators established on the bank sector's level, a situation that can also lead to severe financial problems on the bank customers' level.

The rate of personal credit growth has intensified in 2007, its starting threshold already being on a superior level. There has been noticed an increased preference for credits in foreign currencies, an option which, in the context of an accentuated depreciation of the national currency, can have a negative impact on the credit evolution and on the financial situation of the individual customers who disregarded this influence factor.

The most appropriate person to correctly assess the reimbursement capacity is the credit applicant himself, therefore helping individuals at taking substantiated financial decisions represents the best solution for keeping a safe and undeteriorated financial environment.

By means of some actions organized on a national level, we intend to bring a contribution to the financial education of the general public. They will provide distance courses, including illustrations, animation and short movies, IT tools for determining the endebtment rate or generating scenarios concerning the financial evolution of the population.

A possible instrument for the public financial education could be a specialized website designed as a friendly, easy-to-use interface, containing various tests and useful strategy games, so as to make the assimilation of financial knowledge a much more pleasant process.

The portal will also comprise an area dedicated to the pre-college academic staff, providing not only user-friendly plans for the economy classes, but also suggestions concerning effective and unconventional teaching methods.

A specialized module addressing pre-college and college students, teachers and parents will be also put into place. This will contain flexible easy-to-use free guides, created especially to enhance the financial education of the future banking product and service consumers. The main objective of this module will be helping young people develop the capacity to create a budget, to manage it and to use a series of banking tools, such as: cards, deposits, credits, internet banking, mobile banking.

Last but not least, there will be created a news and comment section, providing intelligible explanations of economy-related events.

At present, Romania cannot provide enough data or analysis concerning either the financial behaviour of its population on a microeconomic level, or the population saving, endebtment and accumulation behaviour, in a climate in which the impact of the aforesaid behaviour upon general wealthfare is obvious.

The financial education of the population has not represented a top priority in Romania so far, although in Western countries, as well as in the new European member states, the supervision authorities attach the utmost importance to this component.

In the United States, The Federal Reserve takes public education very seriously. In November 2007, the FED set up a centralized call centre, by means of which people can contact the central bank experts by phone or e-mail, in order to file complaints against financial institutions or to obtain a diverse range of financial information concerning banking products and services or their consumer rights. Here, the people concerned can find brochures and guides explaining in simple terms the risks and benefits of financial products, from credits with low interest rates in the first year to credit reports, electronic banking and current accounts.

The Financial Services Authority, - the monitoring body of the financial sector in the United Kingdom – is statutorily qualified to contribute to the improvement of public financial education. As a result, the institution is fully involved in disseminating banking product and service information. In this respect, the FSA has prepared several publications where it offers recommendations on how to use financial services. As in the United States, the British institution has created a specialized website providing brochures, guides, calculation schemes and credit, saving or private pension comparative tables to its users.

We can also find similar examples in countries with an economic status much more closer to our own. In Poland, the population financial education effort started in 2003, when a specialized web portal was launched. The portal provides distances courses, assorted with illustrations, animation and short movies. There is even an area dedicated to primary and secondary school teachers, where one can find easy-to-use plans for economy classes, as well as suggestions concerning effective and unconventional teaching methods.

In Hungary, the consumer financial education campaign was also initiated one year before the country's adherence to the European Union. The programme consisted in solving the customer complaints, editing useful brochures and publications and launching a media campaign drawing attention to important current financial problems. The financial product comparative tables scored the highest public success.

On the national level, in February 2007, the banks from Romania initiated a series of projects aiming at improving customer services. The longest and most extensive of these projects is the one having in view consumer education. In this respect, Radu Gratian Ghetea, the president of the Romanian Bank Association, has indicated that the above-mentioned project is meant to be a long-term, fairly continuous initiative. The elaboration of the consumer education strategy and programme was incumbent to the Special Initiative Committee, a partnership between the Romanian Bank Association , the National Bank of Romania, the Finance Ministry and Consumer Protection, sustained by the Convergence Programme, run by the World Bank.

Within the draft report concerning public service policy on the European level issued on the 12th of March, 2007 by the Economic and Monetary Affairs Committee of the European Parliament, one refers to the necessity of giving more alternatives to the bank product and service consumers, highlighting the fact that promoting financial literature and access to accurate information and unbiased counselling on investment stands for a crucial element. One also heartily applauded the creation of the Consumer Group for financial services, as well as the attempts to involve the users'representatives in expert and consultant groups; nevertheless, one also notices that the interests of the financial industry still prevail over those of the customers and end-users; the report recommends opening a European budgetary line in order to finance the expertise of the financial market for consumer organizations.

By means of the present project, we respond to the Committee's initiative to increase the level of population financial education and we answer to its invitation to step up the effort to create specific programmes and websites, while following the call to integrate these initiatives with the elementary school education.

The proposed project will comprise media campaigns and the setting-up of the web portal for the financial information of consumers. It proposes itself to modify and update the information on the websites belonging to the involved institutions, to implement consumer alert systems, to suggest elements specific to the financial education to be included in the academic curriculum, to launch modules for comparing financial products. The project responsibles have chosen a step-by-step strategy envisaged to unfold over a period of two years.

The main objective of the proposed project refers to upgrading the level of population's financial education by presenting both the benefits the customers can enjoy while using various banking tools, and the risks to which the bank product and service consumers are exposed.

The reason for setting this objective stems from the increasing risk that the fast dynamics of crediting might lead to cases of over-endebtment or irresponsible use of the loans, alongside the expansion of the bank sector. This risk is aggravated by the fact that the long-lasting transition period, as well as the still poor quality of life have given rise to a strong appetite for consumption, which leaves little space for a reasonable financial planning of the family budget.

Moreover, as the financial institutions are extending their presence in Romania, they begin to provide products and services with a higher degree of sophistication, yet mostly unfamiliar to the general public. For example, the banks offer credits in foreign currencies on a large scale, recently even in more exotic currencies (the Swiss frank, although few people are aware of the associated exchange rate risks. Another case is that of intensive proliferation of home loans with low interest rates in the first year, without the interest adjustment mechanism being properly presented to the public.

If initially the information, education and consultance activities are directed towards all the categories of banking product and service consumers, we subsequently intend to develop special programmes within the project addressing some particular categories: debtors with financial problems, first-time home buyers, young people, credit card users, first-time bank customers, low revenue consumers, retired people, etc. Among these, the young and the senior citizens are the most vulnerable.

Ethics is important both in setting-up and in carrying out the project. In the education and consultance activity, the stress falls on adopting an ethical behaviour, a greater attention being given to the quality of the teaching material, as well as to the ways of presenting it, all of these triggering in the long run the interest for the training, information and consultance provided by the project.

The education and consultance provided by the project must be achieved from a neutral stand with regard to the financial and banking institutions, thus any reference to bank products and services on the market at a given moment should be avoided. This aspect will be carefully monitored by the project coordinator.

The ethics in scientific research activities is based on an aggregate of moral principles and procedures to observe them. The partners involved in the present project will follow and observe Law no. 206/2004 concerning appropriate behaviour in scientific research, technological development and innovation, as well as Law no. 8/1996 concerning royalties and associated rights.

Complying with the specific EU legislation and international regulations in the banking-finance field is also included.

In order to attain the proposed objectives, we offer an elaborated work plan, so as the public is provided the best knowledge possible of banking instruments. Based on the information obtained in the research stage, we will put into practice an education and assistance system which contribute to the increase in efficiency, effectiveness and quality of the financial educations of banking product and service consumers.

As we have mentioned before, the financial assistance and education project specialized in banking products and services will be based on a mixture of measures aiming both informing, training, and assisting consumers. This mixture represents the most appropriate way to achieve objectives, because it provides the opportunity of using multiple communication channels.

The experience of other countries has shown that such projects have a decisive impact on the financial culture level, as well as on the wealthfare of the people.

The programme will develop around the web portal and will contain several dissemination channels for the education and assistance facilities: on-line or printed publications (brochures, guides, trimestrial reports, e-mails, letters), phone or forum-based assistance services, free courses, public awareness-raising campaigns, symposiums, workshops, motivational software, financial strategy games.

The project proves its viability in the sense that it is harmonized with the European and national strategies of providing financial education to the consumers and it aims to become an instrument of implementing these strategies with the general public.

If the level of financial education of the general public is usually fairly low, one can notice an even more disturbing situation with certain categories of consumers. We refer mostly to people with primary or highschool education, with low revenues or belonging to an ethnic minority (the Rroma minority in particular).

The project results will be exploited as it follows:

- the resulted studies and reports – through extensive dissemination with the interested scientific community, by means of articles, scientific communications, the website of the project;
- the education module, containing material especially created to allow tranforming the acquired financial knowledge into action tools;
- the assistance module available to the banking product and service consumers, by means of which they can analyze the main steps to be taken in order to repay their debts and to invest afterwards in an apropriate and aware manner, by responsibly assuming the risks they are exposed to, in order to achieve their financial objectives.

The main project beneficiary is the banking product and service consumer, this category including all the citizens of age, regardless their level of training, social status, age, occupation, property or other demographic, social or economic criteria.

The project addresses also to the bank service providers, to the Special Initiative Committee, to the Romanian Bank Association, to the National Authority for Consumer Protection, to the National Bank of Romania, as coordinating and monitoring body of the national banking system, as initiator of monetary and credit policies, as „judge" of financial relations between banks and their customers.

According to the activity plan, we intend to support an intensive promotion of the end-products, by publishing scientific material in specialized magazines, by organizing conferences with the participation of the RBA, NBR, NACP, finance-banking institutions, specialized companies and, last but not least, by intensively and directly promoting the project on the Internet. The web portal will provide information concerning the main bank credit offers, thus each visitor (individual or legal person) will be able to assess its reimbursement capacity and assumed risks. Each visitor of the system will practiclly obtain a score on the basis of which he/she will be recommended the best bank offer possible at the moment.

THE COMPETITION IN ROMANIAN BANKS

Harangus Daniela

Tibiscus University Timisoara, Department of Economics, Address: Timisoara, no. 20 Aries Street, sc. B, ap.10, Telephone: 0256 – 462753, E-mail: danaharangus@yahoo.com

The banks, as large financial intermediaries, are themselves placed in a global environment. Globalization will bring about a new online economic world, the so-called cyber-economics, a world in which competition in the banking sector acquires new dimensions and features. In Romania, the banking system was organized on modern basis, on the occidental performance principle. Competition in Romanian banks led to the approach of a new dimension in the client relations management, to an increase of the innovative role and to the regulation of bank management, the role of the bank informatics and to the re-organizing and efficiency of some bank activities. The emergence of new foreign bank societies on the Romanian market led to the assignment of the banking system on a new corridor of performance, due to the intensification of competition and the increase of offer for new complex bank services and products for the clients.

Key words: Romanian banking system, competition and regulation, the new dimension of the bank- client relation, bank activities performance.

PAPER CONTENT

In Romania, after 1990, a modern occidental banking system, based on the principle of bank universality was created.

The reform of the Romanian banking system in the period of transition toward the market economy led to its structuring on two levels or the two-tier banking system, respectively the central bank (The National Bank of Romania) and commercial banks. This new structure of the banking system meets the current requirements of the Romanian economy. The organizing of the Romanian banking system on the two levels assured, by law, the autonomy of the Romanian National Bank from the executive power, and to commercial banks a statute of stock companies. The commercial banks, from an organizational point of view, develop their activity in a way similar to private companies, being led and managed by the general stockholders meeting and by structures ensuring a current management, meaning the president, the vice-president, the management board, etc. Commercial banks have a horizontal organization, formed of departments, directions, services, offices, works compartments, etc. Banks also have a vertical organization, meaning territorial, composed of branches, county branches, agencies, representatives and works points.

In order to be able to face competition, Romanian commercial banks have this vertical organization. It is developed by the territorial bank central, in order to efficiently unfold current activities, with the compliance to the uniform and unitary procedures and bank work normative. Each of these organizational territorial bank structures have attributions, responsibilities and subordinations, that are well defined and delimited by the “mother” bank, meaning the Commercial Bank Central, being a juridical person.

The profound transformations which took place in the organization of the Romanian banking system in the transition period are based on the internal bank legislation, harmonized with the provisions of the community and the directives of the European Union in this area. Legal regulations also contributed to the consolidation of the Romanian banking system and its part in the economy.

The strengthening of the stability and the solidarity of the Romanian banking system was due to progress on the line of macro- stabilization, corroborated with the bank efforts for consolidating their position on the domestic market. The emergence of new foreign bank societies on the Romanian market led to the assignment of the banking system on a new corridor of performance, due to the intensification of competition and the increase of offer for new complex bank services and products for the clients.

The dimension of competition in the bank sector is also given by the large number of banks activating on the market. Therefore the componence of the banking system on property forms in the period 2000-2006 and the evolution of bank numbers at the end of the analyzed period are as follows:

Table 1

The structure of the banking system on forms of property number of banks

	2000	2001	2002	2003	2004	2005	2006
Banks, out of which:	33	33	31	30	32	33	31
banks with integral or majority state capital, out of which:	4	3	3	3	2	2	2
- with integral state capital	1	1	1	1	1	1	1
- with majority state capital	3	2	2	2	1	1	1
banks with a majority of private capital, out of which:	29	30	28	27	30	31	29
- with a majority of domestic capital	8	6	4	6	7	7	3
- with a majority of foreign capital	21	24	24	21	23	24	26
branches of foreign banks	8	8	8	8	7	6	7
Total banking system	41	41	39	38	39	39	38

Source: The Romanian National Bank - Annual Report, 2003 (p.87); 2005 (p. 36), 2006 (55).

The process of cleansing the bank sector and the entrance on the Romanian market of foreign banks led to a strong competition in the Romanian banking environment. As a consequence the market quotations held by domestic banks diminished in the favor of the foreign segment.

The evolution of market quotations for banks and branches of foreign banks in the period 2001-2006 is as follows:

Table 2 The bank market quotations (%)

	2001	2002	2003	2004	2005	2006
Banks with Romanian capital, out of which	44.8	43.6	41.8	37.9	37.8	11.4
- with a majority of state capital	41.8	40.4	37.5	6.9	6.0	5.5
- with a majority of private capital	3.0	3.2	4.3	31.0	31.8	5.9
Banks with a majority of foreign capital	47.3	49.0	50.5	53.6	54.7	82.9

Source: The Romanian National Bank - Annual report, 2003 (p.84), 2005 (p. 35), 2006 (p.53).

At the end of 2005 from the point of view of the invested capital original country in foreign banks and bank branches on the Romanian banking market, the first three places were taken by Austria, Greece and Holland, followed by Italy, France, Hungary, USA, Great Britain, Germany, etc. AII these foreign participations in the capital of credit institutions in România brought a new tendency in the activity of Romanian banks and its unprecedented development.

Also an important moment in the consolidation and strengthening of the competition in the Romanian banking system was the moment of the bank crash, marked by the introduction of the Law no. 83/1998 regarding the procedure for bank bankruptcy. Starting that date all the banks with negative capital or unable to make payments were eliminated from the system, after many years. From this point of view, we can consider that beginning with 2002-2003 the Romanian banking system operates according to the principles of a functional market economy.

The new dimensions of competition in Romanian banks take into account the following aspects:

- the re-dimensioning of the client segment (the market) depending on the bank policy and strategy, be it retail or corporate bank;
- the development and diversification of the bank product and service portfolio, that is offered to clients, be they traditional or sophisticated clients;
- the improvement of quality and structure within the portfolio of credits managed by commercial banks;
- the approach of a new strategy in relation to clients, respectively the personalization of relationships, insurance of counseling and consultancy services for clients, the knowing and inventory of client information, the approach of an effective communication with clients and the consolidation of their trust in the bank;
- the re-dimensioning of the importance of client satisfaction;
- the efficient organization of front-office activities and all bank activities which have to do with the clients;
- the development of an organizational culture that would come to the support of relational strategies with the clients, that are adequate for their specificity;
- the efficient management of bank risks and especially of the credit risk;
- the establishment of new priorities in bank management, taking into consideration that in
- the bank management of the 21st century a new relational strategy with clients was imposed;
- the organization of the entire bank activity on the profitability principle.

In the complex transformation process of the banking system in România in a European context, an important part is played by the regulation and innovation of bank management. Analyzing the report innovation- regulation in the Romanian bank management we think the accent must be placed on regulation. The plea for regulation is based upon the consideration that in the banking environment regulation is the one assuring financial- banking discipline and is statutory on correct client relations. Without clear and precise regulations the banks, which are considered the most disciplined financial entities in the economy, are not going to succeed in aligning to the requirements of the new Basel Accord II. The issue of innovation and regulation in the bank management shall win in time a well- deserved place in the culture and civilization of banks in the 21st century.

In order to face competition, banks activating on the Romanian market oriented themselves also towards the externalizing of some bank activities, which are situated under the profitability limit for the bank total.

Also, in order to deal with competition banks oriented towards the development of informatics systems. In the bank practice the vital importance of the informatics system is well- known, both for the quality and operationally of management decisions, and for the successful unfolding of bank operations. Without a performing informatics system banks can no longer face the very large volume of bank operations, for a more and more numerous bank clientele, which is diversified and exigent. Beside the large volume of bank operations which must be effected by the bank, there is also the issue of the speed with which these must be processed, making bank transfers in very short time or online. Generally informatics applications used in the Romanian banking system are based on the evaluation criteria established by the internal bank norms. This orientation of commercial banks is due to a great prudence and the strict respecting of their own internal norms, but also to the instability of the Romanian economic climate. In order to deal with competition, the Romanian banks developed performing computing systems.

THE NEW DIMENSION OF BANKING KNOWLEDGE IN THE GLOBAL ECONOMY

Harangus Daniela

Tibiscus University Timisoara, Department of Economics, Address: Timisoara, no. 20 Aries Street, sc. B, ap.10, Telephone: 0256 – 462753, E-mail: danaharangus@yahoo.com

The diversity and complexity of banking activities have emphasised the role and the importance of knowledge in the banking domain. This new online economic world has led to an exponential development of banking knowledge. Being the most disciplined financial entities, the banks are especially interested in banking knowledge. This is not limited only to the knowledge of work norms and banking procedures, to the use of algorithms for calculation of financial banking indicators. In this IT era, the diplomatic and psychological dimensions of banking knowledge have been developed. There are three main types of knowledge: factual knowledge, practical knowledge and knowledge by acquaintance. Banking knowledge also represents a source of risk prevention, and especially fraud risk. In the global economy, banking knowledge has acquired new dimensions.

Key words: banking knowledge, global economy, banking information, global markets.

PAPER CONTENT

The banks are great financial intermediaries activating within global economy. A series of global products as cards, Internet banking, Home banking, etc. can be found in their portfolios of products and banking services. At the same time, in their customer portfolio there are also corporate customers (large transnational corporations), that are activating in the global environment.

The diversity and complexity of banking activities have emphasised the role and the importance of knowledge in the banking domain. In order to define the new dimension of banking knowledge in the global economic context one has to start with defining knowledge.

Knowledge is defined in *Romanian Explanatory Dictionary* as having two aspects:

- reflecting in consciousness of an existent reality independent from the knowledgeable subject;
- having certain knowledge, information about a subject or a matter.

Gnoseology or theory of knowledge, a branch of philosophy, studies the possibility, the sources, the forms, and the regulations of knowledge. Thus, knowledge implies possessing information about a subject. The banks have access to three categories of information. The present legislation regulates the information circulation depending on the criterion of its degree of accessibility. Based on this criterion, the global analysis of the valid legal provisions allows for information to be divided into three categories:

- information with unrestricted access;
- internal data and information;
- restricted information.

In the category of information with unrestricted access there is public information and information for public interest. Their defining characteristic is the degree of public openness. The banks operate with a large area of public information, as for example: information registered in the registry of commerce regarding shareholding, equity capital, headquarters, administrators, public information in the Official Gazette, in written press, etc. This information provides the bank with certain level of knowledge regarding its customers.

Internal data and information are an intermediary category between information with unrestricted access and restricted information. It is created or received by the bank, circulating freely usually within the bank. It is of great importance for each bank to have the complete inventory of data and information with which it operates.

Restricted information is the one whose circulation is limited either by law or corporate internal banking regulations. Usually there are two kinds of restrictions: regarding persons (subjective restriction) and regarding categories of information (objective restriction). All these categories of information assure banking knowledge.

In the context of world economy globalisation, in the era of Digital Economy the access to information is no longer restricted by time and space. Information storage regardless of its volume does not represent a problem for banks any more. This new online economic world has led to an exponential development of banking knowledge.

Banking knowledge also represents a source of risk prevention, and especially fraud risk. The dimension of fraud risk for a bank implies three aspects. They refer to fraud risk by bank management, employees, or customers. In order to protect the bank in crisis situations when the bank is constrained to rapidly implement multiple new requirements, there is a need for quick solutions to maintain the credibility in social and economic environment and to manage conflict situations. Banking knowledge permits a decrease of decision risk, credit risk, market risk, etc. Banking knowledge leads to a greater degree of social responsibility regarding priorities and objectives of banking activity.

Being the most disciplined financial entities, the banks are especially interested in banking knowledge. This is not limited only to the knowledge of work norms and banking procedures, to the use of algorithms for calculation of financial banking indicators. In this IT era, the diplomatic and psychological dimensions of banking knowledge have been developed. The implementation of global banking products is the result of knowledge of global macro-economic context as well as of necessities and priorities prescribed by global economy.

In the post-industrial connotation the notion of knowledge implies an extended dissemination of knowledge in a global world. In order to assure the continuity of banking activity, banking knowledge offers:

- transparent, complete and accurate information issued in the banking system;
- creation of a favourable image of the bank, image which will motivate the customer's interest for the institution;
- a thorough approach and check-up of various possible scenarios for the development of reaction capacity in crisis situations;
- the necessary condition for displaying the economic truth;
- outlining bank politics and strategies based on the social and economic context in which the bank activates;
- efficient management of banking activity.

Being a notion with a subjective characteristic, knowledge is unequally distributed and its capitalisation depends on: life experience, personality, natural aspirations and qualities of the individual.

Knowledge has two dimensions: common or subjective and scientific or objective. Common or subjective knowledge refers to common sense while scientific or objective knowledge implies the use of ideas and scientific reasoning. Banking knowledge makes use of the two dimensions, the common and the scientific. Both dimensions materialise in banking activities as well as in its relations with customers.

A system of banking knowledge comprises specific elements of knowledge paradigm, useful in the following domains:

- strategic management (social, administrative) of the bank;
- executive, actual, operative management;
- global risk administration, i.e. risk decrease and fraud prevention;
- promoting new knowledge and social control;
- knowledge management, i.e. efficient use of information possessed by the bank with the aim of obtaining best economic and financial results.

In order to eliminate the danger of fraud in the bank there are opinions stating that it is safer if the decisions are based only on a single econometric system of optimisation, using the informational system which will eliminate contingency and subjectivism. However, in banking activity this proves to be not only impossible but undesirable as well, as thus, work procedures would eliminate the use of intuition, creation and knowledge. The banks take into consideration the experience as well as safe practice in the domain.

To outline the dimensions of banking knowledge one has to start from the philosophical questions regarding knowledge, which belong to either epistemology or the philosophy of spirit. The two groups of questions can be separated approximately, considering that the first analyses the nature of knowledge, and the second analyses the nature of the knowledgeable subject.

There are three main types of knowledge:

– factual knowledge, or "knowledge that", which implies knowledge of bank regulations and instructions;
– practical knowledge, which implies "knowledge how". In banking activity this knowledge is materialised in implementation of banking norms and instructions;
– knowledge of people, places and things, or knowledge by acquaintance. In banking environment this knowledge implies knowledge of customers.

The three main types of knowledge that constitute the component elements or the dimensions of banking knowledge are shown in the figure below:

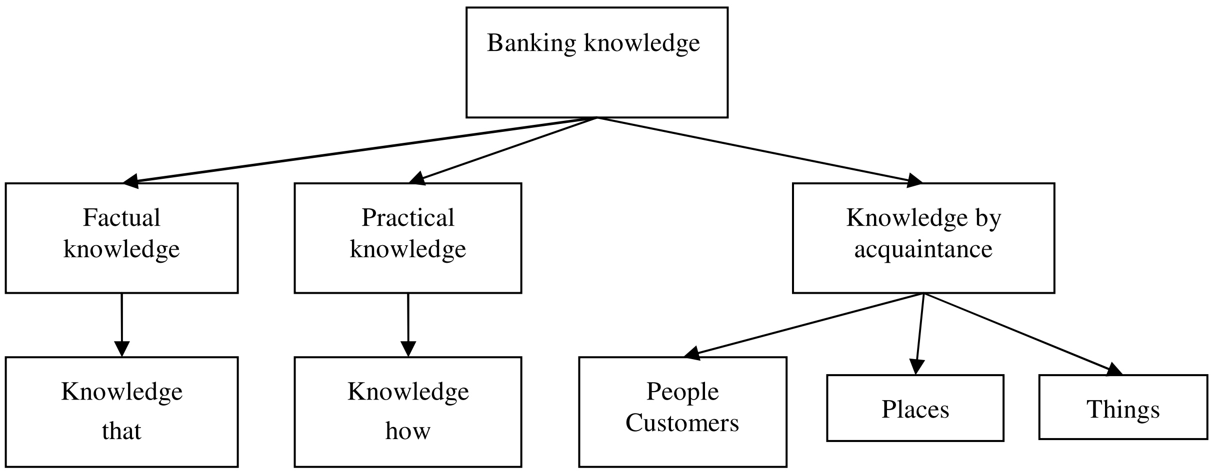

Figure 1. Dimensions of banking knowledge

In the global economy, banking knowledge has acquired new dimensions. It is no longer limited to bank norms and instructions or to the national juridical and economic context in which the bank activates. Nowadays, banks activate on global markets and manage banking products and services as cards and Internet banking. In this context banking knowledge implies:

– use of information from global economic environment;
– knowledge of universal laws that are producing economic booms, economic crisis, and other economic events;
– knowledge of European legislation regarding economic and banking domain.

Stabilisation of the Romanian banking system requires a strategy of the organisational management of banking information which comprises elements of banking knowledge.

In the context of world economy globalisation both banking activity and banking knowledge have acquired new dimensions. Banking performance depends for the most part on the dimension of banking knowledge.

Abstract. Since it inception TARGET has formed a benchmark for processing euro payments in terms of speed, reliability, opening times and service level, and has contributed to the harmonization of business practices in the European Union. TARGET 2 is on track from 19 November 2007. In TARGET 2, all banks in the EU, irrespective of where they are located will be offered high – quality services, functionality and interfaces, as well as a single price structure. This will level out the playing field for banks across Europe. TARGET 2 will ultimately benefit from, and evolve with, its users' expectations and requirements.

Keywords: single technical platform, flexible liquidity management services, operational day, multi - addressee access, core pricing scheme, migration groups.

1. The initial TARGET system

TARGET is the Real Time Gross Settlement system (RTGS), offered by the Eurosystem. It is used for the settlement of the central bank operations, large value euro interbank transfers as well as other euro payments. It provides real time processing, settlement in central bank money and intermediate finality. TARGET stands for **T**rans-European **A**utomated **R**eal-time **G**ross settlement **E**xpress **T**ransfer system and it was created by interconnecting national euro RTGS systems and the ECB payment mechanism. It went live in January 1999. The launch of the single currency necessitated a real-time payment system for the euro area.

With €1.9 trillion settled every day, TARGET, is one of the three largest wholesale payment systems in the world, alongside Fedwire in the United States and Continuous Linked Settlement (CLS), the international system for settling foreign exchange transactions. The TARGET system has a decentralized structure consisting of 16 national RTGS systems and the ECB's payment mechanism (EPM), which are interlinked to provide a uniform platform for the processing of inter-Member State euro payments. TARGET began operations on 4 January 1999 at the same time as the launch. Since then, TARGET has provided real-time payment processing and intraday finality to almost all credit institutions in the EU. Moreover, TARGET serves the monetary policy needs of the Eurosystem and promotes the integration of the euro money market. With its special focus on large-value payments related to inter-bank operations, TARGET helps to reduce systemic risk. TARGET has long operating hours, being open from 7 a.m. to 6 p.m. CET on each of its working days, with a cut-off time of 5 p.m. for customer payments. TARGET is a highly reliable system. In 2005 the overall availability of TARGET was 99.83%, compared with 99.81% in 2004 (TARGET availability is defined as the ratio of time during which TARGET components are fully operational to TARGET opening hours).

The decentralized structure of TARGET

2. The new features of the TARGET 2

TARGET2, which will replace the current decentralized infrastructure, has a single technical platform and features new functionalities designed to meet the future needs of financial markets. In building this new system, the Eurosystem is aiming to:

- provide a harmonized level of service on the basis of a common technical platform;
- achieve a high level of cost recovery and have a single price structure applicable to both intra-national and cross-border payments;
- meet the new demands of users, as well as those resulting from the future connection to TARGET of the countries that joined the European Union on 1 May 2004.

The Eurosystem has developed the features and services of TARGET2 in close cooperation with TARGET users. In November 2005 the Eurosystem published the User Detailed Functional Specifications (UDFS, version 2.0), which give TARGET users the information they need to start the technical development and implementation work related to TARGET2. The principal innovations of TARGET2 are as follows:

1. *A single technical platform* - the most important innovation is the consolidation of the technical infrastructure.TARGET2 will replace the decentralized technical structure of the current TARGET system with a single technical platform, known as the Single Shared Platform (SSP). Three Eurosystem central banks – the Banca d'Italia, the Banque de France and the Deutsche Bundesbank – will jointly provide the SSP and will operate the platform on behalf of the Eurosystem.
2. *TARGET – WIDE flexible liquidity management services* - There is increasing demand among payment system users for enhanced liquidity management services and liquidity-efficient RTGS systems. In response, TARGET 2 will offer state-of-theart liquidity management tools, such as prioritisation of payments, liquidity reservation (also for the settlement of payments in ancillary systems), definition and implementation of sender limits and active queue management.
3. *Support for payments with a debit time indicator* – TARGET 2 will take into account the increased time-criticality of payments, particularly in the context of CLS, by making it possible to submit transactions with a debit time indicator.
4. *Pooling of intraday liquidity* - Liquidity pooling will be achieved by grouping a number ofaccounts.TARGET2 will offer two variants for liquidity pooling: i) the virtual account; and ii) consolidated information. In the virtual account option, a payment order submitted by a participant belonging to a group of accounts will be settled if the payment amount is smaller than or equal to the sum of the liquidity available on all accounts (including any credit lines) in the group. Otherwise the payment order will be queued.

The consolidated information option is an information tool: it will give comprehensive information to the participant subscribing to the service about the liquidity position of all of the entities of the group at any given moment. Such information will also be provided in the virtual account option. However, payment amounts will be checked only against the liquidity available on the individual RTGS account of the sending participant. The liquidity available on other accounts in the group will not be used to settle the payment. In the event of insufficient liquidity on the sending bank's account, money will need to be transferred to that account.

5. *Interaction with ancillary systems* - TARGET2 will provide cash settlement services in central bank money for all kinds of ancillary systems (ASs), including retail payment systems, large-value payment systems, foreign houses and securities settlement systems (SSSs). The main advantage of TARGET2 for ASs is that they will be able to access any account on the SSP via a standardized interface.
6. *Strengthened the business continuity measures* - TARGET2 will offer the highest possible level of reliability and resilience, as well as sophisticated business contingency arrangements commensurate with the systemic importance of the TARGET2 infrastructure. The business continuity concept of TARGET2 consists of a multi-region/multi-site architecture. There will be two regions. In each region, there will be two sites some distance from each other. This

will be combined with the principle of region rotation in order to ensure the presence of experienced staff in both regions.

7. *Information and control module* - TARGET2 users will have access, via the information and control module (ICM), to comprehensive online information and easy-to-use liquidity control measures appropriate to their business needs. Users of the ICM will be able to choose what information they receive and when. Urgent messages (e.g. system broadcasts from central banks and warnings concerning payments with a debit time indicator) will be displayed automatically on the screen. Through the ICM, TARGET2 users will have access to the payments module (PM) and the static data (management) module. Depending on the decision of the relevant central bank with regard to the use of the optional modules offered by the SSP, participants may also have access to the home accounting facility of the central banks and the applications for reserve management and standing facilities.
8. *TARGET 2 directory* - the TARGET 2 directory will contain information on each institution that can be addressed in the TARGET2 system, and will be updated on a weekly basis to support system participants in their routing of payment instructions. The directory will use TARGET2-specific information provided by TARGET users during the SSP registration process in combination with SWIFT-related information. The TARGET2 directory will be an electronic product/service provided to the direct participants by the Eurosystem.
9. *Operational day* – in order to better meet users' business needs, the operational day in TARGET2 will be longer than that of the current TARGET system. TARGET2 will start the new business day on the evening of the previous day. The night-time window will be available from 7.30 p.m. to 6.45 a.m. the next day, with a technical maintenance period of three hours between 10 p.m. and 1 a.m. The night-time window will facilitate the night-time settlement of the different ancillary systems in central bank money with finality, and will also support cross-system settlement during the night. Settlement of ASs will take place in dedicated accounts. During the night-time window, liquidity transfers via the ICM between RTGS accounts and the dedicated sub-accounts will be possible. Ancillary systems and their participants will be able to choose whether or not to enable this liquidity transfer functionality, or to limit the functionality. Banks may alternatively decide not to participate in night-time settlement. The Eurosystem believes that the night-time window will generally increase the efficiency of night-time settlement and will favour initiatives such as cross-system delivery versus payment.

	Time	Description
Daytime	6.45 a.m.-7 a.m.	Preparations for daytime operations
	7 a.m.-6 p.m.	Day trade phase
	5 p.m.	Cut-off for customer payments
	6 p.m. + 15 min.	General cut-off for the use of standing facilities
End of day	6 p.m. + 30 min.	Cut-off for the use of standing facilities on the last day of a minimum reserve period
Start of day	6.45 p.m.-7 p.m. (1)	Start-of-day processing
	7 p.m.-7.30 p.m. (1)	Provisioning of liquidity (from standing facilities, intraday credit, home accounts) until start of procedure for ASs
Night-time window for AS	7.30 p.m. (1)-10 p.m.	Automated start of procedure message to set aside liquidity until start of cycle message of ASs, and ancillary system night-time processing (ancillary system settlement procedure 6)
	10 p.m.-l a.m.	Technical maintenance period of 3 hours. The system is shut down
	l a.m.-6.45 a.m.	Night-time processing (ancillary system settlement procedure 6)

Opening day for TARGET 2

3. Access for TARGET 2

A number of options are provided for the access to TARGET 2. These include direct or indirect participation, "addressable BICs" and "multi-addressee access" to the system, also known as "technical BIC access".

1. Direct participation - the criteria for direct participation in TARGET2 is the same as for the TARGET system. Direct participants will hold an RTGS account in the PM of the SSP with access to real-time information and control features, and will therefore be able to: i) submit/receive payments directly to/from the system; and ii) settle directly with their national central bank. Direct participants will be responsible for all payments sent or received on their account by any TARGET2 entity (i.e. indirect participants, addressable BICs and multi-addressee access entities as described below) registered through them. To connect to TARGET2, direct participants will require a direct connection to SWIFT's secure IP network via their own SWIFT interface or via a SWIFT Service Bureau. For the exchange of payments information, TARGET2 will use the SWIFTNet FIN service, while the SWIFTNet services "InterAct", "Browse" and "FileAct" will be used for information and control services.
2. Indirect participation - implies that payment orders are always sent to/received from the system via a direct participant. Payments are settled in the direct participant's account in the PM of the SSP. Indirect participants will be registered by and under the responsibility of the direct participants, acting on their behalf, and will be listed in the TARGET2 directory. Only supervised credit institutions established within the EEA can become indirect participants.
3. Addressable BICs – another category of access already available in the current TARGET system is that of TARGET2-addressable BICs. Any direct participant's correspondent or branch that holds a BIC is eligible to be listed in the TARGET2 directory, irrespective of its place of establishment. Moreover, no financial or administrative criteria have been established by the Eurosystem for such addressable BICs, meaning that it will be up to the relevant direct participant to define a marketing strategy for offering such status. It will be the responsibility of the direct participant concerned to forward the relevant information to the appropriate national central bank for inclusion in the TARGET2 directory (for technical reasons, an indirect participant/addressable BIC can be linked to only one direct participant). Addressable BICs will always send and receive payment orders to/from the system via a direct participant, and their payments will be settled in the account of that direct participant in the PM of the SSP. Although technically there is no difference between an indirect participant and an addressable BIC (The TARGET2 directory will distinguish between indirect participants and addressable institutions) in legal terms, only indirect participants will be recognized by the TARGET2 system and as such benefit from the protection of the Settlement Finality Directive (in those countries where such protection has been granted).

4. The TARGET Core Pricing Scheme

The Eurosystem has set up a pricing structure for the TARGET2 core service which will eliminate the current differences in pricing between intra-national and cross-border transactions, as well as increase cost-effectiveness for its users. The price of a TARGET2 payment will range between €0.125 and €0.80.

Option A			
Monthly fee			**€100**
Flat transaction fee			€0.80
Option B			
Monthly fee			**€1,250**
	Transaction volume		Transaction
Band	From	To	fee
1	1	10,000	€0.60
2	10,001	25,000	€0.50
3	25,001	50,000	€0.40
4	50,001	100,000	€0.20
5		above 100,000	€0.125

The pricing scheme for the TARGET 2

Payments settled on the accounts held in the national central banks' proprietary applications, also known as "proprietary home accounts", will be charged more than the TARGET2 fee (i.e. more than €100 + €0.80

per transaction).This will serve as an incentive to shorten the transition period and move to the PM of the SSP as quickly as possible.

The Eurosystem has decided that ASs interacting with TARGET2 should be subject to a pricing scheme comprising a transaction fee plus a separate fixed fee charged to each system, irrespective of where settlement takes place (e.g. in the PM or in proprietary home accounting (PHA) applications). A fixed fee of €12,000 per year will be charged to each ancillary system that settles in central bank money, irrespective of whether it settles in an account held at the SSP or in an account held in the central banks' home accounting application. A second fixed fee in the range of €5,000 to €50,000 per year will be charged to each ancillary system depending on the size of the system. In addition, all transactions that are settled for ASs will be charged according to a degressive transaction fee scale still to be specified in detail by the Eurosystem.

The liquidity pooling service (virtual account option and consolidated information option) is an optional and separately priced core service. The charge for liquidity pooling ser vices will be €1,200 per account per annum for the consolidated information option and €2,400 per account per annum for the virtual account option (which includes the consolidated information option). Furthermore, within a group of accounts (with either the consolidated information option or the virtual account option) group pricing will apply, which means the degressive transaction fee will be applied to all payments by members of the group as if they were sent from one account.

The following pricing will apply to the various ways of participating in TARGET2, in addition to TARGET2 transaction fees. In addition, direct participants will be charged a one-off registration fee of €20 for each registration of an indirect participant and €5 for each registration of an addressable BIC (including BICs of branches of direct and indirect participants) in the TARGET2 directory.

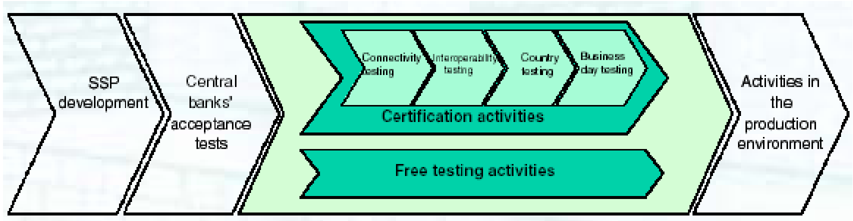
Type of participation	Monthly fee per account/BIC
Direct participation	€100 or €1,250 depending on the scheme chosen (see the TARGET2 core pricing scheme above)
Multi-addressee access	€80 per BIC address in addition to the BIC of the account of the direct participant
Unpublished account in the PM of the SSP	Direct participants who do not want their BIC to be published in the TARGET2 directory will pay €30 per account (BIC) per month in addition to the monthly fee above

Other pricing elements

5. User testing and migration groups

The objective of user testing is to ensure that users have made the necessary technical, procedural and operational adjustments to be ready for TARGET2. User testing started in May 2007 after the acceptance tests performed by the national central banks and will closely reflect the organisation of the migration groups (details below). Both structured tests and free tests are organised at institution, country and European level. In addition, the testing strategy will give due consideration to the specific situations faced by multi-country players. For each migration group, TARGET2 user testing are divided into two main activities, taking place in parallel:

- *Certification activities* – certification tests comprise four distinct steps, which have to be completed in a specific sequence. Tests first of all involve individual institutions (certification and interoperability tests), then national banking communities (country tests) and eventually the whole TARGET community (business day tests). Certification tests are compulsory for all TARGET2 users.
- *Free testing activities* – when the system is available for free testing, TARGET 2 users can perform any kind of testing activity. Free tests are optional, but TARGET 2 users are encouraged to make use of this option in order to be fully prepared for certification tests.



TARGET 2 user testing

The Eurosystem is defining TARGET2 test cases and scenarios. In parallel, a TARGET2 user test guide is being prepared to inform TARGET2 users about the testing procedures. A TARGET2 test-related information system (T2TRIS) is being developed to facilitate coordination and communication between all stakeholders during the testing phase. This web-based application will provide TARGET2 users with all the information needed for the preparation, planning and performance of, and reporting on, TARGET2 user testing activities. The T2TRIS is available to all TARGET2 users via the TARGET2 website from the last quarter of 2006.

The migration to TARGET2 will be carried out by "country groups", allowing TARGET users to migrate to TARGET2 in different waves and on different pre-defined dates. Each wave will consist of a group of national central banks and their respective national banking communities. The number of migration groups will be limited to four. TARGET users will be allocated to the first three groups, while the fourth group will be held in reserve as a contingency measure. The total migration period will be limited to six months (or ten months if the fourth group is used).

Group 1 19 Nov. 2007	Group 2 18 Feb. 2008	Group 3 19 May 2008	Group 4 15 Sep. 2008
Austria	Belgium	Denmark	Reserved
Cyprus	Finland	ECB	for
Germany	France	Estonia	contingency
Latvia	Ireland	Greece	
Lithuania	Netherlands	Italy	
Luxembourg	Portugal	Poland	
Malta	Spain		
Slovenia			

Composition of the migration groups

Different tools are being designed to facilitate the migration to TARGET2, e.g. the national migration profiles and ancillary system profiles, operational workshops, registration and changeover procedures.

6. Conclusions

Since it was launch, TARGET has made a significant contribution to the integration of the financial markets in Europe by providing its user with a uniform payment and settlement infrastructure. Given the wide ranges that TARGET 2 will offer, the Eurosystem expects to see even greater progress once the transition to the new system is complete.

TARGET 2 will contribute to the harmonization of the business practices of its user and can therefore be seen as a stimulus for further consolidation. Moreover, TARGET 2, is expected to help consolidate the internal process such as treasury and back office functions and promote the harmonization of the ancillary systems interfaces throughout Europe.

Summary: Undercapitalization and undercrediting of the national economy in the period of transition to the market economy necessarily requires the strengthening of the role of credit as a genuine factor of growth and increase of the productive capitals. The financing of the capitalization process becomes more valuable in the present stage of our country development, imposing itself as an objective need. It is thus compulsive to define a new concept in the speciality literature, namely the concept of "durable crediting" according to which the credit must have as a main goal the capitalization of the national economy which, in its turn could constitute an essential condition for a durable future crediting. The starting point in supporting and defining this concept underlines the importance of the capital in all economic processes.

Key words: durable crediting, capitalization, capital suitability, management of capitalization,

1. Introduction

Le parcours de l'actuelle étape de développement de l'économie roumaine doit affronter à des réalités cruelles dont la compréhension et le dépassement ne peuvent pas être possibles sans la réorientation des politiques à l'égard du capital. De cette façon il s'impose que le processus de capitalisation soit traité avec priorité dans les conditions où l'économie roumaine est à présent déficitaire en ce qui concerne le niveau du capital entraîné dans les processus économiques productifs[9].

Dans le plan mondial de nombreuses revues de grande circulation internationale[2] (quottées ISI) accordent des espaces pour les articles qui traitent le problème de la capitalisation du secteur bancaire et du milieu des affaires. Parmi celles-ci on rappelle: Journal of Money Credit and Banking (U.S.A), Journal of Finance (Oxford), Journal of Banking & Finance (Amsterdam). Dans la revue Journal of Money Credit and Banking on a publié en novembre 2007 l'article des auteurs Valeriya Dinger et Jurgen von Hagen intitulé *Does Interbank Borrowing Reduce Bank Risk*. Ceux-ci font un analyse empirique des banques des pays de l'Europe Centrale et de l'Est, y compris la Roumanie, en concluant qu'il s'impose urgemment une massive recapitalisation de celles-ci[4].

Pour cela une meilleure implication du marché financier est nécessaire pour la constitution, l'augmentation mais aussi pour la protection des capitaux. En ce sens on a essayé de lancer d'autres concepts - "la capitalisation de sécurité" et "la capitalisation but"[7]. La capitalisation de sécurité permet aux banques d'affronter les retraits de dépôts à n'importe quel moment, en posant de problèmes seulement du point de vue de ses coûts. La politique de la capitalisation de sécurité sera influencée par des facteurs tels la rate d'intérêt, l'insécurité du flux de dépôts, l'intérêt de référence de la Banque Nationale de la Roumanie ainsi de suite. La capitalisation but présuppose, selon notre conception, une augmentation des capitaux à travers l'attirance des fonds du marché primaire de capital suivie, après une période, par l'accroissement de la valeur de marché des entreprises sur le marché secondaire.

La qualité du processus de crédit constitue un deuxième aspect majeur dans le processus de capitalisation bancaire[3]. Plus le portefeuille de crédits est plus important, plus le processus de capitalisation se déroule de manière plus accélérée et à long terme[6]. La reconsidération de la catégorie de crédits non performants est nécessaire aussi, au sens de l'élargissement de celle-ci et de la compréhension dans le contenu d'autres catégories de crédits, à côté de ceux situés hors le bilan.

La méconnaissance des thérapies basée sur le crédit mais aussi la faible implication des marchés financiers et des institutions financières bancaires dans le processus de capitalisation ont constitué des éléments qui ont freiné l'accroissement économique et implicitement le développement plus rapide de notre pays après 1989.

La privatisation, la restructuration, le système de crédit, la politique fiscale, doivent encourager la constitution et la consolidation des capitaux – facteur de production, qui se trouvent à la disposition des entreprises, mais surtout l'augmentation de l'intérêt pour la capitalisation au détriment de la satisfaction des besoins personnels des propriétaires de capitaux.

Le processus de capitalisation de l'économie roumaine ne peut pas être conçu sans l'existence correspondante des ressources de financement. Les problèmes avec lesquels se confronte l'économie nationale et de la résolution desquels dépend l'atteinte des objectifs dans le processus de consolidation de l'économie de marché et de l'accroissement de la prospérité économique, peuvent être dépassés seulement à travers une capitalisation correspondante de tous les secteurs d'activité.

2. Les crédits non performants et la double décapitalisation de l'économie nationale

Les crédits non performants sont associés dans la pratique bancaire de la Roumanie aux crédits non remboursés, mis en évidence hors du bilan des banques et pour lesquels on a commencé la procédure d'exécution forcée. Ce catalogage est étroit et nocif, d'autant plus que les crédits non performants provoquent une double décapitalisation de l'économie nationale, soit au niveau des banques qu'au niveau des agents économiques.

Vu les effets extrêmement négatifs des crédits non performants sur l'économie nationale, il s'impose une reconsidération immédiate de ceux-ci.

Premièrement, pour l'économie nationale, un crédit non performant est aussi celui, qui, bien qu'il fût remboursé, a provoqué de graves déséquilibres dans l'activité des agents économiques, à travers l'utilisation non correspondante et nocive grâce à plusieurs causes :

- le désir des managers des sociétés commerciales d'obtenir, à tout prix, un crédit bancaire, sans avoir la dimension correcte du marché et le potentiel de la firme concernant l'augmentation des dépenses imposées par un éventuel accroissement du chiffre d'affaire,
- la réalisation de quelques importations d'outillages et d'installations à crédits ou par l'intermédiaire des lettres de garantie bancaire qui, après le montage et la mise en œuvre n'ont jamais atteint les capacités projetées,
- le financement des investissements à crédits à court terme, les managers préférant cette combinaison inefficiente à cause des pratiques rigoureuses exigées par les crédits d'investissements (plan d'affaires, étude de faisabilité, la projection des sources de remboursement, la constitution du cash-flow à long terme), ayant une fausse dimension et supra sollicitant le potentiel des autres affaires du groupe qui devait supporter les coûts et les remboursements des crédits,
- l'utilisation des crédits dans des buts personnels, pour le payement des dividendes, des sponsorisations etc.

De manière concrète, les déséquilibres générés aussi que l'aggravation des performances financières se sont manifestés à travers l'accroissement de la perte enregistrée au niveau du résultat financier à cause de l'augmentation des dépenses et des intérêts; l'augmentation des dépenses d'exploitation liées à la mise en œuvre des outillages, sans augmenter aussi les revenus de l'exploitation de façon correspondante ; l'accroissement continu du fonds de roulement en sens négatif suite du financement des investissements des sources à court terme; la diminution du chiffre d'affaires; la perte de certains fournisseurs à cause de l'arrière enregistrée à l'égard de ceux-ci. Finalement, ces causes ont conduit à l'enregistrement des pertes du total de l'activité et implicitement à la décapitalisation des agents économiques.

Deuxièmement, on a démontré - en pratique - le fait qu'au niveau des banques non seulement les crédits tirés hors du bilan génèrent l'augmentation des dépenses et l'obtention des pertes, mais aussi les crédits vieux et mal gérés, qui consistent à la maintenance et au prolongement successif des lignes de crédit du portefeuille des banques, pour lesquelles les sociétés commerciales ont payé seulement des intérêts, sans rembourser rien du crédit proprement dit; l'échéance et le rééchelonnement successif des crédits par objet, qui a permis la transformation de certains crédits à court terme en crédits à long terme; la transformation d'une catégorie de crédit dans une autre catégorie de crédit; l'accord de crédits pour le remboursement d'autres par la même banque ou par des banques différentes.

Par la suite, la décapitalisation produite au niveau des banques a été générée par les suivantes causes:

- la création de commissions spécifiques de risque de crédit et d'intérêt,
- l'augmentation des dépenses concernant les intérêts pour les sources attirées qui devaient réaliser les placements non profitables,
- la diminution de la confiance de la population dans la banque dans les conditions où un crédit non performant a été médiatisé,
- l'aggravation de l'image de la banque dans les milieux internationaux dans le cas où les crédits non performants sont provenus de l'exécution d'une lettre de garantie ou de la garantie de certains billets d'ordre,
- le vieillissement du portefeuille de crédits, qui a privé les banques de la possibilité du crédit d'un groupe d'agents économiques des secteurs plus profitables et en vertu duquel les banques se sont créées des stratégies pour le futur,
- la diminution des sources de crédit qui produisent profit, étant connu le fait qu'en pratique les coûts d'un crédit non performant sont couverts par le déroulement d'un volume de crédits performants plus grand,
- l'enregistrement de certains revenus des intérêts de manière artificielle, soumis à l'impôt;
- la réduction des liquidités pronostiquée, à cause du fait que les intérêts ne sont pas payés à échéance.

Du point de vue macroéconomique, la décapitalisation de l'économie nationale soit au niveau des banques soit au niveau des agents économiques a généré des dérèglements monétaires, un blocage financier, et la limitation de l'activité de commerce extérieur. La reconsidération de cette catégorie de crédits a eu comme point de départ, il est juste un peu tard, la Banque Nationale qui, par l'intermédiaire des règlements émis, peut contribuer décisivement à réduire les effets négatifs de ceux-ci.

3. Le crédit durable – cause et effet dans le processus de capitalisation de l'économie roumaine

L'introduction par la Banque Nationale de la Roumanie du règlement no.5/2002 concernant la classification des crédits et des placements, aussi que la constitution, le régularisation et l'utilisation des commissions spécifiques de risque de crédit, constituera assurément le commencement de la transposition et en pratique du concept de crédit durable qu'on essaie de lancer et de définir distinctement dans la littérature de spécialité.

Du point de vue du concept de crédit durable, l'accord de crédits doit avoir comme but la capitalisation des agents économiques. Le règlement no.5/2002 ne doit pas être interprété du point de vue de la diminution ou de l'extension de l'activité de crédit mais du point de vue de la qualité des portefeuilles, qui, détermineront à la fin la capitalisation des agents économiques, des banques et de l'entière économie nationale.

Le crédit durable deviendra dans ces conditions une cause de la capitalisation de l'économie nationale, la qualité du portefeuille de crédits jouant un rôle important dans l'accélération du processus de capitalisation ou même d'intégration européenne.

Plus le portefeuille de crédits est plus performant plus le système bancaire est plus sûr et peut contribuer grâce à l'augmentation des capitaux à la réalisation des objectifs pas à pas dans le processus de capitalisation[1].

Pour constituer une cause de la capitalisation, il n'est pas suffisamment que la performance économique et financière des agents économiques soit déterminée strictement en conformité avec les règlements introduits. L'analyse économique et financière doit mettre l'accent aussi sur l'état des indicateurs après l'accord du crédit, vu que, à travers l'accroissement des dettes en même temps avec la valeur du crédit, la liquidité, la solvabilité et le degré de débit s'aggravent. Ainsi, la performance devient-elle un concept qui contient en même mesure aussi des anciennes informations mais aussi des données à caractère de pronostique. Dans ces conditions, le calcul des principaux indicateurs de l'analyse des crédits devrait tenir compte aussi de la valeur des crédits pour lesquels on fait l'analyse en question.

L'introduction dans le calcul des indicateurs du volume des crédits qui sont sollicités par les débiteurs mène à la réduction du risque à l'égard de l'apparition de certains crédits non performants. En même temps ce mode de calcul devrait changer les conceptions incorrectes de certains fonctionnaires de banque conformément auxquels les crédits sont accordés lorsque le client "va bien ", mais aussi de certains managers de firme conformément auxquels les crédits sont accordés lorsque le client "va mal ".

A son tour, la capitalisation de l'économie nationale constituera une cause du crédit durable. Cette conclusion est fondée premièrement sur le mode de conception des actes normatifs en vigueur, qui imposent un niveau correspondant minimum des capitaux autant pour les institutions bancaires que pour les agents économiques qui participent au marché du crédit. Deuxièmement, l'augmentation des capitaux des participants au marché du crédit permettra aussi la réorientation des politiques de crédit des banques vers d'autres segments de marché moins crédités jusqu'à présent, tout comme l'accès plus rapide vers le crédit des agents économiques et en spécial vers des produits de crédit qui correspondent mieux aux nécessités de financement.

Employés dans le but de l'augmentation des capitaux, les crédits viseront dans une première étape l'assurance des équilibres financiers au niveau de l'activité d'investissements[8] (le fonds de roulement) et, au niveau de l'activité courante (le nécessaire pour le fonds de roulement). Dans la situation où le fonds de roulement est négatif à cause de l'accroissement des actifs immobilisés outre les capitaux à long terme, il s'impose une capitalisation urgente de l'agent économique et la contraction de crédits à long terme avec des périodes de grâces convenables permettra l'accroissement des actifs immobilisés de sources correspondantes. Si les actifs qui circulent sont plus petits que les dettes à court terme, il en résulte un nécessaire de fonds de roulement négatif, qui, s'il ne peut pas être couvert avec le surplus résulté au niveau de l'activité d'investissements (fonds de roulement positif), doit être réalisé des crédits bancaires à court terme.

Pour que la relation d'interdépendance entre les capitaux et le crédit devienne plus concrète, un rôle important jouera à l'avenir la structure financière ou la structure des capitaux. Le crédit constituera une cause de la capitalisation de l'économie nationale à condition que le financement des capitaux à structure soit fait des sources correspondantes, dans le sens que les investissements doivent être réalisés de sources à long terme et les activités d'exploitation des crédits à court terme, n'étant pas permis le transfert de la source de financement de l'activité d'exploitation à l'activité d'investissements.

L'augmentation des capitaux dans le cadre de la structure financière implique, à son tour, aussi l'accroissement correspondant des sources de financement, dans les conditions actuelles de l'économie nationale étant préférée une pondération plus grande des capitaux prêtés à la structure des capitaux[5]. L'augmentation des capitaux prêtés représente un pas important dans la mise en évidence du concept de crédit durable vu le fait que dans la théorie économique et financière aussi l'on a constaté du point de vue mathématique que si la rate de l'intérêt est plus basse que la rentabilité économique de la firme, l'augmentation du degré de débit a un effet bénéfique sur la valeur de la rentabilité financière.

Le concept de crédit durable ne sous-estime pas le rôle des autres éléments économiques et financiers, l'un d'eux étant la rentabilité économique, qui, si elle est plus basse que la rate de l'intérêt pour les crédits, alors le crédit a un effet négatif sur l'activité économique et financière, menant à la réduction de la rentabilité financière des agents économiques.

Summary: In the context of European integration, the development of economical and commercial changes between Romania and European states must be sustained especially by bank system. The apparition of Romanian companies on European markets, the developments of imports and the common realization of some productivity objectives are impossible without the guarantees offered by the bank system. Because of emission guarantee letters in the name and the count of the clients, the banks assure practically the unrolling of transactions without an effective finance, assuming an entire risk which results from the encroaching upon the obligation of the contract between partners. The guarantee interferes just in the moment of participating to auction about the contracting of different works or about the realization of some imports and it is ending with the final act of using the goods by the beneficiaries.

Key words: guarantee bank letters, extra-balance sheets engagements, downstream, executing guarantees, provisions

1. The Extra-Balance Sheets Engagements in the Process of Capitalization

The extra-balance sheets play a very important role in the banking process of capitalization. Bank practice demonstrates that sometimes they are made with superficiality and from this reason we have negative consequences upon the stability of the bank system. So, we must insist on the implications of these in bank activity because the fundamental extra-balance sheets about we will talk about are structured like in table no 1.

The extra-balance sheets with function of assets are those engagements that banks must afford at any time from their own treasury. The most used extra-balance sheets with function of assets are:

- the limit of bank credits approved by the banks. After the approvement of the bank its value is recorded in the accounting of the bank in an extra-sheet count until the clients use effectively his money according to the objective of the contract. When the client use it the sum is recorded in balance sheet being simultaneously deleted from the extra-sheet evidence;
- guarantee bank letters and downstream. This are engagements assumed by banks in the name of clients, so that the banks will sums of money in the future to the purveyor and to creditors of the clients in the conditions in which the last of them will carry out their contractual obligations (downstream) or the conditions in which the client of the bank don't carry out their contractual obligations (guarantee bank letters).

Elements of Assets	Elements of Passive
901 Engagements favorable to other banks	**902** Engagements received from other banks
903 Engagements favorable to clients	**904** Engagements received from financial clients

9031 Opening the conforming credits	**912** Bails, downstream and other guarantees received from other banks
9032 Acceptance and engagements for pay	**914** Guarantees bring by clients
9039 Other engagements favorable to other banks	9141 Guarantees received from public administrative institutions
911 Bails, downstream and other guarantees gave from other banks	9142 Guarantees received from assurance companies
9111 Confirms of opening documentary credits	9143 Guarantees received from financial clients
9112 Paying acceptance	9144 Immovable mortgage
9119 Other guarantees gave to other banks	9145 Pledges with dispossessing
913 Guarantees gave for clients	9146 Pledges without dispossessing
9131 Bails, downstream and other guarantees	9149 Other guarantees received from clients
9139 Other guarantees gave for clients	

Table no.1 Extra-Balance Sheets Engagements

As much as these extra-balance sheets engagements remain recorded in extra-balance sheets evidence as a results of the fact that the people that solicit finance do not use it or they do not carry out the contractual obligations, in practice they do not give the proper attention and the legislation does not include the obligatory classification of those as in the case of balance-sheet credits, it does not include the obligation of making provisions.

For the banking activity, these extra-balance sheets with the accounting asset function represent "late effect bombs" of which explosion may lead to fast decapitalization. An example in this sense is given by Bancorex, of which downfall because obtaining losses was attenuated as implications over the banking system in some measures like: passing under special administration on a limited period of time, taking unprofessional by the The Authority of Turning Accounts of Banking Assets, the deposits transfer of natural persons towards BCR. The Government Ordinance nr. 39/1999 approved closing Bancorex by letting it be overtaken by BCR with all the assets and passives remained, including the extra-balance sheets elements and concrete obligations.

In 10th of December 1999 The Minister of Public Finance has emitted a guarantee in the favor of BCR by which it was covered any obligation that appeared before concerning the extra-balance sheets engagements taken from Bancorex. The debt limit was of 58 billion lei for the sums expressed in lei and 324 million dollars for the sums expressed in foreign currency. The overtaking of Bancorex by BCR would not be possible without the existence of this kind of guarantee, because the obligations BCR would have to face in the future as a following of the extra-balance sheets engagements could have destabilized even the biggest bank, with disaster effects over the Romanian banking system.

The classification of extra-balance sheets engagements of asset presented in the period 2000-2004 in conformation to table nr. 2.

Billions of lei

Anul	Total	Standard	In observation	Substandard	Doubtful	Loss
2000	34936,7	34321,5	36,5	126,4	216,4	236,0
2001	48571,4	48358,8	44,7	5,9	5,4	156,6
2002	75063,5	74758,0	12,5	182,2	1,7	109,0
2003	99882,2	68733,0	23596,2	4203,4	373,4	2976,2

Table nr.3 Exposure of elements outside the extra-balance sheets for which there aren't constituted supplies 2005-2007

As total rate of extra-balance sheets in the situation presented in figure nr. 2

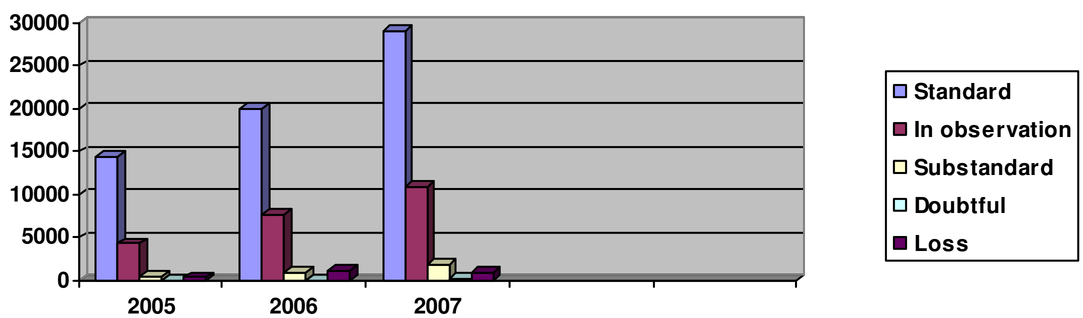

Fig. nr. 2 The extra-balance sheets quality structure 2005-2007

(Source: Monthly bulletin of BNR at the date of 31.12.2006 and 31.01.2008)

Although the standard category occupies the biggest rate, we consider that it is benefic the constitution of reserves for the engagements that are classified in the loss category. In this way we can avoid a decapitalization provoked by the balance-sheet of these sums.

2. Developing the commercial transactions using the bank guarantee letters

About negatively influencing in a smaller measure the banks treasury it is imposed to use on a wider scale extra-balance sheets. For this, a financing model of a transaction of import export[259] based only on bank guarantee letters would have the following steps:

- Transmitting the offer along with the guarantee letter of participation to the auction emitted by the importer or by the exporter bank, depending on who organizes the auction,
- Signing the commercial contract with the special clauses concerning emitting letters of guarantee of advance restitution, of payment, of good execution and of good functionality;
- The exporter commands its bank to emit guarantee letters of advance restitution,
- The guarantee letter of advance restitution emission and transmission over the banking channel to the importer,
- Paying the advance in the exporter's account stipulated by the advance restitution guarantee,
- The exporter commands its bank to emit the guarantee letter of good execution,
- The emission and transmission on bank channel of the guarantee letter of good execution,
- The importer orders the emission of the payment guarantee letter,
- The emission and transmission on banking channel of the payment guarantee letter,
- Delivering the merchandise or performing the service,
- The exporter orders the emission of the guarantee letter of good functionality,
- Emitting and transmitting on bank channel the good functionality guarantee letter.

Transmitting the guarantee letters on banking channel is done for verifying the authentic signatures of the emitting bank. In these conditions, every letter of guarantee must have a clause of identification conforming to which the guarantee letter execution request must come from the emitting bank by a bank of first rank.

We will forward present some advantages and characteristics of using these types of extra-balance sheets engagements.

The guarantee letter of participating to the auction guarantees the good intentions of the tendered and it is deposed to the beneficiary along with the offer. The emitting bank will pay the sums foreseen when the tendered is on one of the following situations: revokes the offer after opening it and before adjudication; revokes the offer after adjudication; being the winner of the auction, does not sign the acquisition contract in the term of availability of the offer; being the winner of the auction, does not constitute the guarantee of good execution[260].

The guarantee value is settled usually as a percent of the merchandise value (up to 10%) and the availability may reach even 6 months. Once passing over the terms of evaluation of the offers there can appear also the first risks for the tendered (the price risk and the market product risk).

The guarantee letter of advance restitution guarantees returning the advance received by the exporter, transforming it in a real financing instrument. This affirmation is as realist as can be as long as the advance received is used depending on the transaction object for prepare payments for the export or launching some new lots of products in fabrication. The clause of entering in availability must be conditioned by the effective receiving of advance in the exporter's account opened at the emitting bank. The reducing clause will mention that the guarantee value is diminished with a percent cote from the value of every delivery, cote equal with the one from the advantages. In this case the guarantee availability automatically contains automatically the whole delivering period.

In practice there have been met some cases in which taking profit from the lack of experience of the importer concerning guarantees, it was mentioned in the guarantee that the guarantee value is reduced with the value of the delivered merchandise. The guaranteed value will be equal with the advance guarantee but it will be also introduced the mentioning of interest payment calculated from the advance delivering date and until the payment date in execution of the guarantee.

---

[259] Ilie Dragoş, *Durable Creditation*, Publishing-House Sitech, Craiova, 2005, p.167

[260] Negruş Mariana, *International payments and guarantees*, Publishing-House ALL, Bucharest, 1996, p. 305-306

The payment guarantee letter is requested in the commercial transactions of our country with the foreign countries as long as the Romanian companies are not known on the European markets and still find suspicious their goodness and seriousness. The purpose of the payment guarantee letter was understood wrongly by the patronages of the Romanian companies, who by their attitude they had at executing them they have considered that it is more like a payment instrument. And so, there have been registered arrears in paying the contractual sums and the banks have paid from their own treasury.

Executing a guarantee creates a negative image to the emitting bank in the corresponding banks round. The entering in availability clause must be conditioned in the merchandise delivering moment or when fulfilling the services, in which situation the presentation of the execution request of the guarantee must be presented and the documents to attest the merchandise delivery or fulfilling services.

In practice, there are met more and more cases when the guarantee is unconditioned by the presentation of export documents, situation in which exists the risk of executing the guarantee letter without the guarantee beneficiary to have delivered the merchandise or fulfill the service. This situation appears in the international practice concerning protecting the guarantee beneficiaries for the eventual stoppers put by the banks from countries with a higher risk in the process of their execution.

The guarantee letter for the good execution is solicited by the importer as long as at its turn has ordered its own bank to emit the payment guarantee letter in the exporter's favor. This way the importing company is sure that the export will fulfill its contractual obligations in the quantum and terms stipulated in the commercial export contract. Usually the guarantee value is in 10% of the commercial contract and its availability covers the time of the contract's execution.

The guarantee letter of good functionality covers the risks with which the importer may confront after delivering the merchandise, that being: products that may not correspond qualitatively or a defect service from the exporter at the products for which it is accorded a period of guarantee. The importers will negotiate as much as possible the emission of a technical guarantee as much as the intern market that will absorb the respective products refuses the weak quality products and with the guarantee periods unsatisfying. The guarantee availability will cover integrally the technical guarantee which the importer accords to the products offered before towards selling on the intern market.

3. Conclusions

Emitting the letters of guarantee by the banks is done after a rigorous analysis the same as in the case of the credits. For avoiding the elaboration of some multiple documents of constitution of guarantees of materials for every letter of guarantee, it is imposed that the banks finish accords of guarantee with their customers for emitting more guarantee letters in the frame of an approved plan. In this case the operation of the emission grows more and the costs of emission go lower, the clients having a real advantage for developing their relations with the exterior.

In the crediting activity, in the future the banks must orient over the guarantees on the business plans, the phase-ability or the company guarantee. Only this way the capitalization process can be developed and the activity of crediting will not be strictly conditioned by the existence of a cover of material goods at the level of national economy.

THE RELATIONSHIP BETWEEN THE BANKING LEGAL ENVIRONMENT CHARACTERISTICS AND BANKING RISK MANAGEMENT ACTIVITIES

Iuga Iulia

University "1 Decembrie 1918" of Alba Iulia, Faculty of Science, N. Iorga Street, no. 11-13m iuga_iulia@yahoo.com

Abstract: The role of the financial intermediaries such as banks is that to channel savings towards investors. In a modern economy banks do this by maintaining a delicate balance between risk taking and risk management. Our goal here is to examine ***the relationship between bank risk taking and risk management activities and the quality of the legal environment****. Examining this relation is interesting because theoretical studies in this direction are ambiguous and this can be proved by considering the role of the collateral, a very widely spread and widely used risk amelioration mechanism.*

Keywords: banking legal environment, risk management, transition economies

The banking field of the countries in transition remarkably developed in the last 15 years. The bank activity from most countries in transition actually exceeded the specific trauma of transition. Therefore, the banks of these countries are very much alike those of anywhere else at the beginning of the 21st century.

A surprisingly great number of studies that provided information about bank performances were carried out, but not many things about their position about assuming risks and the way in which this is influenced by the bank environment are known. The institutional area of a country differs a lot from that of all the others. Berger and Udell (2002) [1.], Berger et al. (2001) [2.] and Haselmann and Wachtel (2006) [3.] proved that banks differently react according to the existing institutional regime. Berger and Udell (2002), for example, found out that banks are more willing to offer finance to debtors they do not hold insufficient information about into a better legal system. That is to say, if reliable guarantee regulations do exist, the banks will grant credits to risky debtors even though they do not have sufficient information, such as, financial statement or statement of account. From this point of view, the improvement in the bank legislative area is associated to a high level of risk assumed by the banks.

The bank activity of the countries in transition has rapidly got over four different stages (see Bonin and Wachtel 2003) [4.]. The first stage of bank development for the economies in transition meant the setting up of banking institutions at the beginning of the 90's. During the planned economy era – mostly unknown -, the only existing financial institutions were appendix for the state mechanism and bank activity, in the contemporary sense of the word. The commercial banks were separated from the payment central banking system. Anyway, the role of these institutions was mostly unchanged. The state banks financed state enterprises, quickly becoming insolvent. The second stage of the banking transition process consisted of banking crashes and systemic crisis that affected in a negative way all economies in transition after 1990 (see Bonim and Wachtel 2005) [5.]. The third stage consisted of a long process of reorganization by privatization and the intermission of foreign banks. Most banks were private property and the foreign banks dominated the bank activity in the countries in transition at the end of the century. The forth stage brings us to the present moment. In most economies in transition banks are safe, competitive and adequately regulated institutions. The bank activity from the period of transition left aside any kind of track from the period of the planned economy. The research made in the field of the transition economy is exhaustive and the problems about risk assuming and administration still remain with no kind of investigation. The first studies about the bank activity in the transition period were focused on the bank institutions creation and structure (see Corbet and Mayer 1992 [6.], Udell and Wachtel, 1995 [7.]). Accordingly as the transition process developed, the research interest focused on the bank performances and the bank activity efficiency later on. Recent studies approached the bank crises, the processes of reorganization and privatization that marked the transition period. Haas and Lelyveld (2006) [8.] and Haselmann (2006) [9.] finally focused on the consequences the foreign banks intermission brought upon the bank sector stability. The studies concerning the risk management carried out by the banks in the economies in transition are rare because the information about specific bank activities is very limited.

Kager (2002) [10.] focuses especially on banks at individual level and pointed out that the non-performance credit problem persists in many banks having economies in transition, Romania included. In Haselman and Wachtel's work (2007) [11] the three following points resume their discovering: 1. Certain bank groups differ at the risk level; for example, the foreign banks from the European Union and the big ones disclose a less probable loss by comparison with their competitors. Still, they are not but slight differences that are generally statistically insignificant and this issue reveals the fact that the bank markets are relatively homogeneous and no groups of banks that can take excessive risks may be identified. 2. They did not find out a clear connection between the risk taking activity by the banks and their legislative environment. Their discovering still reveals the fact that the banks that carry out their activity in a less secure institutional area retain more capital and assume themselves less credit risk. 3. The banks that take on more risk administrate it by the setting up, for example, different risk administration departments or obtaining information about the borrowers. These banks also have the tendency to retain more capital.

Nevertheless, banks adapt themselves to the area in which they operate by adapting their own capital. Haselmann and Wachtel (2007) [11.] pointed out that the differences at the legal environment level alter the credit portfolio composition. The banks do not have comprehensive information at their disposal when they engage themselves in a crediting process because the debtors are aware of the risk of their investment project. There are still some stipulations that may be included by the banks in their credit contracts for combating with the lack of information. Bester (1985) [12.] pointed out that the pledge may serve as warning instruments, taking into account the fact that the true risk degree is revealed by the guarantee size that the debtors are willing to produce. A good legislation to regulate the system of pledge and appropriate institutions to apply it are necessary for efficient warning instruments such the guarantee to exist. A growing reliability of the law and the agreements concerning the guarantee system may lead to the development of the guarantee employment for combating with the insufficiency of information and the generalized risk reduction. A debtor may use the same goods as pledge for different credit contracts or decline its handing in case of debt redemption impossibility in a poor regulated environment. A more developed institutional environment is associated with a greater availability to use the guaranteed credits and an intense credit activity in this respect. This is accordingly with the data from the juridical and financial literature that indicates a positive connection between the rights of the creditors and the credit market development. (La Porta, et al., 1997, 1998). [13], [14.].

The guarantees are the juridical means that give to the titular creditors either priority to other creditors concerning the unwilling pursuit of specific assets from the debtor's fortune or the possibility to unwillingly pursue another person that obliged himself together with the debtor. The essential function of the guarantees is to diminish or eliminate the loss risk the creditor takes from debtor's insolvency. The concept of guarantee is defined neither by the Romanian civil or commercial legislation, nor by those of the other countries, and general dispositions applicable to any forms of warrant do not exist either. Only different types of guarantees are regulated and there are special stipulations specific to certain types of warrant. This legislative gap was completed by the juridical literature and different opinions about the concept of guarantee that have been stated [15.] **We mention that no studies about guaranty legislation and the quality of the legislation assessment means have been done in Romania in the field of bank perception**.

The Basel Agreement II or, as it is also called, The International Convergence of Capital Measurement and Capital Standards – a Revised Framework, has been finalized and signed by the Basel Committee in 2005 and progressively implemented by the countries from the European Union from the 1st of January 2007 (with certain impairment of the advanced methods of risk evaluation that had to be applied up to the 1st of January 2008) [16]. The Agreement itself is not compulsory either for the countries that are members of The Basel Committee or other states. The stipulations of the Agreement in Europe are taken over by European Directives obligatory to transpose in the national legislation of the states that are members by virtue of understandings of the gentlemen agreement type. It is the situation of the Directive known as the capital Adequacy Directive. Capital Requirements Directive CRD published in the Official Journal of the European Union on the 30th of June 2006 actually represents a combination of two Directives: The Directive 2006/48/EC concerning the setting up and development of the credit institutions activity (revised [17]) and the Directive 2006/49/EC about the investment societies and credit institutions capital adequacy (revised [18]). Romania, as member of the European Union, has to apply the European Directives stipulations according to the Basel Agreement II. A new package of normative documents in the domain of bank capital adequacy (The Government's Urgency Decree no. 99/2006 regarding credit institutions and capital adequacy, subsequently approved, in 2007, by the Law no. 227; The Order no.12/2007 of the National Bank of Romania regarding the reference of the minimal capital requirements to credit institutions; The Regulation of the National Bank of Romania and Romanian National Securities Commission RNSC no. 22/27/2006 regarding the credit institution and investment firms capital adequacy; the Regulation of the National Bank of Romania and RNSC no. 18/23/2006 regarding private funds of credit institutions and investment firms; the Regulation of the National Bank of Romania and RNSC no. 13/18/2006 regarding the fixation of capital requirements for credit institutions and investment firms) was adopted in the context of the preliminary training of the Romanian banking system for the process of implementation of the Basel II Agreement stipulations in Romania. The concept of capital adequacy is therefore present in our country, too, but in the first years of development of the Romanian banking system, the specific legislation made references to the capital requirements only (art. 40-43 of the Banking Law no. 58/1998 which in the present is abrogated) and the same concept was taken over by the national regulations (for example: the Government's Emergency Ordinance no. 99/2006 regarding credit institutions and capital adequacy) only when the Basel II Agreement has been implemented. The reference formula elaborated by the Bank Supervisors Committee from CEBS Europe that represent instruments necessary for bank supervising according to Basel II have been taken over and adapted for the Romanian banking system. It is about the Common solvency ratio REPorting framework that we are talking about. They were transposed at the individual level and consolidated through the Order of The National Bank of Romania no. 12/2007 regarding the reference of the capital minimal requirements for credit institutions and the FINancial REPorting stipulations that were transposed at individual level and consolidated by the Orders of the National Bank of Romania no.6/2007 and 13/2007 regarding the financial situation of credit institutions according to The International Standards of Financial Report. The references of the COREP type that commercial banks carry out at the National Bank of Romania stipulate the transmission of information that certifies if the credit institutions do respect the prudential requirements regarding the proper funds and capital requirements, credit risk, market risk and the operational one at individual level as well as the consolidated one. The references of the FINREP type represent an important intermediary between the bookkeeping information and the prudential one as well as an instrument used by the supervisors for checking the prudential information.

The national legislation according to the Basel Agreement II suggests two alternatives concerning the **credit risk** evaluation: - *the standard method*, according to which the capital requirements are calculated having in view the debtor's type and rating and allows the possibility of determining the credit quality also by using the evaluations made by institutions of credit external evaluation, - *the internal models*, having two possibilities: basic and advanced internal models that give to the bank the possibility for risk evaluation according to the specific features of each disposal. The risk weight and the capital that is due to it are determined by quantitative entrance combinations provided by credit institutions and formula specified in the Agreement based on modern risk management techniques that involve statistic evaluations. Regarding to the **market risk**, the national legislation according to the Basel II Agreement suggests two measurement alternatives of the interest rate risk, the share price risk , the currency circulation risk, the wares price risk and the transaction of options risk for market risk evaluation: - *the standard method* mesures these components of the market risk by applying weights upon the positions in the transactional portfolio that is held for determining the losses in and extra balance positions owing to the inauspicious fluctuations of the market prices. – *the internal methods* permit us to fix the market risk by using the VAR Calue at Risk models on the basis of a set of quantitative and qualitative criteria and stress testing rigorous programs. The national legislation according to the Basel II Agreement suggests three measurement alternatives for **operational risk** evaluation: - the basis indicator approach, in which a single risk indicator of 15% is used at the level of a bank in order to calculate the capital requirements on the basis of a fix percentage of 15% from the annual average income registered in the last three years. – the standard approach that implies the grouping of the bank activities into eight groups and the proper funds requirement is determined separately for each category by applying a specific coefficient between 12-18% upon the gross proceeds from the last three years. – the advanced evaluation approach, where the capital requirements are calculated on the basis of the internal data of the banks regarding the operational loss through methodologies, as well as those of income volatility, those based on assets evaluation, parametrical models etc.

The European Commission adopted the **THE WHITE BOOK regarding the European Union mortgage credit market** integration on the 18^{th} of December 2007. The following situation is presented in the document: the financial services providers may offer Trans- frontier mortgage credits in different ways: by their local presence (e.g. branches, subsidiaries, fusions and acquisitions); direct distribution channels (e.g.: by phone or internet); or local intermediaries (e.g. brokers). The financial service providers may also engage into trans-frontier activities through mortgage portfolios acquisition from a mortgage creditor in a different state member. The differences of juridical order, the existence of fragmentized structures (for example, credit registers), as well as the lack of an appropriate juridical framework in certain aspects (for example, for mortgage financing) creates juridical and economic obstacles that restrict the trans-frontier loans and hinder the development of the pan-European strategies capable of financing. That is why the European Commission tries to eliminate the disproportioned obstacles in order to reduce the sale cost of mortgage products in the European Union. The impact study that encloses the present White Book suggests that a new legislation would signify the most adequate option of policy for accomplishing the established objectives in certain domains, but the European Commission believes that new analyses and consultations with the interested parts before a final political evaluation regarding the most appropriate way to be followed represent a necessity. The Commission is going to analyze a rigorous impact study that is going to include a quantitative analyze for costs and profits of the different options of policy for all aspects in view especially according to the principles stated regarding the best way to legislate and assure that the expected profit is not going to be overcome by the costs. The Commission believes that it is premature to take a decision before the end of this study and carry on new consulting with the interested parts if a directive would represent the necessary added value. In 2008 the European Commission: 1. is going to finish a revised version of the European Standardized Information Sheet – ESIS) upon the credits for lodging using the positive results obtained by the Group of Experts convened by the Commission in 2006 and formed of creditors and debtors, taking into account the initial results of the tests made by the Commission within the customers in 2007, as much as possible (especially regarding the warning about risks and foreign currency loans); 2. is going to test the revised version of the ESIS sheet in all member states on a large scale; 3. will examine to what extent the stipulations regarding APRC and included in the directive regarding the consumption credit may be extended to the mortgage credit either in the present form or in a way that has to take into account the specific features of the mortgage credit. The European Commission will publish up-to-date board tables containing objective information about the costs and duration of the landed registering and, respectively, prescribing procedure in all member states. In 2008, the European Commission will present a recommendation based on an adequate impact study. That recommendation: 1. is going to invite the member states to secure that the prescribing procedures are completed in a reasonable time and at reasonable cost and their landed book registers are available on line; 2. will encourage the member states to adhere to the EULIS project [European Land Information Service with 10 participants up to present that want to facilitate the trans-frontier access to landed property on line (www.eulis.org.)] financed through the eContent program of the European Commission; 3. invites the member states to secure more transparency and reliability for the landed book registers;

The institutional (legal banking) environment differs a great deal from one country to another. The European countries adhering to the EU in 2004 were forced to establish the creditor's rights and to ensure proper legal regulations while most of the other countries were not subjected to this kind of external reforming pressure. Thus, institutions in this countries offer, on average, less protection to creditors (see EBRD 2004 and Pistor 2000). There are no signs that one particular group of banks in transition has taken excessive risks. The bank markets in transition economies are relatively homogenous varying only slightly regarding banks in different regions, belonging to different ownership groups or having a different size. What's interesting is that we didn't find one single study to present the relationship between the level of risk banks take and the Romanian legal environment they operate in. However, banks operating in an unsafe environment generally maintain a higher level of capital/assets. And banks with a higher risk rate, comparing to their competitors, develop more risk management activities. This suggests that banks in transition economies have learned by now how to manage the risks. Banks that have access to files within the Payment Incident Bureau, Credit Bureau, and Banking Risk Bureau tend to have a considerably lower probability of default than the ones that don't have access to the information. In conclusion, credit Institutions must undertake all necessary precautions to obey local requirements regarding the execution of the collateral security. Credit institutions must ensure that there is a legal frame allowing them, as creditors, to have a first rank preference right regarding the secured debt, except those cases when the national law confers this first rank preference right to preferential, according to legal or procedural stipulations.

SPECIAL LETTER OF CREDIT ARRANGEMENTS

Ivan Mihail Vincentiu

Oil and Gas University of Ploieşti, 39 Bucharest street, Ploiesti, Faculty of Economics, mihailivan@yahoo.com, 0722 602 320

Commercial letters of credit facilitate the movement of goods into the channels of trade. A letter of credit is a written undertaking by a bank (issuing bank), acting at the request and on the instructions of its customer (applicant for the credit) to make payment to, or to the order of, a third party (the beneficiary).

For a credit to be transferable, the exporter must arrange for the importer to have a credit opened expressly stipulating that is transferable. A beneficiary may require financing in order to complete the manufacturing of merchandise or to purchase items to fill a particular order. A red clause credit helps achieve this.The applicant and beneficiary may wish to have a letter of credit structured to satisfy a long term contract requiring the constant supply of merchandise over a specific time period. This can be accomplished with a revolving letter of credit.

Key words: letter of credit, issuing bank, advising bank, payments, negotiation

Introduction

Commercial letters of credit facilitate the movement of goods into the channels of trade. They provide even more protection to the exporter than does the collection. That is why an exporter may refuse to conclude a sales contract unless it provides for shippment and payment under a letter of credit.

A letter of credit is a written undertaking by a bank (issuing bank), acting at the request and on the instructions of its customer (applicant for the credit) to make payment to, or to the order of, a third party (the beneficiary), accept and pay bills of exchange (drafts) drawn by the beneficiary, authorize another bank to effect such payment or to pay, accept or negotiate such bills of exchange (drafts).

The terms and conditions of the credit must be complied with before payment, negotiation, or acceptance can be made.

In issuing the letter of credit, the importer's bank (issuing bank) substitutes its credit standing for that of the importer, thereby assuming the credit of financial risk in full. If the beneficiary's documents comply with the terms and conditions of the letter of credit, he or she is promised payment from the issuing bank (and perhaps confirming bank), independent of the ability- or willingness – of the importer to pay.

Transferable credit

When the exporter is an intermediary between a supplier and the importer, in other words is the beneficiary, a transferable credit allows him to transfer all or part of his rights under credit to a third party (the transferee). Still, the transferee must comply with the terms and conditions of the transferred credit in order to receive payment.

For a credit to be transferable, the exporter must arrange for the importer to have a credit opened expressly stipulating that is transferable. It must be clearly stated that the credit is ''transferable''; no other terminology is accepted. Terms such as ''divisible'', ''fractionable'', ''assignable'' and ''transmissible'' do not render the credit transferable and will be disregarded.

Before transfer can be made, the exporter must send a written request to the transferring bank. The transferring bank, wheter it has confirmed the credit or not, is under no obligation to effect the transfer except to the extent and in the manner to which it has expressly consented, and until bank charges in respect of such transfers are paid.

The Uniform Customs and Practice for Documentary Credits (the U.C.P.) established the conditions under which credits may be transferred and specified the rights and obligations of the parties. The U.C.P. provide that a credit may be transferred only once. Consequently the credit cannot be transferred at the request of second beneficiary to any subsequent third beneficiary.

The terms ''assignment of proceeds'' and ''transferable'' credits sholud not be confused; they are entirely different. Unlike a transferred credit, the beneficiary maintains sole rights to the credit and it is solely *responsable for complying with its terms and conditions. With an assignment of proceeds, the beneficiary of a letter of credit assigns all or part of the proceeds under a credit to a third party (the asignee). For the asignee, an assignment means only that the paying bank, once it receives notice of the assignment, undertakes to follow the assignment instructions, if and when payment is made. An assignment of proceeds does not provide the asignee with any rights under the credit. He is dependent upon the beneficiary for compliance, and thus this arrangement is more risky for the assignee than a transferred credit.*

According to the U.C.P. „the fact that a credit is not stated to be transferable does not affect the beneficiary's rights to assign any proceeds which he may become entitled to under such credit, in accordance with the provisions of the applicable law."

As an alternative to the transferable credit, the exporter, being an intermediary between a supplier and an importer, might ask the advising bank or a third bank to issue a second letter of credit in favor of the supplier ,using as collateral a letter of credit issued in the exporter's favor by the importer. When one letter of credit is used as security to obtain the issuance of a second letter of credit to cover the same transaction, that arrangement is known as ''back-to-back''- letter of credit**.**

Associated risks make most banks reluctant to enter into back-to-back credit arrangements.

Anticipated compliance and eventual payment under the first credit should provide some assurance of payment under the second, but performance under the first credit may become impossible, either through acts of the parties involved, government edict, or other causes. For example, the actual supplier (the beneficiary of the second credit) may perform under his credit covering the domestic movement of goods and thus be entitled to payment. It is possible that the shipper(the exporter of the beneficiary of the first letter of credit)will be unable to perform under his or her letter of credit because of a strike by dock personnel preventing the international movement of goods before the expiry date of the first credit.

The intermediary's bank, which opened the second credit, will still have to pay the beneficiary of this credit if documents are in order and will look to the shipper/intermediary for reimbursement. If he cannot on-ship to the ultimate importer, he will not be able to obtain payment under the first credit and may not be able to reimburse his bank. For this reason,if a bank agrees to issue a second credit with the first collateral, it will generally seek assurances that the exporter could, if necessary, make repayment from his general financial resources.

In order to protect its interest further, the bank issuing the second credit may require that the first credit be confirmed by them before considering issuance of the second. As stated earlier, for these and other reasons most banks will generally prefer their customers to utilize ,if possible, transfer or assignment of proceeds arrangements rather than back-to-back letters of credit.

Red clause

A beneficiary may require financing in order to complete the manufacturing of merchandise or to purchase items to fill a particular order. A red clause credit helps achieve this (this name is derrived from the historical practice of placing a notation in the credit in red ink to identify this option.).

Upon the instruction of the importer, the issuing bank authorizes the advising or confirming bank to make a cash advance to the beneficiary against the beneficiary's written undertaking to present documents evidencing shipment in compliance with the credit term. A red clause permits the exporter to obtain an advance of part or all of the amount of the credit, as specified in the credit.

Later, when the letter of credit is drawn under, the paying or negotiating bank deducts the amount of the advance, and any interest due as a result, from its payment to the beneficiary. Should the beneficiary fail to ship or meet the credit requirements, the paying or nagotiating bank looks to the issuing bank to obtain reimbursement for the amount of the advance plus interest. The issuing bank then changes the account of the importer. Before agreeing to an exporter's request for a red clause credit, the importer should consult his or her banker to ensure an understanding of the risk involved.

Installment credit

The applicant for an letter of credit may need to be assured of receiving the merchandise over a period of time in certain given installments. When a bank issues an installment credit or a credit stipulating shipments by installment within given periods, that credit should clearly state „Shipment must be effected in the following installments."

For example, the bank should not leave it up to the beneficiary to determine wheter a clause „Ship Style No.1 no earlier than January 1, and no later than January 31; Ship Style No.2 no earlier than February 1 and no later than February 28; and Ship Style No.3 no earlier than March 1 and no later than March 31", is to be interpreted as an installment requirement.

Revolving credit

The applicant and beneficiary may wish to have a letter of credit structured to satisfy a long term contract requiring the constant supply of merchandise over a specific time period. This can be accomplished with a revolving letter of credit.

A revolving letter of credit contains instructions which allow the beneficiary to draw for specified amounts over specified periods.

The revolving credit uses the same letter of credit to cover numerous schedules shipments over a long period without the necessity of issuing new credits or amending the existing credit; it restricts the amount available for each shipment and controls the frequency of shipments and amounts available.

There are similarities and yet major diffrences between installment and revolving credits. The diffrence can represent significant risks for all parties involved. For example, with an installment credit, should the beneficiary miss one of the installments, the credit is no longer available for future installments.

Revolving credits are either ''cumulative'' or ''non-cumulative''. These classifications control the amounts available for drawing.

For example, the consequence of non-shipment in a specified period under an installment letter of credit is that the letter of credit ceases to exist. Under a revolving non-cumulative letter of credit, the consequence is the loss of the amount for that period.

Deferred payment

Under a deferred payment credit, after shipment the exporter presents complying documents to the negotiating/paying bank. Instead of drawing a draft on the bank or applicant when the documents are presented, the exporter authorizes the bank to release documents against the bank's obligation to pay on a future date as specified in the credit.

An exporter may be called upon by the buyer to provide financing under a letter of credit for the term beyond six months. In this case, a letter of credit providing for the drawing of a time draft for acceptance by the bank (i.e., a banker's acceptance) might not be appropriate because the acceptance would be ''ineligible for discount''.

The issuing/confirming bank therefore makes a promise of future sight payment(s). For incurring this liability, the bank asseses a deferred payment comission, usually a fee proportional to its regular acceptance comission,adjusted for the longer period.

If the beneficiary requires interim financing, he or she may be able to use the issuing/confirming bank's promise of future payment to obtain credit from his or her bank. The beneficiary will not be able to ''discount'' any paper for this financing, as in this case of a banker's acceptance transaction, because a deferred payment credit does not provide for the creation of a negotiable instrument which may be sold in the secondary market. The bank would have to fund the loan from its own sources, so the interest rate would usually be higher than the cost of acceptance financing.

Bankers' acceptances

A bankers' acceptance is a time draft drawn on and accepted by a bank and payable at a fixed or determinable future date. By accepting the draft, the bank conveys its unconditional promise to pay the face amount of the draft to any holder in due course who presents it at maturity. It is a short-term, self liquidating, fixed-rate method of financing where the instrument used to evidence the debt is a draft and not a note, as is the case in coventional lending. The result:lower rates of interest or cost to the borrower.

Bankers' acceptances play a vital role in trade finance. Banks substitute their credit standing for that of their customers by accepting drafts and advancing discounted funds to the borrower.

A key feature of the bankers' acceptance is its marketability. Bankers' acceptances may be sold to investors in the open market, resulting in short-term financing for importers and exporters. For these parties, acceptance financing is similar to issuing short-term private paper, although the administrative cost of acceptance financing is far less than issuing private paper.

Bankers' acceptances can be created either from the letter of credit transactions or from time drafts drawn independently of a letter of credit.

A typical example of a bankers' acceptance occurs when an importer draws a draft on his or her bank to finance imported merchandise arranged for under a letter of credit payable at sight, a collection, or a purchase on open account. By drawing a draft on the bank, independent of the letter of credit, the importer receives financing to pay for the imported merchandise. The revenue from the sale of the imported merchandise sholud then be used to pay the acceptance at maturity.

For example, Board of Governors of the Federal Reserve system regulates the bankers' acceptance market in the U.S. by modification of the definition of eligibility from time to time, by restrictions on the types of transactions from which eligible acceptances may arise, and by restrictions on amounts banks may create for individual customers and in the aggregate.

Acceptances are generally clasified as:

1. Eligible for discount at the Federal Reserve
2. Ineligible for discount at the Federal Reserve

Eligible for discount

Acceptances that are eligible for discount at the Federal Reserve are sold at more favorable rates in the acceptance market than ineligible acceptances, providing importers and/or exporters witk lower-cost acceptance financing. Currently, the basic criteria for eligiblity are as follows:

- the term of the draft cannot exceed six months
- the shipment must be „current", that is, the acceptance must be created within a reasonable time (usually 30 days) after shipping date of the goods
- the underlying transaction must fall into one of the following categories:
- the import or export of goods, either from the U.S. or between foreign countries.
- the domestic shipment of goods within the U.S. crossing state borders or travelling a minimum of 25 miles from point of origin.
- *the storage of readily marketable staples in the U.S. or a foreign country, provided the bank possesses a warehouse receipt or other such documents conveying the security title to the goods at time of acceptance until maturity. A readily marketable staple is defined as an article of commerce, agriculture or industry, of such use to make it the subject of constant dealing in ready markets with such frequent quotations of price to make:*

1. the price easily and definetly ascertainable
2. the staple itself easy to aquire by sale/purchase at any time.

Ineligible acceptances

Acceptances which are not eligible for discount by the Federal Reserve are defined as ''ineligible'' acceptances. The Federal Reserve requires that, unlike eligible acceptances, ineligible acceptances are not exempted from the definition of deposit and as such an ineligible acceptance is subject to reserve requirements.

The result is that the rates on ineligible acceptances generally are less favorable to importers or exporters than those on the acceptances that are eligible for discount. Despite this, ineligible acceptances can be less expensive than other short-term financing instruments and in some cases still provide attractive financing options.

Les transactions électroniques deviennent de plus en plus complexes, grâce au système qui se développe de manière permanente, aux technologies d'équipements et aux logiciels, ainsi qu'à l'environnement virtuel dans lequel ils opèrent (Internet ou Réseaux à Valeur Ajoutée). La valeur de l'information s'appuie sur son intégrité et, dans le cas où le système de sécurité ne permet pas la réalisation de cette demande, l'information va perdre sa signification.

Les institutions financières utilisent des jetons d'authentification générateurs de mots de passe pour identifier les clients commerciaux afin de permettre l'accès à distance au système des opérations via Internet. L'infrastructure de clé publique (PKI) peut incorporer des cartes à puces intelligentes qui contiennent l'accréditation de l'utilisateur et un certificat numérique

Keywords : sécurité électronique, l'information, e-banking

La sécurité électronique est définie par certains experts comme « les politiques, recommandations et actions nécessaires afin de minimiser le risque afférent aux transactions électroniques, risque qui se réfère en particulier aux créneaux dans le système, des intrusions ou vol ». autres la définissent comme « tout moyen, technique ou processus utilisé pour protéger le volume d'information d'un système ». La valeur de l'information s'appuie sur son intégrité et, dans le cas où le système de sécurité ne permet pas la réalisation de cette demande, l'information va perdre sa signification. Dans ce contexte, les spécialistes de la Banque Mondiale considèrent que la sécurité représente une modalité de créer de la plus valeur, devenant ainsi une préoccupation majeure de l'institution pour laquelle doit s'implémenter.

Ainsi, la Banque Mondiale recommande un système de sécurité des opérations bancaires déroulées via Internet, qui soit structuré sur 12 niveaux : le responsable avec la sécurité, l'authentification, firewalls, le filtrage active du contenu, le système de détectage des intrusions, les logiciels antivirus, le cryptage, le teste de la vulnérabilité, l'administration adéquate du système, les applications de gestion de la politique bancaire et le plan d'action contre les incidents. Les aspects-clé du fonctionnement d'un système de sécurité sont : l'accès, l'authentification, la confiance, la non- rejection, la confidentialité et la disponibilité.Les banques prendront des mesures adéquates pour vérifier et authentifier le niveau de l'autorisation des clients qui font des opérations d'e-banking sur leur propre réseau bancaire. L'authentification comprend deux processus : l'établissement de l'identité des nouveaux clients et l'autorisation des nouveaux clients ou de ceux qui existent déjà. La vérification de l'identité fait référence aux procédures, aux techniques et aux processus employés pour établir l'identité d'un client lorsque celui-ci ouvre un compte. L'autorisation fait références aux procédures, techniques et processus utilisés pour déterminer si un client ou un employé a le droit d'accès à un compte bancaire ou l'autorisation d'effectuer une certaine transaction sur ce compte bancaire.

Dans toute opération, il est essentiel de confirmer si un certain canal de communication, une transaction ou une demande d'accès est légitime dans le contexte de sécurité donné. Dans ce sens, les banques développeront des mesures de vérification de l'identité et d'autorisation des nouveaux clients, de la même manière et avec les mêmes procédures que pour les clients existants au moment de l'initiation des transactions électroniques. La vérification des clients pendant la déclaration du compte d'utilisateur est très importante, réduisant les risques de validation d'identités frauduleuses d'accès aux applications de scannage et de vol des comptes d'accès. Les erreurs d'une banque dans l'authentification des clients peuvent avoir des effets très graves, des fraudes contre la banque, de l'atteinte à l'image de celle-ci, des écoulements d'informations confidentielles et jusqu'à l'implication de la banque dans d'autres opérations de fraude d'autres entreprises ou à la transgression des normes financières locales.

Les banques utiliseront des méthodes d'authentification des transactions pour ne pas rejeter et pour enregistrer les opérations sur les comptes des clients via e-banking. Le fait de ne pas rejeter les opérations garantit l'intégrité de l'origine des transactions du point de vue de l'expéditeur. De cette façon, l'expéditeur de la transaction électronique est empêché de rejeter la réalisation de la transaction. Il est possible également de vérifier si la transaction n'a pas été altérée à une date ultérieure. A cause du risque assez élevé dû aux difficultés d'identification et d'autorisation des entités en cours de négociation, il est possible que les transactions ayant subi des altérations ou des détournements puissent être l'objet de réclamations des clients afin de les rejeter.

Pour réduire ces effets, les banques doivent faire des efforts considérables afin de s'assurer que :

- Les systèmes e-banking ont été prévus afin de réduire le nombre de transactions mal transmises, et les utilisateurs comprennent les risques associés à toute transaction qu'ils réalisent ;
- Toutes les entités impliquées dans une transaction sont clairement identifiées et autorisées, et la communication se fait sur un canal sécurisé. Le système e-banking devra garder le contrôle de la sécurité du canal de transmission en cours de transaction ;
- Les transactions financières sont protégées contre les possibles altérations qui, si elles surviennent, doivent être détectées.

La modalité pratique pour réaliser tout cela est d'utiliser les certificats numériques par une infrastructure de clés publiques ou de signature électronique, technique reconnue légalement dans plusieurs pays du monde.

Les Étapes dans l'établissement des politiques de sécurité

• **Établir les objectifs de sécurité**. En planifiant les conditions requises pour la sécurité d'un système, il faut tenir compte d'une série d'objectifs :

- confidentialité – il s'agit de protéger l'information contre une lecture ou un copiage par des utilisateurs qui ne sont pas explicitement autorisés à ce faire ;
- intégrité des données – protège les données contre les altérations ou les pertes accidentelles ou voulues ;
- disponibilité – impossibilité de désactiver un service sans droits octroyés en ce sens ;
- contrôle – définit l'accès au système, en protégeant le système contre l'accès non autorisé des utilisateurs ou des programmes ;
- audit – permet l'identification des problèmes apparus et met en relief les dommages subis. pour cela il faut qu'il existe des enregistrements (journaux) des activités du système. Cet objectif en milieu bancaire est plus important que la confidentialité ou la disponibilité.

• **Définir les risques**. Cette étape impose l'analyse de tous les risques existants, après quoi peuvent être panifiées des politiques et techniques adéquates de protection.

L'analyse des risques peut se faire par l'intermédiaire de plusieurs méthodes, l'une tournée vers le volume des risques, les autres vers le volume des coûts :

- **MARION** – est une méthode utilisée dans le milieu bancaire et des affaires, développée en plusieurs sous ensembles, comme suit :

MARION-AP	pour l'analyse des risques pour les ordinateurs séparés	IBM PC/APPLE
MARION – RSX	pour l'analyse au niveau des grands réseaux	main frame
MARION – PMS	pour l'analyse des petites affaires	IBM PC/APPLE

MARION – H	pour la gestion des ressources humaines	main frame

- **CRAMM** – méthode se préoccupant des risques et non les coûts ;
- **NIST** (National Institute of Standards and Technology) et NCSC (National Computer Security Center), apparues aux États-unis, ont mis au point un ensemble d'applications pour le développement de la recherche dans le domaine des méthodologies et des techniques de maîtrise du risque.

• **Calculer la faisabilité.** Est composé de deux éléments :

a) le coût de production, qui doit tenir compte des coûts des réparations/remplacements, des arrêts de travail, de l'image de la société bancaire, etc. En général, ces coûts sont estimés sur une échelle de coût minimal et maximal ;

b) le coût de la prévention, qui doit évaluer, en argent, les coûts imposés par les techniques destinées à contrecarrer chaque menace. Évidemment, plus la solution de sécurité est complexe, plus son coût est élevé.

• **Réaliser les politiques de sécurité, en concordance avec les objectifs**. Au cours de cette étape, est définie une politique générale de règles destinées à l'ensemble des services ou sous-domaines, suivie de politiques particulières pour divers biens protégés.

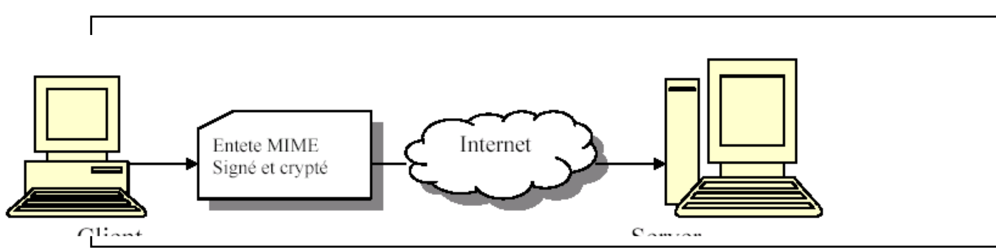
• **L'audit et la qualité des mises en application**. C'est une étape très importante, vu qu'au cours de cette étape il peut être constaté si la politique de sécurité fonctionne et sur quels paramètres. C'est une activité continue ayant le rôle de réglage de la politique de sécurité.

La sécurité dans les systèmes d'Internet Banking

Les créateurs de la version initial du protocole HTTP se sont proposés de créer une méthode de communication des informations multimédia (graphique, vidéo, audio). mais ils se sont vite rendu compte que HTTP deviendra la colonne vertébrale d'un incroyable nombre d'applications commerciales. Au fur et à mesure que le Web ait commencé a être utilisé de plus en plus pour des raisons commerciales, tant les entreprises que les utilisateurs particuliers ont reconnu la nécessité de la sécurité des transactions de type « end-to-end », en défit des transactions pas assurés de type « hop-by-hop ». Afin de répondre aux demandes de plus en plus accentuées pour des standards de sécurité sur le Web, Internet Engineering Task Force a lancé une demande de proposition en 1994. S-HTTP a été conçu par Entreprise Integration Technologies (EIT) comme résultat de cette demande.

S-HTTP (Secure Hypertext Transport Protocol) est une version modifiée de HTTP (Hypertext Transport Protocol) qui inclue des facilités supplémentaires de sécurité.

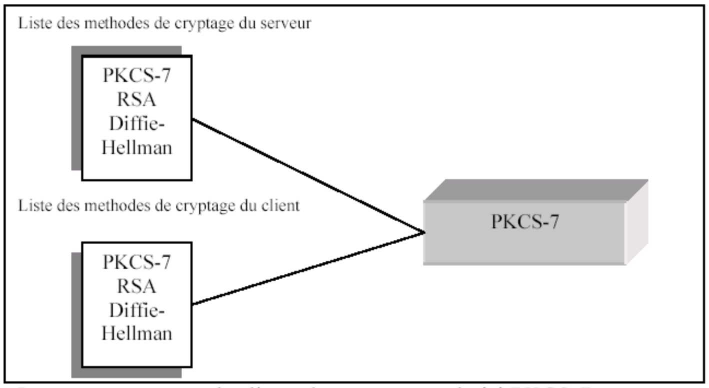
Les implémentations S-HTTP comprennent le cryptage des documents Web envoyés par Internet, et le support pour les signatures digitales. S-HTTP permet au client (browser) la capacité de vérifier l'intégrité des messages Web en utilisant un code d'authentification des messages (Message Authentification Code – MAC). S-HTTP éteint le modèle de transaction HTTP et les caractéristiques d'une transaction pour implémenter en HTTP le support de sécurité. La conception S-HTTP offre des communications sures entre un client et un serveur HTTP. Le but principal de S-HTTP set celui de permettre des transactions commerciales entre différentes types d'applications. Les différentes méthodes utilisées par S-HTTP pour assurer la sécurité du message comprennent une méthode de signature, une méthode de cryptage, un utilitaire de transmission des messages et des vérifications de la signature.



ajoute
us de
à HTTP

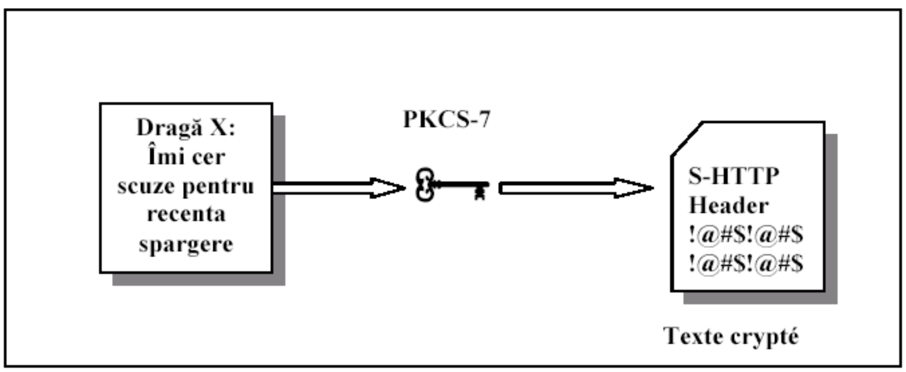
Les messages HTTP contiennent deux éléments principaux : l'entête du message (indique au destinataire la modalité du traitement) et le corps du message (par exemple, un entête qui indique le fait que le MIME du corps du message est de type Text/HTML demande au récepteur de traiter le corps du message comme un doc HTML (Hypertext Markup Language).

Afin de créer un message HTML< le serveur combine ses propres préférences de sécurité avec celles du client. Par exemple, si le serveur est défini comme Public key Encryption Standard 7 (PKCS-7) et la liste de cryptage du client comprend PKCS-7, le serveur va crypter le message utilisant PKCS-7, comme suite :

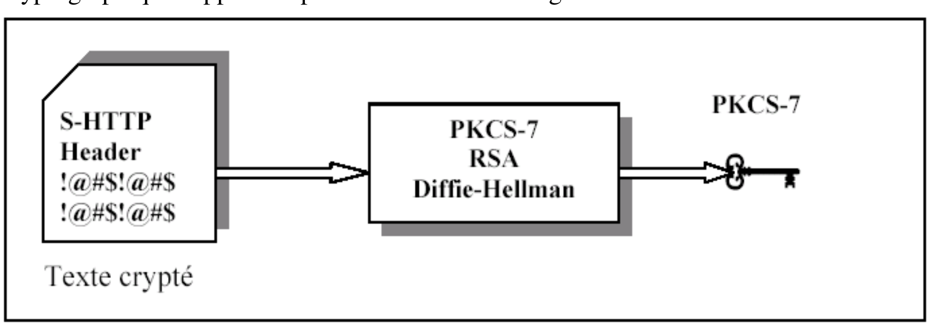


Le serveur compare les listes de cryptage et choisi PKCS-7

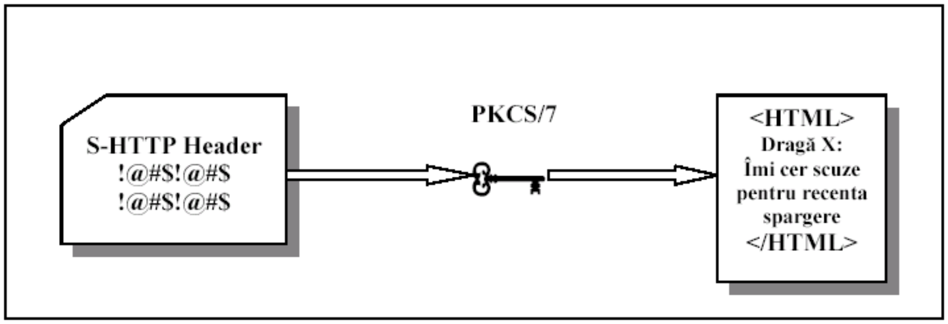
En appliquant une méthode de cryptage acceptée tant par le client que par le serveur, le serveur va crypter le message de type simple texte afin de créer le message S-HTTP. n continuation on représente la modalité de cryptage d'un message par le serveur et la création du message cripté.



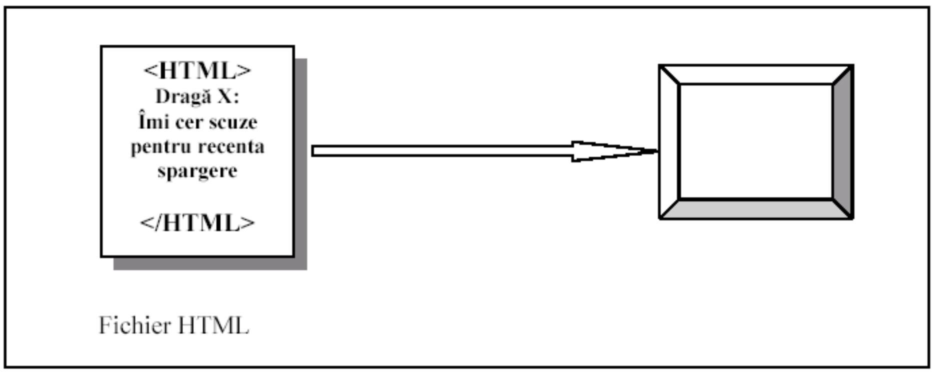
S-HTTP utilise trois données d'entrée pour créer un message HTTP : la transmission du texte simple, les préférences de cryptage du client et celles du serveur. A son tour, le destinataire du message (le client) utilise trois données d'entrée similaire afin de décrypter le message S-HTTP et pour accéder au texte du message. Pour décrypter le message S-HTTP, le client doit lire l'entête pour découvrir les transformations cryptographiques apportées par le serveur au message :



Apres avoir identifié le standard du cryptage indiqué dans l'entête du message par comparaison avec un des systèmes de cryptages connus, le client décrypte le message utilisant une certaine combinaison entre le matériel des clés de l'émetteur et celui du récepteur. Dans la suivante schéma, le client appliquera au message S-HTTP sa propre clé privée pour décrypter le message :

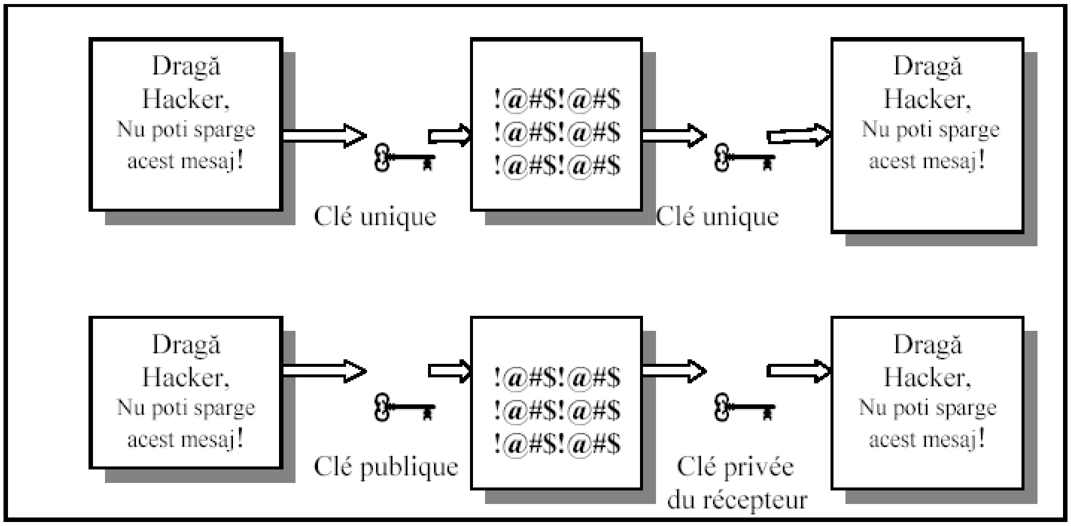


Après avoir décrypté le message, le client va lister les données HTTP encapsulées ou les autres données dans son browser :

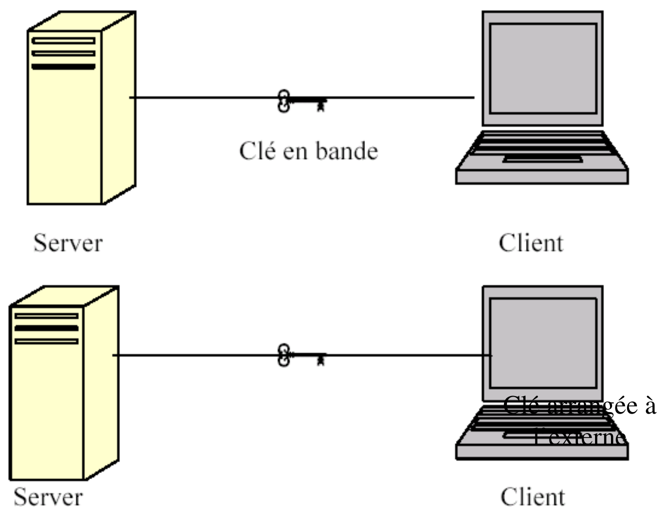


Dans un crypto système avec clé symétrique, les 2 parties utilisent la même clé pour crypter/décrypter les messages. En utilisant S-HTTP, les seuls qui connaissent la clé sont le client et le serveur, fait qui contribue à assurer la confidentialité. Le crypto système avec clé asymétrique dispose de 2 clés distinctes : une clé publique (à disposition de tout le monde) et une clé privée, qui diffère selon l'utilisateur. Pour transmettre un message confidentiel en utilisant un crypto système avec clé asymétrique, l'émetteur utilise la clé publique du récepteur pour crypter le message. Le crypto système avec clé asymétrique assure une totale confidentialité puisque uniquement le récepteur dispose de la clé privée nécessaire (propre) avec laquelle on peut décrypter le message.

Les crypto systèmes avec clé symétrique et asymétrique :

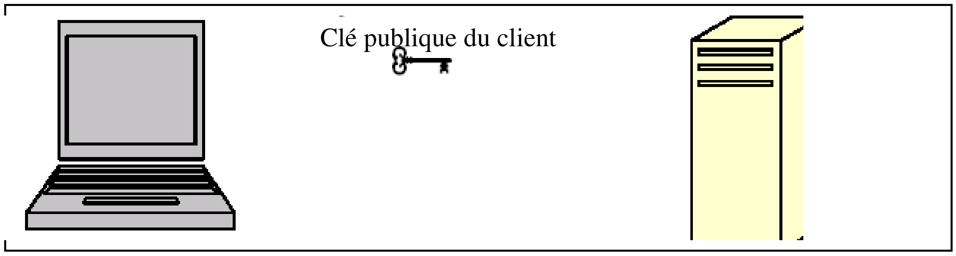


S-HTTP a défini deux mécanismes différentes de transfert/utilisation des clés. Le premier transfère la clé publique « en bande » et l'autre utilise des clé arrangées à l'externe. Dans le premier cas, le serveur crypte la clé privée en utilisant la clé publique du client et la renvoi à celui-ci. Dans la deuxième méthode, utilisée plus largement dans les systèmes Intranet des entreprises, le client et le serveur réalisent le transfert des clés manuellement. Etant donné que la plupart des utilisateurs ont accès aux clés via le WEB, la première méthode est utilisée dans la grande majorité des cas.

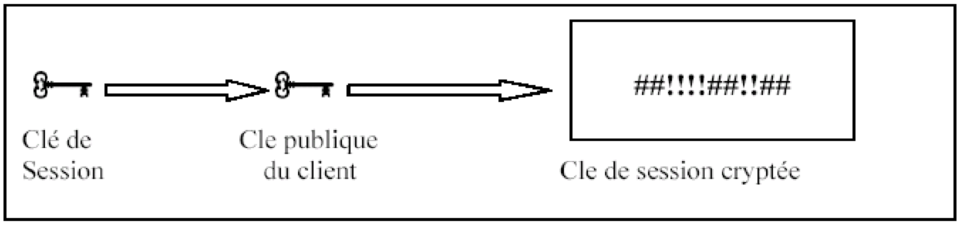


Pour mieux comprendre le transfère « en bande », voyons la modalité dans laquelle le client et le serveur interfèrent au moment où le client visite un site Web sure. La transaction HTTP se réalise dans les suivantes étapes :

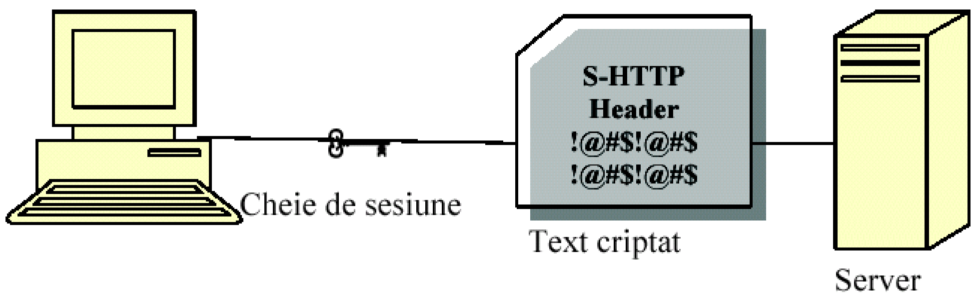
- quand le client visite le site Web S-HTTP, il envoi une demande de connexion vers le serveur pour initier la transaction. A son tour, le serveur va toujours répondre avec un message « Connexion réussite » (Connection Successful).
- Après avoir reçu ce message, le browser du client va transmettre au serveur sa clé publique et le crypto système dans le cadre duquel le client s'était fait créer sa clé publique (RSA, PKCS-& etc) :



– Après réception de la clé publique du client, le serveur consulte la liste des crypto systèmes acceptées, pour vérifier s'il peut accéder ainsi à la clé publique du transfert :



Après avoir établi une connexion réussite avec le serveur, le browser du client crypte chaque transmission adressée au serveur en vertu de la clé de session :



Appart S-HTTP, les serveurs utilisent d'habitude aussi un deuxième protocole, Secure Soket Layer (SSL) – pour assurer une communication sécurisée avec les clients.

A mentionner aussi que S-HTTP accepte une large variété de mécanismes de sécurité pour les clients et les serveurs HTTP.

Conclusion

Établir clairement les spécifications du système e-banking dans le but d'organiser des flux de données et des procédures de travail pour chaque système bancaire (bases de données ou applications). La division des attributions entre les sous systèmes est une mesure de contrôle interne, prévue pour réduire le risque de fraude dans les processus opérationnels, assurant l'autorisation correcte, l'enregistrement et la conservation en sécurité des transactions électroniques. Cette méthode est importante afin d'assurer l'exactitude et l'intégrité des données, mais aussi en tant que méthode de prévention de la propagation des transactions frauduleuses à tous les niveaux du système. Si les attributions des sous systèmes sont bien déterminées, une possible fraude produira des dommages uniquement lors de la tentative de pénétration dans le système, sans affecter les autres niveaux.

Vu l'ingéniosité des personnes ou des organisations malveillantes pour dissimuler de fausses transactions, cette méthode de sécurité doit également faire l'objet d'entretien et d'adaptations continuelles.

Abstract: Romania's adhesion to the EU has lead to changes in the economy and implicitly in the banking system. The steps prior to adhesion consisted in adapting the Romanian banking system to the European norms. The Romanian factoring market has developed by several credit institutions. The advantages of factoring for the adherent and factor recommend this service as a modern financing, crediting and risk management tool. The present study is an analysis of the evolution of factoring in Romania, starting from the worldwide and European tendencies. By comparisons there will be established the position of Romania on the EU factoring market. The sources of the data processed in the research are Factor Chain International and publications of Romanian financial institutions. By its outcomes, the research is useful to the participants on the financial and credit market, to the academic environment and to economists concerned in this field.

Key words: internal factoring, external factoring, regress factoring, debts management.

1. The Importance and Usefulness of Factoring Services

For many companies, selling on an international market represents a true challenge. It is true that this activity can prove to be a very profitable one, but business success implies risks taking. Different habits, currency systems, laws and language, continue to create obstacles in front of commerce, in a world where communications and information technology allow for processing orders regarding foreign relations within seconds.

One of the biggest problems confronted by exporters is the increasing insistence of importers for the exchange to be made under commercial credit conditions. Therefore, the counter-value of the merchandise is cashed weeks or even months after the deliver. On the other hand, many organizations consider that granting such buyer credits can generate severe problems regarding cash-flow management. Moreover, problems can occur in case the importer postpones the payment after the initially stipulated term or worst if he makes no payment whatsoever for insolvability reasons.

International factoring provides a simple solution, regardless if the exporter is a small company or a large one. The role of factoring is to collect the amounts due from abroad, by calling for importers in their own country, in their own language and upon local usages. Thus, the distance, cultural, economical and hour differences are no longer a problem. Moreover, factoring ensures protection against non-payment to exporters. The credit institutions' (factors) promoting factoring services represents a current problem worldwide. The advantages of international factoring have proved to be very attractive for the participants to international exchanges. Today, the form of financing by factoring is considered to be an excellent alternative to other traditional financing forms. This means that the conditions for international factoring can be regarded as favorable in all countries, not in the developed, but also in the developing ones.

Romania's adhesion to the European Union brings in new players on the financial market as a whole and in the banking system in particular. This increase of competition, as well as the correlation with the prudential norms and good practices of the European Union increases variety in the financing offers and in the services provided by credit institutions. It is upon this view that we will analyze the features of the Romanian factoring market.

2. Analysis of the Factoring Evolution Worldwide

Although Romania is an insignificant financial market on world level, we consider that an overview image over the factoring worldwide will allow us to make a more relevant identification of this product's place in Romania.

In respect with the evolution of the total factoring volume worldwide, we can notice that throughout 2000-2006 such increased by 80%, which demonstrates an increase of the interest for this financing form, both of the users and of the financing institutions. Given the fact that the factor takes over non-payment risks in the case of external factoring and only in some cases for the internal one, it is interesting that worldwide internal factoring has the largest share in the total (graph 1).

	2000	2001	2002	2003	2004	2006
Total factoring	623 840	685 682	724 197	760 392	860 215	1134 288
Internal factoring	578 997	644 659	681 281	712 657	791 950	1 030 598
International factoring	44 843	41 023	42 916	47 735	68 265	103 690

Graph1. Factoring Structure Worldwide

There can be seen that in the analyzed period international factoring increased with approximately 130% in 2006 compared to 2000. This demonstrates that we assist to a major development of financing by international factoring. Also, signals exist that more and more businesses adopt this product as a way of shifting from letter of credit based sale to open account sale. Importers demand more favorable payment conditions, and factoring allows for exporters to accept open account payment, upon commercial credit conditions, without worrying about "overdue debts", or problems regarding the cashing of external invoices.

In respect with the geographical distribution of the operations, the FCI reports show that the most developed factoring market is in Europe, holding 71% of the world volume. Following in the top there are the Americas and Asia-Pacific area with equal shares of 13% in the world volume. During the past years a strong increase was noticed of financings by factoring, especially in expanding economies in the Central and Eastern Europe. As shown bellow, this tendency is also felt in Romania.

3. Factoring in Romania

The opening of Central and Eastern Europe to the international financial and credit market has brought factoring operations into participants' attention. Even though the factoring market is still emerging, an increase is noticed in the interest for this financing modality in many Central and East European countries, Romania included.

Factors Chain International (FCI) is an umbrella organization for independent factoring institutions worldwide and has become today the largest international factoring network. Upon its establishment in 1968 internal factoring services were available only in North America and a few European countries. The concept of international factoring was still new and limited in sense, due to lack of geographical coverage. The founding members of FCI noticed the existent potential for international factoring, also acknowledging the need and opportunity for such an organization. The organization's main purposes were to introduce factorings in countries where it didn't exist and to create an institutionalized members' collaboration framework. In respect with its relation to Romania, on April 1, 2007 five members activated in Factors Chain International: BCR SA, BRD Group, Unicredit Romania, Factoring Company IFN SA and ING

Commercial Finance IFN SA, yet annual reports refer to the activity of more institutions. In 2006 such performed factoring operations amounting to euro 750 millions. The amount doesn't seem important if compared to the European level, but the increase by 30% compared to year 2005 is significant. There can't be noticed that Romania is placed last among Central and Eastern European countries, yet its market is a lot more developed than the Bulgarian one (euro 35 millions in 2006). Last years' increase in the factoring volume in Romania demonstrates an opening of the participants to international trade for this financing form (Table 1).

Table 1. Volume of factoring operations in Europe (selection)

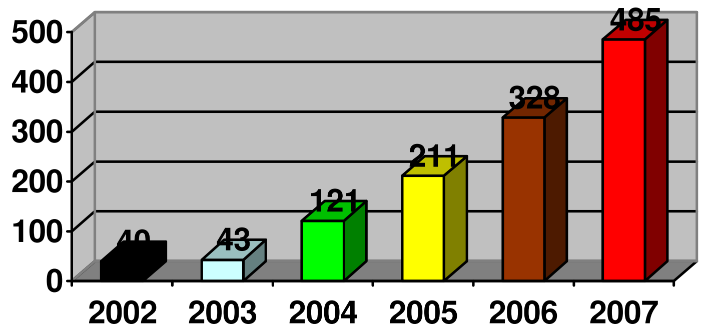
In the current period there can be said that the Romanian factoring market is a well organized one, even though these products and services have been brought in relatively recent and the factoring operations volume is not too large. The most used factoring services are the internal factoring type ones and external factoring without regress. The most important factors are commercial banks, yet some non-banking institutions also exist, out of which the most active is the Factoring Company.

4. Study on the Evolution of the Factoring Volume and Structure in BRD Group

BRD Group Societe General was established in 1923 along with the constitution of the National Company for Industrial Credit. In time, it has undergone a series of changes. The initiation of factoring services in Romania took place in 1992, yet the important step was made in 1993 by the affiliation to Factors International Chain, BRD being the first banking institution of full member statue in this organization. In the BRD factoring products portfolio there can be found both internal and international factoring (export and import). The bank provides its clients with factoring product in the versions with or without regress upon the client. Depending on the situation, clients can access the entire factoring services package: invoices financing, debt management, collection, coverage of non-payment risk, or a combination of at least two of them.

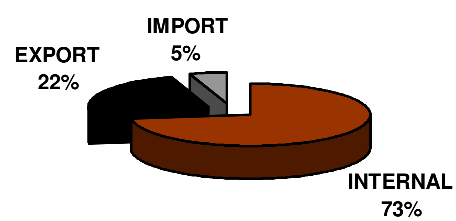
By analyzing the period 2002-2007 there can be noticed that in the first years the level of factoring operations performed by the Group was of approximately euro 40 millions. As such is due to the fact that the product was less known to the economic environment, as well as to the fact that the crediting activity was spreading. Starting 2004 BRD factoring has significantly increased, the bank reaching its factoring market leader position. By the end of 2005 a new boost was registered, by 75% from one year to the other.

In 2006 the bank obtained euro 328 millions turnover from factoring, representing an increase of 55% compared to 2005. The value of the operations performed in 2006 provided the bank with a very strong position on the market, as the volume of euro 328 millions represented approximately 40% of the total factoring in Romania (euro 750 millions in 2006).



Graph 2:BRD factoring volume (millions of euro)

In 2007 the total volume of the factoring operations reached euro 485 millions, by an increase in the operations of 47% compared to 2006 (graph 2). In respect with the operations' structure, in 2006 internal factoring had a share of 73% of the total, external factoring 22% and the rest of 5% was represented by import factoring. There can be noticed that internal factoring holds the highest share in the factoring operations portfolio, while the rest is divided between export and import factoring. Import factoring is a less used product in the local banks' offers. In the structure of the operations, the largest increase of approximately 50% was registered by internal factoring operations, which reached a level of euro 357 millions, whilst the volume of international (export and import) factoring volume increased by 47% compared to 2006. It is interesting to study if these annual increases are correlated to the dynamics of adherents or if a similar number of clients are using factoring more.



Graph 4:Factoring structure in 2006

From the data disclosed by the bank it results that in 2006 BRD was managing by factoring a portfolio of over 360 clients and 700 debtor clients or BRD non-clients. Compared to the same period of the previous year, the number of clients calling for factoring had increased by 40%, representing over 100 new companies enlarging the initial portfolio. In 2007, the number of clients increased again up to the level of 496, corresponding to a portfolio of over 1000 debtors and over 180.000 administered invoices.

By correlating the data regarding the volume of factoring operations to those regarding the number of clients calling for BRD factoring services, an increase trend can be noticed at both, yet the increasing rhythm of the clients' portfolio is smaller compared to the increase of the factoring volume. It seems that the understanding of the product, the development of the Romanian business environment and a more enhanced promotion of factoring services have lead to the increase of the number of users thus increasing the factoring volume. The same trend was also registered in the case of other factors. In order to provide a complete image of the Romanian factoring market we will briefly refer to the activity of other factors.

In the case of BCR group the initiation of factoring operations was made in 1998 by external factoring. The internal factoring product was introduced later on in 2001. BCR's market share for factoring operations is of approximately 33%. The significant boost period started in 2005, when BCR became a full member of the Factor Chain International. The BCR factoring turnover for factoring in 2005 slightly exceeded euro 130 millions with an increase of 51% compared to 2004.

In the case of ING group, the factoring operations are made by ING Commercial Factoring. The institution mainly addresses to small and medium enterprises, focusing on internal factoring. This is due to the fact that ING Commercial Finance is not yet a member of Factor Chain International. ING's factoring offer includes internal factoring with or without regress, external factoring without regress, as well as a portfolio of services such as: invoices financing due from 7 to 90 days, on-line reporting system, debtors monitoring, risk coverage in external and internal factoring, collection services. ING's factoring products are destined to enterprises registering a turnover of at least 1 million euro a year. The market covered by ING is of 5% of the total.

The Factoring Company is an institution specialized in factoring services, member of Factors Chain International. It was established in October 2006 and its shareholders are Transilvania Bank and Intermarket Bank Austria. Products portfolio is comprised of a series of factoring products; internal factoring is provided in Factoring, Plus factoring, Premium factoring and Total factoring. What differentiates these products is that they comprise one or more factoring services. For instance, Factoring only provides the services of invoices financing, Premium factoring includes besides invoices financing the debtors' risk of non-payment, while Total factoring includes besides the two said ones the debts management service.

The Factoring Company also provides external and import factoring services, yet in this case the way of achieving the products portfolio is not the same, as external and import factoring can be found in a particular product each, including all factoring services. In respect with operations volume, Factoring Company achieved in its first months of existence a turnover of euro 12946, and the turnover for 2007 was of euro 116 millions.

All these examples refer to an increasing factoring operations market. It can be noticed that more and more participants to the international commerce have understood the benefits of the factoring services. Using factoring is of immediate impact over the client's cash-flow, transforming due cashing into open cashing. Thus, factoring allows for business development without immobilizing assets in real guarantees and for an efficient debts management.

5. Conclusions

The factoring package comprises integrated services both for internal factoring operations and for export ones, as debts financing, debts administering and management and, as the case might be, taking over insolvability risk. The product provides a financing alternative to companies undergoing their business development phase, to those in their maturity phase, and especially to those having debts from exports and/or internal deliveries.

Compared to the European market Romania can hardly be seen as a share in the total operations (0.092% in the total in 2006). However, there can be noticed good growing rhythms from one year to the other. The comparison with other Central and Eastern European countries in the European Union is most cases unfavorable to our country: in 2006 the total factoring volume was of euro 1311 millions in Slovakia, 2880 in Hungary and 4425 in Poland, compared to euro 750 millions in Romania. Nonetheless, our country overcame countries such as: Bulgaria, Croatia, Slovenia. It is important to underline that although less numerous, the financial institutions active on the Romanian factoring market undergo an impressive activity, although some have been operating only for a few years. The present research demonstrates that Romania faces a considerable diversity of factoring products (internal, external, export, import, with or without regress), which indicates rapid adaptation to the market's needs. There can be said that on the Romanian financial market the factoring services are fairly sophisticated and thorough.

Considering the growth rhythm of the factoring operations' volume throughout last years, we consider that a tendency exists for potential users to open to such sort of financing. Nonetheless, we consider that the product is not yet accessible to small sizes exporters on one hand due to the fact that factoring services are not known, and on the other hand due to relatively high costs. We believe a mediating campaign from factors would be welcomed and could help increasing the performances of factor-banks, and also to the development and fluidization of national territory and upon export. Also, it is our opinion that the use of international factoring services provides a financial safety climate to any company, allowing it to enter new markets upon European competitiveness conditions.

LOAN SYNICATIONS

Ocnean Monica

Banat's University of Agricultural Sciences and , Veterinary Medicine Timişoara, Calea Aradului Nr 119, Tel 0256277029, monicaocnean@yahoo.com

Syndicated credit agreements are those in which more than one bank agrees to provide a common borrower a credit facility on common terms and conditions. Syndicated lending is among the largest and most flexible sources of capital in the world. There are several types of syndicated credit facilities: revolving credit facility, term loan, bridge loan, standby credit facility, standby letters of credit, hybrid facilities and project financing.

Main factors that influences the credit syndication market are: bank policies (early 1990s banks were under pressure to rebuild capital positions and ensure adequate returns on assets) and cost comparisons (demand for syndicated medium term bank credit facilities is very much driven by comparisons with the cost of alternative source of funding in the public debt markets – bonds issuing). The participants in the loan syndication market are as follows: sovereign borrowers, financial institution, corporations and LBO (leveraged buy out) deal sponsors/funds.

Key words ***:****Syndicated credit, revolving credit facility, term loan, borrowers pricing, bank ,sharing of credit risk.*

DEFINITION: Syndication credit agreements are those in which more than one bank agrees to provide a common borrower a credit facility on common terms and conditions governed by a single legal document. A " bilateral " credit agreement, on the other hand, exists between one bank and a borrower.

As a distinct asset classes, the investor base has now expanded beyond commercial banks to include institutional investors such as insurance companies, finance companies and mutual funds. While commercial banks remain the dominant players in originating, structuring and distributing bank credit facilities, syndicated credits are now being arranged by investment banks (and borrowers themselves in same cases). Given the additional liquidity of bank loans, investors are now better able to evaluate relative –value among investment opportunities as such distinction between public and private debt securities and bank loans is blurring.

TYPES OF SYNDICATED CREDIT FACILITIES

Revolving Credit Facility :A credit facility which offers a borrower a specific commitment but under which amounts may be drawn, repaid and re-borrowed during the life of the agreement. The commitment may be structured to reduce over the life of the credit facility (amortize).

Term Loan :Term loans are usually drawn down in one lump sum or in various amounts (tranches) over a specific period of time (drawdown or availability period) and mature in more than year. Repayments may be scheduled at various intervals, in varying amounts, or with a single payment at maturity (bullet maturity). Unlike a revolving credit, once repaid, amounts may not be re-borrowed. Bridge LoanBridge loans can be used as part of acquisition financing to provide short term funding, if necessary, during the tine gap when an acquisition closes and the sale of bonds in the high yield bond market. Investment funds are now often set up for this purpose.

Standby Credit Facility:Standby credit facilities are similar to revolving credit facilities but are expected to remain undrawn, in reserve, in order to provide liquidity enhancement. The facility is typically used to support commercial paper or medium-term note financing. If the issuer is unable to roll over his commercial paper, for example, he could drawdown under his standby credit facility.

364-day facility:Standby credit facilities with an expiration date of not more than 364-days fall outside the Bank for International Settlements (BIS) capital adequacy guidelines requiring banks to hold capital against undrawn commitments of one year or more. As a result, for investment grade borrowers, these credits are often priced with lower fees than for a longer term commitments. Capital required on amounts outstanding is the same, regardless of term, so pricing in recent years on 364-days credits is now more in line with multi-year facilities. Multi-year standby commitments backing commercial paper, however, allow for the commercial paper outstanding to be classified as " Long term Debt".

Swingline:Standby credit facilities can also be "swinglines". Swinglines are typically authorized as sub-facilities within the overall commitment used for very short term funding needs, i.e. less than 30 days.

Standby Letters of Credit:Standby letters of credit (SBLC's) can serve to enhance the credit of the borrower in relation with a third party by adding the credit rating of the banks in the syndicate to support that of the borrower. It enables the borrower to get funding from sources that are not prepared or are unable to accept the credit risk of the borrower on his own.

Examples:

Uses of SBLC's for credit enhancement include private placements and commercial paper programs. Standby letters of credit are also used in project financing and in export financings to support bids, performance and work completion, as specified in the underlying commercial contracts.

Hybrid Facilities:Various funding options are included in one credit facility, available for use at the borrower's discretion. These facilities have included: bankers' acceptances, multi-currency options, " competitive bid option" short term notes, all of which can be offered under longer term commitments. These come under acronyms such as MOF's (Multi Option Facilities), and NIFs (Note Issuance Facilities).

Derivatives:A complex form of financing where expected cash flow from a completed project is looked to as the source of repayment, with no or limited recourse to the project sponsor, so as to have minimal impact on the sponsor's balance sheet or creditworthiness. The cash flow and assets of the project are usually supported by direct or indirect guarantees via instruments such as take-or-pay contracts, tolling contracts, or long term operating contracts combined proven underlying assets.

Sponsors and lenders:Project or " off balance sheet " financings are often sponsored by companies in capital intensive industries such as utilities, transportation, heavy manufacturing, construction, and energy production and processing. These companies have a variety of motives for segregating a financing as a project financing – credit, accounting, tax, expanded sources of financing, etc.

Banks and institutional investors who have the analytical and technical expertise to understand and evaluate a project's risks are in best position to structure the project financing necessary to meet the objectives of the sponsor, lenders and/or leasors, and equity investors. Project credits can be either funded and/or unfunded.

Projects with strong undertakings and explicit guarantees of investment grade sponsors or other third parties have a broader array of capital markets (public and private) instruments available to them than do transactions without this support.

MARKET CHARACTHERISTICS

Syndication lending is among the largest and most flexible sources of capital in the world. In the United States, syndicated credit volume has grown from only USD 137 billion in 1987 to USD 1.O17 billion in 1999, up from USD 872 billion in 1998. As a comparison, in 1998 syndicated loan volume in Europe was about USD 300 billion.

The market has been moved from being driven by LBOs in the 1980s to being dominated by investment grade borrowers refinancing existing credits, arranging commercial paper back up credit facilities, and for financing acquisition-related deals in the 1990s. However, investment grade opportunistic refinancing died in 1998, leveraged lending and acquisition finance picked up much of the slack.

In the early 1990s, banks were under pressure to rebuild their capital positions and ensure an adequate return on assets on any new lending. Consequently, banks tightened lending policies and pricing went up. In an environment, of strong capital bases and high liquidity, banks aggressively seek loans and the volume of new deals increases, with severe pressure on loan fees and margins, lengthening of maturities and relaxation of covenants. Capacity to make loans can dry up quickly in the face of a global crisis such as occurred in the half of 1998 or more recently the sub prime crises occurred in 2007.

Demand for syndicated medium term bank credit facilities by higher-quality borrowers is very much driven by comparisons with the cost of alternative sources of funding in the public debt markets. Bank credit facilities tend to be more expensive, therefore are often used for bridge acquisition financing and as standby facilities when attributes like speed and flexibility may be considered more important than cost.

Investment grade companies also normally obtain short term financing in the commercial paper market more cheaply than from a ban loan. However, concerns about the risk of rolling-over maturing commercial paper usually make the support of a medium term committed bank standby facility a prudent part of corporate treasury management. Therefore, as the need for working capital increases, the need for bank lines increases.

Acquisition and LBO-related loan transactions are dependant on the overall volume of M&A activity and institutional investor demand for debt of non – investment grade issuers, i.e. the high-yield bond market.

PARTICIPANTS IN THE LOAN SYNDICATION MARKET

Users of Syndicated Credits

Sovereign borrowers

1.Governments

2.Government agencies

3.Supranational borrowers

Financial institutions

Corporations

LBO deal sponsors/funds.

Credit Quality

Borrowers can be investment grade, below investment grade, or non-rated. The market was dominated by large LBO transactions in the late 1980s but is now dominated by investment grade borrowers rated A or BBB. However, discretionary refinancing by high quality borrowers dropped in 1998, leveraged loan volume increased from USD 194 billion in 1997 (17 % of the market) to USD 273 billion in 1998 (31 % of the market). Perceived credit quality varies within the ratings categories.

For example, the BB-rated, near investment grade, market segment is a broad category. It can include companies which have high leverage but good cash flow as well as non-leveraged companies with strong capital positions but volatile earnings, small size, or even negative net worth. As in all rating categories, pricing within a particular rating varies by industry or by individual companies within any industry. For example, media or communications companies may fall into a higher risk category (along with leveraged recapitalizations) than an industrial with similar leverage and fixed charge coverage ratios.

The major rating agencies have initiated a system of rating bank loans. Unlike bond ratings, this is not intended to rate the risk of default but the risk of ultimate loss. Most banks, however, have been using numerical ratings systems and is not clear that institutional investors have strong demand for the service.

BENEFITS OF LOAN SYNDICATIONS FOR BORROWERS

Deals can be tailored to a specific borrower's needs, arranged and committed in a matter of weeks, even days. Type of transactions can include standby and working capital facilities, acquisition financings and project financings, and be funded in one or more currencies. Different tranches can have different maturities and repayment schedules.

It is relatively easy to arrange and negotiate with an agent bank to structure one comprehensive credit agreement rather than separate bilateral agreements with many individual banks, especially with complex or " story " transactions. No lengthy SEC registration is required.

More competitive pricing, terms and conditions (that might be available from bilateral agreements) may be obtained. In an environment where banks are aggressively seeking new loans, the cost of credit facilities may also compare favorably with other capital market products.

Bank credit agreements usually have more rigorous financial covenant than public debt issues. However, generally more of a relationship exists with bank lenders than with institutional or retail investors, making the initial structuring and any subsequent amendments to the transactions easier (than a private placement, for example).

Substantial amounts of committed funding can be obtained in the bank loan market, on relatively short notice due to the many participants in the market. It may also be the primary or only source of medium term capital available to non-investment grade borrowers.

BENEFITS FOR LENDERS

ENHANCE RELATIONSHIP

A bank may use its ability to arrange syndications to enhance its relationship with a borrower and cross-sell other business opportunities. To finance an acquisition, a bank may, for example, provide a leveraged loan syndication, a bridge loan, a high-yield bond underwriting and the derivatives for managing the interest rate risk, i.e. " one-stop shopping ". Top tier banks get most of a client's business.

SHARING OF CREDIT RISK

The overall size of a transaction may be too large to book within one institution or a bank simply wants to limit its concentration of exposure to any borrower, industry or country. A top tier bank usually must make the largest underwriting commitment, this is only possible if the bank has good secondary market distribution capabilities.

YIELD ENHANCEMENT

A bank may be looking to enhance return on risk assets by arranging the transaction and taking a disproportionate share of associated up-front fees, relative to the amount of the credit facility or loan retained on its books.

SOURCE OF EARNINGS

It may be a source of earning assets to a bank or other investor that may otherwise be unavailable for them.

FINAL CONSIDERATIONS

In the western mature markets, syndication lending represents one of the largest and most flexible sources of capital (funding) in the world. In Romania, only a few syndicated loans were raised so far. In general the issuers were very large companies, either with local ownership or local subsidiaries of large international corporations. The local subsidiaries of foreign companies we re the most active players in this field as they are already familiar with the benefits associated with syndicated loans.

In the coming years, the local market will see more and more syndicated deals, both with local (the participants are only banks that are active on the local market) and international (banks without local presence will participate as well) execution. The main driver behind this development is the local companies.

Local companies (domestic players) have grown tremendously in the last years. Some of the major local companies have reached levels of business that require a more sophisticated approach in managing their capital structure. Their needs for funding are quite high and the best solution for them is to seek syndicated loans rather than negotiating bilateral credit agreements with several financial (bank) institutions.

POSSIBLE MODEL FOR THE PORTOFOLIO RISK EVALUATION

Piciu Gabriela-Cornelia

Centrul de Cercetări Financiare şi Monetare "Victor Slăvescu", Calea 13 Septembrie nr. 13, Corp B, gabriela_piciu@yahoo.com, 0722287888

Possible model for the portfolio risk, is the novelty element brought data necessary for the constitution, correction and systemic processing of risk information by the bank's specialists, such that at their basis they could appreciate the relevant values of the variables associated to the risks and determinant activities.

Cuvinte cheie: matrix instrument,modeling, portofolio risk

The financial-banking system knew, in the last decades a complex expansion process, an institutional, instrumental, and procedure diversification and differentiation. The banking products and services were multiplied and adjusted to the conditions generated by an economy oriented towards globalization, informatization and liberalization. Within this context it was registered the relative rupture of the financial-banking flows and operations from the real economy's processuality, the functional and behavioural autonomization of the financial-banking entities, as well as the induction of a volatility and un-predictibility in the evolution of the parameters and monetary and financial characteristics of the real economy. It was evidenced, in the dynamics of the financial-banking system, the extension and intensification of uncertainties and risks associated to them, which became defining characteristics of the financial-banking environment, the risks having a determination exogeneous to the financial system. The expansion of the activites of the banking institutions on the internationalized financial markets have generated and amplified and maintained, a complex network of risks, of different intensities' nature, individualized or generalized on the financial-banking markets, induced and propagated in the economic and social systems of different dimensions.

Operating with innovating and volatile products, in a strongly informatized and de-materialized environment of services, the banking and financial institutions are oftenly using instruments and procedures oriented towards high banking efficiencies and towards the constitution of a financial-banking configuration-strongly polarized, forming and directing the demand of the clients for banking products and services towards investitional combinations and „puzzles" bearers of uncertainties and risks.

The protection against risks, their effect diminution, effects measured by the losses generated, the coverage and the insurance for the financial institutions, confronted with the risks' diversity has led to the continuous improvement of the risk management, to the innovation and diversification of the management instruments.

The banking regulations, the derivative instruments, the techniques for portfolios' diversification, the norms and modalities for resource, deposits and capital protection, are ways through which these institutions are trying to control the effects, often devastating, of the financial risks impact.

The global and formal approach of the impact of risks on the banking activities, particularly on the quality, the value of the assets managed by the bank—these being the primary source of gains—and, why not, on the losses of the bank, can be achieved by applying the matrix instrument.

The matrix offers the possibility of underlining, determining, and interpreting the causal interdependencies, determinative among the risks—which affect the banking assets in an insecure economic-financial environment—and possible and expected profits from assets managed by the bank, the level of these profits being determined by the winnings or probable losses of the bank.

The matrix reveals the network configuration of these interdependencies between profits and risks, making possible the statistical presentation of the *matrix co-variations* between the assets managed by the bank and, through these, the determination of the correlation between the assets, depending on the risks simultaneously affecting them.

Establishing the Model

It is obvious that the matrix interprets the *assets portfolio* of the bank as a *unitary asset*, with a value, a profit, determined by the global and interactional impact of risks on the assets included in the portfolio, viewed as its integrative elements, their relationship with the portfolio being one of intrinsic codetermination.

The matrix model for global evaluation of the risks, with which the financial entity is being confronted, in our case the bank, takes into account the following *categories of variables*:

*Factorial variables, F.V.***,** which underline the factors generating the risks the bank is confronted with; they fall into two categories:

Exogenous variables, G.V., environmental, they are related to the quality of the economic, financial, social and political environment of *being favorable or not* to the banking activity in question, and it reflects the external factors, which are not generated and cannot be controlled by the bank;

The States, S, of these variables are dual:

P = favorable, permissive (1)

A = unfavorable, aggressive (0)

Endogenous variables, D.V., active, they underline the qualities and abilities of the bank in disposing or not of the possibilities of properly accomplishing the banking activity in question.

The States, S, of these variables are dual:

F = the bank disposes of the ability to complete the activity (1)

N = the bank encounters difficulties in completing the activity (0)

The combination of these four states results intro the following factorial states of the bank:

11 = the bank holds an excellent, permissive, and aggressive active and environmental state

10 = the bank shows a favorable environmental state, but it lacks the ability of capitalizing its environmental advantage, displaying liabilities;

01 = the bank disposes of an unfavorable environmental situation, being confronted with a hostile environment, provided that it disposes of the necessary capacity of performing its activity, displaying an adequate action situation;

00 = the bank has an adverse environmental situation and a contractive action situation. (Table 1).

Environmental variables Action variables	1	0
1	11	10
0	01	00

Table 1: The combination of two factorial variables of Matrix Model for the Portfolio Risk Evaluation:

The four factorial states form the *factorial states vector, FSV, made up by factorial coefficients, CF*, with values between 0 and 1, their total being 1:

Action variables, A.V., which reveal the *banking activities* taken into account by the model, these activities being materialized into banking products managed by the bank, as its *assets*, characterized by differential *profitability*, with its levels affected by risks. The suggested simplified model has taken into consideration the following *categories of assets, C.A.: credits, C; titles, T; derivatives, D; currencies, V; cards, R.*

The assets are characterized by two defining attributes in relation to the bank:

- *the asset importance, A.I.*, which depends on the bank's specialization, on the clientele's traits, on the available technology etc, the importance being the *intensity attribute, IA*, of the asset. The values of this attribute oscillates between 1 and 5;

- *the asset profitableness, A.P.*, depends on the conjecture, the life cycle, the economic and social environment, representing the income or loss expected by the bank after making a transaction with the asset, forming the *extensional attribute, EA*, of the asset, its values depending on the banks characteristics, being both positive and negative.

- the risk variables, R.V., underline the specific risks with which the given banking activities are being differentially confronted, the suggested model taking into consideration the following *categories of risks: C.R.*:

1. *non-payment risk, N.R.*, represents the possibility of actually not cashing in the fluxes of income expected by the bank at the time limit, also being a credit risk;
2. *rate of interest risk, I.R.***,** represents the possibility of unfavorable variations in the rate of interest with an impact on the bank's performances;
3. *currency risk, C.R.*, represents the possibility that the volatility of the financial assets prices be able to affect the currency transfers and therefore the bank's profit;
4. *portfolio risk, F.R.*, represents the possibility of registering losses by the bank due to an unfavorable composition of the portfolio of owned assets;
5. *price risk, P.R.*, represents the possibility that the volatility of the financial assets of the bank be able to negatively affect the bank's profit, through induced losses.

The risk variable, as the action variable, is defined by two attributes:

- *the risk intensity, R.I.*, reveals the level of impact the risk has on the bank, on its importance for the bank, the very intensive risks having a determinant contribution in diminishing the bank's interest in that particular asset. This attribute's values will oscillate between 1 and 5;
- *the risk probability, R.P.*, underlines the possibility, the eventuality of the risk manifesting itself in the case of the given asset, the percentage values oscillating between 0% and 100%.

Determining the profitability of the assets and the probabilities of the risks involves the bank specialists' systematic, correct, and operational integration, gathering, and processing of the information on income and risks, so as to be able to appreciate the expected and relevant values of the two attributes associated with assets and risks.

Based on the six variables, states, and attributes presented, the matrix model for risks evaluation (MMRE), synthetically presented in the (table 2) chart, can be elaborated

V.A.			V.R.			V.F.
C.A.	I.A.	R.A.	C.R.	I.R.	P.R.	
C			R.N.			
T			R.D.			
D			R.V.			
V			R.P.			
R			R.F.			
$\sum$			$\sum$			

Table 2: The matrix model for risks evaluation (MMRE)

The Methodology and Manipulation of the Model

The essence of the matrix model lies in the global and punctual liaison of assets categories, A.C., with risks categories, R.C., and, based on the values of each of their attributes, as well as on the binary values of the factorial variables, the determination of an aggregated risk of the portfolio of the five assets in question is attempted.

In what follows, the methodological stages of building the matrix model, as well as the hypothetical practicality of the model, are presented.

1). The evaluation of the *factorial coefficients, F.C.*, used to determine the *vector for the factorial coefficients, VFC,* which are hypothetical in the case of the proposed model; the states vector, which applies to the ensemble of the bank's portfolio, is presented in the table 3.

factorial states	11	10	01	00
factorial coefficients	0,10	0,30	0,40	0,20

Table 3: The states vector (factorial states, factorial coefficients), which addresses the ensemble of the bank portfolio

2). The evaluation of **the** ***profits matrix, PM*****,** of the 5 assets of the portfolio in the 4 factorial states (Table 4).

State Asset	11	10	01	00
C	X1	X2	X3	X4
T	X5	X6	X7	X8
D	X9	X10	X11	X12
V	X13	X14	X15	X16
R	X17	X18	X19	X20

Table 4: Profits matrix PM

3). The evaluation of the assets *importance vector, AIV,* meaning the importance of every asset, evaluated on a scale from 1 to 5, for the bank: *AIV =(i5 i2 i3 i4 i1)*

4). The *assets value matrix, AVM*, in its 4 states, is determined by the multiplication of AIV by PM, the matrix cell, AVC, underlining the value of each asset in each factorial state: AVM = AIV x PM

5). The risks-assets interaction allows us to develop a first matrix, the *identification matrix, IDM,* which underlines the existence, represented by *, or the non-existence of the impact of risk on the asset, this matrix selecting, identifying, and enumerating the individual risks which affect the assets portfolio, the matrix presenting itself as follows: Table 5.

VA VR	C	T	D	V	R	$\sum$
RN	*	*	*		*	4
RD	*	*	*	*	*	5
RV		*	*		*	3
RP		*	*		*	3
RF		*	*	*		3
$\sum$	2	5	5	2	4	18

Table 5: Identification matrix IDM

The matrix underlines the fact that, from a total of 25 possible individual risks, PIR, the portfolio is affected by 18 risks, IFR, the intensity of the impact being measured with the aid of the *infliction rate, IR.*

$$rf = \frac{RAF}{RIP} \times 100$$

The analysis shows that the most frequent risks are the rate and the currency risks, with 5 *points of infliction* each, and the most affected actives are the credits, with 4, and the titles, with 5 points of infliction.

6). The matrix of probabilities in risks associated with assets, MPA, is drawn with j representing the assets in columns, and, on the rows, is stands for the probabilities of associated risks. The filling in of the matrix cells starts from the matrix of identification, the numbers in the matrix cell, N.P., representing the difference between the 100% certain situation, and the possibility of risk occurrence, R.P., according to the identification, the evaluation of probability being either subjective, based on experience, flair or expert consulting, or empirical, objective, based on the history of probabilities proper to other banks, the banking system etc. In order to obtain the risk probability, R.P., a subtraction is done as follows: P.R. = 100 – N.P.

For example, in the case of credits, C, the probability of risk for the rate of interest, RI, is 65%, the corresponding cell in the matrix having the value of 35% = 100% - 65%. In the table 6, an hypothetical situation of this matrix is presented.

Risc / Activ	C	T	D	V	R
P(RN)	Y1%	Y2%	Y3%	Y4%	Y5%
P(RD)	Y6%	Y7%	Y8%	Y9%	Y10%
P(RV)	Y11%	Y12%	Y13%	Y14%	Y15%
P(RP)	Y16%	Y170 %	Y18%	Y19%	Y20%
P(RF)	Y21%	Y22%	Y23%	Y24%	Y250 %

Table 6: The matrix of probabilities of the risks associated with the actives

$$\sum_{i=1}^{5} k_i = 1$$

i = risk

7) The *vector of risks intensity, VRI,* is evaluated; the elements of the VRI vector represent the *intensity coefficients, k*, with values ranging from 0 to 1, according to the bank's perception of risks, these coefficients being specific to each bank, with the definition rapport being:

8) The *matrix of the risks impact, MRI*, is determined, in association with the portfolio assets, by multiplying VRI by MPA:

9) The *matrix of the risks portfolio, MRP*, is determined by multiplying AVM by MRI.

The cell of the MRP matrix underlines the conventional value of each of the 5 portfolio risks, in each of the 4 factorial states, which we call the *value of the state risk, VSR*.

10) The portfolio's expected values of risk are determined, being called the *expected value of risk, EVR*, as an average of the values of state risks, according to the following formula:

$$\overline{EVR} = \frac{\sum_{s=1}^{4} VSR_s}{4}$$

Apply the formula to the 5 categories of risks.

11) Determining the deviation of each VSR from EVR, thus obtaining the *median deviation of risks, MDR*, for all risks and states, according to the MRP matrix, deviations which form the *median deviations matrix, MDM*, presented below: $MDR_{is} = VSR_{is} - EVR_i$

Where I = the risk, s = the factorial state.

12) The *squares of median deviations of risks, SMD*, are determined by elaborating the *matrix of squares of median deviations, MSD*.

$$SMD = (MDR)^2$$

13) The *variation* of each category of risks which affect the portfolio, $\sigma^2(R)$, is determined by adding up the SMD of every risk according to the following formula:

$$\sigma^2(R_i) = \sum_{s=1}^{4} SMD_{is}$$

14) The intensive variation of the portfolio, IVP, is determined by adding up the results form multiplying the risks variations, $\sigma^2(R)$ by the risk intensity coefficients, k(R), according to the formula below:

$$IVP = \sum_{i=1}^{5} \sigma^2(R_i) \times k_i$$

15) The *standard portfolio deviation*, $\sigma(PF)$, is determined.

16) The *portfolio risk, PFR*, is determined by dividing the portfolio deviation by the number of the risks.

$$RPF = \frac{\sigma(PF)}{5}$$

The models for the selection of efficient portfolios have the crucial benefit of objectively assessing the curve of investment opportunities (the efficient frontier) in risky assets. This is the «production» curve which the financial market can offer to the capital investors.

It can even be stated that this curve is objectively characterized by decreasing efficiency. The marginal ratability rate decreases as the risks assumed are higher and higher until they reach the maximum limit, when the rate becomes equal to zero. Beyond this «saturation point» of the risk, the marginal profit rate becomes negative and makes the continuation of the investment irrational.

ABSTRACT: One of the most important tasks of the management of a bank is to estimate and properly cover the bank's need of liquid assets. On long term, the profitableness of a bank may be negatively affected in case the bank detains in its portfolio too many liquid financial assets as compared with its needs; yet, on the other hand, fewer liquid assets may determine severe financial problems, especially for small banks, and may generate even bankruptcy.

KEYWORDS: asset, banking system, investments, liabilities.

One of the most important tasks of the management of a bank is to estimate and properly cover the bank's need of liquid assets. On long term, the profitableness of a bank may be negatively affected in case the bank detains in its portfolio too many liquid financial assets as compared with its needs; yet, on the other hand, fewer liquid assets may determine severe financial problems, especially for small banks, and may generate even bankruptcy.

Bank liquids represent the object of administrating banking liquid assets and liabilities having various degrees of liquidity. They represent banks' ability of assuming their financial obligations and express the assets capacity of being rapidly changed into money, with minimum expenditures.

An improper level of liquids may determine, in case of certain unforeseen diminishing of cash money, the necessity of contracting supplemental resources implying higher costs, a fact that diminishes profitableness and affecting solvability.

At the same time, a excessive liquids diminish the assets' profitableness determining the getting of poor performance.

One of the main tasks of bank management is to estimate and completely cover the needs of bank liquid assets.

The need of liquid assets and the capacity of the bank to foresee such needs is hard to be measured as the deponents' perception and trust (both of the present and of the potential ones) in the bank and the monetary market are quite important as well as hard to be estimated.

The risk of liquids may result in the credit institution's impossibility of making payments towards its clients as a result of changing the ratio between the long term credits and the short term credits and of non-correlating with the structure of liabilities.

Long term investments are generally higher than the credit institution's long term resources; as a result of such circumstances banks have to face two situations:

- They may be not able to assume their short term contracts;
- They may have short terms of payment while their investments might have long term payments.

In order to avoid liquids risk banks should do a proper correlation of their liquid assets and their liabilities regarding the duration of mobilization and use of resources.

The problems that may determine a liquid crisis are both external and internal. Accordingly, the external causes that determined the two important liquid crises during the time are the following: the economic crisis of the 30s, unexpected stock exchange crashes such as the "black month" of October 1987, the macro-economic policies promoted by the government that either reduce liquid assets in economy or diminishes the trust in the banking system and national currency.

The internal causes that determine the starting of a liquids crisis are due to the credits' losses and other non-performing investments that may cause a lack of balance in banks' cash flows, the diminution of the business potential of the banks and, as a consequence, of their incomes, as well as the diminishing of the trust in the banking institutions materialized in an increased rhythm of funds withdrawal.

The diminishing of the bank's rating may, as well, determine the decrease of the clients' trust in that banking institution having as a result the diminution of the incomes coming from commissions and interests, the improper diversification of funds resources (of the financing sources).

On the other hand, liquid risk may result out of two reasons: one of them is connected with the assets of the bank's balance sheet, the other one is connected with liabilities. The risk connected with the bank's liabilities appears each time the deponent clients want to immediately and suddenly operate the withdrawal of their money; under such circumstances the bank have to borrow supplemental funds or to sell certain liquid assets.

The most liquid asset of a bank is cash money, the bank primarily resorting to it in order to meet its clients' demands of withdrawal. Nevertheless, banks exhibit a tendency of minimizing cash money detaining as they practically bring them no profit. In order to get incomes out of interests, the majority of the banks invest fewer cash money in liquid assets and/or with longer term maturity.

The majority of the assets may be changed into cash money at a certain moment; yet the immediate change into cash money may sometimes be done at extremely high costs. The price the owner of such assets has to accept in case of an urgent sell may be much lower than in case he/she would have at hand a larger time interval during which the price might be negotiated. Accordingly, certain assets may be liquidated only at lower prices, called "fire-sales prices", subsequently threatening the bank's solvability.

The administration of liquid risk implies a distinct approach of short term administration, of treasury administration, and of long term administration.

Short term administration implies the precise measurement of the bank's liquids risk.

Treasury administration implies the determining of an optimum structure of the bank's assets in order not to register losses whenever assuming the liquids risk.

Long term administration of liquid risk helps the bank elaborate its crediting policy as it is well-known the fact that liquids are a constraining factor of crediting activity.

A useful tool employed by the management in predicting the net income out of short term interest is GAP analysis done with a view of profiling the difference between the investments and the term ressource at certain time intervals. Such gaps specific to each interval of maturity may determine the elucidation of certain aspects connected with short term liquids as well as with long term liquids.

The goal of such an analysis consists in the identification of the potential problems that might appear within the liquid assets of a financial and banking institution. The gaps accordingly determined should be diminished in order to reduce liquids risk.

A gap represents the difference between the assets and the liabilities due during the same interval of maturity. This value is also known as liquid's position.

A liquid's position is defined as follows: for a class of terms of payment it is the difference between the assets and the liabilities. It is accordingly calculated for each class, being a sum, duration and term index of the changes operated by the bank. The level of this index emphasizes the discrepancies between the term of payment and the types of maximum funds with which the bank is going to deal with, time after time.

$$Lp_i = ASSETS_i - LIABILITIES_i$$

$ASSETS_i$ = assets of i class term of payment

$LIABILITIES_i$ = liabilities of i class term of payment

- *The gap is positive* when the due assets > than the liabilities due during the same interval of maturity; accordingly, during this interval there are enough resources to make the payments demanded by the clients. One should assume that only those clients whose resources are due during this interval of maturity are supposed to withdraw their sums and the afferent interests.

- *The negative gap* may be a problem especially in case it is registered during close maturity intervals. The resources due during this interval cannot be covered out of investments due during this interval; the banking institution is forced to use before the term of payment other liquid assets with a view of creating the needed liquids.
- *The cumulated gap* during several maturity periods represents the algebraic sum of the gaps during those intervals. The significance of this index: it gives the banking institution the possibility of correlating the resources and the due investments until a certain date in order to face the payments demanded by the clients.
- *The gap index* synthesizes the size in a relative value of the difference between the investments and the resources due during the maturity interval, namely compared with the total assets. Important levels (over 10%), especially the negative ones, should be quickly improved with a view of diminishing the risk of liquids. The gap positive indices having significant values may point a lack of balance of correlating the investments maturity with the resources employed, a gap that might grow (towards negative values) during those maturity intervals.

In order to illustrate by examples the gap analysis in a bank we have chosen the structure of the assets and liabilities on December 31st 2007, classified according to residual maturity (the time interval calculated beginning with the analysis date – that can be quarterly, monthly, weekly or daily – and the date of the effective term of payment of the assets/liabilities element) – Table 1

The level of the assets and liabilities on December 31st 2007

Gap, cumulated gap, gap index (%)

(Lei) Table 1

	Up to 3 months	Between 3 months and 1 year	Between 1 year and 5 years	Over 5 years	Total
Assets					
Cash money and short term funds	18680.9	-	-	-	18680.9
Sums received from Central Banks	106336.4	4147.9	98,5	-	110582.8
Treasury certificates	57879.	76608.7	8296.1	438.2	143222.4
Sums to be received from other banks	102177.4	15193.7			117371.1
Credits and advance payments given to the clients	27649.0	73596.6	32214.4	5742.0	139202.0
Participations	-	-	-	7687.4	7687.4
Fixed assets	-	-	40000	45440.1	85440.1
Other assets	37622.3	-	1320.8	860.3	39803.4
Total assets	350345.4	169546.9	81929.8	60168	661990.1
Liabilities					
Deposits from other banks (drawn)	63841.6	9113.9	17769.9	27959.1	118684.5
Clients	319251.4	121783.7	52019.1	-	493054.2

deposits					
Other obligations and provisions	10018.6	5830.6	4101.7	30300.5	50251.4
Total liabilities	393111.6	136728.2	73890.7	58259.6	661990.1
Liquidity net gap	(42766.2)	32818.7	8039.1	1908.4	
Cumulated gap	(42766.2)	(9947.5)	(1908.4)		
Gap index (%)	(12.2%)	19.35%	9.81%	3.17%	

The following conclusions may be drawn out of the analysis of the above GAP Table:

- On a up to 3 months term (remaining maturity) resources attain their term of payment more quickly than investments ; this fact may be a potential problem for the credit institution when all resources attaining their term of payment are not prolonged anymore;
- The negative gap up to 3 months shows the fact that the liabilities due during the period 31.12.2006 – 31.03.2007 overpass the assets due during this period; in case due resources are not renewed, the credit institution should sell assets that do not attain their payment term in order to face withdrawals; within the internal market, the large majority of the assets' sales are done through State titles (REPO operations or sales on secondary market);

Among the measures banks should pay attention to we can notice the following ones:

- Drawing of supplemental resources on at least 3 months term;
- The investment of supplemental resources in liquid investments having a up to 3 months payment term;
- The re-modeling of the longer terms investments policy with a view of diminishing the share of more than 5 years payment term investments.

The methodology of liquids management should deploy according to three co-ordinates: the establishing of the profile of the bank's liquids, the establishment of the desired level of liquids of the assets and the analysis of the cash flow during various periods of time.

The getting of the desired level of liquids has in view the noticing of certain minimum demands regarding reserves; accordingly:

- -Monetary authorities require banks to keep a certain part of the total sum of their deposits at the Central Bank;
- -Compulsory reserves are required in order to discourage banks to extend their investments;
- -In a lot of countries the level of the reserves varies according to the type of the deposit (transit deposits require higher liquid demands than term deposits).

The main strategies of liquids management that improve the structure of the assets are the following:

- The extension of credits and overnight investments;
- The extension of inter-banking credits;
- The acquiring of short and medium term negotiable titles;
- The repayment of due credits;
- The securing, namely the change of credits into titles;
- Few investments into fixed assets.

The following strategies improve liquids due to the change of the structure of accounting liabilities:

- The diminishing of inter-banking deposits;
- The emission of long term negotiable titles and deposits;
- The prolongation of the medium duration of liabilities portfolios;
- The emission of capital as subordinated debt or the emission of ordinary or preferential stocks;

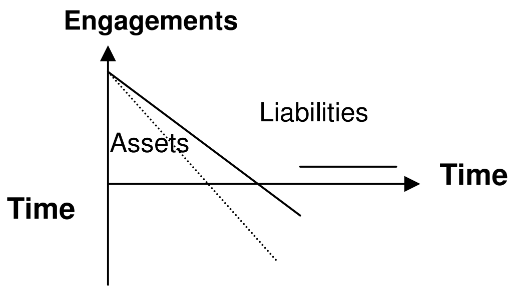
– The obtainment and maintaining of a high credit rating.

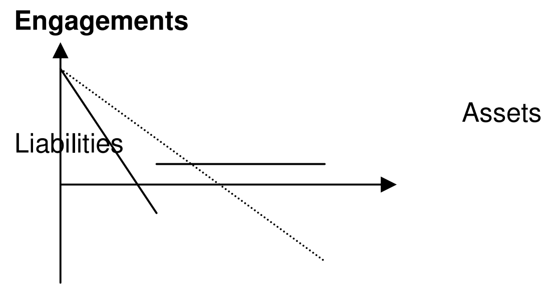
Whenever immunization lacks the size of the gap between the payment term of the engagements and the resources determines, for a certain period, a global perspective of liquids, namely of its “consolidation” degree.

Accordingly:

– The balance sheet is over-consolidated (Fig.1), in case the existent assets are more rapidly paid off than the existent resources. The exceeding resources resulting with the lapse of time are available in order to finance new operations.
– The balance sheet is under-consolidated (Fig.2), in case the assets are more slowly paid off than the resources. New financing is necessary in order to cover the gap.

Fig. 1 – Over-consolidated balance sheet ***Fig. 2 – Under-consolidated balance sheet***

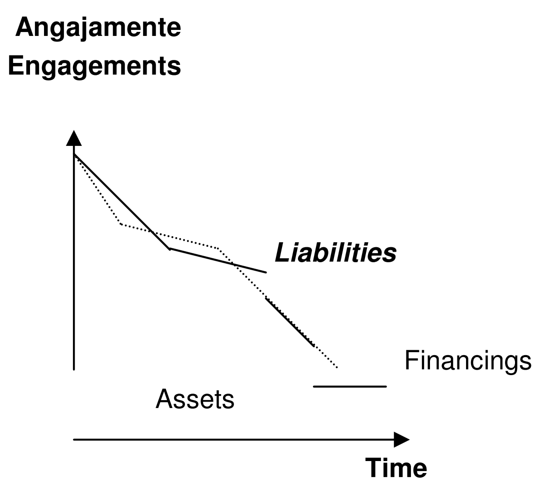


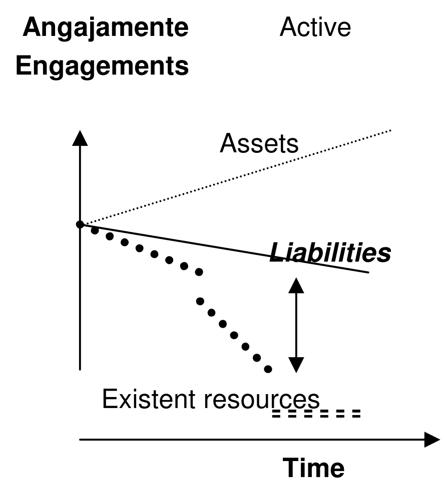


– The balance sheet is perfectly consolidated (Fig.3) when future financing needs are equal with the new resources.

In case the profile of the resources includes both the existent resources and the new financings the bank employed, the graph is quite different (Fig. 4)

Fig. 3 – Perfectly consolidated balance sheet ***Fig. 4 – Profile of new financings***

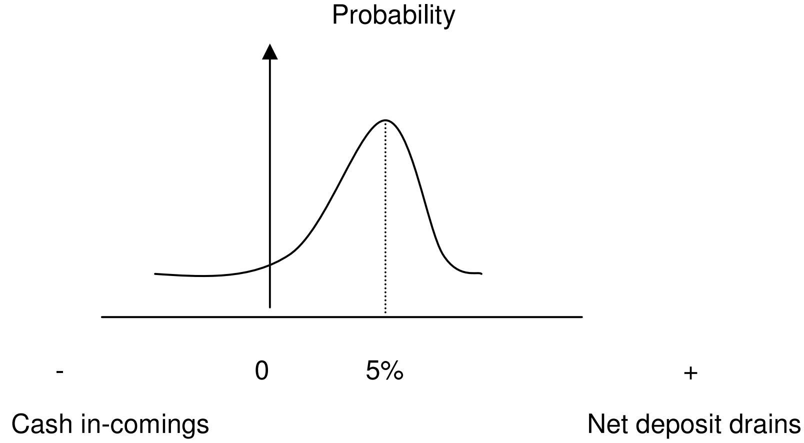




In time, the management of a bank may predict the distribution probability of the net deposit drains every normal banking day.

Net deposit drains = Cash deposit withdrawals – Cash deposit in-comings

Let’s take into consideration the following possible distributions:



Distribution has its higher level at 5% net cash drains, a fact that implies that the bank expects that about 5% of its funds represented by deposits might be withdrawn every banking day having the highest probability. The bank is going to receive accordingly new deposits in order to counteract the effect of cash withdrawal. In order to determine a growth of the banking field, net medium deposit drains of the majority of the banks should reflect higher funds in-comings than the clients' accounts withdrawals.

This optimum level might be possible when the maximum level of distribution probabilities is placed on the left to 0.

At such a level, for example of –2%, the bank has net cash in-comings.

In practice, the administration of liquids risk mainly consists in the following:

- The giving in, mortgage or pledge of due titles of the bank's portfolio without excessive losses;
- The identification of new resources with marginal costs inferior to the medium profitableness of the bank's investments.

Abstract: In the last years,in the context of financial globalization, it has been registered a significant development of the financial markets, but also an increase of the instability of the interest rates, of exchange rates, of prices in general, that determined the creation of new instruments and of protection markets against risks. Within those, one should mention from the point of view of the spectacular development and of the economic implications, the derivative financial products and markets on which these are negotiated.

The paper analyses the role of financial derivatives in managing financial risks in the process of financial globalization and their implications on the systemic risk, on the banking activity, and on the monetary policy.

Key words: financial globalization, financial markets, derivatives markets,banking activity, monetary politics, systemic risk, risk management.

1. Introduction

In the last two decades, the financial systems of the majority of the world states were marked by profound transformations. The process of deregulation, subdivision and non-intermediation, the financial innovations, the new informational and telecommunication technologies determined the financial globalization process and influenced significantly the financial systems both of the developed countries and of the ones in course of development. Thus, these are characterized by the free circulation of the capitals, the creation of liquid financial and inter-connected markets, the intensification of the competition between markets, as well as between the financial institutions.

Under these changes, it has been registered a significant development of the financial markets, but also an increase of the instability of the interest rates, of exchange rates, of prices in general, that determined the creation of new instruments and of protection markets against risks. Within those, one should mention from the point of view of the spectacular development and of the economic implications, the derivative financial products and markets on which these are negotiated.

2. Recent Developments in the Global Derivatives Markets

The derivative financial products allow the protection against the risks regarding the currency, the interest rates, credit etc., but they are used also for performing arbitration and speculation operations. The main derivative products are represented by the forward contracts, futures contracts, option contracts, and swap contracts and from 1990 a major innovation is brought by the credit derivatives.

By means of the derivative products, the participants from different markets can be protected against the fluctuations of the interest rates, of the exchange rates or of other prices of the assets.

In the last thirty years the use of derivatives and the range of products available for companies have grown spectacularly worldwide. According to the estimations made by the Bank for International Settlements (BIS) in its statistics about the evolution of the volume of traded derivatives, the total market value of derivatives increased from 94.253 billions of US dollars in 1998 to 613.089 billions of US dollars in June 2007 as figure 1 shows.

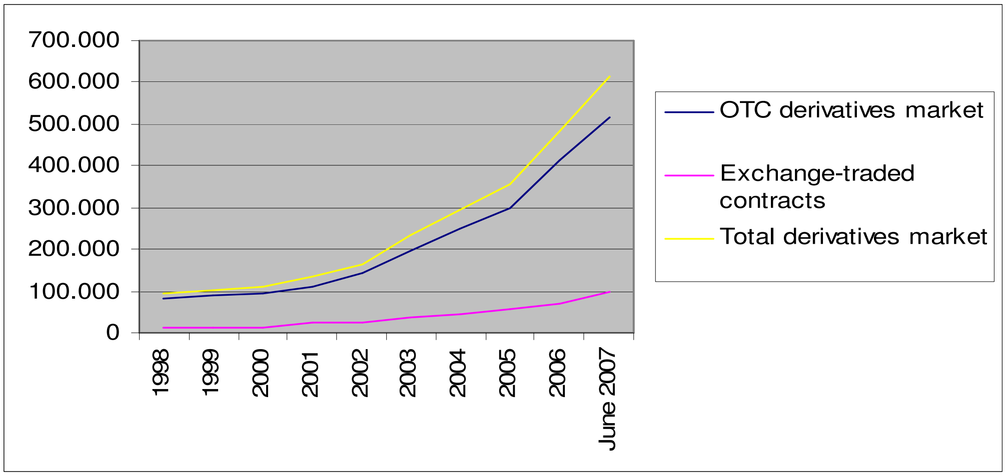

Figure 1 Evolution of global derivatives markets in 1998-2007 (notional amounts in billion of US dollars)

Source: Bank for International Settlements, www.bis.org

In June 2007, the total amount of derivatives traded over-the-counter was \$516.407 billions, from which 52.64% represents interest-rate swaps. In 1987, the notional amount of interest-rate swaps outstanding was \$865 billion; 20 years later, it was \$271.853 billion, implying growth at an average annual rate of 15 percent. The growth of interest rate contracts was mainly due to market participants' changing perceptions about the future path of policy rates. Consequently, the increase in turnover was greatest in derivatives on short-term interest rates, both futures and options, whereas activity in long-term bonds contracts declined slightly.

In terms of outstanding, however, OTC markets are five times bigger than organized markets. In fact, it is not possible to compare the statistics for the amounts outstanding in the two types of market because the figures for organized markets reflect open interest only (i.e. positions not offset by countervailing transactions).

The notional amount of exchange-traded derivatives (options and futures) grew from \$13.935 billion in December 1998 to \$96.682 billion in June 2007. By far the most commonly traded derivatives on organized markets are interest rate contracts, accounting more than 50% of the total number of contracts in the last five years. The international derivatives market CME Group continues to expand its position as the world‘s largest derivatives exchange with record open interest on the exchange.

3. The Influences Exercised by the Significant Usage of the Financial Derivatives

The financial derivatives have as main function the risk's transfer; they allow to stand a risk considered bearable and to transfer the undesired risk part towards other operators that accept it due to their position opposite to the respective risk or from the desire to perform speculative operations.

The transfer of the risk by means of the derivative products can be accomplished due to their capacity to establish prices for risks and to separately negotiate different elements of the price risk for the support-assets, on the one hand; on the other hand due to the lever effect of these products, allowing the users to negotiate the risks without being necessary to acquire or sell the support-assets [4, p.100]. The leverage effect of the derivative products allows the users of these products to achieve a considerable volume of operations with limited expenditures and with reduced transaction costs. For example, the futures agreements allow the opening of positions, immobilizing only a low level of liquidities under the form of the guarantee deposit. In a similar way, the option agreements allow the opening of positions if the option's buyer pays a bounty that can be modified according to its expectations of gain.

The leverage effect that characterizes the derivative products stimulates the performance of speculation operations that are much easier to be achieved on the derivative markets in comparison with the markets of the support-assets, a fact that explains the considerable growth of the speculative positions and of the volatility of the markets, but also of the losses if the anticipations do not come true. Thus, the derivative products can constitute also a factor of instability for the markets.

The main function of the derivative of protection against risks allows the reduction of the incertitude by using these products so that one can better appreciate if he/she contributes to the creation of a more favorable climate for the development of international transactions and investments.

The development of the derivative financial products can also contribute, under normal conditions (where no tensions appear on the markets), by stimulate of the transactions from the support-assets markets. This is due to the fact that the derivative products facilitate the coverage of risks, stimulates the investors to acquire support-assets and this allows the development of the respective assets' markets, the amelioration of the liquidity and their efficiency. For example it was observed that the derivative markets facilitate the issuance of securities of the public debt because they allow the agents that buy them to protect themselves against the interest rates' risk.

In the context of financial globalization, the accentuated development of the financial markets and especially of the derivative financial products' market has significant implications also over the activity of the bank institutions. As a result of the deregulation, subdivision and non-intermediation process, it was registered an intensification of the competition between the bank financial intermediates and the non-bank ones, the diversification of the bank institutions' activities and, at the same time, the reassessment of the role of the banks in the economy.

In respect to the derivative financial products' markets it was established a considerable involvement of the bank institutions on these markets, aiming to improve the financing conditions, the administration of the own risks but also of the clients' risks. The banks take part on the derivative markets both as dealer of derivative financial products as well as users, being at the same time the main intermediates on the markets, according to the agreement. Thus in some countries where the process of bank non-intermediation is accentuated (for example in Great Britain or USA), the operations with derivative products performed between the banks hold the predominant share from the total number of transactions from the derivative markets.

The increase of use of the derivative financial products at the level of bank institutions, in the context of bank non-intermediation has contributed to the development of their operations on the financial markets that means the diversification of bank activities and of income resources.

At the same time, it can be observed the fact that, in the event in which the bank institutions develop activities with derivative financial products without complying with the bank caution, there appear errors in the bank system that can determine the manifestation of a system crisis.

Another significant influence of the fast development of the derivative financial products is the one of the monetary policy. The accentuation of the financial innovation process in general and the increase of the usage degree of derivative financial products in particular have determined the growth of the monetary policy's complexity and the difficult evaluation of its impact over real economy.

Since the turn of the millenium, the amount outstanding of futures and options on short-term interest rate has grown significantly. Statistics and econometric evidence show that there is a the relationship between turnover in this market and changes in policy rates operated by central banks, both actual and expected [3, p.1]. The volume of trading with interest rate derivatives appears to respond mainly to changes in expectations of future interest rates.

The outlook for monetary policy promoted by the central banks represents an important driver of activity in the derivatives market. Even if central banks control only the short-term interest rate, their actions have an impact on the whole spectrum of yields and on other asset classes. A study conducted by the Bank for International Settlements on the G3 economies (SUA, Japonia şi UE) show the existence of a relationship between monetary policy and turnover in exchange-traded derivatives [3, p.1]**.** The market participants' changing perceptions about the future path of policy rates tend to have to have an important impact on activity in most exchange-traded money market derivatives. In the same time, anticipated changes in spot rates have no effect on the turnover in most exchange-traded money market derivatives. Increased uncertainty about future central bank actions is also associated with higher turnover.

The development of derivative financial products influences the transmission speed of monetary policy decisions, supposing that they can attenuate their efficiency [5, p.109]. For example, using swap agreements on the interest's rate could delay or accelerate the impact of the directive interest rates' modifications performed by the central banks over the debtor economic agents, in the following manner: the economic agents that anticipate the decisions of restrictive monetary policy and owe a variable interest rate have the possibility to limit the impact of these rates over the financing plans by modifying the loan's characteristics, respectively by transforming the initial loan (contracted at a variable interest rates) in a loan with a fix interest rate. Under a reversed situation, the economic agents that anticipate a relaxation of the monetary policy can accelerate its effects over the financing plans by transforming the debts, employed at a fix interest rate into debts at a variable interest rate. But such an influence of the derivative products is limited and manifests itself on the short term if we take into consideration the fact that the anticipations can be incorrect. Moreover, even in the case in which the anticipations prove to be correct, not all economic agents can act in the same manner and so some of them will be eventually affected by the modification of the directive interest's rate.

Another aspect regarding the implications of the derivative financial products over the monetary policy aims the influence over the transmission mechanisms of this over the real economy. For example, the use of derivative products can attenuate the role of the exchange rate's mechanism. This is due to the fact that the economic agents that perform foreign trade activities can protect themselves against the fluctuations of the exchange rate by means of the derivative financial products (especially by means of swap agreements on currencies, futures and currency options). But, on the long term, the fluctuations of the exchange rate influence the price level and, consequently, the production decisions of the economic agents.

The development of derivatives markets influences also the structure of monetary aggregate. The low cost of hedging or the low interest rate risk of T-bonds have determined a reduction oh the risk associated and transform them in alternative to banking deposits, which represents components of monetary aggregate.

The markets of the derivative financial products offer new information to the monetary authorities, regarding the anticipations of the participators on the markets over the prices' future evolutions of the support-assets. Such information can be used by the central banks for a better grounding of the monetary policy decisions.

After the 1990s, the crises registered on stock exchange and real estate markets of numerous countries reflect the important role of the price of real estate shares and goods within the mechanisms of transmission of the monetary policy as their value is sensitive to the fluctuations of the interest rates. What is more, the practice shows that the prices of real estate goods grow significantly in comparison to the share prices, in the context of the excessive relaxation of the crediting conditions in a country.

The problem of the derivative financial products that has been discussed for a long time in the literature, regards their impact over the stability of the financial systems and their role in the occurrence of the systemic risks. Although it is well known the fact that the main function of the derivative financial products is to offer protection against financial risks, one should never forget that, at the same time, they build an instability factor due to the leverage effect that allows the opening of significant speculative positions (for example the case of Long-Term Capital Management). The practical experience highlights the fact that the derivative products can, during periods of tension, amplify the instability of the prices and emphasize their fluctuations.

In respect to the role of the derivative financial products in the occurrence of the systemic risks, some specialists in this field are frequently invoking, as an example, the case of the credit derivatives. The market of the credit derivates has registered in the last years a very fast development and the value of the transactions with credit derivates are significantly increasing, according to the estimations of the International Regulations' Bank, from 180 billion USD in 1997 to 42.580 billion USD in June 2007. [1, p. 104]. Although the market of the credit derivatives is much more restricted in comparison with other markets of derivative products, the accentuated development of the transaction with credit products would reflect the fact that the credit risk is considered much more important in comparison with the exchange rate risk or interest risk.

Credit derivative products appeared in the early 90s in USA and represent a new instrument of protection against the credit risk, used on large scale by the banks. By means of the credit derivatives, the bank institutions transfer the credit risk to some investors, such as insurance companies, mutual funds or hedge funds.

The fast development of the credit derivatives markets can determine the apparition of financial crisis (for example, the recent USA crisis from the bank and real estate market that had significant implications also over other countries, including over our country), because the transfer of the credit risk is performed mainly towards the investors much less capitalized and that are not bound to some strict regulations. At the same time, these markets are "Over the Counter" markets that through their nature are less transparent. Moreover, the significant implication of the bank institutions in the transactions with credit derivatives highlights the use of these products without complying with the bank cautiousness; a fact that can determine can determine the manifestation of instability at the level of the bank system and even the apparition of the systemic risk.

4. Conclusions

In the last years, in the context of globalization, the financial systems from the majority of the world states register significant economic transformations, especially through a very fast development of the markets of derivative financial products (especially of the credit derivatives) and through the intensification of the hedge funds activity. In this context, the financial systems have become more complex and less transparent so that the monetary authorities confront themselves with difficulties regarding the evaluation of potential risks that threaten the financial stability.

The financial crisis that manifest themselves in the context of financial globalization (especially the crisis from the Asian markets and the recent crises from USA) have determined the intensification of the preoccupations of the monetary authorities from different countries, including of some international institutions (The International Monetary Fund, The Bank of International Settlements) so that they evaluate the implications of the speculative derivative financial products (hedge funds) over the financial stability. Such preoccupations have at least two reasons. On the one hand, a large proportion of the transactions with derivative financial products are being performed by the banks and, consequently, the use of those products that don't comply with the bank cautiousness could determine the instability. On the other hand, the intensification of the direct relations between the bank institutions (especially between the most important banks) and hedge funds can be the source of financial instability of systemic type.

The disastrous effects of the financial crisis, manifested in the context of financial globalization, impose the preoccupation of the monetary authorities for the rigorous analysis of the relationship among the prices of the shares, of the real estate and the economic activity, as well as for the outline of the monetary models that include the prices of these assets for the orientation and the evaluation of the monetary policy.

Abstract: Urban and rural areas differ in many aspects. One of them is the relevance of agricultural in rural areas. Agricultural is distinct from other sectors because of the seasonality, geographic limitations, price volatility and dependence on natural conditions. Moreover, the rural populations are often poor and have great difficulties in managing risk, coping with shocks and accessing consistent cash-flows. These differences may affect the characteristics necessary for the success of the financial institutions operating on rural markets.

This paper outlines the various risks of rural finance, discusses the cost involved in agricultural lending and presents techniques for risk and cost reduction.

Key words: rural lending , credit, agriculture, financial institutions,risk, costs

The Risks of Rural Lending

Moral Hazard

As in any lender-borrower relationship, there is a general problem of moral hazard that is the result of specific personal characteristics and decisions of each individual borrower. In this regard, rural population do not differ from any other borrower group in terms of information, incentives, monitoring and enforcement problems associated with the lending process.

Production and Yield Risk

Agricultural yields are generally uncertain, as natural hazards such as the weather, pests and diseases and other production calamities impact on farm output. Even slight changes in weather conditions - less rain than usual - can seriously impact on farm production. Pests and diseases may spread quickly, leading to a loss of part or all of the crop's produce. The soil quality of the plots as well as their location also significantly influence productivity and yield risk. Seasonality of agricultural production provides an additional risk.

For all these risk management techniques, the experience of the small farmer is the core requirement for good results. Accordingly, prudent lending decisions need to be based on an assessment of the management capacity of the farmer.

Price and Market Risk

Price uncertainty due to market fluctuations is particularly significant where market information is lacking or scanty, or where markets are imperfect – features which are prevalent in many developing countries. The relatively long period of time between planting a crop or starting livestock activities and the realization of farm output implies that market prices may change from

what has been projected. This problem is particularly relevant for longer term agricultural activities, such as perennial tree crops like apples or citric culture, as several years lie between planting and first harvest. Price fluctuations may be particularly severe in export markets. Over-production, however, may also considerably influence domestic market prices. In many countries, price uncertainty has increased with liberalization of agricultural marketing. Market risk also includes the potential losses involved in marketing agricultural products. Transportation, as has been pointed out earlier, is a major challenge in many rural areas. Substantial losses may also occur due to a lack of appropriate storage facilities.

Lack of Diversification

Price and market risk, as much as production and yield risk, is higher for farmers concentrating on a single crop or livestock activity. Accordingly, many farmers apply risk diversification techniques to reduce these risks. Complementing market-oriented production with subsistence farming is one particular safety-net arrangement, which provides survival measures once yield, production, price and market risks diminish the profits made. Besides this, many farm households incorporate in their overall diversification strategy also non-farm activities.

Lack of Collateral

Most small farmers possess little to no assets. Even fewer small farmers possess land titles or goods which are traditionally used as loan collateral by banks. The most accepted asset for use as loan collateral is land, because it cannot be removed but can generally be transferred at a specific market price. Small farmers' land, however, may also have a very limited value if there is no land market. Land titles may also be unavailable or costly to obtain. Finally, land registration is often imperfect in many countries.

Political Risk

Political interference in agricultural markets is a common feature to be found in many developing countries. Price intervention in agricultural markets, for example, is popular, as low food prices are in the interest of urban consumers. On the other hand, fixed prices for agricultural produce are also a frequently used political tool to ensure a certain level of income for small farmers. Agricultural lending has a long-standing history of political intervention and distortion, which substantially contributed to the disinterest of commercial lenders in this business.

The Costs of Rural Lending

Lending to small farmers can be a costly endeavor. As a matter of fact, lending in rural areas is generally more expensive than lending in urban areas. Clients are widely dispersed, and long distances have to be traveled by loan officers and/or customers. Lending in small amounts is, in general, more costly than lending in bigger amounts, as the cost of assessing, monitoring, and following up on loans does not decrease with the size of the loan. Rather, substantial parts of administrative lending costs are of a fixed nature.

The key cost driver in lending is the necessity to obtain substantial information about the potential borrower and to be able to do a close monitoring. Information is vital in assessing and managing risk.

Dispersed Clients

Low population density coupled with dispersed location of rural clients make the provision of formal financial services costly. Both from the lender's and borrower's perspective, the long distances between communities and the inadequate rural transportation facilities in many developing countries increase the costs of loan appraisal, loan monitoring and enforcement of loan repayments.

Limited Existing Information Base on Potential Customers

There is a general absence of credit histories as few financial institutions offer the possibility to generate a track-record with them. Beginning a relationship between the agricultural lender and a client is particularly costly and involves substantial "start-up" information costs. The lender must capture key first-hand information from the borrower, which requires time and experienced staff. After establishing a track record with the agricultural lender, the information costs diminish.

Limited Written Documentation to Base Credit Assessment On

Small farmers usually show a low level of formal education and are not used to manage written documents or keep records. Consequently, the loan appraisal must often be based on capturing first-hand information by interviewing the potential borrower.

Complexity of Economic Activities of Rural Households

This diversity in farm and non-farm income-generating activities of rural households requires better knowledge of the farm household financial situation. This can extend the bank staff time (and expenses) needed for loan appraisal. It may also require the setting of individual loan repayment terms. It is likely to increase the costs of training agricultural loan officers.

Demand for Variations in Lenders' Institutional Capacity

As agricultural production, the agricultural lending business is largely seasonal. Given the fact that seasonal agricultural activities are very time-sensitive, credit appraisals must be carried out within a short period of time and timely loan disbursements must be ensured. Consequently, the institutional capacity of agricultural lenders must adjust to these variations of credit demand during the year. There might be a need for additional, temporary staff in financial institutions during peak periods while in other months a reduced workload in agricultural lending must be off-set by other lending activities. Cost-effective planning for adequate staff and institutional capacity (liquidity requirements) is therefore a challenging endeavor.

Risk and Cost Management in Rural Lending

Given the complex risk structures and high administrative costs, efficiency is essential in agricultural lending. Thus, implementing streamlined policies, procedures and tools is a must. However, standardization in agricultural lending has to deal with the challenge of a high degree of heterogeneity of the farmer clientele and the complexity of economic activities within each farm household.

Risk Management

In order to reduce **production, market and price risks**, the following measures can be taken:

- An assessment of the specific risks that are associated with different agricultural production activities in different areas is essential in determining the potential risk exposure of lenders.
- Loan appraisal should include a thorough assessment of the borrower loan repayment capacity and his creditworthiness; also external risk factors of farm production should be taken into account.
- Individualized loan products and loan repayment schedules that are set in accordance with the loan repayment capacity of the borrower reduce the risk of loan default
- Collaboration with organizations which know farmers well reduces client information costs and risks of lenders.
- Rural lending should start in production zones that present low risks; operations can then gradually be expanded to more risky areas.
- The loan term and repayment installments are tailored to the estimated net cash flow of the prospective borrower. Farmers who rely only on farm production activities normally pay back their loans in one installment after selling their farm produce. Others are capable of repaying their loans in periodic installments. These farmers have a more diversified income base with relatively stable monthly income flows from non-farm activities and salaries or remittances from other family members.
- Loan portfolio diversification serves to protect rural lenders against covariant risks. Rural lenders should diversify their loan portfolio by financing a mix of loans with different lending purposes, loan terms and loan repayment schedules. Still, rural lenders need to set ceilings on the share and volume of total farmer loans by zone.
- Managing of external risks through insurance (single-peril crop insurance, multi-peril crop insurance, crop-revenue insurance, livestock insurance, equipment insurance, house insurance, health insurance etc).
- Staff incentives systems motivate staff and effectively increase their lending productivity. The loan portfolio growth and loan portfolio quality should be an important reference point in performance-based incentives for loan officers.

In order to reduce **moral hazard related risks**, the following measures can be taken:

- Clear information should be given to borrowers on the financial conditions of loans and loan repayment obligations (interest rates and fees, collateral requirements, loan repayment terms and contractual loan obligations). The objective of client education is to promote a positive credit culture and to foster mutual respect between the lender and the borrower.
- Co-signing of loan contracts and moral persuasion are effective means to enhance good credit discipline. Sometimes, both husband and wife sign the loan contract. This extends the lender-borrower relationship to the whole household and it deepens the sense of obligation by the borrower.
- Close contacts between the lender (loan officers) and the borrower are conducive for an atmosphere of mutual trust that improves credit discipline.
- Partnerships with agricultural products processors in well integrated marketing chains can significantly reduce the risks (and costs) of rural lending. The intervention can be applied in the selection process: processors' field agents know the producers and can make a pre-selection based on their personal knowledge of the producers' morality and ability; this contributes to greatly reducing the intermediation expenses for the lender; in order to ensure that the pre-selection process done by the agro-processors is done seriously, it is preferable that they carry a portion of the risk.

Risks from changes in domestic and international policies can be alleviated through the following measures:

- Rural lending institutions should be free of political interference in their daily management.
- Rural lenders regularly need to monitor policy and market changes that affect their rural (especially agricultural) clientele.

Collateral substitutes replace more conventional types of loan guarantees and can provide important loan repayment incentives. These types of collateral have a more psychological than actual market value. Among the various types of collateral substitutes we can mention:

- Group guarantee in case of group lending. Even if all financial transactions are conducted directly between the bank and the individual group members, peer group pressure, however, is activated at the time when loan repayments are due, as new loans will be only provided when all members of the group have fully repaid their loans.
- Pledge assets. In the case of small loans to low income borrowers, the assets involved have a limited market value, but they are highly valued by their owners who would have difficulty in replacing them. Typically, these goods include household appliances and furniture as well as farm equipment.
- "Symbolic" forms of loan collateral. These can include the physical possession of land title documents by the bank during the course of the loan. Pledges of future crop harvests and household savings are also accepted, although they are not legally enforceable.
- Co-signers or guarantors. Two types of guarantors can be used: i) "moral guarantors", who have a close relationship with the borrower household, are required for small loans. They are used mainly as prevention against moral hazard. ii) "personal guarantors", on the other hand, are appraised in the same way as the borrower and, in the case of loan default, they are responsible to meet all the loan obligations.
- Guarantee funds available in different countries.
- Lending risk insurance. Banks can contract global non-payment insurance with an insurance company for all its rural loans. The costs of this insurance are worked in the interest rate charged to each individual customer; the insurance replaces other collateral requirements.
- Partnership schemes agricultural products processors in well integrated marketing chains. The intervention can be applied in the recovery process, by deducting installments directly from the processors' payments to the producers that would be assigned to the bank; this arrangement requires signing a three party agreement.
- Partnerships with agricultural equipment suppliers in order to facilitate liquidation of collateral in case of need.

Cost Reduction

Rural lending is a costly business because it serves a **dispersed rural clientele**. Many of the cost reduction strategies, as outlined below, involve heavy initial overhead costs. This implies that they do not produce a return in a short period of time and an assessment should be made of their long-term cost effectiveness. Main strategies to reduce the financial transaction costs include the following:

- Adopting a cluster approach: choosing larger villages with good agricultural potential and with a village headman who is willing to participate actively in lending activities such as spreading information and organizing meetings.
- Using innovative information and communication technology (various forms of branchless banking-model)
- Decentralization of lending decisions to branch staff and loan officers.
- Delegation of parts of the appraisal, disbursement and monitoring procedures to other groups that are in close contact with the borrowers, e.g. community groups/associations, business development centers etc.
- Applying appropriate route-planning to avoid excessive traveling and reducing transport costs.
- Investing in qualified, well trained and highly motivated field staff in order to have has a positive impact on the lending productivity.
- Using a standard loan appraisal form with standard loan assessment indicators, which are computerized.
- Using simplified loan appraisal procedures to reduce the time required for loan processing, loan approval and loan disbursements.
- Defining borrower pre-selection criteria to sort out borrowers with an insufficient repayment capacity or unwillingness to repay at the earliest stage possible of the loan appraisal.

Limited existing information on potential clients as well as **limited written documentation** can be reduced by the following measures:

- Close contacts with local organizations and networks provide relevant client information.
- Loan officers with agricultural knowledge, good communication skills and well accustomed with the local region can significantly reduce the time and costs of collecting information and to prepare the credit files.
- Effective management information systems provide crucial information (appropriate client information system and a comprehensive database which tracks customer performance and economic activity profiles).

Seasonality and complexity of activities in rural households require specialized and well trained loan officers. The productivity of rural (agricultural) loan officers, in contrast with urban lending activities, is subject to seasonal fluctuations. Diversification of the rural loan portfolio in terms of location and lending purposes helps to balance the uneven staff work load due to the seasonality in agricultural lending. At the same time, the skills, knowledge (background in agronomy, farm management, rural economy) and personal qualities of the loan officer are prerequisites for efficient loan appraisal.

ABSTRACT:Country risk is a relatively new concept in economical reasoning, that has entered in researchers attention only in 70es. The assessment of country risk by the international financial institutions, has extended in the same time with the increasing of external activities of private commercial banks in course of development.

KEYWORDS: country risk, economic growth, banking system, budget deficit

Most of the human actions present a certain dose of uncertainty and risk, due to the man, and also because of environmental elements.

Country risk is a relatively new concept in economical reasoning, that has entered in researchers attention only in 70es. The assessment of country risk by the international financial institutions, has extended in the same time with the increasing of external activities of private commercial banks in course of development.

The assessment of country risk has as an aim pointing out the difficulties that can occur in paying the bonds by a certain country that comes with its external affairs. Until the 70es, losses because of country risk factors had been neglected, reason for which private banks granted loans way to much over the prudence limit, especially to rich natural resources countries from Latin America. As a consequence, debt crisis from 80es has unbalanced the entire international financial system, causing great losses to external creditors. Then it became obvious that ignoring country risk is a source of uncertainty and risk that can lead to eliminating firms from the market. The only way to reduce the ambiguity is to know very well the economical, political and social external conditions, exactly what is wanted to know with evaluating the country risk.

In the next tab we have a presentation of the assessment of country risk, elaborated with Euromoney method, for Romania and Bulgaria. It contains the period between 1993 – 2005, and the changes in two respectively five years.

Assessment of country risk for Romania and Bulgaria. between 1993 – 2005

Country	**1993-2005 (%)**	**1993-2005 (%)**	**1995-2000 (%)**	**2000-2005 (% modificated)**
BULGARIA	28,65%	8,59%	0,47%	17,92%
ROMANIA	-5,33%	14,68%	-42,50%	43,58%

Romania joined the EU on 01.01.2007, but this accession was coupled with strict supervision is numerous areas. The EU will continue to monitor Romania’s progress in meeting these requirements and may invoke so-called safeguard clauses up to three years after accession. The accession treaty provides for safeguard clauses in the areas of economic integration and common market as well as justice and home affairs. Possible sanctions in this respect are export barriers for foodstuffs and a reduction in EU structural and agricultural funds. In addition, transition periods have been established for the free movement of Romanian workers. The Commission may also introduce measures to ensure the correct administration of EU policies. This concerns the areas of food safety, air traffic safety, agricultural subsidies, the judicial system and the fight against corruption.

Economic growth in 2006 was driven primarily by domestic demand, which was supported by higher wages, an increase in private credits and a loosening of fiscal policies. Growth is forecast to slow somewhat in 2007 due to lower real wage increases, a more restrictive fiscal policy and declining foreign demand.

Economic success has led to a weakening in the balance of foreign trade, but the negative effects of this development were moderated by strong confidence resulting from EU accession and a high pace of investment activity. However, the exchange rate risk may increase over the medium-term if the budget deficit and current account deficit rise and income from privatizations declines at the same time.

The textile industry has become one of the most important sectors of the economy, employing more than 20% of the workforce. In addition, the role of Romania as a location for automotive component suppliers is growing. Strong development is expected in the foodstuff production and processing sector as well as waste disposal, technology and energy.

Despite this overall impressive economic performance, there is considerable need for reforms in many areas. Excessive red tape, persistent legal uncertainty, a deficient infrastructure, widespread corruption and the fact that 35% of the total workforce is employed in the agricultural sector reduce Romania's attractiveness to foreign investors. FDI reached a record level of EUR 8 billion in 2006, but a decline is forecasted for 2007.

Economic relations with Austria are considered excellent, with more than 3,500 Austrian investments registered in Romania since 1990. Goods with a value of more than EUR 1.8 billion were exported to Romania in 2006, which represents an increase of 30% compared to 2005. Exports from Romania to Austria amounted to EUR 800 million in 2006. This makes Romania a very important trading partner for Austria, more important than some EU countries and equal to Russia.

Selected Indicators 2003 to 2008 for Romania

Key Data	**2003**	**2004**	**2005**	**2006**	**2007**	**2008 (f)**
GDP (real in %)	5.2	8.4	4.1	7.1	6.3	5.5
Consumer prices (%)	15.3	11.9	9.0	6.5	5.3	4.5
Gross fixed capital formation (real in %)	9.1	10.8	13.0	12.5	13.0	13.4
Unemployment (%)	7.2	6.3	5.9	6.1	6.3	5.2
Budget deficit (in % of GDP)	-2.2	-1.1	-0.8	-0.9	-3.1	-2.4
Merchandise imports (million EUR)	22,200	30,200	37,300	52,000	60,000	55,400
Merchandise exports (million EUR)	17,600	23,500	27,700	36,600	40,800	36,000
Current account (million EUR)	-3,100	-5,700	-7,800	-13,800	-18,200	-13,200

During the third quarter of 2006, GDP growth rose by a real 6.7% over the comparable prior year period. This represented the strongest quarterly development since the start of transition as well as a slight increase over the real growth of 6.6% recorded for the previous quarter. The structure of GDP components on the demand side point to a slight improvement in the pattern of growth, whereby the gap between positive effects of domestic demand and the negative effects of net exports declined moderately compared with both 2005 and the first half of 2006. Consumer spending increased by a strong 7.4%, as individuals grew more confident in their capacity to earn and spend more.

The high pace of economic expansion will continue in 2007, supported by favorable external conditions and solid growth in domestic demand. Although only a marginal decline in inflation is expected, private consumption should remain resilient. Forecasts also indicate a positive short- to medium-term outlook for investments. Accession to the EU has highlighted Bulgaria's advantages as a low-cost location for businesses and this, in turn, has created additional stimulus for the inflow of foreign capital. In addition, the more than four-fold increase in the potential volume of EU grants will contribute to GDP growth over the short run.

After years of self-imposed constraints (to keep the large current account deficit in check), access to the structural and cohesion funds is likely to spur capital expenditure in the public sector during 2007. During debates over the new federal budget, the Minister of Finance underscored the plans of the ruling coalition to press ahead with the implementation of several large infrastructure projects. The new budget reflects an increase of 22% in spending over the base year to a level of EUR 1.3 billion (or 5.3% of projected GDP).

The seasonal decline in inflationary pressure during the summer came to an end in September. Inflation accelerated during the last three months of the year to a level of 6.5% in December and 7.3% on average for the whole of 2006. The general increase in the price level resulted primarily from a sharp rise in food prices.

The most recent statistics provide a mixed picture of external economic performance. The current account deficit – which is viewed as the major weak point in the economy – increased from 9.4% in 2005 to 12.9% of GDP during the period from January to November. However, the foreign trade deficit has remained essentially unchanged at roughly 20% of GDP for more than a year. Merchandise exports were 27.4% higher in year-on-year comparison at the end of November, and thereby exceeded the 24.2% increase in imports.

Selected Indicators 2003 to 2008 for Bulgaria

Key Data	**2003**	**2004**	**2005**	**2006**	**2007**	**2008 (f)**
GDP (real in %)	4.5	5.7	5.5	5.8	6.0	6.3
Consumer prices (%)	2.3	6.1	5.0	7.6	6.8	4.7
Gross fixed capital formation (real in %)	13.9	13.5	19.0	21.0	16.5	12.0
Unemployment (%)	12.7	13.0	12.0	10.0	9.2	8.5
Budget deficit (in % of GDP)	-0.4	1.5	2.3	3.0	1.0	1.5
Merchandise imports (million EUR)	8,900	11,000	13,800	17,400	21,400	25,000
Merchandise exports (million EUR)	6,700	8,000	9,500	11,300	13,400	15,000
Current account (million EUR)	-1,600 -	-1,600	-2,400	-3,100	-3,900	-3,400

GPD growth accelerated during 2006 and is expected to peak in 2007. EU accession has underscored the positive attitude of international investors and will keep foreign direct investment above 10% of GDP for the fifth year in succession. The pace of economic development will also be supported by an increase in capital expenditure by the public sector and strong growth in private consumption. However, opportunities for reducing the current account deficit will be limited because rising fuel prices and higher demand for investments will absorb the positive effects of the steady increase in exports. The strengthening of the country's competitive ability remains a key priority of economic policy, but will require the continuation of structural reforms. The government agenda for 2007 will be focused on preventing the activation of safeguard clauses and ensuring the maximum possible utilization of EU grants.

In 2006 Coface Romania has made public Romania's rating emitted by Coface Group. Romania has been been included for the first time in the A category of country risk, being assessed with the A4 mark. Coface emits ratings for 151 countries, analyses 44 million companies from all around the globe and it's a global leader in export loan insurance, and has a quotation of 25%.

If in 2005 Bulgaria had been been evaluated by Coface with B+ while our country had B, Romania ascended another level in the hierarchy, to A4, instead Bulgaria maintained its rating. The rating is reflected also in indicators like life standards purchasing power, that in Romania are better comparing with other countries in course of development. For example, according Coface analysis, in Romania exist 69 computers per 1000 inhabitants, while in other countries in course of development is 37 (the regional average is 84 computers per 1000 inhabitants).

The main consequence of A4 country rating for Romania is that it will enhance the access on international markets and the credit limits of Romanian companies for commercial credits, from their external partners, other international creditors or from financial risk insurance companies. This will lead to an increase of commercial relations volume especially in EU countries and enhancement of Romanian business environment credibility on international scale.

Abstract: This study is aimed to describe the actual stage and the developing opportunities for settlement of the debit payment instruments in Romania. We present the settlement system of the debit payment instruments during the period 1999 until present. We underline the actual stage of the compensation of the debit payment instruments through Transfond and comparatively with the description of the automatic process of the debit payment instruments. We examine the technical ways to preparing the debit payment instruments, especially the two proposals for operating the debit instruments through truncation – the truncation at the source and the flexible truncation method.

Key Words: Debit Payment Instruments, Automated Processing Solutions

Introduction

Among the banks' operations we identify the banking specific operations carried out directly by the banks, pertaining to the essence of the banking activity, like issuing and administering payment instruments and making payments. The operative and efficient functioning of the national banking payments system leads to a more frequent utilization of this system by the population and the economic entities.

In such an economic context, the interest of banking societies and of the national banking authority – National Bank of Romania – is to develop and maintain viable payment systems. Otherwise, National Bank of Romania carries out operations with banking companies and other credit institutions, consist of regulate and supervise payment systems, ensure services of compensation, depositing and payment. The involvement of the National Bank of Romania in building a modern national banking payment system is obvious. We affirm that relying on the structural changes at the level of banking payments, sustained by National Bank of Romania.

We chose the debit payment instruments as the object of the study, because from 2007 in Romania there is a project to automated processing of the debit payment instruments. Initially, this new system had to be operational starting at 1 April 2008, according to the agreement between national authorities and the World Bank. But this date was impossible to respect, especially because of the delays in the primary legislation adoption which modifies conditions for the debit payment instruments. From the moment of the legal framework adoption it is foreseen that it would be needed an almost 4 months transition period from the present processing way, manually towards an image processing method. In the 11-th of April 2008 were published the modifications of debit payment instruments legislation in the Official Gazette of Romania, which will be applied in 30 days from their publishing. Then in a 30 days term, the National Bank of Romania must elaborate norms for the primary legislation application.

The processing of the debit payment instruments through Transfond

The study of the settlement of the debit payment instruments did not make without the presentation of the role of Transfond society. In the year 1999 the Romanian National Bank decided to externalize the funds transfer operations and the compensation operations, and in the year 2000 is created according to the engaged settlements to the European Union, the National Company of Funds Transfer and Settlements Transfond SA, as an operator of the national payments system and the majority stockholders are the National Bank of Romania (33,33%) and the main banks that are operating in the Romanian banking system (66,67%). In the year 2001, became operational the externalizing the payments activity decided by the National Bank of Romania towards Transfond SA (excepting the funds transfers related to the State

Treasury). The Transfond SA company took the old locations of the National Bank of Romania (42 locations) where the compensation took place and the payments instruments circuit with or without cash or paper support, meaning that the payment document had to appear in physical shape at the payer, not being possible the electronic circuit of the payment documents (as well as for the less and unequal development of the banks infrastructure, as well as for not existing the needed legal settlements).

The Transfond SA Company had as main purpose for its activity financial intermediations and auxiliary activities of the financial institutions, as it follows:

- Operating the funds transfers realized as net or gross shape between the banks, State treasury and other financial institutions through settlements accounts or other types of accounts and irrevocable and no conditioned settlements of these transfers in the current accounts and the evidence accounts maintained through law by National Bank of Romania, including agent for the central bank;
- Recording and the transfer for the property over the state creations through evidence accounts of these ones opened in the name of owners recorded and maintaining its evidences, including as agent for the central bank.

The national payments system in the Transfond SA situation functioned in Romania until the year 2005 and during its functioning supported many changes at the procedural level. The credit payment instruments are settled into the elements of the SEP – Electronic Payments System, which function from 2005. But, in April 2008 the debit payment instruments are still settled up classically by Transfond.

In the framework of net settlements of the debit payment instruments through Transfond Company, each day of labour of the year had an imposed compensating session of the inter-banking payments, in its units in territory (41 units) and the central of Transfond (country capital city Bucharest), in special rooms prepared for this, in the morning. The compensatory session is lead by a compensation inspector. Each unit participating names an agent to represent it in the sessions, agent who has the task of preparing the compensation session and of participating as a representing of the banking unit in this session. The preparation of the compensation session is developed outside of the territorial units Transfond. The debit payment instruments are grouped on destination bank (receiving). Between the compensation agents of all banking units that participated at the session, the envelopes are exchanged, envelops that contained the debit instruments packages and compensating centralized dispositions and their annexes, available for the debit payment instruments. After receiving of the envelops with the packages of compensatory instruments where meant for banking units that represented them, each agent verifies them, assures them and goes back to its banking unit. The debit payments instruments are divided between the valid paying instructions and the refuses for the justified cases. These refuses are presented to the correspondents banking units in the second part of the compensatory session.

An overview on the future of the debit payment instruments

To understand the special case of the debit payment instruments in their quality of means of payment, we present the main characteristics of the debit payment instruments. *The bill of exchange* is the document through which a person, the drawer or the issuer, gives an order to another person, the drawee, to pay at maturity, an amount of money to a third person, the payee, or upon his order. *A promissory note* is a document through which the issuer undertakes to pay to the payee, or upon his order, an amount of money, at maturity, in a certain place. Consequently, the promissory note intervenes between two persons, and not three, as is the case of the bill of exchange. Unlike the bill of exchange, it does not contain the payment order addressed to another person, but only the acknowledgment of his own payment obligation. *A check* is a document through which a person, the drawer, gives an unconditional order to a bank, the drawee, in which he or she has available funds to pay, upon the presenting of the writ, an amount of money to another person, the payee. The payee can be the drawer himself (check of withdrawal). The debit payment instruments shall take the form in writing and the document shall comprise the mandatory mentions stipulated in the Law no. 58/1934 and no. 59/1034.

These mentioned regulations did not essentially modify from 1934 and their elements are inadequate to the development of the actual banking area. It is imposed the change of the national regulations. More precisely, the Romanian legislation said that the payments using debit payment instruments are conditioned by their physical transmission between the banking societies involved, so this kind of payments is not made by electronic compensation nowadays. In this circumstances there is a need to change the existing banking regulations (which imply the physical circulation of the debit instruments) because in present the banking settlements with payment debit instruments, being intra or inter banking, are marked by the physical transmission of the debit instrument by postal circuit. In this way we have an unjustified increase of the duration of settlements with payment debit instruments. Also, there is the risk of losing the debit payment instruments.

All the time after ’90 years, in Romania was very important to change the banking regulations which imply the physical circulation of the debit payment instruments. This need became acute in the last years, after 2005, because the banking settlements with payment debit instruments, being intra or inter banking, are marked by the physical transmission of the debit instrument by postal circuit. In this way we have an unjustified increase of the duration of settlements with payment debit instruments.

In December 2007, National Bank of Romania sent to European Central Bank a request for an opinion on two draft emergency ordinances amending Law No. 58/1934 on bills of exchange and promissory notes and Law No. 59/1934 on cheques. In February 2008, the European Central Bank delivered the opinion. The amendments proposed in the draft emergency ordinances are follows: to regulate truncation; to define the concept of signature on cheques, bills of exchange and promissory notes more clearly; to eliminate post-dated cheques, the *allonge* and data/references to data on the back of cheques, bills of exchange and promissory notes; and to introduce a single period for presenting a cheque for payment, regardless of whether it is payable in the city where it was issued.

European Central Bank approved an opinion - advice of payment - on two draft emergency ordinances amending Law No. 58/1934 on bills of exchange and promissory notes and Law No. 59/1934 on cheques. Based on opinion gift by the European Central Bank, were elaborated two law projects, which are on the order list of the Romanian parliament starting with the year 2008. The legislation modification on the cheques, bills of exchange and the promissory notes was necessary for the implementation of the new project of automatic process of the debit payments instruments.

After the first components of the SEP since 2005 (ReGIS, SENT and SaFIR), at the level of the National Bank of Romania of the Romanian Association of Banks and TransFonD began the project named PAID 07-The Automatic Process of the Debit Instruments (Palade, 2007). The project will assure the transition to the un-centralized way of processing characterized by the physic exchange of the debit payment instruments to a centralized way, based on the transmissions of the electronic payment imagines and messages and the electronic compensation of the last ones thought the SENT system.

So, after lot of years of primary changes, in March 2008, the two Government Emergency Ordinances No. 38 and No. 39 amending the debit payment instruments framework – Law No. 58/1934 on bills of exchange and promissory notes and Law No. 59/1934 on cheques. Until now, in Romania the debit payment instruments – the cheques, bills of exchange and promissory notes - are still settled up classically on paper support in the daily compensation meeting at Transfond. The technical aspects of the reimbursements based on the debit payment instruments must make the object of the second legislation given by National Bank of Romania this thing being foreseen for the first part of the year 2008.

The automatic process of the debit payment instruments is supposed to immobilize and un-materialize the instrument at the unit of the beneficiary where is presented for the first time for the settlement. The un-materialization means to capture and transfer all the information’s owned by the physical instrument, together with the scanned picture of this, in a standard electronic message, which is given by the beneficiary bank in the SENT system and then to the bank unit of the payer for checking and compensation. The electronic message process is realized based to a procedure similar applied to the direct debit instructions in the SENT system. The electronic message scurried by the electronic signature, has the same legal value as the physic instrument. The solution assures the process automation creating the possibility of the integrated process of those instruments and assures a low process time. In order to apply such a solution is necessary the legal frame modification regarding the cheque the bill and the order ticket which foresees the compulsory to present the physical instrument of payment.

Changing the debit instruments’ processing implies the removal of paper support circulation by truncating the debit instruments at the beneficiary’s bank, the electronic transmission of the debit payment instruction and of the image, the payment’s validation based on the debit instrument’s scanned image protected by using the digital signature techniques and the guarantee of a high security and automation degree for operating the debit instruments, with low costs and quicker processing.

The truncation of a payment instrument consists of catching the payment information on electronic support and stopping the paper support circulation, the further operating of the payment instruction-taking place only in electronic field. The new image processing technologies allow the payment validation using the digital image of the payment instrument. The automatic operation of the debit payment instruments through the Electronic Payment System would means:

- The truncation of the debit instruments takes place at the beneficiary's bank where the debit instrument is firstly presented for payment;
- The payment instruments are caught on electronic support using specialized machines and will be sent to ACH in MT104 folders, XML format, similar to the direct debit messages;
- The both sides image of the debit instrument is obtained by its scanning either with machines specialized for catching the payment instruments or with usual scanners. The banks will use digital signature techniques for certifying the accordance between the electronic image and the paper support original of the debit instrument and for the further image's legalization;
- The paper support payment instruments won't be sent on interbanking circuit, they will be archived at the entrance in the banking system where the truncation operation takes place, at the beneficiary's bank;
- The debit instruments will be electronically presented for payment through the automatic compensation house SENT as follows: the debit payment instrument and the digital image of the payment instrument are sent from the beneficiary's bank to the central of the bank, from there to SENT where they are registered and sent further on at the payer's bank through his central bank
- The validation of the payment is realized on the debit payment instrument's scanned image at the payer's bank;
- The compensation of the debit payment instruments will take place through SENT similarly to the direct debit operating - the "exception" method, through which the payment confirmation is implicit (the system considers to be accepted for payment all the debit instruments for which it wasn't received a denial from the payer's central bank);
- The debit instruments' images will be kept in three locations: the beneficiary's bank where the truncation took place, the payer's bank and Transfond as a trusted party, so the possible disputes would be quickly solved;
- The participants at the debit instruments operation through truncation will obey the rules referring to the compulsive maximum durations of settlement for debit instruments which will be imposed by regulations.

There are two proposals for operating the debit instruments through truncation the truncation at the source and the flexible truncation variant. In the first way, the truncation will take place at the beneficiary's bank using specialized technology for catching the payment information and the images; the process has been previously briefly described.

The flexible truncation method is the same as the other one, the distinction being that both the location for truncation in the beneficiary's banking structure and the level of specialization for the technology used is decided by each bank, according to the volume of debit instruments operated in the territorial units and to the amount of investment that the bank wants to realize for this purpose. The banks can make a technological mix using less specialized machines for reading the bare code and usual machines for scanning the debit instruments. The truncation flexibility does not imply derogations from the maximum terms of operation, which will be mentioned in regulations.

Conclusions

For the automatic operation of the debit payment instruments there was a need for some changes in this domain, both at the regulation level and at the territorial network level of each bank. The regulations regarding the debit payment instruments had to be adapted to permit the debit instruments' electronic presentation for payment. National Bank of Romania will elaborate the technical norms regarding the debit payment instruments. Banks must adopt a bare code for the debit payment instruments, which would be personalized by the issuer's bank (drawer or subscriber) by completing the codes' line. For this purpose, when delivering the notebook with debit instruments the bank would imprint a bare code on the white band of each leaf of debit instrument with the following information: the issuer customer's IBAN, the number and series of the debit instrument and the transaction code (payment instrument type). There is also necessary the numbering, giving series and keeping the promissory notes and bills of exchange' evidence in the same way as for the cheques' issuing in order to uniquely identify each debit instrument.

For facilitating the automatic processing of the debit instruments and for increasing the accuracy degree of the beneficiary's dates taken from the electronic support at the bank's counter there is recommended the encashment note's personalization by the bank, writing the IBAN code of the name of the account on the encashment note which will be used when he is in the position of beneficiary.

The increase in the volume of data to be transmitted on the internal communication network of each bank especially determined by the transmission of folders with scanned images of the debit instruments brings the need for adapting this increase to the volume of debit instruments, which are truncated by each territorial unit. The machines and the software for imprinting and reading the bare code, for catching and operating the images are another investment decision depending also on the encoding standard which will be adopted (one-dimensional or bi-dimensional bare code) and on the truncation variant chosen by each bank, truncation at the source or flexible truncation.

The paper approaches the merchant banks activity in the context in which the financial markets integration degree and the political boundaries have become less and less relevant to the banking institutions due to the globalization, to the banks international opening, to the financial and techonological innovations, to the deregulation and the process of European integration.

Key words: foreign banks, banking integration, banking performances, financial stability

1.Introduction in the foreign banks activity

The banking activity often acquired an international dimension which outlined itself for the first time in the Renaissance period, moment in which appeared the first banks that unrolled an international activity, such as the Doctor's Banks from Florence. The process continued in time, so that the industrialized world undergoes nowadays the third wave of banking internationalization. The first wave includes the international movement of the capitals, which took place from 1870 until the beginning of the First World War, a period in which the English colonial banks owned the supremacy. The second wave took place, as temporal setting, between the two World Wars, being underlined by the distinctive feature of theAnglo-American financial rivalry and by the New York's supremacy over London, a tendency stopped by the economical crisis from 1929.

At the beginning of the 60's of the last century, the American big commercial banks initiated the third wave of banking internationalization. As their activity was constrained by a very rigid national regulation from the ending of the 19'th century, strengthened after the stock crash on the Wall Street, in 1929 which hindered their inside activities development and diversification, the American banks established themselves in London City, which enjoyed a free banking legislation. This situation led to the creation of a real offshore market, of the Eurodollars, situated in London. The big American banks could therefore help the development of the American multinationals, by assuring the capitals necessary to the investment financing in Europe. The example was rapidly copied by their homologues from the British colonies, by the Japanese, French, who yet did not manage to prejudice the American banks reputation. At the beginning of the 80's of the last century, the banking internationalization process acquired a new shape due to the indebting crisis of the developing countries and to the deflation which caused the decrease of the nominal interest rate and which allowed the resuming of the bond markets' activity to the prejudice of the international banking mediation. This process brings forward in the international stage foreground the American investment banks, the English merchant banks and the Japanese title banks, and constrains the commercial banks to modify their international strategy. With this respect, the commercial banks strengthen their position on the capitals international market, developing activities specific to the merchant banks. This last phase of the internationalization is inseparable to the development of the title transactions and led to the American, European and Japanese banks consolidation. Japan became in the 80's of the last century the first world creditor and Tokyo the second financial world market, its stock capitalization outrunning the one of New York (during 1989-1990).

We add the fact that, if in the 19'th century, the multinational banks branches were highly concentrated in the developing countries, starting with 1960, the multinational banks proved to be much more interested in the already developed countries. Moreover, another characteristic of the contemporary multinational banks is the tendency of giving up to the retail banking activity, existing nowadays the widely spread conviction that it would not be best for a foreign bank to follow up this kind of strategy, excepting the purchasing of a local bank.

In the last years, the financial markets integration degree increased and the political boundaries became less and less relevant for the financial institutions, due both to the rapid increase of the foreign investments in this field in the most part of the world countries, and to the changes occurred in the juridical field, which eased the access on various markets. In this context, the globalization, the markets international opening, the financial and technological innovations, the deregulation and the process of European integration modified in a decisive way the competitive field of the banking institutions, making them up-to-date their development strategies.

2. Considerations regarding the transnational banking activity

The extension of the bank's activity overseas by opening units in other countries than the origin one, has the final purpose of developing the activity and increasing the incomes, but the reasons that can made them act in this sense differ from case to case, as such:

- in order to follow and sustain its big exporting clients (this was the main reason for the developing the activity of the British banks like Overseas Banks and Clearing Banks), the biggest part of the banks activity being related to the national enterprises activity overseas;
- the intention of the banks specialized in certain operations to practise their banking activity in other countries, where these operations are not, or are insufficiently practiced (it is the case of the American merchant banks activity, of the international acceptance activity of the British banks or of the French financial institutions which developed their leasing activities in Italy and Spain);
- the extension in the insufficiently developed countries from the banking point of view (the case of the new industrialized countries or of the countries from Central and East Europe);
- the extension in the countries with an intense financial activity, hoping to easily obtain the profits (the establishment of banks in London at the end of the 19'th century, in New York at the end of the World War II or in Tokyo almost 20 years ago).

Among the factors that contributed to the transnational activity development distinguish the following:

- ▪ the activity's restrictive regulation in the residence country - in this case the bank develops, on the foreign countries, activities that are forbidden on the national market. An example is given by the way in which both the Japanese banks and the American banks got involved in the European capital markets, activities which they couldn't develop on the national markets because of a more restrictive legislation. This factor tends to stimulate the creation of foreign branches in the financial centres where the legislative background is permissive;
- the risk diversification – a strategical factor is represented by the banking activities diversification through the multinational operations. Therefore, the banks can reduce the risks by diversifying the disposals and directing them towards fields which are not correlated one to another, but, in case of a recession, all the markets are affected. By applying the diversification principle at the international level, the banks try to reduce the impact of a recession felt on a country's market, by extending the activity on other markets, hoping that these will not confront themselves with recession periods at the same time with the national market. Yet, the experience of the 1990 years shows that the diversification done by the banks from the developed countries by entering on the markets of the developing countries or on the markets in development, can sometimes lead to the increase of the exposing risk, especially by the increased ratio of the non-performant credits;
- the expansion of the international commerce – in many cases the banks try to provide global services to the clients who develop international operations, by opening branches in the countries in which the big industrial companies extended their activity. The main reason for this attitude is that the value of the transactions unrolled with this type of clients will become significant. The bank will want to maintain its position, therefore, will not want that an operation unrolled overseas by its clients be taken over by another bank, especially if it is a branch of a competing bank;

- the capital export – the activity's extension overseas is caused by the valorization of the capital's offer on the internal market. The banks from the developed countries, such as the United States and Japan, extended their activity overseas as a means of identifying some new investment opportunities. This objective is best accomplished by a continuous presence at the international level, so that the opportunities actively be identified and not just passively accepted in the moment in which they appear;
- the jurisdictional area – the risks afferent to the external credits considerably reduce by creating a new branch in the residence countries of the credit beneficiaries. For example, regarding the credit guarantess, the afferent documents and the creation procedure can be implemented in conformity with the local legislation, a fact that will not raise problems in their carrying out process (if the debtor does not respect his payment obligations). Thus, a branch's costs overseas can be justified by a high level of the redeeming rate, the presence on a foreign country contributing to the improvement of the credit portofolio quality. The reason would be not only the possibility of a better evaluation of the credit request, but also the discouragement of the fraudulent tendencies due to the possibility of easily taking legal proceedings of this kind of documents;
- the participation on the market – many banks extend their activities at the international level in order to participate on different markets that can represent: either sources of additional funds, modalities for the valorization of the available funds, or a combination of the two. In the first case, a bank from a developing country can establish a branch in a developed country in order to absorb funds for investments in the residence country. In the second case, a bank that posesses resources can enter on a flourishing foreign market in order to take advantage of the existent opportunities. Moreover, the banks which have international activity can participate on a foreign market in order to beneficiate of stability and a high degree of liquidities (like the London market of the eurocurrency). In case a bank anticipates the appearance of a future opportunity on a certain market, it will want to be present on that market in adavance, thus many banks open branches overseas.

A banking society, willing to extend itself on foreign financial markets by opening banking unities on the other countries' territories, confront itself with a series of „ barriers", of which the most representatif are the following:

- *the technological barriers:* the establishment of a new banking society implies the alignment to the technologies used by the banks from that country. This aspect is important in the unrollment of the relations with the other banks, by using the existent technologies which refer to: payments, the transfer of the messages of payments made through the existent network in that country, so on. Yet, the technological networks imply high investments, with long term redeeming.
- *the notoriety barriers:* which refer to the resonance that the banking society has or not in the respective banking system*;*
- *the mobility barriers:* these refer to the bank's capacity of penetrating the territory and getting close to the clients, the extension of the network implying yet important costs and a period of establishment, which represents a barrier for the new created banking societies;
- *the strategical barriers*: refer to the bank's development perspectives depending on the respective market's conditions and on the general climate;

3. The functioning of the foreign banks

A bank's modalities representation and functioning on the international markets can take one of the following shapes:

- *The subsidiaries:* - are those banking units implemented by the „ mother bank" in other countries than the origin one and are characterised by the fact that they have juridical personality;
- *The branches* – operate under the mother-bank responsability (without having a separate juridical statute). In the main, the simplicity of this fact is only illusory, because, due to the

fiscal or even administrative reasons, the operations done in a foreign country have to be recorded separately as if it was all about a distinct society;

- *The representation offices or the „ representances*" (known in the United States under the name of Loan Production Offices) – can not unroll transaction activities, being exactly what results from their denomination, that is only a representation centre of the central headquarter in a different country. These collaborate especially with the clients who have businesses in the bank's origin country. The representations' opening procedure is, generally, very simple and does not demand many formalities, often being the prelude of agencies or subsidiaries' opening or of banking acquisitions in the respective country.

In the context the European market opening, a significant number of banks tried to create a beyond boundaries banking network on the European Union territory, this internationalization being followed by an increase of the rivalry and, implicitly, as a response to this one, by a concentration of the banking field.

In France they are considered foreign banks, those banks at which foreigners, and particularly the foreign banks, posess the majority of the capital. At the beginning of the year 2000 there existed more than 165 foreign banks, of which 61 hailed from the European Union. Moreover, in the following period, there were registered requests from many foreign institutions, their increasing number in the French banking system getting close to 300. It is observed at the same time a strong presence of the British banks, a relatively recent implantation of the Italian banks (1988) and a weak presence of the German banks.

The development of the foreign banks' activity ***in Germany*** was tardier and less important than the one in France, due also to the fact that the German banks participate in a great measure at the big enterprises' capital. The foreign banks mostly serve the clients who share their nationality.

The implantation of some foreign banks ***in Italy*** was, for a quite long period of time, very weak, due to the fact that the opening of some new banks was strictly regulated, and also because these ones were subjected to some administrative constraints imposed to the banks. In 1985, after a regulation, the foreign banks were no longer restricted from buying an Italian bank and, also, the foreign banks could open themselves branches in Italy under the same conditions in which the Italian banks could open units in the respective countries, conditions which regarded the balance sheet total, the organization's solidity, the staff's competence, so on. Subsequently, the numebr of the foreign banks' subsidiaries increased, especially of those that have France and Germany as origin countries. After 1987, as a result of the Italian banking system deregulation and passing to private possession which stimulated the rivalry, certain foreign banks withdrew their branches (especially the specialised institutions). Moreover, the big Italian banks underwent a decline period also because they centered only on the big enterprises and did not direct on the retail market too, considering the fact that these big enterprises began borrowing more and more from the finacial market.

Great Britain had always been the most open one to the implantation of foreign banks, which tried to open subsidiaries in this country, especially in London, which knew a permanent prosperity even in the periods in which the country confronted itself with economical difficulties. More, they were also attracted by the stimulating policy of England's Central Bank, regarding the authorization and regulation of the banks' functioning. Later, the centarl bank's control hardened, but the already present foreign banks did not withdraw their subsidiaries. The first foreign bank that opened itself a subsidiary in England was a French one (The Discount National House/Bank from Paris), in 1865, so that, subsequently, the foreign banks numeber increase, due to both the existent facilities on the British market and to some favourable circumstances such as the stock exchange deregulation which stimulated mostly the foreign merchant banks. It can also be underlined the fact that, although the number of the banks authorized as British banks decreased in the last decade at approximately 200, the number of the authorized banks increased, due to the more and more powerful presence of the foreign banks, this fact reflecting the role of Great Britain and London as an international financial-banking system.

The foreign banks access ***in Spain*** was accomplished much later. At the beginning, because the economical development was insufficient for attracting the foreign banks, there existed only three subsidiaries implanted in Spain: Credit Lyonnais (from 1875); The London and South American Bank (from 1916) and Societe Generale (from 1919). A very restrictive legislation (from 1940)was practically blocking all the implantations of new foreign banks, a single derogation of these regulations being given in 1914, for the Banca Nazionale de Lavoro. Later, the restrictions regarding the extension of foreign banks in Spain diminuished, so that, in 1987, a decree stipulate that the regulations be identical, both for the national banks and for the foreign ones, a fact that led to the setting up of many new foreign banks, both through opening subsidiaries and by taking over in share at the Spanish national banks. The foreign banks centered mainly on offering long term loans to the enterprises, due to the Spanish banks' lack of interest for this type of clients, and also on operations specific to the merchant banks, which were practically unknown to the Spanish banking field.

Although the ***United States of America*** banking legislation had always been retrictive towards the foreign banks implantations, these couldn't resist to the need of being present in one of the most prosperous world countries and whose financial centre had become as important as the one in London. Still, the foreign banks, in comparison with the American banks, beneficiated of some competitive advantages. Thus, the foreign banks, although subjected to a double regulation (the ones of the respective state and the ones of the federal government) like the American banks, unlike these ones, they could open subsidiaries in various states, having at the same time the possibility to unroll activities specific both to the investment banks and to the commercial banks, without being subjected to the obligatory supplies system. Due to this fact, there has been voted, at the initiative of the Supply Federal System, an international banking document, by which the foreign banks were obliged to set up the obligatory supplies, to draw deposits superior to the amount of 100.000 USD and to comply with the same limitations in the banking activity as the American banks did. The implantation of the foreign banks in the United States continued to increase, so that, in 1981, by setting up „ The international banking facilities", the foreign banks be receiving some advantages: they were no longer subjected to the obligatory supplies system and the interest were not taxable. Yet, they had to comply with some regulations, like the drawing of deposits bigger than 100.000 USD and on term longer than two days. The only way by which the successful American banks could develop their activities, in the context in which the internal market had reached saturation point, was by opening subsidiaries overseas. This process was considerably sustained by the consolidation of the American dollar's role as a world-wide supply currency. All these facts contributed to the creation of a strong tradition in the multinational banking activity of the big American banks.

The Japanese banking system is very dynamic, the banks extending themselves a lot, especially on the east coast, mainly towards the Asian clients. On the international level, these hold 50% of the activity of all foreign banks, the banks from continental Europe holding only 30% and the British banks 10%. Japan was very restrictive when it came to implanting foreign banks, their authorization being made in a very small number. Because the national clients were devoted enough to the Japanese banks, the process implanting of the foreign banks was more difficult. Later, the Japanese government, as well as other countries too, (the beginning of the 20th centruy in England, in the years 1970-1980 in the United States), had to prove a wider opening regarding the international banking activity, which led to the increasing of the foreign banks' number in Japan. The most numerous foreign banks in Japan are the ones of American, British and French origin.

At present, the cultural and social differences between the countries make that the strategy based on acquisitions in which the local brand is kept, be, at least for a long period of time, the most appropriate one.

4. The foreign banks' role in the Central and East Europe banking system consolidation

The banking scenery in Central Europe changed considerably, as long as the governments continued to encourage the foreign banks to acquire important institutions. In the last years, this tendency strengthened by: taking over the Ceska Sporitelna bank, from the Czeck Republic, by the Erste Bank from Austria; by taking over the biggest retail bank from Czech, Investicni a Postovi Banka by the Nomura International, and Citibank bought Bank Handlowy from Polland; on the other side, the Cesksiovensk Obchodni Banka and the Bank Pekao from Polland were sold to the KBC Belgian bank, respective Unicredito; the Polish bank Zachodni was sold to Allied Irish Bank, as for Hungarian Foreign Trade Bank, this one had already been under foreign property for many years.

More than in any other region on the map, the foreign banks considerably took over the control over the banking system in Central and East Europe and, taking into consideration the massive takings over and thepassings to private possession that are on the point of being finalized, it is doubtless that the foreign banks govern this field.

According to the declarations of the Reconstruction and Development Bank, the share of the total banking actives owned by the banks with a majority foreign share holding was in 1994 of only 5% but in 1998 increased to 32% and due to the big number of transactions in the following years, especially on the biggest banking markets from Polland, Czeck Republic, Hungary and Romania, the experts believe that this share increased to 53% in the year 2000, so that in the following years there be registered shares of approximately 57%. The increase does not stop here, the Romanian example being self-evident – over 90% of the banking system is governed by the foreign banks.

BANKING RISK MANAGEMENT

Şimon Adrian

Universitatea „Petru Maior" Tîrgu-Mureş, Facultatea de Ştiinţe Economice, Juridice şi Administrative, Str. N. Iorga nr. 1, adr_simon@yahoo.com, telefon 0745/235211

Abstract: General banks, investment banks, and mutual funds have to control and select the risks inherent in the management of deposits, loans portfolios of securities, and off-balance-sheet contracts.

Since the risks that a bank has to manage are diverse, several classifications have been proposed, some of which are standard. Thus, economists have put forward the fundamental distinction between microeconomic or idiosyncratic risks, which can be diversified away through the law of large numbers, and macroeconomic or systematic risks, which cannot. Unlike insurance companies, which essentially deal with microeconomic risks, banks generally have to deal with both types of risks.

The credit activity of banks is affected by default risks, which occur when a borrower is not able to repay a debt (principal or interest).

Liquidity risks occur when a bank must make unexpected cash payments. This type of risk essentially comes from the specificity of the demand deposit contract: unlike the creditors of other kinds of firms, depositors are allowed to demand their money at any time. Consequently, the deposit activity is affected by the risk of an unexpected massive withdrawal by depositors.

Default risks

Defining and measuring credit risk is equivalent to determining how the market evaluates the probability of default by a particular borrower, taking into count all the possibilities of diversification and hedging provided by financial markets. In part, the level of risk depends on the institutional arrangements to which the banks are subject, either through the interbank money market or through specialized institutions created for this purpose.

Clearly the riskiness of a loan will be affected by the existence of:

- collateral
- compensating balances
- endorsement

But other characteristics of the credit market will also be relevant: Do banks share information on their creditors? How is the bankruptcy process settled? Notice that in the process of international competition, as well as in a process of market integration like the one undergone by Europe, differences between these institutions or regulations across countries are fundamental not only because they may represent a barrier to entry, but also because they may tend to concentrate some banking activities in the countries that provide the more efficient institutions and regulations.

Evaluating the cost of default risks

To understand how default risk affects the competitive pricing of loans, this discussion will begin with a simple approach that will justify me use of the risk spread (the difference between the interest rate on a risky loan and the risk less rate for the same maturity) as a measure of the credit risk of an asset.

Indeed, this discussion will show how the risk spread is determined by the boor- Rower's probability of default. It will then proceed to examine a more complete approach based on option pricing (Merton 1974).

A simple interpretation of risk spread

Assuming that default risk is diversifiable and that the bank under consideration can indeed diversify this risk away through a large population of borrowers, the only thing that matters is the probability of default. Credit scoring methods, the analogue of actuarial techniques used by insurers, allow banks to estimate a priori this probability of default based on the observable characteristics of the loan applicant.

From a financial viewpoint, the value of such a loan (subject to a diversifiable credit risk) is nothing but the expected present value of the borrower's repayments. Leaving aside interest rate risk for the moment, assume that the refinancing rate r is constant, and take e^{-r} as the one-period discount factor. Consider now a risky loan, characterized by a series of promised repayments (Ci, Cz,..., Cn) at future dates (t_1, t_2,..., t_n). Assume for simplicity that if the firm defaults, the bank receives nothing. The expected cost of default risk for this loan can be measured by the difference between:

$P_0=\sum C_k e^{-rtk}$ (1)

the value of the loan if there were no default risk, and

$P=\sum C_k p_k e^{-rtk}$ (2)

the value of the risky loan, where p_k denotes the probability that the k-th repayment will not be defaulted, assuming that there are no partial repayments.

In practice, however, the most commonly used instrument for evaluating the cost of default risk is the difference (spread) between the yield to maturity R of the risky loan and the refinancing rate r. R is defined implicitly by the equation

$P=\sum C_k e^{-Rtk}$ (3)

and this determines the value of the spread s = R - r.

Bierman and Hass (1975) and Yawitz (1977) have proved the following simple result:

If the firms' default follows a Poisson process of intensity λ, the spread s is independent of the characteristics of the loan. It is equal to the intensity of the Poisson process:

$s = \lambda$ (4)

Proof`In a Poisson process of intensity λ, the probability of survival at date

$t_{k`}$ is by definition

$P_k=e^{-\lambda tk}$

Combining 2, 3, and 5 yields

$\sum C_k e^{-Rtk}=\sum C_k e^{-\lambda tk} e^{-rtk}$

This equation in R has a unique solution, independent of C_1,..., C_n:

$R=r+\lambda$

Therefore:

$S=R-r=\lambda$

Consequently, if one considers corporate debt of a certain type, the spread can be considered as the instantaneous probability of failure λ. that the market assesses implicitly to the particular class of borrowers under consideration.

For instance, a spread of fifty basis points indicates a failure probability of

$1-e^{-\lambda}$= 0.5 percent per year.

The option approach to pricing default risk

The simple approach just explained relies on three assumptions that are not very satisfactory: (1) the instantaneous probability of failure is constant and exogenous, (2) credit risk is completely diversifiable, and (3) in case of failure, the residual value of the firm is zero. Consider now what happens when these assumptions are relaxed.

When credit risk is not completely diversifiable, a risk premium must be introduced, and the analysis becomes more involved. However, financial markets provide insurance possibilities for banks. Therefore the risk premium quoted by banks must be in line with the ones prevailing in the securities market. This remark will allow development of a model for pricing risky debts following Merton (1974).

Liquidity risk and asset liability-management

The ALM group in a traditional bank is also responsible for the management of liquidity risk. As defined earlier, it is the risk that a bank is unable to meet its liabilities when they fall due. Liquidity risk is normally associated with the liabilities side of the balance sheet when depositors unexpectedly withdraw their financial claims. Assuming the liquidity preferences of a bank's customers are roughly constant, the problem usually arises if there is a run on the bank as depositors try to withdraw their cash. A bank liquidity crisis is normally triggered either by a loss of confidence in the bank or because of poor management practices, or the bank is a victim of a loss of confidence in the financial system, caused, possibly, by the failure of another bank. Contagion and systemic risk are discussed in detail in the next chapter. However, if the bank experiences an unusually high deposit withdrawal rate, and lacks the cash or is unable to borrow the money quickly, it is faced with liquidating its longer-term investments, possibly in a market where other banks and investment houses are also selling, pushing down prices.

A bank can also experience liquidity problems on the asset side of the balance sheet, caused by large numbers of unexpected loan defaults. Banks have also been caught out granting credit lines which they do not expect to be drawn down, but which are subsequently used by the borrowers. If an economy goes into recession relatively quickly, these banks may see firms drawing down their credit lines all at once, which will put pressure on their liquidity. There is also liquidity risk linked to off-balance sheet transactions and to a slow-down or collapse in the payments system.

If a bank does experience liquidity problems, the central bank is usually willing to lend to them at some penal rate, which is costly for the bank. Also, the central bank will have to be reasonably certain that the problem is one of illiquidity and not insolvency. Banks will borrow funds on the interbank markets or from other sources before they approach the central bank, but again, this is costly for the bank, and undermines its profitability.

The objective of liquidity risk management should be to avoid a situation where the net liquid assets are negative. Gap analysis can be used to manage this type of risk. The gap is defined in terms of net liquid assets: the difference between net liquid assets and volatile liabilities. Liquidity gap analysis is similar to the maturity ladder for interest rate risk, but items from the balance sheet are placed on a ladder according to the expected time the cash flow (which may be an outflow or an inflow) is generated. Net mismatched positions are accumulated through time to produce a cumulative net mismatch position. The ban can monitor the amount of cash which will become available over time, without having to liquidate assets early, at penal rates.

The Bank of International Settlements (2000) has outlined a maturity ladder approach, which consists of monitoring all cash inflows and outflows, and computing the net funds required.

The ALM group in a bank is not normally responsible for risk management in other areas, though how risk management is organized does vary from bank to bank. In some banks, the ALM group has been replaced by a division with overall responsibility for risk management, but credit risk continues to be managed separately. Increasingly, 21st century banks have a division with overall responsibility for coordinating risk management.

The management of interest rate risk has moved beyond the traditional gap and duration analysis because banks have increased their off-balance sheet business and the use of derivatives.

At the individual level, liquidity management is not fundamentally different for banks than for other firms. It can even be seen as a particular case of the general problem of managing inventories of any sort.

Liquidity is an important service offered by a bank and one of the services that distinguishes banks from other financial firms. Customers place their deposits with a bank, confident they can withdraw the deposit when they wish, even if it is a term deposit and they want to withdraw their funds before the term is up. If there are rum ours about the bank’s ability pay out on demand, and most depositors race to the banks to withdraw deposits, it will soon become illiquid. In the absence of a liquidity injection by the central bank or a lifeboat rescue, it could become insolvent since it can do nothing to reduce overhead costs during such a short period.

Maturity matching (getting rid of all maturity gaps) will guarantee sufficient liquidity and eliminate liquidity risk because all deposits are invested in assets of identical maturities: then every deposit is repaid from the cash inflow of maturing assets, assuming these also risk-free. But such a policy will never be adopted because the bank, as an intermediary, engages in asset transformation to make profits. In macroeconomic terms, provided there is no change in the liquidity preferences of the economy as a whole, then the withdrawal of a deposit by one customer will eventually end up as a deposit in another account somewhere in the hacking system. If banks kept to a strict maturity match, then competition would see to it that the bank which invested in assets rather than keeping idle deposits could offer a higher returns (and therefore, greater profitability compared to banks that simply hold idle deposits.

At the microeconomic level, the maturity profile of a bank's liabilities understates actual liquidity because term deposits rend to be rolled over, and only a small percentage of a bank's deposits will be withdrawn on a given day. This is another for argument for incurring some liquidity risk. Given that the objective of a bank is to maximize profit/shareholder value-added, all banks will have some acceptable degree of maturity mismatch.

SETTLEMENT/PAYMENTS RISK

Şimon Adrian

Universitatea „Petru Maior" Tîrgu-Mureş, Facultatea de Ştiinţe Economice, Juridice şi Administrative, Str. N. Iorga nr. 1, adr_simon@yahoo.com, telefon 0745/235211

Abstract: Settlement/ payments risk is created it one party to a deal pays money or delivers assets before receiving its own cash or assets, thereby exposing it to potential loss. Settlement risk can include credit risk if one party fails to settle, i.e. reneges on the contract, and liquidity risk - a bank may not be able to settle a transaction if it becomes illiquid.

A more specialized term for settlement risk is Herstatt risk, named after the German bank which collapsed in 1974 as a result of large foreign exchange losses. The reason settlement risk is closely linked to foreign exchange a market is because different time zones may create a gap in the timing of payments. Settlement of foreign exchange transaction requires a cash transfer from the account of one bank to that of another through the central banks of the currencies involved. Bankhaus Herstats bought Deutschemarks from 12 US banks, with settlement due on 26th June. On the 26th, she American banks ordered their corresponding German banks to debit their German accounts and deposits the DMs in the Landesbank (the regional bank was acting as a clearing house). The American banks expected to be repaid in dollars, but Herstats was declared bankrupt at 4 p.m. German time - after the German market was closed but before the American market had closed, because of the 6-hour time difference. The Landesbank had already paid DMs 10 Bankhaus Herstats, but the US banks had not received their dollars. The exposed US banks were faced with a liquidity crisis, which came close to triggering a collapse of the American payments system.

Settlement risk is a problem in other markets, especially the interbank markets because the volume of interbank payments is extremely high. For example, it can take just 10 days to turn over the annual value of the GNP of a major OECD country - in the UK, it is roughly £1- £1.6 trillion. With such large volumes, banks settle amounts far in excess of their capital. Netting is one way of reducing payments risk, by allowing a bank to make a single net payment to a regulated counterparty, instead of a series of gross payments partly offset by payments in the other direction. It results in much lower volumes (because less money flow-through the payments and settlement systems), thereby reducing the absolute level of risk in the banking system. Netting is common among domestic payments systems in industrialized countries. At the end of each day, the central bank requires each bank to settle its net obligations, after canceling credits and debits due on a given day. If the interbank transaction is intraday, the exposure will not appear on a bank's balance sheet, which is an added risk.

However, settlement risk is still present because the netting is multilateral. The payments are interbank, and banks will not know the aggregate exposure of another bank. Any problem with one bank can have domino effect. If one bank fails to meet its obligations, other banks along the line are affected, even though they have an indirect connection with the failing bank, the counterparty of exchange. Given the large of volume of transactions in relation to the capital set aside by each bank, the central bank will be concerned about systemic risk – the failure to meet obligations by one bank triggers system-wide failures. Most central bank/regulators deal with this problem through a variety of measures, capping multilateral exposures, requiring collateral, passing the necessary legislation to make bilateral and multilateral netting legally enforceable, or imposing penalty rates on banks which approach the central bank late in the day.

Market or price risk

The modem theory of portfolio management has been developed by Sharpe (1964), Lintner (1965), and Markowitz (1952). As such, it is of course interesting for banks, which often hold large portfolios of marketable assets. More importantly, this portfolio theory has also led to another paradigm for banking behavior, essentially developed by Pyle (1971) and Hart and Jaffee (1974).

The idea is to assimilate all assets and liabilities of the bank into securities of a particular sort, and to consider the whole bank itself as an enormous portfolio of these securities. In this approach, the only specificity of the bank's liabilities is that they correspond to short positions in the bank's portfolio.

- *General or systematic market risk* is caused by a movement in the prices of all market instruments because of, for example, a change in economic policy.
- *Unsystematic* or *specific market risk* arises in situations where the price of one instrument moves out of line with other similar instruments, because of an event (or events) related to the issuer of the instrument.
- A bank can be exposed to market risk (general or specific) in relation to:
- *Equity*
- *Commodities* (e.g. cocoa, wheat, oil)
- *Currencies* (e.g. the price of sterling appreciates against the euro)
- *Debt securities* (fixed and floating rate debt instruments, such as bonds)
- *Debt derivates* (forward rate agreements, futures and options on debt instruments, interest rate and cross-currency swaps, and forward foreign exchange positions)
- *Equity derivates* (equity swaps, futures and options on equity indices, options on futures, warrants)

Thus, market risk includes a very large subset of other risks. Two major types of risks are currency and interest rate risk. If exchange rates are flexible, any net short or long open position in a given currency will expose the bank to *foreign exchange* or *currency risk*, a form of market risk.

Interest rate risk

Interest rates are another form of price risk, because the interest rate is the "price" of money, or the opportunity cost of holding money in the narrow form. It arises duet interest rate mismatches. Banks engage in asset transformation, and their assets and liabilities differ in maturity and volume. The traditional focus of an asset-liability management group, within a bank is the management of interest rate risk, but this has expanded to include off-balance sheet items, as will be seen below.

Capital or gearing risk

Banks are more highly geared (leveraged) than other businesses individuals feel safe placing their deposits at a bank with a reputation for soundness. There are normally no sudden or random changes in the amount people wish to save or borrow, hence the banking system as a whole tends to be stable, unless depositors are given reason to believe the system is becoming unsound.

Thus, for banks, the gearing (or leverage) limit is more critical because their relatively high gearing means the threshold of tolerable risk is lower in relation to the balance sheet. This is where capital comes in: its principal function is to act as a buffer by supporting or absorbing losses. Banks which take on more risk should set aside more capital, and this is the principle behind the Basel risk assets ratio. Banks need to increase their gearing to improve their return to shareholders. To see the link, consider the equation below:

ROE = ROA x (gearing multiplier)

Where:

ROE: return on equity or net income/equity

ROA: return on assets or net income/assets

Gearing/leverage multiplier: assets/equity

Operational risk

The Bank for International Settlements defines operational risk as: "The risk of direct or indirect loss resulting from inadequate or failed internal processes people, and systems, or from external events." (BIS, 2001, p. 2 7)

The definition of operational risk varies considerably, and more important, measuring it can be even more difficult. The Basel Committee has conducted surveys of banks on operational risk Based on Basel (2003), the key types of operational risk are identified as follows:

(1*) Physical Capitol*: the subsets of which are: damage to physical assets, business disruption system failure, problems with execution and delivery, and/or process management.

Technological failure dominates this category and here, the principal concern is with bank s computer systems. A crash in the computing system can destroy a bank. Most banks have a duplicate system which is backed up in real time, in a secret location, should anything go wrong with the main computer system. When banks and other financial institutions had their premises damaged or destroyed as a result of "9/11", they were able to return to business quite quickly (in alternative accommodation), relying on the back-up computer systems. More generally, the loss of physical assets, such as buildings owned, is a form of operational risk. However, banks take out insurance against the risk of fire or other catastrophes and to this extent; they have already hedged themselves against the risk. To the extent they are fully hedged, there should be no need to sec aside capital. Problems with physical capital may interfere with process management and contribute to a break down in execution and/or delivery.

(2) Human Capital: this type of risk arises from human error, problems with employment practices or employees' health and safety, and internal fraud. An employee can accidentally enter too many (or too few) zeroes on a sell or buy order. Or a bank might find itself being fined for breach of health and safety rules, or brought before a employment tribunal accused of unfair dismissal. In addition, employees can defraud their bank, but this is discussed in a separate category below.

(3) Legal: the main legal risk is that of the bank being sued. It can arise as a result of the treatment of clients, the sale of products, or business practices. There are countless examples of banks being taken to court by disgruntled corporate customers, who claim they were misled by advice given to them or business products sold. Contracts with customers may be disputed. One of the most recent and costly examples of shoddy treatment of clients is the implicit" admission, in 2003, by all the major investment banks that they failed to control the conflict of interest between research and investment banking divisions. In addition to fines summing up to hundreds of millions, these banks face civil law suits from angry clients who claim they acted on paid advice from research departments to invest in certain stocks, only to find there was no solid research to back the recommendations, but rather, pressure from corporate finance divisions to bid up the price of one or more shares.

(4) Fraud: the fraud may be internal or external to the bank. For example, the looting of his company's pension by Mr. Maxwell affected the banks because they were holding some of the assets he had stolen from the funds as collateral. Another illustration of this form of risk is the Hammersmith and Fulham Council case. This London borough had taken out interest rate swaps in the period December 1983 to February 1989. The swaps fell into two categories, one for hedging and one for speculation. With local taxpayers facing a bill of tens of millions of pounds, the House of Lords (in 1991) declared all the contracts null and void, overturning an earlier decision by the appeal court. Barclays, Chemical, the Midland, Mitsubishi Finance International and Security Pacific were the key banks left facing \$400 million in losses and \$15 million in legal fees. Examples of internal fraud include rogue trading. Nick Leeson brought down Barings with losses of \$1.5 billion, and John Rusnak was convicted of fraud at a US subsidiary of Allied Irish Bank, which cost it \$750 million.

As can be seen from the classification above, factors contributing to operational risk are not necessarily independent of each other. Internal fraud could be classified as a human capital risk. If an employee sues because of breaches in health and safety, it falls in both (he human capital and/or legal risk sub classifications. Certain payment risks may also fall into the operational risk category. For example, in 1985, a major US bank experienced computer problems which prevented it from making outgoing payments. It was forced to borrow \$20 billion from the Federal Reserve to meet these payments. Simultaneously, payments to this bank from other banks could not be made, so they flooded the interbank markets, forcing down the federal funds rate by 3.

Thus, an operational failure created settlement and liquidity risks. Or if a borrower is granted a loan based on a fraudulent loan application and subsequently defaults, it will be recorded as a loan loss, and therefore, a credit risk issue, even though the fraud was the original source of the problem.

Abstract: Based on a long series of papers analyzing stock returns behavior we can speak generally about the stock exchange as a speculative market in the sense of the stable paretian hypothesis. Still, there are significant differences from a market to another and in many cases biases from normality are too insignificant in order to justify a radical change of approach. This radical change is less needed especially when the aggregating interval of price changes gets big enough, for example if we speak about weakly or monthly returns, cases in which the non normality hypothesis can be accepted in a comfortable way.

Keywords: stock returns, probabilistic distributions, stable paretian hypothesis

The Gaussian hypothesis regarding stock return distributions

There is a long tradition among the specialists from the financial area in considering that in speculative markets financial assets prices (especially stocks) behave in a manner similar to a random walk process. The random walk theory is based on the following hypothesis: changes in stock prices (and indirectly the stock returns) are independent random variables respectively changes in stock prices follow a certain probabilistic distribution. The first one to introduce a certain model for stock prices behavior (but also for commodities traded on designated exchanges) was Louis Bachelier in 1900[261]. The simplest and in the same time the most important model presented by Bachelier is built as following:

If $P_{(t)}$ represents the price of a stock at the end of the t period, then it is assumed that subsequent changes of this form[262] *$P_{(t+T)}$-$P_{(t)}$ are independent random walk variables, which follow a normal law of distribution (Gaussian) with a null mean and a variance proportional with the T interval dimension.*

Despite the fundamental importance of the process presented by Bachelier, model that is now known as "Brownian movement", the financial realities emphasize the fact that this model cannot explain in a satisfactory way the historical trading data accumulated in certain exchanges since the second half of the XIX century and this is due mainly because the empirical distributions associated with price differences such $P_{(t+T)}$-$P_{(t)}$ are too peaked in order to be compatible with Gaussian samples.

Still, in order to advocate the Gaussian hypothesis regarding price changes in financial speculative assets, [Osbourn, 1959][263] used a series of arguments based on the effects of central limit theorem from the probability theory. He rationalized as it follows: if price changes from a transaction to the other are independent and identically distributed random variables (iid) and they have a finite variance and the transactions are uniformly distributed in time, then the central limit theorem assures that price changes along a certain interval (day, week, month, year and son on) are normally distributed, being just sums of changes from a transaction to another. In other words, if the number of transactions gets bigger and bigger, aggregating random variables associated with the corresponding price changes will lead to random variables which tend to follow a normal law of probability.

[261] Bachelier, L., 1900, *Theorie de la speculation*, Gauthiers-Villars, Paris.
[262] This model of Bachelier assumes in an implicit manner that the variance of the differences $P_{(t+T)}$-$P_{(t)}$ is independent from the $P_{(t)}$ value. There are some reasons to expect that the standard deviations associated with ΔP to be proportional with the price level and for this reason mainly, many modern authors suggested that the original condition regarding P(t) differences to be changed with the condition of independence and normality of ln P(t) differences.
[263] Osbourn, M. F., 1959, „Brownian Motion in the Stock Market", *Operations Research*, vol. 7, pag. 145-173.

In this kind of conditions, for the stocks recording an acceptable liquidity (over 300-500 transactions per day) the central limit theorem assures a convergence of daily price changes (or daily returns) towards a normal distribution law. This conclusion is very important because it is validating the initial conditions of many fundamental models in finance, models using usually stock daily returns. Empirical proofs in assessing normality for price changes were offered beginning with the year 1950. Thus, [Kendall, 1953[264]] found that weekly changes of wheat price at the commodity exchange of Chicago and the prices of the most important stocks listed at the London Stock Exchange follows with a certain approximation a normal distribution law while [Moore, 1962[265]] reaches similar results in the case of changes of the price logarithm for a sample of stocks listed at New York Stock Exchange.

The stable paretian hypothesis

Starting with the year 1960, critical opinions related to the normality hypothesis advocated mainly through papers written by Bachelier and Osbourn found a strong argumentation in the person of Benoit Mandelbrot, professor at Harvard University. He considered that the previous empirical studies had unjustified amplified certain correlations between empirical distribution of stock price changes and the normal distribution neglecting in the same time some significant biases from normality. In this direction were brought in debate the empirical studies carried out by Kendall and Moore both of them concluding that the extreme tails of the empirical distributions are higher (they contain a bigger proportion from the total probability) compared with normal distributions. In other words, extreme variations, both the negative and the positives ones, are much more frequent than a normal distribution would imply. Conform to Mandelbrot's opinion these biases are sufficient in order to justify a new radical approach of the random walk theory for speculative financial assets. This new approach, known as the stable paretian hypothesis, is based mainly on two ideas: the variances of the empirical distributions are behaving as they were infinite respectively the empirical distributions are behaving like non-Gaussian members of a limit distributions family that is the stable paretian hypothesis.

From the beginning, the expression of radical changed approach is justified by the fact that the variance of the empirical distributions generally is assumed to be infinite, a hypothesis with very important consequences. Thus, from a purely statistical approach, if the variance associated with the distribution of populations of first order price differences ($P_{(t+1)}$-$P_{(t)}$) is infinite than the variance associated with samples from these populations represents in itself an insignificant measure of dispersion. Moreover, if the variance is infinite than merely all statistical methods which are starting from assumptions of a finite variance will be, in the best case, very weakened from the significance point of view and they might finalize in very misleading answers or results (a fundamental example is running regressions using the least squares method). In consequence, due to the fact that previous empirical researches regarding the speculative financial asset prices were founded on statistical techniques which consider a finite variance, the real value of many of them is thus untruthful if Mandelbrot's hypothesis were to be confirmed by empirical data.

For this purpose, we remind the fact that the first tests of the stable paretian hypothesis were made on a limited number of speculative price changes series and that each direct test on this unprocessed and unsmoothed data found a behavior which was predictable by the paretian hypothesis. Ulterior tests confirmed that in the case of speculative financial assets price changes (and we speak mainly about the stock and cotton prices) first order differences of prices' logarithm follow paretian distributions. A rigorous empirical research of the stable paretian hypothesis was made by Eugene Fama in his renowned article from 1965[266], the resulted conclusions stressing the following:

„[…] in particular, Mandelbrot's hypothesis asserts that the empirical distributions of price changes are fitting better into the category of stale paretian distributions with a characteristic exponent smaller than 2 compared with the normal distributions category (which are after all stable paretian distributions but with a characteristic exponent equal to 2). The conclusion of this paper is that the Mandelbrot hypothesis seems to be sustained by the empirical data. To this conclusion we have reached only after an extensive and complex testing was carried out."

[265] Moore, A., 1962, „A Statistical Analysis of Common –Stock Prices", *University of Chicago*, PhD dissertation.
[266] Fama, E., 1965, „The Behavior of Stock Market Prices", *Journal of Business*, vol. 38, pag. 34-105.

Following these serious documentations of stock returns behavior we can speak generally about the stock exchange as a speculative market in the sense of the stable paretian hypothesis. Still, there are significant differences from a market to another and in many cases biases from normality are too insignificant in order to justify a radical change of approach. This radical change is less needed especially when the aggregating interval of price changes gets big enough, for example if we speak about weakly or monthly returns, cases in which the non normality hypothesis can be accepted in a comfortable way.

Still, the existence of too high frequencies in the case of extreme variations impose the consideration of the stable paretian hypothesis in order to be able to intervene on this kind of markets with a certain level of rationality and in the virtue of efficiency thus implied is necessary to known the statistical characteristics of the probability distributions from the stable paretian family and also their influence on stock returns' behavior.

The stable paretian distribution laws family

The starting point of the stable paretian hypothesis is represented by the works in mathematical analysis related to the notion of stable distribution. A certain distribution assumes a conservation of the distribution characteristics when identically distributed variable are summed up. This means that if two variables x and y are distributed according to a stable distribution then their sum x+y is identically distributed. Notable contributions to this field of stable distributions were made by the French mathematician Paul Levy which deducted the characteristic function associated to all stable distributions. The results of his research were materialized in his book "Theorie de l'addition des variables aleatoires" published in 1937, a point which marked the beginning of some future developments mainly in the field of probability theory and statistics.

Not without any interest is the fact that Benoit Mandelbrot, the enthusiastic advocate of the stable paretian hypothesis in the area of speculative markets, represents the continuation of a special series of doctoral advisors – PhD students. Thus, he was the student of Paul Levy at the Ecole Polytechnique of Paris, which was the student of Jacques Hadamard (accidentally Dreyfus brother in law) which was the student of Charles E. Picard, the last two being two of the greatest mathematicians of the last century.

As I have mentioned earlier, the characteristic function associated to all stable distributions was deducted

$$\log f(t) = \log \int_{-\infty}^{\infty} e^{iut}\, dP(\tilde{u} < u) = i\delta t - \gamma |t|^{\alpha}\left(1 + i\beta \frac{t}{|t|} tg \frac{\alpha\pi}{2}\right)$$

by Paul Levy in the specialized literature being used generally under its logarithm form:

From the above characteristic expression it cam be noticed that when defining stable paretian distribution four factors are needed ($\alpha,\beta,\delta,\gamma$) as opposed for example to the case of the normal distribution defined only by two, the mean and the standard deviation. We present the four parameters and their significance.

1. *Location parameter* (δ): if $\alpha>1$, it represents the expected value (mean) of the distribution.
2. *Scale parameter* (γ);
3. *Skewness index* (β): can take values between –1 and 1;
   (a) if $\beta=0$ then the distribution is symmetrical;
   (b) if $\beta>0$ then he distribution exhibits a positive asymmetry and the degree is increasing as β approaches 1;
   (c) analog for $\beta<0$ mentioning that the asymmetry is negative.
4. *Characteristic exponent or stability parameter* ($0<\alpha\leq 2$).

From the above four parameters, the characteristic exponent α is the most important if we are considering comparing the Gaussian hypothesis with the stable paretian because α determines the height (the probability/frequency) of the extreme tails and can take any value within the (0,2] interval. The two hypothesis are identical only when $\alpha=2$[267]. If $\alpha\in(0,2)$ then the extreme tails of the paretian distribution are

[267] The logarithm of the characteristic function for the normal distribution is: $\log\ f(t) = i\mu t - \frac{\sigma^2}{2}t^2$, with $\alpha=2$, $\beta=0$, $\delta=\mu$, $\gamma=\sigma^2/2$.

higher than those of the normal distribution with a total probability increasing with α moving from 2 to 0. A very important aspect is that the variance exists and it is finite only in the case when $\alpha=2$, that is only for the normal law in all other cases being infinite. On the other hand, the expected value exist for any value of $\alpha>1$. In conclusion, the stable paretian hypothesis advocated by Mandelbrot says that for probability distribution associated to the subsequent price changes the characteristic exponent α is situated within the (1,2) interval and as a consequence these distributions have an expected value but their variance is infinite.

Because the conflict between the two hypothesis are concentrated especially near the α value, a rational choice between the two hypothesis at least at a theoretical level can be made only by estimating the true value of the α parameter. But this task is not an easy one because the explicit expressions of the densities for stable paretian laws are known only in three cases: the normal distribution ($\alpha=2$), the Cauchy distribution ($\alpha=1$, $\beta=0$) and the coin tossing experiment ($\alpha=1/2$, $\beta=1$, $\delta=0$, $\gamma=1$). Without the knowledge of any other density functions is very hard to introduce and prove different assumptions related to the behavior of α estimates in the case of samples. Still, significant empirical progresses were made in this matter in [Fama, 1965].

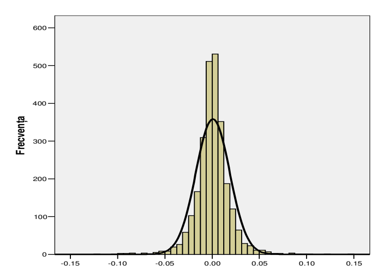
Financial implication of the stable paretian hypothesis at the Bucharest Stock Exchange

In this section e will graphically analyze the probability distribution associated with the logarithmic returns of the two main indexes at Bucharest Stock Exchange (BSE), that is BET and BET-FI as well as two intensely traded stocks, Banca Transilvania (TLV) and SIF Moldova (SIF2). In the same time the main statistical characteristics will be summarized in table 1. For each stock or index we will consider the relation between the empirical distribution and a normal distribution having as parameters the average and the standard deviation corresponding to the observed sample of returns. In the case of the BET index we used a sample of 2,571 daily logarithmic returns in the period 19.09.1997-7.02.2008, a graphical representation of the empirical probability distribution being in displayed in figure 1.

As it can be easily noticed, the empirical returns around the zero value are much more frequent than the normal distribution would imply, this one being marked with a continuing line in the chart resulting the pronounced leptokurtic character. A more detailed view, available in figure 2 reveals also a perspective upon the extreme returns, positive and negative, again much larger than the Gaussian hypothesis would imply. On the other hand, it seems that the asymmetry degree is not so high since the designed coefficient takes a small value of just 0.1 compared to the zero value (see table 1). Still, speaking about all the returns from the sample we can conclude that the distribution of the empirical returns is more peaked and presents extreme tails more preeminent than a normal distribution indicating a rejection of the Gaussian hypothesis and an acceptance of the stable paretian.

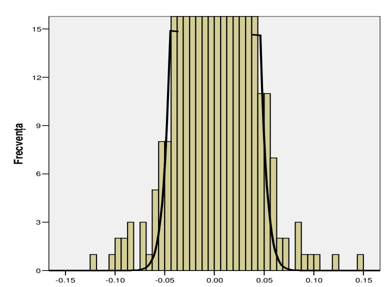
In a similar way, the above conclusions remain valid for the five financial companies index, BET-FI (sample formed by 1.778 returns, observed in the period 31.10.2000 and 7.02.2008), a higher volatility being noticed respectively a kurtosis coefficient more close to the normal distribution.

Figure 1: Histogram of the daily returns in the case of the BET index (1997-2008)



Source: Author's manipulations in SPSS.

Figure 2: Histogram of daily returns in the case of the BET index (1997-2008) (detail)



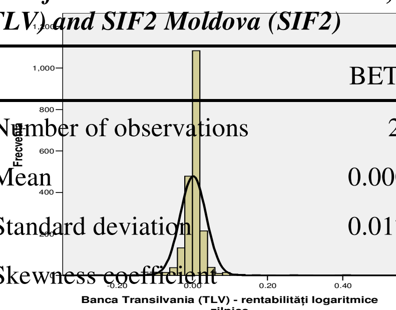
Source: Author's manipulations in SPSS.

Related to this observation, we consider that an intuitive aspect also exists for the relation between the volatility associated to a probability distribution and the high density of the returns around the zero value. For a stock or a market index which is little traded at large periods of time a liquidity problem arises caused mainly by a low interest from the part of the investors for the specific financial asset. In this kind of conditions, the daily average volatility in the case of a sample with an acceptable financial and statistical dimensions (recommendable over five years of trading) will be somehow low because of the days in which the financial asset does not record large price changes or, more sadly, when it is not traded. In such periods, the returns will be very close to the zero value leading to a leptokurtic distribution with high frequencies around the zero value.

When we analyze the empirical distributions of the TLV and SIF2 stocks, we can notice in the first place the significance with whom the individual characteristics of those are exhibited (see table 1). Thus, both stocks exhibit a significant positive asymmetry of 2.59 and 1.47, because the two stocks have recorded high price growth rhythms in this period of time. On the other hand, the kurtosis coefficient records very high values of 45.29 and 38, because the null or very small returns were not compensated by some more volatile evolutions of other stocks like it was the case with two indexes previously analyzed. The two significant biases, related to the asymmetry and the kurtosis as well as an inspection of the associated charts are leading to a rejection of the Gaussian hypothesis. In the same time, it is also empirically verified that the indexes returns are approaching significantly closer to the Gaussian hypothesis than the returns of individual stocks.

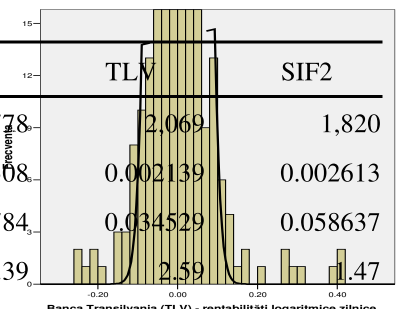
Based on the previous exemplifications we can state some financial implications of the stable paretian hypothesis. Firstly, this hypothesis implies that on the speculative markets the equilibrium prices are formed as a consequence of much more extreme variations compared to the Gaussian hypothesis. This means that a paretian market is inherently riskier than a Gaussian one, aspect reflected by a variation interval associated to the expected value of the return higher respectively a bigger loss probability.

Figure 3: Histogram of daily returns in the case of Banca Transilvania



Source: Author's manipulations in SPSS.

Figure 4: Histogram of daily returns in the case of Banca Transilvania (details)



Source: Author's manipulations in SPSS..

Table 1: Main characteristics of the empirical distributions of he daily returns in the case of the BET and BET-FI indexes, respectively the stocks Banca Transilvania (TLV) and SIF2 Moldova (SIF2)

	BET	BET-FI	TLV	SIF2
Number of observations	2,570	1,778	2,069	1,820
Mean	0.000774	0.002308	0.002139	0.002613
Standard deviation	0.017909	0.023784	0.034529	0.058637
Skewness coefficient	0.10	0.39	2.59	1.47
Kurtosis coefficient	10.46	8.97	45.29	38.00

Secondly, on a paretian market the speculators cannot assure themselves constantly against huge losses using instruments like the stop-loss orders and this is due mainly because while for a Gaussian market a huge variation is likely to be formed by many smaller changes on a paretian market it is very probable that the huge change to be the results of just a few large price changes[268]. This means that if the market will record a downfall in the stock prices, this correction will be very rapidly and not allowing for many intermediate prices necessary for the execution of the stop-loss orders. This aspect could be very easily noticed at Bucharest Stock Exchange (BSE) especially in January-February period of the years between 2004 and 2007 and of course 2008. When during a trading session at the stock exchange, many stocks

[268] The proof can be found in the following article: Darling, D., 1952, „The Influence of the Maximum Term in the Addition of Independent Random Variables", *Transactions of the American Mathematical Society*, vol. 15, pag. 95-107.

record price falls of more than 5% it is almost impossible for the investors to protect themselves through this stop-loss orders or different derivatives instruments.

In this article we look at all important features of project financing. In a project financing,, lenders initially look to the cash flow from the project being financed rather than the corporation or corporations seeking funding. The moving party in a project is its promoter or sponsor. The ultimate goal in project financing is to arrange a borrowing for a project which will benefit the sponsor and, at the same time, be completely non-recourse to the sponsor, in no way affecting its credit standing or balance sheet. This can be accomplished by using the credit of a third party to support the transaction. Different guarantees and undertakings of different partners may be used in each time frame to provide the credit support necessary for structuring a project financing. Most large projects employ different lenders or groups of lenders because of the different risks involved as the project facility progresses through construction to operation, and the different ability of lenders to cope with and accept such risks.

Key words: project financing, SPV, sponsor, credit, lender.

WHAT IS PROJECT FINANCING?

Structured financing is a debt obligation that is backed by the value of an asset or credit support provided by a third party. The special purpose vehicle (SPV) or special purpose entity (SPE) is the entity that acquires the asset and sells the securities to purchase the assets. Structured finance is used by corporations to fund major projects so that the lenders look to the cash flow from the project being financed rather than corporation or corporations seeking funding. This financing technique is called ***project financing*** and uses the SPV to accomplish its financing objectives. Discussions associated with project financing tend to focus on large complex projects. This might lead one to the conclusion that the project financing principles discussed in this article have little application to smaller, more ordinary financings.

Although the term "project financing" has been used to describe all types of financing of projects, both with and without recourse, the term has evolved and a more precise definition is: *A financing of a particular economic unit in which a lender is satisfied to look initially to the cash flows and earnings of that economic unit as the source of funds from which a loan will be repaid and to the assets of the economic unit as collateral for the loan.* A key word in the definition is "initially." While a lender may be willing to look initially to the cash flows of a project as the source of funds for repayment of the loan, the lender must also feel comfortable that the loan will in fact be paid on a worst case basis. This may involve undertakings or direct or indirect guarantees by third parties who are motivated in some way to provide such guarantees. Project financing has great appeal when it does not have a substantial impact on the balance sheet or the creditworthiness of the sponsoring entity. Boards of directors are receptive to proceeding with projects which can be very highly leveraged or financed entirely or substantially on their own merits. The moving party in a project is its *promoter* or *sponsor*. A project may have one or several sponsors. The motivation of construction companies acting as sponsors is to profit in some way from the construction or operation of the project. The motivation of operating companies for sponsoring a project may be simply to make a profit from selling the product produced by the project. In many instances the motivation for the project is to provide processing or distribution of a basic product of the sponsor or to ensure a source of supply vital to the sponsor's business. The ultimate goal in project financing is to arrange a borrowing for a project which will benefit the sponsor and at the same time be completely non-recourse to the sponsor, in no way affecting its credit standing or balance sheet. One way this can be accomplished is by using the credit of a third party to support the transaction. Such a third party then becomes a sponsor. However, projects are rarely financed independently on their own merits without credit support from sponsors who are interested as third parties and who will benefit in some way from the project. There is considerable room for disagreement between lenders and borrowers as to what constitutes a feasible project financing. Borrowers prefer their projects to be financed independently off-balance sheet with appropriate disclosures in financial reports indicating the exposure of the borrower to a project financing. Lenders, on the other hand, are not in the venture capital business. They are not equity risk takers. Lenders want to feel secure that they are going to be repaid either by the project, the sponsor, or an interested third party. Therein lies the challenge of most project financings. The key to a successful project financing is structuring the financing of a project with as little recourse as possible to the sponsor while at the same time providing sufficient credit support through guarantees or undertakings of a sponsor or third party, so that lenders will be satisfied with the credit risk. There is a popular misconception that project financing means off balance sheet financing to the point that the project is completely self-supporting without guarantees or undertakings by financially responsible parties. This leads to misunderstandings by prospective borrowers who are under the impression that certain kinds of projects may be financed as stand-alone, self-supporting project financings and, therefore, proceed on the assumption that similar projects in which they are interested can be financed without recourse to the sponsor, be off-balance sheet to the sponsor, and be without any additional credit support from a financially responsible third party. It would be a content circumstance if it were possible simply to arrange a 100% loan for a project (non-recourse to sponsors) which looked as though it would surely be successful on the basis of optimistic financial projections. Unfortunately, this is not the case. There is no magic about project financing. Such a financing can be accomplished by financial engineering which combines the undertakings and various kinds of guarantees by parties interested in a project being built in such a way that none of the parties alone has to assume the full credit responsibility for the project, yet when all the undertakings are combined and reviewed together, the equivalent of a satisfactory credit risk for lenders has resulted.

Reasons for jointly owned or sponsored projects

There has been an increasing trend towards jointly owned or controlled projects. Although most corporations prefer sole ownership and control of a major project, particularly projects involving vital supplies and distribution channels, there are factors that encourage the formation of jointly owned or controlled projects that consist of partners with mutual goals, talents, and resources. These factors include: The undertaking is beyond a single corporation's financial and/or managerial resources; The partners have complementary skills; Economics of a large project lower the cost of the product or service substantially over the possible cost of a smaller project if the partners proceeded individually; The risks of the projects are shared; One or more of the partners can use the tax benefits. Greater debt leverage can be obtained. The joint sponsors also select the legal form of the SPV (corporation, partner, limited partnership, Limited Liability Company, contractual joint venture, or trust) that will be satisfying their tax and legal objectives.

Credit exposures in a project financing

To place a project financing into perspective, it is helpful to review the different credit exposures that occur at different times in the course of a typical project financing.

- Project financing risks can be divided into three time frames in which the elements of credit exposure assume different characteristics: - engineering and construction phase; - start-up phase; - operations according to planned specifications. Different guarantees and undertakings of different partners may be used in each time frame to provide the credit support necessary for structuring a project financing.

Projects generally begin with a long period of planning and engineering. Equipment is ordered, construction contracts are negotiated, and actual construction begins. After commencement of construction, the amount at risk begins to increase sharply as funds are advanced to purchase material, labor, and equipment. Interest charges on loans to finance construction also begin to accumulate.

Project lenders do not regard a project as completed on conclusion of the construction of the facility. They are concerned that the plant or facility will work at the costs and to the specifications which were planned when arranging the financing. Failure to produce the product or service in the amounts and at the costs originally planned means that the projections and the feasibility study are incorrect and that there may be insufficient cash to service debt and pay expenses. Project lenders regard a project as acceptable only after the plant or facility has been in operation for a sufficient period of time to ensure that the plant will in fact produce the product or service at the price, in the amounts, and to the standards assumed in the financial plan which formed the basis for the financing. This start-up risk period may run from a few months to several years.

Once the parties are satisfied that the plant is running to specification, the final operating phase begins. During this phase, the project begins to function as a regular operating company. If correct financial planning was done, revenues from the sale of the product produced or service performed should be sufficient to service debt—interest and principal— pay operating costs, and provide a return to sponsors and investor

Some projects are financed from beginning to end with a single lender or single group of lenders. However, most large projects employ different lenders or groups of lenders during different risk phases. This is because of the different risks involved as the project facility progresses through construction to operation, and the different ability of lenders to cope with and accept such risks. Some lenders like to lend for longer terms and some prefer short-term lending. Some lenders specialize in construction lending and are equipped to monitor engineering and construction of a project, some are not. Some lenders will accept and rely on guarantees of different sponsors during the construction, start-up or operation phases, and some will not. Some lenders will accept the credit risk of a turn-key operating project, but are not interested in the high-risk lending during construction and start-up. Interest rates will also vary during the different risk phases of project financing and with different credit support from sponsors during those time periods. Short-term construction lenders are very concerned about the availability of long-term "take out" financing by other lenders upon completion of the construction or start-up phase. Construction lenders live in fear of providing their own unplanned take out financing. Consequently, from the standpoint of the construction lender, take out financing should be in place at the outset of construction financing.

Key elements of a successful project financing

There are several elements that both sponsors and lenders to a project financing should review in order to increase the likelihood that a project financing will be successful. The key ones are: a satisfactory feasibility study and financial plan should be prepared with realistic assumptions regarding future inflation rates and interest rates; the cost of product or raw materials to be used by the project is assured; a supply of energy at reasonable cost has been assured; A market exists for the product, commodity, or service to be produced; transportation is available at a reasonable cost to move the product to the market; adequate communications are available; building materials are available at the costs contemplated; the contractor is experienced and reliable; the operator is experienced and reliable; management personnel are experienced and reliable; untested technology is not involved; the contractual agreement among joint venture partners, if any, is satisfactory; the key sponsors have made an adequate equity contribution; satisfactory appraisals of resources and assets have been obtained; adequate insurance coverage is contemplated; the risk of cost overruns has been addressed; the risk of delay has been considered; the project will have an adequate return for the equity investor; environmental risks are manageable. When the project involves a sovereign entity, the following critical elements are important to consider ensuring the success of a project: a stable and friendly political environment exists; licenses and permits are available; contracts can be enforced; legal remedies exist; there is no risk of expropriation; country risk is satisfactory; sovereign risk is satisfactory; currency and foreign exchange risks have been addressed; protection from criminal activities such as kidnapping and extortion; existence of a commercial legal system protecting property and contractual rights.

The best way to appreciate the concerns of lenders to a project is to review and consider some of the common causes for project failures, which include the following: Delay in completion, with consequential increase in the interest expense on construction financing and delay in the contemplated revenue flow; Capital cost overrun; Technical failure; Financial failure of the contractor; Uninsured casualty losses; Increased price or shortages of raw material; Technical obsolescence of the plant or equipment; Loss of competitive position in the marketplace; Poor management; Overly optimistic appraisals of the value of pledged security, such as oil and gas reserves. In addition, for projects in a foreign country, the following are causes for project failures: government interference; expropriation and financial insolvency of the host government. For a project financing to be successfully achieved, these risks must be properly considered, monitored, and avoided throughout the life of the project.

While the sponsor or sponsors of a project financing ideally would prefer that the project financing be a non-recourse borrowing which does not in any way affect its credit standing or balance sheet, many project financings are aimed at achieving some other particular credit impact objective, such as any one or several of the following: To avoid being shown on the face of the balance sheet; To avoid being shown as debt on the face of the balance sheet so as not to impact financial ratios; To avoid being shown in a particular footnote to the balance sheet; To avoid being within the scope of restrictive covenants in an indenture or loan agreement which precludes direct debt financing or leases for the project; To avoid being considered as a cash obligation which would dilute interest coverage ratios, and affect the sponsor's credit standing with the rating services; To limit direct liability to a certain period of time such as during construction and/or the start-up period, so as to avoid a liability for the remaining life of the project; To keep the project off-balance sheet during construction and/or until the project generates revenues. Any one or a combination of these objectives maybe sufficient reason for a borrower to seek the structure of a project financing. Liability for project debt for a limited time period may be acceptable in situations in which liability for such debt is unacceptable for the life of the project. Where a sponsor cannot initially arrange long-term non-recourse debt for its project that will not impact its balance sheet, the project may still be feasible if the sponsor is willing to assume the credit risk during the construction and start-up phase, and provided lenders are willing to shift the credit risk to the project after the project facility is completed and operating. Under such an arrangement, most of the objectives of an off-balance sheet project financing and limited credit impact can be achieved after the initial risk period of construction and start-up. In some instances, the lenders may be satisfied to rely on revenue produced by unconditional take-or-pay contracts from users of the product or services to be provided by the project to repay debt. In other instances, the condition of the market for the product or service may be such that sufficient revenues are assured after completion of construction and start-up so as to convince lenders to rely on such revenues for repayment of their debts.

Project financing is sometimes called off-balance sheet financing. However, while the project debt may not be on the sponsor's balance sheet, the project debt will appear on the face of the project balance sheet. In any event, the purpose of a project financing is to segregate the credit risk of the project in order that the credit risk of lending to either the sponsor or the project can be clearly and fairly appraised on their respective merits. The purpose is not to hide or conceal a liability of the sponsor from creditors, rating agencies, or stockholders. Significant undertakings of sponsors and investors in projects subject to the Financial Accounting Standards Board must usually be shown in footnotes to their financial statements if not in the statements themselves. Because project financings are concerned with balance sheet accounting treatment, familiarity with accounting terms used to describe or rationalize balance sheet reporting is important. Terms such as contingent liability, indirect liability, deferred liability, deferred expense, fixed charges, equity accounting, and materiality are used to rationalize the appropriate positioning of entries in a sponsor's financial statements and footnotes. Accounting rules for reporting these types of liabilities are under continual review, as the accounting profession grapples with the problem of proper and fair disclosure and presentation of objective information to stockholders, lenders, rating agencies, guarantors, government agencies, and other concerned parties.

Corporations set target rates of return for new capital investments. If a proposed capital expenditure will not generate a return greater than a company's target rate, it is not regarded as a satisfactory use of capital resources. This is particularly true when a company can make alternative capital expenditures which will produce a return on capital in excess of the target rate.

Project financing can sometimes be used to improve the return on the capital invested in a project by leveraging the investment to a greater extent than would be possible in a straight commercial financing of the project. This can be accomplished by locating other parties interested in getting the project built, and shifting some of the debt coverage to such parties through direct or indirect guarantees. An example would be an oil company with a promising coal property which it did not wish to develop because of better alternative uses of its capital. By bringing in a company which required the coal, such as a public utility, an indirect guarantee might be available in the form of a long-term take-or-pay contract which would support long-term debt to finance the construction of the coal mine. This, in turn, would permit the oil company's investment to be highly leveraged and consequently to produce a much higher rate of retur

There are often other side benefits resulting from segregating a financing as a project financing which may have a bearing on the motives of the company seeking such a structure. These benefits include: credit sources may be available to the project that would not be available to the sponsor; guarantees may be available to the project that would not be available to the sponsor; a project financing may enjoy better credit terms and interest costs in situations in which a sponsor's credit is weak; higher leverage of debt to equity may be achieved; legal requirements applicable to certain investing institutions may be met by the project but not by the sponsor; regulatory problems affecting the sponsor may be avoided; for regulatory purposes, costs may be clearly segregated as a result of a project financing; construction financing costs may not be reflected in the sponsor's financial statements until such time as the project begins producing revenue. In some instances, any one of the reasons stated above may be the primary motivation for structuring a new operation as a project financing.

Tax benefits from any applicable tax credits, depreciation deductions, interest deductions, depletion deductions, research and development tax deductions, dividends-received credits, foreign tax credits, capital gains, and non-capital start-up expenses are very significant considerations in the investment, debt service, and cash flow of most project financings. Care must be used in structuring a project financing to make sure that these tax benefits are used. Where a project financing is housed in a new entity that does not have taxes to shelter, it is important to structure the project financing so that any tax benefits can be transferred to parties in a position currently able to use such tax benefits.

Project financings are complex. The documentation tends to be complicated, and the cost of borrowing funds may be higher than conventional financing. If the undertakings of a number of parties are necessary to structure the project financing, or if a joint venture is involved, the negotiation of the original financing agreements and operating agreements will require patience, forbearing, and understanding. Decision making in partnerships and joint ventures is never easy, since the friendliest of partners may have diverse interests, problems, and objectives. However, the rewards and advantages of a project financing will often justify the special problems that may arise in structuring and operating the project.

COMMERCIAL INFORMATION AND CREDIT ANALYSIS PRESENTED IN A LOAN MEMORANDUM

Truica Luiza Denisa

UniCredit Tiriac Bank , Relationship Manager Corporate, PhD. Student – Academy of Economic, Studies, Bucharest, Bucharest, 7th Brinduselor Str. , building G3, ap. 14,3rd district, denisa.truica@unicredit.ro, 0728.80.80.93,

For financing corporate companies, banks use own and varied forms of loan memorandums which gather commercial and financial knowledge about the client. Credits granted to companies, whether public or private, generally comprises loans for working capital and for fixed assets, financing such as overdrafts, term loans, syndicated loans, and revolving credit and working capital loans. Banks do analyze a set of basic and additional criteria such as the ability of continuing business, the expected future cash flows, security and collateral, the rate of return to the bank as well as the level of the whole business which the bank has done with them. Credit papers needed for the conclusion of the convention between the bank and a potential client are governed by Law No 58 – the Banking law and procedures issued by NBR. The composition and quality of a bank's loans should be reflected in its loan policy.

Key words: client, loan, analysis, ratios, bank

A loan is the immediate possession of resources in exchange of a future payment promise involving also an interest payment that rewards the lender. Before granting any loan, it is necessary for the lender to know the purpose of the credit same as its legal purpose. On corporate segment, types of credit vary.

Generally, banks have their specific lending policies, which may change from time to time due to the market conditions or government regulations. Their policies are essentially based on the evaluation of the related risks such as the credit risk, interest rate risk and concentrated risk. The lending may be also authorized at a branch level if the branch portfolio allows that. In order to make proper lending decisions, banks purposely observe a set of general lending principles such as age and state of health, stability, integrity and honesty, sources of income, regular expenditure, existing connections, ability to manage financial affairs as well as margin, purpose, amount, repayment capability and security.

As corporations and companies represent the major category of clients, for the corporate lending banks do analyze a set of basic and additional criteria such as the ability of continuing business, the expected future cash flows, security and collateral, the rate of return to the bank as well as the level of the whole business which the bank has done with them. The usual procedures which banks apply in the loan granting to corporate borrowers specifically include submission of the application and required information, evaluation of the information, initial evaluation of the proposed security, negotiation, approval, legal examination of the security, signing of the contract, disbursement of the amount and recovery of the capital and interest. The credit granted to companies, whether public or private, generally comprises loans for working capital and for fixed assets, financing such as overdrafts, term loans, syndicated loans, and revolving credit and working capital loans.

The subjects of a loan memorandum

Overdrafts**:** Overdrafts are usually granted to those companies desirous to use the credit amount not as a whole but rather in accordance with their needs and for a certain period without having to pay interest on the entire amount but on the term agreed for interest calculation. In such cases, whenever the company gets excess of capital it can repay parts of the credit and, consequently, decrease the amount outstanding.

Export Financing: As most major companies deal with exports, banks can offer short time credit to exporters until they recoup the money from importers, upon a collectibles guarantee for the lending bank.

Loans for Fixed Assets Financing: Such loans essentially include short-term, medium-term and long-term loans with respect to maturity. The security for such a lending may be uncovered, covered by cash equivalent, by personal guarantees or mortgage assets, collateral and, according to the type of repayment, it may comprise equal capital amortization, equal installment payment, specific terms, fixed or floating interest etc. When loans in foreign currency are expected to be granted, banks usually tend to hedge their positions in the foreign currency but, very often, they rather speculate.

Syndicated Loans: Unlike the participation loans, the syndicated ones consist of an agreement specifying that two or more banks accept to directly lend to the same borrower or borrowers. In such a case, one of the banks plays the role of the agent bank while the others participate by own portions in the syndicate, the risks being shared by all of them.

The loan memorandum

There are five stages to any new lending:

1. Introduction of the customer;

Lenders always choose their clientele. An important source of new business for most lenders is introductions from professional advisers such as accountants and solicitors. But, a bank has no obligation to lend to customers introduced in this way.

2. The application by the customer;

The application (credit request) can take many forms but should include a plan for repaying the loan and an assessment of the contingencies, which might reasonably arise, and how the borrower would intend to deal with them. It might be in detailed written form, or not.

3. Review of the application;

During this stage all the information must be tested. It is sometimes difficult to remember all the points to be covered during an interview and many lenders use a check list (a mnemonics) including: - character (about the individual's character); - capital; - capability/ability; - purpose/destination; - amount; - repayment; - terms; - security/insurance. Ability - this aspect relates to the borrower's ability in managing financial affairs and is similar to character (about skill, experience of the manager). Amount - Is the customer asking for either too much or too little? There are dangers in both and it is important therefore to establish that the amount requested is correct. The amount requested should be in proportion to the customer's own reasons and contribution. Repayment - It is important that the source of repayment is made clear. Where the source of repayment is income, the lender will need projections to ensure that there is a surplus of funds to cover the repayment after meeting other commitments. Insurance - The canons of lending should be satisfied of available security.

4. Evaluation and

5. Monitoring and control.

Both steps aim to establish the risk involved. Listing the pros and cons of a proposition is helpful.

Under the provisions of the Law No 58 – the Banking law, the credit documentation needed for the conclusion of the convention between the bank and a potential client are the following:

- Credit request;
- Current financial situation of the applicant and of any of its guarantors, including the projected cash flows for the repayment of credit and principals;
- Description of the guarantees for the entire payment of the debt, and if necessary an analysis of the goods representing the guarantee;
- Description of the credit conditions containing the credit value, the interest rate, the repayment procedure, the scope for using the credit;
- Specimen of signature for each person that authorized the credit and the name of the bank;
- Annual Balance Sheet and Profit and Loss Account for the last three years of operation (plus annexes);
- Company's Overview;
- Description of the current activity/ financial info;
- Description of the project proposed for credit granting;
- The cash-flow statement for the entire loan period.

As a summarize, it should be mentioned that before any loan is granted, the following questions must be answered by the customer: how much is required? the purpose of the loan (legal, moral and within the policy of the government and the bank, National Bank of Romania); length of time the advance is requested? (how long the money is required and whether the outstanding debt will be repaid monthly, quarterly etc); the source of repayment. Any customer must have sufficient resources to repay (capital + interest) the bank within the stipulated agreed time. The sources of the repayment could be from wages, dividends, an inheritance and profits and so on.

Credit analysis

Credit analysis is the process of assessing the risk of lending to the business. The so-called credit risk must be evaluated against the benefits that the bank expects to derive from making the loan. The direct benefits are simply the interest and fees earned on the loan and possibly, the deposit balances required as a condition of the loan. Indirect benefits consist of the initiation or maintenance of a relationship with the borrower that may provide the bank with increased deposits and demand for a variety of bank services.

Credit risk assessment has both qualitative and quantitative dimensions; the former are generally the more difficult to assess. The steps in qualitative risk assessment are primarily gathering information on the borrower's record of financial responsibility, determining his or her true purpose for wanting to borrow funds, identifying the risks confronting the borrower's business under future industry and economic conditions, and estimating the degree of commitment the borrower will have regarding repayment. The quantitative dimension of credit risk assessment consists of the analysis of historical financial data and the projection of future financial results to evaluate the borrower's capacity for timely repayment of the loan and, indeed, the borrower's ability to survive possible industry and economic reverses.

The essence of all credit analysis can be captured in four basic factors or lines of inquiry:

- The borrower's character – most bankers agree that the paramount factor in a successful loan is the honesty and goodwill of the borrower;
- The use of loan funds – determining the true need and use of funds requires good analytical skills in accounting and business finance;
- Primary source of repayment – the analyst's accounting and finance skills are crucial in determining the ability of the borrower to repay a loan from cash flows. He must ascertain the timing and sufficiency of these cash flows and evaluate the risks of cash flows falling short.
- Secondary source of repayment – the collateral value should cover, in addition to the loan amount and interest due, the legal costs of foreclosure and interest during foreclosure proceeds. Even if the collateral is the preferred secondary source of repayment, others can be guarantors and co-makers, but in such cases, the collection usually requires expensive litigation and results in considerable ill will between the bank, borrower, and guarantor. In credit investigation, banks usually resort to the following sources of information:
- Customer interview – it provides the most important information needed in credit investigation, including the type and amount of the loan required, sources and plans of repayment, eventual collateral and guarantors, previous and current creditors, primary customers and trade suppliers, accountants, main officers and shareholders etc.
- Internal sources – credit files on any current or previous borrowings, checking account activity, other previous or current deposits, liabilities, income sources, assets, expenses and revenues etc.
- External sources of information – specialized service agencies, newspapers, magazines etc.

Before granting a credit/loan, a bank makes a trustworthiness financial analysis of the customers. The main trustworthiness ratios which summarize the four categories of financial ratios are:

Leverage ratios

$$\text{Long-term debt ratio} = \frac{\text{long-term debt}}{\text{long-term debt} + \text{equity}}$$

$$\text{Debt-equity ratio} = \frac{\text{long-term debt}}{\text{equity}}$$

$$\text{Total debt ratio} = \frac{\text{total liabilities}}{\text{total assets}}$$

$$\text{Times interest earned} = \frac{\text{EBIT}}{\text{interest payments}}$$

$$\text{Cash coverage ratio} = \frac{\text{EBIT} + \text{depreciation}}{\text{interest payments}}$$

Liquidity ratios

$$\text{NWC to assets} = \frac{\text{net working capital}}{\text{total assets}}$$

$$\text{Current ratio} = \frac{\text{current assets}}{\text{current liabilities}}$$

$$\text{Quick ratio} = \frac{\text{cash} + \text{marketable securities} + \text{receivables}}{\text{current liabilities}}$$

$$\text{Cash ratio} = \frac{\text{cash} + \text{marketable securities}}{\text{current liabilities}}$$

$$\text{Interval measure} = \frac{\text{cash} + \text{marketable securities} + \text{receivables}}{\text{average daily expenditures from operations}}$$

Efficiency ratios

$$\text{Total asset turnover} = \frac{\text{sales}}{\text{average total assets}}$$

$$\text{Average collection period} = \frac{\text{average receivables}}{\text{average daily sales}}$$

$$\text{Inventory turnover} = \frac{\text{cost of goods sold}}{\text{average inventory}}$$

$$\text{Days' sales in inventories} = \frac{\text{average inventory}}{\text{cost of goods sold}/365}$$

Profitability ratios

$$\text{Net profit margin} = \frac{\text{net income} + \text{interest}}{\text{sales}}$$

$$\text{Return on assets} = \frac{\text{net income} + \text{interest}}{\text{average total assets}}$$

$$\text{Return on equity} = \frac{\text{net income}}{\text{average equity}}$$

$$\text{Payout ratio} = \frac{\text{dividends}}{\text{earnings}}$$

$$\text{Plowback ratio} = 1 - \text{payout ratio}$$

$$\text{Growth in equity from plowback} = \text{plowback ratio} \times \text{ROE}$$

Financial ratios presented in a loan memorandum

While analyzing a company’s financial statements, the credit analyst might be overwhelmed by the sheer volume of data contained in the income statement, balance sheet, and statement of cash flow. Therefore they use only few ratios to summarize the firm’s leverage, liquidity, efficiency, and profitability.

All credits have a destination precise and mandatory which can not be changed by the borrowers. Credits are granted under guarantees that are written the credit contract. The guarantees must cover the maximum amount of credit, amount consisting in the principal and interest. The bank shall reserve the right to verify to its customers (borrowers) the permanent existence and the integrity of the ensured guarantees during the whole period of the credit. In the case in which the bank shall establish the non-observance of the contractual terms, it shall withdraw the credits before the maturity date. During the validity of the credit, the beneficiaries of the credits have the obligation to deposit to the bank their balance sheet and the financial statement.

Lending

Bank loans finance different corporate groups in the economy. Manufacturers, distributors, service firms, farmers, builders, homebuyers, commercial real estate developers, retailers, and others all depend on bank credit. The ways in which banks allocate their funds strongly influences the economic development of the community and nation. Every bank bears a degree of risk in its granting of credit, and, without exception, every bank experiences some loan losses when certain borrowers fail to repay their loans. Whatever the degree of risk taken loan, losses can be minimized through highly professional organization and management of the lending function.

The composition and quality of a bank's loans should be reflected in its loan policy. The policy sets out the bank's lending philosophy and specifies procedures and means of monitoring lending activity. A written loan policy should serve to obtain three results:

- produce sound and collectible loans;
- provide profitable investment of bank funds;
- encourage extensions of credit that meet the legitimate needs of the bank's market.

A meaningful loan policy will express strategies in concrete terms. The desired loan mix should be quantified. The loan mix expresses the diversification sought by the bank in its loan placements. Diversification reduces the level of default risk that is associated with large concentrations of loans in a single category.

The bank's liquidity strategy should be indicated, because it acts as constraint on lending activity and because liquidity is partly determined by the maturity structure of the loan portfolio. The desired size of the loan portfolio expresses the bank's intended aggressiveness in expanding its loan portfolio. A highly aggressive loan policy has both a bright side and a dark side. The bright side is that a large loan portfolio might increase bank earnings. The dark side is that an aggressive policy might lead to lower credit standards, marginal loans, and an unacceptable amount of risk. Most borrowers are exposed to risks that threaten their ability to repay their bank loans. However, all collaterals brought as security should be insured. Most banks conduct loan reviews to reduce losses and monitor loan quality.

Loan reviews consist of a periodic audit of the on-going performance of some or all of the active loans in a bank's loan portfolio. Its essence is credit analysis, although, unlike the credit analysis conducted by the credit department as part of the loan approval process, credit analysis in loan review occurs after the loan is in the books. Other than its basic objective of reducing loan losses, some intermediate objectives of loan review are as follows:

- to detect actual or potential problem loans as early as possible;
- to provide incentive for loan officers to monitor loans and report deterioration in their own loans;
- to enforce uniform documentation;
- to ensure that loan policies, banking laws, and regulations are followed;
- to inform management and the board about the overall condition of the loan portfolio;
- to aid in establishing loan loss reserves.

Whatever means are used to conduct loan reviews; the following points should be covered:

- financial condition and repayment ability of borrower;
- completeness of documentation;
- consistency with loan policy;
- perfection of security interest on collateral;
- legal and regulatory compliance;
- apparent profitability.

When a problem loan is detected, the responsible officer should take immediate corrective action to prevent future deterioration and minimize potential loss.

Summary: E-banking risk arises from fraud, processing errors, system disruptions, or other unanticipated events resulting in the institution's inability to deliver products or services. This risk exists in each product and service offered. Institutions should determine the appropriate level of security controls based on their assessment of the sensitivity of the information to the customer and to the institution and on the institution's established risk tolerance level.

Keywords: e-banking, risk management, security

1. E-banking risks

E-banking is defined as the automated delivery of new and traditional banking products and services directly to customers through electronic, interactive communication channels. E-banking includes the systems that enable financial institution customers, individuals or businesses, to access accounts, transact business, or obtain information on financial products and services through a public or private network, including the Internet or mobile phone. Customers access e-banking services using an intelligent electronic device, such as a personal computer (PC), personal digital assistant (PDA), automated teller machine (ATM), kiosk, or Touch Tone telephone.

In Romania, over 23 banks implemented and offer now e-banking services. The continuous development of the supporting technology, information security and e-banking strategy reflects on the increasing number of the e-banking customers. According to Communications and Information Technologies Ministry, the number of e-banking users and the transactions performed in this system, as well as the value of these transactions, registered a spectacular rising, displayed in the graphics below:

Year Index	2004	2005	2006	2007
E-banking customers	18.259	44.538	100.799	187.471
Transactions number	1.968.170	2.244.067	3.546.549	4.851.427
Transactions value (euro)	7.911.987.706	11.566.348.720	20.510.170.662	44.830.322.635

Source: Communications and Information Technologies Ministry

While the risks and controls are similar for the various e-banking access channels, this essay focuses specifically on Internet-based services due to the Internet's widely accessible public network. Accordingly, this project begins with a discussion of the two primary types of Internet websites: informational and transactional. Informational websites provide customers access to general information about the financial institution and its products or services.

Risk issues examiners should consider when reviewing informational websites include: Potential access to confidential financial institution or customer information if the website is not properly isolated from the financial institution's internal network; Potential liability for spreading viruses and other malicious code to computers communicating with the institution's website; and Negative public perception if the institution's on-line services are disrupted or if its website is defaced or otherwise presents inappropriate or offensive material.[2]

Transactional websites provide customers with the ability to conduct transactions through the financial institution's website by initiating banking transactions or buying products and services. Banking transactions can range from something as basic as a retail account balance inquiry to a large business-to-business funds transfer. E-banking services, like those delivered through other delivery channels, are typically classified based on the type of customer they support. The following table lists some of the common retail and wholesale e-banking services offered by financial institutions.

Since transactional websites typically enable the electronic exchange of confidential customer information and the transfer of funds, services provided through these websites expose a financial institution to higher risk than basic informational websites. Wholesale e-banking systems typically expose financial institutions to the highest risk per transaction, since commercial transactions usually involve larger dollar amounts. In addition to the risk issues associated with informational websites, examiners reviewing transactional e-banking services should consider the following issues:

- Security controls for safeguarding customer information;
- Liability for unauthorized transactions;
- Possible violations of laws or regulations pertaining to consumer privacy, anti-money laundering, anti-terrorism, or the content, timing, or delivery of required consumer disclosures

2. Transaction risk

Transaction risk arises from fraud, processing errors, system disruptions, or other unanticipated events resulting in the institution's inability to deliver products or services. This risk exists in each product and service offered. The level of transaction risk is affected by the structure of the institution's processing environment, including the types of services offered and the complexity of the processes and supporting technology.

In most instances, e-banking activities will increase the complexity of the institution's activities and the quantity of its transaction/operations risk, especially if the institution is offering innovative services that have not been standardized. Since customers expect e-banking services to be available 24 hours a day, 7 days a week, financial institutions should ensure their e-banking infrastructures contain sufficient capacity and redundancy to ensure reliable service availability. Even institutions that do not consider e-banking a critical financial service due to the availability of alternate processing channels, should carefully consider customer expectations and the potential impact of service disruptions on customer satisfaction and loyalty.[1]

The key to controlling transaction risk lies in adapting effective polices, procedures, and controls to meet the new risk exposures introduced by e-banking. Basic internal controls including segregation of duties, dual controls, and reconcilements remain important. Information security controls, in particular, become more significant requiring additional processes, tools, expertise, and testing. Institutions should determine the appropriate level of security controls based on their assessment of the sensitivity of the information to the customer and to the institution and on the institution's established risk tolerance level.

Generally, a financial institution's credit risk is not increased by the mere fact that a loan is originated through an e-banking channel. However, management should consider additional precautions when originating and approving loans electronically, including assuring management information systems effectively track the performance of portfolios originated through e-banking channels.

Funding and investment-related risks could increase with an institution's e-banking initiatives depending on the volatility and pricing of the acquired deposits. The Internet provides institutions with the ability to market their products and services globally. Internet-based advertising programs can effectively match yield-focused investors with potentially high-yielding deposits. But Internet-originated deposits have the potential to attract customers who focus exclusively on rates and may provide a funding source with risk characteristics similar to brokered deposits. An institution can control this potential volatility and expanded geographic reach through its deposit contract and account opening practices, which might involve face-to-face meetings or the exchange of paper correspondence.

Compliance and legal issues arise out of the rapid growth in usage of e-banking and the differences between electronic and paper-based processes. E-banking is a new delivery channel where the laws and rules governing the electronic delivery of certain financial institution products or services may be ambiguous or still evolving. Laws governing consumer transactions require specific types of disclosures, notices, or record keeping requirements. These requirements also apply to e-banking, and banking agencies continue to update consumer laws and regulations to reflect the impact of e-banking and on-line customer relationships.

Institutions that offer e-banking services, both informational and transactional, assume a higher level of compliance risk because of the changing nature of the technology, the speed at which errors can be replicated, and the frequency of regulatory changes to address e-banking issues. The potential for violations is further heightened by the need to ensure consistency between paper and electronic advertisements, disclosures, and notices.

3. Risk management

E-banking has unique characteristics that may increase an institution's overall risk profile and the level of risks associated with traditional financial services, particularly strategic, operational, legal, and reputation risks. These unique e-banking characteristics include: Speed of technological change, Increased visibility of publicly accessible networks, Less face-to-face interaction with financial institution customers. Management should review each of the processes discussed in this section to adapt and expand the institution's risk management practices as necessary to address the risks posed by e-banking activities.

Financial institution management should choose the level of e-banking services provided to various customer segments based on customer needs and the institution's risk assessment considerations. Institutions should reach this decision through a board-approved, e-banking strategy that considers factors such as customer demand, competition, expertise, implementation expense, maintenance costs, and capital support. Some institutions may choose not to provide e-banking services or to limit e-banking services to an informational website.

Financial institutions should periodically re-evaluate this decision to ensure it remains appropriate for the institution's overall business strategy. Institutions may define success in many ways including growth in market share, expanding customer relationships, expense reduction, or new revenue generation. If the financial institution determines that a transactional website is appropriate, the next decision is the range of products and services to make available electronically to its customers. To deliver those products and services, the financial institution may have more than one website or multiple pages within a website for various business lines.

Financial institutions should base any decision to implement e-banking products and services on a thorough analysis of the costs and benefits associated with such action. Some of the reasons institutions offer e-banking services include: Lower operating costs, Increased customer demand for services, and New revenue opportunities.

The individuals conducting the cost-benefit analysis should clearly understand the risks associated with e-banking so that cost considerations fully incorporate appropriate risk mitigation controls. Without such expertise, the cost-benefit analysis will most likely underestimate the time and resources needed to properly oversee e-banking activities, particularly the level of technical expertise needed to provide competent oversight of in-house or outsourced activities.

Security threats can affect a financial institution through numerous vulnerabilities. No single control or security device can adequately protect a system connected to a public network. Effective information security comes only from establishing layers of various control, monitoring, and testing methods. While the details of any control and the effectiveness of risk mitigation depend on many factors, in general, each financial institution with external connectivity should ensure the following controls exist internally or at their TSP.

Conclusions

A financial institution's board and management should understand the risks associated with e-banking services and evaluate the resulting risk management costs against the potential return on investment prior to offering e-banking services. Poor e-banking planning and investment decisions can increase a financial institution's strategic risk. Early adopters of new e-banking services can establish themselves as innovators who anticipate the needs of their customers, but may do so by incurring higher costs and increased complexity in their operations. Conversely, late adopters may be able to avoid the higher expense and added complexity, but do so at the risk of not meeting customer demand for additional products and services. In managing the strategic risk associated with e-banking services, financial institutions should develop clearly defined e-banking objectives by which the institution can evaluate the success of its e-banking strategy.

AUDIT PROCEDURES REGARDING THE INFORMATION THAT MUST BE CONTAINED IN THE FINANCIAL SITUATION OF CREDIT INSTITUTIONS

Vlad Mariana,

"Ştefan cel Mare" University of Suceava, University Street, no. 9, Suceava 720225 Romania, 0230/216147, e-mail: *marianav@seap.usv.ro,*

Vasilache Vasile

"AL.I. CUZA" University of IaşI, Carol I Street, no.11, Iaşi, 700506 Romania, 0744538413, e-mail: wasilachecristi@yahoo.com

The auditors must obtain sufficient adequate audit proofs, to be capable of issuing the reasonable conclusion upon which the audit opinion must be based on. The great majority of the audit evidence are collected from the interior of the audited entities, having as base the accounting evidence, which include in general the initial and justifiable accountancy registrations.

Keywords: the audit proof, balance sheet, profit and loss account, assets and liabilities, credit, bank.

Starting from the peculiarity of bank activities, global knowledge of the credit institution, as an objective of the audit plan, has as purpose not only identifying the operations, product and services offered to the customers, but also identifying the risks that can have a significant incidence upon the accounts, conditioning in this manner the initial control planning and the ulterior mission planning. In this manner, the auditor must pay attention to: conjuncture factors of the monetary market: performances and decline, main bank transactions, corresponding banks, anterior financial reports, degree of introducing and extending of informatics' technology, accounting system and internal control system, respectively: accounting policies adopted by the bank and their evolutions in the previous years, estimations contained in the audit reports of the last years, used procedures by the anterior auditors, realized tests, contained findings in the control document and their capitalization, account examination and balance sheet content, respectively: identifying the assets and liabilities by their inventory and their result capitalization, functioning of the computerized accountancy and financial information systems in order to identify interruptions, falls, errors, interior or exterior bank frauds, correct asset and liabilities representation in the balance sheet, of the capitals and of the results, establishing the significance limit and audit risk evaluation. So, the domains where the auditors and the assistants can be solicited for some knowledge are very vast and for completing the engagement, the auditor will solicit sufficient expertises on bank aspects, that must be relevant for the bank activity audit and expertises in the informatics technology system and communication networks used by the bank.

The auditor must obtain sufficient adequate audit proofs, to be capable of issueing the reasonable conclusions upon which the audit opinion must be based on. The great majority of the audit evidence are collected from the interior of the audited entities, having as base the accounting evidence, which include in general the initial and justifiable accountancy registrations as: verifications and registrations of the electronic fund transfers, bills, contracts, general journal and annual accounts book, accounting registries and other financial fittings that are not reflected in the official accounting registries; other evidences as working documents and cost calculation sheets. Among these information provided by the audited medium, the auditor must solicit collateral information, afferent to the external medium of the audited entity, based on received confirmations from commercial partners, other credit institutions, evaluative agents, etc. The procurement of the audit evidences, with the purpose of reaching some reasonable conclusions, based on which the auditor can fundament his opinion are done through audit procedures, so that the auditor could: obtain a good understanding of the entity and its medium, inclusively internal control, for evaluating the risks of some significant defalcations at the level of the financial situation, called "risk evaluation procedures", to test when it is necessary the operational efficiency of the indicators in preventing or detecting and correcting the significant defalcations of the financial situations, called "control tests" and to be able to detect significant defalcations through "fund procedures", including here all the detail tests for transactions categories, balance on current accounts and presenting information by means of the "fund analytical procedures". Regardless of the procedure chosen to collect audit evidence, rarely one of these can be the only method for obtaining an audit certainty. When it is used in conjunction with other audit evidence sources, each procedure can still provide and important part of the reliability of the audit evidences. The auditor must chose professional audit procedures and their application level, in order to optimize the audit mission, from the viewpoint of the process time but also of audit costs. In those circumstances, choosing the adequate procedures is a professional reasoning problem. Applying the audit procedures imply usually the selection of some elements out a multitude, which will be tested by the auditor, and based on which the auditor formulates his opinion extrapolating the obtained results of the entire multitude.

As a conclusion, during all his mission, the auditor seeks to obtain the proof elements that permit him to certify upon the annual financial situations, using procedures and techniques regarding the control of the justifying documents, physical observation, analytical exam. For obtaining the evidence elements, the control techniques used are the following: physical inspection and the observation, direct confirmation from a third party, examination of the documents, arithmetic control, analysis, estimations and confrontation between information and documents, analytical examination.

The credit institution accountancy has as essential function to exhaustively register economical-financial operations with the purpose of periodically obtaining and presenting under the form of a synthesis - financial documents, the patrimony situation and also the global result. There is a consensus in affirming that the financial documents must provided those who use them the necessary information needed in decision making. And still, although it is a question of an essential thing in determining the assigned objectives of the financial documents, is difficult to make a user hierarchy and to specify their own needs. The main users of the contained information in the annual financial situations of the credit institutions are: Board of Directors of the credit institutions, shareholders wishful to know the use mode of their bank contribution, National Bank of Romania as an issuance and control centre of the circulation money, financial organisms as budgetary income collecting organisms, customers, debtors and creditors, depositors in current accounts or deposits, stock market companies, other credit institutions with which the credit institution comes into credit and loaning relations, security operations or other businesses.

At credit institution level, accounting synthesis works are done periodically, consisting in general situations or on components of the economic mechanism, from which it can synoptically result the assets and passives, solvency, capitalization, debt degree and other information. The accounting synthesis papers are made according to the legal provisions, half-yearly and annually and at any time the situation asks for it, as new share issuance, merger, reorganization, change of unit's administration, etc. In an ensemble view, the annual situation is materialized in the annual financial situations (or annual accounts). According to the banking legislation in force, the credit institutions are obligated to present the National Bank of Romania their financial situations, done on individual base and, if there is the case, on consolidated base, only after have been audited by the approved financial auditors of NBR. Starting with January 1, 2006, the credit institutions must make also a different set of financial situations, corresponding to the International Financial Reporting Standards for proper information need of the users. The main components of the financial situations drawn up by the credit institutions are similar to the ones that must be done by the economic agents, as the following: the balance sheet with structures specific to the credit institutions, profit and loss account with structures specific to the credit institutions, the situation of proper capital modifications, situation of the treasury flux, annotation in the annual financial situations. The information contained in the synthesis situations are grouped in general on financial years (reporting and previous year) for creating the possibility to follow the dynamic of the patrimony evolution, types of credits and loans, in lei and in foreign exchange, on destinations, residents or non residence customer groups and depending on many other characteristics.

The diagram of the ***balance sheet*** for the credit institutions is different of that for economic agents. In this manner, the elements of the active patrimony are registered in their liquidity order. The first elements are the cash, reserves in current bank accounts, and the immobilizations are registered at the end of the assets. The liabilities contain the bonds or debts in the order of sight or term due date, and the capital with its components are registered at the end of the liability. From this perspective we can conclude that a priority attention is given to the actual and perspective solvency analysis. Besides the asked information of other international accountancy standards, the balance sheet must contain specifications, at least at the following asset and liability elements that are to be audited (see table).

ASSETS	LIABILITIES
1. Balances of account other bank	1. Deposits from other banks
2. Instruments on the monetary market	2. Deposits received from other sectors of the monetary market
3. Securities held for transactions	3. Capital and reserves
4. Other financial assets	
5. Investments in branches and associates entities	
6. Credits	

Table: Balance sheet for the credit institutions

The following audit procedures does not constitute an exhaustive list of procedures that can be taken and it doesn't even represent a minimal requirement according to which these must be taken. When auditing the *balances of account other banks*, the auditor must have in view the confirmations from third parties. If the balance held by other banks is the result of a large number of transactions, receiving the confirmations from other banks is a more convincing proof regarding the existence of the transactions and resulted inter-banking balances, than in the case of adequate internal controls. Also, the auditor takes into consideration if the accounts balances at other banks, existent at the date of the financial situations, are the expression of the good-will commercial transactions or if any significant variation towards the normal levels or stipulated reflect the transactions done mainly to form an non-natural impression upon the bank's financial position or to improve the liquidity indicators and asset rates. Where the cosmetization phenomenon appears in a form in which distorts the perfect image of the financial situations, the auditor asks the administration to adjust the balances presented in the financial situations, or to make supplementary information presentations in the annotations. If the administration cannot do this, the auditor takes into consideration the modification of the audit report. In auditing the following balance elements: *instrument on the monetary market* and *securities held for transactions,* the auditor must take in consideration the need of making a physical inspection or confirming the money amounts with the external custodian credit institutions, and also confronting the amounts with the accounting registries. Takes into consideration if he must test the corresponding registration based on engagements of the obtained income from monetary market instruments, if the relation between the owned securities and afferent input is a reasonable one, if all the significant profit and losses from selling and re-evaluations have been reported accordingly to the financial report framework. In discovering some debts and unregistered losses, the auditor tests the existence of agreements of term selling and rebuying. When they evaluate the instruments on the monetary market, will keep in mind the adequate degree of the evaluation techniques used in proportion with the issuer's creditworthiness, while in the evaluation of transactional securities, he will take into consideration the financial report framework, in which are prescribed different evaluation basis for the securities classified in the banking system, depending on the purpose for which are owned: transaction, portfolio investment or for anti-risk coverage. If the administration' intentions change, the used evaluation base also modifies, meaning that the possibility of modifying the asset classification offer the administration the possibility towards a fraudulent financial report, being available the recognition of a profit or avoiding the recognition of a loss. As a consequence, when the securities have been transferred from one category to another, the auditor should obtain sufficient and adequate evidence for supporting the statements and financial situations according to the revised intentions. *Other financial assets* are those elements that suppose some current fund investments, as the acquisition of security assets. The auditor must examine the base documentation for supporting the buying of these assets in order to determine if all the rights and obligations (as are the liabilities) have been correctly accounted. Due to the fact that there are no markets for such assets, is difficult to obtain an independent proof of their value. For that, in their evaluation the auditor must take into account the adequate degree of the used evaluation techniques as the nature and extent of any devaluation analysis that the administration has made and if the results are reflected in the asset value. In many cases, *the bank investment audit in subsidiaries and associated entities* is not different from the audit of such investments owned by any other entity. Still there are some special aspects that create some problems regarding the bank operations. So, the auditor takes in consideration if the afferent financial obligations are registered as debts of the bank and will pay attention at the implications of any legal or practical requirements so that the credit institution shall provide future financial support or ensuring the maintenance of the subsidiaries' operations and associated companies. The main audit concern is to make adequate the registered provisions for the *credit* afferent losses. For establishing the nature, extent and period of the activity to be developed, the auditor takes into consideration the following factors: the trusting degree that is reasonable for establishing the specific bank system for classifying the credit quality, ensuring procedures that all the documentation is correctly finished, internal credit revision procedures and internal audit activity, information examination based on which the bank evaluates and monitors the country risk and the criteria used for this; make up the credit portfolio, with a special attention for: concentrating the credits towards the debtors, commercial and industrial sectors, certain geographical regions, certain countries, increase for representation of the personal credits (a few valuable credits versus a lot of small value credits); credits given to the affiliate parties; for non performance credits a special attention is given to the previous years, regarding expenses and examinations done by the regulatory organisms. Besides those non performance loans identified by the administration and where is the case by the banking regulation organisms, the auditor takes into consideration the supplementary information sources for discovering the credits that could not be indicated up to then. These include: different internally generated lists, as credits presented in pursuit lists, bank loans in arrears, non engaged credits, personnel credits, etc. In auditing the depositors' deposit accounts, the auditor evaluates the internal control system upon the depositors' accounts, taking into consideration also the process of analytical procedures and confirmation of medium balances and expenses with the interests for evaluating the acceptability degree of registered deposits' balance. Also, it determines if the obligations afferent to the deposits are classified according to the regulation norms and relevant accounting principles. When the credit institution presents a risk due to the economic dependency of some important depositors or when there is an excessive due-date deposit concentration in a certain moment, the auditor takes into consideration the necessity of presenting information. The banking regulation authorities give a special attention to the capitals and bank reserves in the monitoring process at the bank activity level and determining the dimension of the bank operations. Minor changes concerning the capital or the reserves can have a great impact upon the credit institution' capacity of continuing to function, especially if there is close to the permitted minimum level of the capital indicators. In these circumstances there are great pressures on the administration to get involved in fraudulent reports by a wrong classification of the assets or liabilities or by their description as being less risky then in reality. So, the auditors take into account: if the capital and reserves are adequate regarding the regulation purposes, if the information presentations have been accounted and if these are correspondingly and according to the legislation applicable for the financial reports.

In the **profit and loss account** are presented on one side, the registered expenses in the reporting period and on the previous period (fiscal activity), in total sum or on structure, and on another side, grouped similar incomes and expenses.

In principle, based on the difference between the incomes and expenses the year result is obtained: profit and loss. Normally, two of the most important elements for determining the banks' profit are the interest incomes, respectively expenses afferent to the interests. These have a direct relation with the assets, respectively interest liabilities. For establishing the correctness degree of these relations, the auditor must examine the degree in which the reported incomes and expenses vary regarding the accounted values based on medium balances and declared rates of the banks during the year. Such an examination can determine the existence of some significant values of non-performance credits or unregistered deposits. Plus, the auditor can take into consideration how reasonable the bank declared rates are in comparison to the ones that characterized the market during the year for similar credit and deposit classes. For the deposits afferent debts, this kind of evidences can indicate the difficulties linked to liquidity or financing. In the same manner, the commission incomes, constituting also a massive component of a bank's profits, generating usually a direct relation with the obligations volume afferent to the sources that the commissions have been gained. So, the auditor must take into account if the registered value is complete and with the analytical procedure analysis must establish if the reported amounts are reasonable. Among these aspects, the auditor must verify if the incomes refer to the period covered by the financial situations and if are accounted according to the applicable financial reporting framework.

The bank must provide in the **Annotations** the following information: - the nature and sum of the irrevocable credit engagements; nature and sum of the engagements besides the balance, as: financing engagements – in favour of other banks, received from other banks, in favour of the clientele or received from the financial clientele, liability engagements given to other banks, received from other banks, given to the clientele or received from it, an analysis of the assets and liability elements, classifying them into a significant manner depending on the due-date, depending on the left period from the balance sheet to the contract due date, accounting method used for observing and get to losses of the doubtful/irrecoverable collectives; details referring the provisions' movement for irrecoverable collectives losses; the total amount representing the provision for debt losses; reserves made for the bank risk out of the gross and net profit if are presented separately, global sum of the assured liability elements, also the nature and accountancy value of the assets given for security.

Taking into consideration these requirements, the auditor must establish if the annotation at the finance situation of the bank are in correspondence with the framework applicable for the financial reports, pursuing that for each information, to control its presence and realization.

THE IMPLEMENT ROLE OF TARGET SYSTEM FOR HIGH VALUES

Voica Irina – Elena

Constantin Brancusi University of Targu-Jiu, Faculty of Economics, Aleea Teilor Street, Building 8, No. 2, Apartment 19, E-mail irynavoica@yahoo.com, Phone: 0723553659

The Target system, one of the most worldwide used payment system, continued to participate in fitting process of monetary market in euro curency and to play a major role in the task of putting in harmony application the single monetary policy. The system is conceived in order to allow the initially payment to be finish in a matter of few minutes, through a special communication network (interlineking system). TARGET is the main tool for introduction the. Eurosystem policy and create one single banking market in Europ.

Keyword: Target system, highly value transfers, electronic transfers, cash flow

The introduction of euro currency since 1999, determined the achievement of all financial transactions between these states in new settlement coin.This issue implied the adoption of one unique payment method between the countries from euro zone, which is connect to national payment systems of the member states.

Nowdays, to European Union level is working the payment system of inter-banking high value transactions, known under name of TARGET (Trans-European Automated Real-Time Gross Settlement Express Transfer System). The procedure was initiated since 1995 by European Monetary Institute de Institute (becoming later European Central Bank) and was in operational phase since january 1999.

The TARGET system is composed from 15 national payment systems RTGS (National Real Time Gross Settlement System), connected/linked through one electronic automate processing dates network, to whom it adds the own payment system of European Central Bank EPM (European Central Bank Payement Mechanism).

Through this mechanism has done approximate 90% from highly value transfers of European Union, having the role of ensurance the payments made between european central banks, on raw base and in real time, no matter the system used by every country and minimize the risk of no payment until this risk nearly vanish.

The TARGET system structure is one of uncentralised type, including:

- the national systems with raw payments made in real time from member countries;
- the supervise mechanism of Central European Bank;
- the interconnect network between central banks.

The European Central Bank' s role is not to involve in the payment system, but hold one control system which allows the working day closing into a final and irrevocable position. In change, the central national banks detain the task to collect the payment messages from the internal participants and to transmit only in available fund limits of them and in limit of granted credit facilities.

The direct participants to electronic transfers through TARGET method are the banks and internal credit institutions .The central banks could authorise other institutions to participate in system as treasury departments of member states, the compensating/clearing houses and discount institutions, the financial investment firms, other institutions from public area who can open accounts to customers, all authorised and supervised by central bank ot other authorities recognised/high reputation in this field.The admission of straigth/direct members is make accordingly to adequate financial capacity of instutution, taking into account the minimum number of transactions, the necessary technical understructure in concordance to the standard level and central bank approval.

The architecture of target eurosystem includes one technical element and one outlook of interconnect of central banks with European Central Bank through a communication network, named Interlinking throughout are changing the payment messages.Too, the central banks have to their disposal one Standard

Interlinking element, which ensure the message transforming from internal standard to community standard.The structure and functioning mode of TARGET procedure is illustrate in Figure no. 1.

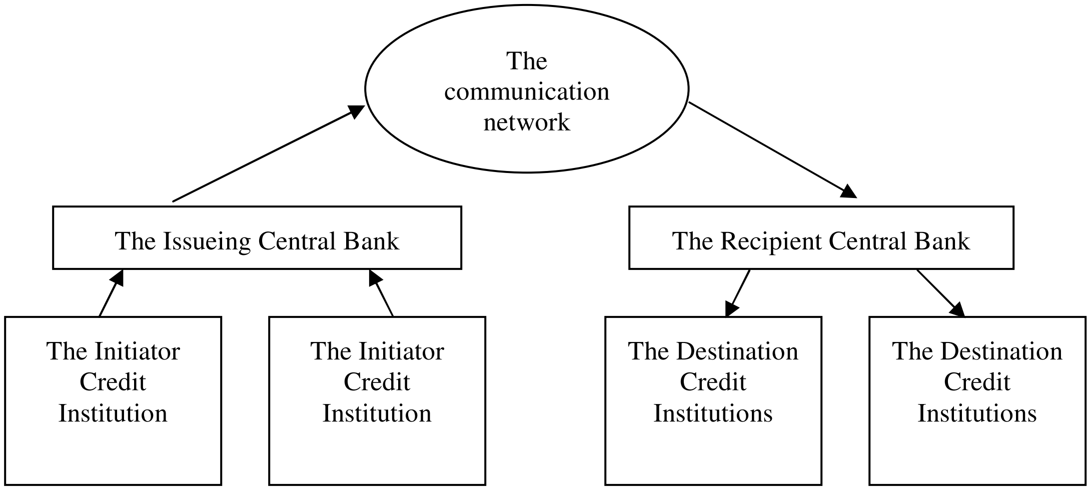

Figure no.1 The operational cash flow of payments through TARGET system

The operational payment flows through target method are illustratted below:

- the initiator credit institutions transmit the codify payment message to the central bank from own country;
- the issueing central bank verifies the message transmitted by the initiator credit institutions (un-codify, verify the bank's code), validates the payment, formats the message and transmits it through the communication network to the recipient central bank;
- same time, pour forth/debt the initiator's bank account and credit the interlinking-initiator bank account;
- the recipient central bank verifies the message, the recipient bank affiliation and retransmit the payment message to the recipient credit institution; simultaneously, debt the interlinking-issueing bank account and credit the recipient bank account;
- the recipient bank must to confirme, in a 30th minutes timeframe, to the initiator bank, the payment discount.
- In the frame of TARGET system can be develop the following application types, illustrating as a rule the credit transfers:
- direct/straight payments in connection to central banks operations of eurosystem;
- discount the account balances for high values payment systems;
- the internal banking payments system and commercial payments.

The TARGET system takes part to optimum functioning of monetary market in euro coin expresion and, thanks to the fact that credit operations are make through this system, has a major role in introduction of unique/single monetary policy. Through the TARGET system are processing a lot of other payment operations, due the fact that those issues offer discount services in real time in central bank's money, having a vaste market covered. Still the begining, TARGET functioned/worked without problems and full of success, having, accordingly to statistics, an increasing trend regarding the discount of bigger and bigger number of high value payments in euro.

As an example in 2006 year, 89% from total volume of high value payments in euro, had been proceeded through this system. The daily average/mean of payments proceeded through discount system TARGET was increased with 10%, both volume and value point of view. From the following tabel (Tabel no. 1) which illustrates the payment traffic TARGET in 2006 year, by comparison with the registred traffic from the previous year, it has been ascertained an increase of the transaction volumes and values. 96,75% from total amount of payments between member states, had been proceeded in a time frame of five minutes.

		2005	2006
The transactions volume (no.)			
Total	Total	76.150.602	83.179.996
	Daily Mean	*296.306*	*326.196*
Intra- member states	Total	58.467.492	64.162.211
	Daily Mean	*227.500*	*251.617*
Inter-member states	Total	17.683.110	19.017.785
	Daily Mean	*68.806*	*74.580*
Value (thousand million. Euro)			
Total	Total	488.900	533.541
	Daily Mean	*1.902*	*2.092*
Intra- member states	Total	324.089	348.764
	Daily Mean	*1.261*	*1.368*
Inter-member states	Total	164.812	184.777
	Daily Mean	*641*	*725*

Tabel no.1 The payment traffic Target

Source: Central Bank European

It is available to all credit transfers in euro between the interconnected banks, without any lower or upper limitation regarding the transfer value. The transfers can be procedeed both, between the banks from the same member state, also between the banks from different member states.

The TARGET system is conceived in order to allow an initiate payment to be finish in a maximum timeframe of few minutes. This timeframe, named operational time, starts from the moment when is proceeding the debt account of the person which send the money and it finishes in moment when credit the transfer beneficiary's account. Same time with confirmation, by the system, of recipient address, takes place simultaneously the credit of beneficiary's account, who can dispose immediatly by the money.

The TARGET system is functioning only in working days ,from Monday to Friday, to 7 a.m. to 6 p.m., to which it adds the exceptions afferent to national happiness days when the respective elements are closed.

By the day's end, the banks detain highly debit positions or highly credit positions, in report to the compensate system.Until next day, one of them become owner of deposits which must to be placed in investments, others hold debt positions and must to obtain short term deposits in order to resist to specific obligations from the payment system. The intermediary is the National Central Bank. The management rate of interest used for this proceeding has the goal to equal the value of one economical indicator illustrating the monetary policy in short term operations.

In order to ensure one highly operativity degree for proceeding the payments through this system, in order to be possible the payment facilities through open positions, the participate banks must to hold some supplementary warranties. Based on these quaranties, the participate banks could obtain daily free credits granted by the National Central Banks.

The warranties afferent to credits offered in euro coin are settled by every National Central Bank and could result also from other Central Banks.The credit mechanism represents a main component of monetary policy system introduced by National Central Banks, to Central Bank European recommnendations.

Due the major role of central pillar, which is played by this system on market and due to cover area, is essential to ensure an appropriate protection level against one extended risks area, in order to ensure an efficient functionality, without problems. It is an important issue the settlement of some emergency measures against an eventually system risks, which can affect the payments with highly importance degree. The system risk supoposes" undoing the payment obligations by one participant could conduct others participants to difficulties, generating thus a chain reaction, which will determine a general financial crisis.

The system must ensure the achievement of these payments without delays, even in especially times. În this direction, the eurosystem method estabilished emergency measures for proceeding ensuring these payments in a good manner, even in a mistaken function of it.

To central banks level, series of extra tests proceeded, and these tests demonstrated the efficiency of eurosystem emergency measures, also the fact that it gathered all the conditions in order to vouch for function without disorders in a crisis situation.

Due to the extent volume of operations made through TARGET, the euro area extended and the increasing of transaction volumes, were introduced since November 2007, a better system:TARGET2.This system allows the access for all participants to the same kind of services, allows using of one unique commision for national and foreign operations, answering to new exactingness imposed by users.

TARGET2 benefits by one single platform (instead of uncentralised platforms) offering new supplementary services(for example: payments ordering, proceeding of programme payments).

The Europen Union's wish is to create, since 2008, a Single Area Euro Payments - SEPA for companies and citizens.First step in this direction was made by introduction of upper version to TARGET system, named TARGET 2. Supplementary to efficiency increasing by using the same system both for internal and foreign payments, the advantages of this new system consist also in harmonize the service's qualities offered by european banks, the access to consolidate informations and the possibility to improve management of money flows.

The Single Area Euro Payments realization is possibble only by joint efforts of all european states, which must to metamorphose gradually the national payment systems into pan-european systems. Too, the instruments, services and national standards must to be substituted with the same pan-european items.

ROMANIA: FROM THE QUANTITATIVE MONETARY AGGREGATES TO INFLATION TARGETING

Resume: The lack of historic capitalism experience, the delays of governmental legislative and economic reforms, the ownership changes of the former state-own banks, the existence of the real negative interest rates on banking deposits, the regional crises (e.g. former Yugoslavia Republic, Kosovo situation), the high costs of financial intermediation, the alternative of financing by arrears, and the lack of legislation in by-law forced recovery of receivables, all that together were challenges affecting the health of banking system.

Key concepts: monetary aggregates, inflation, liquidity, crises

1. Once the Romania moved toward market economy, the presence of a free central banking institution started being necessary in, at least, two decision areas:

- First: the last resort lender or banker for all Romanian banks,
- Second: the monetary policy management.

It can be noticed that since its establishment, Romanian National Bank (RNB) has been constrained to adjust its monetary initiatives to several urgent main objectives: maintaining a healthy foreign currency position or liquidity, and improving the low level of M2-aggregate participation to GDP (e.g. the last one being around 30-33% of GDP – almost two times lower than the performance of other Central European democratic countries like Hungary, Poland, Czech Republic).

The lack of historic capitalism experience, the delays of governmental legislative and economic reforms, the ownership changes of the former state-own banks, the existence of the real negative interest rates on banking deposits, the regional crises (e.g. former Yugoslavia Republic, Kosovo situation), the high costs of financial intermediation, the alternative of financing by arrears, and the lack of legislation in by-law forced recovery of receivables, all that together were challenges affecting the health of banking system.

On such a non-favorable premises' structure including both periodic major macroeconomic disequilibrium and a partial national currency crises during 90's, we were witnesses at the lowering significance for those monetary aggregates chosen as intermediate targets (e.g. the phenomenon of artificially sustaining the currency exchange rate having as consequence a deterioration of foreign reserves) and at the necessity of periodic replacement of those without significance in order to maintain a valid macroeconomic analysis.

Historically, Romanian macroeconomics could be characterized by the followings:

- Inconsistence of favorable influences coming from the price liberalization, increasing participations of services revenue to GDP, or higher direct foreign investment, that were often counterbalanced by the excessive increase of wages and arrears, or by a lack of fiscal stability.
- Long term-effects limitation of monetary aggregates-based policy in the absence of structural reforms, reality that generated a trend of choosing either the less ambitious objectives or the costly compromises. The results manifested as downtrends of credibility and higher levels of annual inflation compared to European Union new-entered economies.

2. Based on the previous circumstances:

The monetary aggregate management of central Romanian authorities was under the impact of punitive measures against those banks being out of the banking security standards including non-legal or quasi-fiscal activities (e.g. roll-over nonperforming loans). It was a moment when, as a result of inflation erosion of banking assets, there started a modification inside the components of monetary aggregates used as reference targets (a swift of importance from the monetary base aggregate toward quasi-money aggregate).

The new challenges for the authorities being in charge of monetary policy consisted of:

- M2 aggregate management,
- Inflation control and reduction,
- Sustainable foreign currency liquidity and international reserves,
- Control of budgetary deficit,
- Better stability for the banking system.

The regular NBR objectives consisted in the fulfillment of commitments related to EU integration, better efficiency of domestic institutional mechanism, better supervisory and payment system, higher degree of M2 participation into GDP.

The monetary policy instruments were dynamically adapted and the consequence/performance was an inflationary neutrality in the end (or an inflation rate with one digit) - recorded into a monetary context characterized by liquidity excess and amplified sterilization operations. Unfortunately the distortions generated by the stage of administrative money control has continued to be present on quite important scale. NBR has recently adopted restrictive decisions related to the indebtedness size limitation on retail market, and also to the authorized banks' capacity for lending in foreign currency.

Open market operations have continued to be used as an essential instrument toward money sterilization. Among such operations a central role was played by the state-securities repo reverse activity and the drawing of deposits.

3. As a consequence of the fact that NBR was forced to accommodate high fiscal and quasi-fiscal deficits, doubled by the loses recorded among the state companies and in agriculture area, the monetary aggregates recorded amplified fluctuations:

Econometric analysis according to the monthly NBR statistics, proved a high significant correlation on long term between M2, industrial output, and Romanian currency deposits drawn by NBR. Additionally excessive role of M2 upon inflation has proved that in case of Romania the price dynamics is not an exclusive monetary phenomenon. Besides, NBR has used M2 as monetary anchor because that indicator had a better significance compared to monetary base, looking to increase the availability of money offer in the same direction with GDP's dinamics but at a slower slope.

Due to M2's accelerated increase, back by the increasing commercial deficit and the dynamics of loans and arrears, there was identified a hidden latent inflation well-administrated by the central bank through monetary sterilization interventions. Thus, the low linear slope of the monetary base was mainly a response at the high interest rate policy.

4. It is ought to be mentioned, that the existence of a continuous dynamics and innovation among the banks' management instruments of liquidity and financial investments, did not allow NBR to apply exclusively a monetary policy based on a single interventionist instrument.

- As a particularity for Romania, during 2000-2005 period, it was noticed the absence of statistical correlation between the interest rate spread and the values of M1 or M2 monetary aggregates. Thus, the overall economic environment was characterized by the presence of targeting the monetary aggregates instead of inflation.
- Also, due to excessive liquidity on the capital market, the banks started to have important deposits at NBR that were far above the minimum reserve requirements, and thus the monetary policy interest rate has acted more as an opportunity cost instruments instead of being a marginal cost of last resort financing. So, the influence of interest rate was smaller than the one of monetary aggregates.
- Additionally, we consider that the relation between NBR interventional instruments and monetary aggregates was more powerful than that between the same interventional

instruments and inflation, due to the fact that the monetary aggregates include in their contents the most of banks liabilities.

5. It is sure, that up to the end of year 2004, NBR's monetary policy strategy had wear the particularities' "suit" of monetary targeting that had meant the use of monetary base as operational objective, and M2 as intermediate objective. Then, the strategy turned step-by-step toward inflation targeting. It is ought to pinpoint the fact that monetary policy appealed quantitative targets both at operational and intermediary levels. The major attempts of using extensively the exchange rate as anti-inflation anchor failed during 90's, while the exchange rate strategy was not proper for such interventions due to overall adverse monetary conditions and costs. Thus, the inflation successfully slowed down from extreme levels of almost 300% (1993 year) to almost 9% (year 2005). Such performance is still away or below compared to the performance of new-entered European Union members, but it is a trend that should continue. At the same time, the disinflation's move was not linear during that period, as there were moments when new inflation peaks were recorded (in 1997 and 1999).

- For the last three years (2004,2005,2006), Central Bank has adopted a gradually intensified monetary policy as a result of a high dynamic investment and consumer demand. The danger of exceeding the sustainable commercial deficit was a real issue for each of last years.
- By its deposits interventions, NBR looked for controlling the inflationary expectations under incertitude conditions especially on inter-banks market.
- Adopting an official inflation targeting since 2005, NBR strategy has also been sustained by a favorable free exchange rate environment. The viability of that interdependence relied on the maturity-reach effects of previous structural reforms that allowed an export competitive advantage.

6. Concluding, the shift from monetary targeting toward inflation targeting was done under the influences of following events:

- The existing pressure coming from refinancing the public debt and from the necessity to remain in certain boundary with the budgetary deficit. Thus, the governmental deficit financing was done mainly from foreign markets in order to slow down the interest expenses. That move affected the liquidity of the domestic stock exchange and money market in case of government securities, and led to high difference between yields offered by NBR and Public Finance Ministry.
- NBR assigned monetary control and liquidity management functions on the mechanism of minimum required reserves. The differences among the interest rates paid on domestic currency reserves and those on foreign currency reserves were justified as a measure to discourage both the excessive lending in foreign currency, and also the speculative orders upon the domestic currency exchange rate. Thus, the minimum required reserves mechanism reflected the constrains existing in the operational environment of the last years monetary policy.
- Romanian strategy was deeply hurt by the low development of its financial markets, and the low level of monetization (e.g. % M2 in GDP).
- A precondition of potential success in the case of inflation targeting was fulfilled - the improvement of taxes collection and the reduction of money laundry.
- The important amounts of quantitative increases in Foreign Direct Investment (yearly Euro 4 billion), and also in the rest of M2's components, forced the necessity of a new strategy based mainly on non-monetary aggregates.

DISCREPANCIES BETWEEN THE CREDIT CONTRACT AND THE GENERAL BUSINESS CONDITIONS. MORAL AND LEGAL IMPLICATIONS

Voiculescu Mădălina Irena

At the beginning of 2008, a series of clients of a commercial bank from Romania received an unwanted "gift": a notification by means of which they were informed that the bank had decided to raise the bank fees associated to the credit portfolio; as a consequence, they were to pay a supplementary 0.5% worth monthly fee, applied to the credit balance; therefore, the new terms imposed a recalculation of the monthly installment, as well as the draw up of a new reimbursement schedule, which could be obtained at branch of the bank where the account had been opened.

There are also bank clients that, while reading the contractual clauses, have raised the problem of the legality of these modifications, thus realizing that there is no provision in the contract that gives the bank the right to introduce a new fee or to modify the existing one over the credit's period of validity.

Key-words: credit contract, general business conditions, bank fees

An "error" that made things worse

The bank issued a public communiqué announcing the modifications on the 28th of January, a month and a day after the clients were sent the notifications, a week after the modifications came into effect and after the bank received the first signals of discontent from the part of several clients concerning the new contractual provisions.

The second paragraph of the communiqué mentioned that "out of error, the modification was also notifies to a series of clients which were not affected by the respective adjustments." However, the announcement claimed that the modifications had been operated in the information system of the bank for the entire database and assured the interested parties that reversal invoices would be transmitted to those who had received the notification "out of error".

It is obviously very difficult to establish if a real error was made or the bank decided to rectify its position following the harsh reactions from the part of many of its clients. It does not matter so much, anyway. What finally counts is the fact that the bank reacted, thus assuming the responsibility for that error, at least partially.

Unfortunately, the communiqué left several problems unsolved. Which were those contracts which allow, at least in the bank's opinion, the introduction of the new fee and which are not? Why did the bank resort to that new harmonization of its fees, due to raise the credit costs, as the bank itself implicitly admitted? Why did they not deliver the new reimbursement book to the clients' residences, together with the notification, as did other banks that substantially changed their crediting costs? What were the solutions for those who wanted to unilaterally denounce the contract?

Contracts with ambiguous provisions

We have tried and found out the answers at the bank's representatives, who promptly and openly responded to our inquiries concerning the clients aimed by the bank notification.

First, we have been informed on the types of contracts for which the bank will not apply the new provisions. They are the ones which do not mention an management fee in the "fees" chapter or which wrongly mention it.

For example, the formulation in one of the contracts concluded by one of the bank's clients is the following: "a fee to cover the administration expenses related to the loan, further termed as management fee. The management fee is of 4% and is calculated as a percentage of the entire amount of the loan, as mentioned in the third chapter, "Terms of Loan". The management fee is collected on loan approval, in cash or by debiting the borrower's account". The respective clause DOES NOT refer in fact to an management fee, but to a credit approval fee; as a result, the clients having signed such contracts will be exempted from paying the new fee.

The clients encountering formulations like "an annual fee to cover the administration expenses related to the loan, further termed as management fee. The management fee is calculated on an annual basis as a percentage of the entire amount of the loan, as mentioned in the third chapter, "Terms of Loan". For the first year of crediting, the management fee is collected on loan approval; for the rest of the period, it is collected at the beginning of each year of crediting, together with the annuity."

The bank claims that, in this case, we are not dealing with the introduction of a new fee, but with stage payments of the same fee over several months. However, the situation is at least questionable – the initial formulation mentioned an annual fee, while the new version specifies a monthly fee. The bank argues that, in several contracts concluded with its clients, there are formulations which give it the right to modify the fees. "The contract is submitted to the general business conditions", reads one of the formulations. Another stipulated that "the terms of the contract are consistent with the terms of the general business conditions".

However, both above-mentioned formulations are immediately followed by a statement that can give rise to interpretations. "In case of conflict (or disagreement) between the contractual and the General Business Conditions' terms, the terms and conditions of the hereby contract prevail."

The bank also sustains that, even if there is no such provision in the contract stipulating that "the bank cannot modify the fees" or that this management fee "is fixed over the entire validity period of the contract", the credit contract and the general business conditions are not in conflict.

In other words, the bank considers that it acted in conformity with the credit contract and the general business conditions, the latter coming to supplement the credit contract's provisions when not mentioned otherwise. There is also the possibility of another interpretation, according to which the contract prevails over the general business conditions in the light of the general law principle stating that the special rule departs from the general one.

It is interesting the fact that in the contract, a certain level of the monthly fee is settled (for example, 0.2% calculated on the monthly balance), without any other specifications. In its replies sent to the discontented clients, the bank considers itself entitled "to modify the level" and "to operate modifications (introducing penalties, fees, taxes or new costs), while informing the clients in due time of all the operated modifications, in accordance with the general business conditions.

According to the Communication Department of the bank, taking into account the dysfunctions occurred in some territorial units, no penalties will be applied to those paying their first monthly installments in 2008 in conformity with the old reimbursement books. More than that, all the clients unhappy with the new conditions will be granted the possibility to annul the credit contracts WITHOUT any prepayment fees until the end of April.

The bank will also inform the clients who received notifications by mistake that they will not be affected by the operated modifications. The President of the bank's Administration Board insisted that he would not hesitate to present his excuses in person to all the clients affected by the bank's "error".

It is important that the civil society watch closely this subject and involve whenever similar situations arise with other commercial banks, if elements bringing further clarifications or information are to appear.

Moreover, the necessity to create the institution of the banking mediator is becoming stringent; the mediator should adopt a neutral position, he should be a true arbitrator of the conflicts between the bank and its clients; therefore the expenses associated to the creation and the functioning of the respective institution should not devolve upon the banks, as the mass-media speculated at a certain point. In the same respect, a deeper involvement from the part of the National Authority for the Consumer Protection is needed, as the respective institution is legally entitled to take measures to protect the interests of the banking product and service consumers.

By virtue of acknowledging that a banking credit contract is, in fact, an adhesion contract, those provisions referring to the levels of the bank fees must be clearer and more accurately formulated, so that not to allow interpretations; on the contrary, the provisions stipulating the interest rates are much more articulately drawn up. This necessity becomes even more stringent in the light of the fact that the banking offer equally addresses to all the categories of citizens, some more or less familiar with the legal or banking terminology. Moreover, the authors of the present article propose that every credit contract should have enclosed the General Business Conditions (usually posted only on the bank's site), so that they are known by the clients when signing the credit contract.

Abstract: There are different systems of financial supervision, specific to the country in which they are applied. In Europe, there are three main supervisory models, each one with advantages and disadvantages. This paper analyses the characteristics of these models, in the European countries.

Keywords: financial supervision, supervisory institutions, European countries.

The search of an adequate format for the regulation and supervision of financial system has stirred considerable interest in Europe in the last years.The EU member states have chosen different models to supervise their financial systems. We can identify at least three main models, that are currently in force in EU member states: the centralized model, a single supervisory authority; the vertical model, an institutional supervision; and the horizontal model, a supervision by objectives. Each model has its specific characteristics.

The Centralised Model

The centralized model, or single supervisor, provides only one supervisory authority over all financial system. This model was adopted especially in the early stage of financial systems when the central bank dominated, being the only supervisory institution.

The financial system's changes during the time, for example the fast growth of conglomerates, have determinated some national governments to review the structure of financial supervision. Nowadays, the single supervisor usually differs from the central bank and is responsible for supervising and regulating all the segments of financial sector: banking, securities markets, insurance.

In Europe, this model was first established in the late -1980s, in the Scandinavian countries.

Denmark established its single supervisor on January 1988, the Finanstilsynet, as part of the reorganization of the Ministry of Industry.

As a consequence of the banking crises of early 1990s, Sweden established in 1991 an authority named the Finansinspektionen, which is now responsible for supervising activities over all financial system, it promotes the stability and the efficiency of the financial system, ensures the protection of consumers, it performs also a regulatory activity, by issuing norms that market participants have to respect[269].

United Kingdom established the centralized model, too. In 1997, the former Securities and Investment Board changed its name in the Financial Services Authority (FSA). In 1998, all the regulatory powers on prudential supervision of the Bank of |England were transferred to the FSA. This new institution (FSA) is a private company, independent from the government, even though its board is appointed y the Treasury.

In Germany, in May 2002, the Federal Financial Services Supervisory Authority (FFSSA) was established as the single supervisor, while the Central Bank (Bundesbank) remained with a role in banking supervision. FFSSA has a functional and organizational autonomy, even though it is under a legal and supervisory control of the Ministry of Finance.

In Austria there were two main supervisory authorities: the Federal Minister of Finance, for banking and insurance supervision, and the Federal Securities Authority for securities markets. In April 2002, was created the Austrian Financial Market Authority, as a single supervisory institution, with the role of supervising banks, securities markets, insurance sector and pension funds.

---

[269] Enrico Maria Cervellati, Eleonaora Fioriti Financial Supervision in EU Countries, , SSRN Working Paper Series, January 2006, p 4;

Ireland created in May 2003 a single supervisory institution, the Irish Financial Services Regulatory Authority, which took over the responsabilities held before by the Central Bank and other supervisory authorities.

In Belgium there were two supervisory institutions: the Banking an Finance Comission, created in 1935 with the role of banking and securities superviser, and the Insurance Control Office, created in 1975 with the role of supervising the insurance companies, mortgage companies, pension funds and insurance brokers. Since 2004, in Belgium there is a centralized model supervision, represented by the Banking, Finance and Insurance Commission.

The Vertical Model

This model developed as a consequences of the great crises of 1930s. It represents an institutional supervision, a segmentation of the financial system in three main sectors: banking, securities and insurance; the supervisory competences being well defined for each main sector.

This vertical approach facilitates the practical implementation of supervisory powers, it avoids useless duplications of controls and can reduce regulatory costs; conversely, it is not able to ensure a stabilizing system of controls in a context characterized by a fast growth of financial conglomerates, progressive integration of financial markets, blurred borders of the financial sectors.

Greece is the only pure example of this model in Europe. The financial sector supervision is divided in with three groups of authorities, that have responsibilities over, respectively, the banking sector, the securities market and the insurance segment. Credit institutions are supervised by the Central Bank, the Hellenic Capital Market Commission and the Directorate of Insurance Enterprises and Actuaries of the Ministry of Development, General Secretariat of Commerce. The Supervision Division of the Bank of Greece, verifying the conformity with the rules of capital adequacy, liquidity, quality of assets and provisions. The Hellenic Capital Market Commission is a self-governing institution which acts under the jurisdiction of the Ministry of National Economy: it supports the stability of the capital market, it safeguards investors' interests and it enforces their confidence on a smooth functioning of the market. The Directorate of Insurance Enterprises and Actuaries has tasks and competences about the regulation of the insurance sector, focusing its attention on the solvency of the insurance companies[270].

Even if they present elements of supervision by objectives, the supervisory architecture of Spain and Portugal are based on the vertical model.

The Spanish supervisory system is represented by four authorities: the Bank of Spain, that supervises credit institutions; the National Securities Market Commission, whose role is to supervise the capital markets and to ensure their stability and transparency as well as investors' protection; the General Insurance and Pension Funds Directorate, a public institution within the Ministry of Economy, responsible for supervising the insurance sector; and the Directorate General Treasury.

Portugal's financial system is regulated by three authorities: Central Bank of Portugal, the Securities Market Commission and the Portuguese Insurance Institute, each one having a supervisory and regulatory role in the area that is under its jurisdiction. In the idea of the financial system development, in 2000, was established the National Council of Financial Supervisors, to cooperate among supervisory authorities

The Horizontal Model

This model is based on a supervision by objectives. Each supervisory function is under the jurisdiction of a given authority, independently of the supervised subject. There is no strict separation between sectors, each authority has cross-sector regulatory and supervisory powers in pursuing is function.

Italy's financial supervisory system is based on the institutional model, but mainly includes elements of the supervision by objectives, as well as other peculiarities. The Italian's vertical model is structured in several authorities: the Bank of Italy, responsible for the banking sector; the Insurance Commission, responsible for the insurance segment; and the Securities Commission, for the securities markets. There are also others authorities: the Pension Funds Commission, that supervise pension funds, and the Antitrust Authority, even thought the antitrust supervision of credit institutions remains responsibility of the Central Bank of Italy.

[270]Enrico Maria Cervellati, Eleonaora Fioriti - Financial Supervision in EU Countries, , SSRN Working Paper Series, January 2006, p 8

The institutional model has been implemented in the insurance and banking sectors, while the horizontal one in the supervision of the securities markets. The Italian financial system is regulated by two basic legal provisions: the Banking Law and the Securities Law. The Italian banking sector is supervised by two institutions: The Credit Committee, an inter-ministerial committee, presided by the Ministry of the Treasury, which enacts general and political directives; and the Ministry of the Treasury, that issues ordinances[271]

The Bank includes a General assembly of participants, a superior council, which has administrative and advisory tasks and a Governor, appointed for life, who represents the Bank and has responsibilities for financial and credit supervision.

France is an example of a hybrid supervisory system, in which elements of the institutional and horizontal models overlap. The legislative framework is represented by several fundamental acts: the Securities and Exchange Ordinance (1967), that established the Opérations de Bourse (COB)., the first Stock Exchange Commission in Europe; the French Banking Act 84-46 (1984), with the role of credit institutions supervision; the Statute of the Bank of France (1993); the Insurance Code, that regulates the activity of the Insurance Commission.

The Banking Act established three supervisors: the Banking Regulatory Committee; the Credit Institutions Committee; and the Banking Commission. In 1996, the Financial Activity Modernization Act 96-597, transposed the European Investment Services Directive into the French legislative system, amending the Banking Act. This act extended the jurisdiction of the above-mentioned supervisory authorities and of the National Credit Council to cover all investment service providers, credit institutions and investment firms, too. The names of the first two bodies were modified into Banking and Financial Regulatory Committee and Credit Institutions and Investment Firms Committee.

In the French securities markets supervisory system, until 2003 there were two securities market regulators and supervisors: the Conseil des Marchés Financiers (CMF) and the Commission des Opérations de Bourse (COB). For a supervisory system more efficient and transparent, now, in France, there is a single authority supervising the securities markets, the Autorité des Marches Financiers (AMF) in which the previous two authorities have merged together with the Conseil de Discipline de la Gestion Financière. The AMF is organised as an independent public authority with legal personality[272]

A more simple supervisory system is the one of the Netherlands that is also an example of shift from the institutional to the horizontal model of supervision. Formerly, the supervision system on insurance and banking sectors was industry based: the Nederlandsche Bank, mainly supervised credit institutions, while the Pensioen & Verzekeringskamer, supervised pension funds and insurance companies. On October 2004, these two authorities merged into a single supervisory authority. The supervision on securities market, instead, has been attributed to the Netherlands Authority for the Financial Markets since March 2002. Therefore, if in the past supervision had been focused on different segments of the financial sector, nowadays it is along functional lines: the Central Bank and the Insurance Supervisory Authority are responsible for ensuring prudential supervision, while the Authority for Financial Markets performs conduct of business supervision.

Conclusions

It is hard to choose a model, because each one has advantages and disadvantages, each model is specific to the country in which they are applied.

The EU member States have chosen in practice different supervisory models. The pure institutional model seems not to be adequate to the current financial systems, characterized by the blurring of borders between sectors, by the rising of financial conglomerates and the development of cross-sectoral instruments. In fact, even the countries that have a vertical kind of supervision as their basis have turned, at least to some extent, to the supervision by objectives. Interestingly several countries have decided to adopt the single supervisor model. First adopted by the Scandinavian countries, after the choice of the United Kingdom, several other EU countries have chosen this model to better cope with the new financial environment they face.

---

[271] Eddy Wymeersch-The Structure of Financial Supervision in Europe; Aboaut Single, Twin Peaks and Multiple Financial Supervision, European Business Oranization Law Review, Vol 8, No 2/2007 in SSRN Working Papers, p 43;

[272] Eddy Wymeersch-The Structure of Financial Supervision in Europe; Aboaut Single, Twin Peaks and Multiple Financial Supervision, European Business Oranization Law Review, Vol 8, No 2/2007 in SSRN Working Papers, p 42;

While the member States are moving to the horizontal model, both with multiple authorities or with a single supervisor, the choice at the European level is going in the very opposite direction. Following the Lamfalussy report, the supervision of the European financial system is organized in a vertical way. In other words, even if it is not possible to define the best model of supervision from a theoretical point of view, the contradiction between the choices made by the single member State and the one taken at the EU level clearly arises[273].

THE FINANCIAL INTERMEDIARIES, A DANGER FOR THE BANKS

Zapodeanu Daniela

Popa Claudia Diana

University of Oradea, Faculty of Economics, University Street, No.1, 410087, Oradea, mes_carla@yahoo.com, 0741206643

Abstract: The presence of the financial intermediaries - that make the link between the economics agents, with the needs of resources and the one with surplus of resources - determinates the evolution of the banking system and the structure modification of these. What is the difference between a bank and a financial intermediary? The bank distinguish itself from the financial intermediary through its capacity of taking inside the costs and its informatic efficiency, and so the incomes are growing. Does the financial intermediaries represents a danger for the banks?

Keywords: financial intermediary, bank, capital.

Financial liberalization has led to many changes in the banking area and to the development of financial instruments for the commercial agents. Even if the changes have manifested themselves differently, there is a common perception regarding the banking system in the new context. This common perception regards the powerful growth of the capital request -.to whom the offer had continuously adapted, in comparison to the request of the non banking commercial agents regarding the financial services and products- and also the dematerialization of the financial and monetary assets. Difficulties had determined the banks to reconsider their position regarding their liabilities, thereby using brightly their own resources.

The evolution of the banking activity on a global level stands under the sign of three main vectors: deregulation, disintermediation and openness[274].The process of deregulation, started at the end of the 70's and continued on into the 80's had reduced the differences between many banking systems, due to the rebate of the regulations and the liberalization of the financial intermediaries.

Put it differently , the recent financial deregulation proves that the banking profession can be replaced with different for financial intermediation.

The saving and investment processes, in the capitalist economies, are made and organized around financial intermediation, being therefore basic elements for the economic growth. Financial intermediation has a log history, because people had always felt the need of a third person to opinionate on big decisions.

In the modern era economy, financial intermediation has known a huge development and diversification, being pushed by the imperfection and dynamics of the internal and international financial markets-thereby the partners involved in different transactions are affected by the difficulty of obtaining information as soon as possible about the future evolution of the market and about the participants to this market-which leads to a series of risks[275].

In this conditions, the institutions for financial intermediation act as an interface with multiple options, for the capital owners and for those who need this capital for the development of their business and also for the management of some business portfolios, doing some speculative transactions or to develop some other activities.

In today's' context of the markets' globalization and general globalization which leads to permanent innovations in the financial area, the role of the financial intermediaries becomes a very important one.

---

[274] Oprițescu Marin and co- The Impact of Globalisation on the Bnking System, in rev. Finances- Chalenges of the Future, I year, no 1/2002, Universitaria Publisher, Craiova,2002,p. 28

[275] Ana Popa- coord., Financial Intermediaries- Institutions of the Modern Financial Market, in Financial Institutions of the Competitive Economy, , Universitaria Publisher, Craiova,2002,p.171

Financial intermediaries offer a wide range of integrated services to their clientele with a continuously growing degree of complexity, in the context of a development without precedent of the financial relationships. Mainly, the activities of the financial intermediaries can be grouped under different categories, from offering advice to the capital buyers and sellers to the gathering and processing of a huge range of economic, social, political information and also activities that require direct involvement as in financing , facilities, insurances. The latter means a warranty of the intermediation activity's quality and also a source of supplementary gains for the intermediaries.

The basic services offered by the financial intermediaries are the following;

- financial consultancy, offered to the investors regarding the possibilities of investing or the management of the owned portfolio;
- the supervision of the real and financial markets;
- classical transactions, regarding the purchase and sale of financial assets on the market and also other transactions regarding the national and international payments and settlements;
- financing the economic activity, the national and international investments and that of the foreign commerce;
- managerial expertise, as in offering consultancy in business management;
- underwriting financial operations,by offering banking collaterals for the international payments, collateralizing the issue of financial securities;
- the insurance against financial risks.

Financial intermediation has a series of advantages and disadvantages.

The main advantages which evolve from intermediation on the national and international financial markets are determined by informing and counseling the users and also by the direct involvement, as a guarantee of the financial intermediations' quality. Some of these advantages are:

- financial consultancy, offered to the investors and capital users;
- the possibility of better gathering and valuing the existing information on the market;
- additional facilities offered to the users and capital owners, a part of these being taken over by intermediation institutions.

The disadvantages of financial intermediation are:

- big transaction costs, due to collection of taxes, fees and commissions;
- the loss of direct contact with the international financial market, therefore some investors aren't sensitive anymore to the markets' signs;
- the existence of a routine in the relationship with the financial intermediary, many markets being led according to the solutions offered over the time by important intermediary firms.

Taking into account all these aspects we can conclude that financial intermediation contributed and contributes mainly to the growth of allocating capital resources and covering some risks, with real economic benefits.

On the financial market intermediation is achieved with help from the credit institutions, which are institutions specialized in offering funds to the population under different forms- to finance their activities on a short, medium or long term. There are a multitude of credit institutions which differ from one another from an organizational stand point, from the segment of populating they target, from the type of funding they offer, from the type of supervision they are under.

The recent financial deregulation proves that the banking profession can be replaced by different institutions for financial intermediation. Under these terms we are entitled to ask ourselves if the banking profession is in decline due to the fact that prudential protection becomes less and less effective rather than protective. Difficulties (questions) are far from the considerations that a bank ought to have. Since the scandals of Enron, Parmalat, behavior ethics of banking people, stock holders and auditors must be reinvented. For the beginning, ethics means business discipline with all that is good or bad, with moral duty and obligations.

In this context, we can say that banks have become more vulnerable. The monopolies have been undermined by the penetration into the market of new suppliers financial services. This has had consequences both at the level of the prices at which their products aresupplied and at that of their profit margins. The enormous increase of derivatives and the role played by off balance sheet items have generated instability for the banking system. The competition and the structural changes will lead banks to redefine their skills[276]. The study prove that even small banks can compete as long as they well capitalized and follow prudent risk and credit norms.

The important question is: do the market work or do it need an external intervention to regulate them? A proper legal frame is neded to protect the deveopement of the institutions for financial developement as entities good integrated in the financial system. In many developing economies, the legal frame for specialised financial institutions is ambiguous, dissipaited and incomplete. Represssive regulation could slow down the developement of these financial isntitutions and at the same time a permisive structure of the regulation could leave place for the arbitrary. Even when there is an adequate legislation, putting it into aplication could leave many voids. All these factors could slower the developement of the financial system in general, and at the same time it affects more seiously the financial institutions that are not supported by an eficient legal frame work.

With regard to finding the most appropiate institutional structure to supervise the activities of the institutions for financial intermediatio, this decision must be taken according to the number and size of these institutions but also their links with the banks and other financial entities of the financial system.

Concentrating the regulation and supervision of all the types of institutions under the same supervisory framework would help ;the supervision would be more eficient. A unique supervisory structure facilitates the adoption of a common set of standards for the institution with the same risk profile.

In a structure with several supervisory entities, there should be given attetntion to the legal power of every entity separately, to tthe idebtification of the conflict areas as well to the double regulations. Such a concentrated system is a source of discontinuities and amibuities which lead to all sorts of problems in the process of regualtion and supervision in many countries.

The fact that the institutions for financial intermediation need reguation doesn’t necesarilly mean that all of them need it in the same style, definitely not as the banks need it. The supervisory authority must establish the priorities into alocating its’ supersvisory capacity.

After establishing the priorities, there must be taken reinsurance measurements into protecting the intermediation institution from the excesive request for reports, when they don’t show major changes in their portfolios from one period to another. For these institutions, the aquracy and complexity of the reports are far important than their frequency.

In the process of elaborating regulations for the institution for financial intermediation, it must be taken into consideration the fact that regulation for the banks should adapt to the specific profile of these institutions:

- regulation must minimize th enegative effects over the competition and incourage it; negative and unappropiate regulation could have a negative impact on the institutions for financial intermediaton;
- regulation must define in an obvious way the limits of the law and the permited activities which could be undertaken by the institutions for financial intermediaton;
- similar risks and functions must be supervised in the same manner to minimize the arbitrary; fiancial institutions that relate to the banks ought to be supervised in the same way as the banks;
- the links between the institutions for financial intermediaton and other institutions of the financial sector should be carefully monitorised. The exposure to risk by investing in other sectors must be constantly monitorised because these links makes each sector vulnerable to the evolution of the other ones.
- the unique risks to which the institutions for financial intermediaton are exposed must be taken into account when the prudential frame work is establisehd and their supervision is settled;the supervisory institution must aknowledge the specific risks to which the institutions for financial intermediaton are exposed. When possible the prudential framework must be specific established for the institutions for financial intermediaton;

[276] Elisabeth Paulet, European Banking – Historical Roots and Modern Challenges, Lavoisier, Paris, 2005, p. 189

- costs and benefits must be taken into consideration wheb establishing the means for supervision. The institutions with a lower risk profile don't need to be burdened with excesive supervisory requests;
- the focus should be on the bigger and more complex institutions for financial intermediaton.

The banks will be called upon to redefine the servicies and products that the best reflect their skills. Thus the concept of a completely integrated banks, such as recommended by the European authorities, will appear obsolete and will give way to a concept focused on market strategy.

ACCOUNTANCY

AUDITING – HISTORY AND PERSPECTIVES

This paper refers to the audit process as to a very complex activity. There have been significant changes as the time passed by, changes that were necessary in order to keep up with the clientâ€™s demands and the dynamic business environment. Despite the fact that there are certain stages to be followed while auditing, despite the standardized audit procedures, there however, remains the one element that adds value to the marketplace, and that is the auditor, as a human being. He bears the responsibility for the completeness, validity and accuracy of the financial statements. Therefore, he must be that skillful employee, who knows very well the procedures, puts them effectively into practice and yet has time to specialize and keep in touch with the latter methodologies developed by audit scholars. He is the key element, the relationship manager. And the audit process depends on many variables, but above all, stands the auditor.

Key Words: auditing risks

There are not so many studies and researches about auditing in Romania. This field is quite new and ready to reveal its secrets. Our professionals must permanently keep in touch with their colleagues from developed countries, with great tradition in this activity. However, it is also true that they have to know the origins of the concept, the manner it appeared and developed, and the mechanism behind it. Therefore, in this paper we try to highlight some aspects about auditing, as they are referred to in international accounting literature.

Everything is about people and auditing is not an exception. Negotiations, discussions over a specific issue are "fluid", so they change repeatedly. This continual redefinition refers not only to the object of the negotiation, but also to the negotiation roles and relationships between participants. The actions and expectations of the chief financial officer seem to define the auditor's role and the relationship's parameters. The auditor expresses the desire of building an "ideal" relationship where to assume the role of the "expert advisor" rather than that of a "police officer". Nevertheless, he does not have a certain strategy to convert the collaboration into a proactive relationship.

Auditor-client management negotiation research is still understudied. Accounting literature mostly concentrates on the auditor. However, a negotiation involves at least two parts. As Lewicki, Barry & Saunders (2006) point out, it was only in the recent years when researchers started to examine these negotiations in the context of a relationship where the participants have a substantial history and anticipate a long-term cooperation.

McCracken, Salterio & Gibbins (2008) talk about the so-called "shadow negotiation". This pertains to a negotiation of the roles and actions that parties can take, simultaneously with the negotiation itself over real issues. In the same paper, the three authors initiated a study over several companies and interviewed auditors and chief financial officers. Cooper & Robson (2006) undertook a similar research. They both "examine how accounting and audit decisions are made". The results showed that the chief financial officers define the roles and the relationship. Some of them consider this collaboration as being proactive if auditors are consulted before operating the transactions, in order to ensure that the financial statements are of "high quality". This perspective is highly appreciated by the auditors, who wish all their professional relationships to follow this pattern.

Some other chief financial officers position the auditors into a "reactive" relationship. They consider the financial statements as being theirs and consequently, they do not consult the auditors regarding the correct exercising of the accounting principles and regulations. This is the reason for not identifying in time inconsistencies of any kind; the financial officer is strongly committed to his position and thus, the negotiation process is even more difficult. While some auditors reject the role of "police officer" and the reactive relationships, others gladly accept them, with the belief that, in time, they can change the situation in their favor.

In the end, no matter the case, auditors remain the relationship managers, responsible with keeping the client satisfied and the cooperation in a good state (Kolb & Williams, 2000).

One can describe or characterize an activity like auditing in many ways. Peecher, Schwartz & Solomon (2007) chose to emphasize four dimensions of the audit, which are:

- audited companies use new business models (that is, a description of how the entity intends to create value in the marketplace; it includes that unique combination of products, service, image and distribution, but also the organization of the personnel and the operational infrastructure used in order to accomplish the tasks), processes and business strategies;
- there is major concern and responsibility for detecting fraud resulting in misstated financial statements;
- although not so frequent, the audit failures are due especially to the inadequate control of the risk elements;
- it implies planning and organizing audit quality control for every individual engagement.

The environment of activity and the context of business have an enormous impact on the company, on risks in general, and on audit risk in particular. By audit risk, we mean the probability that the auditor will issue an inappropriate opinion when the financial statements contain one or more misstatements (like departures from generally accepted accounting principles).

Despite the business model complexity and market threats, the auditor must opine on the veracity of the financial statements. They capture retrospective and prospective consequences of the business through numerous estimates and complex documentation. The auditor has to develop new methods in order to verify their reasonabless as well as strategies for acquiring additional, sufficient evidence to sustain their accuracy.

At the beginning, audits focused on detecting bookkeeper fraud. Later, as companies developed and began to emerge as popular business structures, auditors focused on honest presentation of income, according to accounting principles. Such desideratum can be compromised by intentional or unintentional misstatements. Generally, when considering the latter situation, the auditors assume their responsibility. Otherwise, they try in a variety of ways to minimize responsibility. Intentional distortion of the reality can arise when an employee illegally misappropriates assets, but even more important and serious, when management appeals to such behavior, and more, they distort the financial statements.

Some reasons for most of the auditor judgment errors are:

- failure to sufficiently understand the client's business;
- failure to verify management's observations and explanations;
- lack of exercising professional skepticism on unusual or last-minute transactions;
- inadequate appreciation and evaluation of risks.

The last deficiency is a consequence of the others, especially of the first one. Risk is inevitable if the auditor cannot obtain an overall and deep understanding of his client's business.

.... The first audit risk model (ARM) in equation form appeared in 1972 (AICPA, 1972) as it follows:

Audit Risk (AUR) = Inherent Risk (IR) $\times$Control Risk (CR) $\times$Detection Risk (DR),

where:

- AUR – the risk that the auditor expresses an inappropriate opinion when the financial statements are not properly drawn and consequently, they can influence the economic decisions of users;
- IR – the susceptibility of a possible error assuming that there were no internal controls;

- CR – the risk that a significant misstatement which could appear in documents, individually or aggregated with others, will not be prevented or detected and corrected in time by the company's internal control;
- DR – the risk that the auditor will not identify important distortions individually or when aggregated.

Sometimes IR and CR combine into a single term, which refers to the risk that the financial statements are inaccurate before audit is performed.

This model was designed in order to help auditors to select the proper size of the sample that would achieve audit objectives. Often, DR is decomposed in other two terms: analytical procedures and tests of details. On their turn, these so-called tests of details divide into sampling and non-sampling risks. The latter do not pertain to the model because they are determined by factors that lead to an incorrect opinion of the auditor, for other reasons than vicious sampling. On the other hand, risks due to sampling arise because of the possibility that the auditor's deduction, based only on the sample, may be different from the conclusion reached if the entire population were part of the same audit procedure (IAASB, 2005).

Consequently, audit risk may be determined both by previous distortions in financial statements and by the likelihood that the auditor does not detect these distortions, if they exist, during the audit process.

There is a logical issue about risk. It refers to the extent in which the client is aware of the methodology that will be applied by the auditor. In such situations, those particular clients who deliberately wish to deceive the auditor, know exactly how and where to place misstatements so that they may go undetected.

In time, researchers have identified several imperfections of the model. Therefore, they developed the so-called Strategic-Systems Auditing, an appropriate and necessary means of enhancing audit quality.

Not so long ago it would have been inconceivable for an audit firm to aim national and international acknowledgement by offering a standard product rather than a highly specific professional service. Colin Sharman, the international chairperson of KPMG, a global network of professional firms providing audit, tax and advisory services, recently proposed the ideal of standardization. He talks about achieving uniform, global brand awareness, a common vision of the organization and a common set of products and processes. "That is equivalent to what we want to do with consultancy services", Sharman commented.

The world of auditing and accounting has changed significantly. Only a short while ago, the consultants of the major audit firms assumed that their clients wanted a service that "would delve into the specificities of their problems, coming up with tailor made solutions that related to their identity, their products, their history, their corporate culture and their managerial needs" (Hopwood, 1998, p. 515). However, as the author himself says, things have changed. Apparently, clients want to be the same. They are now solution oriented rather than problem focused. Consequently, honor and glory can be attained by being like everyone else. The same philosophy exists in another major audit firm, Ernst and Young: "we help organizations look at what needs to go right in order to achieve their strategic business objectives as well as managing the threats of what could go wrong". You have to think positive, to find solutions and to repeat the algorithm.

Likewise, companies in audit industry have challenged all aspects of the traditional audit. Professionalism has been replaced with business sharpness. Ernst and Young, for instance, look for people with a broad range of skills, and not necessarily with professional education. They will have the opportunity to specialize and to gain experience as they work.

In practice, audit firms are seen as complex and highly structured networks of rules and standard operating procedures.

In the 1980s, researchers and scholars debate about the role of structure and qualification in audit process. Because of the rapid growth of the audit procedures and practices, the expansion of the personnel, improvements in technology and the exigencies of reducing costs, accounting firms began to design and implement highly structured processes. Bamber, Snowball & Tubbs (1989, p. 286) describe structure as "the arrangement of people, tasks, and authority to achieve more calculable and predictable control over organizational performance". Cushing & Loebbecke (1986) consider that audit structure includes organizational and technological arrangements, which on their turn comprise prescribed audit tools and decision aids. In other words, audit structure suggests a mechanical approach to decision-making process, which narrows the set of actions available to individual auditors in certain circumstances.

The development and expansion of the audit structures marked many aspects of the audit process, for example: refinements of statistical sample, risk detection tests, analytical procedures, decision-making aids, and going concern evaluations (that is, a company's ability to make enough money to stay afloat, to continue to operate. If a company is not a going concern, it means the company has gone bankrupt). Therefore, audit structure was often viewed as a consequence of top-down dictates from the management of large audit firms trying to minimize the risk of serious judgment errors within the audit process. Even so, in order to turn audit into a successful activity it is necessary to provide more value to the clients. Hence, scholars reached the conclusion that audit must become part of the "mosaic of risk management" (Knechel, 2007).

Around 1994, a very simple concept emerged among the most influential members of the academic and audit community: "Business risk drives audit risk" (Eilifsen, Knechel & Wallage, 2001).

Onwards we illustrate the concept (see Fig. 1), adapted from Lemon, Tatum & Turley (2000).

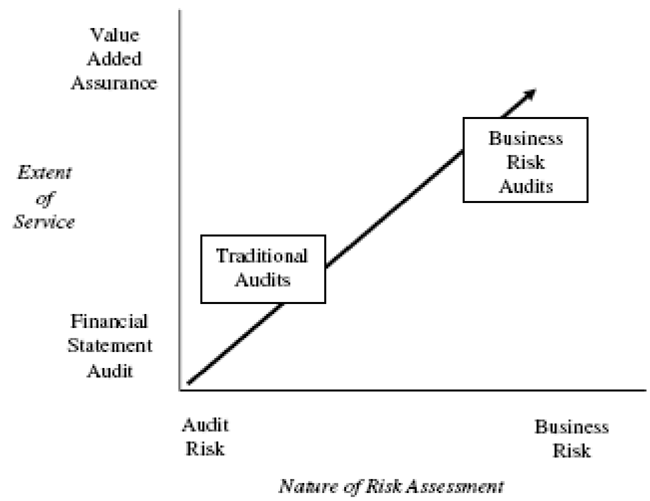

Fig. 1. Risk in audit process

Source: Lemon, Tatum & Turley, 2000

This notion was not something new and unprecedented. Nevertheless, it seems that it was simply the perfect time for it to be acknowledged and appreciated for what it really is. Consequently, anything that has the potential to increase risk and to determine the organization not to meet its objectives is seen as a source of increased audit risk. Understanding the essence and the importance of this notion, many audit firms, starting from the most representative like Ernst & Young, KPMG or PricewaterhouseCoopers put it into practice. For instance, Ernst & Young undertook their Audit Innovation project; KPMG began development of The Business Measurement Process. Thus, they led to significant changes in the way an audit procedure was planned and conduced.

Analyzing the results gathered from surveys in United Kingdom, United States and Canada, Lemon identified the following reasons for adopting an audit risk methodology:

- improve audit effectiveness and efficiency;
- keep up with technological change;
- add value to client service;
- encourage international cooperation;
- facilitate product differentiation;
- reduce auditor engagement risk.

Therefore, the auditor needs to see the entire organization and its environment in order to understand the nature of the challenges to be faced and solved.

After ABREMA (Activity Based Risk Evaluation Model of Auditing), a normative model of financial statement auditing, there are five stages in an audit engagement. Each stage corresponds to a critical decision made by the auditor during the audit process. The stages and the decisions made are:

- Client acceptance/retention stage - based on a preliminary knowledge of the client's business, the auditor undertakes several activities so as to determine whether to accept or reject a prospective client (or retain or relinquish an existing client) - the accept/reject decision;
- Audit planning stage - based upon a detailed knowledge of the client's business, the auditor undertakes various activities in order to decide upon an appropriate audit approach for each account balance;
- Control testing stage - applicable only where the audit process includes reliance on one or more control procedures. In such cases, the auditor gathers evidence regarding the effectiveness of the control. Where the controls are not as effective as was believed in the previous stage, the auditor would change the planned audit approach. The corresponding decision is whether one should continue to trust the management's internal control procedures;
- Substantive testing stage – the auditor gathers substantive evidence (regarding the completeness, validity and accuracy of the documents) of individual account balances and transactions, the primary objective of which is to determine the extent of misstatements;

Opinion formulation stage – the auditor expresses an opinion on the financial statements as a whole (the audit opinion decision), based on the evaluation of the extent to which the financial statements are consistent with his knowledge of the entity, including his conclusions concerning the misstatements identified, if any.

Consequently, the main objective of the auditor is to form and communicate to the users of the financial statements an opinion on their reliability and veracity, counting on audit evidence of sufficient quantity and appropriate quality.

As a conclusion, we can say there still are many issues that need to be clarified, in order to reach some common ground and to combine successfully the theoretical concepts with practice.

CHALLENGES OF A DYNAMIC AND COMPLEX ENVIRONMENT ON MANAGEMENT ACCOUNTING

Almăşan Alina Carmen

West University of Timisoara, Faculty of Economics and Business Administration, I.H. Pestalozzi nr.16, 300115 Timisoara, aalmasan@hotmail.com, tel: +20-256-592552; +40-724-837831

The far more competitive environment has profound implications for cost management systems. The knowledge of product costs, cost control and performance measurement are more important than they have been in the past.

Three major factors are causing changes in management accounting today: shift from a manufacturing-based to a service-based economy, the increase of the global competition and advances in technology.

Traditional cost accounting systems have tended to focus only on the production phase and do not pay attention to the product's life cycle costs. It must take a close look at the company's entire value chain, because this can help managers to identify opportunities for cost reduction.

Key words: environment, competitiveness, competition, costs, management accounting

1. Introduction

Once with Romania's E.U. integration, the Romanian companies are forced to cope with a bitter competition. On such competitive market, in a continuous evolution, the companies must have the capacity to permanently and actively maintain. On global level, the things are moving from the idea of competitiveness only through high quality and low prices to a new concept which will put the accent on factors like: knowing the market, the competition, firms' capacity to adapt to the environment quick changes, the receptivity to the new, as well as the quickness of assimilating the new ways of communication.

2. The features of the economic environment

Any competitions presume the existence of at least three participants: two competitors and the environment. In a loyal competition, the positive and negative effects on competitors are tending to mutual compensate, with a positive effect on the environment.

All the companies are acting on the market, the place where all the transactions are deployed and their competitiveness is assessed. The market is the place where the consumers' wishes (expressed through demand) and producers' wishes (determined through offer) will meet.

Taking into consideration the impact of the Internet on all life aspects, as well as the quickness of important changes appearance, in the recent years the market concept gets a new dimension, once with the e-commerce development. This type of activity assures the access to the new markets, representing the essential tool of globalization.

This phenomenon – e-commerce – can lead to the change of economic system, markets, consumers' segmentation, changing the costumers' behaviour, employment market, all these aspects creating the premises to pass into the new economy. Peter Drucker thinks that "in time, the e-commerce will kill the traditional multinational companies" (Drucker, 2004, p.65), because it is necessary to reorganize these companies, totally different than it is now. At the same time, the manner of performance measurement is changing, being necessary to redefine the term of performance.

The changes which take place in society and we are witness to, moving from the industrial economy to the new economy, knowledge-based, are generated by two factors: technical revolution and globalization process.

The technical revolution brought significant changes regarding the company's organization and operation such as operational process improvement (automatization), which permits to manufacture better products, at lower costs, rising this way the accessibility to a wider category of consumers.

The globalization process isn't a new one, but it is the result of some changes at the world economy level which stressed in the recent years. The raise of the border barrier, the appearance of multinational companies, the growth of internal and external markets competition, the increased importance of the resources, the way which are consumed, all these represents both causes and effects of globalization.

With the change of manufacturing and distribution processes, appeared some changes regarding the consumers' behaviour. If at the beginning of 20^{th} century the market was a "seller market", when Henry Ford assert that "the car can have any colour, as long as it is black", in the last decades the market become a "buyers market", a market where the consumers establish the rules. In these circumstances, for a company, the market analysis and costumers demand analysis become essential. The companies will be forced to stop selling what they produce in order to sell what the market demands.

3. The status of management accounting in Romania

Management accounting, after adopting the accounting law no. 82 / 1991, which adopted the dualist accounting system, was put aside of financial accounting. The companies' attention was oriented to the appropriate organization of financial accounting, which objective is to provide information especially to the third parties (shareholders, creditors, government agencies etc.). In Romania, the financial accounting was (and probably still is) oriented toward answering the fiscal agencies needs, which are perceived as the main users of the financial statements.

Under these circumstances, the management accounting played for a long time the role of "Cinderella", the 105 point from the Regulation for applying the accounting law which states that "the manner in which the management accounting is organized remains at the latitude of every entity, in accordance with the peculiarity of the activity and with their own needs" was being understood as an option regarding the organization or not of management accounting. Probably, the economic environment and the legal framework at that time accepted a situation like this. But, the Government Decision no 61 / 2001 stipulated, expressly, the organization of financial and management accounting "adapted to the activity peculiarity".

The management accounting addresses to the company's management, it must provide those information based on which the decisions can be based. "The management accounting has a basic principle: the applied practice or technique must generate useful information" (Needles et al, 2000, p.857).

Because the management requirements change continuously, management accounting evolves too. The strong international competition generates new philosophies of action, giving new significations to the information "produced" by management accounting.

The main objective of management accounting is the cost calculation, but the adopted techniques and procedures must follow permanently the management requirements, because, nowadays, the companies are structured very much different from their past organization.

In these circumstances, the cost calculation and management become a very important issue for firms.

4. Computing the costs or managing the costs?

Cost calculation, in most of Romanian companies, serves only for inventories evaluation (lastly, in fiscal purposes) and it is a less real support in decision making process. This doesn't means that an accurate calculation for inventories evaluation isn't necessary; on the contrary the fact that cost information is included in financial statements must make aware the companies of its importance.

The change is the only constant in business world. According as decision changing, the managers' information needs are changing too. The accountant must adapt its system to the changes appeared in managerial practices and techniques. An accounting system, which offers valuable information in a certain situation, can generate less valuable information in a different context.

The accounting systems have to know the realities of the today's complex business environment. Beside the indication of the problems which a firm confront with, the accountant have to take part at problem solving too.

In nowadays, three factors are causing the changes which intervene in management accounting:

- moving from a production-oriented economy to a service-oriented one;
- the growth of international competition;
- technological innovations.

The service sector experienced an important growth. In such an environment, the product associated services are getting more significance. Besides, the services can make the difference between products.

International competition has increased in the recent years as a result of the reduction, or even removal of the barriers from certain markets. In order to be a competitive firm, a company must know the effects of the cost decisions and the accountants must support managers to foresee these effects.

The far more powerful influence on management accounting in the last decades is having the innovations in technology. These changes affected both manufacturing and accounting process, once with the capacity growth and reduction of the new technologies costs. The automatization of manufacturing process had lead to the use of computerised equipments to the prejudice of the hand work.

Calculating and managing the costs should be one of the most important activities of an enterprise. For a better cost control it is necessary to permanently associate the resources to the results, being more important the results-efforts ratio that the cost amount. However will be the cost of an activity, it represents a loss if will not generate the desired results. In order to achieve this desideratum, the maximum capitalization of the opportunities is very important and it shouldn't follow exclusively the profit maximization.

Peter Drucker identifies four cost types (Drucker, 2001, p.70), in term of their reference to the result:

- the productive costs – represent the costs of the efforts made in order to offer to the client the value they desire and are disposed to pay for; for example, production costs, advertising costs, information costs, sales cost, and packaging cost;
- the support costs – don't offer any value by itself, but it can be avoided; for example, transport cost, order following costs, costs of financial and accounting activity control; in all traditional calculation systems, part of these cost are treated as overheads;
- the surveillance costs – are the cost of activities which don't mean to do something, but to stumble the appearance of undesired events;
- the loss – the cost of the resources which don't generate the expected results.

5. The obsolescence of the traditional cost accounting

A cost control demarche requires an approach on entire enterprise, not only at a certain component, because reducing the cost in one component exists the risk of growing the cost of another component; in time, this could lead to the growth of total costs. An efficient way to reduce the cost could be the removal of those activities which do not bring the expected result, not only restricting them.

Traditional cost accounting regards the tracing of direct costs on cost object and an overhead costs allocation, usually made based on labour hours. This is a useful approach as long as the indirect cost amount is reduced. It is the situation from a few decades ago. Instead, today, the indirect costs increased, the only costs which can be traced without equivocation on cost object are perhaps the raw material costs. Even the direct labour expenses are more and more reported on labour hour, rather than to the volume of activity.

The resource consumptions for every product are uneven. In the traditional cost systems, the overhead allocation based on labour hours leads to the consumptions unification, reaching to the ”subvention” of the less consuming products by those who consume more than average.

Another important aspect is that on a market, the bigger and developed is the more that market contributes to the product differentiation. To cope with the competition, the enterprises have to turn more and more to the client. It should answer to the individual demands, adapting their offer and production, implicitly, in order to satisfy the diverse demand of every client. The products or services diversity, as well as the clients, can direct to the complexity growth of the operations which the enterprise must realize.

Now, an important issue is the quick "ageing" of the products, some of them having a life cycle of few years, instead some may have a life cycle of a year or less. From this reason, it should be analyzed the entire life cycle costs, cycle which include five stages:

- the product planning and designing;
- the preliminary product projecting;
- the detailed designing and testing;

- the production;
- the delivery and services offered to the clients.

The planning of these costs is a crucial matter, when it comes to the decision regarding the beginning of a new product manufacture. When the products life cycle is less than a year, the enterprises do not have sufficient time to adjust their pricing policies or production techniques, once the product was launched into production. That, it is appropriate for the management to be sure in a certain measure, before deciding to manufacture the product, if all life-cycle costs are covered.

Peter Drucker observed that "as long as 90% of the results are generated by the first 10% of the events, the 90% of the costs are increased by the other 90% of the events" (quoted by Kaplan & Johnson, 1987, p.241).

The traditional cost accounting systems tend to concentrate only on the production costs, not paying attention to the other costs.

The efforts made for removing those costs which don't add value to the product or service should be oriented to the entire value chain, which can support managers to identify the opportunities for cost reduction.

Some enterprises prefer to bring new product on the market, without trying with any cost, to obtain these products at lowest costs. The clients buy such products for their unique characteristics.

These firms success is assured by elements like producing the high performance products, fast delivery, adaptability to the costumers' requirements, specialized products, etc. Producing them at lower costs become a secondary objective, because the gross margin of these products will be anyway very high, their price being determined by the value offered to the client and not by the cost.

Competitive environment has profound implications on cost accounting system. Knowing the costs, controlling them as well as performance assessment are far more important aspects that it were in the past. As an answer to this environment, the firms extended their products / services offered to the clients, making more difficult the cost allocation for different products.

The quality improvement, inventory reduction, making the manufacturing process more efficient and increasing the automatization degree conducted to the decrease of direct costs, simultaneously with the increase of indirect costs.

6. Conclusions

Certainly, a lower cost isn't enough to assure the market success of a good, but it is needful. Besides this, the image, the design, the client acceptance, the service and fast delivery are aspects which can contribute to the product-service "package" addressed to the market.

In a competitive environment such the present and, certainly, the future is, the challenge consist in adopting a more flexible demarche in conceiving an efficient cost accounting system, of an cost control system, as well as of an performance measurement system.

William Vatter (quoted by Kaplan & Johnson, 1987, p.241) emphasize that the accounting system is most valuable to management, not when it answers questions, but when it raises them.

Growing competition in all areas has brought to the reducing of enterprises results. In these conditions (the demand and manufactured products diversity, reduction of product life-cycle, development of support activities, the growth of overhead costs importance etc.) the cost determined through traditional cost accounting prove it self viable only in enterprises with a relatively simple production system, which manufacture a small number of products and direct costs have an important amount.

Regarding the management accounting, there were moments of „glory", but also periods of searching and attempts in finding its identity, not only in Romania, but in developed countries.

It is doubtless that without a well organized accounting information system and without a cost accounting system adequate to the managers' requirements and to the environment where it activates, managing the company's resources will suffer because it will be impossible for the managers to make decisions based on information provided by the accounting.

In order to emphasize the role of management accounting I will end with something what two distinguished professors (Robert Kaplan and Thomas Johnson) said twenty year ago. "Poor management accounting systems, by themselves, will not lead to organizational failure. Nor will excellent management accounting systems assure success. But they certainly can contribute to the decline or survival of organizations".

THE COMPETENCES AND THE IMPACT OF EVALUATION CATEGORIES ON THE FIDELITY OF ACCOUNTING INFORMATION

Antonescu Ligia

University of Craiova, Faculty of Economy and Business Administration, ligiaantonescu@rdslink.ro

0723.753.469

Summary *: Due to the fact that accounting evaluation has severe rules and principles, the economic evaluation has the role to assure the reflection of informational valences of an economic entity in order to mark out its capacity to produce future incomes. Even if the role and the characteristics of accounting evaluation are incontestable, we have to mention this process' consequences on the fidelity of accounting information, considering that a rigorous analysis cannot be realized without detecting the informational liaisons between the balance-sheet and evaluation.*

Key words *: fidelity, accounting information, accounting evaluation, international practice.*

The analysis of evaluating process' implications on accounting information cannot be realized without a perfect perception of the heterogeneous and diverse character of this process, of evaluation types, grouped and based on very relevant and specific criteria.

From the object point we view, we can distinguish assets evaluation, assets groups evaluation, economic assets evaluation (work-rooms, departments, factories, warehouses, shops), companies evaluation.

From the purpose point of view, we can distinguish: *accounting evaluation*, realized with the occasion of booking the economic operations, of the stock-taking and the elaboration of balance-sheet; *administrative evaluation*, in fiscal purpose, for determining ratable value, and also those asked by law regarding the patrimony's re-evaluation in case of public companies; *economic evaluation*, with the purpose of reference to market conditions.

We also have to remind the role of the method user for evaluation – in this case we can distinguish patrimonial evaluation, result based evaluation (performance, profitableness, turnover), evaluation based on actual net cash-flow, stock evaluation, combined evaluation (patrimony and profitableness).

Because the evaluations are meant to satisfy a certain purpose, we join to specialist's opinion that affirm the existence of two main types: accounting evaluation and economic evaluation.

The accounting evaluation is used in different methods, in measuring patrimonial phenomenon and operations and also with the occasion of inventory and balance-sheet elaboration. The balance-sheet gives "a true image of the patrimony, of financial situation and company's results only if the patrimony's evaluation rules are followed"[277].

There are four general rules of patrimonial elements' evaluation :

- evaluation at the moment of entry into the patrimony or input value (book value), depending on the asset's acquirement way: purchase price including customs duties, transportation, assembling and putting into service costs; production cost for the company's products; utility value, depending on the market price, for similar products and on product's condition, if it's received free of charge or donated; contribution value for the goods representing a contribution to social capital;
- evaluation at the moment of inventory – is made at the actual value or utility value of each element, named inventory value;
- evaluation at the end of the accounting period, patrimonial elements being evaluated and reflected in the balance-sheet at the input value or correlated with inventory's results;

evaluation at the moment of output from the patrimony, through sale, destruction or products' consumption, using specific methods for stocks – FIFO method (first input – first output); LIFO method

[277] C. Staicu, M. Mihai, T. Ciurezu, Bilantul contabilsi raportarea de semestru, Editura Universitaria, Craiova, 2000, pag.43

(last input-first output); CMP method (weighted average cost, calculated after every input or monthly by proportion between the total value of initial stock and of the inputs and entered quantity); registration or standard price method, but with the distinction of the differences accountable to acquisition prices or production costs. The utilization of any evaluation method must respect the principle of permanence, being justified the maintaining of the same method during some consecutive accounting periods.

Coming back to a previous problem, we mention that **the accounting evaluation has a major weakness**, in the sense that in all four evaluation moments it is used the historical cost, only partly corrected at the annual inventory and balance-sheet closing, with the reversible and irreversible depreciation of asset elements.

Another weakness of this evaluation form appears when in this calculus of financial and efficiency indicators it is taken the whole advanced capital, immobilized and circulating assets, even if a part of them doesn't participate in obtaining company's results (unutilized physical capital, damaged stock, voided orders, non-vendible products etc.).

Unlike the accounting evaluation, the *economic evaluation* relates the evaluated object to market conditions. "*The rational market value is the price, conveyed in money or equivalent, which a buyer and a seller could accept if the property would be sold on open market in a rational period, in the case that the seller and the buyer had valid information and either one of them isn't forced by the necessity to act*"[278].

The company's value in this hypothesis is the correct one, determined by a neutral evaluator. Many times, the economic evaluation for selling-buying is determined by some motivation, the market value or the effective price of transaction deviating from this value.

Trying a critical and comparative approach, we can day that, compared with the accounting evaluation which has strict rules and principles, the booking reflecting the patrimony in a given moment, the economic evaluation has the role to adjust the patrimony in order to produce future earnings.

We agree to the specialist's opinion that "*the economic evaluation consists in a complex of techniques, proceedings and methods to value the products, the assets, the company at the market level, ensuring the comparability with this*"[279].

The functional liaisons between liquidity/exigibility, the grouping of reference elements based on exploitation cycle functions, allow three versions of financial balance-sheet: liquidity balance-sheet; functional balance-sheet; capital-resources-liquidity balance-sheet (also called "pool des fonds" in the sense of mobilizing the resources for capital preservation and obtaining optimal treasury flows).

The classification criteria are presented in table 1 and the types of balance-sheet on liquidity criteria, in table 2.

	Depending on the belonging to the operating cycle (assets and liabilities)	**Depending on liquidity (assets) or exigibility (liabilities)**	**Depending on intrinsic nature (assets) or origin (liabilities)**
ASSETS	Immobilized	More than 1 year	Operation (activity' s necessary)
ASSETS	Cyclical	Less than 1 year	Financial
LIABILITIES	Permanent capital	More than 1 year	Own capitals
LIABILITIES	Cyclical debts	Less than 1 year	External capitals
	FUNCTIONAL BALANCE-SHEET	**LIQUIDITY BALANCE-SHEET**	**CAPITAL / RESOURCES / LIQUIDITY**

[278] M. Gradinara, D. Bucataru, C. Mihai, Evaluarea intreprinderilor in economia de pita, Editura Junimea, iasi, 1997, pag.34

[279] N. Sichigea, M. Dracea, D. Berceanu, T. Ciurezu, Gestiunea financiara a intreprinderii, Editura Universitaria, Craiova, 2000, pag.210

Table 1 The classification criteria for the three versions of financial balance-sheet

Balance-sheet on liquidity criteria	
RETREATED NET ASSET "LIQUIDITY"	**RETREATED LIABILITIES "LIQUIDITY"**
Immobilized net assets (more than 1 year)	Stable resources (more than 1 year)
Immobilized and distributing expenses	Own capitals
Trade fund, patents, licenses	Loans and leasing
Own tangible assets	Supplier debts
Rent tangible assets	Fiscal debts
Financial assets	Other debts
Client debts	
Current assets (less than 1 year, current exploitation)	Current debts (less than 1 year, current exploitation)
Merchandise inventories	Supplier debts
Working material inventories	Fiscal and social debts
Intermediate and final products	Other debts
CLIENT DEBTS	Current debts outside the exploitation
Other debts	Loan and leasing
Current assets outside the exploitation	Fiscal and social debts
Financial assets less than 1 year	Other debts
Other debts	
Active treasury – available funds	Negative treasury – current account cropping, protested debts, failure debts
TOTAL RETREATED NET ASSET	**TOTAL RETREATED LIABILITIES**

Table 2 Balance-sheet on liquidity criteria

This balance-sheet is considered less satisfying for financial analysts. The reclassification criteria based on annual cycle becomes arbitrary towards the operational character of the value concept with sensitive engagements to small fluctuations of the period. A reclassification of informational "utility" is detested by the jurisprudence.

Regarding the functional balance-sheet, there are two presentation forms : one in which it is utilized a retreated gross asset (table 3) and another in which it is utilized the retreated net asset (table 4).

Regardless of the chosen form, we consider that this kind of balance-sheet is closer to accounting logic of classifying patrimonial elements and the evaluation is better "underlined", his role in alignment of the accounting information to the actual level market being perfectly accentuated.

FUNCTIONAL BALANCE-SHEET (UTILIZATIONS = GROSS ASSETS)	
"FUNCTIONAL" RETREATED GROSS ASSETS	**"FUNCTIONAL" RETREATED LIABILITIES**
Tangible assets (more than 1 year) gross	Stable resources (more than 1 year)
Immobilized and distributing expenses gross	Own capitals
Trade fund, patents, licenses gross	Amortization and depreciation provisions
Own tangible assets gross	Loan and leasing
Rent tangible assets gross	Cyclical exploitation debts
Financial assets gross	Supplier debts
Exploitation current assets gross	Fiscal debts
Merchandise inventories gross	Other debts
Working material inventories gross	Cyclical debts exceeding exploitation
Intermediate and final products gross	Fiscal and social debts
Client debts gross	Other debts
Other debts gross	Negative treasury
Active treasury net	
SUM TOTAL	SUM TOTAL

Table 3 Functional balance-sheet (utilizations = gross assets)

FUNCTIONAL BALANCE-SHEET (UTILIZATIONS = NET ASSETS)	
"FUNCTIONAL" RETREATED NET ASSETS	**"FUNCTIONAL" RETREATED LIABILITIES**
Tangible assets (more than 1 year)	Stable resources (more than 1 year)
Immobilized and distributing expenses net	Own capitals
Trade fund, patents, licenses net	Amortization and depreciation provisions
Own tangible assets net	Loan and leasing
Rent tangible assets net	Cyclical exploitation debts
Financial assets net	Supplier debts
Exploitation current assets net	Fiscal debts
Merchandise inventories net	Other debts
Working material inventories net	Cyclical debts exceeding exploitation
Intermediate and final products net	Fiscal and social debts
Client debts net	Other debts
Other debts net	Negative treasury
Active treasury net	

SUM TOTAL	SUM TOTAL

Table 4 Functional balance-sheet (utilizations = net assets)

In our opinion, the first version is preferable. Depreciation and provisions are resources in liabilities and the assets are calculated as gross values. This fact permits the calculus of financial concepts – the need for working capital, financing table, self financing capacity through stable resources.

In the model of capital-resources-liquidity balance-sheet, assets are understood as an investment portfolio with a "composite" structure: immobilizations, working capital need, financial assets and liabilities are analyzed as a resource portfolio with internal and external origin, the debts being structured depending on the due date, as it is shown in table 5.

	ASSETS	**LIABILITIES**	
Risks and economic profitableness	Exploitation assets Immobilizations	Own capitals	Financial profitableness
	Working capital need Treasury		
Invested treasury Financial risk	Financial assets immobilizations	Stable financial debts	Financial risk

Table 5 The model of capital-resources-liquidity balance-sheet

The evaluation of balance-sheet is determined in terms of risks. This approach is separate from the judicial vision on the balance-sheet and allows a better appreciation of company's evolution in a long period of time, in terms of strategy – investment/financing.

The functional balance-sheet appreciates the evolution of the financial equilibrium, for risks on short term. The "capital-resources-liquidity" balance-sheet appreciates the evolution, strategy and risks on long term.

The manifestation of property real right involves assumes responsibility for two kinds of decisions : investment decisions and financing decisions.

The operation of investment assumes asset acquisitions to the purpose of increasing owners' fortune. The asset portfolio has a main component in tangible assets and a second component in exploitation net asset.

The financing operation pursuits the distribution between own funds and financial debts – the distribution and capitalization of results – alternative choice between the internal financing and external financing.

The financing structure in the balance-sheet is based on two components : own capitals and financial debts.

The balance-sheet model represents the adequate answer to users' needs, in quantitative and qualitative terms of equilibrium report which characterizes the management of patrimony resources.

The annual accounts are made based on closing of accounting period, founded on inventory, by determining in real proportion the patrimonial structures that have to give a real image of the patrimony, of the financial situation and of the result.

From the juridical point of view, the balance-sheet reflects in assets real rights and property conditioned rights (goods, rights – debts), and in the liabilities reflects debts (external liabilities – debts to third parties, internal liabilities – debts to owners).

From the economic-financial point of view, the balance-sheet reflects the resources invested by the company, their utilization after their nature, own capitals, which regroupes funds or benefits, foreign capitals which represents disposed funds from the third persons. In the balance-sheet the reference amounts appear at effective values, conforming the book registration value with the inventory value, respecting accounting rules.

The international practice shows that the balance-sheet model can be connected to the management accounting system as well as to the fiscal or juridical accounting system.

In the first case the balance-sheet represents the economic reality and assures the rigour of management control, in the second case the balance-sheet is used as a mean of fiscal and juridical control.

The recent developments oppose two conception plans: the “economic” optics towards the “juridical” patrimonial traditional optics.

The juridical conception emphasizes the property rights measured according to accounting principles, in a “prudent optics”.

The economic conception emphasizes the real functioning of the company, independent of juridical rules.

The debate has its origin in the works of Eugen Schmalenbach and it is made very actual by the numerous surveys which favour the functional analysis of the balance-sheet, but cannot hide the complexity of the priblem : there are many ways to approach the evaluation from the perspective of economic environment in which the company performs, and the juridical optics is favourized if the mane users are the creditors, the revenue authority.

Pure conceptions are rare. The juridical optics may borrow many elements of economic optics as the normalizing executive institutions adapts the norms and juridical obligations according to the economic reality.

We consider that in high inflation periods the necessity of re-evaluation imposes on a high degree of generality, but in the juridical optics a rigid model cannot exist, and the choice is a matter of accommodation

THE PERSPECTIVES AND THE OPPORTUNITY OF EVALUATION FROM THE ANGLE OF THE RELATION EVALUATION – ACCOUNTING – REPORTING

Antonescu Ligia

University of Craiova, Faculty of Economy and Business Administration, ligiaantonescu@rdslink.ro 0723.753.469

Antonescu Mihail

University Spiru Haret, Faculty of Financial and Accounting Management Craiova, Mihail.Antonescu.DJ@mail.mfinante.gv.ro, 0740.223.764

***Summary**: Regardless of the moment and the presentation stage of accounting data, the arguments of calculus and evaluation are integrated as a unit, inseparable from the accounting methods, being required by the existence and operation of the system. The evaluation is generated by the necessity to measure the complexity, being perceived as an alternative in solving the problems.*

***Key words**: evaluation, accounting data, opportunity, convergence, interdependence.*

Trying an approach which can assure the accentuation of evaluation demarche, we consider as necessary the marking-out of the established connexions between accounting and evaluation, deferring the interdependences between these fields of activity and the accounting data reporting. In the accounting theory and practice, the evaluation is based on two major principles: the utility value and time.

The utility shows the opportunity cost or the agreed sacrifice at a moment in order to make an asset to satisfy user's solvent need, if he accepts the utilization or sells on the market. Time aims the evaluation's moment in the past, at present or in the future.

On these facts we add the necessity to ensure the maintenance of financial capital and the valid calculus of the result.

The basic principles of stability of monetary unit, the historical cost, the cautiousness – opposite to the administration periods with monetary stability are convergent to the criteria mentioned above.[280]

There are numerous authors which define the evaluation as a process of quantification. Regardless the definitions' tone, it is generally accepted that the conveyance in money of the heterogeneous matter submitted to observation through accounting assures the homogeneity of the substance. Through quantification the quantitative elements are arisen in equivalence relations, enforcing criteria, conditions and restrictions on measure report between the compared amounts and establishing system properties based on the major components and on the causal relations of dependence between them.

The equivalence regards the stable report, invariable between the natural physical expression of the measured element and the quantity of monetary substance corresponding to the estimated element.

From the accounting point of view, the evaluation is "a particular form of quantification"[281], which unifies and guarantees the unity of principles, procedures and investigation instruments.

The finality of accounting is source and reason for a just disclosure of causal reports between truth, constructed reality and the medium of the constraints submitted to observation.

We consider necessary to discuss the objective "reason" of evaluation, what principles, objectives and factors characterize the evaluation and in what ratio the existence of monetary substance as an intrinsic value can or cannot assure an authentic reference of measure.

---

[280] Ristea M., Noul sistem contabil din Romania, Ed. Cartimex, Bucuresti, pag.56

[281] Feleaga N., sisteme contabile comparate, Editia a 2-a, Ed. Economica, 2000, pag.127

The crystallization of evaluation rules and principles has been determined by the request of objectivity's acceptance. We consider the current meaning of the term in accounting, but also the evaluation of a company's part (assets, activity, partition of ownership).

The evaluation presumes the determination of an objective reference quota which serves as a base in transactions between partners for simplifying the reasoning, selling-buying deeds with grounding in fixing a price. We can speak in this manner about quantification, evaluation, calculus, operational need of precise figures towards the reference systems and when the negotiation rights of parts is admitted – figures which can be proved, judged and appreciated with a rational – controllable justification which can be entered by an assessor bade on a complex analysis of the economic activity.

We consider that the evaluation has sense and significance only if it's based on method[282]. Regardless the object, the research field will be objectively represented only if the rules and procedures, standards and norms are respected. The reading of liabilities, the procedure of an expert appraiser, the analysis of population data are real situation which presumes methodical competences.

The evaluation also justifies its role when is choice validated by collective options, opposite to the will of an entity which excludes the singularity : the reference position must be determined, the action is common, the renunciation is anonymous, the function and competence exertion is on a superior level compared to the egocentrism.

The evaluation is a perfectible act, between the pressure of the moment and the interest of moral promotion of principles and norms. It also pursuits some ideas functionally dependent of distinction and clarity requirement, as knowledge elements which give sense to the knowledge based on experience.

The evaluation has always "a certification finality of evidence with measurable certainty"[283]. Anything accepted to be true is obvious or derived with arguments based on evidence. Empirically, the evidence can be subjective or deceptive, but the transfer from the appearance to the substance of things enables the logical distinction between the formal truth and the material truth , determining the criteria which must be satisfied by the reasoning (formal conformity).

The description or the impartial discourse of evaluation must ensure the detaching from interests, beliefs or preconceived ideas and if the truth matches the reality, it will be generally accepted.

The accounting is a unitary, coherent and indivisible system of evaluation, booking, calculus, analysis and control for managing and interpreting the flow generated by the existence, movement and transformation of the elements submitted for observation.

We consider the patrimony " an open system with references of structural unit"[284] : judicial, economic, financial, administrative. Any stable arrangement has a reference conveyed in money through the unity of reports as a unit. The entity being unique and indivisible, the measurement of its components and of the relations between them necessarily involves the unifying of all flows and information, with the same common denominator, the monetary unit.

This necessity derives from the fact that all means, methods and work techniques of accounting exist, do their job and form a unit only if the evaluation represents an objective reference of the reality.

Any accounting system arises, operates , permanently pursues and interprets "the own life" of economic organism – which involves the stability and unity of rules, means of evaluation and calculus, systematization, classification and generalization of data.

The establishment of reality through stock-taking, the classification and correct systematization of patrimonial exchange on corresponding accounts, the revelation of calculus sizes from the accounts' structure, the analytical grouping and the establishment of the composition of synthetic balance, the check-up of the reality and accuracy of booking, the synthesis of data at the closing of accounts, the calculus of results are conclusive examples which represent moments of accounting flow of data's processing, based on evaluation.

[282] Ristea Mihai, Dumitru Corina Graziella, Contabilitate aprofundata, Editura Universitara, Bucuresti, 2003, pag.92

[283] Isfanescu Aurel, Robu Vasile, Anghel Ion, Tutu Anca, Evaluarea intreprinderii, Editor Tribuna Economica, Bucuresti, 1998, pag.58

[284] Danescu T., Conturile anuale – documente de sinteza si de raportare contabila, Colectia Universitaria, Editura dacia, Cluj Napoca, 2000, pag.102

Generally speaking, we can say that no matter of the moment and presentation stage of accounting information, the calculus and evaluation arguments are integrated as a unit, being asked by the existence and functioning of the system as a whole.

The evaluation has a formal dimension, through acts, procedures and competences in translating the standards into real communication practices – human competence, prescriptive competence, public certified competence by an authority, asked competence, individual competence, collective competence – which are pragmatic dimensions for the company's strategy, for the economic life and its consequences.

In the accounting survey case, the forced report is always unequal in the sense that you cannot control or impose a point of view regarding the content established by the expert. An evaluator must demonstrate flexibility, no vanity, attention, empathy, trust and competence in particular situations, liberty in formulating references and solutions for various experiences.

The evaluation demarche must formulate solutions for a variety of users. The unicity of accounting and of the balance-sheet is contradictory to the multiplying of "images" for some parts of truth – each with its own truth.

The totality of technics of patrimony size's current establishment, the records, calculus, reflection and pursuit during the accounting period designates current evaluation operations regarding: patrimony structures on primary elements, separate moments in patrimonial values' circuit, calculus and registration operations, primary analytical establishment of patrimony's substance, the determination of analytical details of structure and of the direct recognizable elements in the estimation's structure, the distinct reflection of differences between sizes and pre-established values, the factual control of reality, the certification of estimations' conformity, the ensuring of evaluation acts' unity and comparability in time and space.

Based on the equilibrium relation Assets – Liabilities = Net situation (own capital), we agree to define the important aspects of the elements mentioned above. Based on the finality of producing financial reports, the evaluation reveals its opportunity in describing transactions' final results , grouped in classes with the same economic characteristics.

An asset represents a company's controlled resource as a result of some past events and which will generate future economic benefits for the company. The future economic benefits incorporated in assets represents the potential of contributing directly or indirectly at the cash flow or equivalents for the company. This potential can be a productive one, being part of company's working activity. Any cost reduction process becomes the alternative for cash output's reduction. The company uses assets for production and the solvable customer demand's satisfaction contributes to a cash action, which represents an advantage. An asset can be separately used or together with another assets, can be changed with other assets, can be used to square a debt or can be distributed to the company's shareholders. The majority of assets has a physical form. The material form isn't important, there are many situations assets are defined by the certitude of future economic benefits. The assets signifies real rights or property conditioned rights.

A debt is an actual obligation of the company which derives from past events; by its settlement we can expect economic benefits from resources' exit.

"A debt is a commitment or a responsibility to action in a certain way"[285]. The law can force a company to settle its debts, issued from contracts or legal requirements. Usually this represent amounts of money which must be payed for received goods or services. There is a distinction between current debts and future engagements. The redemption of a current debt can be made by cash, asset transfer, replacement of the debt with another debt, debt transformation in capital, or creditor's renunciation of his right.

Also from the evaluation point of view, we must recall the specific of own capital, which represents the shareholders' residual interest in company's assets after the redemption of all its debts. There are distinctive structures – shareholders' funds, retained earning, reserves from profit sharing. The re-evaluation or the adjustment of assets and liabilities' value determine own capital's increase or decrease. These are included in own capital as adjustments for maintaining the capital or as re-evaluation reserves.

From the evaluation point of view, the capital has more distinctive significations:

- stable financing resources, which ensures the productive physical capacity for profit earning, private or professional earning resulted from risk-taking in a competitive environment;

[285] Caraiani Chirita, Olimid Lavinia, Bazele contabilitatii, Editura ASE, Bucuresti, 2001, pag.79

- monetary-financial value which guarantees net assets maintaining, nominal or in purchasing power;
- shareholders' material or financial contributions , based on a legal association contract which establishes administration obligations and gives payment right (property's usufruct) – as residual interest, after obligation's redemption, based on the nominal value of stock, as an expression of a property right;
- the creditors' general mortgage right, the material guarantee of continuity and of the financial position;
- non-exigible and intangible liabilities, particularly capital's due date being the company's lifetime, legal guarantee of continuity.

"Earning profit is necessary in order to maintain the financial capital"[286] and the profit can be earned only if the net asset value at the end of the period is bigger than the net asset value at the beginning of the period (excluding the distributions or shareholders' contributions). The profit represents the nominal capital's increase during the period or the increase of the invested purchasing power, calculated over the inflation ratio level.

In order to maintain the physical capital, price changes that affects company's assets and liabilities are considered adjustments to maintain the level of capital and not profit.

The necessity of company's evaluation is also determined by the requirement of balance-sheet's correction, asked by the legal frame of economic activities , asked by the need of an elaborate and valid economic and financial analysis of the company, in order to present it in a real situation to shareholders, creditors and employees, corrections that appear due to the characteristics of a competitive economy and especially due to the following factors:

- the existence of free prices, that impose for managers the need to bring up to date the information from company's reports (historical cost information), depending on the price evolution on market;
- the mechanism of national currency's exchange rate, which acts from outside the company, being determined by macroeconomic phenomenon and processes pertinent to foreign exchange and to relations with international institutions and financial organizations;
- the company's housekeeping, regarding the bookkeeping methods, consumption 's evaluation methods, capital depreciation methods, because one of the company's financial management characteristics is the functional autonomy – the management chooses the appropriate methods for an efficient housekeeping, respecting the principle of method's permanence in order to assure the comparability of results.

In our country's specific conditions, the company's evaluation is pertinent to privatisation, being needed to reduce state's influence in economy and to increase the private property's share as a guarantee of a future efficient activity. For privatisation, the evaluation is mandatory due to the following:

- the majority of patrimonial elements from the company's accounting doesn't reflect market values, even if has been tried the prices' bringing up to date, but this was realized on subjective requisites;
- the company's achievements cannot be extended and it cannot define future previsions, because these are not the effect of a normal situation (the inflation had a very high level during the transition period; the economic, an incomplete usage of production capacities;; the high interest rates and the lack of money resources, etc.).

But the company's evaluation in mandatory is the following situations:

- in any moment when changes take place in the size and structure of subscribed capital (issuing new stocks, summing of undivided profit, stock transfer to another shareholder etc);
- in any moment when changes take place in shareholders' number or structure;
- in commercial transactions (acquisitions, divesting, merger).

[286] Bran P., Finantele intreprinderii – gestionarea fenomenului microfinanciar, Editia a 2-a, Editura Economica, Bucuresti, 2003, pag.39

In case of acquisition operations, the evaluation methodology is different, depending on acquisition's nature. If it's the case of a classic acquisition, the investor makes a long-term investment, trying to buy the majority package of shares. In this case, he will ask a detailed evaluation methodology for a conscious decision. If it's the case of a financial investment – buying a certain part of other company's capital – the investor's purpose is the placement of money with a superior efficiency. Usually, this kind of investment is represented by stock buying at stock exchange and requires less complicated evaluation procedures.

In case of divesting operations, the evaluation problem is similar, buy it's regarded from the seller's point of view. In case of selling without special characteristics, the seller can be in one of the following situations: the sale of a small company to an important group or the sale of a company in a difficult situation. In both cases, but especially in the second one, the seller cannot afford a normal evaluation of the company, because there are many candidates for taking it over. Anyway, the evaluation's result cannot have significant differences from a situation to another, the evaluation methods being similar – only the negotiators' power will make the difference between the adjudgement price and the real value.

In case of merger, the calculus is more refined, because is the case of evaluating two companies, with an advantage for one of them. The evaluation has specific dimensions if the merger is made between two companies of the same shareholder, if it's the case of small companies which redefine in the judicial plan for simplifying their presentation in front of a third party.

At the level of big companies, the fusion usually initiated by a parent-house has the object of savings resulted from the regrouping of some services. In case of inheritance, the necessity of evaluation is given by the inheritance right. Based on this evaluation, the inheritor can make a buying offer to the other inheritors, for taking their parts. In case of partition between spouses after a divorce, the evaluation of common possessions, including companies, is necessary for compensating one the spouses.

In both cases, the evaluation methods must consider the administrative, judicial rules in order to establish a reasonable price and to avoid any part's prejudice. In case of evaluation for mortgage or bankruptcy, this must consider the specific banking norms and the bankruptcy procedure, the difficult situation of the company, which will automatically lead to an undervalue.

In case of expropriation, the properties can be expropriates for public interest by authorities (the construction of a transport way, of a public edifice, an area's systematization), in this case the owner receiving a compensation which represents the market value of the company and the losses until the company's relocation. As a support in case of litigation, the company's evaluation establishes the loss due to improper products received from the suppliers or to wrong quality standards, which is detrimental to the economic situation and to the company's image. The problem of company's evaluation has particular emphasis in the actual stage, when there are companies' buying-selling between parts from different countries. It is necessary to adopt some standard evaluation practices, in order to permit an homogeneous vision in the world, being necessary to elaborate international evaluating standards and norms or to find some compatibilities between regional institutions.

Abstract: *During the audit process of the financial situations, the auditor has a great responsibility in detecting the significant falsifications of the information due to fraud. The International Federation of Accountants (IFAC), the representative international structure of the accounting profession has elaborated the International Audit Standard 240 The Auditor's responsibility to analyze the fraud in an audit of financial situations which establishes the regulations and offers the recommendations concerning the procedures that must be applied by the auditor in order to detect the significant falsifications consequent to fraud which influences the fidelity of the information presented in the financial situation. The auditor can identify a falsification in the financial situations and in this case he must analysis if such a falsification can indicate a fraud and when such a clue exists.*

Keywords: responsibility, audit, fraud, standards

Introduction

The International Audit Standards (ISA) 240 The Auditor's responsibility to analyze the fraud in an audit of financial situation, elaborated by IFAC through its structure IASAB and assimilated by the professional structure from our country, the Romanian Financial Auditors Room, is put in practice by the financial auditors when they audit the annual financial situations of the economical entities.

This standard establishes the regulations and offers recommendations which are applied by professional accountants during the audit process.

Fraud and error

ISA 240 makes the distinction between fraud and error and defines two types of fraud relevant for the auditor:

- Falsifications that are caused by the misrepresentation of the assets;
- Falsifications that are caused by the fraudulent financial reporting, meaning the basic action that has provoked a falsification of the financial situations was done intentionally or/and unintentionally.

The concept of error means a falsification of the financial situations made unintentionally, including the omission of an amount of money or a presentation, as follows:

- An incorrect accounting estimation as a consequence of the misinterpretation of the facts;
- A mistake that has appeared during the data research and processing from the financial situations;
- A mistake in applying the accounting policies regarding evaluation, recognition, amortization and depreciation of the entity's assets.

Fraud is a deliberated action done by one or more persons from the society's leadership, employees or third parts, action which involves the use of false pretence in order to obtain an illegal or unjust advantage.

Fraud is an action initiated by one or more persons and can be determined by one of the following events:

a) falsification of documents and records;
b) actives' misappropriation or theft;
c) wrongful assignment of some actives, with influences on the continuity of the entity's activity;
d) elimination or partial registration of a transition's results in order to make the financial statements look better;
e) misapplication of accounting policies so to embezzle the entity's assets and performance etc.

Fraud is determined by the intent to deceive, the desire to obtain undeserved advantages as a consequence of shortcomings' existence in the functioning of an entity after some unproductive controls.

The auditor will be concerned with the fraudulent actions leading to a significant falsification of financial situations. The fraud involving persons from the leadership level is known under the name "managerial fraud" and the one involving only entity's employees is named "fraud by employees' association".

The deliberated falsifications are classified in two categories:

1. Falsifications emerging from the financial reporting;
2. Falsifications emerging from the assets' dilapidation.

The fraudulent financial reporting represents falsifications or omissions of the information from the financial situations made intentionally with the aim to misinform and mislead the persons using the financial situations (shareholders, clients, providers, employees, banks etc.).

The fraudulent financial reporting can be done through the next methods:

- Manipulation, falsification, and modification of the accounting entries or of the vouchers on which the financial situations are based;
- Misinterpretation or the deliberated omission of events, transactions or other important information from the financial situations;
- The bad application with intention of the accounting policies.

The fraudulent financial reporting can be due to the manipulation of the incomes by the entity's leadership to cheat the persons using the financial situations over the performance and profitability of the economical entity.

For example:

- underestimation of costs and over evaluation of incomes will lead to the registration of a higher profit to be given to the shareholders;
- underestimation of assets and over evaluation of debts will lead to the establishment of a higher net active;
- overestimation of the shares' value on the stocks' market.

The dilapidation of assets means the theft of an entity's assets and it is most often done by the employees. Dilapidation can be done through different methods:

- Fraudulent receipts – accumulation of the frauds in debt accounts or the orientation of the receipts toward personal accounts;
- Theft of tangible and intangible assets;
- Payments for goods and services undelivered yet;
- The use of the society's assets in personal interest.

The dilapidation is accompanied by false records or documents with the aim of covering up the missing assets. Financial auditors are dividing frauds depending on their nature such as:

- frauds referring to the financial statements' elaboration and presentation;
- frauds having for results the entity's operations, significant reduction of the activity, which determines the risk of continuity;
- frauds affecting the personnel policy(employees health, work safety etc.);

- frauds affecting the environment and its protection, which determines the risk of continuity for the activity.

It can be said that fraud determines the entity's managers and employees degree of honesty and trust. The primary responsibility for the prevention and detection of frauds and errors belongs to the leadership as well as to the management of the society.

The accent falls on preventing frauds, and it can determine individuals to not commit fraud because of the possibility to be discovered and punished. The creation of a culture of the organization and ethical behavior is necessary in any society and it must be communicated and sustained by the persons in charge of leadership (surveillance, control, management).

The active surveillance of those in charge of the leadership means a continuity of the internal control, the analysis of the financial situations' safety, the efficiency and efficacy of operations, of the conformity with the legislation and regulations in use.

It is obvious in the present days that the fraud phenomeneon has reached globalization as well considering the number of high profile frauds that have kept the public attention lately, being discovered inside of some of the most prestigious multinational companies. The list is very long and includes cases such as ENRON in USA, Parmalat in Italy and Group Societé Génèrale in France. A study conducted in 2005 at the University Martin Luther from Hale, Germany, made on a sample of over 3600 international companies, has indicated the percent of each type of fraud, as shown in Table 1.

Table 1

Nr.	Fraud type	%
	delapidation	22
	FinancialStatements Manipulation	19
	Corruption and Bribery	19
	Fals Pretences	15
	Falsification	9
	Money Laundering	7
	Others	9

Types of fraud

Source: Nadir Ali, Considerations about the Internal Audit Role in the Prevention and Detection of Fraud, in Financial Audit Review, nr. 6/2007

The study proves that only 26 % of frauds were identified by internal audit, while 34 % were discovered by chance.

The auditor's responsibilities

The auditors' main objective during his audit mission of financial situations, seen as a whole, is to obtain a reasonable assurance that the financial situations do not contain significant falsifications caused by frauds or errors. The auditor can not obtain an absolute assurance of the fact that the significant falsifications of the financial situations will be detected by using the audit tests because of the inefficacy of the internal control and the fact that the audit evidences he holds are more persuasive than conclusive.

In order to obtain a reasonable assurance, the auditor:

1. maintains an attitude of professional skepticism during the entire audit process;
2. analyses the possibility of the society eluding the controls ;
3. admits that it is possible the procedures used to detect errors or falsifications consequent to fraud are not adequate.

The professional skepticism is an attitude which involves an inquisitive mind and a critical evaluation of audit evidences. Preserving an attitude of professional skepticism imposes the permanent analysis of the reasonable character of the answers given by the leadership delegates during investigation as well as of the other information those persons have given.

When the audit process is done by a team, the team members must debate upon the possibility of the existence of a potential for significant falsifications of the financial situation consequent to fraud. The debate is a very good occasion for the more experienced team members to share their knowledge about the manner and place in which significant falsifications of the financial situations consequent to fraud might emerge. Discussion keeps up an inquisitive mind, without taking in account the convictions of some team members about the honesty and integrity of the society's leadership. The debate usually includes:

- Exchange of ideas between team members about the manner and place in which the emergence of significant falsifications of the financial situations consequent to fraud might emerge can be suspected, the entity's leadership can commit and hide fraudulent financial reports and the assets of the entity can be dilapidated;
- Analysis of the circumstances that can prove an incomes' manipulation;
- Analysis of the factors that might put pressure on the management or others to commit fraud;
- Analysis of the leadership's involvement in the surveillance of the employees with access to cash money or other assets that can be dilapidated;
- Analysis of unusual changes in the life of the leadership members or employees;
- Analysis of the types of situations that can indicate the possibility of a fraud;
- Analysis of the risk of leadership eluding controls.

International Audit Standard 240 "The Auditor's responsibility to analyze fraud in the audit of the financial statements " mentions:

- responsibility for preventing frauds and errors belongs to the entity's leadership, that have the obligation to implement and operate continuously through adequate systems of accountancy and internal control;
- the financial auditor, though "it can not be hold responsible for frauds and errors prevention", has the obligation to plan and make the audit so to obtain a reasonable assurance that the financial statements are not significantly embezzled consequent to recorded frauds and errors.

The manager's responsibility is at maximum in regard to the prevention or investigation of fraud, corruption, bribery, as well as establishing the necessary measures for the case in which alarm signals might appear from this point of view. For example:

- omissions or errors in the providers' and clients' identification data on the fiscal receipts;
- disagreements between the information on the receipt and on the order form;
- disrespect for the information privacy;
- close relationships between the persons in charge of supply and entity's providers, thus appearing the opportunity for taking bribe;
- a third person almost always winning the auctions for undertaking goods or services;
- using certain methods of payment or cash in the country as well as abroad etc.

The audit process, though developing in conformity with the legal and professional procedures and standards, does not absolve the auditor of the obligation to answer in front of the instance in one of the following situations:

a) when the leadership of a company pretends the auditors determined them to think that certain decisions were right and it was not fraud or error;
b) when persons, that have become shareholders later on, pretend that they have registered losses buying shares from the audited firm because of the financial audit report;
c) when third parts involved, taking into account the audit reports, declare they initiated business relationships with the audited firm;
d) when the company's new owners discover that the financial statement is not in conformity with the reality;

e) when a company's liquidator considers that the financial statement was not reflected in the accounts, so the audits provoked losses to the creditors.

In all the cases above, though the professional assurance exists, it might not be enough for covering the professional risks.

Audit procedures

In order to identify the risks of significant falsifications of the financial situations, the auditor or the audit team can apply the following procedures:

1. organizes meetings between the leadership and other persons from the society for the identification and treatment of the fraud risks;
2. analyzes if one or more factors of fraud risk are anticipated;
3. analyzes other information necessary for the identification of the risks of significant falsifications consequent to fraud.

a) to understand the environment of the society, including the environment of the internal control, the auditor questions the management about:

- the way in which the managements communicates to the employees its vision concerning the creation of culture of honesty and ethical behavior;
- the way in which the managements communicates to the leadership the aspects related to the identification fraud risks within the entity;
- procedures used by the management to identify the fraud risks, the accounts' balances or the transactions that are considered to be exposed to fraud risks;
- the risk evaluation done by the management of the society that financial situations can be falsified significantly consequent to a fraud.

The auditor must interview the management concerning its own evaluations of fraud risks, because it is responsible for the entity's internal control and for elaborating the financial situations. The auditors questions all the aspects related to the process of researching the unproved accusations of fraud, internal or external ones, affecting the society.

The auditor can also interview about the existence or suspicion of fraud:

- employees from different levels of authority;
- employees involved in the initiation, processing and recording uncommon and complex transactions;
- the judicial counselors within the entity;
- the person in charge of ethics, whether there is one.

The auditor also interviews the persons in charge of the society's leadership to determine if they have knowledge of real or suspected frauds.

b) to understand the entity's environment, including internal control, the auditor must analyze the presence of one or more factors of emergence for the fraud risk.

Because the fraud is usually hidden, it is very difficult to detect it, but due to the acknowledgement of the entity's environment, the auditor can identify events or conditions that indicate the existence of a stimulus or pressure to commit fraud.

These events or conditions to commit fraud are named "factors of fraud risk emergence", like:

- an ineffective control environment can bring out the occasion to commit fraud;
- granting important stimuli if certain unrealistic profit goals are achieved can create the premise to commit fraud;
- the necessity to fulfill the expectations of a third part to obtain supplementary capital infusion can create pressure to commit fraud.

The auditor must take into account the procedures applied for implementing an official ethical code. When a small entity is concerned it is possible that a written ethical code do not exist but the entity has developed in time a culture pointing out the importance of integrity and ethical behavior through oral communications and the example the entity's management gives.

c) for the development of analytical procedures to understand the entity and its internal control, the auditor analyzes the unusual and unexpected that might indicate risks of significant falsification consequent to fraud.

The auditor develops certain expectations about plausible relationships which are reasonably expected to exist while applying analytical procedures. The analytical procedures include the procedures concerning the incomes accounts aiming to the identification of unusual and unexpected relationships which can prove the existence of certain risks of significant falsification consequent to fraudulent financial reports (e.g. fictional sales).

d) for understanding the entity's environment, as well as its internal control, the auditor must analyze other information indicating risks of significant falsification consequent to fraud.

The information found by the auditor during the process of accepting and keeping of a client, as well as the experience gained during other audit missions, can be important for the identification of risks of significant falsification consequent to fraud.

The auditor uses the professional reasoning and analyzes the size of the possible falsifications of financial situations in order to identify and evaluate the risks of significant falsification consequent to fraud. Suspicion of fraud or error must be present in the auditor's report, because the following situations can appear:

- fraud and error have a significant result on the financial statements, for which reason the financial auditors will express a cautious opinion or declare the impossibility of expressing an opinion because of the limits imposed by the audit;
- financial auditors can not evaluate the fraud or error's effect upon the financial statements, being prevented by the entity from obtaining the adequate and sufficient proofs necessary for the evaluation, in which case the financial auditors will express a cautious opinion or declare the impossibility of expressing an opinion because of the limits imposed by the audit.

The auditor can identify a falsification in the financial situations and in this case he must analysis if such a falsification can indicate a fraud and when such a clue exists, the auditor must analyze the implications of falsification in relation with other audit aspects, especially those related to the credibility of the leadership's declarations. The auditor's responsibilities are different in each country and the obligation to confidentiality can be evaded in certain situations through a legal status, law or court order. In some countries, the auditor is compelled to report the emergence of frauds to the authorities when the leadership and the management of the entity do not take corrective measures.

Conclusions

Aspects that lead to significant falsification consequent to fraud can emerge during the process of auditing the financial situations.

The auditor will communicate and argument his communication to the entity's leadership and management the fraud aspects that lead to the significant falsification of the financial situations. The auditor, after consulting a legal expert:

- may give up the audit mission;
- makes the audit report after he communicates his discoveries to the entity's management which decides, if it is the case, to redo the accounting documents;
- reports to the authorities the fraud aspects discovered depending on the legislation in use.

The collaboration between auditors and the audited entity's managers has a major importance in the prevention of frauds and errors concerning:

- the correction of the weak points in the control of the entity whenever they are identified by the auditor;
- the improvement of internal control system and accounting system;
- the elaboration of a set of proposes and recommendations for improving the activity in its assembly.

Abstract: Manipulation of financial information which is called by several terms such as earnings management, income smoothing, creative accounting practices, aggressive accounting or account manipulation, prevents the allocation of resources in the most efficient areas in the economy. The scope of this paper is to relate the causes, the main motivations behind their application, the objectives, the methods and the consequences of manipulation in financial reporting. Creative accounting is not a new technique, but it can be seen as a costly one. Businesses feel the pressure to appear profitable in order to attract investors and resources, but deceptive or fraudulent accounting practices often conduct to drastic consequences.

Key words: creative accounting, window dressing, fraud, account manipulation

Introduction

Accounting manipulation is defined as when the managers of an organization intentionally misstate their financial information to favourably represent the entity's financial performance. Managers of nonprofits organizations may have incentives to manipulate their reported program-spending ratios because donors use them in determining contribution decisions.

Accounts manipulation represents the use of management's discretion to make accounting choices or to design transactions so as to affect the possibilities of wealth transfer between the company and society (political costs), funds providers (cost of capital) or managers (compensation plans). In the first two cases, the firm benefits from the wealth transfer. In the third, managers are acting against the firm. Figure 1 summarizes the principles of accounts manipulation.

The accounts manipulation has a direct influence in modification of the apparent performance (as measured, for example, by the earnings per share) and/or a modification of the company's financial structure.

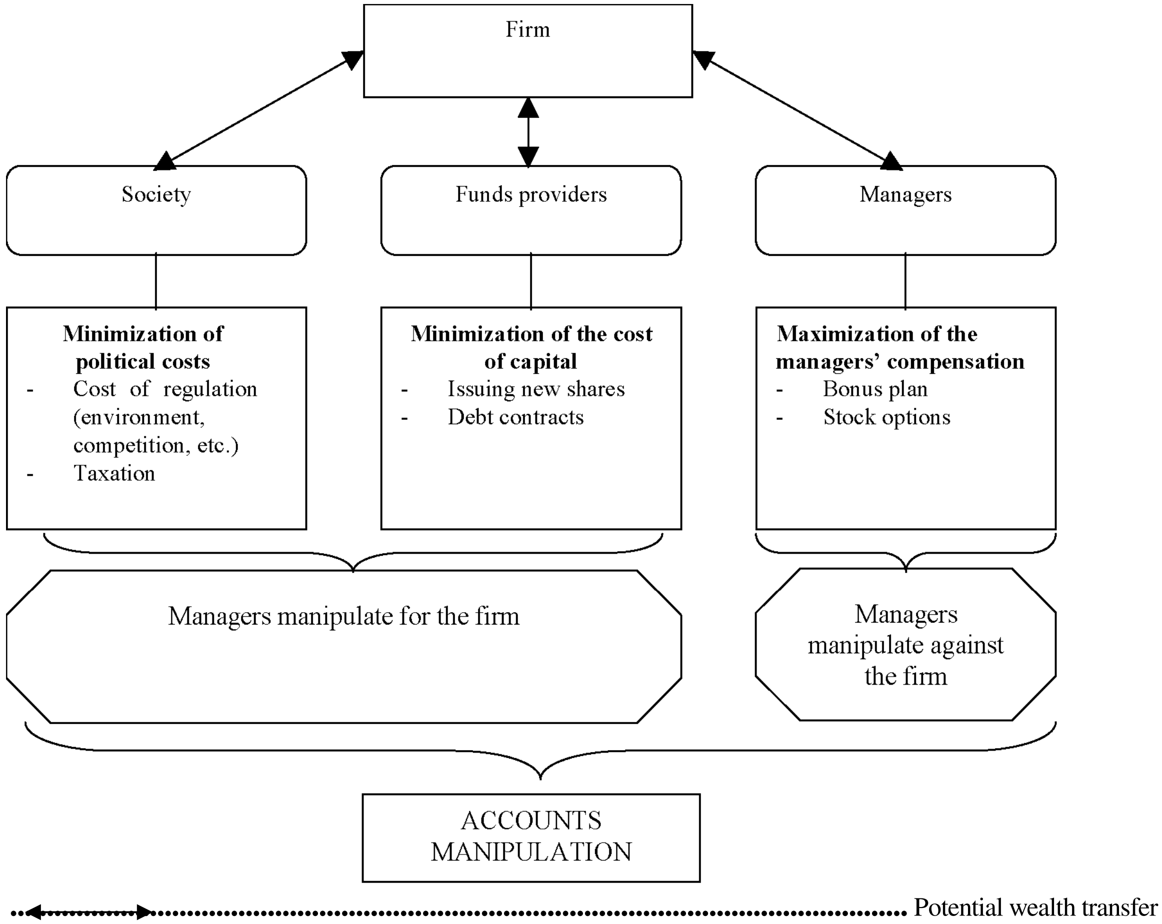

Figure 1 - Principles of Accounts Manipulation

Theoretical Aspects of Creative Accounting

In spite of the fact that the concept of creative accountant is frequently used in business literature, we cannot say that there is a definition generally accepted.

Some authors consider creative accountant 'an assembly of techniques, options and freedom room left by accounting regulation, without moving away from laws or accounting requirements, allowing to the managers to change the financial result or the financial statements' face'(Gillet, quoted by Shabou and Boulila Taktak, 2002). Others see creative accountant as 'an assembly of procedures in order to change the profit, by increasing or decreasing, or to misrepresent the financial statements, or both of them' (Stolowy 2000).

The development of economical, juridical and social activities and the stress of financial information users made the accounting innovation a necessity, and furthermore the development of the creative accounting. This type accountancy evolved in Britannic economies due to the freedom ensured to the accounting professionals and presently lies between legal form and the core of transactions or events. From the practitioners' view, the creative accounting development was encouraged by the base and alternative treatments permitted for solving one issue. Generally, an accounting issue can be solved in at least two methods, each of them with different effects on the company's financial position and performance. The academicians consider the creative accounting was encouraged by the flexibility of the regulations.

As IFRS 1 'The financial statements' reporting' in order to bring out and to present the right financial information, the following conditions have to be taken into account;

- The concordance with IFRS stipulations;
- The possibility to depart from IFRS, if according to the stipulation the right information is not obtained;

- The reporting of additional information in order to present a complete image of transactions and events.

Generally, the creative accounting is badly treated, as a negative creation, designed to prepare the financial statements in order to respond managers' requirements regarding the company's financial position and performance. Therefore, the financial statements are rather a misrepresentation of the company's performance that a true reporting.

The negative treatment of creative accounting does not exclude the positive one, being considered as an innovation that leads to engineering capable of responding the question: How can we administrate the resources in the most efficient way in order to build performance?

Simultaneous treatment of creating accounting as an instrument to accomplish the accounting interests, but also as accounting engineering, depend upon accounting policies agreed. According to IFRS 1 'The financial statements' reporting', the accounting policies represent the specific principles, fundamentals, rules or practices used by the company's management in order to bring out and to present the financial information.

Choosing the best accounting alternative to reflect accurately the reality and company's interest depends on the creative accounting. As a result, some authors consider the Britain window-dressing practice as form of creative accounting. This technique consists in realizing operation that lead to profit or loss, depending on the interest. Different accounting policies lead to different results. In this respect, it is considered that there have to be chosen that policies able to report:

a) significant information for business decisions;
b) believable information able to
    b1) report fairly, correctly and honestly the transactions and events;
    b2) reflect the economical substance of the transactions and events, not only their juridical form;
    b3) be impartial against all types of users;
    b4) be cautious, by preventing the overvaluation of the result;
    b5) be complete, through the significance and cost of information.

One of the creative accounting aims is represented by the income smoothing technique. This consists in deliberate using of accounting policies aimed to report a net income series with a low fluctuations within over a period in order to avoid the fairly report to the shareholders. This way, the management pursue to reduce the net income's fluctuations from one period to another.

The multitude of methods used by creative accounting and engineering differ with the substance. Recently the creative accounting was associated with fraud in accountancy and the accounts' lifting as a method in fraud's waiting room.

Even if both the creative accounting phenomenon and accounting fraud appear in companies with financial difficulties and are aimed to misreport, there has to make a difference between them: creative accounting represents the manipulation of the accounts according to accounting regulation and the law, while the techniques that break the law are considered accounting fraud. Therefore, we can conclude that the company using the creative accounting, benefit from the legislative niches and the flexibility of regulation in order to misreport the financial statements.

Consequently, even if the creative accounting use is not an illegal practice, it is clear, that managers in financial difficulties, are looking to solutions, no matter there are unethical. Otherwise, the half truth and the lie can be suspected as fraud.

Techniques of creative accounting

Six main areas are considered the "source of inspiration" for the creative accounting: flexibility in regulation, a lack of regulation, a scope for management that assumed some targets for the future, the timing of some transactions, the use of artificial transactions, but also the reclassification and presentation of financials. It was proved, that even in highly regulated countries such as USA the accounting environment afford, a great deal of flexibility (Largay, 2002; Mulford and Comiskey, 2002). In order to be understood, we proceeded to the detail of these:

1. Flexibility in regulation. Generally the regulation, particularly the accounting regulation permits flexibility in choosing a policy to follow; the International Accounting Standards let the financial management to choose between valuation of the non-current assets at depreciated historical value or at revaluated value. The management may decide the change of the policies, and these shifts are difficult to be identified a few years later (Schipper, 1989).
2. Lack of regulation is meeting in some areas in every domain. In most countries accounting regulation is limited in some areas, for example in Romania there is few mandatory requirements for transactions with futures and stock options or for the recognition and measurement of pension liabilities.
3. Management can use their discretionary position in order to obtain the financial position and stability they assumed; for example, the managers decide the increase or reduce of the provisions for bad debts (McNichols and Wilson 1988).
4. The timing of some transactions offers to the management the opportunity to increase the revenues, when the operating profit is not satisfactory, and to create the desired impression in the accounts. The existing stocks in company's patrimony, that have a significant higher value compared to the historical value, may be sold only when the operating profit is not satisfactory.
5. The artificial transactions are often used in order to manipulate the balance sheet amounts or to move the profits between accounting periods. These transactions are realized by entering in a controlled transaction with two or there parties, one of them, most of the times, a bank. Such arrangements consists in selling of an asset at a higher/lower rate than in an uncontrolled transaction, and then leasing it back for the rest of it useful period, compensating through the rentals the price difference.
6. Reclassification and presentation of financials are relatively less analysed in accounting literature. However, in reality the companies often proceed to make up the amounts in order to obtain good level of profitability, liquidity or leverage ratios. Most of the times, the numbers are smoothly modified in order to improve the investors' perception. As explained by Niskanen and Keloharju (2000): 'the idea behind this behaviour is that humans may perceive a profit of, say, 301 million as abnormally larger than a profit of 298 million'. Their study and others (e.g. van Caneghem, 2002) have indicated that some minor massaging of figures does take place in order to reach significant reference points.

Techniques that define creative accounting are not new, but experience has shown that most of the times may prove extremely expensive. In order to attract investors and to appear profitable to the shareholders, employees, creditors, suppliers and other categories, the companies can decide to misstate the financials; this practise often lead to drastic consequences. The manipulation of the conduct to a mismatch of the financial position and of the results with the "fair presentation" zone, as shown in Figure 2, which implies that the profit will not represent the long-term capacity of the firm to generate earnings.

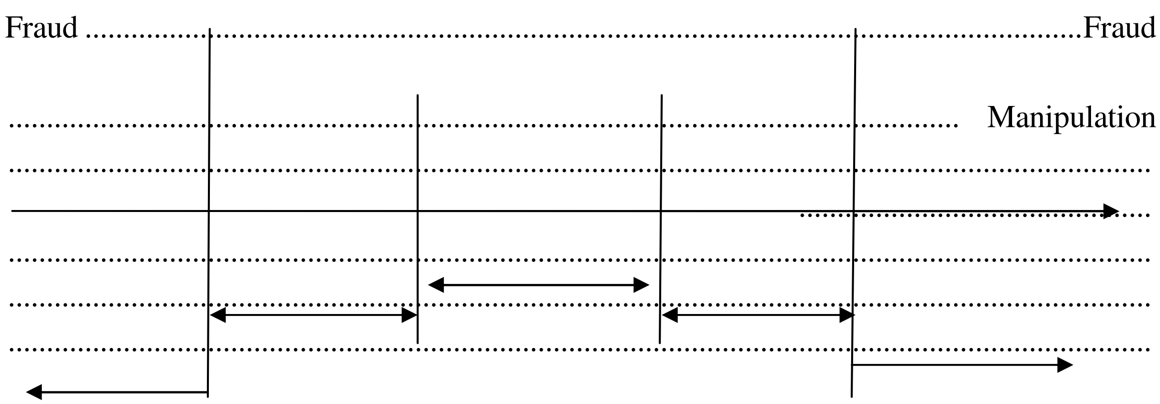

Figure 2 - Accounts manipulation and fair presentation

Reasons and consequences of creative accounting

The conflicts of interest among different interest groups represent the real causes of creative accounting: the managers are interested in paying less taxes and dividends, the shareholders in gain higher dividends, the employees to obtain better salary and higher profit share, the authorities to collect more taxes. It can be easily seen that the interests are tremendous divergent and creative accounting is deepening it. In this respect, David Schiff (1993: 94) has warned the investors that taking a company's financial statements at face value can be 'a recipe for disaster'.

Managing shareholders' interest is to pay less tax and dividends. Investor-shareholders are interested to get more dividends and capital gains. Country's tax authorities would like to collect more and more taxes. Employees are interested to get better salary and higher profit share. But creative accounting puts one group or two to advantageous position at the expense of others. One day the present authors had an opportunity to have a discussion with the Chief Accountant of an enterprise in this regard. The Chief Accountant told, in the course of conversation, that he was determined to retain profit for the expansion of his existing unit and establishment of new ones. Quite naturally, his interest was to pay less tax and less dividend and, accordingly, to 'create' financial statements. This type of creative accounting has led David Schiff (1993: 94) to warn investors; in general that taking a company's financial statements at face value can be 'a recipe for disaster'.

The investors often go wrong by taking into consideration only one ratio, as earnings per share (EPS), ratio that can be 'boosted by the stroke of an accountant's creative pen'. David Schiff (1993: 94-95) considers that there are six main ways used by the companies to increase their earnings: (1) by hidden of the pension liabilities, (2) by capitalizing the expenses instead of writing them off, (3) by realizing an faster increase of the receivables or inventories versus sales, (4) by reaching negative cash flow, (5) by consolidating the affiliates' incomes and net worth, and (6) by following seemingly conservative practice in a situation of reverse direction. Jim Kennan, the Attorney General of Victoria, in a speech before members of the Australian Society of Accountants, pointed out that financial statements, which inflate the financial position and the performances of companies by manipulating the figures (i.e., through creative accounting) should be stamped out, because bring the investor in great difficulties in order to distinguish between the made up financials and the truly financials. We considered this message may be used to stress the main effects of creative accounting:

1. The confusion created among the stock exchange investors, because the figures shown by financial statements are often inflated and the difficulty of investors' to distinguish between the fair and unfair statements.
2. The prospectuses of the listed companies do not always offer a detailed picture the financial positions and performance.
3. The techniques used by creative accounting can "impress£ the investors only over short time periods, while the financial position goes worse, this cannot be hide anymore and these methods are helpless.
4. The long time effect of such practise is the distrust of the investors conducted by the collapse of companies that take advantage of these techniques.

The question we raise is: Are these creative practices always a bad thing or can they ever be justified? As figure 2 shows, manipulation is not fraud. It is a matter of interpretation. This will be a case study of our future research.

UNFINISHED PRODUCTION EVALUATION AND BOOKKEEPING IN THE ENTITIES IN THE FURNITURE INDUSTRY

Bănuţă Mariana

The University of Piteşti, The Faculty of Economic Sciences, Contact address: Piteşti, Str. Târgu din Vale, no. 1, Argeş, Romania, Email: banuta_mari@yahoo.com, Telephone: 0745770820

Abstract: I believe that ***stocks*** *represent one of the "key" elements of the operation process, especially in the case of the industrial entities (and implicitly those in the furniture industry) which intervene during the whole purchase – production – selling cycle. For this reason one can state that the superficial or inadequate treatment of the stock management and accounting may represent a hindrance in obtaining the industrial company performance or may be a factor calling into question the continuity of the activity.*

I have analysed, in the article, the method used for the evaluation and bookkeeping of unfinished production in the entities the furniture industry and I rendered my own view concerning this topic and I also made proposals for the contribution to the increase in accuracy of the evaluation of unfinished production.

Key words: unfinished production, stocks, the furniture industry, finished products

The furniture industry is one of the "victorious" sectors of the Romanian economy, and also one of the few manufacturing areas that have a positive contribution to the commercial balance. The dynamics of this economic sector is eloquently emphasized by the increases, from year to year, of the volume of the manufactured furniture and of its sale.

The production in course of being manufactured is that production that has not undergone all the phases or stages of processing provided in the operating process, as well as the products that have not yet undergone the tests and the technical acceptance or that have not been completed with all the necessary accessories, and constitute unfinished production.

In the studied specialized materials related to production management, some suggestions are made for the **evaluation of the production in course of being manufactured**, function of the production organization (on orders, on unique pieces or on continuous).The production in course of being manufactured can be analyzed:

a) **In point of its physical aspect**, including all raw materials and other included tangible assets active, present in the various stages of the manufacturing process, for the manufacture of the finished products from the list of goods of the company;
b) **In point of value**, including all the working costs incurred in order to obtain it up to the currently undergoing processing stage. Consequently, the costs of consumable, energy, depreciation, wages and their related contributions, etc., corresponding to the stages of the manufacturing process performed up to that particular moment are added to the value of the raw materials in course of being processed.

The assessment of the actual stocks of production in course of being manufactured, **expressed physically**, is made by stocktaking of all the orders or products being processed, by a commission especially established for this purpose.

The assessment of the value of stocks the size of which is decided on the basis of stocktaking is made on each and every order or product, by using three calculation methods:

1. based on the degree of technical finishing;
2. on units or on operations;
3. based on the average cost of a manhour.

* **The calculation method based on the degree of technical** is used in the production organized on **orders** and on **unique pieces**. It implies two working stages:

Stage 1 → the degree of technical finishing of the order or product in course of being manufactured is determined. This degree is expressed by a **technical finishing coefficient - kft**, calculated function of the tariff wage costs afferent to the order or product to which it is related. For this purpose, the tariff wage costs incurred up to the moment of the stocktaking are compared to the tariff wage costs provided for the completion of the order or product.

Stage 2 → it has as an object **the assessment of the value of the production in course of being manufactured that is in stock – Spce**. For this purpose the production cost of the order or product is multiplied by the previously calculated technical finishing coefficient.

Example: Assuming that until the end of March the tariff wage costs incurred up to the stocktaking moment amounted to 30,000 lei for the manufacturing of order 102 (400 units of "Rebecca" two-door wardrobe), while for the completion of the whole order, the wages should amount to 80,000 lei.

The technical finishing coefficient: **Kft = 30 000 / 80 000 = 0.375**

The calculation of the value of the production in course of being (Spce) is made by multiplying the production cost of the order (number of products included into the order x pre-calculated production cost for that particular product) by the previously calculated technical finishing coefficient.

In my opinion, it is recommendable that the actual production cost obtained following a calculation for the same product included into the order, in a previous accounting period should be taken into account rather than the pre-calculated production cost (especially in the case of the modification of the value of the calculation items included into the pre-calculated production cost, due to the fact that revisions and adjustments cannot keep up with the changes occurred from the moment of the pre-calculation onward).

Assuming that, for the completion of order 102 that includes 400 units of wardrobe, the production cost of all the products included into the order would have been 280 000 lei (400 units x 700 lei / unit). As a result, **Spce = 280,000 lei x Kft = 280,000 lei x 0.375 = 105,000 lei**;

This value will be attributed to the production in course of being manufactured, in the case of order 102, at the end of March.

* **The calculation method on units or operations** is used for complex products, when the production cost for each unit or technological operation of the product in course of being manufactured can be assessed (it is applied in the machine industry).

* **The calculation method based on the average cost of a manhour** is used in the case of complex products, when all the components of the product in course of being manufactured have approximately the same pattern of production costs.

I believe that the last two methods of assessing the production in course of being manufactured cannot be applied to the products obtained by the entities in the furniture industry, which is why I am not going to describe them in detail.

Following the research performed in entities in the furniture industry, concerning the evaluation of the production in course of being manufactured, I can assert that the **accounting or indirect method** is used. This method is conventional in nature, because the calculation of the costs related to the production in course of being manufactured is made on the basis of accounting data and data of operational accounting, and no stocktaking of this production is performed.

According to this method also presented in the specialized literature, the cost of the production in course of being manufactured is assessed on each calculation item, on the basis of the data in cost accounts that have collected costs on calculation items reflecting in the debts the total actual costs, and in the credits the cost of the finished production, the balance of debts representing the actual cost on the unfinished production:

The calculation formula is as follows:

The cost of the production in course of being manufactured	=	Total costs collected on cost bearers	–	(Quantity of finished products delivered at the warehouse	x	Appraisal unit cost)

The evaluation of the finished production delivered to the warehouse is made function of **the standard cost** or **the actual cost of the previous accounting period.** A disadvantage of using this method is that the differences between recording price and the actual cost calculated at the completion of the whole manufacturing order are reflected in the cost of the last batch of products delivered to the warehouse.

In what the assessment and bookkeeping of the unfinished production in the **management accounting** are concerned, I am underlining that the correct assessment of the production in course of being manufactured is attached special importance for the accurate calculation of the cost of the finished production, as well as of other company activity performance indicators, such as profit, rate of return, etc. For example, the overestimation of the production in course of being manufactured leads to the unjustified reduction of the cost of the finished production, thus artificially increasing profit and respectively the rat of return. On the other hand, the underestimation of the production in course of being manufactured has opposite effects, influencing in an unfavourable manner the activity of the company.

Due to the strong competition that manifests itself in the field of furniture manufacturing/commercialization, the managers at various hierarchic levels need information related to the predetermination of expenditures and of the cost development, to the operational monitoring of the actual amount of costs and of their pattern, of the deviations from the planned level, of the causes that have 1produced these deviations.

The method on orders, used in cost calculation, by a significant number of entities in the furniture industry, is one of the classic, traditional methods of calculation. Due to their application methodology, the traditional methods have been widely criticized, as they do not meet the requirements of modern management, thus requiring adaptation and improvement. A disadvantage of this method consists in the fact that, in the case of the entities in the furniture industry, due to the period needed for the completion of orders, (an average of two months), at the end of the accounting period there are many orders in course of being manufactured, and the assessment and evaluation of the unfinished production are labour intensive and may influence the accuracy, quality and efficiency of the calculation indicators.

If, out of an order, only a certain quantity of products has been completed and delivered to the warehouse, these finished products are usually evaluated at the actual production cost of the previous accounting period. This type of evaluation leads to the alteration of the costs related to the production in course of being manufactured and implicitly of the costs of the finished products when the order is completed, especially if the actual production costs vary from one accounting period to another.

My proposal concerning the assessment / evaluation of the unfinished production also implies an additional effort from the employees involved into cost calculation with the purpose of calculating the degree of technical finishing and of the elements included into the unfinished products. For example, in the case of an order that will include 50 units of LUFA night tables model 4520 (order xxxx), if, 45 units were completed u1ntil the end of the accounting period, I will assess the value of the unfinished and finished production as follows:

For the 45 units of finished products, the degree of inclusion of the elements constituting the production cost is 100%.

Actual cost of 45 units (for the finished production)	= (100%	x	Raw material and direct material costs	+100%	x	Direct wages and accessory costs	+100%	x	CIFU ratio	+100%	x	CGS Ratio)

where CIGU= equipment maintenance and operating costs

CGS=workshop general expenses

For the 5 units of unfinished products, I will analyze, for each of them: the value of the raw materials and direct materials provided for expenditures and included in the unfinished products, as well as the finishing percentage in point of directly productive workers' labour. I assume that:

	Raw materials and direct materials	Direct labour (Y % from the total required for completion)
For the first unfinished unit	100%	60%
For the second unfinished unit	40%	20%
For the third unfinished unit	70%	42%
For the fourth unfinished unit	100%	80%
For the fifth unfinished unit	20%	10%

If the raw materials and direct materials are taken from the warehouse for the whole order and are made available for expenditure, the percentage taken into account will be 100%.

I propose that CIFU and CGS ratios for the unfinished production should also be taken into account in the same percentage corresponding to the direct labour. Consequently:

The actual cost of the unfinished production for the 5 units = **Raw material and direct material costs** (100%+40%+70%+100%+20%)

\+

Direct wages and accessory costs (60%+20%+42%+80%+10%)

\+

CIFU ratio (60%+20%+42%+80%+10%)

\+

CGS ratio (60%+20%+42%+80%+10%)

= $\frac{330}{100}$ **Raw material and direct material costs** + $\frac{212}{100}$ **Direct wages and accessory costs** + $\frac{212}{100}$ **CIFU** + $\frac{212}{100}$ **CGS**

We assume that, for order xxxx, the amount accumulated on the debit of account **921 "Core business costs. Analytic order xxxx**" is composed of:

Raw materials and direct materials		
$\underbrace{921}_{\text{cheltuielile activitatii debaza}} \cdot \underbrace{01}_{\text{cheltuieli directe}} \cdot \underbrace{01}_{\text{componente lemn}} \cdot \underbrace{xxxx}_{\text{comanda}}$ *core business costs* · *direct costs* · *wooden components* · *order xxxx*	Core business costs. Analytic Direct raw materials (wooden components)/order xxxx	$\left.\begin{matrix} 921.01.01.xxxx \\ 921.01.02.xxxx \end{matrix}\right\} \rightarrow 40{,}000$ lei

921.01. $\underbrace{01}_{cheltuieli\ directe}$. $\underbrace{02}_{materiale\ directe}$ .xxxx *direct costs* *direct materials*	Core business costs. Analytic Direct materials/order xxxx	
Direct labour and accessories		
921.01. $\underbrace{03}_{manopera\ directa}$. $\underbrace{01}_{valoare\ manopera\ directa}$ .xxxx *direct labour* *direct labour value*	Core business costs. Analytic Direct labour /order xxxx	$\left.\begin{matrix} 921.01.03.01.xxxx \\ 921.01.03.02.xxxx \end{matrix}\right\} \rightarrow 21{,}000$ lei
921.01.03. $\underbrace{02}_{contributii\ aleunitatii\ cuprivire\ la\ manopera\ directa}$ .xxxx *Contributions paid by the company in relation to the directly productive labour*	Core business costs. Analytic Contributions paid by the company in relation to the directly productive labour /order xxxx	
CIFU Ratio		
$\underbrace{921}_{cheltuielile\ activitatii\ de\ baza} . \underbrace{02}_{CIFU} . \underbrace{xxxx}_{comanda}$ *core business costs CIFU order xxxx*	Core business costs. Analytic equipment maintenance and operation costs ratio / order xxxx	921.02.xxxx $\rightarrow$6,000 lei
CGS Ratio		
$\underbrace{921}_{cheltuielile\ activitatii\ debaza} . \underbrace{03}_{CGS} . \underbrace{xxxx}_{comanda}$ *core business costs CGS order xxxx*	Core business costs. Analytic workshop general costs / order xxxx	921.03.xxxx $\rightarrow$4,200 lei
Total production costs (finished and unfinished production) /order xxxx		= **71,200** lei

By taking into account the actual finished and unfinished production costs we will have:

$\rightarrow$**for the finished production**	: 45× raw material and direct material costs	+45× direct wages and accessory costs	+45 ×CIFU	+45 ×CGS
$\rightarrow$**for the unfinished production**	: 3.30× × raw material and direct material costs	+2.12 × direct wages and accessory costs	+2.12 CIFU	+2.12×CGS
Total finished and unfinished production costs	=48.30× × raw material and direct material costs	+47.12× direct wages and accessory costs	+47.12CIFU	+47.12×CGS
48,30× raw material and direct material costs	= 40.000 lei	$\Rightarrow$ × **raw material and direct material costs / unit**	$= \frac{40000}{48{,}30}$ lei	**=828.157 lei /unit**

47,12× direct wages and accessory costs	= 21.000 lei	⇒ **direct wages and accessory costs / unit**	$=\frac{21000}{47,12}$ lei	**=445.671 lei / unit**
47.12× CIFU	= 6,000 lei	⇒ **CIFU / unit**	$=\frac{6000}{47,12}$ lei	**=127.334 lei / unit**
47. 12 ×CGS	= 4,200 lei	⇒ **CGS / unit**	$=\frac{4200}{47,12}$ lei	**=89.134 lei / unit**

Consequently, we will have:

Total costs for the finished and the unfinished production	**Finished production costs**	**Unfinished production costs**
Raw materials and direct materials = 40,000 lei	45 x 828.157 = 37,267 lei	3.30x 828.157 = 2,733 lei
Direct labour and accessories = 21,000 lei	45 x 445.671 = 20,055 lei	2.12x 445.671 = 945 lei
CIFU = 6,000 lei	45 x 127.334 = 5,730 lei	2.12x 127.334 = 270 lei
CGS = 4,200 lei	45 x 89.134 = 4,011 lei	2.12x 89.134 = 189 lei

We will perform the bookkeeping of the unfinished production on elements of cost as follows:

933. xxxx	=	**921. xxxx**	4.137 lei
The cost of the unfinished production. Analytic order xxxx		Core business costs. Analytic order xxxx	

In the financial accounting, the bookkeeping of the unfinished production (in course of being manufactured) is performed as follows:

At the end of the month, the unfinished production is highlighted on the basis of the data in the operating accounting, at the level of the actual production costs:

331	"Products in course of being manufactured"	=	711	"Stock variation" 4.137 lei

At the beginning of the next month, the resumption of the unfinished production entries are made by the opposite accounting formula

INVENTORY EVALUATION AT STOCKTAKING

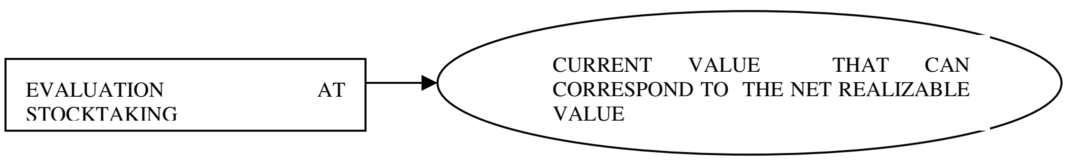
Bănuță Mariana

The University of Piteşti, The Faculty of Economic Sciences, Contact address: Piteşti, Str. Târgu din Vale, no. 1, Argeş, Romania, Email: banuta_mari@yahoo.com, Telephone: 0745770820

Abstract: All companies perform the inventorying of their patrimony, (including the stockable items, at the beginning of their activity, on the occasion of mergers or liquidations, whenever it is necessary during the accounting period, (due to internal need for information, replacing the gestionarului, etc.) and compulsorily at the end of the accounting period before drawing up the financial statements. I have treated, in my article, problems related to inventory evaluation at stocktaking, the method used for their inventory, the settlements of shorts and overs at stocktaking, setting the values that will be recorded following the stocktaking as well as the inventory evaluation at stocktaking according to the rules applicable in other countries.

Key words: stocks, stocktaking, settlement, current value, book value, inventory evaluation

Irrespective of the nature of their activities, all companies perform the inventory of their patrimony, (including the stockable items), usually at the end of the year, when these items are evaluated at their **current value** also known as book value that can correspond to the **net realizable value** (representing the assessed price that could be obtained during the normal activity, minus the costs estimated for the product finishing or/and the costs necessary for its sale).



However, we can ask the question: "What are the guidelines of the economists and the other specialists involved in the calculation of the value of the stocks to be inventoried?

From practical research and by studying the applicable regulations, we can assert that, besides the indications provided by the norms concerning the organization and performance of stocktaking of the asset and liability items, professionalism is needed both for the actual performance of the assessment of the real quantities in stock and also for the evaluation of their book value.

Although my intention is not to mention aspects related to the organization, I would like to specify a few recommendations that are useful to entities in their stocktaking.

For example:

The evaluation of factual stocks is made by counting, weighing, measurements or cubation, on a case-by-case basis. The goods found in their intact original packages are only unpacked at random, this method being mentioned in the related inventory lists.

For **liquids** (thinners, paint, varnishes, etc.) **the effective quantity of which can only be estimated by decantation and measurement**, the content of the recipients – calculated function of their volume, density, composition, etc. is checked by taking samples from these recipients, and taking into account the density, composition and other characteristics of the liquids that are fount either organoleptically, or by measurements or by laboratory tests, as the case may be.

If various types of **stocks**, the **weighing and measuring** of which would need **significant expenses or would lead to the degradation of the respective goods**, can be inventoried on the basis of technical calculations (for example: wood that is being pressed, veneers, etc. in an entity in the furniture industry), then the inventory method as well as the technical data on which the calculations were based are mentioned in the inventory lists.

The stocks found with the employees on the date of the inventory (that are generally inventory-item type materials: work and protection equipment, tools, instruments, etc.) are inventoried and put on separate lists, together with the persons responsible for their custody. Within the description of their formations and work places, the goods will be centralized and compared to the data in the technical and operating records, as well as to the accounting data.

All the stocks that are being inventoried are mentioned in the inventory list that must be drawn up on storage places, accounts and goods categories and the inventory committee has the obligation to inspect all the places where goods that are subject to inventory might be stored.

The goods belonging to other companies (in custody, to be sold on commission, to be processed, etc.) are inventoried and put on separate lists. The inventory lists used for these goods will also contain information related to the number and the date of the delivery and reception document and of the supply document, as well as other useful information. The inventory lists mentioning goods belonging to third parties are also sent to the Romanian or foreign private person of legal entity who owns the respective goods, on a case-by-case basis, within maximum 15 days from the completion of the stocktaking, and the owner of these goods has the obligation to notify the possible inadequacies within 5 days from the reception of the inventory lists. If no confirmation is received within **this** term, the recognition of the accuracy of the data written in the inventory lists is implied. In case of inadequacies, the respective company has the obligation to clarify the situation of the respective differences and to communicate its findings to the private person of legal entity who owns the respective goods, within 5 days from the reception of the notification.

For the depreciated, unusable or deteriorated stocks, still stocks or stocks that are hard to sell, orders that are being manufactured, abandoned or suspended, separate inventory lists are drafted.

The stocks **that are being dispatched** are inventoried by the supplying companies, while **the stocks purchased that are in course of being supplied** are inventoried by the purchasing company and are specified on separate inventory lists.

Before starting the stocktaking of the production **in course of being manufactured, and that of the** semifinished articles internally manufactured, it is necessary that:

- all the parts, assemblies and aggregates the processing of which has been completed should be delivered to warehouses on the basis of documents;
- all the residual products and waste should be collected from sections or workshops, and all the recording documents should be drawn up;
- all the recording documents should be drawn up and the situation of the semifinished products the usage of which is doubtful should be clarified.

In the case of **the production in course of being manufactured** both the products that have not yet passed through all the phases (stages) of the processing required by the production operating process as well as the products that although finished, have not passed the technical acceptance tests or have not been completed with all their parts and accessories will be inventoried.

Raw materials, materials, prefabricated parts, spare parts, semifinished products, etc., **that are found in the work places and are not being processed**, **are not** considered production in course of being manufactured. They are inventoried separately and are returned to the accounts from which they have come, while the costs are diminished, and after completing their stocktaking their accounting will be performed in the initial expense accounts.

As I have mentioned before, the inventory evaluation, on the occasion of the stocktaking, is made at the **current value** of each article, called **book value**, set function of **de the usage, condition and market price of the goods**.

When the book value of the stocks is set the **principle of prudence** will be applied, according to which all the value adjustments due to depreciation will be taken into consideration. Consequently:

- If it is found that **the book value**, set function of the goods usefulness for the company and of the market price, **is higher** than **the value with which it is recoded in the accountancy**, **the accounting values will be recorded** in the inventory lists***;***
- If the **book value** of the goods **is lower than** the accounting value, ***the book value*** *will be specified in the inventory lists****.***

Stock type assets ate evaluated at their accounting value, except for the found depreciations. If the **accounting value of the stocks is higher than their book value**, the value of the stocks **is diminished down to their net realizable value** by the **establishment of a depreciation adjustment.** The depreciation adjustment is recorded irrespective of the economic situation of the company, even if the company has book losses.

For the stocks for which depreciations were found, on the basis of the separately drafted inventory lists, **the inventory committee makes proposals** concerning **the establishment of depreciation adjustments**, while also mentioning all the causes that led to these depreciations.

For all the overs, shorts and depreciations that have been found concerning stocks, the inventory committee must receive written justifications from the persons responsible for their management. On the basis of the received justifications and of the analysed documents, the inventory committee establishes the nature of the shortages, losses, damages and depreciations that have been found, as well as the nature of the excess, proposing, in compliance with the applicable legal provisions, the method of settlement of the differences between the book data and the real ones, resulted following the stocktaking.

- If **overs** are found in the accountancy, the respective goods will be evaluated at their just **value**.
- If **shorts** are found in the accountancy **that are imputable**, the managers will take the measure of imputing them at their replacement value.

By **replacement value** one understands the acquisition cost of goods (including the stock type ones) with characteristics and wear that similar to the one that is short at the date when the damage is found, comprising the purchase price on the market to which all the non refundable taxes, including the VAT and the transport, supply and other costs necessary in order to record the respective goods in the accountancy are added. In the case of stocks that are short and that are to be imputed and **cannot** be purchased on the market, the imputing value is set by a specialist committee.

Moreover, we must take into consideration that, when the value of the debt is assessed, in the cases I which the shorts are not considered offences, the **compensation of shorts with the possible overs** will be taken into account, provided the following conditions are fulfilled:

- that there is the risk of mistaking one sort of the same goods, due to the resemblance of the physical aspect: colour, pattern, model, sizes, packages or other elements;
- the found shorts or overs should concern the same accounting period and the same account.

Compensation is not admitted if there is poof that the shorts found are due to theft or degradation of the respective goods from fault of the persons who are responsible for managing these goods.

The lists with the sorts of product, merchandise, semifinished products, raw materials, packages and other material values that meet the compensation conditions due the risk of being mistaken are approved by the administrators and are used for internal purposes within the respective entity.

Example concerning the compensation of overs with shorts (for the accounting period 01.01.2006 – 01.01.2007, at Account "PFL Warehouse", bookkeeper Ionescu Dan in an entity in the wood industry.

Overs			Shorts		
PFL 2.8 mm thick → $7m^3$ x 4 lei = 28 lei			PFL 3 mm thick → $10m^3$ x 5 lei = 50 lei		
PFL 4 mm thick → $5m^3$ x 6 lei = 30 lei			PFL 5 mm thick → $3m^3$ x 6.3 lei = 18.9 lei		
TOTAL	12 m^3	58 lei		13 m^3	68.9 lei

The case: quantity "+" < quantity "-"

value "+" < value "-"

In order to compensate the found overs, first we must make sure that this type of stock (PFL) is included into the list with the sorts of stocks that meet the compensation conditions, internally approved within the entity by the administrator. After the verification, if the other conditions related to the risk of being mistaken, to the accounting period and the actual accounting are also met, we observe the following rules:..

- initially, we **equalize the quantities, by eliminating the overs from calculation** (consequently we must have the quantity of 12 m^3, we will eliminate 1 m^3 from the quantities that are found as being "-").

The elimination of the overs from the calculation is made starting with the sorts that have the lowest unit prices, in increasing order.

Overs			Shorts	
PFL 4 mm thick → $5m^3$ x 6 lei = 30 lei			PFL 5 mm thick → $3m^3$ x 6.3 lei = 18.9 lei	
PFL 2.8 mm thick → $7m^3$ x 4 lei = 28 lei			PFL 3 mm thick → $10m^3$ x 5 lei = 50 lei	
TOTAL	12 m^3	58 lei	$13m^3$	68.,9 lei

↓

I will eliminate

1 m^3 from

the quantities "-"

Starting from the lowest

prices "5 lei"

Following the elimination we will have:

Overs		Shorts	
PFL 4 mm thick → $5m^3$ x 6 lei = 30 lei		PFL 5 mm thick → $3m^3$ x 6.3 lei = 18.9 lei	
PFL 2.8 mm thick → $7m^3$ x 4 lei = 28 lei		PFL 3 mm thick → $9m^3$ x 5 lei = 45 lei	
12 m^3	58 lei	$12m^3$	63.9 lei

Consequently, I have eliminated, from the quantities found as being "-", $1m^3$ x 5 lei = 5 lei

- we compare the total value of "+" with the total value of "-"

Overs	Shorts
58 lei	63.9 lei → value > value of the shorts of the overs 63.9 lei 58 lei

- 5.9 lei that will be a minus value of 5.9 lei
- the entity must not incur damages:
- the quantity shortage, eliminated by compensation (1 m^3 x 5 lei = 5 lei) will be imputed to the bookkeeper
- the minus value, fond following the compensation, that is 5.9 lei, will also be imputed to a person found responsible.

Consequently, the estimated minus difference found following the and the application of all the deduction quotas representing the damage incurred to the company is retrieved from the persons found responsible in compliance with the applicable law.

Note: If there were excess quantities or values at the application of the first two rules , they were recorded.

The proposals included in the record of the inventory committee are presented within 3 days from the completion of the stocktaking operations, to the administrator of the entity. The administrator, with the approval of the finance and accounting department manager and of the legal department manager, decides, within maximum 5 days upon the reception of the record, on the solution of the proposals that are made in compliance with the law. The stocktaking results must be registered in the technical and operating records within maximum 3 days from the date of the approval of the inventory record by the administrator.

A specialized paper presents **the evaluation of stocks at inventory**, according to the **American system.** For example, when stocks are inventoried, they must be evaluated at their **lowest value between the cost and the market value**, with the exception of some cases in which they can be evaluated at a higher price.

When it is obvious that a goods value that is used within the current operations of the company has become lower than their cost (the acquisition or production cost) as a result of their becoming obsolete or deteriorated, or of changes in prices or of any other cause, the difference must be registered to the losses of the respective accounting period. In these cases, the estimation to the lowest value between the cost and the market price is used.

In the expression "the lowest value between the cost and the market price" the notion "**market price"** is **the equivalent of** that of ***current replacement price***, provided the following two **conditions** are observed:

- The market value must not be higher than the net realization value (i.e. the estimated price from which the costs predicted for the completion of the product and the ones necessary for making it available to the customer are deduced);
- The market value must not be lower than the net realization value, decreased by a provision related to a normal margin.

Function of the nature and composition of stocks, the rule of the lowest value between the cost and the market price can be directly applied at the level of the item, on categories of stocks or for the entire stock.

In exceptional circumstances, the stocks pot can be **evaluated** to a **value that is higher than the acquisition or production cost**. For example, precious metals that have a fixed monetary value without a significant trade cost can be evaluated at their monetary value at the date of the inventory. Other exceptions concern the case when it is practically impossible to estimate a low approximate cost and when it is possible to immediately sell the goods to a (rated) market value and the goods are unidentifiable (fungible).

When stocks are evaluated to a higher value than the sale price, this should be mentioned in the attachment.

In **France,** at the moment of the stocktaking, **the current value** is used as evaluation basis.

The general case (with the exception of bonds) presents a current value:

Current value = Venal value

The venal value (PCG): is the price presumed to be accepted by the possible purchaser, in the condition and at the place of the goods; this value must be assessed function of the situation of the company.

The venal value, a value always difficult to assess, must take into account:

- The price "reference": the market
- The usefulness of the goods for the company, function of its future "exploitation" (the "exploitation continuity" principle is taken into account)

In practice, its assessment is difficult, but also indispensable.

On the basis of the inventory register[287] and of the trial balance drawn up on 31 December **the balance is drawn**, as part of the annual financial statements, the items of which correspond to the recorded data, harmonized with the real situation of the asset and liability items set for the inventory.

PARTICULAR ASPECTS REGARDING THE USE OF CONSOLIDATED STATEMENTS AGAINST THE BACKGROUND OF THE EUROPEAN ACCESSION

Berheci Maria

"Alexandru Ioan Cuza" University of IASI, Faculty of Economics and Business Administration, e-mail: maria_lia24@yahoo.com,

Abstract: The decision of an investor to place capitals in a business is conditioned by obtaining intelligible cost-effective information. To this purpose, quoted multinational companies that make consolidated accounts had to use one only accounting referential, that are the IAS/IFRS regulations. In other words, an equivalence was established between accounting practices at an international level that create the premises for the understanding and the comparability of the financial statements of companies from various countries, the international accounting harmonization being conceived as means of economic integration and also as means of the large international financial markets transparency and efficiency. This study focuses on highlighting the particular aspects (advantages and limits) with regard to the use of the information contained in consolidated financial statements.

Key words: consolidated financial statements, use of information, group of companies etc.

General considerations

Consolidated accounts represent the informational product given to the users that are interested in business groups. By group of companies we understand a parent company and its subsidiaries. It goes without saying that the business scope of the business groups surpasses national borders. They are the consequence of the economy going global and implicitly of external development and financial markets going global. To characterize it briefly[288], the globalization of the financial markets is the consequence of the following directions and measures: the un-regulation and the liberalization of the capital circulation world-wide; the adoption by developed countries of external capital-related convergent policies; the increase of the power of institutional investors; the increase of population's savings as financial placement; the internationalization of banking activities.

With regard to the use of the consolidated financial statements, we see that if from the very beginning the consolidated accounts were made to meet own management needs or upon the request of the parent company, afterwards, as a natural consequence of the *enhanced importance of the consolidated accounts in internal and external reporting*, it became necessary to make and issue financial statements for business groups. Attention can be drawn to some shortcomings of the individual accounts of the parent company that are *advantages*[289] of the consolidated accounts in the area of the financial information, that is: the turnover recognized in the profit and loss account of the parent company shows both the external sales and the sales within the group; the profit of the parent company may be affected by the loss of a subsidiary; the financial structure of the parent company may be compromised by the high debt ratio of another company within the group; the performance of the subsidiaries are noticeable only when dividends are shared and specified in the profit and loss account of the parent company, but their results may be different etc.

Making financial statements enables the supply of full information about the entire economic status of the group, which will lay at the basis of the decision-making by the users of financial and accounting information. For instance, in the *consolidated balance sheet*, the interest titles held by branches are replaced with their debts and assets, like the parent company would be the owner. In the same manner, *the consolidated profit and loss account* presents the results of all the entities within the group, after the necessary eliminations. All these aspects show the true position of the consolidated accounts in the hierarchy of financial statements.

---

[289] **Guedj, N.**, *Finance d'entreprise. Les règles du jeu*, Editions d'Organisation, Paris, 2001, pp. 242-245.

Of course, besides the advantages that the consolidated financial statements bring to their users, they also present a series of *limits*. First, the variance of the consolidation perimeter impairs the comparability of the information from one exercise to another. Then, the contribution of each entity within the group is less shown by the consolidated financial statements, as the global debt ratio may conceal significant individual debt ratios. As some authors say[290], "one of the challenges of the consolidated accounts is the fact that every user searches to find in them an image of the group , but the nature of the image is not always the same: economic for some, financial for a few, patrimonial for others and sometimes the three altogether". Consequently, a solid use of the financial statements of a group of companies should refer both to consolidated account and to the relevance of individual accounts within them.

Characteristics of particular structures of consolidated financial statements

It is known that the *goodwill* regularly appears in consolidated financial statements and accounts for the difference between the purchase price of the interest (titles purchased) and the corresponding fraction of the re-valuated net asset at the purchasing time. In time, several accounting treatments of the goodwill were approached, from its recognition as asset within incorporeal fixed assets (depreciable or not) up to the deduction from equity capital at the purchasing time (the British treatment). And the international accounting regulations retained until 2003 the idea of activating the goodwill and its systematic depreciation during its use. But, as the regulation IAS 22 "Business combinations" was revised and it was changed into IFRS 3 "Business combinations[291], the goodwill acquired further to a business combination should be recognized as asset starting with the purchase time. Moreover, the new regulation forbids the depreciation of the goodwill acquired in a business combination, but requests its annual depreciation or even more frequently, if certain circumstances show there is any depreciation. It seems just logical to give up the depreciation of the goodwill, if we consider that neither participation titles are depreciated, nor there is a direct connection between these (goodwill and interest title). Moreover, expenses might double as a series of expenses are made to maintain or increase the purchased economic advantages. Then, another explanation of the failure to depreciate the goodwill and to replace it with the depreciation test may be also the consequence of the introduction of the fair value in accounting, some authors'[292] state, and we agree to them.

Another element that occurs only in consolidated financial statements is represented by the *emphasized titles*, as structure of financial fixed assets. The last national accounting regulations regarding the consolidation are true to the European directives[293] and contain various precisions to this respect. We synthesize as follows some of the most significant aspects. The titles that are in equivalence are specified in the consolidated balance sheet when an entity included in the consolidation has a significant influence over the operational and financial policy of an associated company in which it holds an interest title. The part of profit or loss of the associated companies that is assignable to such interests is presented in the consolidated profit and loss account at the elements "Profit or loss of the financial year afferent to the associated companies". The investment in an associated company is accounted using the *method of equivalence* since the day it becomes an associated company. If in the countries of continental Europe the equivalence is considered a method of consolidation, in Anglo-Saxon countries it is seen rather as a method of valutation.

Another particular feature of the structure is that only the consolidated accounts refer to the *differences of conversion* as a result of the foreign enterprises' conversion of financial statements in the consolidation currency. IAS 21 "The fluctuating effects of the exchange rate", revised, keeps a single method of conversion, as compared to the previous standard, i.e. the closing price method which means that the assets and debts for each presented balance sheet must be conversed at the closing price of the balance sheet date, the revenues and the expenses must be conversed at the exchange rates of the transaction dates (or at a medium course) and all the resulting exchange rate differences must be acknowledged as a separate

constituent of the personal capitals (exchange rate differences). In other words, when a group includes individual entities with different functional currencies, the results and the financial position of each entity are expressed by means of a currency they have in common, so as the consolidated financial statements could be presented.

Minority interests are the amounts attributed to subsidiary companies belonging to other persons than the entities included in the consolidation. The national regulations mention that they must be presented in the consolidated balance sheet in the form of personal capitals and distinguished by the capitals of the company owning the subsidiary companies as separated by two constituents: the profit or the lost financial year corresponding to the minority interests and other personal capitals. In the literature of the field[7], there are two theories with respect to the treatment of minority interests that is the theory of economic entity and financial theory. According to the former (mentioned by national references), the minority interests are included *in the personal capitals*, the quota to the net assets of the subsidiary company being genuinely determined for both categories of owners (the owning society and the minority ones). With respect to financial theory, the minority interests are mentioned in the balance sheet at *debts*, determined either by right book values or the subsidiary company assets and liabilities, the differences of purchase being presented only for the corresponding share of the parent company, as compared to the theory of economic entities, according to which the difference of purchase is applied to the whole value.

Problems encountered in the analysis of financial position and performances at the level of business groups

The analysis of financial position and performance at the level of business groups mainly involves the same techniques as in the case of individual enterprises but particular problems with difficulties of interpretation may also arise. In this sense, we could mention the following difficulties: problems created by the evolution of the consolidation perimeter, the incapacity of the group's financial statements to give full information on the transactions between the subsidiary companies of the group and difficulties encountered in the analysis of activity department results.

If, at the level of an individual enterprise, its size and structure are known at any time, at the level of company groups, there can be changes in size from a period to another, according to the purchases and cessions of subsidiary companies that took place. Certainly, the analysis of group performances is directly linked to the *evolution of the consolidation perimeter*, as a purchase or cession of a subsidiary company brings important changes and affects both assets and financial flow. Such significant changes should be eliminated so as to ensure a proper comparison and the right interpretation of the performance registered by a group from a period to another. In most cases, modifying the integration rate of the subsidiary companies is determined by reasons of financial improvement, as an entity with favorable results that aims at global integration, while the equivalence method is chosen for a society with negative results. In order to come to apply the aforementioned methods, the group acts as directed.

The transactions between group companies have in view the fund transfer between them, sometimes, with the purpose of manipulating the results of financial improvement. We are aware that a group of enterprises is also a fiscal entity because each company of the group brings profit and pays taxes for it. In this case, there can be transfers of benefits from the entities of highly fiscal areas towards the companies of low or null fiscal countries. Besides the fiscal objectives, a group of enterprises definitely aims at improving its value. The policy for establishing the internal cession prices influences all performance indicators. For instance, in the case of a sale transaction between the parent company and a daughter one, if the cession price is lowered, the the parent company result will also be diminished, while the daughter's one will be raised. Thus, when the price of sale is raised, the situation changes the other way round, the result of the parent company being raised as opposed to minority interests. At a group level, the result will be the same after the carried out eliminations, also if the revenue tax quota is the same for both entities. If the revenue tax quota is different, for example, higher for the parent company and lower for the subsidiary one, in this case, the result will be higher for a price of sale and lower if the the price of sale is increased. Consequently, an increase of the group result is performed when the internal cession prices are lower, in the aforementioned tax conditions.

[7] **Săcărin, M.,** *Business groups and landmarks of consolidated account interpretation*, Economic Publishing House, Bucharest, 2002, p. 117.

Another aspect usually encountered at the level of business groups is *department information.* In groups with diversified activities on various geographical areas, segment reporting is necessary and unavoidable, as long as accountancy, by its products, must give new and useful information to the interested parties in their decisions. In IFRS 8 "Operational segments"[8], it is mentioned that segment information is always necessary to satisfy the needs of financial statement users. More precisely, the international norm regulates the principles of financial reporting on operational segments to help the users of financial statements understand better the entity's prior results, evaluate better the risks and benefits and give more pertinent opinions on the entity as a whole. The IFRS 8 approach is called "management approach" and it ensures the conformity of external financial reporting to the internal one which allows the external users to see the entity segments as same as the managers. With respect to segment reporting, the initial accountancy standard, before the revision, asked for the information to be reported on segments of activity departments and on geographical segments. On the contrary, the revised standard asks for the information to be reported on activity segments **or** geographical ones. Although the department information has a strong informative content for the users of financial statements, there are also cases in which the company management is reluctant to the publishing of department information because it might cause prejudice to their own interests, as the competition might use it. However, one thing is clear, i.e. publishing department information allows a better management of risks and benefits of the group activities as they can be observed for each department or geographical areas.

Another issue that is noted only at the level of groups and enterprises refers to the date of drafting the consolidated financial statement. The accountancy regulations see to the established date for the drafting of consolidated financial statements to be the same with the date for drafting the financial statement of the parent company. If the reporting dates are different (i.e. that of the parent company and of the subsidiary ones), some completions must be carried out due to the effects of transactions or significant events that have taken place between these reporting periods. It is important for the difference between the reporting date of a subsidiary company and the one of the parent society not to be longer than 3 months.

We know that the performances of the enterprise can be appreciated, firstly, from the perspective of the *result,* as main indicator of financial statements, both individual and consolidated (included in the balance sheet, the profit and loss account, the situation of personal capitals and of treasury flows, when drafted according to the indirect method). Yet, another performance indicator of the entity, even more objective than the previous one is the cash-flow determined and included in the treasury flow statements. Even if the framework of the consolidated treasury flow abides to the same drafting regulations as the one for individual enterprises, a series of peculiarities might arise, as we would like to point below. *Firstly*, the treasury flows between the parent company and the entities comprised by the consolidation must be eliminated and, according to the consolidation method applied (global integration, proportional or equivalent), they will be included in the framework of treasury flows, the cash flows of consolidated entities. *Secondly*, the cash-flows correspondent to the purchase and cession of subsidiary companies must be presented separately in the category of flows generated by investments[9]. *Thirdly*, in the framework of consolidated treasury flows, exchange rate variations may appear, as a result of financial statement conversion of foreign subsidiary companies. The latter ones, even though presented separately in the category: "Effects of currency exchange rate variation", do not appear as classified according to the three operational categories: exploitation, investment and financing, so as to quantify the influence of exchange rates to the level of each flow category.

A few aspects of gainfulness and risk at the level of society groups

Gainfulness can be viewed as a homogeneous indicator for the performance of an entity because it takes into consideration the results and capitals invested to obtain these entities. However, at the level of entity groups, a series of features may appear, firstly linked to the type of result had in view, if we take into account the fact that several results are found here: the result of the group, of the parent company, the global result (both of majorities and minorities), etc. Secondly, both gainfulness (especially the economic one) and the result per share are influenced by the purchases and cession performed by the group. In most

[8] **Feleagă, L., Feleagă, N.**, *A new dimension of the convergence process between the international accountancy references and the American one: IFRS 8 Operational segments publishing*), in the Magazine "Contabilitatea, expertiza şi auditul în afaceri" (Business Accountancy, Survey and Audit) no. 1/2007, p. 38-42.
[9] *** see the annexes to IAS 7 "*Cash flow statements*".

cases, a diminution of economic gainfulness (caused by the growth of assets) and a result reduction per share (due to the increase in the number of shares) mark the group's purchase of other enterprises.

In the following part, we will focus on highlighting some particular aspects in the analysis of *financial gainfulness* at the level of company groups. The features are a result of the fact that, as opposed to individual financial statements, the consolidated ones are defined by a lower homogeneity, generated by the existence of majority and minority share holders, on the one hand, and the heterogeneity of group companies, together with the consolidation methods used (global, proportional and equivalent integration), on the other hand.

We know that financial gainfulness means result reporting, that is net result as a general rule, to capitals invested by the share holders. In the case of company groups, the following variables can be taken into account: the global result and the personal global capitals (both of majorities and minorities), the result of parent company, its own capitals or group result (which returns to the majorities) and its own capitals. We could ask ourselves which would be the most objective choice from all possible alternatives? We believe that it is the following example: the parent society owns 80% of the actions of a subsidiary company. The former sells products to the latter at a cession price: a) lower; b) higher. After calculations and consolidation, the results, the personal capitals and the financial gainfulness are the ones presented in the table below.

Table no. 1. Establishing financial gainfulness for a company group

Indicators (Ron and %)	**a) Lower price of sale**	**b) Higher price of sale**
Global profit	555,000	555,000
Group profile	457,800	465,000
Parent society profile	69,000	105,000
Minority profile	97,200	90,000
Personal capitals – Total	3,155,000	3,155,000
Personal group capitals	2,617,800	2,625,000
Personal capitals of the parent company	2,069,000	2,105,000
Minority personal capitals	537,200	530,000
Global financial gainfulness	17.59%	17.59%
Group financial gainfulness	17.49%	17.71%
Financial gainfulness of the parent company	3.33%	4.99%
Minority financial gainfulness	18.09%	16.98%

From the data above, we notice that global financial gainfulness (both of majorities and minorities) is the same, regardless of the changing value applied to the price of sale. This is because the mutual transactions are eliminated. However, group financial gainfulness is greater, if the price is higher (17.71%, as opposed to 17.49%). Financial gainfulness of the parent company shows growth, but from the group's perspective, this is not a relevant indicator as it is incomplete. The decreasing financial gainfulness, with respect to minority interests, leads to the fact that changing cession prices damages them, as opposed to majority and minority financial gainfulness, as result of the fund transfer from the subsidiary company to the mother one. Thus, we conclude that in the case of a company group, its financial gainfulness is more relevant than its global financial gainfulness or other partial gainfulness. Moreover, it was proved each time that any fund transfer from subsidiary companies to the parent ones (which own a higher percentage) makes the majorities' result grow as opposed to the minorities' one.

The risks that an entity can be exposed to are in direct ratio with the entity, being directly related to its gainfulness and because all options regarding gainfulness determination at the level of group companies also influence the risk degree. Furthermore, in the case of a company group, the operational space is much larger than in an individual enterprise so, the risk can also be diminished. In the literature of the field[10], we can find various cases of analysis and interpretation. For instance, a group's indebted degree is established on the basis of individual capacities belonging to the group and not according to the consolidated balance sheet, if the latter is in its advantage. As a conclusion, the interpretation of the pieces of information must be performed cautiously.

LEGAL AND ACCOUNTING ASPECTS REGARDING SUBSIDIES RECEIVED FOR HIRING STUDENTS AND GRADUATES OF EDUCATIONAL INSTITUTIONS

Bengescu Marcela

University of Pitesti, Economic Science Faculty Piteşti, Str. Negru Vodă, No. 27, m_bengescu@yahoo.com, 0721248109

Romanian legislation stimulates company management to practice a estimative management of work positions, by granting them public aid for sustaining the effort to train and adapt personnel to the complexity of work tasks. Within the present paper we have proposed to approach legal and accounting aspects regarding public aid awarded to companies for hiring students and graduates of educational institutions. For this purpose, we have analyzed legal texts which regulate the aspects of the theme of the paper and we have solved actual cases inspired by the activity of Romanian commercial companies.

Key words: employer, incentive, financial, subsidies, accounting.

Legal aspects regarding subsidies received for hiring students

According to the provisions of Law no. 72 of March 26th 2007 regarding the stimulation of integrating students in the labor market „The employer hiring students during their vacation time benefit from a monthly financial incentive equal to 50% of the national gross minimum wage guaranteed, for each student".

The financial stimulus is awarded by employer request from the unemployment insurance budget, for a period of 60 working days within a calendar year.

According to the methodological norms for the application of the provisions of Law no. 72/2007 regarding the incentive for hiring students, approved by Government Decision 726 of July 4th 2007, in order for the employer to benefit from the monthly incentive he must fulfill the following criteria:

a) To conclude for each student, throughout the holiday period: a) an individual labor contract for a predetermined period, full-time or, as the case may be, part-time; or b) a temporary labor contract only if the duration of the temporary work mission is equal to or smaller than the period of school vacation.

b) To conclude a convention with the county workforce agency, or the Bucharest workforce agency, within 30 days of the date the students on vacation were hired. The template for this convention is included in the methodological norms.

In order to benefit from the monthly amount, the employers have the obligation of forwarding the following documents to the agency:

a) The monthly statement regarding the nominal evidence of the insured persons and the payment obligations to the unemployment insurance budget corresponding to the respective month, in original and in facsimile.

b) The nominal table elaborated according to the model outlined in the Norms.

c) Working time and payroll, in facsimile.

The deadline for turning in these documents is the 25th of the month following that for which the monthly incentive is requested.

Accounting of financial incentives received for hiring students

The financial incentive is awarded to the employers, monthly, for each student, proportionate with the actual time worked by the students in question throughout their vacation period for that month, without exceeding the number of hours corresponding to the normal work program.

The amount representing the financial incentive is deducted by the employer from the contribution for unemployment insurance which he is obligated, in accordance with the law, to transfer monthly to the unemployment insurance budget account.

In case the amount due representing the financial incentive is larger, then the difference is paid through the county workforce agency, or that in Bucharest, from the unemployment insurance budget, within 5 working days of the date the documents were forwarded to the entity: 1.monthly statement regarding the nominal evidence of the ensured and of the payment obligations to the unemployment insurance budget corresponding to the respective month, in original and facsimile; 3. working time; 4. copy of the payroll.

Example: t the beginning of 2008 an economic entity has 50 employees who are entitled to monthly salaries in the total amount of 41,000 RON. In February 2008, 4 temporary labor contracts have been concluded, with 4 students, each of the students with a salary of 600 RON. Each student has a time sheet of 5 working days, with 8 hours a day; the month of February has 21 working days.

Solution:

According to the valid legislation:

a) the total salary fund is equal to 41,000 RON + 4 students x 600 RON/21 working days in the month x 5 days worked for each student = 41,571 RON ;

b) for salaries awarded to the 54 graduate employees the company does not owe a contribution to the unemployment fund, and therefore the contribution of the employer to the unemployment fund is: 1% x 41,571 RON = 416 RON

c) company benefits from subsidies in the amount of 238 RON, i.e. :

500 RON/21 working days x 5 days of work x 4 students x 50% = 238 RON

Where 500 RON represents a gross minimum base salary for the economy, during 01.01-06.30.2008.

d) the amount of 238 RON will be retrieved through deduction from the employer's contribution to the unemployment fund.

Statement: According to the dispositions of art. 17 letter a) of Law no. 387/2007 for the approval of the state social insurance budget for 2008 the contribution owed by employers to the unemployment insurance budget according to art. 26 of Law no. 76/2002, with modifications, is 1% during January-November and 0.5% starting with December

Observation: For the payment of the contribution to the unemployment fund, the employer will perform a transfer of 178 RON, i.e. the difference after the monthly incentive is deducted.

Accounting analysis

Explanation	***Debit account***	***Amount***	***Credit account***	***Amount***
Salaries owed to personnel:	***Expenses with personnel salaries***	***41.571 RON***	***Personnel-salaries owed***	***41.571 RON***
The contribution of the unit to the unemployment budget:	***Expenses regarding the contribution of the unit to the unemployment aid***	***416 RON***	***Liabilities regarding the contribution of the unit to the***	***416 RON***
The deduction of the monthly incentive :	***Liabilities regarding the contribution of the unit to the unemployment fund***	***238 RON***	***Income from operational subsidies for personnel payment***	***238 RON***

Statement: In the spirit of the disposition of art.8 of Government Decision no. 726 of July 4th 2007 for the approval of the Methodological Norms of applying the provisions of Law no. 72/2007 regarding the stimulation of hiring students “Establishing and ending the right of employers to benefit, according to the law, from monthly financial incentive contained by the law is made based on the decision issued by the executive director of the county workforce agency, or the Bucharest workforce agency.”.

Legal aspects regarding the subsidies received for hiring graduates of educational institutions

According to the provisions of art. 80 of Law 76/2002 regarding the unemployment insurance system and the stimulation of employment, employers which hire graduates of educational institutions for an undetermined period are exempted, throughout a period of 12 month, from paying the contribution owed to the unemployment insurance budget, corresponding to the hired graduates, and receive monthly, throughout this period, for each graduate:

a) 1 national gross minimum base salary, valid at the time the graduate was hired, for high school graduates or graduates of vocational schools;
b) 1.2 national gross minimum base salary, valid at the time the graduate was hired, for graduate of superior secondary educational institutions and post high school institutions;
c) 1.5 national gross minimum base salary, valid at the time the graduate was hired, for university graduates.

Provisions regarding subsidy grants are applied in case the employers hire, indefinitely, graduates of educational institutions, which, were not employed on the date of their graduation. Also, the subsidies are awarded for situations in which employers hire university graduates that did not pass third diploma examination.

In order to benefit from these subsidies, employers must sign a convention with the county workforce agency or with the Bucharest workforce agency. The convention is concluded annually for each generation of graduates.

According to legal provisions, graduates should be hired indefinitely only to cover a vacant position. Positions that have be recreated after less than 6 months since the date the work relation was terminated for personnel reduction purposes are not considered vacant positions.

The period for awarding subsidies has a duration of 12 months since the date the convention was concluded. The monthly amount is calculated proportionate with the actual time worked by graduates in the respective month. Employers benefiting from subsidies have the obligation to keep the persons for which they receive these subsidies for a period of at least 3 years since the date the labor contract was concluded.

The law states the penalty for the employer that decides to terminate the labor relation prior to the three year term. The penalty consists of the employer's obligation to return in whole to the workforce agency the amounts received for each graduate, plus the corresponding interest, calculated at the level of that awarded by the state treasury for the unemployment insurance budget.

These dispositions have the role of preventing downsizing for reasons that cannot be attributed to the employee.

It is necessary to mention that graduates may be eligible for obtaining subsidies only once for each form of education, within 12 months of the date they graduated their studies.

The accounting of subsidies received for hiring graduates of an educational institution

In order to establish the monthly amount, employers have the obligation of handing the county workforce agency or the Bucharest workforce agency, along with the monthly statement regarding payment obligations to the unemployment insurance budget, a nominal table elaborated according to the requirements stated by the Methodological Norms.

Example: At the beginning of 2008, an economic entity has 50 employees, who are entitled to monthly salaries in the total amount of 41,000 RON. In the month of February, 4 labor contracts were concluded, indefinitely, with 4 university graduates, each graduate with a salary of 1,000 RON.

Solution:

According to the valid legislation:

a) the total salary fund is equal to 41,000 RON + 4 x 1,000 RON = 45,000 RON ;

b) for the salaries given to the 4 graduates, the company does not owe a contribution to the unemployment fund, therefore the contribution of the employer to the unemployment fund is: 1% x 41,000 RON = 410 RON;

c) the company benefits from subsidies in the amount of 3,000 RON, i.e. : 500 RON x 1.5 x 4 employees = 3,000 RON

Where 500 RON represents a gross minimum base salary for the economy, during 01.01-06.30.2008.

The amount of 3, 0000 RON will be retrieved as follows:

a) 410 RON by deduction from he employer's contribution to the unemployment fund;

b) 2.590 RON from the unemployment insurance budget.

Total 3.000 RON

Accounting analysis:

Explanation	*Debit account*	*Credit account*
	Expenses with personnel salaries	***Personnel-salaries owed***
Salaries owed to personnel:	***45.000 RON***	***45.000 RON***
	Expenses regarding the contribution of the unit to the unemployment aid	***Liabilities regarding the contribution of the unit to the***
The contribution of the unit to the unemployment fund:	***410 RON***	***410 RON***
	Liabilities regarding the contribution of the unit to the unemployment fund	***Income from operational subsidies for personnel payment***
The deduction of the monthly incentive :	***410 RON***	***410 RON***
	Other amounts to be received similar to subsidies	***Income from operational subsidies for personnel payment***
Receivables for the difference to be retrieved:	***2.590 RON***	***2.590 RON***

Observation: In this case, the employer benefits from the following two facilities: 1) exemption from the contribution to the unemployment insurance, corresponding to the hired graduates; 2) the partial retrieval of the salaries granted to the graduate.

In case students and graduates are hired the economic entity receives a single financial stimulant, materialized in the partial recovery of the salaries of the hired students and graduates.

Legal provisions regarding the accounting of operational subsidies for the payment of personnel

According to no. 1752/2005 subsidies may be classified in two major categories: subsidies corresponding to assets and subsidies corresponding to income. The subsidies analyzed within the present paper are part of the second category, i.e. subsidies corresponding to operational revenue.

Within the Romanian accounting system these subsidies are the object of records in the credit side of account 7414 “Income from operational subsidies for the payment of personnel” and are reported in the ”Profit and loss account” with the minus symbol, in the Personnel Expenditure position.

In conclusion, the analyzed subsidies appear as a form of compensation for the personnel expenses paid for in a previous accounting period.

ELIMINATION OF PARTIALLY AMORTIZED FIXED ASSETS

Bengescu Marcela

University of Pitesti, Economic Science Faculty Piteşti, str Negru Vodă, No. 27, m_bengescu@yahoo.com, 0721248109

The present paper analyzes the accounting and fiscal aspects of the elimination operation for tangible fixed assets that are partially amortized. For this purpose, we have started from the definition of the elimination operation and observations have been made regarding the capacity to approve the elimination of fixed assets. Two ways have been presented to solve the operation of removing fixed assets that have not been fully amortized from accounting. A fiscal analysis has been outlined regarding: the contribution to the environment fund, adjusting the value added tax and the fiscal deductibility of expenses, that can be diminished with the value that has not been amortized.

Key words: elimination, tangible fixed assets, VAT adjustment, fiscally deductible, tax, contribution.

General Notions

Elimination is a complex way of exiting consisting of operations such as demolitions, disassembly of tangible fixed assets, capitalization of assemblies, subassemblies, spare parts and resulted materials.

According to the dispositions of art. 21 of Law no. 15/1994, republished, the elimination of the activity of a fixed asset is made with the approval of the board of directors of the economic entity. Within the month following the approval of the elimination, for the fixed assets for which the entry value has not been fully recuperated, the calculation of the amortization will be ceased.

After the approval of the elimination of the fixed asset, the company is going to proceed to its capitalization. The capitalization procedure is approved by the entity that has approved its elimination.

The capitalization of the components resulting from the elimination of fixed assets may be made by one of the following methods:

a) the sale of the resulting components, in their present state;
b) using the resulted components for the creation or completion of other fixed assets;
c) the capitalization of the resulted components, by turning them into recoverable materials.

The elimination of fixed assets is made by an elimination committee appointed by decision of the administrative entity that has approved the elimination. Upon elimination, the company proceeds to the disassembly of the fixed assets and to the capitalization of the resulted components by either selling them or using them as spare parts within the company. Establishing the value of the resulted components is the responsibility of the elimination committee. ....

Upon elimination, the fiscal value that has not yet been amortized is taken into consideration; this value represents the difference between the fiscal entry value and the value of the fiscal amortization, out of which the amounts resulted from their capitalization are deducted.

Accounting aspects

The following are recorded in accounting: • the elimination of the tangible fixed assets from the accounting evidence, • the expenses corresponding to the demolition, or disassembly operations, • material values resulting from the elimination. The recording value of the fixed assets that were eliminated from accounting by elimination can be partially or fully amortized.

Example: The elimination of a partially amortized tangible fixed asset.

A company eliminates a means of transport with an entry value of 15.000 lei, normal working life of 5 years, 80% amortized. The expenditure incurred with the elimination is equal to 5.000 lei. From the disassembly, the following have resulted: spare parts amounting to 500 lei and metallic waste amounting to 900 lei. The spare parts are received in the unit's storage facility, and the metallic waste is sold to an authorized collector.

Solution:

Explanation:	6xx Expense accounts	3xx Inventories	28x Amortizations regarding fixed assets	xx Third parties
Expenditure brought on by the elimination	5.000	500	80	4.420

Materials resulted from the Disassembly	3024 Spare parts	3021 Auxiliary materials	7588 Other operational income
	500	900	1.400

Version 1

	3024 Spare parts	3021 Auxiliary materials	2133 Means of transport
Version 2	500	900	1400

Commentaries: In specialized literature a solution arose according to which the metallic waste resulting from the elimination should be reflected in the debit side of account 346, "Residual products".

In regard to this situation, we believe that using account 346 is adequate for companies who perform either of the two as a main activity: production or processing of ferrous or non-ferrous materials. As regards the recording of the materials resulted after the elimination by debiting the inventories account in correspondence with the credit side of an income account, we believe that it is more adequate to adjust directly the value of the means of transport that is not amortized, with the equivalent of the materials resulted from the elimination (formula: 3xx = 21x).

The respective alternative offers the possibility of eliminating the income account from the accounting formula for the recording of materials obtained after the disassembly and is supported for the following reasons: (1) the condition for recognizing an income are not met, because an input of materials is reflected, thus the opposite of transferring the property right; (2) the value recovered through an input of materials diminishes the expenditure with the value that has not been amortized (6583 = 21x).

Eliminating the means of transport from the accounting, by taking into account the cumulated amortization, amounting to 15.000 lei x 80% = 12.000 lei. In the first version, the remaining value is 15.000 lei – 12.000 lei = 3.000 lei.

Explanation	*6583 Expenses regarding transferred assets and other equity operations*	*2813 The amortization of installations, means of transport, livestock and plantations*	*2133 Means of transport*

The outflow of the means of transport that was incompletely	***3.000***	***12.000***	***15.000***

In the second version, the record value was reduced with 1,400 lei.

Explanation	***6583 Expenses regarding transferred assets and other equity operations***	***2813 The amortization of installations, means of transport, livestock and plantations***	***2133 Means of transport***
The outflow of the means of transport that was incompletely	***1.600***	***12.000***	***13.600***

The sale of the metallic waste, under the hypothesis that the sale price is 900 lei, the supplier and the beneficiary are legal persons that are registered for VAT purposes:

Explanation	***461 Various debtors***	***7588 Other operational income***
Sale invoice	***900***	***900***

Observation 1: According to the dispositions of the Fiscal Code, art. 160, the delivery of metallic waste is part of the program to simplify procedures regarding VAT. Starting with December 1st 2007, for the invoices issued for deliveries for which simplification measures regarding VAT are applied, suppliers are obligated to add the notification "reverse taxation", without writing the corresponding tax.

Observation 2: In the sale invoice of the metallic waste the contribution to the environment fund is written, calculated by applying the 3% percentage to the income generated by the sale of ferrous and non-ferrous metallic residue. This contribution is calculated, withheld and declared by collector agents, authorized under the conditions specified by OUG no. 16 of January 26th 2001, republished, regarding recyclable industrial waste management (M.O. no. 104 din February 7th 2002).

Explanation	***6021 Expenses with auxiliary materials***	***3021 Auxiliary materials***
The auxiliary materials sold are eliminated from	***900***	***900***

For the analyzed case, the contribution is 900 lei x 3% = 27 lei, and it is withheld and transferred to the collector agent.

Explanation	***5311 Cash***	***635 Expenses with other taxes, fees and assimilated transfers***	***461 Various debtors***
Receipt of cash payment for the value of the metallic waste sold minus the 3%	***873***	***27***	***900***

Tax adjustment

The provisions of art. 149 (4) letter d) of the Fiscal Code impose the adjustment of the tax which was initially deducted in the situation where the capital asset ceases to exist, with the exception of the cases in which it is proved that the respective capital asset was the object of a delivery or of a delivery to self for which the tax is deductible.

The adjustment is performed only once for the entire period of adjustment remaining, including the year in which the obligation for adjustment occurs, and amounts to 1/5 or, as the case may be, 1/20 a year, of the value of the tax initially deducted.

Example 1: A taxable person buys a fixed asset whose normal working life is 7 years, on November 30th 2007, costing 100,000 lei + VAT (19% = 19.000) and deducts 19.000 lei. On December 2nd 2009, the fixed asset is eliminated.

12. 2007	***2008***	***2009***	***2010***	***2011***	***2012***	***2013***	***11 2014***
					1/5	***1/5***	

Fig. 1 Adjustment period remaining 5 years – 3 years including the year of elimination

In this case, there is an adjustment in favor of the state, of two fifths of 19.000 lei, i.e. 7.600 lei.

In the month that the adjustment is made, the following recording is also made:

Explanation	***635 Expenses with other taxes, fees and assimilated transfers***		***4427 Collected VAT***	
VAT in favor of the state	***7.600***			***7.600***

The amount of 7.600 lei is reported in the VAT statement, line 24: "Adjustments for equity goods"

Observation: The adjustment of the tax is not performed in case of equity goods that have been destroyed by natural calamities or in case of force majeure. Also, the adjustment is not performed in case it is proven that the respective equity good has been the object of a delivery or a delivery to self for which the tax is deductible.

According to the Methodological Norms for the application of art.149 of the Fiscal Code "the adjustment of the deductible tax corresponding to equity goods is not performed, in case the amount resulting subsequent to the adjustment is smaller than 1,000 lei".

Profit Tax

According to the Methodological Norms for the application of the Fiscal Code, the expenses recorded as a result of eliminating a fixed asset with a fully amortized entry value are expenses that are performed with the purpose of generating taxable income. We believe that these dispositions refer to expenses generated by the disassembly of fixed assets.

Considering the provisions of art. 21 of the Fiscal Code, according to which: "In order to determine the taxable profit, only expenses made for the purpose of generating taxable income, including those regulated by valid legislation are considered deductible.", we believe that, in case of fixed assets that have not been fully amortized, the difference between the value remained and the value of the materials resulting from the disassembly is a non-deductible expense upon the calculation of the taxable profit.

Abstract: Different political, economic and cultural traditions give rise to great diversity between public sector accounting systems in different countries. The paper presents a literature review of the accounting principles and financial reporting in Europe, the financial statements and the relationship between financial and budgetary accounting.

The IPSAS perhaps provide an opportunity for European accounting, and in future, national governments should attempt their accounting systems to the IPSAS.

The paper contributes to the development of some points of view regarding the adoption of the IPSAS by the European countries accounting systems and the harmonization of the European public accounting systems.

Key words: International Public Sector Accounting Standards, European Union institutions, public accounting.

1. Introduction

During the last decade the public sector has been affected by the introduction of significant reforms in the public accounting system in the international context. The aim of the public sector reforms is to overcome bureaucratic obstacles so that managers can use their limited resources more efficiently (Pina, Torres, 2003). Acounting played a crucial role in the public management development once the autonomy in public service organizations increased (Lapsley, 1999).

Under the new public sector reform, different public institutions have transformed their financial statements to incorporate accrual accounting principles. In several countries there is considerable debate regarding the scope and format of accrual accounting systems (Heald & Dowdall, 1999, Hodges & Mellet, 1999).

2. An international comparative view of public sector accounting

The use of the cash or accrual basis of budgeting and accounting was seen as a great divide between the public and private sector with the public sector practicing cash accounting and budgeting, and the private sector using accrual methods. The better the financial information, the increase in the cost transparency and the valuation of public sector assets (Graham A., 2005) have persuaded many countries to adopt the accountancy system to their own needs. During the reform process they have put into practice numerous intermediate variants between the extremes of cash and accrual budgeting and accounting. The reasons for the different national systems may be due to the culture, the historical background or the structural elements of these countries. Also the specific objectives and the principal users of the financial reporting, the financial resource suppliers and the influence of public accounting regulatory bodies imply different national accounting systems.

In the Western democracies there are two main broad styles of public management: Anglo-American and European Continental types. Anglo-American countries (Australia, Canada, New Zeeland, United Kingdom and the United States) have undertaken territorial decentralization and have adapted the private sector experience to the public sector. They are more likely to introduce market mechanisms and notions of competitiveness and envisage the citizen primarily as a consumer of services or as a client (Pina, Torres, 2003). The European Continental countries (Belgium, France, Germany, Greece, Portugal, Romania and Spain) are influenced by structures inherited from a bureaucratic and hierarchical public administration, grounded in administrative law (Pina, Torres, 2003).

With regard to the connection between accounting and budgeting in the international context three alternative models (Brusca, Condor, 2002) stand out:

1. The accounting system is limited to the registration of budgetary operations

In this case the financial accounting is limited to the budgetary information and only the transactions that affect the budget are registered. This is the general case in Germany.

2. The budgetary system and the accounting system are connected

The connection between accounting and budgetary information is established in such a way that the accounting system allows the monitoring of the budget. In this group are generally the Continental European countries (Italy, Portugal, France, Romania and Spain) where the influence of budgeting concepts and law of the accounting and reporting system is very important. Therefore, given that the resources are allocated through the budgetary process, the budget is converted to the primary instrument for accountability.

3. The budgetary and the financial accounting systems are two independent systems

In this alternative there is no connection between the budgetary and the accounting information, so that on the one hand accounting statements are produced and contained in the Financial Report, and on the other hand budgetary statements are produced to fulfill legal requirements. The public institutions produce the financial information presenting the same statements as the business entities, without taking into account budgetary obligations. This is the case in the Anglo-Saxon countries: Australia, Canada, New Zeeland, United Kingdom.

Table 1 shows the status of accrual accounting and budgeting in some countries, revealing that most countries have introduced aspects of accrual accounting and more are intent to do so in the future.

Although there is a wide acceptance of the application of the accrual systems for the production of accounting statements, there is no consensus with regard to the production of the budgetary statements. The tendency of most countries is to produce budgets according to the accrual criterion, producing a forecast statement of revenues and expenses, cash flows and the financial situation. European Union member countries are required to prepare government forecast and financial statements in accordance with the European System of Accounts (ESA 95) (Athukorala, Reid, 2003). It appears that all the European countries have adapted or are intending to adapt ESA 95. In the European Union the free circulation of information is essential. An important item is the converging and the harmonization between the public accounting system in different countries.

COUNTRY	**ACCRUAL BUDGETING**	**ACCRUAL ACCOUNTING**	**CONSOLIDATED ACCRUAL REPORTING**

The need for public accounting system harmonization in European Union countries is justified by the existence of a European common market, because of which it would be desirable to elaborate complete financial statements for the European Union which allow us to give a complete image of the financial situation of the whole, with the object of easing the decision-making processes at the European level. In particular, the reasons and benefits for demanding trans-national harmonization of governmental and financial reporting in the European Union are the following:

- The need to establish comparisons between different countries, so that the accounting systems are more comparable.
- The need for consolidating financial statements of the member countries to get an overall picture of the financial situation of the Community.
- The need for an equal treatment of European Union grants and European Union dues in the national accounting systems, so that for example, the use of funds awarded by the European Union is more transparent and national governments can better be held accountable for proper and efficient spending.
- The need of the citizens, as well as possible investors, to compare the situation of different member countries, who would need comparable information on the financial position and changes in the financial position of the member countries. The citizens should also be able to compare the performance of different countries.
- European Union Institutions could adopt the generally accepted accounting principles in the European Union and their financial statements could be understood by all European citizens. Thus, we would have comparable accounting systems between different countries and between them and the European Institutions.
- The harmonization of public accounting could contribute to guarantee the proper functioning of the common market.
- The harmonization of public accounting systems would bring about the comparability of the values that are used in analyzing whether different countries comply with the parameters established in the Treaty of Maastricht, which is, without doubt, an important question.

- The European professionals of public accounting and auditing would have a common benchmark of reference.

To the above reasons we could add accounting harmonization at international level referring to the Macroeconomic Accounting. In spite of the European System of Integrated Economic Accounts (ESA), which makes National Accounting comparable and useful for economic comparisons between countries, it can be said that this information is insufficient in a world of continuous and growing international political, economic and financial interdependencies. In the framework of public accounting transformations and the implementation of accrual accounting in the public sector, The International Federation of Accountants (IFAC) submitted the "Guideline for Governmental Financial Reporting" in 1998 to assist governments at all levels in the preparation of their financial reports on the accrual basis. This IFAC Guideline, together with the International Accounting Standards (IAS) submitted for the private sector, provide the basis for the International Public Sector Accounting Standards (IPSAS) developed by the Public Sector Committee (PSC) of IFAC.

The application of international accounting standards to the public sector could obviously contribute significantly to the provision of comparable, relevant and understandable financial information by European governments. There are a lot of reasons for the updating the accounting systems at central, regional and local government level. In the case of Anglo-Saxon countries, preconditions for adopting IPSASs are doubtless more positive, especially because of the world-wide influence of other countries with this cultural background which is working hard to promote the development of IFAC international standards.

The use of alternative criteria in public accounting systems leads to different results concerning the financial statements, the income and expenditure statements and the balance sheet. In spite of these, public accounting harmonization is taking its first steps through the efforts of INTOSAI (International Organization of Supreme Audit Institutions) and IFAC (International Federation of Accountants) at global level. The standards of INTOSAI have mainly focused on the elaboration of a conceptual framework for public accounting information. The IFAC standards entered into more detailed recommendations on accounting practices adapting the International Accounting Standards for public entities under the influence of the Anglo-Saxon Model and passing over the importance of the budget from the Continental European Model or of the features of public sector accounting (Brusca, Condor, 2002).

Although some international organizations (OCDE and European Union Institutions) have adapted the International Public Sector Accounting Standards (IPSAS), different countries, especially from the Continental European area, are not very interested in adopting them because of the difference to the continental accounting tradition.

3. Conclusions

In this paper we have tried to offer a complete view of the situation of public accounting information in the international context, showing that in recent years most of the countries studied have introduced important reforms in their public accounting systems. The most characteristic aspects of these reform processes are the implementation of accrual accounting, the approximation to business accounting and a general concern to introduce techniques that allow the improvement of public administration management.

Although the reforms have taken some similar directions and in this sense the degree of convergence is perhaps higher than ten years ago, the truth is that public accounting systems show very little homogeneity, accounting diversity being one of their characteristics.

The main differences appear between the accounting systems of the Anglo-Saxon area and Continental European countries, because the accounting traditions vary considerably between them. In the Continental European area more importance is given to the budget and legal control, and the information is mainly directed towards the legislative and executive power. On the other hand, in the Anglo-Saxon area more importance is given to the electorate and general public and operational accountability is preferred to legal accountability.

In any case, neither can it be said that within these groups there is homogeneity, because similar criteria are not adopted and furthermore the state of the reforms varies from one country to another.

Although it may appear that diversity in public accounting systems has no negative effects, it leads to a lack of comparability of information and the consequent difficulties of interpretation for the user who is not aware of the accounting standards. Nevertheless, it is true that the effects of diversity, at least for the moment, do not have the same transcendence as in the business sector.

Among the reasons and benefits that can be put forward in favour of international accounting harmonisation in the public sector, we can highlight the following: externalisation of financial activity of public administrations, aiding the elaboration and comparability of macroeconomic accounting and easing the generalised modernisation of accounting systems in less developed countries. To these reasons, we should add, in the case of the countries of the European Union, the existence of a common European market, because of which the member countries and multinational organisations need comparable and true information about the financial situation of the countries in the Union, which will ease the analysis of the Maastricht Treaty requirements.

We must also be aware of the existence of diverse obstacles and difficulties which indicate the hard and costly road it is still necessary to walk, such as the importance of the legal framework, cultural and language differences and, above all, the attitude of public administrations themselves, inasmuch as they do not see the benefits of the comparability of the information at supranational level.

In spite of the difficulties, public accounting harmonisation is taking its first steps and some international bodies have begun a process that illustrates this, and which has the objective of lessening the differences between different countries. At global level we can highlight especially the harmonisation efforts carried out by INTOSAI and IFAC.

We can ask ourselves to what extent IPSAS can really be a useful tool in the harmonisation of public sector accounting, bearing in mind that different countries are not very interested in adopting them. This is especially true in the Continental European area, because IPSAS have a different philosophy to the continental accounting tradition.

At the moment, there is an open debate about the necessity of these standards and what success they will have. It is too early to know what will happen in the future, and it will also depend on the final situation in the business sector. Even so, it is true that these standards are serving as a stimulus for accounting reform in some international organisations, such as OCDE or European Union Institutions.

PARTICULARITIES OF ACCOUNTING REGULATORY PROCESS IN SEVERAL EASTERN EUROPEAN AND FORMER SOVIET UNION COUNTRIES

Bogdan Victoria

Cristea Stefana-Maria

University Lucian Blaga Sibiu, Faculty of Economics, Department of Finance-Accounting, stefana_cristea@yahoo.it

Abstract: After the break up of the Soviet Union in 1992, Russia and other former soviet members were forced into changing their planned economic system into a viable market economy. In such a market economy the means of production are mainly privately owned, the state creates the general legal framework in which economic activities take place, and these activities are supposed to respond to market forces. The respective transition obviously has important consequences on accounting - which used to be State's instrument of economic administration and it nowadays became an instrument at the disposal of the business community.

Our study is a descriptive and explorative research about the accounting regulatory process in the sample countries. The main goal of our analysis is to find out which are the significant changes in accounting regulations and identify the particularities of the regulatory process.

Key words: accounting, EE countries, IAS/IFRS, DAS

Introduction

Over the last years, considering the multilateral and rapid development of international economic cooperation, free capital flows and multinationals' activities – all of these actively sustaining the growing role of international accounting harmonization and international accounting standards in the national accounting systems - a special attention was given to research on accounting regulatory process. Keeping in mind above all that this issue has not been investigated sufficiently in the specialized scientific literature; we have selected carefully the topic of the present research. Several times researchers had been encouraged by the interest of financial statements' users and preparers in analyzing only the standards with less consideration to the dynamics of the process itself - which implies new standards' elaboration and existing standards' improvement. Such approach is incoherent and it oversimplifies the accounting regulatory process. It is impossible to judge upon the necessity or relevance of standard setting, if there is no understanding of the historical accounting traditions/conditions of a particular state, cultural determinants, business environment and other factors influencing regulatory process.

We consider that only by identifying the reasons that lie behind standards' elaboration and improvement, the particularities of this process and the evolution over the years, it is possible to draw conclusions on a consistent pattern of accounting regulatory development and point out its future trends.

Our paper is structured as follows. The next section consists in a review of the main literature works conducted in the last decade, highlighting the relevant issues of accounting regulation changes in several Eastern European and former Soviet Union countries (referred to as sample countries from now on). Within this section, based on the literature analysis, it is also discussed briefly how the organizational change theory and the phased approach can be used to analyze the accounting changes within a specific country. In the third section, the authors state the research topic and describe the research methodology concerning the present paper. The subsequent two sections refer to the accounting regulatory process in the sample countries, by presenting firstly the theoretical aspects of the regulatory process as well as the factors influencing the respective process; secondly, the development and implementation of Domestic Accounting Standards (DAS) in accordance with IAS/IFRS. The last section includes concluding remarks on the study.

Literature review

The study of the accounting regulations in Eastern Europe, and especially in the former Soviet Union, is a rather new research area, which has evolved during the last decade after the fall of communism. Earlier research done by Seal (1995: 659) viewed the post-communist countries „as a bloc" with common problems and challenges. However, as expressed by Roberts (2002: 9), there are not two countries with identical accounting systems. In a similar manner, Bailey (1998: 1462) estimates the Central and Eastern European countries as heterogeneous ones, finding themselves at different stages of conversion from the commanded economy. During the last decade, a number of papers have been dedicated to the practice and development of accounting in the Eastern and Central European countries. Several publications (Kosmala-MacLullich, 2003; Strouhal, 2007; Jindrikovska, 2007; King, 2001) address the subject of financial accounting and auditing in Poland, Czech Republic, Hungary, Romania, Slovenia and other CEE countries but fewer publications refer to countries like Ukraine, Moldova or Russia, (Enthoven, 1998; Bailey, 1982; Richard, 1998). Preobragenskaya and McGee (2003) did research on the relationship between IAS and foreign direct investments (FDI) in Russia and on the state of auditing.

In general, these publications can be broadly divided into three groups. The first set of papers describes the development of a particular country's accounting system in general terms. In majority, these investigations indicate state-of-the-art-type studies, are mostly descriptive in character and not use any strong theoretical framework (Bailey, 1995; Alver, 1998). The second set is dedicated to particular issues that are analyzed based on a certain theoretical framework, in the context of an individual country. For example, the true and fair view concept (Sucher, 1996; Kosmala-MacLullich, 2003), organizational aspects of the accounting reform (Seal, 1995), the relationship between accounting and taxation (Jaruga, 1996; Holeckova, 1996). In the third group, the works have a comprehensive and comparative character, analyzing various aspects of accounting development in several transitional countries (Bailey, 1995, 1998; Parker and Nobes, 2002). These sets of investigations on different countries of Eastern Europe provide a framework for analysis and exemplify some of the issues encountered when accounting practices are developed which may be relevant for evaluating the sample countries experience in our study.

Previous research analyzed the accounting system's changes in different EE countries using the theories of organization and organizational change as theoretical framework for their investigation (Laughlin and Gray, 1988; Laughlin, 1991; Seal, 1995), while others concerning the transitional countries suggested application of a phased approach to the accounting reform (Bailey, 1998; Seal, 1995; King, 2001; Haldma, 2003).

Our methodological approach

When doing research there are two ways of gathering and processing data: quantitative and qualitative research. Quantitative research is commonly used for statistical purposes where there are many measurable data presented. The nature of the data is easily validated and can be presented numerically (Lundahl & Skarvad, 1992). Qualitative research could be described as research for "soft" data, which means that data is not easily presented in diagrams and figures and answers the questions "how?" and "why?" rather than "how many?" (Merriam, 1992).

Andersen (1998:18) describes several different goals of a research with a deeper involvement for each step: descriptive, explorative/problem-identifying, explanatory/understanding, diagnostic, problem-solving/normative and intervention-oriented.

Our research subject is the accounting regulatory process and how it is reflected in theory and practice. As pointed out in the introductory section, the aim of this paper is to describe the accounting regulatory process and its particularities as a consequence of IAS/IFRS implementation in the sample countries. This study will qualify as *descriptive research* since the main goal is to describe an issue rather than to interpret it. Furthermore, it is also *explorative or problem-identifying* research and because of its relative novelty may represent a good basis for further studies in the same area of research.

Since we depict the accounting regulations in the sample countries we believe that our study belongs, as we pointed out above, to the descriptive research field that has the purpose "*to document the phenomenon of interest*" (Remnyi et. al., 1998). Miles and Huberman (2000:10) describe a qualitative analysis as three flows of activity, namely:

- data reduction,

- data display and
- conclusion drawing/verification.

In our study we rely on secondary and not on primary data. This is in accordance to Arbnor and Bjerke (1997) who argue that in descriptive studies it is useful only to use existing secondary data. When writing about secondary data we refer to Howard and Sharp (1983), who define secondary data as information that were already collected by others and published in some form. In our case, we used books, previous research reports, articles and homepages as main secondary resources.

Theoretical aspects of accounting regulatory process

As the comparative analysis of literary sources shows, there is no consensus among the researchers on the types of accounting regulatory processes. Most of the scientists underline the concepts of accounting standardization and harmonization, but forego to define these concepts, confining themselves only to establish the differences among them. For example, Radebaugh and Gray point out that harmonization has more flexible approach than standardization, which aims unification. On his turn, Nobes defines harmonization as the creation of coherent, still not obligatory, standardized accounting practices. According to him, this is the way to achieve the general information's commensuration. Russian scientist Stukov connects the concept "harmonization" directly to the modalities of potential development of European continental accounting, which historically bases itself on German accounting tradition; but refers "standardization" to the process of IAS/IFRS elaboration and application, which still is greatly influenced by the Anglo-Saxon accounting practices. Arpan defines harmonization in a very picturesque way: "feasible, yet slow and wandering process".

Accounting regulatory process is not just a mechanical process, which is expressed as a compilation of existing accounting methods. This is creative work, being under influence of a multitude of factors. None of the accounting theoreticians denies this thesis; still complete consensus has not been reached yet about the factors range. Without any doubt, accounting regulation is an integral part of national accounting system. However, in the same time, there are factors, which define accounting regulation do not touch other aspects of accounting system.

After, studying ample literary sources, the authors concluded that the most important factors influencing accounting regulatory process are as follows:

- legislative and taxation system;
- business financing sources and international corporate activities;
- professional accounting organizations;
- accounting doctrine;
- economical and cultural factors;
- involvement of the national, regional and international institutions;
- inflation.

Accounting regulations in the sample countries

The accounting regulations enforced by the transition countries during 1991-1996 contributed their integration into the international accounting environment. Therefore, among other improvements that took place in accounting, during the transition period, the main priority was represented by the financial accounting. This approach was justified, as it was foremost necessary to guarantee that all national companies are able to prepare their financial statements in compliance with national accounting regulations and the generally accepted accounting principles. However, it is evident, that both accounting as a whole and financial as well as management accounting in EE transition economies underwent revolutionary changes in the first half of the 1990s. The main problem was how to build a forward-looking and flexible accounting regulatory system, which would enable to surpass the transition-related difficulties and to integrate into the European accounting framework.

Table 1. Sample of countries

Russia	Ukraine	Moldova	Georgia	Kazakhstan

The traditional system (see Table 2) based on accounting laws would have been too inflexible to reflect the rapid changes in transition circumstances. Nevertheless, Van Hulle (1993: 390) expressed the idea that the use of the law as a means of standard setting can also be seen as an interesting mechanism against too frequent and sometimes unnecessary changes. But this was not the case of our sample countries, because of the lack of a stable and effective accounting regulatory system.

On the other hand, breaking free from a central planned accounting regime had caused a spread of accounting disharmony among the former socialist countries. Our sample countries based their legislations on Codified Roman Law principles. Therefore, one of the first priorities was to set up an accounting regulatory system based on accounting laws. The enforcement related data of the new accounting legislations in the sample countries are listed in Table 2.

Table 2. Accounting regulations in the sample countries

Country	Enforcement year	Accounting regulation

Professional accounting bodies

As previous research reveals: in all CEE countries there are professional accounting organizations reestablished after the collapse of the communist regime and which are more or less involved in the accounting regulatory process (Bogdan, Cristea, 2008). This is also the case of all the sample countries. We have to underline that these countries also have an institution functioning as regulatory body (Ministry of Finance / Ministry of Justice) and an Accounting Council or Board.

Table 3. Regulatory and professional accounting bodies in the sample countries

Country	Law on companies	Regulatory body	Professional accounting and auditing bodies
Russia	Companies Act (1995)	Ministry of Finance	Audit Chamber of Russia Institute of Professional Auditors (IPAR) Moscow Chamber of Auditors National Federation of Consultants and Auditors (NFKA) Russian Collegium of Auditors Association of Accountants & Auditors of the Commonwealth

Developement of DASs in the sample countries

The purpose of the current paragraph is to present the status of DASs development in the sample countries, underline the role of MoF and/or of the national standard setter and to refer shortly to the main particularities of the national accounting environment.

Thus, **Moldavian Accounting and Auditing Standards (NAS and NSA)** are issued by a Division of the Ministry of Finance mostly through translation of IAS/IFRS and ISA. Article 9 of the Law on Accounting states that „the Ministry of Finance shall develop the methodology of accounting, unified chart of accounts, samples of accounting registers, forms of financial reports, methodological instructions for their completion, as well as accounting standards, compulsory for entities, required to keep accounting books." The preparation of the standards is carried out by the Division of Accounting Methodology and Audit, which consists of twelve permanent working staff of the MoF with Civil servant status. The Division of Accounting Methodology and Audit issued the existing NAS and NSA respectively between 1996 and 1998 and in 1999-2000 for the most part, with the support of international donors, mainly USAID. According Article 13 of the Accounting Law, a so-called Methodological Consultative Council under the MoF is in charge of „reviewing and development of proposals on disputable issues regarding accounting and financial reporting."

Modova's NAS have been initially developed on the basis of IAS, but they have not been extended or updated for a number of years. None of the changes made to previously adopted IAS are reflected, and later IFRS have no equivalent in Moldova. The MoF has issued „Comments on the application of NAS" for a number of standards in order to provide guidance on how standards should be used in specific circumstances considering theoretical examples. In the absence of a NAS on important matters that can involve material amounts - and because the level of disclosure under NAS is less demanding than under IAS/IFRS - the financial information prepared under the NAS is incomplete, if not inaccurate in certain cases.

An important aspect is that the *MoF has developed a specific accounting standard for small and medium enterprises,* which is useful for bookkeeping but needs some simplification and does not provide SMEs with a clear financial reporting framework. NAS 4 *Accounting by Small Business Entities* was developed pursuant to Article 14 of the Accounting Law in order to provide a set of „principles of accounting, preparation of accounting registers and financial statements" adapted to SMEs' less complex transactions and resources. It includes an indicative chart of accounts that limits the types of entries to a few basic categories of assets, liabilities, equity, revenues and expenses, as well as certain off-balance sheet items. Financial statements prepared in accordance with NAS 4 are defined as follows: „balance sheet, income statement, annex to the financial statements and explanatory notes" (NAS 4, paragraph 42). However, no definition is given of the content of those notes, or which of the disclosures required by NAS 5 *Presentation of Financial Statements*, can be omitted or adapted. Moreover, NAS 4 does not set out any principles for the recognition of transactions and for assets and liabilities' measurement.

As we pointed out previously in our study, accounting in **Kazakhstan** is generally governed by the provisions of the Law on Accounting and Financial Reporting. This Law was amended quite recently on February 28, 2007. Under the new Law, individual entrepreneurs using a special taxation regime in accordance with taxation legislation do not have to keep books and compile financial reports. The other categories of SMEs are required to report using **KAS**, developed on the basis of IAS/IFRS. A more simplified KAS will be developed for subjects of small entrepreneurship such as those who prepare simplified taxation declarations. The new Law does not restrict SMEs from choosing to apply IFRS. The recently amended Accounting Law requires that all public interest entities and large businesses prepare their financial statements in accordance with IFRS. Thus a certain part of the accounting and financial reporting standards applicable in Kazakhstan are set by the IASB. *The Ministry of Finance is responsible for the development and approval of the national accounting and financial reporting standard - KAS*.

The ROSC team conducted a compliance gap analysis, which shows that while there is a generalized belief that IAS/IFRS and KAS (for large enterprises and financial sector) are broadly aligned, the gap is quite significant. There are significant differences between the accounting policies used and disclosures made under KAS and those which would be required under IFRS. This suggests that the differences between KAS and IAS/IFRS are bigger than claimed. The following examples highlight the most significant differences between KAS and IAS/IFRS and their likely impact on the financial statements of *public interest entities*:

- The carrying value of property, plant and equipment (PPE) under KAS differs significantly from that under IAS/IFRS. There is no requirement in KAS similar to IAS 29 Financial Reporting in Hyperinflationary Economies, to apply adjustments to non-monetary assets and liabilities. Companies revalued PPE using „capital assets coefficient cost increases determined by the State Committee of Kazakhstan on Statistics and Analysis".
- Impairment of assets (PPE) may not be recognized. There is no equivalent to IAS 36 Impairment of Assets, in KAS, which may lead to the overstatement of PPE.
- Recognition and measurement of financial instruments. There is no equivalent of IAS 39 Financial instruments: Recognition and Measurement, and also there is no concept of financial instrument or fair value measurement in KAS. The measurement principle under KAS 8 Accounting for Financial Investments may significantly mislead users of financial statements and raises significant concerns about the stewardship of the lender.
- Provisions for employment benefits may be understated. KAS do not have a standard similar to IAS 19 Employee Benefits.
- Provisions for legal or constructive obligations may be understated. There is no standard similar to IAS 37 Provisions, Contingent Liabilities and Contingent Assets, though contingent liabilities and contingent assets are briefly addressed in KAS 27 Unpredicted Items and Subsequent Events.
- Deferred tax liabilities may be under or over-stated. KAS 11 Accounting for Income Tax, on accounting for deferred tax is based on the original version of IAS 12 Income Taxes, and does not include recent IAS revisions.
- KAS do not include any provision similar to those of IAS 41 Agriculture. Agricultural enterprises apply a transaction-based, historical cost accounting model, so do not report any

income until the sale of the product. Bookkeeping is done in accordance with the Model Chart of Accounts and Methodical Recommendations developed by the Ministry of Finance and costs incurred as a result of agricultural activities are initially posted to a „temporary manufacturing account" and subsequently transferred to „inventories of finished goods" at harvest and „cost of goods sold on eventual sale".

Since **Ukraine** gained its independence, two major developments occurred with respect to the accounting standards: (i) the development of National Bank of Ukraine (NBU) accounting rules, and (ii) the development of **Ukrainian Accounting Standards.** While the legislation suggests that these standards are consistent with IAS, a review of the existing standards made by the ROSC team in 2002 highlights a couple of interesting points:

- *NBU accounting rules* – developed by the National Bank of Ukraine in cooperation with various contributor agencies – are fairly consistent with IAS. However, a large number of differences remain.
- *Ukrainian Accounting Standards* produce financial statements that are intended principally to meet the information needs of the tax authorities. For instance, UAS 7 Tangible Assets allows the use of tax depreciation methods (among other methods) that may not reflect the pattern in which the asset's economic benefits are consumed by the enterprise. Prepares of such financial statements tend to use tax methods where permitted, and do not give much attention to the quality of information that does not directly affect tax computation. UAS financial statements differ materially from IAS/IFRS financial statements.

As we noted above, there are significant differences between UAS and IAS/IFRS. Thus, many of the IAS/IFRS requirements do not exist in national accounting. Some significant differences between UAS and IAS are found in the World Bank ROSC Accounting and Auditing in Ukraine (2002, 15 August), described below:

- *UAS do not appear to embrace the comparability attribute*. Comparability is necessary for users to evaluate the financial statements of an enterprise over time to identify trends in its financial position and performance. Certain changes in accounting policies were required by the adoption of a new or revised UAS.
- *The Accounting Law sets out that the going concern is a principle rather than an assumption (IAS).* Nevertheless, this positioning is specific to countries with European-continental accounting model. Under such circumstances, it is not clear whether an enterprise should prepare its financial statements in the event that circumstances indicate it may not operate based on going concern.
- *The Ukrainian disclosure requirements are very limited in comparison with IAS/IFRS.* Some major existing differences may mislead a reader who is not well informed about UAS. For example, sales are reported in the income statement inclusive of value-added tax (UAS 3 *Income Statement*) and there are limited disclosure requirements.
- *There is not yet a requirement, as in IAS/IFRS, to identify reportable (business or geographical) segments.* There is also no requirement to disclose detailed information on the reportable segment's revenue, results, assets and liabilities.
- *Ukrainian disclosure requirements on related-party transactions are not as detailed as those of IAS/IFRS.*

The following issues in accounting standard-setting process in Ukraine should be underlined:

- In spite of the efforts made by the Accounting Methodology Board, a gap exists between local requirements and IAS. AMB resources are not sufficient to keep up with the ongoing changes and adjustments to IAS/IFRS.
- The AMB's standard-setting process is slow and gradual.
- While UAS and the existing accounting standard-setting process play a significant role for SMEs, they fall short of the expectations and needs of financial statements' users when it comes to banks, insurance companies, listed companies, and any other appropriate public interest entities.

On the other hand, in **Georgia** there has been ambiguity in the legal framework as to what accounting standards actually applied in the corporate sector. The ambiguity results from potentially conflicting requirements and lack of clarity as to what standards have legal backing:

- The Law on Entrepreneurs sets out simplified financial reporting requirements for small enterprises, defined as enterprises employing less than 20 employees with an annual turnover not exceeding GEL 500.000 (approximately US $ 279.000);
- However, the Law on the Regulation of Accounting and Financial Reporting dated February 5, 1999 states that all legal entities, except small enterprises, are required to prepare financial statements in conformity with IAS and temporary accounting standards. The Accounting Law was supplemented in 2005 by two Regulations of the Accounting Commission as follows:
- Regulation no. 9, dated April 5, 2005 enacted „simplified (temporary) accounting standards" for small enterprises;
- Regulation no. 11, dated April 6, 2005 adopted IAS/IFRS issued by IASB in 2004 as the standards applicable in Georgia.

It has to be noticed that the proposed draft Law on Accounting and Audit had clarified the financial reporting requirements for Georgian companies. Thus, under the draft Law, banks, insurance companies, stock and commodity exchanges, issuers of securities and investment institutions must apply IFRS and all other private entities can apply either IFRS or domestic standards. There are no exemptions for „small enterprises". It is worth mentioning that there are two main processes involved in setting accounting standards in Georgia: (i) the translation of IAS/IFRS, and (ii) the development and adoption of „temporary accounting standards" applicable to those entities not required by Law to use IFRS. Both processes are currently overseen by the Accounting Commission.

The GFPAA has developed a reduced set of accounting standards, which have been approved by the Accounting Commission and adopted by the Ministry of Justice. These *„temporary accounting standards"* for small companies are derived from IFRS and exclude the IFRS provisions that the GFPAA deemed irrelevant for small companies. The GFPAA has also developed a further reduced set of standards for use by non-profit legal enterprises. The draft Law adopts these standards for entities that do not have an auditing obligation. Both of these sets of reduced standards are seen as temporary in anticipation of Accounting Standards for SMEs, which are being developed by IASB. The Accounting Commission intends to adopt the IASB SME standards once these can be translated.

The GFPAA also develops and publishes user guides in Georgian for IFRS and for both sets of temporary accounting standards. These guides are comprehensive and are similar in length to the published translations of IAS/IFRS and the set of reduced standards. While Georgian legislation, including the proposed draft Law, recognizes IFRS or IFRS-based requirements as the applicable financial reporting standards, late and poor translation of the standards is overridden by regulators, leading to „standard gap" differences between Georgian accounting requirements and „full IFRS". As the World Bank's Accounting and Auditing ROSC emphasizes the general perception that - with the exception of banks - the financial statements in Georgia are of low quality.

Conversely, all companies in **Russia** are required to keep accounting records in order to provide complete and reliable information on business activity for external and internal users. There are some alternative accounting requirements for small companies. Thus, small companies may have simplified accounting records and present simplified accounts. Current accounting regulations are based on the Law on Accounting (1996), Russian Accounting Standards and various regulations of the Ministry of Finance.

The Russian government has been implementing a program to harmonize its domestic accounting standards with IAS/IFRS since 1998. The Ministry of Finance developed Russian Accounting Standards, which aimed to correspond as far as possible to IAS/IFRS. Despite these efforts essential differences between DAS and IFRS remain. Since 2004 all commercial banks are obliged to prepare financial statements in accordance with both DAS and IFRS. Full transition to IFRS is delayed and is expected to take place starting from 2011.

Table 4. Russian Accounting Standards vs. IAS/IFRS

Russian Accounting Standards	**IAS/IFRS**
Accounting policy of an organization	IAS 8

Registration of construction contracts	IAS 11
Accounting for assets and liabilities whose value is denominated in a foreign currency	IAS 21
Financial statements of an enterprise	IAS 1
Accounting for inventories	IAS 2
Recording of the fixed assets	IAS 16
Post balance sheet events	IAS 10
Economic contingencies	IAS 37
Income of an enterprise	IAS 18
Expenses of an enterprise	No equivalent
Accounting information on the affiliated persons	No equivalent
Segment information	IFRS 8
Recording of state assistance	IAS 20
Recording of non-material assets	IAS 38
Accounting for loans, credits and the related service costs	IAS 23
Information on discontinuing operations	IFRS 5
Research & development cost accounting	No equivalent
Accounting for tax profit calculations	IAS 12
Accounting of financial investments	IAS 32, IAS 39, IFRS 7
Interests in joint ventures	IAS 31

Another point that could be made about Russia's adoption of IAS/IFRS is that even the standards that have been adopted may not always represent the current original version. For example, the Russian standard on income taxes is based on the old version of the IAS income tax standard, not the new one. This fact is acknowledged within the Russian accounting community but it may not be well-known outside Russia.

Another less known fact about DAS is that the Russian versions of the standards that have been adopted are not mere translations from the English language. In many cases these are abbreviated, simplified versions of the original English IAS/IFRS. RAS tend to be much shorter, more detailed and conceptual. They usually cover only a fraction of IAS/IFRS content. In short, it may not be accurate to state that Russia has adopted IAS/IFRS. It would be more eloquent to say that RAS are simply based on IAS/IFRS. Often the differences between RAS and IAS/IFRS are not large or important. However, the difference may be substantial, such as in the area of accrual principles.

But not all Russian enterprises that are trying to attract foreign capital are using IAS/IFRS. Some of them are using US GAAP. One of the deciding factors when selecting which set of internationally recognized financial reporting standards to use has much to do with the preferred capital market where to get listed in the future. If they are targeting the US capital market, they often decide to use US GAAP. Those who decide to tap into the European capital market often choose IAS/IFRS.

Conclusions

First - as results from previous research conducted by other authors and the present study - there is no driving force of the accounting reform in the sample countries, from an organizational perspective. No organization wants to protect both accounting and the public interest. The pressure to reform the accounting in the sample countries is coming from the market. Enterprises that want to raise capital, either by debt or equity financing, need to prepare financial statements according to IAS/IFRS. Potential investors demand it. That is the reason that causes the change, not government bureaucracy.

Also, as an outcome of our attempt to review the main particularities of the accounting regulatory process in the sample countries, there are certain preliminary conclusions to be stated:

- accounting is part of the legislative system in all the sample countries;
- there are professional accounting bodies in all the sample countries;
- in some of the sample countries (Ukraine, Moldova, Georgia) beside the professional bodies there is a Council or a Board involved in the standard setting process;
- in almost all the sample countries except Georgia, beside the Law On Accounting and specific regulations, there are DASs applicable in practice;
- similar to the CEE countries (Bogdan, Cristea, 2008) we recognize a tendency to assimilate the IAS/IFRS in each sample country's accounting regulations.

The stated conclusions are to be considered only preliminary; as we intend to develop a more comprehensive and extensive research on this topic in the nearest future. Nevertheless, it is worth mentioning that one valid conclusion of our present research is that the convergence towards IAS/IFRS has to be accomplished by valuing the particularities of domestic accounting doctrine.

Abstract: The business community has admitted that the accounting is "the language of business". They are using the accounting to communicate the existence and the evolution of the financial situation and also of the performance for the economical entities. Financial information is a form of a language. The purpose of this paper is to investigate the various elements of financial reporting frameworks and practice in the context of the Internet. The Internet has emerged as a recent medium of presentation of corporate information in the United States, Germany, Great Britain, but also in the Central and Eastern European Countries. Actual disclosure by companies from CEE was investigated in order to compare de jure and the facto financial reporting disclosure.

Key words: financial reporting, Internet, disclosure, CEE countries

Introduction

In the modern business environment the objective of financial reporting is to assemble financial information useful for investors, information simplifying decisions related to investment and granting loans. In the last fifteen years, the Internet and applications of it have been increasingly widely employed in modern business operations. In developed countries, the Internet is used with increasing frequency for financial reporting. In our days, numerous Internet applications are successfully employed in business, such as e-commerce, Internet banking and advertising.

Currently, the levels of disclosure vary widely between companies within countries and on an international level, in relation to financial reporting disclosure on websites. Our intention in this empirical research is to identify the national and international regulatory frameworks that shed light on the minimum level of disclosure required of companies. Thus, the financial reporting elements were broadly classified as basic financial reporting elements such as financial reports, corporate social responsibility reporting elements, corporate governance elements and audit reports. A sample of the 10 largest listed companies, by market capitalization, was selected from each CEE country. The companies' websites were then investigated in relation to financial reporting disclosure on the Internet.

In the Czech Republic, Estonia, Hungary, Latvia, Lithuania and Poland all 10 of the companies surveyed in each country have an English language website. 94% of the 110 CEE companies surveyed have an English language website. 85% of the 110 CEE companies surveyed have either a 2004, 2005 or 2006 English language annual report online by April 15, 2007. In general, companies in the Czech Republic, Hungary, Poland and Slovenia disclose the most information online. Companies provide more information on corporate governance than on environmental or social policy. Also, corporate governance codes continue to significantly impact reporting on corporate governance issues in certain countries. Nine Polish, seven Czech and seven Slovene companies disclose implementation of a corporate governance code in their annual report.

In our study one reporting language, called the XBRL is also investigated. XBRL is short for eXtensible Business Reporting Language. It's an XML – based markup language developed for financial reporting. XBRL transforms financial information from blocks of text into interactive data by providing an identifying tag for each line item of data. Using tags, XBRL can be leveraged to facilitate better and faster financial analysis model building, and comparisons between companies and across borders.

The results of the empirical research carried out show that CEE largest listed companies have a lack of a uniform approach to financial reporting disclosure on the Internet. Financial reporting disclosure on the Internet ranges from none to extreme detail, including voluntary reporting disclosures for corporations on the Internet. Also it was found that XBRL reporting language used by CEE companies is at this point in time, in its experimental stage.

Literature review on financial reporting disclosure requirements

Adhikari and Tondkar (1992) identified the disclosure requirements of various countries. The hypotheses developed by Adhikari and Tondkar (1992) relevant in respect of this research included:

H1: In countries with higher GDP per capita, stock exchanges are likely to have more rigorous levels of disclosure requirements;

H5: In countries with greater number of domestic listed companies, stock exchanges are likely to have more rigorous disclosure requirements.

Their sample for the study was 41 stock exchanges, each located in a different country. Additional data were gathered from the International Financial Statistics, National Account Statistics and other sources for numeric data gathering.

Adhikari and Tondkar (1992) found that H1 emphasizing the relationship between the degree of economic development and the level of disclosure requirements was not supported. No significant relationship was found between the type of economy and the level of disclosure requirements. H5 stating that stock exchanges with more domestic listings would have more rigorous requirements was not supported by the results either. Also they found that the most disclosure required was by the New York Stock Exchange, followed by the London Stock Exchange, Singapore being in third place, followed by Toronto, Hong Kong and Japan, France, Kuala Lumpur, Amsterdam and finally Sydney. Frankfurt ranked even further down after Milan. Adhikari and Tondkar 's (1992) research may suggest that larger stock exchanges have more rigorous financial reporting disclosure requirements.

A research on the practical application of financial reporting on the Internet in individual countries was carried out in Sweden by Hedlin (1999), concluded that most of the Swedish corporations that are quoted on the Stockholm stock exchange do use Internet financial reporting. Similar research was carried out into quoted Spanish companies, in which it was shown that only 19% of the companies in the sample presented any extensive financial information on the Internet, according to Growthorpe and Amat (1999). Research done in Ireland in 1998 showed that 37% of quoted Irish companies published their financial reports on the Internet (Brennan and Hourigan, 1998). A recently research done by Pervan (2006) showed that twenty of the sample companies made use of Internet financial reporting and eighteen had no such practice. This investigation was carried out on a sample of 38 joint stock companies quoted on Croatian bourses, the shares of all of them being actively traded. Companies that use Internet financial reporting on the whole publish the annual reports together with the reports of their auditors. Empirical data showed that the firms that used Internet financial reporting were on the whole larger and more profitable and their shares were more active on the bourses than the shares of companies that had no such reporting practice.

Another approach in this research area is to discover what differences are in the financial reporting on the Internet of listed corporations from different countries. An example of such an investigation is the comparative research on the application of financial reporting on the Internet by American, British, and German quoted companies of Deller, Strubrnrath and Webber (1999). The investigation showed that 91% of American, 72% of British and 71% of German corporations practiced Internet financial reporting. It was shown, also that only rarely in all three countries investigated was a format suitable for calculations used (7-13%).

Khan (2006) focused on the domestic regulatory requirements in relation to financial reporting in various countries. The requirements have been used as a benchmark for comparison. If sample companies have not met the disclosure requirements, then the concept of a gap between de jure and de facto financial reporting will be supported, in relation to financial reporting on the Internet. The regions covered in Khan's study included: high income countries, upper middle income countries, lower middle income countries, low income countries and other countries.

Khan (2006) used a sample of 177 companies selected from four sub-groups: hotels, diversified companies, multinational companies listed on the NYSE and multinational companies listed on the LSE. The companies' websites were investigated in relation to financial reporting disclosure on the Internet. For companies that did not have their own primary websites, further investigation was carried out as to whether financial reporting information was provided on secondary websites. It was found that 82 companies had annual reports on their websites and 7 companies had interim results only. The financial reports of these companies were then studied in order to determine the nature and level of disclosure in relation to the financial reporting elements and disclosure scores were formulated. In relation to the adoption of the Internet for financial reporting purposes, it was found that 33 companies had no financial information on their websites and that 55 companies did not have annual reports online because they did not have websites. The research conducted indicates that only 67 percent of the companies with websites had some kind of financial information on their websites.

Theoretical grounds – Globalization and the Internet

According to Tomlinson (1999) globalization is a process in which complex interconnections are rapidly developing between societies, institutions, collectives and individuals world wide. Thus the reports provided by a Chinese company can be accessed by a user in another country. This is leading to better and more transparent reporting in order to attract capital.

Barr (2000) has described the Internet as a paradigm shift for communication. McMahon (2006) has suggested that this definition provided by Barr (2000) has come from Thomas Kuhn's work "The Structure of Scientific Revolutions" (1962). Kuhn (1962) has described paradigms as universally recognized scientific achievements that for a time provide idealistic problems and solutions to a community of practitioners. McMahon (2006) has claimed the Internet to be "the greatest surveillance tool known". In his study McMahon (2006) has extended this concept to consider the affect of the Internet as a surveillance tool in countries like China, which are based on the Confucian system. In these countries the individual is strongly a part of the system, the family and the nation. This impacts the company as well, since these companies were owned by the government not long ago. As results of the privatization process and the listing on the stock exchange locally and internationally, the reporting requirements of these companies have changed as well. There are more stakeholders interested nationally and on a global scale.

McMahon (2006) has pointed out that in such countries the government has maintained power by controlling what information is released to the public. But with the introduction of mediums like the Internet this control is diminishing and globalization is coming into play in these countries as well.

According to the modern framework, the objective of financial reporting is to supply useful information to stakeholders. Financial reporting as understood in this paper implies the creation and presentation of accounting information useful to stakeholders. It is well known that accounting information is contained in financial reports that have to be prepared according to a national or international conceptual framework. For the current age is characterized by the globalization of economies and the increasingly liberal flows of people, goods, and capital, financial reporting takes on a new dimension, and is gradually become the language of global business. In this context it is realistic to expect a growth in all Internet based business applications as well. Corporations may, if they want, publish their financial reports on the Internet and thus make them easily accessible to a large number of users, all around the world. If the financial reports are Internet published, users can find them fairly simply and rapidly if they know the URL. But even if they do not know the exact address, they can search for the financial reports that interest them with the help of various Internet search engines.

Webster (2002) has mentioned the concept of "Globalization of Communications" and had described it like a phenomenon as supportive as well as contradictory. He has expanded on this point by mentioning that the information provided by companies via mediums such as the Internet may have a negative consequence for the company. An example can be a news release that would negatively affect the share price of the firm. At the same time, mediums like the Internet are offering exposure of the company to many more audiences than was possible without the presence of the Internet. Webster (2002) further explains that globalization requires and at the same time enhances an "information infra-structure". According to this author following are the elements of this infra-structure:

- World-wide expansions of services that collect information, analyze and distribute it, and add value by analyzing and collating it.
- Globalization requires the construction and where necessary, enhancement of computer and communications technologies.

- This information structure has resulted in the growth of information flows at a quite extraordinary rate.

The point Weber (2002) has made is that technologies such as the Internet are supporting and are being supported by the globalization process. This exposes the company to a wider range of users, thereby increasing responsibility to provide quality information to not just one, but multiple sets of users.

Research methodology

In order to investigate the usage of corporate reporting on Internet by CEE countries, we explored the company websites selected by market capitalization in the PFS Program USAID. This PFS Program has done in February 2008 a Survey of Websites of the Largest Listed Companies in 11 CEE Countries. In most cases, the market capitalization statistics are dated December 31, 2007.

Table 1 CEE countries

Bulgaria	***Croatia***	***Czech Republic***	***Estonia***
Hungary	***Latvia***	***Lithuania***	***Poland***
Romania	***Slovakia***	***Slovenia***	

The survey analyzes information available on the company website and/or in an annual report available in electronic format on the company website. The record date for disclosures is February 15, 2008. This survey distinguishes whether the company provides information on management, management board members and board of directors/supervisory board members directly on the corporate website or indirectly, meaning that information is not found on a separate page of the company website but instead is noted in an annual report available in electronic format on the company website. The criteria for the survey were determined after analyzing best practice among blue-chip companies in the EU and internationally.

Table 2 List of Companies Surveyed – CEE Countries

Country	**Companies**
Bulgaria	Bulgarian Telecommunication, Chimimport, CB First Investment Bank, Sopharma, CB Bulgarian American Credit Bank, Druzhba Staklarski Zavodi, CB Economic & Investment Bank, CB Central Cooperative Bank, Zarneni Hrani Bulgaria, Lead & Zinc Complex PLC-Kardzhali
Croatia	Zagrebacka banka, Privredna banka Zagreb, HT-hrvatske telecomunikacije, INA, Pliva farmaceutika, Erste&steiemarkische banka, Konzum, Adris grupa, Societe generale-splitska banka, Croatia osiguranje
Czech Republic	Cez, Erste Bank, Telefonica O2 Cezech republic, Komercni banka, Central European Media Enterprises, Unipetrol, Zentiva, ORCO Property Group, PRAZSKA Energetika Group, Philip Morris
Estonia	Eesti Telekom, Tallink Grupp, Olympic Entertainment Group, Tallinna Kaubamaja, Tallinna Vesi, Merko Ehitus, Silvano Fashion Group, Eesti Ehitus, Arco Vara AS, Saku Olletehase
Hungary	MOL, OTP, Magyar Telekom, richter, Orco Property Group, ELMU, TVK, Egis, FHB, Danubius
Latvia	DnB NORD Banka, Latvijas Gaze, Latvijas kugnieciba, Ventspils nafta, Liepajas metalurgs, Latvijas Krajbanka, Grindeks, Olainfarm, Valmieras stikla skiedra, Latvijas balzams
Lithuania	Lietuvos Energija, VST, Rytu slirstomieji tinklai, TEO LT, Lietuvos Dujos, Lifosa, DnB NORD bankas, Lietuvos Elektrine, Sanitas, Snoras
Poland	PKO Bank Polski, PKN Orlen, Bank PEKAO, KGHM Polska Miedz,

	Telekomunikacja Polska S.A., Bank Zachodni WBK, GTC, Polskie Gornictwo Naftowe I Gazownictwo, BRE Bank, Polimex-Mostostal
Romania	Petrom, BRD – Groupe Societe Generale, ALRO, Banca Transilvania, CNTEE Transelectrica, SIF Transilvania, SIF Oltenia, Rompetrol Group N.V., SIF Banat Crisana, SIF Muntenia
Slovenia	Krka, Petrol, Telekom Slovenije, SAVA, Mercator, Gorenje Group, Luka Koper, Pivovarna Lasko, Intereuropa, Istrabenz
Slovakia	Slovnaft, Tatra banka, Vseobecna uveroba banka, MATADOR, Dexia banka Slovensko, OTP Banka Slovensko, Tatravagonka, Smurfit Kappa Sturovo, SES Tlmace, Chemko Strazske

Our study is based on secondary data provided by the PFS Program in the survey, mentioned above, conducted in two phases. The aim of our research is to analyze the first phase of the survey that analyzed whether each of the companies included in the sample provided the following:

- A local-language website;
- An English-language website;
- A list of management and management board members available online;
- Additional information on management/management board members available online (brief biographical information about each member of management);
- A list of board of directors/supervisory board members online; and
- Additional information on board of directors/supervisory board members available online (brief biographical information about each member of the board).

Undoubtedly, Internet Financial Reporting will become increasingly popular worldwide. The IFR implementation by companies creates new challenges to management in charge of establishing the control framework and to internal auditors in charge of reviewing the controls. Lymer (1997) has argued that fulfilling the apparently straightforward model of IFR (companies provide, users use), in practice, leads to many complex issues in four aspects:

- What to report
- When to report
- How to report
- Who is responsible to report.

These are some main problems occur when such a study is done. Our research is oriented also, towards finding answers for the questions rose above.

The research findings are based on the search on company profile, the analyze of Reporting on Corporate Social Responsibility (CSR) by the largest listed companies in 11 CEE countries, and the data provided by the PFS Program surveys – Investor Relations Online and Reporting on CSR published annually. The PFS program surveys analyzed disclosure of Environmental, Social and Governance (ESG) data by listed companies in CEE in order to:

- enable these companies to benchmark their disclosure reporting against peers on a national and CEE regional basis;
- enable these companies to benchmark their disclosure against peers in other emerging markets;
- collect time series on CEE corporate disclosure that practitioners can use to chart progress and identify trends;
- collect time series on CEE corporate disclosure that researchers can use as control data or analyze in greater detail;
- identify best practice in the CEE region;

- report on the corporate disclosure practices of this CEE peer group to a wide range of constituencies;
- collect practical micro-economic data that can be presented at conferences, seminars and workshops;
- stimulate the writing of case studies about the disclosure practices of this peer group.

PFS Program Survey's Findings for the Ten Largest Listed Companies in 11 CEE Countries

On February 15, 2008 in nine of the sample CEE countries surveyed, each of the ten largest listed companies has a local-language website. In Bulgaria and Lithuania, nine of the ten companies surveyed have a local-language website. Each of the ten companies surveyed in Czech Republic, Estonia, Hungary, Latvia, Poland, Slovakia and Slovenia has an English-language website. 90% of the companies surveyed in Bulgaria and Lithuania have an English-language website. 80% of the companies in Croatia and Romania have an English-language website. The percentage of companies with an English-language website has remained relatively consistent for the past three surveys. It has increased steadily since the first survey was conducted in August 2001, when only 71% of the companies surveyed had an English-language website.

According to the conducted survey at the same time 90% of the 110 companies provide a list of management online and 63% provide additional information on management online. The best performers are Czech Republic, Estonia, Hungary, Latvia, Poland and Slovenia, where 100% of all companies surveyed provide a list of management online. Disclosure of additional information varies widely, ranging from a short biography, previous work experience and description of duties. Information available online about management increased significantly in comparison with the previous survey and all previous surveys. 87% of companies surveyed provide a list of board members online and 52% provide additional information on board members online. The best performers are: Hungary 100%, Czech Republic and Slovenia 90% and Estonia 80%.

As an important result of the survey mentioned above, 51 of the 110 companies from CEE provide information on all categories surveyed in the basic PFS Program: local-language website; English-language website; list of management, list of board members; additional information on management and additional information on board members. These 51 companies were analyzed further regarding the ideal website recommendations.

Companies from our sample that use Internet financial reporting on the whole publish the annual reports together with the reports of their auditors. In addition, most of the companies use the PDF format for the reports that they publish.

XBRL: Online Financial Reporting Language

XBRL is an extension of XML, which stands for Extensible Mark-up Language. Extensible is a useful feature that allows the user to use XML in more than one way. Mark-up means that XML gives definitions to text and symbols. Language implies that XML is a method of presenting information that has accepted rules and formats. XBRL is an open specification language for software that uses XML data tags to describe financial information for public and private companies and other organizations. It allows different parties to enhance the creation, exchange and comparison of business reporting information. Business reporting includes, but is not limited to, financial statements, financial information, non financial information and regulatory filings such as annual and quarterly financial statements.

XBRL is a technical reporting language and the most important component of it is the taxonomy. XBRL taxonomy is a fundamental component of the language, in simple terms it can be defined as a set of codes based on a set of accounting principles, which can be used to classify various elements of a company's financial statements. According to Richards & Tibbits (2002) the minimum information required to build XBRL taxonomy is the XBRL specification and the appropriate accounting standards, plus two sets of information including the sample financial statements for the Big 4 accounting firms and the actual annual reports of companies.

The XBRL taxonomy based on the IAS/IFRS has gone through various stages of evolvement. Most countries have adopted January 2005 as the date for incorporating the IAS/IFRS in the national financial reporting. From Khan's (2006) point of view this can cause uncertainties for certain corporations, who may not have specific guidelines to follow regarding particular items, if they were use XBRL for reporting purposes, using the IAS/IFRS. These elements would relate specifically to industries such as the banking industry as well as in general.

According to Zabihollah and Turner (2002) the advantages of XBRL include more accurate financial reporting, with fewer errors due to reduction in human involvement, resulting in more reliable and relevant information. Other benefits described by the authors mentioned above include faster, more accurate electronic searches for information, because of identification of each instance of information specifically through the attached label. Another benefit mentioned is continuous auditing. Bovee et al (2002) has emphasized that XBRL has the capability of providing near continuous financial reporting. This continuous release of data should prevent major fluctuations in stock prices following periodic release of financial information. Rogers (2003) has described XBRL as the promise to help make public companies more uniform in the way their financial data are communicated, presented and reported to investors. Rogers has also projected that XBRL would also promote truly transparent financial information in annual reports, quarterly statements and other documents. SEC's mandatory stand on the use of XBRL would encourage all organizations to adopt XBRL as their reporting language.

Cuneo, on the other hand, (2002) has shifted the focus to the viewpoint of executives as far as XBRL and its adoption is concerned. Cuneo (2002) has pointed out that PriceWaterhouseCoopers and the Economist Intelligence Unit have presented a five-step recovery plan for financial institutions suffering from lack of public confidence including endorsement of XBRL. Cuneo (2002) has proposed that the use of XBRL would make it harder for managers to hide information in footnotes, thus increasing the integrity of financial reports. This point relates back to the study done by Hodge, Kennedy & Maines (2002) where it was found that the use of XBRL would allow better and faster extraction of data and would thus make it easier for users to get a better picture presented in the whole of the financial data rather than just the body of the financial statements.

On the other hand, Hannon (2003) has pointed out that presently SEC can only review 16% of the 14.000 annual corporate filings by public companies. The solution presented by Hannon (2003) is the use of XBRL based analytical software that would allow the SEC to analyze all the 14.000 corporate filings and thus discovering anomalies in financial reporting an easier task.

Concluding remarks and further research

Due to recent developments in information technologies, CEE companies are using the Internet to disclose accounting information and other non-financial data through their web sites. CEE countries are thus following a universal trend to use the Internet as a way to provide instant and simultaneous access to accounting information, particularly to existing and potential investors. As we mentioned already this paper investigates the degree to which the Internet is being used by CEE companies listed on stock markets, to voluntary disclosure financial and non-financial information. The web sites of these companies were examined according to PFS Program Survey conducted in 15 February 2008.

The web offers a number of possible features for corporate reporting. Financial reporting practices on Internet requires adequate preparation, proper regulations, control and effective structure for its better functioning. In this context of Internet Financial Reporting and results derived from the PFS Program Survey, our paper drew the attention to the following main issues:

- the standard setters, for example IFAC and FEE and regulatory body for listed companies SEC, are to extend the content of standards to regulate the content of digital financial reporting;
- necessary Internet specific rules with respect to interlinking of information, performance data, press releases on recent events and price sensitive information and updating web site data after a certain interval are required to be developed;
- the domain name of individual companies must be highly restricted so that it cannot be used by others;
- instead of other formats of financial reporting on Internet, consistent use of XBRL should be encouraged so that extraction of specific information by data identification and analysis of the same will be easier;

- further research should be carried out in order to prevent manipulation of digital data and guarantee the authenticity and reliability of the corporate information distributed via Internet to the users' satisfaction.

These are only preliminary conclusions. Our attempt will be continued and developed in further researches.

Abstract: A decision is a judgment. It is a choice among alternatives. It is rarely a choice between good and bad. In the best case it is a choice between "almost good" and "probably bad". In the best case it is a choice between two action directions of which none can say it is closer than the other one of what is good. Our demarche is included on the line of granting the decision maker with the most important weapon, information. In this paper, I tried to emphasize those instruments that help the manager in carrying out the performance criteria in the conditions of global economy. The complexity of the economic activities in competitive conditions imposed by the market economy determines the growth of the role of the economic-financial information in taking decisions. The quality of the current decisions and those taken on long term and also the results predicted by the entity depend on the quality of information.

Key words: managerial accounting, decisional processes, information, control systems.

Systems of managerial control

A system of managerial control is a method of gathering and using information in order to support and coordinate the planning and control decisions as part of an organization and for guiding the behavior of managers and employees. The system of managerial control gathers and presents information for the managerial control at different levels:

1. The general level of organization- for example, the stock exchange course, net profit, the investments profitableness, the exploitation treasury flow, the total number of employees, the control of pollution and community contributions.
2. The consumer's level/ of market- for example, the consumer's satisfaction, the necessary time for answering the consumers' requests for certain products and the cost of competitive products.
3. The level of individual production means- for example, the costs of raw materials, labor costs, the rate of absenteeism and accidents in certain divisions or economic functions (such as research and development, production and distribution).
4. The level of individual activity- for example, the necessary time and costs afferent to receiving, stocking, assembly and coordination with the goods from a warehouse the proportions of rejects, the break downs and the number of processed units repeated on a line of production, the number of selling operations and the income per employee in sales, the number of deliveries per employee at the distribution centers.

As these examples indicate, the managerial control systems collect financial information (for example, the net profile, the costs of the raw materials and the stocking costs) and non financial information (for example, the necessary time for answering the clients' changes, the rate of absenteeism and accidents). A part of information, such as the net profit or the number of deliveries per employee, is obtained from inside the company. Another part, such as the stock exchange course or the costs of the competitive products, is obtained from outside the company. Some company's present non financial and financial information in a single report named *balanced board panel.*

The managerial control systems refer to formal and informal control systems. The formal managerial control system of an entity includes the settlements, procedures, performance indicators and motivation plans that determine the managers and employees' behavior. The formal managerial control system is made of several systems. The system of management accounting is a formal accounting system that offers information regarding costs, incomes and profits. Other formal control systems are the human resources system, which offers information regarding the personnel recruitment, training, absenteeism and accidents such as the quality systems, that offer information regarding rejects, break downs, repeated processing and late deliveries to clients.

The informal managerial control system includes aspects such as common values, mutual obligations of the company members, its culture and unwritten norms regarding an acceptable behavior from the part of the managers and employees. Examples of slogans of a company meant to strengthen the values are:

"To us, quality is the number 1 task" and "The low prices are only the beginning".

The evaluation of the managerial control system

On order to be efficient, the managerial control systems must be tightly related to the company strategies and objectives. Different examples of strategies develop innovative products in order to increase the market quota in the key segments or the maximization of the short term profit through reducing costs and giving up on long term risky investments in research and development. Let us imagine that management decides, in a wise way or not, to maximize the short term profit. In this case, the managerial control system must support this objective. The control system should offer managers information, such as the marginal contribution for each product, in order to help them take short term decisions. Also, the control system should establish the bonuses obtained by managers according to the short term profit.

The managerial control systems must be projected in order to be in conformity with the entity structure and managers' responsibility to take decisions. For example, the situation of the manager responsible for the research and development department of a pharmaceutical company. In his case, the managerial control system should put the accent on certain research and development activities that re necessary for certain projects, on the necessary number of specialists, on the dates programmed for the conclusion of different projects and on the elaboration of reports through which are compared the effective results with the budgetary ones.

In continuation, we will analyze the case of a manager of operational level responsible with the production, selling and distribution of food products. The managerial control system of his entity should offer information about the clients' satisfaction, the market quota. The costs of production and profitableness of the production line, information that helps the manager plan and control better the operations. The manager of the production line needs totally different information from those necessary to the manager of the research and development department of the medicine company. Still, in both cases, the information offered has the purpose of helping the manager in the decisional process.

The efficient managerial control systems should also motivate managers and employees. The motivation is the desire to reach a certain objective (the aspect of purpose agreement) combined with the ulterior tracking of that objective (the effort aspect).

The purpose agreement appears when individuals and groups work in the direction of reaching the objectives of the organization, meaning the managers that work in their own interest, undertake actions according to the general objectives of the superior management. For example, in the budgeting of the capital expenses, taking decisions based on the bringing up to date the long term treasury flows at the requested rate of profitableness leads to the closest results to the objective of the entity. But if the managerial control system evaluates managers on the basis of short term profit according to the cumulative accounting, the managers will be tempted to take decisions that maximize the profit of the cumulative accounting, but which do not correspond to the long term interests of the organization on the whole.

The effort represents the actions undertaken on order to reach a certain objective. This is more than a physical effort, such as a worker's effort to produce in amore alert rhythm and includes physical and intellectual actions.

The managerial control system motivates managers and employees to make efforts through a variety of rewards related to the reaching of objectives. These rewards can be financial (under the form of money, company shares, the use of a company car or the quality of a club member) or non financial (such as the power and the pride to work for a successful company). The managerial control systems must be according to the organizational systems. An organization that has a decentralized structure has an extra element that must be taken into consideration, meaning the efficiency of the managerial control system.

Decentralization is the freedom to take decisions, which is given to managers from all the inferior levels of the organization. Autonomy refers to the degree of freedom in taking decisions. The greater the freedom is, the greater is the autonomy. As we talk about aspects related to decentralization and autonomy, we use the term subunit in order to refer to each part of the organization. Decentralization gives managers and employees the right to undertake decisive actions.

Total decentralization means minimum constraints and maximum freedom to take decisions for managers situated at the lowest levels of the organization. Total centralization means maximum constraints and minimum freedom to take decisions for managers situated at the lowest levels of the organization. The enterprises structures are situated somewhere in the middle of these two extremes because there are benefits and costs afferent to the decentralization.

Which is the best degree of decentralization? Managers try to choose the degree of decentralization that maximizes the benefits in comparison with costs. From a practical point of view, the superior management rarely quantifies the benefits or costs of decentralization. Still, the cost - benefits approach helps concentrate on problems. The supporters of the taking decisions decentralization process and choosing responsibilities by the subunits managers identify the following benefits (Marchand, D.A. 2000):

1. It increases the sensibility towards the local necessities. Good decisions can not be taken without good information. In comparison with the superior managers, the subunit managers are better informed regarding clients, competitors, suppliers and employees, and also in which concerns the local factors that affect performance, such as the reduction method of costs and quality improvement. There can also be identified two advantages of decentralization: the improvement of the company knowledge related to market and the improvement of clients attendance.
2. It leads to gains thanks to the acceleration of the taking decision process. Decentralization accelerates the taking decisions process generating an advantage in the competitive area in comparison with the centralized organizations. Centralization slows down the decision process as the responsibility for decisions increases form one level to the other on the organizational structure.
3. It increases the motivation of the subunit managers. The subunit managers are more motivated when they can put into practice their own initiative: “Decentralization= Creativity= Productivity”.
4. It supports the development and learning at a managerial level. Through the distribution of more responsibilities to managers there can be made groups of experienced and talented managers that can meet the responsibilities at a higher managerial level. In this way, the company can also determine who do not have the necessary managerial qualities. The decentralized units offer an environment of training for the general managers and a transparent confrontation environment of the best ideas concerning the product.
5. It increases the concentration of the subunit managers. The manager of a subunit of small dimensions concentrates better in a decentralized environment. A small subunit is more flexible than one of large dimensions and can adapt faster to the opportunities that are always changing on the market. Also, the superior management, exempted from the burden of the daily operational decisions, can offer more time and effort for the strategic planning oriented towards the organization as a whole.

The supporters of a more centralized decisional process (Charles T. Horngren, 2006) identify the following costs afferent to the decentralization of the decision process:

1. Suboptimal decision process (named also non congruent or non functional decision process) which appears when the benefits obtained by a subunit after some decisions are exceeded by costs of the benefit losses for entity. This cost is registered because the superior management renounced at the decision process.

A suboptimal decision process can appear when:

a) It lacks harmony or congruence between the general purposes of the entity, the purposes of subunits and the individual ones of the decision factors or

b) The subunit managers are not informed about the effects of the decisions on other behaviors of the entity.

The suboptimal decisions are taken mostly when the subunits of the entity are mostly interdependent, like in the case in which the final product of a subunit is used or sold by another subunit. For example, a production manager evaluated on the basis of production costs may not respond to the request from the part of the marketing department to program an urgent order for a certain client if the production program changes and that will lead to the increase of the production costs. Still, from the point of view of production, the supply of that product to the client can be preferable for the reason that the client is ready to pay a higher price, and also from the point of view of the company, which expects this client to make many other orders in the future.

1. The manager's attention focuses on subunits and not on entity, on the whole. The managers of certain subunits can be considered in competition with the managers of other subunits of the same entity as they were competitors form the outside. In consequence, the managers can be reticent in which concerns the partitioning of information or offering help when another subunit faces an emergency situation. Also, the subunit managers can use in their own interest the information they have referring to the local conditions and not for reaching the entity objectives. For example, they could request from the mother enterprise more resources than they need in order to reduce the effort they must make.
2. The costs afferent to the information gathering increase. Managers can spend too much time obtaining information about the subunits of the entity in order to coordinate their activities.
3. It is reached a duplication of actions. More subunits of the company can develop the same activity separately. For example, there can appear a duplication of the personnel functions (accounting, human resources, judicial aspects) if an entity is strongly decentralized. The centralization of these functions helps with the strengthening, organization and the reduction of the resources necessary for these activities.

In order to choose an organizational structure that can implement the strategy of an entity, the superior managers must compare the benefits and costs afferent to decentralization. Often, this comparison must be made for each function. For example, the function of the financial inspector can be extremely decentralized in other purposes (such as the management of receipts from accounts and the development of strategies for the profit taxation). The budgetary decentralization and that of report allows the subunit marketing manager, for example, to adapt the already made report to the specific information that he needs in order to take better decisions an increase profit. The centralization of the profit taxation strategies offers the organization the possibility to balance the profit obtained by a subunit with the losses registered by another subunit in order to evaluate the impact on the organization.

The carried out studies put into evidence the fact that the majority of the decisions taken at a decentralized level and less at a corporative level, are those that are related to provisioning, to the range of products and promotion. In these compartments, the subunit managers must take fast decisions on the basis of local information. The decisions related to the type and the long term financing source are often taken, and not so often at a decentralized level. In these cases, the managers have better information about the financing conditions on different markets and can obtain the best interest rate. The decentralization benefits are in general bigger when the entities face uncertainties in their activity area, situations that request a good knowledge of methodology and less interdependency between divisions.

In order to measure the subunit performances in the centralized and decentralized entities, the managerial control system uses a type or a combination from the four types of responsibility centers:

- Costs center- the manager is responsible only for costs
- Income center- the manager is responsible only for incomes
- Profit center- the manager is responsible for costs and incomes
- Investment center - the manager is responsible for investments, incomes and costs.

A wrong conception that can be observed in the majority of cases is the conception that a profit center and in certain cases an investment center is the synonym of a decentralized unit, and a cost center is the synonym of a centralized unit. The profit centers can be combined with a strongly centralized organization and the cost centers can be combined with a strongly decentralized organization.

For example, the subunit managers of a division organized as a profit center can have less freedom in taking decisions. They could be obliged to request the agreement form the central head office for each expense that exceeds let us say 10.000 euro and can be obliged to make what the personnel desires at the head office. In other entities, the divisions can be organized as cost centers, but their managers can have great freedom in which concerns the capital expenses and the choice of the services and raw materials sources. Shortly, the denominations of "profit centers" and "cost centers" are independent from the centralization or decentralization degree of a company.

Conclusions

The management of the activity of an organization implies the carrying out of a decisional process whose complexity is determined by the hierarchic level on which is situated the responsible human factor and the necessity for documentation and substantiation of that decision. Costs represent a key element in the management of the economic systems.

Information is a product of the human mind, is the fundamental capital, the central cost and the essential resource of economy (P. Drucker). That is why, for the development of the management control it is necessary the study of the relation between information and decision. The relation between these two elements can take different shapes, according to the decisional universe in which is situated:

1. As part of the cybernetic vision on enterprise, "the decision is taken according to information; the most important thing is to improve the information offered to the decision maker" (H. Loning, 1998). This postulate is based on:
   - The informational determinism – the information determines and explains the decision;
   - Sequentially – the information precedes the decisions;
   - Pertinent information- according to the reality
2. Reality is not something exterior, but it is a construction, because the observer is part of what he observes: this vision bears the name of constructive paradigm. In this case, "to decide means to produce the possible and the impossible".

Essential in the process of decision elaboration and the post-decision analysis, accounting introduces evaluation instruments of the enterprises performances. It is possible and necessary the improvement of the accounting information qualities, with influences on the decisional act, in this sense we can underline:

1. The five phases of the decision process are: information gathering, the prevision establishment, the choice of an option, the application of decision and the results analysis.
2. In order to be significant in which concerns taking a decision, a sale or an expense must satisfy two conditions: a) must be a future sale or expense and b) the total amount must depend on the decision.
3. The decision criteria can be quantitative and qualitative. The quantitative criteria are expressed through numbers. Some can be expressed in monetary units, others not. The qualitative criteria, such as the employees' mood can not be measured through numbers. The decisions must be based on these two criteria categories.
4. The unit costs can mislead the decision factors in two ways: a) when the unit costs include the expenses that are not significant for the examined decision and b) when the unit costs calculated with different volumes of production is compared. The fixed unit costs are often misinterpreted as variable costs. It is suggested the use of total costs rather than the unit costs in order to analyze the elements of a decision.
5. There are often met two traps when the significant expenses are studied: a) to believe that all the variable expenses are significant and b) to believe that no fixed expense is significant.
6. The opportunity cost represents the loss of gain that results from the fact that we give up to allocate a limited resource to an alternative operation. The notion of opportunity cost appears when a resource may have different utilizations and when we renounce to some of them. The opportunity cost that must be included in the significant costs in which concerns a certain

decision represents the net profit of the best utilization of the resources in the lack of taking that decision.

7. For choosing from more products under the capacity constraint, the decision factors must privilege the product for which the reserve per unit of the factor is rarely maxim.
8. The sales and expenses established for the future are the only ones that must be significant in taking decisions. The accounting net values of the equipments represent the expenses of the past. It is not significant in taking the decisions of renewing these equipments.

APPLICABLE ACCOUNTANCY THEORIES ON THE CAPITAL MARKET

Bologa Gabriela

Agora University Oradea, The Faculty of Economical Science, Dobrogeanu Gherea, nr.20, Oradea, gabi_fiat@yahoo.com***, 0724 214533***

Abstract: Traditionally the accountancy theory developed as a structure of principles that describe the practice.The sufficient conditions for a market to be efficient are: the lack of the costs of the title transactions; all the information to be valid, free and balanced for all the market participants; transaction participants in the capital markets to have homogeneous foreseeing regarding the implications of the obtained information.

Key words: capital market, accountancy theory, decisions, financial information.

Traditionally the accountancy theory developed as a structure of principles that describe the practice. This conventional structure evolved step by step in time as a pragmatic ground that makes the role of the user of the accountancy not to be recognised until recently in the literature of speciality.

Ideally the accountancy theory has to provide to those who make the decisions or elaborate the accountancy politics tools that permit accepting the best solutions, in these procedural problems that come in contact with there is a 'collection' of accountancy theories that are frequently in conflict. The difficulties regarding the working out of a general valid and acceptable theory devolve from the discrepancy regarding the accountancy goals.

The accountancy theory can be defined as a logical way of thinking, represented by a set of exhaustive principles that:

- offer a general frame to refer to through the accountancy practice to be evaluated;
- to direct the development of new practices and procedures (Hendrikson E., 1991)The accountancy theory has to be used for explaining the present usage; the goal is to realise their understanding.

By definition each theory is a set of clauses or sentences interconnected with the help of some logical rules or judgement. The theory has to contain hypotheses or premises that can be tested or conclusions based on valuable judgements. The main test of the theory is its ability to explain and foresee (Walt and Zimmerman, 1986). The traditional orientation of the accountancy theory (before the adopting its standards) was interested mainly in distillation the practical experience. So, at first the accountancy theory was first descriptive concentrating especially on the observation of the accountants' behaviour instead of noticing the real world phenomena (Sterling, 1967). The conventional theory couldn't distinguish between a theory set up and the testing of this theory implications (for example, the accountancy principles are selected as part of the theory, due to the general acceptances, the acceptance is the sole valid condition of these principles).

Efficient market theory

Efficiency is frequently considered as one of the essential goals in economy and accountancy, But what does the efficiency concept represent and how does it manifests on the capital market, with a strong international character? The answers to these questions come next.

The examination of the capital market reactions at the accountancy data publishing supplies a set of testable theories that don't depend on the individual usage of the investment, because it analyses the aggregate behaviour of all the participants. The capital market study is concentrated on the society as a whole and it would be a mistake to assume that the market ideal behaviour determination can be realised through the concentration of attention at each individual level.

The capital market role is to provide funds for those who make efficient decisions. The importance of the financial information result firstly from the necessity of ideal allocation of the limited resources among the procedures so that the gross internal product to be maximised. Secondly the piece of information is necessary to allow the persons who invested to have an ideal portfolio of titles at an accepted risk level (Hendrikson, 1991).

The efficient market theory is based on the assumption that the capital market is highly competitive. That the price of the valuable titles is moving free, up to the balance point between the demand and offer for each title when new pieces of information are available and liable to alter the expectances. The valuable title price is modified up to a new balanced position (it is about the relative price that modifies when new relevant information appears).

The level of the price will be the result of a certain number of factors regarding the general economic conditions (interest level, inflation level) and some specific factors connected to the situation and evolution of the emitter's title or psychological elements (rumours).

A capital market is considered efficient when the valuable titles prices reflect integral and fast every piece of information considered relevant (irrelevant information are not taken into consideration on the market). As a conclusion, every information that is proved to be relevant is rapid and with accuracy prevailed by the price of the valuable title. In the economic way an efficient market is not necessarily a perfect market.

It is important to mark that the capital market efficiency is not a perfect predictive power from the behalf of those who invested. The current prices of the valuable titles represent the best evaluation of economic value on the base of the existent information. The sufficient conditions for a market to be efficient are (Hendrikson, 1991):

- the lack of the costs of the title transactions;
- all the information to be valid, free and balanced for all the market participants;
- transaction participants in the capital markets to have homogeneous foreseeing regarding the implications of the obtained information.

These aspects are sufficient in the set up of the theoretic model of the efficient market, but they are not necessary in the real world. The only necessary condition for a market to be really efficient is that every relevant information to be included and without prejudice in the price of the valuable title. When the efficiency of the capital market is discussed in the financial literature, in fact it is about the problem of price set up. The process through which the value of a title is decided is not discussed. In the capital market it has to exist a certain number of potential buyers and sellers of the same titles, the opinions regarding the real value of the title are different. Some of those who invest can be more informed, others will try to estimate the next results, using past pieces of information.

The last price represents the general agreement of these litigious opinions when we notice the homogeneity of the ideas and actions it means that the efficiency of the capital markets is lees certain. Here it is the problem of the way in which we put together the different opinions and individual tendencies of all the participants on the market. If the capital market is efficient then the valuable titles prices should reflect all the available pieces of information.

A market is efficient if, due to a set of information it is impossible to obtain economic benefit from transactions because of knowing some points of view (Watt and Zimmerman, 1986). So that, having a number of pieces of information (for example the accountancy results annually published) this is worldly accepted by all market participants and the competition determines on a certain level the prices to allow the obtaining of an income equal with the market risk (the economic profit is zero because the profit is the same as the paid price).The market risk can be obtained from the market return. In an uncertain world there are several levels for return instalment for every risk level.

The tests done ignored the costs of the obtaining information. These costs vary considering the wanted set of information (for example the cost for obtaining information referring to the preceding periods is low compared with the costs for obtaining confidential information from the managers of the companies.

We can divide the ways of manifestation of the efficient market into 3 categories (depending on the conclusions resulted from the empirical researches): the weak form, the half strong form and the strong form of the efficient market.

1. **The weak form of the efficient market** considers that the set of information Et contains only the past pieces of valuable titles or only the information about the old values of the title transactions. This kind of information is available for a high number of users at a low cost so that no unusual benefits can be obtained this way. The new information is included in the

price; if the new information will be gradually included in the price, the modification of the price of the title could offer a hint about the size and direction of the next change of the price.

A capital market is efficient in the weak form if it doesn't permit the obtaining of a profitable stock exchange evaluation of the valuable titles, using the included information in the past prices. On such a market all the available information was already used and taken into consideration in the price of the transactional assets. This means that the prices on such a market will have a random evolution because at random means unexpected. This theory comes in contradiction with the chartist thinking which sustains that the practice of shares can be foreseen by studying the past change of the prices, using conventional tendencies and methods.

2. **The half strong form of the efficient market** considers that the information It contains all the available information (both past and the present ones) existent on the market at a determined (t) time. These pieces of information are already available at a low cost, so we can not notice unusual income in this case. Although the accountancy information doesn't represent the only source of public information about the companies it is an important element in the decisions. This form of am efficient market assumes that when the annual accounts are published the information contained in these reporting documents had already been known or anticipated (for example the current profit of the financial activity can appear in the newspapers before the publishing of the annual accounts.

So that the price of the valuable title will reflect the information in the moment when this becomes available through publishing or anticipating, no more price adjustments are necessary when the annual accounts are published (the information was already included in the price. The annual accounts still represent a confirmation of the foreseeing of those who invested and permit checking the relevance of the other alternative sources of information. Empirical researches done to test the efficient forms of the capital markets draw the conclusion that nowadays only the half strong form or the efficient market theory can be revealed in a certain number of value stock exchange around the world (NYSE, London Stock Exchange).

3. **The strong form of the efficient market**: in the empirical tests realised for validating this form the information will have all the pieces of information known by everybody at the t time. All the information about the past, present and future of the companies include the confidential information about managerial plans for interests, price strategies. There are still very few chances for such a market to be real.

If the accountancy would serve social functions then it should publish all the relevant information as soon as possible to minimise the possibility that some participants to use the advantage of holding some private information, information that permit them to obtain an outstanding gain. Here we deal with the gain's transfer from one participant to another. Another consequence of the using of the private information by a small group of participants would be the fact that in this case the resources aren't ideally allotted.

The next question is on what level the available information analyse on the market is appealing for emitting a high income if the efficient market theory proves to be real? Many statistics resulted from empirical researches proves that this theory is valid only in some stock exchange in the world, at least in its half powerful form (Samuels and others, 1995). In 1985 Jensen sustained that ' the efficient market theory is the best-settled fact among the social studies. No theory was better documented than the efficient market theory. And there are several scientific studies which indicate that in stock exchange from USA the price of the valuable titles contain all the existent information (Jensen, 1986).

It also has to be noticed the difference between the American and European stock exchange. The New York and London stock exchanges proved to be efficient while the Paris and Frankfurt had provided little proves and about the other European stock exchanges can't be said anything (Samuels and others, 1995).

Scientists on both sides of Atlantic keep analysing for more than twenty years the way in which the price of the title react at new information. It could be considered a blasphemy that the stock exchanges are not efficient. That the valuable title price reflects all the available information on the market it doesn't mean that the price is equal with the fundamental value of the title. The essential problem here is that we don't know what does the fundamental value of a title is (we have to count on evaluating methods which are based on assumptions).

Other difficulties result from the lack of understanding or misunderstanding of the efficient term in the efficient market theory context. Efficiency in these theories means that the price of the valuable titles is adjusted to reflect all the available information and that not everybody interprets in the same way the information.

We also have to present the importance of information asymmetry. In the 80's the managerial policy of reflecting the company results in the most attractive way it became a subtle art representing a frequently used practice in USA and in Great Britain

The manipulation of the results can determine that a small group of participants on the market to have information of which the others can't benefit. In a world in which information is transmitted through multitude channels the capital market learns to make the difference when a company has money problems which can't be hidden forever through accountancy subterfuges. If the difficulties about the cash of some companies become known and the capital market is efficient at least in its half-strong then the present price of the valuable title includes the implications of the difficulties connected by cash flow over the results.

The price will be decided so that those who invest to earn on average the adjustment rate of the market, adjusted at its risk (in the half strong form of efficiency the capital market isn't tricked by the accountancy sums.

Modigliani a Nobel Price winner for economy expressed his concern regarding the capital market efficiency, pointing that there still are irrational participants who make the 'high rationalism' theory of all the valuable market participants, which is the base of the financial models, to be false (Modigliani, 1988). Modigliani thinks that the market failed in evaluating the valuable titles in the important inflation period, which concluded to predictable and repetitive mistakes. Modigliani and Cohn provide a scientific explanation of the capital market shortcomings – the irrationality of a group of participants (Modigliani and Cohn, 1978).

The assertion that the best stock exchanges in the world are efficient was, for a long time accepted as the ultimate truth. To sustain the contrary would have been a conceptual misunderstanding or the agreement with the numerous empirical researches that sustained these rules. But recently these were analysed again and a number of anomalies were repeated.

Fama and French also proved that it is possible to foreseen the shares price from the small companies, contrary to the tests results concerning the efficient market theory done on big companies (Fama and French, 1988). The statistical tests can't detect the possible inefficiency of the market – there are differences between the valuable title prices and their real value.

Nowadays the idea of a efficient market in its strong and half strong forms is weaker because the critics have at least two directions. The firs one refers to the question if we can test the efficiency or inefficiency of a capital market. The new mathematics analyse techniques shows us that there is always an unexplainable foreseeing of the market (the software models offer the opportunity to exceed in performance the market, at least for a certain period). The second direction of the critics is based on the existence of black wholes that are exploited by sophisticated participants:

- Unusual changes of prices on short terms – the market has the tendency to exaggerate on short terms. Highly evaluating the information and low evaluating the base data (for example those who invest exaggerate the income sum and determine the gap between the price and the real value of the share because they have a restrictive orientation about the close future). Those who sustain of the efficient market sustain that these short-term anomalies are rectified or adjusted in a longer period of time.
- Temporal and temporary anomalies – researches from USA demonstrated the modifying tendencies of the prices of the valuable title determined by a set of astonishing elements. When the transactions take place (the prices rise in the first 15 min from the opening of the stock exchange meeting then decrease in the next 45 min – an explanation could be the wick-end effect); the days of the week (it was proved that the income obtained from the transaction of the titles on Mondays are lower than during the rest of the week); months of the year (January demonstrates that the highest income can be obtained due to transactions done in this month; in Great Britain was demonstrated the same phenomena on April, an explanation can be connected with the end of the fiscal year when the necessity of decreasing of the tax base comes and rises the need fir cash)
- Companies size anomalies. On long term the income obtained by share holding of small and medium companies are higher than the average performances of these companies. If the

market is efficient this should happen only when the risk is higher than the average risk of the market. Do the small and medium companies' shares have a higher risk than that of the market? There was an attempt to explain this phenomena from the lack of information point of view. The small and medium companies offer less information than the big ones, so the price of the title doesn't reflect the real value of the companies. The small companies risk, paradoxically its tendency is to rise the average risk of the market but it is not a complete explanation, yet.

- The successful foreseeing possibility of future prices using indicators of price earnings or dividend yield.

On the other hand the theoretical conditions for a market to be efficient are not valid in practice. For example the available information on the market aren't equally given to all the participants. There are confidential pieces of information that are known by the managers of the companies or a small group of persons. The valuable title transactions on the capital market imply high intermediate costs that decrease the hypothetical income. Not all the market participants have a rational behaviour, there are the so called noise traders who use transactions at random or those who take into consideration only the numbers of the economic result.

But which are the conditions for a market to be efficient? The efficiency dynamics is determined by competition: the capital markets will become competitive when there will be several buyers and sellers on which will evaluate the titles trying to obtain unusual high income. The market efficiency doesn't mean that it isn't possible to obtain abnormal income but impossibility of getting them only with the published information. As a conclusion, the role of the market efficiency is that the valuable titles won't be over or low evaluated due to a set of published information. The changes that appear because of the accountancy embellishing of the financial situation of the companies don't modify those title markets.

Even in the functional fixation theory the participants are concentrated on numbers and not on the information content. In the case of the efficient market the content and the meaning of the information will be included in the price and not in the accountancy sum. The efficient market will read only those pieces of information that have a meaningful signification.

Without a direct evaluating method of the benefits supplied by accountancy information to the capital market, the attention will concentrate on the costs. Several types of costs should be taken into consideration:

- the direct costs of the production and publishing information;
- the direct costs of the alternative sources of information;
- the evaluating and analysing costs of the information;
- the cost that those who invested should pay if they would produce the information;
- the indirect costs – for example the negative aspects of publishing the information over a company activity.

The statement cost-benefit indicates that the information which is understood and used by only few persons, it should not be produced. Also the synthetically accountancy documents shouldn't exclude relevant information because the understanding difficulties for some of the users .

In the last years a new research area developed surprisingly – the behaviourist science. This study the way in which the persons look for, modify evaluate and combine the information to draw a conclusion and make a decision. This new subject on the psychology, statistics and management borders is extremely relevant in specific areas like accountancy, marketing and finances.

With all the importance of the economic theories that offer an objective point of view in such a debated domain of the decisions is still important to understand the way individuals evaluate and use information. Of course the economists and psychologists will agree (that is very seldom) that the individuals don't react rationally all the time and in contact with the environment they learn to become more propitious.

HOW WE CAN REDUCED DIFFERENCES IN ADOPTION OF IFRS BETWEEN DIFFERENT COUNTRIES – A POINT OF WIEV BASED ON ROMANIAN ACCOUNTING SYSTEM REALITY –

Botez Daniel

Université de Bacau, Roumanie, Faculté de Sciences Economique, Bicaz, Neamt, str. Cozmitei nr. 2, danbotez@artelecom.net, Tel. 0743826004

Résume : Changer, s'adapter, sont des mots qui circulent beaucoup en Roumanie depuis 18 ans. Faisant partie de l'ancien bloc communiste de l'Est européen, la Roumanie a fait sienne les principes de l'économie planifiée, dont le système comptable, de contrôle et d'audit spécifique à cette période. Apres 1989, le système comptable roumain a connu, pendant la période de 18 ans qui s'est écoulée depuis le changement de régime, trois changements ayant un caractère significatif. Ces évolutions se sont produites sous l'incidence d'un certain nombre de facteurs externes, mais également internes.

Quel doit être le rôle des organisations de normalisation et des organisations professionnelles régionales et de quelle façon peut-on soutenir le processus d'uniformisation des standards face à une mondialisation croissante?

Mots clés : changer, normalisation, organisations professionnelles, standards IFRS

Changer, s'adapter, sont des mots qui circulent beaucoup en Roumanie depuis 18 ans. Il faut accepter de remarquer combien il est difficile de changer, de s'adapter, d'intégrer de nouvelles visions, méthodes, attitudes, etc. Comment accepter facilement de considérer des qualifications, des concepts, des formations, des diplômes, des titres professionnels, du jour au lendemain comme obsolètes, comme inadaptés ? Cela représente pour certains esprits des efforts quasi insurmontables que le temps et les nouvelles générations devraient assumer. Et pourtant le pays, son économie, ses entreprises doivent réaliser cet effort à tout prix.

Il est démontre le lien direct entre la politique économique d` un Etat et son système comptable. Ce lien est encore plus évident dans les pays avec des systèmes de droit bases sur des codes de lois.

Faisant partie de l'ancien bloc communiste de l'Est européen, la Roumanie a fait siennes les principes de l'économie planifiée, dont le système comptable, de contrôle et d'audit spécifique à cette période.

Il est également nécessaire de discuter quelques caractéristiques significatives de cette période étant donne que beaucoup d` entre eux manifestent encore leur reminecence aujourd' hui.

L`économie planifiée a induit l `existence d`un système comptable base sur un plan de compte standardise, avec des opérations comptables unitaires et limitées, sans provocation pour les spécialistes. L`inflexibilité du système comptable a présuppose l` élimination jusqu a la disparition de la nécessite des rationnements en comptabilité. Ceci a génère l`accentuation de l`aspect technique au détriment du concept, changeant la tonalite des discours sur la comptabilité.

Les orientations politiques qui se sont faites jour après la fin des années 1989 ont conduit la Roumanie vers l'adoption d'un modèle de référentiel économique différent : l'économie de marché de type libéral et les méthodes comptables utilisées par une des économies développées de l'Europe, plus particulièrement celle d'un pays vis-à-vis duquel il a existé une relation culturelle compatible forte et profonde. C'est ainsi que le système comptable roumain a assimilé, pendant les premières années, période dite de transition, les éléments fondamentaux de la culture comptable française.

Malgré cela, la reforme du système comptable roumain s` est produit sur fonds de concepts simplistes a propos du système comptable.

Nous ne faisons pas référence aux aspects lies a la normalisation même si celui-ci a connu des dérapages inhérents. Nous devons accepter le fait que la reforme d un système comptable réussit quand se produisent les changements prévus au niveau pratique. Les comptables professionnels sont ceux qui sont appelles a mettre en œuvre et a valider la reforme d` un système comptable. Que se passe t-il si au même moment l` organisation professionnelle est elle-même en reforme ?

La compréhension des difficultés issues d` un changement nécessite aussi le fait d` assumer avec exactitude la conjonction existante. En Roumanie de 1990, la majorité des personnes détenant des fonctions supérieures, y compris dans le domaine comptable et dans la zone de réglementation de celle ci, étaient le produit de l éducation du système communiste. Beaucoup d` entre eux n` avaient plus l` age pour lequel un changement soit une provocation. Pour cela, les années de reforme du système comptable roumain ont été marquées souvent par des attitudes nostalgiques voir même de recul.

Cette conjoncture, un rapport comptable oriente de façon prioritaire pour l` information fiscale et une profession comptable en formation donne un contour des coordonnées d actions de la comptabilité roumaine de l époque.

Le système comptable roumain, a subi l'influencé par les changements et événements qui ont eu lieu au plan international au début de l'an 2000 et qui ont touché des entreprises multinationales de premier plan, sans négliger les décisions réglementaires qui ont suivi et qui ont engendré des modifications significatives du système comptable roumain, suite à des débats politiques difficiles entre ceux étant pour le maintien de la référence au plan comptable français et ceux proposant l'adoption des US GAAPS, voir les UK GAAPS, voir les standards IAS/IFRS.

De ce fait, le système comptable roumain a connu, pendant la période de 18 ans qui s'est écoulé depuis le changement de régime, trois changements ayant un caractère significatif.

Ces évolutions se sont produites sous l'incidence d'un certain nombre de facteurs externes, mais également internes.

I. La réaction immédiate du Président Bush aux USA, suite aux affaires ENRON, WORLDCOM, etc., dont des effets se sont propagés jusqu'en Europe et en Asie est à l'origine de modifications essentielles par rapport aux référentiels comptables et d'audit.

Sous l'influence impérieuse de ces modifications, le système comptable roumain a essayé de s'adapter, tout en continuant de stabiliser un système comptable crédible.

Une caracteristique de ces scandales financiers aete le degre eleve des rapports errones de la situation financiere emis par les. La perte de credibilite des informations financieres a cree une situation sans precedent, amenant des mesures sans precedent. La loi Sarbanes-Oxley, a cree le Public Company Accounting Oversight Board – P.C.A.O.B.

On a parle alors d` un fait sans precedent , la fin de l` autoreglementation des professions comptables aux Etats Unis.

- La perte de credibilite en l'informations fournies est devenue un probleme prioritaire sur l'agenda de l'organisme international des professions comptables. La Federation Internationale des Experts Comptables - IFAC - a sollicite a un groupe operatif de travail un rapport pour constater la situation et proposer des solutions. Une des constatations du rapport s est refere au fait que la globalisation des marches financiers cree une dimension internationale aux problemes , ou l'interaction entre le national et l'internațional aux rapports financiers, est critique. Les Reglementations nationales existent et dans la majorite des cas , les situations financieres sont presentees en conformite avec celles-ci. Les compagnies qui ont des titres quotees en bourse en dehors de leurpays d origine vont continuer a etre non seulement sujettes aux regles comptables de leur pays d origine mais aussi a celles des pays ou leurs titres sont quotes a la bourse. La presence sur le marchea plusieurs sets de situations financieres emis par la meme firme , mais avec des contenus differents, chacun pretendant qu il offre une image fidele, faiblit la credibilite des informations fournies.

La solution a ces problemes n'est pas l' adoption par chaque pays de standards emis par un autre pays. L` alternative est l` adoption d` un set neutre de standard , emis par l`IASB, qui peut etre accepte dans chaque pays , pour etre adpote comme standard national ou l` incorporer dans les standards existants.

II. A coté de ce type d'influences externes, les milieux politiques, économiques et professionnels roumains, les changements de cadre de vie, ont influencé de façon importante l'organisation de la comptabilité, du contrôle et de l'audit au plan légal. Pour comprendre, il faut mettre en évidence les attitudes des normalisateurs, des organisations professionnelles concernées ainsi que des professionnels eux-mêmes, sans omettre de tenir compte de ces effets par rapport aux marchés des capitaux, à la fiscalisation, la formation, etc.

Bien évidemment, l'influence des facteurs externes sur le système comptable roumain et sur l'organisation professionnelle comptable, a été indirecte. Cependant, les normalisateurs roumains ont essaye de tenir le pas aux changements produits au niveau européen et international. Par ceci s` explique le fait que des 1999 ont été élabores des règlements comptables destinées aux grandes entreprises, dans lesquels ont été repris les lignes directrices des Standards Internationaux de Comptabilité et en 2001 des reformes significatives du système comptable roumain ont vues le jour par la modification des lois comptables dans lesquelles ont été introduites un vocabulaire comptable qui incorpore la système comptable roumain dans le cadre conceptuel international.

Apres l'amendement de la Directive Européenne 4- a en 2003, le normalisateur roumain a pris des mesures nécessaires pour la modification des règlements comptables en accord avec le contenu de la Directive.

En plus des faits de ci-dessus, les organismes professionnels ont prépares des professionnels dans 1le sens des responsabilités et des mesures assumées par l' IFAC. Début 2000, les programmes de formation professionnelle continue contient les thèmes a propos de International Accounting Standards. Dans le même sens, les démarches professionnelles pour les missions de audit font référence a l' International Standards of Auditing.

III. Depuis le 1er janvier 2007, la Roumanie est devenue membre à part entière de l'Union Européenne. Les efforts qui auraient du être consentis aux domaines du chiffre avant cette date n'ont pu être entièrement respectés. Quels sont les challenges qui nous attendent au plan comptable, du contrôle et de l'audit vu le nouveau statut de notre pays ?

Depuis le 1 Janvier 2007, les sociétés commerciales de Roumanie ont a la disposition un cadre légal d` organisation dans lequel ont été introduits les éléments significatifs des principes de gouvernement corporatif de l` OCDE.

A la date de rédaction de cet article (Avril 2008), existe en Roumanie un projet de loi sur l` audit statuaire et la création d un conseil de surveillance des activités d audit statutaire, projet qui a en vue l` implémentation de la Directive 8 sur l'audit statutaire.

Bien évidemment , vont suivre d autres changements qui affecteront, de façon directe ou indirecte, le domaine de la comptabilité et d audit, dans le but de situer le cadre légal et réglementaire roumain dans les coordonnées de l` européen.

Reste en discussion les aspects lies a la perception de chaque professionnel comptable roumain sur son rôle et sur la reforme de la comptabilité et au mode de compréhension des rigueurs déontologiques qui supposent la qualité de professionnel.

Sous quelle forme ceux-ci peuvent-ils contribuer à l'élimination et/ou disparition des décalages existants entre les différents systèmes de rapport financier au niveau européen, entre les pays francophones, voir au plan international?

Quel doit être le rôle des organisations de normalisation et des organisations professionnelles régionales et de quelle façon peut-on soutenir le processus d'uniformisation des standards face à une mondialisation croissante?

Il faut partir d'un double constat :

1/ - Tous les pays européen, leurs entreprises, ne sont pas égaux face à l'adoption des standards internationaux, pour ainsi offrir les meilleurs critères de transparence au plan économique aux investisseurs, renforcer la confiance des fournisseurs et des clients.

2/ - Pourtant, ils affrontent tous de façon égale, avec des armes et des critères différents, les obligations de l'Organisation Mondiale du Commerce, les difficultés d'un marché devenu mondial.

Regardons avec attention ici, les aspects financiers de l'adoption du référentiel IFRS. Est-ce que le fait que certains pays ne disposent pas de moyens financiers suffisants pour assimiler rapidement ces standards ne représente pas pour ceux-ci des handicaps au développement normal de leurs économies, de leurs entreprises ?

Est-ce que cette situation ne justifie pas pour certains un moyen convenable de manque de transparence, utile à exploiter pour favoriser des intérêts particuliers spécifiques, au détriment des citoyens et du pays ?

Ne pourrait-on imaginer un système favorisant l'adoption par les pays d'un standard unique, universel, permettant de conforter une même vision, une même image, une analyse égale où que l'on soit sur notre planète et quel que soit notre langue d'origine pour ainsi renforcer la crédibilité, la sécurité, la qualité des informations financières ?

Une solution pourrait être envisagée, vu les coûts que cela implique pour certains pays : que les pays riches aident les pays qui n'ont pas les moyens, au travers la coordination d'organisations tels que l'UNCTAD et l'OCDE, l'Association Francophone de Comptabilité, vu ses spécificités ayant un rôle central à jouer face aux pays francophones. Les financements étant orchestrés par le FMI et/ou la Banque Mondiale.

Car dit Ovide « le fardeau est plus facile à porter quant on le porte avec de la bonne volonté ».

Ainsi, sans que cela soit une utopie, les pays disposant d'une économie développée, seront en mesure d'agir de façon concrète pour réduire les inégalités existantes dans les pays concernés par le dialogue Nord-Sud, qui trouvera de cette manière un nouvel élan.

Le décalage qui existe entre les pays du fait de cette Tour de Babel que constitue encore aujourd'hui l'adoption définitive d'un standard applicable à l'ensemble des états financiers des entreprises au plan universel se trouve aggravé par les coûts des investissements financiers que leur intégration suppose et que beaucoup de pays ne sont pas en mesure d'assumer, d'affronter dans de bonnes conditions ou en perdant un temps important.

Ne peut-on pas imaginer, dans une prise de conscience générale, que puisse naître un élan de solidarité susceptible d'aider les pays dans le besoin ? Peut-être cette idée, cette initiative, peut prendre forme au sein de la communauté francophone qui ainsi donnera l'exemple.

Sur un autre plan, cette initiative aurait l'avantage et le mérite de forcer la communauté internationale à se mettre d'accord sur le contenu précis et nécessaire de ce standard « universel ».

CONTINUING PROFESSIONAL DEVELOPMENT – A CONCEPT AND REQUIERMENT FOR PROFESSIONAL ACCOUNTANTS

Botez Daniel

University of Bacau, Roumanie, Faculty of Economic Sciences, Bicaz, Neamt, str. Cozmitei nr. 2, danbotez@artelecom.net, Tel. 0743826004

IES 7 IFAC Standard prescribes that member bodies implement a continuing professional development (CPD) requirement as an integral component of a professional accountant's continued membership. Such a requirement contributes to the profession's objective of providing high-quality services to meet the needs of the public (including clients and employers).

This Standard introduces the concepts of continuing professional development as relevant, verifiable and measurable learning activities and outcomes.

Key words: continuing professional development, International Education Standards, professional accountants

Financial scandals that culminated with ENRON and WORLDCOM firms' bankruptcy provoked in USA the providing of some measures concerning the accountancy and audit. Sarbanes-Oxley law, published in July 2002, introduced public surveillance mechanisms of accountancy and audit firms, together with other measures due to assure an increased protection of investors by improving the honesty and safety of information published by the quoted companies.

On this basis, the international organism of professional accountants initiated a series of measures that have as main purpose the regaining of public's trust in the quality of services provided by its members.

Among these measures those initiated by The Committee for Education and finalized by publishing of International Education Standards for Professional Accountants (IES) may be found.

In October 2003, IFAC published the first six education standards (IES 1-6), whose stipulation foreseen, in essence, the following: the establishing of a conceptual frame of international standards for education; access requires in a professional education program (IES 1); the content of professional accountancy education syllabus (IES 2); professional skills (IES 3); the values concerning the ethics and professional behavior (IES 4); practical experience requires (IES 5); the professional capacities and competences assessment (IES 6).

In May 2004 followed the publication of International Standard of Education 7 (IES 7) entitled Continuing professional development: a permanent education program and continuous development of professional competence. The purpose of this standard is to offer references to member organisms in order for these to adopt an engagement concerning the organization of permanent compulsory education for professional accountants, as well of the resources of these programs, to establish for its members the development and maintenance conditions for professional competence, necessary for public interest protection and to monitor and assure the continuous development and maintenance of professional competence of professional accountants members.

The stipulations of this standard are based on the principle of professional individual accountant's responsibility for maintaining and development of professional competences necessary for providing high quality professional services to its clients, employees or other interested persons.

The attendance of the programs implemented by professional organisms concerning the continuous professional development constitutes an integrated part of the requires necessary for maintaining the member quality of each professional accountant.

We have proposed to present and comment upon some of this standard's settlements.

The member organisms should promote the importance of continuous professional competence improvement and should assume the obligation of continuous preparation for all professional member accountants.

Also, all professional accountants have the obligation to maintain and to develop the professional competence according to the nature of their missions and to the professional responsibility that it is presumed. This obligation concerns altogether all professional accountants, no matter whether they are involved in traditional missions of accountancy nature or in other missions.

The permanent education process starts early, in the same time with the general education, it continues with the study program designated to obtaining of the professional qualification and afterwards it is a part from each individual's professional carrier. The continuous professional training program is an expansion of education process that leads to qualification as a professional accountant. The professional knowledge, the abilities, the professional values, ethics and behavior are obtained on the basis of continuous training and are improved according to professional activities and responsibilities of each professional.

The professional organisms should facilitate their members the access to opportunities and resources concerning the continuous professional training and to assist the professionals during these activities.

Also, the professional organisms should require all the professionals the maintenance and development of relevant professional competence for missions that are exerted and in according to professional responsibilities that are engaged.

The continuous professional training program is applied to all professionals, no matter the activity sector where they work and the size of the business, because all professionals have professional ethics obligations, both for clients and for partners of professional cabinets of other interested persons, and have to prove their capacities of engaging the responsibilities in a competent manner. Also it has to be taken into consideration the involvement of all professional accountants, from all activity sectors, in the process of financial reporting, their assuming of responsibility for public and the maintenance of public's trust in professional services. The public is relaying on the good reputation of professional accountants.

More than that, all professional accountants should be aware of the fact that any lacking in competence or digression from professional ethics supposes a consequence upon their reputation and profession's importance, no matter the activity sector or the position where it works.

It should be brought under discussion the fact that all economy sectors met quick environment changes and, in consequence, have to adapt strategic business plans appealing to specific competences of professional accountants.

Professional accountants should evaluate the professional training activities and its results according to continuous professional training program' requires of the organism from where is a part. The continuous training activity may be measured in terms of effort or time, or by other recognized methods that evaluates the competences acquired or developed.

This standard is also based on the principle that a certain part of the preparation activities may be checked. This supposes that the professional training may be checked in an objective manner by a competent source. The other activities of the professional may be evaluated but not necessary verified. For this, the professionals are obliged to keep all the files and documents concerning the continuous professional training, hereby, at professional organisms' request, to be able to provide sufficient elements in order to prove the conformity to the professional organism requires.

The aim of the continuing professional development is to assist the professional accountants in developing the professional competence with the purpose of providing high quality services with the purpose of satisfying the public interest. The achieving of this aim and the fulfillment of the continuous professional training's requires may be made by three different procedures:

- The intercession based on entries, by establishing a specific number of activities as being adequate with the maintenance and developing of professional competence.

This intercession supposes that the professional organisms to solicit to their members to respect the following preparation rigors:

  - To attend at least 120 hours or its equivalent during the professional training activity for each three years period, from which 60 hours of its equivalent in preparation units, to be ascertainable;
  - To attend at least 20 hours or its equivalent each year;
  - The training activities' evaluation procedures and methods should satisfy the above mentioned requires.

The trials that the professionals may use for checking procedure are the following:

- Courses decks, technique materials;
- Attendance dossiers, enrollment papers or confirmation papers from the organizers of the continuous professional training activity;
- The independent evaluation of the attended training activity;
- The confirmation from a lecturer or program organizer;
- The confirmation for a partner of cabinet about the attendance to internal professional training program.

• The intercession based on exits, with the require that the professional accountant to prove, by the procedures that he/she followed, that the professional competence was maintained and developed.

This supposes that the professional organisms would require from the professionals to prove the maintenance and development of the necessary competence by periodic presenting of proves, concerning:

- That have made the object of a checking form a competent source ;
- That a recognized evaluation method was used.

Concerning this intercession, the following may be considered as proves:

- Verification of the obtained training or of the resulted performance;
- Evaluation on the basis of papers or materials published or reviewed;
- Publishing of articles as result of research programs;
- Periodical reexamination;
- Obtained professional qualifications (specializations or other qualifications);
- Activity consigned by objective verification, with reference to external qualification route;
- Qualification routes applied by professional organisms, others than the self-assessment and evidence supply;
- Evaluation objectives that should certify the preparation procedures from the partners of professional cabinets or of the organizers of training programs.
- The combined intercession, which is realized by the effective and efficient combination of the two above mentioned intercessions, establishing a number of compulsory activities and the evaluation method of the obtained competences by other procedures.

The professional organisms should establish systematic procedures to monitor the manner in which the professional accountants fulfill the professional continuous training requires and to establish corresponding sanctions for the digressions from these requires, including for reporting mistakes and for flows in maintaining and developing their competence.

In composition of monitor procedures, the professional organisms should take into consideration the members that have increased responsibilities against the public and to establish more rigorous procedures for them.

The monitor procedures may require that the professional accountant to satisfy periodically the following requires:

- To transmit a declaration concerning the manner in which they respected the ethical obligation concerning the maintenance of knowledge and abilities necessary to be competent;
- To hand in a declaration concerning the manner in which they respected the requires of continuous professional training; and/or
- To provide an evidence of professional training activities or of verification of competence maintenance and development.

Other monitor procedures may include:

- The audit of a sample among the professionals for verification of the conformity with the requires of continuous professional training;

- It may include the reviewing and evaluation of training plans or documents by means of practice inspection procedures; and/or
- To solicit to the partners of professional cabinets to include continuous professional training plans and systems to monitor it in their own programs of quality assurance.

In order to realize the maintenance and development requires of professional competence, the professionals may train themselves by different methods, such as:

- Courses, conferences, seminaries attendance;
- Self-training modules or training programs in the frame of the cabinet ;
- Publishing of papers in professional or university environment;
- The attendance at the technique committees;
- Teaching at courses or sessions of continuous professional training;
- The elaboration of official studies concerning the professional responsibilities;
- Active attendance to conferences, sessions, work groups;
- Writing articles, books on this field;
- Research activity, including the study of professional literature of specialty press, in order to put in practice the knowledge.

Concerning these activities it should be mentioned that a single repetitive activity cannot assure the requires of continuous professional training.

It also should be mentioned the aspect that the measure unit used in evaluation activity of performances is hour. As an alternative, the course hour may be used or its equivalent. In evaluation procedures, the time used for an activity, the units allocated to an activity by an organizer of continuous professional training or the units prescribed by a professional organism may also be taken under consideration.

THE FINANCIAL AUDIT – THE GUARANTOR OF THE TRUE AND FAIR VIEW SUPPLIED BY THE FINANCIAL STATEMENTS

Boța-Avram Florin

Babeş-Bolyai University, Cluj-Napoca, Faculty of Economical Science and Business Administration, St. Teodor Mihali, No. 58-60, 400591, Romania, botaavramflorin@yahoo.com, Tel: 0740-886491

Matiş Dumitru

Babeş-Bolyai University, Cluj-Napoca, Faculty of Economical Science and Business Administration, St. Teodor Mihali, No. 58-60, 400591, Romania, dmatis@econ.ubbcluj.ro, Tel: 0264-418652

Abstract Financial audit has the finality the issue of an opinion regarding the measure in which the financial statements are in according with the supreme scope of true and fair view and the respecting the referential of relevant accounting norms. Because of the subjectivity of this concept of "true and fair view" we can't say that there are relevant instruments for measuring the level of fidelity reflected by the financial statements. Despite the fact that the auditors know that there is no formula, mathematical or other nature, through which to measure, quantify the level of the fidelity, but they have the knowledge and the capacity needed to identify at least those situations in which the true and fair view is not respected, using the professional judgment for establishing the level in which the financial statements gives a true and fair image.

Key words: financial audit, financial auditor, true and fair view, financial statements

The role of the financial auditor is to increase the trust of the users in the financial information presented in the financial statements, to give a reasonable assurance that the accounting information was managed and presented in conformity with the accounting standards and with the general accepted accounting principles. In this way, *International Audit Standard (ISA) I20 "General framework of the audit standards"* says at the third paragraph:

"… the financial statements are made and presented annually and are designated to the common needs of informing of a large number of users. Most of these users take their decision based on these financial statements, being the only source of information, because they have no possibilities to get additional information which should satisfy the specifically informational needs. So, the financial statements should be made in according with one or combination of: International Accounting Standards, National Accounting Standards; and another general framework of financial reporting compulsory and comprehensive, which was settled for using in financial reporting and which is identified in the financial statements".

For underling the essence of the financial audit, the sense of containing and his scope, we consider that one of the relevant definitions of the financial audit is that one issued by the famous American specialist[294]: *"The audit consists in collecting and evaluating some evidence regarding information, in the scope of determination and reporting the level of conformity of the information regarding to a series of pre established criteria. The audit should be realized by a competent and independent person*."

In our opinion we consider that a definition which could completely reflects the essence of the financial audit would be:

„The financial audit is an examination realized by a competent and independent professional person, in that manner in which he can express an opinion very well argued and independently issued, regarding the validity and fairly applying of the standards and accounting principles from the initially referential system agreed and regarding the true and fair view, clearly, coherent and completely expressed in the final financial statements established and presented by a company, the supreme objective of the audit is that one to contribute at the improving of the quality of audit using."

[294] Arens A.& Loebbecke K., (2003), *Audit: O abordare integrată*, Editura Arc

The objectives of the financial audit are presented in the *ISA 200 "The objectives and general principles which governance an audit of the financial statements*" and in according with this the **objective of an audit** of the financial statements is to give the possibility for the auditor to express an opinion regarding the financial statements, if these are established respecting all the significant aspects in conformity with a framework identified by the financial report.

The expressions used in the issue the auditor opinion are **"give a true and fair view"** or **"present in a fidelity mode, respecting all the significant aspects",** terms which are equivalent. For issuing an opinion the auditor have to get the audit evidences enough and adequate, in the measure to be capable to formulate conclusions which will be base for its opinion.

The opinion of the auditor increase the credibility in the financial statements and give a higher level but not an absolutely of certification. The absolute (ideal) level of certification is impossible in audit because of few factors like:

- The necessity of applying the professional judgment of the auditor in his work;
- Using the tests for getting the audit evidence, which are mate on some sample, the testing of the whole information being very difficult even impossible;
- The most number of audit evidence available, through his nature are rather persuasive than conclusive;
- The obviously limits of every accounting systems and internal control.

Despite of increasing of the credibility in financial statements due to auditor opinion, the user of the financial statements do not have to consider the auditor opinion issued in the auditor report the absolute assurance, guarantee of the next viability of the company or of the company efficiency or its productivity generated by the management of the company. We saw the finality of the financial audit mission: the issue of an opinion regarding the measure in which the financial statements respect the supreme condition of true and fair view, and also the conformity with the relevant accounting standards.

Thinking at the fact that the defining the concept of true and fair view is a very moot situation is very hard to measure the level of the objectivity of the issued opinion of the auditor. This difficulty is generated by the fact that we do not have defined the objective instruments for measuring of the fidelity reflected by the financial statements. It is true that are issued norms and accounting standards and audit standards which applying should conduct at the true and fair view but at this moment we do not have a general formula to guarantee the quality of the true and fair view.

With this entire obstacle, the financial auditors faced this challenge having a permanent concerning for improving the method thus to obtain a high level of objectivity and assurance in expressing the opinion regarding the true and fair view. They use the principle that they have at least the necessary knowledge, they have the necessary qualities to identify those situations in which the true and fair view is not respected. To the professional judgment is assigning a major contribution in realizing their demarche in appreciating the true and fair view[295].

For a better understanding of the financial auditor role in evaluating the true and fair image supplied by the audited financial statements, we have to consider few elements specific for the financial audit which can have an influence in evaluating the quality of the true and fair view reflected by the financial statements:

- First of all, the financial auditor will check the conformity of the financial statements with some criteria defined before or much better with a referential accounting system. If this referential system includes the general accepted accounting standards than we can settle the hypothesis that respecting these norms in establishing and presenting the financial statements will assure in the most situations the respecting of the true and fair view. But we can't take to the absolute the certitude given by the respecting of the accounting standards, and this because the standards have settled some situations when it is possible to use alternative treatments, some derogation, in the context in which in this way it contributes to a better true and fair view supplied. These derogations represent the prove of the facts that standards didn't forecast all the complex situations, which could appear in daily activity of a company,

[295] McKee T.E.& Eilifsen A., (2000), W*hat is all the fuss about materiality*- Ohio CPA Journal, October-December, Vol. 59 Issue 4

and that emphasize the relative character of the true and fair view resulted by respecting the accounting standards.

- Another element that we have to consider is the fact that the financial auditor can't check or test every transaction that generates effects in the financial statements because the limited time allocated for the auditing. Because of this we have to accept from the beginning the error rate which could not be eliminated. We can notice here another aspect: **"Which is the level of this error rate which should be accepted, thereby the opinion issued regarding the true and fair view reflected by the financial statements to give a reasonable assurance level?"** The level of this error rate or significant threshold is very important, with direct effects for appreciating the quality of true and fair view reflected by the financial statements. The audit standards define the significant character of information being determinate by the effects which could have the ignorance or its inexact presentation on the economical decisions of the users of this information.
- Another important element is the link between the significant threshold and the user whom is addressed the audit report, the concrete form of the audit work. So, the auditor, when is establishing the significant threshold have to take into consideration the type of user whom is addressed the audit report, and the needs of information of this one. Practically, he has to identify the connection between the economical decisions which could be taken and the information presented in the financial statements. Depending of this connection, he will try to find that errors which if they appear they could have an important influence for the decisional process of the users of the accounting information and depending of these errors he will settle the significant threshold under that limit that the decisional process wouldn't be affected.

The importance of the right establishment of the significant threshold is important because of the next reasons:

- If it is settled at a lower level than is necessary we can have the risk that in the time dedicated to the audit mission to work much more in collecting the data and evidences which would be irrelevant;
- On the other side if the significant threshold is settled at a higher level than is necessary we can have another risk, that one when some important errors, with significant consequences on the decisions of users, wouldn't be detected and in this way the auditor to issue an opinion which assure the true and fair view of the performances and financial position of the company, but in the reality the situation is an opposite one.

The establishing of this significant threshold supposes two difficult problems like:

1. Which are the criterions which the auditor has to consider for settle the significant threshold?
2. How could be dimensioned the correct level for significant threshold for some or another audit mission?

In the most developed countries were made some empirical studies[296] for finding eventually relevant connections between accounting information supplied by the listed companies at the stock exchange and the quotation existing at the bourse. Despite of relevance of some interesting elements of these empirical studies, no one proves any utility for the financial auditors, which try to establish a level of the significant threshold which is a benchmark in the auditing of the financial statements. But these studies underline that the significant threshold is related to the level of the profit because this indicator reflects in the best way the performances of a company in a certain time.

The practical activity proves that the level of the significant threshold settled related to profit varies in an interval between 1% and 10% from the profit, considering in the same time also the criterions like: the company dimension, the specific of the developed activity and, of course, the professional judgment of the auditor. Starting from these premises appears the next question: *Which is the most relevant level of the profit whereat it should be settled the level of the significant threshold: gross profit or net profit?* But it could appears the situation when the profit for some period is out of the normal graphic of normal evolution, and in these circumstances there are used other indicators such as: total assets, total turnover, net

[296] Gray, Manson S., (2000), *The audit process: principles, practice and cases*, Editura Business Press, ediția a II-a, SUA

assets, or a combination between these. We don't have to forget the fact that in settling the indicators that will be considered for establishing the significant threshold we have to analyze a series of aspects: the domain of activity, the level of company, the specificity of the activity of the company, the environment of every company, and of course the professional judgment of the auditor which is affected by the experience and his professional preparation.

The finality of an audit mission of the financial statement is the audit report issued in the final form. The result of the auditor work is concretized in elaborating the audit report, this representing the instrument through which the auditor communicate to the users of the accounting information the characteristics of the financial statements, his argued opinion with the audit evidences, regarding the quality of the establishing and presenting the financial statements, and, of course, regarding the true and fair view reflected by the financial position, financial performances and the changes of the company positions. The signature of the auditor on the audit report should not be underestimated, because this represents a "certificate" which assures a reasonable level regarding the quality of the audited financial statements.

Considering the audit evidences from the audit process and the conclusions after the analyzing of these evidences, the auditor can issue one of the next opinions:

1. **opinion without reserves**

An opinion without reserves has to be expressed when the auditor can conclude that the financial statements present a true and fair view (or show, regarding all the significant aspects, with a high fidelity the financial statements), in according with the general framework of settled financial reported. An opinion without reserves indicates, also, in a deductive mode, that any changes which appears in the accounting principles or in the applying methods of those, and also the effects of these changes were implied and presented correctly in the financial statements.

2. **the opinion with reserves**

An opinion with reserves has to be issued in that situation in which the auditor gets at the conclusion that he can't issue an opinion without reserves, but the effect of any dissonance with the management is not such significant and profound in that measure to be compulsory an adverse opinion or the impossibility of issuing of an opinion. Generally, there are two factors which imply the issuing of an opinion with reserves, and these are:

- Some elements that determine the auditor not to be able to apply all the audit procedures needed for getting the audit objectives, such as the situation that the auditor didn't get the confirmations regarding some liabilities of the client. If the weight of these is significant reported to the total of liabilities, than the auditor can't appreciate objectively the fidelity of the statements regarding the liabilities presented in the financial statements, in this way, being forced to issue an opinion with reserves.
- The situation in which the auditor applies all the necessary audit procedures, in conformity with professional standards, but he discovers some significant errors in the audited financial statements, errors which are not such severe that to imply the issue of the adverse opinion, but imposes the necessity of the issuing of an opinion with reserve.

It is compulsory to mention in the audit report all the significant aspects which implies the issuing the opinion with reserves. This opinion is not an unfavorable one for the client who calls for the audit of his financial statements, because it implies an interpretation like this one: the financial statements present through their assembly a true and fair view, excepting some elements, which, from the point of view of the auditor, can't be used in the substantiation of the decisional process.

3. the impossibility of issuing of an opinion

The impossibility of issuing of an opinion appears when the effect of the limitation of the sphere is such significant and large than the auditor can't get enough audit samples and in consequence he can't issue an opinion regarding the financials statements. An example, in this way, is that one where the management has a negative influence, directly or indirectly, on the process of collecting audit evidences. Another factor that can have an influence for the financial auditor to pronounce the impossibility to issue of an opinion is that situation when there are some uncertain events, which could have an important impact for the financial statements, and because of this reason appears the impossibility to issue an opinion regarding the financial statements till that event haven't place, more exactly a trial which can have the finality in wining or losing the trial and the loosing the trial determines an uncertain future for the company.

Is absolutely necessary to mention in the audit report the reasons that cause the impossibility of issue of an opinion, but without insisting with explications and justifications, for implying subjective interpretation by the user, and this will give to this report a higher credibility than it's necessary.

adverse opinion

An adverse opinion will be issued in that situation in which the effect of an discordant elements is such profound and significant for the financial statements, and the financial statements didn't respect the true and fair view, than the auditor will conclude that is not opportune the issue of an opinion with reserves in the scope of presentation of the incomplete nature or distort of the financial statements. The impact for the user's perception of the adverse opinion is very strong, the message sent being that one the financial statements are completely wrong, they don't give a true and fair view and they mislead. We can consider that the adverse opinion is a warning regarding the quality of the financial statements, and these can't be used in the decisional process.

In the next table we will try to synthesize the types of the opinion which could be inserted in the audit report and also the criterions which imply the issuing of these types of opinion:

No.	*Types of opinion*	**Criterion which implies the issuing of these types of opinion**
1.	*Opinion without reserve*	• **the audit objective was touched** • **there is no significant incertitude** • **there were respected the accounting standards from the referential system settled**
2.	*Opinion with reserve*	• **the objective of the audit was not correct touched, but is possible to be issued an opinion** • **the accounting referential settled was not totally respected or the presentation of the information in the financial statements was not the most proper one, but the auditor considers, in this condition, that the criterion of true and fair view was respected in the assembly of the financial statements.**
3.	*Impossibility of issuing of an opinion*	• **the audit objective was not touched** • **there is significant incertitude with important impact**
4.	*Adverse opinion*	• **the deviation from the reporting criterion is so high that the financial statements don't reflect a true and fair view.**

Table no.1 „Types of opinion in the auditor report"

Conclusions:

1. the financial audit gives a reasonable character of assurance regarding the quality of the true and fair view reflected by the audited financial statement, and this starts from the fact that the financial auditor in getting the audit samples, which are the base of his audit opinion reflected in the audit report, was not confronted with significant anomalies.
2. the significant character is determined by the significant threshold settled at the beginning of the mission, being obviously the connection between the significant threshold settled at the mission start and the quality of appreciating the true and fair view supplied by the financial statements
3. the level of assurance from the financial audit is reflected by the type of the opinion issued through the financial audit report, which represents a message meant to the users of the financial statements regarding the quality of the audited financial statements and the quality of true and fair view reflected by the financial statements.

4. we appreciate that the financial audit gives a guarantee for the quality of the true and fair view supplied by the financial statements, and even if this isn't an absolute one, we consider that the auditor's contribution is very important for the increasing the quality of the financial statements drawn up by the economical entities.

CONSIDERATIONS REGARDING THE INTERNAL AUDIT IN ROMANIA

Boța-Avram Cristina

Babeş-Bolyai University, Cluj-Napoca, Faculty of Economical Science and Business Administration, St. Teodor Mihali, No. 58-60, 400591, Romania, botaavram@gmail.com, tel: 0745-512459

Abstract: The evolution of the economical environment, where the companies works, determines the companies to search all the time solutions for improving the control over the activities developed. A solution is adopting the internal audit function, which offer the answers to the questions which, usual, the managers of the company make them himself referring to the way they and their collaborators could have a better and efficient control as they could have over the activities they have. The necessity of the internal audit function begins to be more important in the context of the Romanian economical environment which is more and more competitive and dynamic. In this article I'll try to get a vision more realistic of the level at which is situated internal audit in Romania, and also I'll try to find that spaces of this complex system, where we have to pass different difficulties paying attention for finding the necessary solutions to resolve them, participating in this way to the progress of the researched theme.

Keywords: internal audit, internal control, internal auditors

The manager of an organization, from private sector or public sector, needs to obtain a reasonable assurance referring to the transactions they have, the decisions they have taken are under control and in this way are touched the scopes of the organization. So, we can say that the internal audit represents the important support of the management of the company for getting to the company's scopes using the systematical activities and very good organized for evaluating and improving the efficiency of the processes of the management and control. The adopting of the internal audit function permits to the management to have more courage in elaborating and adopting strategies, and this facts because the internal audit professionals are working in different spaces and locations of the organization for getting assurance referring to the correct application of the strategy whished by the company, and also how much this proves his efficacy.

The importance of the internal audit is bigger as much as possible the internal audit works in an independent way, without accepting compromises, without having as scope getting the power and without subjectivism. Realized in this way, the internal audit become a tool absolutely necessary to the organizations, and this because of the complexity of the different situations which could appear after mergers, realizing some projects together with other companies.

The result of an internal audit mission is the internal audit report, which is in essence a way of communication, but the value of the internal auditor's work is not gave by this report, and by the way in which the internal auditor have the capacity and possibilities of determining when his recommendations are applied, the evolution and the improving the efficiency of the internal control of the organization in which he activates. We can say in this way that the internal audit department is the key in realizing the internal control because the internal audit gives the assurance over the efficiency and efficacy of the internal control.

If we have in our mind the moment of the appearance of this concept of internal audit in Romania in accordance with the global context, we must admit that the recognizing of the importance of this field of internal audit have been realized late, but this in the context of the domination of the communism system till 1989. The transition to the market economy, which starts in '90 years, was realized very hard, the road to the stable economy was very difficult, finding in this period some bankruptcy of few mastodon organizations. This difficulty was determined also by the instable political strategies used in the economy, which instability we can see it very often in the economical sector.

Step by step the Romanian economy goes to a stable zone and in times with this evolution the managers of the organizations, from private sectors and public sector, have given more attention to the improving of the performances of the organization which they coordinate, and in this way to find efficient and pertinent solutions. If we draw a parallel between the appearance and the developing the internal audit function in

Romania, we can observe some differences which from a point of view are justified by the particularities of the economical environment and the everyone specifically culture.

An important difference which needs more attention could be the facts that in the Romanian economy the trend of internal audit evolution was from this point of view inversed those from the international space. If in the international plan the internal audit function was developed starting from the bigger companies and the multinational companies, extending after to the public sector companies, in the Romania was other way. The internal audit was important at the beginning for the public companies, and prove in this way is the regulations and the laws adopted which regulates the internal audit. After this begin the growing of investing in the Romanian economy, the multinational companies growing in the Romanian economy implies influences of the international practices through which there is the recognizing of the necessity and the efficiency of the internal audit. So, even if the internal audit is at a low level, the internal audit from the Romanian companies is more and more developed, the utility of the internal audit function being bigger and bigger.

The introduction of the internal audit in Romania is relative recent, representing the general effort of the management for a better control in this activity, in the public sector and in the private sector, in the harmonization activity of the internal law system with the European laws, keeping an eye on the efforts made on the integration way in the European Union member countries. The quickly progress of the internal audit implies some confusions, his scopes were not very clear understood by everyone implied in activities in touching with internal audit, and this confusions maybe because of facts that even internal audit's scopes at the global level have been growth very quickly and still progressing.

The concept of internal audit have begun to be used very much in some environments, maybe in excess, and this concept became a fashion, a trend in the context of the Romanian economical environment. This concept was used by different specialists from every sector of activity, some times without knowing what exactly internal audit means. For many times the practical activities prove that the use of this concept in some situations in which was some references to other concept like: internal control, financial control or other terms. Also, there were situations when the confusion was made in the opposite way, and I mean when they must use internal audit term they use other terms with total different signification.

A confusion made with a high frequency by the specialist's referring to this concept, on the evolution of the internal audit in the Romanian economical sector, is making equal the internal audit with the internal control. I have to consider that an influence in making this confusion was from the fact that these two concepts was not very clear delimitated from the beginning of the making laws activities, regulating this new internal audit function. The starting point in regulation of the internal audit in Romanian was the Government Order no. 119/31.08.1999 referring to internal audit and preventing financial control, publicized in the Official Monitor no. 430/31.08.1999. After that law, the regulators were trying to eliminate the confusions made in separating the internal audit by the internal control through the Order no. 332 from 25 February 2000 (which was also abrogated by the Order no. 38 from 15 January 2003 for approving the General Norms looking the realizing the internal audit activities) approving The General Methodological Rules for organizing and the function of the internal audit based on the Government Order no. 119/1999 referring to internal audit and preventive financial control, publicized in the Official Monitor no. 96/03.03.2000, where was presented some precise aspects:

- the internal audit represents a sum of activities and actions correlated between them, realized through specialized structures defined at the level of the public institution in case, or at the next high level of the public institution which based on the plan and on the clear agreed methodology are designated to realize a general diagnostic of the system from a technical point of view, managerial point of view, financial and account side.
- the internal audit is represented by a control type endogen and ex post, detailing the fact that when we refer to the ex post character we have in our mind the operation for the decision, and when we think about the global activity realized by the entire audited system for an year, the internal audit having a simultaneous character. This character is generated by the characteristic of the internal audit for watching to the operations from the aspects of the specifically scopes to check on every moment of its realization. So, the internal control of the public institution is the object of the internal audit.
- we don't have to make confusions between internal control, as a sum of tools used by the management of the public institution, whit the scope of an assurance of a good function of the

institution and internal audit which is a control of type endogen are a control of type evaluation and special a final control, the last from the series of controls made by the own structures of the institution in case.

While all this facts, even if one of the attributions of the methodological rules, mentioned in the up lines, was to bring more light over this two concepts: the internal audit and the internal control, even so there was few rules which still determines to make confusion between internal audit and internal control. A clear example could be the part of these methodological rules, Part 2 - organizing the structures of the internal audit, where are made few underline words:

- ex structures of managerial financial control will be absorbed by the internal audit structures, and this internal audit structures will take the attributions given by the Government Order no. 119/1999 and all the attributions of the ex structures of managerial financial control;
- where there wasn't a structure of managerial financial control will be made internal audit structures as the rule of art. No.6 align. (1) from the Government Order no. 119/1999.

After this, the regulators in this sector were preoccupied by the elaborating of some rules which to delimitate at the level of the public institutions the conceptual part of this two functions, and in this way were published rules for internal audit and separate for internal control, and in this way the confusion were eliminated between this two concepts.

The trend of the law for this concept was delimitated by the publishing of the next few rules:

1. Emergency Government Order no. 75/ 1 June 1999, published in the Official Monitor of the Romania, Part 1, no. 256 / 4 June 1999 was approved with the text modified and added text through the Law no. 133/2002, published in the Official Monitor of the Romania, Part 1, no. 230 from 5 April 2002 and was modified and its text was added through the Government Order no. 67 / 2002 and was approved with the text modified an added text through the Law no. 12 / 2003 published in the Official Monitor of the Romania, Part 1, no. 38 from 23 January 2003. This regulation specifies some terms: terms and conditions of realizing the internal audit activity, definition of internal audit and scopes of internal audit.
2. Ministry of Finance Order no. 1267 from 21 September 2000 for approving the Minimal Norms of internal audit (general framework), published in the Official Monitor of the Romania no. 480 from 2 October 2000, with the principal objective to approve Minimal Standards of internal audit for institutions, representing the general framework for setting the internal audit being compulsory in exercising the internal audit.
3. The Ordinance no. 72 from 2001 (settlement rejected by the Law no. 132 from 19 march 2002) referring to the public internal audit and preventive financial control for modifying and completion of Government Ordinance no. 119 from 31 august 1999 referring to the internal audit and preventive financial control, published in the Official Monitor of the Romania no 339 from 22 may 2002. This settlement underlines an important change of the conceptions and the activity sphere settled by the Government Ordinance no. 119 from 31 august 1999, for the first reason because the title of the ordinance „referring to the internal audit and preventive financial control" was changed to „referring to the *public* internal audit and preventive financial control".
4. Law no. 301 from 2002 referring to approving the Government Ordinance no. 119 from 31 august 1999 referring to the public internal audit and preventive financial control, published in the Official Monitor of the Romania no 339 from 22 may 2002 adds some completions to the settlement from Government Ordinance no. 119/1999 and Government Ordinance no. 72/2001.
5. Law no. 672 from 19 December 2002 referring to the public internal audit published in the Official Monitor of the Romania no. 953 from 24 December 2002 is structured in six principal chapters: generalities (through this are defined the public internal audit, public institution, are settled the objectives of the internal audit and the public internal audit sphere); structure (referring to the management of the public internal audit department from the public institutions and the organization of the central structures UCAAPI and CAPI); attributions (the attributions settled at the level of the of the public internal audit department from the public entities and from the central structures); the unfolding of the public internal audit (are

settled the types of audit); internal auditors (settled the selection, rights, obligations and incompatibilities); contraventions and sanctions.

6. Law no. 84/18 march 2003 for modifying and completion of Government Ordinance no. 119/ 31 august 1999 referring to the public internal audit and preventive financial control published in the Official Monitor of the Romania no. 195 from 26 march 2003. In this new law was settled the distinction between internal control and the public internal audit. In this way, it was modified inclusive the title of Government Ordinance no. 119/ 31 august 1999, becoming the ordinance *„referring to the internal control and preventive financial control”*. So, it is made a big step forward through a clear distinction between this two notions: internal control and internal audit, everyone of this are settled through two separated normative papers with the characteristics of the laws, making in this way the distinction between this two activities: the public internal audit and internal control from the point of view of organization and as realization.
7. Ministry of Finance Order no. 38 from 2003 for approving the General Norms referring to realizing the public internal audit activity published in the Official Monitor of the Romania no. 130 bis from 27 February 2003. The important elements of the Order are structured in five parts:

- **First part**: Application of the general norms of the public internal audit in Romania;
- **Second part**: Methodological norms referring to the public internal audit mission;
- **Third part**: Procedural guide book;
- **Part four:** Charter of the public internal auditor;
- **Part five**: The glossary.

1. Ministry of Finance Order no. 252 from 2004 for approving the Code of Conduct referring the ethics of the public internal auditor published in the Official Monitor of the Romania no. 128 from 12 February 2004. This order abrogates the Ministry of Finance Order no. 880 from 2002 issued with the same scope.
2. Romanian Government Ordinance no. 37/2004 for modifying and completion of settlements referring to the public internal audit, published in the Official Monitor of the Romania no. 91 / 31 January 2004 and the Law no. 106/2004 for approving of this, published in the Official Monitor of the Romania no. 332/16 April 2004. This new settlement represents a step forward for improving juridical framework and the settlements referring to the internal audit, and this brings significant changes for the Law no. 672/2002 referring to the public internal audit and the Emergency Government Ordinance no. 75/1999 republished referring to the financial audit activity.
3. Ministry of Finance Order no. 1702/2005 for approving the Norms referring to the organizing and exercising the activities of consultancy, published in the Official Monitor of the Romania no. 154 / 17 February 2006. This normative act settles the activities of advising from the internal audit activities, and the structure of the norms which regulates the advising activities referring to the internal audit has few elements:

- general instructions which includes the definition of the advising activity;
- advising forms: consultancy, facilitating the understanding, professional forming and perfection;
- types of missions of advising: formal advising missions, informal advising missions, exceptional advising missions;
- Stages and procedures needed for realizing the advising mission.

Conclusions:

Analyzing in assembly the rules referring to the internal audit from his introductions in Romania (1999) and till in present we could underline few conclusions:

1. There is regulated in especially internal audit from public institutions, being less regulated internal audit from private institutions. Private institutions have possibilities and in the same

time they are obligate to realize the internal audit activity in conformity with Internal Audit Standards issued by CAFR.

2. Despite the important confusions made at the beginning between the objectives of internal audit and internal control (this confusion are determined by the regulated system) we can affirm that in present we don't find this kind of confusions, or these are very rare.
3. At the beginning, the internal audit activity starts with some difficulties, but in the present we can consider that in this sector we are on the good road, the management became more and more dependent of internal audit and more aware of the needing and the importance of the internal audit and in this way the internal audit in Romania is at a stage of consolidation and maturating.
4. Looking at the actual stage of the internal audit in the public institutions we can say that we are on the right way of the internal audit, being generated the premises for creating of a real function of internal audit in conformity with the practices from European Union.

EXPORT BY AGENT – A CHALLENGE FOR THE TRADING COMPANIES IN SUCH FIELD, AS PER THE NEW REGULATIONS AFTER THE ACCESSION OF ROMANIA TO EU

Budacia Lucian Constantin Gabriel

Romanian-American University, Faculty for Computer Science in Business Management, 1B Expoziției Ave., Sector 1, Bucharest, lucian.budacia@yahoo.com, 0723.15.85.43

Before the accession of Romania to the European Union, the export by agency, as means of indirect trade of goods aboard, was carried out by exterior trading companies (SCE), which carried out such activities on their behalf, but on the risk and account of export beneficiaries – usually manufacture facilities, which needed to find customers on the international market. After the accession of Romania to the European Union, we can notice two distinct situations for the goods' delivery carried out by means of an agent: 1. the agent acts as proxy, for and on behalf of the principal; 2. the agent acts as commission agent, on his own and for the principal.

Key-words: export, agency, mandate

Until 1.01.2007, namely until the accession of Romania to the European Union, the export by agency, as means of indirect trade of goods aboard, was carried out by exterior trading companies (SCE), which carried out such activities on their behalf, but on the risk and account of export beneficiaries – usually manufacture facilities, which needed to find customers on the international market. Thus, the financial results of the goods' export by means of agency were recorded in the beneficiaries' accounting documents, on whose behalf the export was performed and not in the accounting books of SCE.

After the accession of Romania to the European Union, in accordance with the new Romanian legislation regarding the value added tax, respectively the Law no. 571/2003 regarding the Fiscal Code, as subsequently amended and completed, we can notice two distinct situations for the goods' delivery carried out by means of an agent: 1. the agent acts as proxy, for and on behalf of the principal; 2. the agent acts as commission agent, on his own and for the principal.

1. The agent acts as proxy, for and on behalf of the principal

In such case, the manufacturer from Romania invoices the goods directly to the beneficiary. If the operation is an export (the goods leave the community territory), the invoice shall be VAT free. If the delivery is an inter-community operation (the goods leave Romania, but they are shipped or transported to another member state), the invoice shall be VAT free if the customer proves a valid VAT code and if the freight is proved to be performed between two member states.

Thus, in such case the agent's role is only to establish the connection between the export's beneficiary from Romania and the foreign customer, performing, as per the mandate contract, other duties such as: to pursue the payment of the counter-value of the exported goods, to contract and pay various services abroad – such as: transportation, insurance, etc.

Let's presume we have to export goods by means of agent, for and on behalf of the manufacture facility from Romania, therefore a mandate contract. The facility exports goods in amount of € 20,000, delivery condition – CFR (Romanian Railway Company) – Destination – the country of the foreign customer. The agent-proxy SCE cashes, according to the mandate contract with the facility, the goods' counter-value from the foreign customer by means of a letter of credit, which is then provided, in 2 days time, to the principal – the plant from Romania, according to the contract concluded between SCE and the plant, but not prior withholding the expenses made for the plant, such as the fee in amount of 3% of the CFR value for the exported goods. The export expenses made by SCE for the plant have been transportation expenses in amount of € 2,000. The evolution of the Romanian currency related to euro has been as follows: upon invoicing the external transportation: 1 € = 3.80 lei; for the payment of the external transportation invoice: 1 € = 3.70 lei; for invoicing the fee to the plant: 1 € = 4.00 lei; upon cashing the merchandise from export: 1 € = 3.90 lei, upon the payment of the goods to the plant: 1 € = 3.80 lei.

The accounting procedures related to this export are as listed below:

1. The proxy buys the external transportation service:

2,000 € x 3.80 lei / € = 7,600 lei

624 „Transport of goods and personnel" = 401.1 „Suppliers" (external transport) 7,600

2. Payment of the external transportation invoice

a) RON value upon invoicing: 2,000 € x 3.80 lei = 7,600 lei

b) RON value upon payment: 2,000 € x 3.70 lei = 7,400 lei

Favorable currency difference (a – b): 200 lei

401.1 „Suppliers" (external transport) = % 7,600

5124 „Cash at bank in foreign currencies" 7,400

765 „Foreign exchange gains" 200

3. Cashing the counter-value of the goods from the foreign customer by means of documentary letter of credit

20,000 € x 3.90 lei / € = 78,000 lei

5412 „Letters of credit in foreign currencies" = 462/x „Sundry creditors" (plant) 78,000

4. 4. Invoicing the 3% agent fee to the plant

3% x 20,000 € = 600 €; 600 € x 4.00 lei / € = 2,400 lei

411 „Customers" (plant) = % 7,600

704 „Services rendered 2,400

4427 „Output VAT" 456

5. Invoicing the transportation expenses made on behalf of the plant by SCE to the plant

411 „Customers" (plant) = % 9,044

7588 „Other operating revenues" 7,600

4427 „ Output VAT" 1,444

6. Withholdings borne by the plant out of the amount owed by the plant

Amount owed (credit cont 462/x) ……………..………………………20,000 €

Withholdings: ▪ external transport: …………………………..………2,000 €.

▪ Agent fee ……………………..……………………………..600 €

Net amount to be paid: 20,000 € – 2,600 € = 17,400 €

- RON value of the withholdings, calculated as per the current exchange rate:
- External transport: 2,000 € x 3.70 lei / € = 7,400 lei
- Agent fee: 600 € x 4 lei / € = 2,400 lei

Total RON withholdings as per the current exchange rate (2,600 €): 9,800 lei

- RON value of the withholdings calculated as per the exchange rate valid when the plant undertook the obligation: 2,600 € x 3.90 lei / € = 10,140 lei.
- Favorable currency difference: 10,140 lei – 9,800 lei = 340 lei

462/x „Sundry creditors" (plant) = % 10,140

411 „Customers" (plant) 9,800

765 „Foreign exchange gains" 340

7. Payment to the plant of the net amount of 1,400 €

a) RON value upon cashing: 17,400 € x 3.90 lei = 67,860 lei

b) RON value upon the payment to the plant: 17,400 € x 3.80 lei = 66,120 lei

Favorable currency difference (a – b): 1,740 lei

462/x „Sundry creditors" (plant) = % 67,860

5412 „Letters of credit in
foreign currencies" 66,120
765 „Foreign exchange gains" 1,740

2. The agent acts as commission agent, on his own and for the principal

According the new fiscal code, the commission agent, although only an agent, is deemed - in terms of value added tax - seller and re-seller of the goods, regardless of the fact if such agent acts on behalf of the seller or buyer, principal, with all the consequences arising thereon regarding the value added tax.

To illustrate this second case, let's discuss a practical example: SCE "EXIMTERRA" SRL is an exterior trade company, acting as agent, on its own, but on behalf of the manufacture facility. SCE performs during the fiscal year N the following operations related to *merchandise export by agent with cashing on spot.*

- On 30.05.N, SCE registers the purchase of the goods from the supplier (plant), in amount of € 15,000;
- On 1.06.N, it invoices the goods to the foreign customer, having as delivery condition – EXW, in amount of € 15,000. The fee of SCE is 5% of the external value of EXW, being invoiced on the same day as the goods for export;
- On 5.06.N it cashes, in foreign currency, the counter-value of the goods from the foreign customer;
- ON 5.06.N, it markdowns the currency with the manufacture facility;
- The evolution of the euro related to the Romanian currency has been as follows: on 30.05.N: 1 € = 3.85 lei; on 1.06.N 1 € = 4.00 lei; on 5.06.N: 1 € = 4.05 lei.

The accounting procedures related to this export by agent are as listed below:

1. 1. Registration of the purchase of the goods from the domestic supplier (plant)

15,000 € x 3.85 lei / € = 57,750 lei

% = 401 „Suppliers" (plant) <u>68,722.5</u>

461.2 „Goods for export by agent" 57,750

4426 „Input VAT" 10,972.5

2. Invoicing the goods to the external customer, EXW delivery condition

15,000 € x 4 lei / € = 60,000 lei

411 „Customers" (foreign) = 462.2 „Sundry creditors – export by agent" 60,000

3. Removal of the sold goods from stock

a) RON value upon purchase: 15,000 € x 3.85 lei = 57,750 lei

b) RON value upon sale: 15,000 € x 4.00 lei = 60,000 lei

Favorable currency difference (b – a): 2,250 lei

462.2 „Sundry creditors - export by agent" = % <u>60,000</u>

461.2 „Goods for export by agent" 57,750

765 „Foreign exchange gain" 2,250

4. Invoicing the fee for SCE to the plant

Fee in foreign currency: 5% x 15,000 € = 750 €

Fee in RON: 750 € x 4 lei = 3,000 lei

411 „Customers" (plant) = % <u>3,570</u>

704 „Services rendered 3,000

4427 „Output VAT" 570

5. Cashing the counter-value of the goods sold for export
   a) RON value upon invoicing: 15,000 € x 4.00 lei = 60,000 lei
   b) RON value upon cashing: 15,000 € x 4.05 lei = 60,750 lei

Favorable currency difference (b – a): 750 lei

5124 „Cash at bank in foreign currencies"	=	%	60,750
		411 „Customers" (foreign)	60,000
		765 „Foreign exchange gain"	750

6. Withholdings borne by the plant out of the amount owed by the plant

Amount owed for merchandise, VAT free (credit cont 401) ……………………….15,000 €

Withholdings: ▪ agent fee: ……………………………..….…………………………750 €

Net amount to be paid: 15,000 € – 750 € = 14,250 €

- RON value of the withholdings, calculated as per the current exchange rate:
- Agent fee: 750 € x 4 lei / € = 3,000 lei
- RON value of the withholdings calculated as per the exchange rate valid when the plant undertook the obligation: 750 € x 3.85 lei / € = 2,887.5 lei.
- Unfavorable currency difference: 3,000 lei – 2,887.5 lei = 112.5 lei

%	=	411 „Customers" (plant)	3,000
401 „Suppliers" (plant)			2,887.5
665 „Foreign exchange losses"			112.5

7. Payment of the amount of 14,250 € to the plant
   a) RON value upon invoicing: 14,250 € x 3.85 lei = 54,862.5 lei
   b) RON value upon payment: 14,250 € x 4.05 lei = 57,712.5 lei

Unfavorable currency difference (b – a): 2,850 lei

%	=	5124 „Cash at bank in foreign currencies"	57,712.5
401 „Suppliers" (plant)			54,862.5
665 „Foreign exchange losses"			2,850

8. Concomitantly, the plant pays the amount owed as VAT

401 „Suppliers" (plant) = 5124 „Cash at bank in foreign currencies" 10,972.5

The main conclusion which may be drawn related to the two forms of agency for exterior trade is that using a mandate contract, SCE might avoid "locking up" on short term funds for the payment of the value added tax.

EU – THE REGULATING LEGISLATIVE ENGINE OF ROMANIA IN TERMS OF VAT AFTER THE ACCESSION TO EU

Budacia Lucian Constantin Gabriel

Romanian-American University, Faculty for Computer Science in Business Management, 1B Expoziției Ave., Sector 1, Bucharest, lucian.budacia@yahoo.com, 0723.15.85.43

The accession of Romania to EU involves the obligation to enforce the same rules as the other member states, VAT being a tax which must exist and which must not allow competition disturbance among the economic operators within different member states, as well as non-taxation or double taxation of the same operation in two different member states. The harmonization of VAT within EU has been done gradually. The value added tax (VAT) was established in the Economic European Community in 1970 by means of two "VAT Directives". Representing the indirect tax with the highest weight in the GDP (Gross Domestic Product), the European Union has established an obligation according to which the member states contribute with a share of the cashed VAT to the EU budget.

Key-words: EU, VAT, accession

A. EU regulations regarding VAT

The actions of EU regarding the indirect tax field have as legal grounds articles 90 and 93 of the Treaty for the establishment of EU. The rule governing this treaty is the unanimity one, being grounded, at the same time, on the principle of indirect taxes harmonization, and not their standardization.

The VAT harmonization in EU has been performed in several stages:

1. VAT implementation in all member states (until 1970)
2. standardization of the taxation basis for VAT and VAT shares (1977-1993)
3. passing to a transitory system for VAT, once the unique market is formed and suppression of the border customs (January, 1, 1993)
4. simplification of the VAT system and cooperation of all member states for decreasing the fiscal fraud

1. The value added tax (VAT) has been implemented in the Economic European Community since 1970 by means of two "VAT Directives", having as purpose the replacement of different taxes on manufacture and consumption enforced by the member states, which represented obstacles for the free circulation of goods, taking into account two main reasons: advantages of VAT related to other indirect taxes and, especially, related to the tax on cascade circuit; transparency of the operations regarding the taxation of imports and taxation exemption of exports performed between member states.
2. As it represents the most significant indirect tax in GDP, the European Union has established an obligation for the member states compelling them to contribute with a VAT share to the EU budget. Thus, the following stage has been implemented, respectively the harmonization of the taxation basis for VAT, which means it would be enforced for the same economic transactions in all member states (Directive 77/388/CEE). Such directive has established a harmonization system for VAT and has allowed, at the same time, the settlement of a *Working program intended to fulfill the goal of removing the fiscal borders*, by attempting to harmonize the VAT levels. However, the harmonization has not meant the levels' standardization, but their approach enough to not disturb competition.
3. In order to adjust VAT to the requirements of a Sole Market with no borders (01.01.1993), *the 6th VAT Directive has been amended.* Thus, Directive 91/111/CEE, passed in 1991 and 1992 stipulated:

- *a transitory regime*, which would be completed by unifying the levels;

- *a definite taxation system* for exchanges between member states, which would replace the transitory regime and would be grounded on the taxation in the member state of origin of the goods delivered and services rendered;

The transitory VAT system, in force since January, 1, 1993, has removed fiscal checks on the borders within the Community both for end-consumers and economic agents. By means of the transitory system, the notion of import has been replaced with the notion of inter-community purchase, and the notion of export with the notion of inter-community delivery. This system is characterized by:

- *preservation of the principle of destination* (the passing to the principle of origin is not abandoned and it remains a long term objective of the fiscal harmonization);
- *renouncement to the border fiscal control between member states*;
- *continuation of the efforts to harmonize the VAT levels*;

To such end, the European Community has made repeated proposals to use only two classes of levels, a standard one, ranging between 15% and 25% and a reduced one. The Council of ministers, finances and economy has agreed to keep the minimal standard VAT level to 15% and the member states to take all steps not to exceed such minimum more than 10 percent points when they establish their own standard VAT levels. If in terms of taxation basis, some uniformity has been reached, in terms of VAT levels, there are noticeable differences; thus, the lowest VAT level (15%) is registered in Luxembourg and Cyprus and the highest (25%) in Denmark and Sweden.

Despite the efforts sustained to harmonize VAT, its regime remains terribly complex for economic agents and it maintains a certain "stiffness" of the domestic market. Keeping different taxation rules, non-uniform enforcement of the community legislation and the insufficient convergence of the VAT levels, has led to a certain malfunction of the system. In this respect, in July 1996, the Commission presented a *Working program* to *speed the passing from the VAT transitory regime to a common definite system*. The Program intended, in an ambitious way, to approach general principles regarding VAT (taxation level, the notion of excisable person, exemptions, place for VAT levying – the principle of levying at the source).

4. Although the passing to a definite VAT system was planned for the end of 1996, the European Union still operates as a transitory VAT system, the "levying at the source" system not being completely accomplished. The European Union has made progress for VAT's harmonization, but its management, however, remains complicated, requiring plenty of procedures which need time and money to be completed while fiscal frauds are increasing.

The renouncement to the fiscal control at the member states' borders, given the principle of VAT payment at the source, does not lead to the removal of the notion of "fiscal borders" in terms of goods and services' circulation among member states. The goods and services which are transported from a member state to another member state must be "marked" somehow, bearing a different VAT system than the one related to national goods and services. This means significant costs for the enforcement of the fiscal procedures.

B. VAT characteristics in the European Union

The main characteristics of the value added tax in the European Union are as follows[297]:

- The European system regarding the value added tax has been established and is amended based on the EU directives;
- It had been planed that until 1970 all the states - members at that date to implement the value added tax in their national fiscal systems;
- It has been acted to the standardization of the taxation basis and levels since 1977;
- Some member states have negotiated to obtain VAT exemptions or differential taxation levels for certain regions or territories. Thus, areas such as the Canary Islands, Ceuta and Melilla of Spain, Gibraltar of Great Britain and the Aland Islands of Finland are not under the jurisdiction of the VAT European system and, also, adjustable levying levels have been accepted in Madeira of Portugal;

[297] "EUROCONSULTANȚĂ – ghidul firmei" Magazine , no. 3/ March 2007

- The standard taxation level is established to a minimum level of 15%, the member states having the possibility to increase such level, but not more than 10 percent points.
- Reduced taxation levels, over-reduced levels (below 5%) and zero level are admitted for certain classes of goods and services. The case of the zero level is a characteristic of the 6th Directive, its goal being to establish a minimal taxation level, namely 5%. However, in some member states and, especially in the Great Britain, there has been accepted the preservation of the zero level by means of waiver, without the possibility to widen the action range of such level to other goods and services.
- The use of different VAT levels in the member states has started from the idea that goods and services could be classified in several classes, taking into account the need for them. Accordingly, the luxury class endorses higher taxation levels and the class of essential goods – lower levels. Although states such as France and Great Britain have supported such theory, practice has proved that it does not have the same validity any longer (for instance, in Great Britain, children apparel falls into the zero level while adults' apparel falls into the 17.5% level).
- The rules regarding the implementation of the value added tax on prices, addresses in EU the sale accomplishment. Thus, if the highest part of the sales addresses the end-consumer, prices must include VAT and if deliveries endorse another company, prices must not include VAT.
- The value added tax is due as percent and, thus, it is visible in every stage where commercial transaction occurs, becoming a neutral tax related to the number of commercial transactions;
- All the EU member states enforce the principle of destination in terms of VAT, namely the deliveries of goods and services from a member state to another member state are VAT free in their origin country and subject to VAT payment in the destination country;
- According to the perusals regarding the effects of the value added tax, the following conclusions have been drawn: this tax is advantageous for legal entities because they deduct the VAT afferent to purchases, unlike end-consumers who bear the tax by means of the price paid for the purchased good or service; the rich pay less compared with the poor, the tax acting as a regressive tax; the perusal of how supply and demand act must be performed by taking into account both the tax existence and inexistence, to become, on one hand a fiscal duty for the tax-payer and, on the other hand, a firm source for obtaining public financial results.

C. Considerations regarding the VAT levels enforced by the EU member states

The European fiscal policy may not endorse and must not enforce standardization upon the levels of the member states' fiscal systems. The action of the European fiscal policy occurs in the attunement of the national fiscal systems for the member states and those which candidate to accession, based on the common goals established under the concluded treaties.

Taxes on expenses and consumption represent the class of indirect taxes, a significant resource of income for the central administration budget. Passed initially in France in 1954, upon the initiative of M. Lauré, the value added tax, due to its characteristics, has allowed the action of the European fiscal policy, meaning the harmonization of the taxation basis and of the taxation levels.

The significant moments regarding the harmonization of the value added tax (the implementation of this tax in the fiscal systems of all the member states, the harmonization of the taxation basis and of the taxation levels, the VAT transitory system, and the simplification of the VAT system) are grounded on the provisions of the EEC Directives, respectively: Directive 7, 77/388/EEC (Art. 2, 4, 5, 6, 7 regarding the application range and levied persons; Art. 11, taxation basis; Art. 12, VAT levels; Art. 13, 14, 15, VAT-free operations; Art. 17-20, discounts; Art. 24, 25, 26, special regimes, exceptions); Directive 86/560/EEC regarding VAT reimbursement; Commission Resolution no. 98/527/EEC regarding the prevention of the VAT frauds.

The VAT standard levels, reduced levels and over-reduced levels enforced by the EU member states in 2005 were those listed in the table below:

EU member states	Standard levels	Reduced levels	Over-reduced levels
Austria	20	10	-
Belgium	21	6	-
Denmark	25	-	-
Finland	22	8/17	-
France	19,6	5,5	2,1
Germany	16	7	-
Greece	19	9	4,5
Ireland	21	13,5	4,4
Italy	20	10	4
Luxembourg	15	6	3
Great Britain	17,5	5	-
Holland	19	6	-
Portugal	21	5/12	-
Sweden	25	6/12	-
Spain	16	7	4
UE 15	19,81	8,53	3,67
Czech Republic	19	5	-
Cyprus	15	5	-
Estonia	18	5	-
Latvia	18	5	-
Lithuania	18	5/9	-
Malta	18	5	-
Poland	22	7	3
Slovakia	19	-	-
Slovenia	20	8,5	-
Hungary	25	5/15	-
UE 10	19,2	6,77	3
UE 25	19,51	7,65	3,34

The perusal of the data presented above points out the compliance with the requirements stipulated by EU regarding the minimal and maximum limits as regards the standard level.

It is obvious that only Cyprus and Luxembourg enforce the standard VAT level according to the minimal value stipulated by EU (15%), the explanation for such practice being related to the classification of these states as being part of the area of fiscal paradises with low taxation.

In Germany, Great Britain, Spain, Czech Republic, Estonia, Greece, Lithuania, Latvia, Malta, Holland and Slovakia, the standard VAT level is below the average registered upon EU level while in Austria, Belgium, Denmark, Finland, France, Ireland, Italy, Portugal, Sweden, Poland, Slovenia and Hungary, the standard VAT level exceeds the average registered upon EU level.

Although the fiscal harmonization in terms of VAT has been accomplished regarding the taxation basis and the standard taxation level, it can be noticed that only two states – Denmark and Slovakia – do not use reduced VAT levels while states such as France, Greece, Ireland, Italy, Luxembourg, Spain, and Poland enforce both the reduced level and the over-reduced level.

The enforcement of the reduced VAT levels, both in older and new member states endorses the following products and services: essential food, water supply, medicines, medical equipment for disabled persons, person transportation, books, newspapers, magazines, services of composers and writers, social housing, agricultural products, hotel services, sports events, use of sports facilities, social services, services rendered by crematories, medical and dentistry services, waste collection, street cleaning.

Academia de Studii Economice Bucureşi, Facultatea de Contabilitate şi Informatică de Gestiune, Strada Bozieni nr. 8, bloc 831, sector 6, Bucureşti, stbunea@yahoo.com, 0731037868

RÉSUMÉ : Pour la plupart des entreprises roumaines réste une grande probleme de realisé la publication d' informations financières obligatoires dans les états financières. Il y a beaucoup des informations obligatoires qui ne sont pas obligatoires selon les normes roumaines . L'objectif de cette recherche est de réaliser une analyse des facteurs de contingence sur la publication d'informations financières volontaires et de tirér quelques conclusions pour les entreprises roumaines. Méthodologie de recherche :-revue de la littérature concernant le concept d'information volontaire, les contingences des informations volontaires ; -analyse des pratiques de communication financière utillisées par les entreprises roumaines coté à BVB (les rapports annuels publié sur site internet) et la compairaison avec les bonnes pratiques des entreprises cotées sur les grandes marchés financiers de L'UE ;

MOTS CLÉFS informations volontaires, contingence, bonnes pratiques de communication

1.Introduction

La thème est d'actualité par sa durée: il traverse les changements de normes. Il est essentiel au regard des problèmes qu'il soulève : l'utilisation de données financières par les acteurs (investisseurs notamment) et la présomption latente de manipulation des informations diffusées. Il est important par l'immensité du champ d'investigation qu'il représente : les données volontaires sont excessivement variées et contingentes. L'ambiguité même du sujet et le manque de définition claire nécessitent que l'on se penche plus en détail sur les contours de ces informations ; très largement répandues ; mais mal circonscrites peu interprétables .

2.L'information volontaire : un concept flou

On peut distinguer deux catégories de travaux selon leur approche :

1)Ceux qui rest allusifs ou qui ne la définissent pas : les études de prévision de resultats (Lev&Penman, 1990 ; Kasznik, 1999) ; les travaux sur l'utilisation d'internet (Wong&Zhang, 2003) ;

2)Ceux qui la situent par rapport à une norme établie, supposant que ce qui n'est pas normé, ou obligatoire, est donc volontaire : ces travaux traitent souvent des informations sectorielles (Botosan&Harris, 2000), le choix volontaire du référentiel IASB contre un référentiel local (Dumontier&Raffournier, 1998), l'impact du renforcement des règles sur les informations volontaires (Hope, 2003) etc.

En somme, la définition même des information volontaires manque d'homogénéité. Elle est au mieux définie comme un écart à la norme et souvent apprèhendéé de maniére très parcellaire. En délimitant ce qui est obligatoire nous soulignerons ce qui est, par défaut "volontaire". Les obligations de diffusion d'information comptables et financières se caractérisent par les éléments suivantes :

- Un émetteur : la société
- Un (des) destinataire(s) : actionnaires, administrations diverses,…
- Un référentiel : IFRS etc
- Un contenu, combinant : un format (compte de résultat par nature ou par destination, …) ; un objet de la communication (résultat économique,…), une densité (présentation simplifiée ou normale)
- Une occurrence : périodique (publications annuelles ; trimestrielles, …) ou ocasionalle
- Un vecteur (support papier ou sites Internet pour les rapports annueles, …)

Une dimension importante de l'information volontaire est la temporalité et la pérenité des cadres conceptuels qui nous servent de référence. Une information non normée peut devenir obligatoire après son homologation.

Par comparaison aux information dites "obligatoires" les éléments "volontaires" peuvent être identifiés selon la séquence suivante qui reprend les critères énonces ci-dessus :

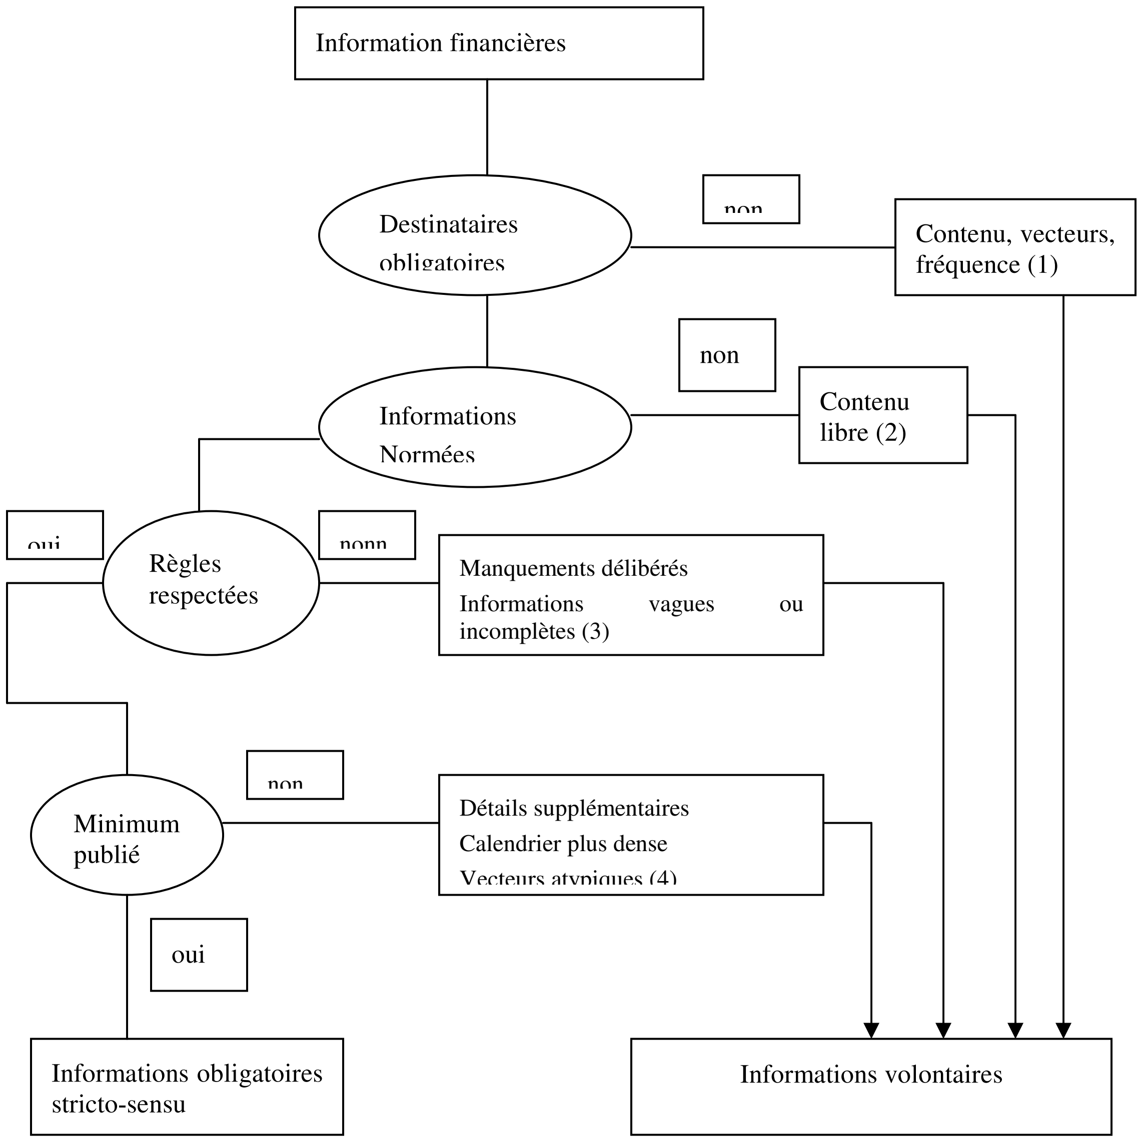

Figure 1 : Informations obligatoires versus Informations volontaires

Lorsque la "cible" de la diffusion n'est pas un destinataire obligatoire, comme les actionnaires ou l'administration fiscale, l'information est totalement volontaire (catégorie 1 de la figure 1), quels que soient le contenu, les vecteurs, etc. Il en aussi des publications diffusées dans la press financière ou sur les sites Internet touchant un public très large.

Lorsque le contenu publié pour des destinataires "obligatoires" n'est pas normé, il relève aussi d'une publication volontaire (catégorié 2 de la figure 1). Dans ce sens, on peut citer la diffusion assez large des "résultats opérationneles" ou celle, plus occasionnelle, des résultats "proforma" par les grands groupes cotés.

Nous considérons aussi comme "volontaires" les absences d'informations (catégorié 3 de la figure 1) : c'est l'absence qui devient un acte volontaire comme la diffusion discrétionnaire peut l'être. Par exemple, l'absence des informations sectorielles est assez courante (Pourtier, 1995), alors que les groupes concernés connaissent tout de même une diversification d'activités. D'une manière plus générale il est difficile d'admettre que des informations obligatoires sont absentes par simple "étourderie".

Enfin, si les informations respectent les contraintes légales (destinataires, vecteurs, délais , contenu) mais sont plus détaillées que le minimum requis (catégorié 4 de la figure 1), elles sont clairement volontaires. Dans ce sens, on trouve les prévisions de résultats, toute information plus détaillée que la norme (données sectorielles par exemple dans certains cas).

3.Contingence des informations volontaires

a) une demande palliative

Les demandeurs d'informations comptables se tournent d'abord vers les informations normées et obligatoires. Celles-ci comportent cependant des limites : rigidité des règles, limites induites par certains principes et une doctrine parfois orientée par les groupes de pression. Pour dépasser le modèle comptable légal, les acteurs seraient alors à la recherche de compléments utiles : Pour faire connaître des informations privées qui ne transparaissent pas aux travers du modèle comptable obligatoire, les dirigeants sont tenté de diffuser volontairement l'information qu'ils détiennent. L'information comptable standard est insuffisante pour apprécier les perspectives de la firme et la désagrégation des données (par segments) est utile (Hayes&Lundholn, 1996).

Les prévisions de résultats doivent servir à réduire l'asymétrie informationnelle (Mai&Tchemeni, 1993). Dans ce sens, la politique de communication volontaire permet de changer la perception de la firme par les actionnaires (Lev, 1992).Mais cette vision de l'utilité a priori des informations volontaires reste une vision normative : elle ne préjuge pas des motivations des dirigeants, conscients de l'utilisation qui peut être faite de leurs communication : Elle suppose que le coût de telles diffusions suffit à garantir leur crédibilité.

b) stratégies des dirigeants et opportunités de diffusion

La nature favorable des informations publiées est le premièr moteur invoqué pour justifier les publications volontaires. En présence de coûts, seules les informations favorables sont diffusées (Verrechia, 1983). Cette approche repose directement sur les hypothèses de la théorie des signaux (Ross, 1978). La propension à diffuser de l'information (concernant le court comme le long terme) augmente avec l'amélioration des résultats (Miller, 2002). Cette politique continue aussi après le tassement des performances mais avec une réticence à diffuser sur le long terme. Les publications de prévisions (plutôt favorables) précédent des opérations de financement .

Nombre de sociétes communiquent de mauvaises nouvelles (notamment en devançant leurs publications).Ainsi, au-delà d'une première analyse naïve des motifs de publication, les travaux ont identifié un comportement plus complexe où le facteur "image et réputation" intervient.

Comme les prévision sont faites à l'initiative des dirigeants (publications volontaires), elles engagent implicitement leur responsabilité et leur crédibilité. Aussi, pour ne pas être taxés de myopie et d'incompétence, ils diffusent les mauvaises nouvelles par anticipation (Skinner, 1994). Plus largement, ils publient des mauvaises nocivelles tout simplement pour montrer leur intégrité de dirigeants, donc leur fiabilité. Dans ce sens, les dirigeants essayent aussi d'assurer la convergence entre leurs prévision (volontaires) et les résultats publiables en utilisant les accrualls (Kasnik , 1999) . La présence d'informations pro forma s'observe chez les firmes dont les résultats sont revus à la baisse (Lougee&Manquardt, 2002).

Valoriser la firme est aussi un objectif implicite des dirigeants. Il les conduit à gérer la nature de leur segmentation sectorielle pour assurer une homogénéité apparente des secteurs et la régularité des résultats par segments (Hayes&Lunoholm, 1996).

4.Catalyseurs et freins aux informations volontaires

Classiquement, la diffusion d'informations volontaires a d'abord été vue comme un arbitrage entre "coût induit" et "contenu favorable". Le coût être lié au poids social, au coût des precès est aussi un facteur dissuasif important.

Le cas des données sectorielles est particulier. Il est directement lié à la position stratégique (diversification, rentabilité des secteurs) des sociétés. Les groupes définissent les segments publiés en évitant d'identifier séparement les secteurs les plus sensibles. Par ailleurs, beaucoup de dirigeants prennent pour prétexte le désavantage concurrentiel pour éviter de diffuser des données sectorielles (acte volontaire).

Internationalisation des activités élargit l'environnement des entreprises. Elles sont confrontées à des acteurs exigeant des informations conforme à certains standards de qualité. Elles sont alors tentées de diffuser plus d'informations, voire d'adopter volontairement les normes comptables internationales.

La propension à diffuser des informations volontaires est aussi liée à la taille des firmes (Dumontier&Raffournier, 1998). La taille est supposée inversement corrélée avec le coût de production de telles informations. Les grandes firmes optent largement pour le vecteur Internet (Laszwad&Fischer, 2003).

Enfin, la culture d'un pays, les usages établis sur certaines places financières dessinent un environnement qui favorise la diffusion des informations (Debreceny&al, 2002).

Les résultats pro forma des sociétés nord américaines (comprendre ici "retraités" de manière discrétionnaire et non-conformes aux normes) sont supposés avoir un pouvoir prédictif supérieur aux résultats classiques respectant les US GAAP (Brown&Sivakumar, 2001). Botosan et Plumlee (2002) montrent que le niveau informatif des rapports annuels abaisse le coût du capital.

5.Analyse des pratiques de communication financière utilisées par les entreprises roumaines coté à BVB (les rapports annuels publié sur site internet) et la compairaison avec les bonnes pratiques des entreprises cottés sur les grandes marchés financiers de L'UE

La revue de la littérature, consacré à l'examen des pratiques de diffusion d'information financière sur Internet, nous permet de distinguer trois types d'études. Une première catégorie regroupe les études descriptives traitant l'évolution des pratiques des entreprises d'un pays sur une période (par exemple, Petravick, 1999 ; Hussey et al., 1999 ; Gowthorpe et Amat, 1999). Ce type de recherche permet de connaître la proportion d'entreprise du pays qui diffusent des informations financières via le Web, le volume et le type d'information présentée en ligne et l'utilisation qui est faite au sein du site des moyens multimédia offerts par la technologie Internet.

Une deuxième' catégorie d'études compare les pratiques de diffusion d'information sur les sites Web des entreprises de deux ou plusieurs pays. Ces études internationales qui ont examiné la publication volontaire des informations financières sur les sites Web sont, toutefois, moins nombreuses (Deller et al., 1999; Lymer et al., 1999) .

La troisième catégorie d'études essaient de mettre en évidence les déterminants de la présentation en ligne d'information via les sites Web des entreprises (Craven et Marston, 1999 ; Debreceny et al., 2002 ; Xiao et al., 2004 ; Marston et Polei, 2004). Ces études ont traité cette question en se basant sur les variables identifiées dans les études antérieures examinant l'offre volontaire des informations supplémentaires dans les autres supports de communication utilisés auparavant par les entreprises (la publication de certaines informations non requises dans les rapports annuels, les conférences téléphoniques….).

A travers leur étude, Debreceny et al. (2002) ont essayé d'expliquer les pratiques de diffusion d'information de 660 firmes de 22 pays. Les auteurs ont testé la relation entre le format de la présentation, le contenu du site Web et la taille de la firme, mesurée par la capitalisation boursière. Pour évaluer les pratiques de diffusion d'information à travers le Web, Debreceny et al. (2002) recourent à une analyse de contenu basée sur la grille originale de l'IASB/IASC. Les résultats de modèles de régression logistique ordinale démontrent que le contenu et la présentation de l'information financière sont positivement et statistiquement associés à la taille de la firme.

Marston et Polei (2004) ont recensé les sites Web de 50 firmes allemandes faisant partie de l'indice DAX 100 entre Juillet 2000 et juin 2003 afin d'étudier l'évolution des pratiques de diffusion d'information via le

Web. L'analyse descriptive démontre que le volume d'information communiquée et la forme de sa présentation ont considérablement été améliorés par rapport au premier recensement qui a été effectué en juillet 2000. Le résultat de l'analyse multivariée décrit une association positive et statistiquement significative entre le niveau de la communication financière via le Web et la taille de la firme.

Nous avons éxaminé les pratiques de diffusion d'information sur les sites Web pour toutes les entreprises cotées au BVB (Bourse des Valeurs Bucarest) pour les exercices 2006 et 2007. Il s'agis de 21 societées cotées à la Catégorie 1 et 36 sociétées cotées à la Catégorie 2.

Pour chaque société nous avons cherché les informations suivantes:

- l'existence de rapport annuel ;
- la consistence de rapport annuel (numeros des pages);
- le référentiel comptable utilisé (les Directives ou IFRS);
- l'importance de l'auditeur ;
- qui sont les actionnaires (le poids des actionnaires étrangers) ;
- la consistence des informations naratifs ;
- la frequence de diffusion ;
- l'existence des informations nonfinancières;
- autres sources des informations.

Les conclusion pour les sociétées cotées à la Catégorie 1:

1. seulement 4 sociétées ont la pratique de realiser le raport annuel (Antibiotice Iaşi, Transelectrica, Impact Developer&Constructor, Petrom). Toutes les autres présente les états financièrs el le raport des dirigeants qui est reçu par une obligation légale de Commision National des Valeurs Mobiliérs.
2. la dimension moyene d'un rapport annuel est de 40 pages (les plus consitentes sont les raports de Antibiotice Iaşi et Petrom qui dépase 100 pages);

- -les poids des informations naratifs sont 10-30% et il s'agis des informations financièrs strictement ;

3. 90% sont auditées par Big Four ;
4. une seule entreprise présente des information concernant la remmuneration de l'auditeur (Alro Slatina) ;
5. une seule entreprise presente le code etique de la companie (Transelectrica);
6. seulement 4 entreprises presente les états financièrs conformement aux IFRS (en Roumanie, pour l'exercice 2007, ont l'obligation d'apliquer les IFRS les gropes cotées pour les etats financièrs consolidées); toutes les autres dréssent les états financièrs selon les Directives Européene (L'Ordre de Ministre des Finances Publiques 1752/2005)
7. une seule entreprise possede une code de gouvernance (Petrom);
8. pour les entreprises qui apliquent les IFRS la pluspart des actionnaires sont étrangers ;
9. deux entreprises seulement présentent des informations sectoriells detaliés (Petrom et Antibiotice Iaşi);
10. deux entreprises seulement présentent le raport écologique;
11. il manque pour toutes des entreprises cotées le bilan social;
12. une seule entreprise présentent le compte de résultats avec la classification des charges selon les fonctions des enreprise (Alro Slatina);
13. 90% des entreprises utilisent la méthode indirécte dans le tableau des flux de trésorerie ;
14. une seule entreprise présente volontairement les soldes intérmédiaires de gestion (Antibiotice Iaşi).
15. une seule entreprise présente des informations concernant les transactions avec les parties liées (Alro Slatina) ;
16. une seule entreprise présente des informations prévisionnelles détaliés (Banca Transilvania).

Les conclusion pour les sociétées cotées à la Catégorie 2:

1. pour la pluspart des entreprises on peut trouvé sur le site Internet le bilan comptale et le raport des dirigeants reçu par CNVM;
2. aucune des entreprises cotées à la deuxieme catégorie aplique IFRS;
3. 14% des entreprises sont auditées par Big Four ;
4. la majorité des entreprises ne present par des informations concernant les politiques comptables utilisées;
5. le contenu faible des notes aux états financières ;
6. la majorité des investisseurs sont roumains ;
7. il manque les informations nonfinanciers ;

Pour identifiér les bonnes pratiques des communication financière des sociétées de l'Union Éuropéene nous avons utilisé la base de données Forbes 2000 qui pérmét l'acces aux raports annuels des premiéres 200 sociétées cotées. Les résultats sont evidement jénantes pour les entreprises roumaines. La dimension moyéne d'un raport annuel est de 200 pages. Il y a des companies avec un raport annuel de 500 pages.

En partant des observations faites sur les grandes companies éuropéene cotées nous avons procéde à identifier les éléments qui peuvent assurer les bonnes pratiques de communication:

- vérification de l'exactitude et de l'exhaustivité de l'information communiquée au public ;
- principes de communication de l'information importante;
- maintien de la confidentialité;
- communiqués de presse;
- rumeurs;
- conférénces téléphonique et webdiffusion;
- rencontres individuells et en groupe avec les analystes, les investiseurs et les medias;
- examen des projets de rapports et des modèles des analystes;
- distribution des rapports d'analystes;
- information prospective;
- périodes de silence;
- résponsabilité relative aux communications éléctroniques;
- recours à des experts externes etc.

6.Conclusion

Les résultats de la recherche amènent vers la conclusion que la définition des information volontaires manque d'homogéneité. L'opportunisme des dirigeants et la contingence des diffusions remettent en cause la validité des valeurs volontairement communiquées. Pour la plupart des entreprises roumaines analysées il manque les principes d'une bonne pratique de communication financière. Les entreprises cotées et auditées par Big Four sont plus transparentes et présentent beaucoup d'information. Pour la plupart les dirigeants des entreprises non cotées les états financières ont un régime de confidentialité (on peut trouver souvent que le bilan comptable ou les états financières simplifiés). Les bonne pratiques de communication financières sont imposées par les sociétés méres étrangères. Malleureussement elles ne fait pas l'objet d'étude approfondit dans les univérsités.

ACCOUNTING TREATMENT OF DEFERRED INCOME TAXES ACCORDING TO THE REQUIREMENTS OF THE ROMANIAN ACCOUNTING REGULATIONS

Abstract: Known as a debatable topic, the relationship between accounting and taxation still represents a field of convergence and divergence, of tolerance and intolerance. Therefore, the Romanian accountant is in permanent pursuit of quality accounting information and its impact on taxation. Currently, a great importance is granted to accounting judgements, and this is magnified by the fact that most fiscal contributions are based on accounting information. Deferred income taxes reconcile accounting profits with income taxes pursuant to the impact of temporary differences between the book value and tax value of assets and liabilities disclosed in the financial statements.

Key words: deferred income taxes, reserves, provisions, accounting.

The adoption of Order of the Minister of Public Finance no. 94/2001 for the harmonization of Romanian financial reporting with the requirements of the 4th Directive of the European Union and of the International Accounting Standards[298] (OMFP 94) accelerated the reorganization of Romanian accounting, based on the International Accounting Standards (subsequently, International Financial Reporting Standards – IFRS).

International Accounting Standard IAS 12 – Income Taxes (*IAS 12*) is known as a difficult regulation in respect to the practical application of its provisions in Romania, especially regarding the recognition of deferred income taxes. Therefore, it is still subject to many actual accounting debates. *OMFP 94* does not explicitly refer to income taxes[299]. Practically, it accepts *in integrum* the application of *IAS 12 – Income Taxes*. We should highlight here the efforts of the Romanian accounting legislators to approve „solutions"[300] regarding the application of legal provisions referring to deferred income taxes, and to grant some current practices the rank of accounting law source, but also the efforts of professional bodies, respectively the Body of Romanian Chartered and Certified Accountants.

Deferred income taxes reconcile accounting profits with income taxes pursuant to the impact of temporary differences between the book value and tax value of assets and liabilities disclosed in the financial statements. Based on the previous assertions we can conclude the following:

The *assessment* of deferred income taxes is based on balance sheet information (known as the „balance sheet method" or the method of variable carry forwards) and not on the income statement. When the book value of assets is smaller than the tax basis, respectively the book value of liabilities is higher than the tax basis we obtain a *deductible temporary difference,* which generally generates receivables for deferred income taxes. When the book value of assets is higher than the tax basis, respectively when the book value of liabilities is smaller than the tax basis we obtain a *taxable temporary difference*, which generally generates payables for deferred income taxes. Although not from the beginning, *OMFP 94* has created the conditions for the appropriate application of the requirements of *IAS 12,* by introducing in the chart the

[298] Romania's Official Gazette, Part I, no. 85/ 20 February 2001

[299] Bunget Ovidiu Constantin – *Contabilitatea românească: între reformă şi convergenţă*, Economica Printing House, Bucharest, 2005, p. 295

[300] Decision of the Minister of Public Finance no. 9/2003 for approval of certain solutions regarding the application of legal provisions regarding income taxes, together with the accounting regulations harmonised with the European Directives and with the International Accounting Standards, Romania's Official Gazette no. 171 bis/2003

following accounts regarding deferred income taxes: *6912 - Expenses with deferred income taxes*, *791 - Revenues from deferred income taxes*, *4412 - Deferred income tax*.

Temporary differences represent the essential element of the variable carry forwards method (the previous version of *IAS 12* allowed the recognition of deferred income taxes based on two methods: fixed carry forwards and variable carry forwards; however, they were based on the income statement and are currently prohibited).

Deductible temporary differences means that the company will have to affect its current results with amounts representing recoverable income tax for current balance sheet items, due to the fact that, up to now, it paid more income taxes, and in the future, for

4412 Deferred income taxes = *791 Revenues from deferred income taxes*

the same balance sheet items, it will pay less (current) income taxes and the income tax receivables will be reversed.

6912 Expenses with deferred income taxes = *4412 Deferred income tax*

Active deferred taxes should be recognised under special precautions. In fact, they represent a future tax deduction and the expressed supposition is valid only if the company achieves sufficient future taxable profits in order to allow the ascertained deduction. We mention below the following situations:

- the company holds sufficient passive deferred taxes vis-à-vis the tax authority;
- the company expects to hold sufficient future profits vis-à-vis the tax authority, from other sources than those from passive deferred taxes;
- the company's fiscal facilities allow the procurement of sufficient future taxable profits necessary for recovering/cancelling active deferred taxes;

Taxable temporary differences means that, in the future, when it will obtain economic benefits (when the value of assets or liabilities is recovered), the company will have to pay amounts, which once represented current income taxes. Therefore, out of prudence reasons, the company should initially recognise the liabilities with deferred income taxes,

6912 Expenses with deferred income taxes = *4412 Deferred income tax*

and at that future date, it should reverse the liabilities with deferred income taxes, because it should have had realised taxable profits for which it will pay current income taxes.

4412 Deferred income taxes = *791 Revenues from deferred income taxes*

We would like to highlight, that income taxes are generated *only* by temporary differences and not by final differences (permanent)[301]. The latest are subject to fiscal and accounting judgements within a definite financial year. They are not „carried forward" to future periods (i.e. protocol expenses, outages, fines and penalties, daily allowance, etc.).

On the other hand, due to accounting and fiscal treatments applied in different ways and in different financial years, there are also situations resulting in temporary differences for other items included in the yearly financial statements, such as:

- expenses with interests and unfavourable exchange rate differences related to the financial year, which do not comply with the requirements regarding full deductibility of that financial year, and which are fiscally carried forward to the next financial years;
- fixed assets disclosed in the balance sheet, which did not benefit of the additional fiscal amortization of 20% or of other amortization regimes not recognised by the tax legislation;
- capitalization of provisions for restoration of damaged land or for environment rehabilitation, which are deductible expenses under the tax law; from the accounting point of view, these provisions are capitalised, and therefore they will be expensed in tranches, by means of amortization;

[301] Mihai Ristea (coordinator) – *Contabilitatea finciară a întreprinderii*, Universitara Printing House, Bucharest, 2004, p. 480

- revenues and expenses related to hire purchases are taxable, respectively deductible during the duration of the contract, and accounting entries are recognised when delivered;
- tangible and intangible assets with a different working life than the normal technical working lives are fiscally recognised (Law no. 15/1994 regarding amortization of capital included in tangible and intangible assets, republished, with subsequent amendments);
- costs recognised as expenses in accounting, which fiscally are considered assets; they will be recognised as deductible expenses in tranches, according to law;

The assessment of deferred income taxes coincides with the assessment of the yearly financial statements. The deferred income tax is calculated by weighing the temporary difference with the valid income tax rate or with the income tax rate to be in force at the date when the asset will be realised or the debt will be paid, based on the legislation in force at the date of the preparation of the financial statements or on the legislation to be in force, but for which exists a reasonable level of certainty at the date of the financial statements (the transition from 25% to 16% starting with 2005 is a good example in this respect).

In the yearly financial statements, the balance of account *4412 Deferred income tax* reflects the nature of the deferred income tax (payable or recoverable) in the future, for the items presented in the financial statements and which have allocated temporary differences.

Recognition of deferred income taxes according to the requirements of *OMFP 94* (and *IAS 12*, by default) assumes consideration of the two moments involved [302], respectively:

- application for the first time of accounting regulations harmonised with the 4th Directive of the European Union and with the International Accounting Standards (known in practice as „restatement”); this assumes transition from the previous accounting regulations (Government Decision no. 704/1993 regarding approval of the regulation for the application of Accounting Law or Order of the Finance Minister no. 306/2002 for the approval of simplified accounting regulations, harmonised with the European Directives) to *OMFP 94*;
- actual application of accounting regulations harmonised with the 4th Directive of the European Union and with the International Accounting Standards;

While the second step, theoretically, does not raise any particular problems for accountants, on the other hand, restatement presumes also some reconsiderations of certain accounting problems treated or not treated based on the previous regulations. It is also the case of temporary differences generated both by application of art. 11 (5) of Law no. 414/2002 regarding income tax[303] (valid until 31 December 2003), and by application of art. 24 (12) of Law no. 571/2003 regarding Fiscal Code[304] (after 1 January 2004, until 30 April 2005). The mentioned tax regulations specified that, under certain conditions, companies can benefit from the fiscal facility of recognising an „additional” amortization of 20% out of the fixed assets’ input value, at the put in function date. Companies, which used this „facility” and reported according to *OMFP 306,* were allowed to recognise this “additional” amortization also from the accounting point of view (connection accounting-taxation!). However, at the end of the financial year, the realised „income tax savings” should have been „allocated to reserves, by means of account *129 Profit distribution = 1068 Other reserves* / separate analytic”[305]. Subsequent to approval of Law no. 571/2003 regarding Fiscal Code and introduction of the fiscal evidence register for income taxes, the facility of 20% could no longer generate an „additional” accounting amortization expense. However, for profit distribution the legislation maintained the restriction regarding allocation to reserves of realised income tax „savings”. We hope that the example below contributes to the understanding of the different approaches and recognitions generated by the application of different accounting regulations.

In October 2003 a company purchased an equipment of 480,000 currency units. The company uses the straight-line method of depreciation over a period of 4 years, according to the provisions of Law no. 15/1994 regarding amortization of capital included in tangible and intangible assets, republished, with

[303] Romania’s Official Gazette, Part I, no. 456/27 June 2002
[304] Romania’s Official Gazette, Part I, no. 927/23 December 2003
[305] Order of the Minister of Public Finance no. 1784/2002 regarding approval of certain measures referring to the closure of the 2002 financial year for juridical persons, which have to prepare yearly financial statements according to Accounting Law no. 82/1991, republished in Romania’s Official Gazette, Part I, no. 21/2003, in Appendix at pt. 30

subsequent amendments, and Government Decision no. 964 regarding approval of classification and normal working lives of fixed assets (currently cancelled by Government Decision no. 2139/2004 regarding approval of the Catalogue for classification and normal working lives of fixed assets). The company decided for the additional deduction of 20% out of the input value at the acquisition date, according to art. 11 (5) of Law no. 414/2002 regarding income taxes.

The accounting amortization is of 10,000 currency units/months (480,000 currency units/4 years x 12 months). The fiscal facility consists in an „additional" amortization of 20% out of the input value. At the equipment's put in function date, the facility amounts to 96,000 currency units (480,000 currency units x 20%). Thus, the value of assets to which the monthly fiscal amortization is calculated amounts to 384,000 currency units (480,000 currency units – 96,000 currency units), and the monthly fiscal amortization is of 8,000 currency units (284,000 currency units/48 months).

Considering that the equipment is used during the entire estimated working life, deferred income tax will be calculated as following:

Year	2002	2003	2004	2005	2006
Net book value at year end (accounting basis)	460.000*	340.000	220.000	100.000	-
Fiscal basis (taxable)	368.000**	272.000	176.000	80.000	-
Taxable temporary difference	92.000	68.000	44.000	20.000	-
Total liabilities regarding deferred income taxes	23.000	17.000	7.040	3.200	-
Initial liabilities regarding deferred income taxes	-	23.000	17.000	7.040	-
Adjustment of initial liabilities for deferred income taxes resulted from the decrease of tax rates (25%-16%=9%)	-	-	(6.120)	-	-
Expenses/(revenues) with deferred income taxes from recognition of temporary differences	23.000	(6.000)	(3.840)	(3.840)	(3.200)

* 480.000 – 2 x 10.000 =460.000

* *480.000 – 60.000 – 16.000 = 368.000*

As one can observe, in 2002, when the equipment is put in function, there is a taxable temporary difference, which results in the recognition of a deferred income tax liability in amount of 23,000 currency units.

23.000 6912 Expenses with deferred income taxes = 4412 Deferred income tax 23.000

This amount decreased by resuming it in revenues related to next periods, when the value of the asset (equipment) is gradually recovered by means of amortization, for instance in 2003.

6.000 4412 Deferred income tax = 791 Revenues from deferred income taxes 6.000

At the end of 2004, the changes in the tax provisions generated an adjustment of liabilities regarding deferred income taxes, due to the change of tax rates from 25% to 16%. The total effect was of 9,960 currency units, which we can divide in the effect of the changes in the taxable temporary differences, of 3,840 currency units (68,000 currency units – 44,000 currency units = 22,000 currency units x 16% = 3,840 currency units) and the effect exclusively owed to the change of tax rates, of 68,000 (25%-16%) = 6,120 currency units.

9.960 4412 Deferred income tax = 791 Revenues from deferred income tax 9.960

Assuming that the company switched to OMFP 94 in 2003, it should have restated the financial statements for the financial year ended as of 31 December 2002, when it reported according to OMFP 306, and when the „income tax savings" were recognised as other reserves (# 1068 Other reserves). Practically, this should have affected own capitals by transferring the „income tax savings" from reserves to liabilities regarding deferred income taxes (an amount of 23,000 currency units).

23.000 1068 Other reserves / separate analytic = 4412 Deferred income tax 23.000

The accounting regulation applicable from 1 January 2006, respectively Order of the Minister of Public Finance no. 1752/2005 regarding approval of accounting regulations harmonised with the European Directives[306] (*OMFP 1752*), gives up the idea of „deferred income tax" and introduces the idea of „provisions for taxes" (*1516 Provisions for taxes*). This account takes over the liabilities regarding deferred income tax. However, *OMFP 1752* proved to be very prudent in respect to receivables for deferred income tax. It no longer contains provisions regarding this economic category, and when the balances of accounts in the trial balance as of 31 December 2005 were transferred to the new chart of accounts, the debit balance of account *4412 Deferred income tax* was allocated to account *1176 Retained earnings resulted from transition to accounting regulations harmonised with the 4th Directive of the European Union*.

The aspects presented above show a fairly interesting development of the approach of passive deferred income tax in Romania. This means that liabilities (the company's current liabilities, resulting from past events; through their settlement the company expects a resources outflow with economic benefits), respectively provisions (debts due or with an uncertain value) are transferred to own capitals (residual interest of shareholders in the company's assets after deducting its liabilities), according to the applied accounting regulation, respectively Order of the Minister of Finance no. 306/2002 regarding approval of simplified accounting regulations harmonised with the European Directives, Order of the Minister of Public Finance no. 94/2001 regarding harmonisation of Romanian accounting regulations with the requirements of the 4th Directive of the European Union and of the International Accounting Standards or Order of the Minister of Public Finance no. 1752/2005 regarding approval of accounting regulations harmonised the European Directives.

Although the 4th Directive of the European Union no. 78/660/EEC regarding yearly accounts of certain types of companies was amended in order to comply with the International Financial Reporting Standards, there are still many problems to be discussed. However, in the near future, the Romanian accounting regulations will „dance" in the spirit of the European regulation, with its performances and imperfections.

In respect to *IAS 12 – Income taxes*, although its application would improve the accurate reporting of expenses/revenues regarding income taxes (i.e. expenses with income taxes are better „correlated" with accounting profits), technically speaking, the functioning mechanism of deferred income tax liabilities is similar to that of provisions for risks and expenses, and, therefore, there should be no significant perception difficulties. However, we recommend granting an increased attention to the economic-financial analysis of financial statements.

The costs are registred in an accounting system in order to help managers in process of taking the various decisions. The costs objects (products and sections) illustrate two goals of internal book-keeping administration, thus: informations supply for plann and control and compute of products cost. In the system of costs book-keeping and calculation on production commands, the object cost is illustrated by one or many various units from a product or a service, named production command. In order to compute costs on production commands is used the effective costs method, which use effectives quotations for alloting the indirect costs and normal costs method, which used budgeting quotations in order to allot the indirect costs; the direct cost are assigned to the commands in the same manner. The costs calculation on commnands is useful in some services companies, such as expert book-keeping and consulting firms, advertising firms, car fixing workshops or hospitals.

Keywords: costs objects, indirect costs, direct cost, effectives quotations, budgeting quotations

The calculation on production commands

In order to compute costs on production commands is used the effective costs method and normal costs method.

The effective costs method is a calculation method based on production commands which use the effective costs in order to establish the cost of various commands. Acordingly to this method, the direct costs are alloting to cost object by multiply the unit effective quotations of direct cost with effective quantities of production factors having direct cost and indirect cost are allotted to cost object based on the effective quotations of allocation for indirect costs, multiply with effective quantities of allocation cost's bases.

The computation of assigned costs alloted to a production, trade or specific services command, follows these phases:

- Identify the command which represents the choosen cost object(for example an equipment manufacture);
- Identify the direct costs of command (for example: the cost of direct raw substances and direct production work);
- Choosing of allot bases for indirect costs on the command (for example: the effective quantity of direct labour hours, hours-machine);
- Identify the indirect costs affiliated to every allocate base, named total/general production expenses(for example: the electric power costs, heating costs, repairs costs, surveillance costs);
- Calculation of unit alloting quotation of indirect costs on command(of choosen alloting base unit qoutation), thus:

$$\textit{The effectiv quotation for allocate the indirect costs} = \frac{\textit{The effective total } \mathrm{costs} \textit{ from indirect } \mathrm{costs} \textit{ plot}}{\textit{The effective total quantities from allocate } \mathrm{costs} \textit{ base}}$$

- Calculation of indirect costs allocated to command:

The indirect cost of command =

= The effective allocate quotation of indirect costs x The effective quantities of costs allocated bases

- Total command cost calculation by adding all the direct and indirect cost allocated and distributed to command.

Based on the achieved result, the calculation system of effective costs illustrates an abolute gross margin and a percentage gross margin, in order to compare the efficiency of various production commnands, to determine why some commands have a low efficiency degree and to proceed to future improvements.

The normal costs mehod is a calculation costs method in which the direct costs are assigned to cost object by multiply the unit effective quotations of direct costs with effective quantities of product factors with direct cost and indirect costs are allocated on cost object, based on budget quotations of indirect costs, multiply by effective quantities of alloting costs bases.

If we use the previous phases, could illustrate the normal costs method in this manner:

- Identify the command which represents the choosen cost object (for example an equipment manufacture);
- Identifify the direct costs of command (for example: the cost of direct raw substances and labour of production);
- The choosing process of allocation bases for indirect costs of command (for example:the budget quantity of direct labour hours, machine-hours);
- Identify the indirect costs associated to every distribution base, named general production expenses (for example: the electric power costs, heating costs, repairs costs, surveillance costs);
- Calculation of unit alloting quotation of indirect costs on command(of choosen alloting base unit qoutation), thus:

:

$$\text{\textit{The budget quotation for allocate the indirect costs}} = \frac{\textit{The budget total } \cos\textit{ts from indirect } \cos\textit{ts plot}}{\textit{The budget total quantities from allocate } \cos\textit{ts base}}$$

6

o C

- Calculation of indirect costs allocated to command:

The indirect cost of command =

= The budget allocate quotation of indirect costs x The effective quantities of costs allocated bases

- Total command cost calculation by adding all the direct and indirect cost allocated and distributed to command.

By comparison the two methods it cab be noticed that, the production cost of command depends on the allocated base used and the value of distribution quotations of indirect costs.

Managers and book-keeping persons collect the information which follow to be registred in evidence and calculation costs system through the *justificatory documents*. In calculation system costs based on production commands are used the following justificatory documents:

- *cost centralizing on production command, named also the calculation costs command memorandum slip*, in which are noticed and gathered all the alloted costs, distributed to a specific command, from the moment of starting production;
- *consumption raw materials bill*, which contains informations related to consumption of direct raw materials by proceeding a specific production command in a specific unit. By adding the cost derived from consumption raw materials bill it is obtaining the effective total cost of raw materials, writen in command production costs centralizing;
- work time evidence bill, which contains informations related to work time consumption in order to execute a specific production command from a specific section.

As a habit, the information gathered from commands costs centralizing are finding again in an analytic record/register. Syntetic account „Goods in progress” from the General Ledger reflects the bounded totals by all unfinish commands, taken from these centralizings or analytic on various commands account bills.

The analytic bills in order to evidence the commands costs and the syntetic account „Goods in progress" registered all the commands costs from starting moment until to completion moment.

The companies pay a lot of attention to justificatory documents corectness, thank to the fact that d commands costs calculation bills fiability depends on informations related to the production factors used.

In many evidence and costs calculations systems doesn't extant anything else except the justificatory documents on computers. The code bars and other methods to information recording in real time decrease the human intervention and make easier the process to obtain a high degree of exactness for dates related to raw materials consumption and work on production commands. The modern informative technologies supply fast and exact information to managers, regarding the products costs, making easier the adminstration and production commands control.

The indirect budget costs regularized at the exercise's end

Using the method of normal costs presents the advantage that we are able to distribute to indirect costs to individually method in a continous mannerand to right time, not only to the end of accounting exercise,when we know the effective level of costs.The method's disadvantage is given by the inexact budget quotation, due the fact that is based on estimations made since 12 months before proceeding of effective expences made; to year's end, we can appreciate that the indirect costs sum disitributed is different by the effective indirect costs sustained by the company.

The underneath-distributed indirect costs appear when the indirect distributed costs sum for an accounting exercise is lower then the effective abide costs sum. *The super-distributed indirect costs* apear when the indirect distributed costs sum in the frame of an accounting exercise is higher then the effective abide/support costs sum.

The underneath-distributed indirect costs (super-distributed) =

Indirect effective costs – Indirect distributed costs

Accounting regularize from exercise's end are recorded accordingly to the following accounting major methods: the adjust distribution quotation method, the proportional repeat distribution method and the method to transfer entirely on expenses in the inventory account „Sold goods cost".

The adjust distribution quotation method computes again all the accounting articles related to general expenses recorded in the General Ledger and in analytic evidences, using the effective quotations of costs distribution replacing the budget quotations.To year's end are made the following phases:

- is calculate the effective distribution indirect costs quotation;
- is calculate again the indirect costs distributed to every command during the year, by using the effective distribution quotation (replacing the budgetone);
- is registred the accounting articles of exercise closing;

As result, each analytic evidence command costs bill and the cost registred on the finish goods, also the final account balances of syntetic inventory accounts „Goods in process", „Finished goods" and „Sold goods cost", illustrates exactly the indirect costs abide by the company. The general adopt of accounting systems on computer decreased the cost related to using the method of distribution quotation adjust.

The proportional revised distribution divides the general expenses sum of underneath-distributed or super-distributed between the final account balance of inventory accounts „Goods in process", „Finished goods"", and „Sold goods cost". Due the fact that to raw materials stocks are not allot production general expenses, this inventory account is not included in proportional repeat distribution.

By using this method are obtained the same final accounting balances of inventory accounts from the General Ledger such as the account balances obtained through the adjust distribution quotation method only in case that the ratio of general production expenses in total costs is teh same for all three accounts.

The proportional revised distribution based on final inventory balance accounts is often used esed, beeing a method less complex which approximate the results achieved by using the shares of internal distribution costs.

The method to transfer entirely on expenses in the inventory account „Sold goods cost". In this case, the total sum of underneath-distributed or super-distributed general expenses is recorded in balance account of the inventory account „Sold good costs" from the year in progress. This method is the easiest manner to regularize the general production expenses underneath-distributed or super-distributed.

Acoordingly to the manner to use the resulted informations, the managers choose the right method, thus:

- if they intent to realize the most elaborated accounting evidences of costs for every command, then is recommended the adjust distribution quotation method;
- if the managers goal is limiting just to present the exact dates regarding the stocks and sold goods costs in financial situations, then is recommended to use proportional revised distribution based on general production expenses distributed from final accounting balances method, due the fact that this method adjusts the accounting balances to the level that would have been registred if it had been used the effective costs method.

Abstract: The character of social science, acquired by accountancy, correlated with the major mutations that were produced in the plane of the normalization and the assure of the convergence in the field, make from what we call now the accounting practice more than a simple application of a specific methodology. Modern accountancy represents not only an instrument through which it is assured the realization of the function of information and assistance of the decisional process, but also, in the actual context, having in mind the products that it provides, and the shape that it takes today, must be regarded as an important factor of influence of the economical-social environment.

Key words: accountancy, science, informatization, professional reasoning, evolution.

Introduction

Accountancy, in its evolutional way, had to answer to the bigger and more diversified demands of the economical activity that imposed to it shapes the more developed as its application field became vaster. “Scrittura doppia” evolved from the simple, clear and precise norms, respected by the merchants in Venice, to the classical shape of the accountancy in double entry, as echo to the necessities of the practical life. Accountancy existed and was constantly perfectioned in all social orders so that it many answer to the informational necessities of the economical lives. Like other scientifically disciplines, accountancy has know various development stages, and the research and the knowledge and the through study of the fundamental concepts.

References concerning the evolution of the accountancy’s role

From high degree practical activity, the knowledge’s of which were empirically acquired, through the successive elimination of the error, accountancy became a scientifically discipline because the increase of its decisional role imposed the systematization of the knowledge’s applied in practice. Besides, this really the reason why it was necessary that the accounting practices be fundamented on an accounting theory and on a conceptual basis, the research starting to play a determinant role in this sense.

The accreditation of accountancy as scientifically discipline is far from being finalized because the opinions referring to this subject are very diverse, starting from the total rejection of accountancy as science, passing then through the stage of science in the “adolescence” phase, so that other authors consider it a “scientifically mature discipline”.

The essay of establishing the status of accountancy is hurting, firstly, to the diversity of the approaches connected to this problem. The definitions, given to accountancy, differ very much both in time and in space, so that at present we don’t identify any consensus in what concerns this subject, that’s why, for the characterization of this discipline, there are proposed a multiplicity of variants, from which we remember the most important: art, technique, informational system, language, social game, science.

Without proposing to make an analysis of the kind of contradictory character of these terms, we will try to make a characterization of accountancy through the angle of the role that it has in sustaining the process of adopting decisions within an economical entity.

Having in mind the emphasized facets of accountancy in the specialty literature (6), and also the evolution in time of the solutions proposed for its definition, it could be realized an order of the explicative models in three main categories:

- accountancy as measurement instrument;

- accountancy as informing instrument;
- accountancy as instrument of social brokerage.

As measurement instrument, accountancy is approached as an activity that has as purpose the reflecting of the economical activity of the enterprise. Viewed in this context, accountancy is especially assimilated to an art of registering or to a technique of administration, points of view that, in our opinion, have a limited character, because reduce is role only to accounting registering.

The approach of accountancy **as informing instrument** coincided to its definition as informational system, represented by "an ensemble of elements (human and material resources) that allow to collection, the processing, the warehousing and the communication of information, in view of talking decisions" (3).

As it is observed, accountancy is no more regarded exclusively as an instrument of monetary quantification of the economical reality, but as a system that has as purpose the providing of information for taking decisions, the representation of reality not being a purpose in itself, but being subordinated to a new concept that aims for the satisfaction for the informational needs. Accountancy continues to accomplish its measurement function, but is subordinated to a purpose, fact that emphasizes new dimensions, through the taking into consideration of the users of information that it produces and also of their needs.

The informational activities, specific to the accounting field, are those that concern the production and the use of the accounting information and they refer to actions that aim the creation, the collection, the warehousing, the processing of data and then the broadcasting of the information. These activities suppose the making of some operations of registering and calculating, and also of actions of analysis, interpretation, grouping, synthesis and use of information for taking decisions.

The perspective on accountancy being extended, through the taking into consideration of the users of the information offered by it, it was emphasized its **function of communication**, because the providing of information to the different categories of users in view of taking decisions is not, in substance, but a communication activity.

In the case of accountancy, we can speak of an accounting or financial communication, within which the connection is established between the enter prize, as transmitter (producer) of information and all those interested in their use, as beneficiaries or receivers of information. The main way of transmitting the accountancy's product is represented by the annual financial situations, the issued information being obtained following the representation of the economical reality of the enterprise through the use of a specialized language, of some specific rules and principles.

So, the accounting information is built using a specific language, certain rules that allow the codification and the decodification of the represented data, all these assuring the ordered and intelligible representation of the economical reality. The usefulness of the accounting information within the financial communication is proven in the conditions in which the receivers use it to understand the economical reality and to take decisions.

Thus it appeared the idea of defining accountancy as a "formalized language", being generically named a "language of businesses", characterized through three dimensions (2):

- the accounting syntax, represented by the ensemble of rules and procedures that must be followed for the registering of transactions and the creating of accounting synthesis documents, starting from the symbols that form the accounting vocabulary – in this case the emphasis put on the function of representing the economical reality;
- the semantics of the accounting language that treats the significance of the signals transmitted by accountancy – with emphasis on the informing function;
- the pragmatic aspect that refers to the communication of accounting information and the way of using it by different users – again the emphasis is put on the informing function.

The description of accountancy in this shape is characteristic to the accounting present thinking, this change of perspective affecting both the external accounting report – the normalization through the conceptual accounting frame defines the purpose of the financial situations as being the providing of information for taking decisions, and the internal one – from an accounting of costs becoming a managerial one, the emphasis being put again on its role of providing information to the manager for adopting decisions.

Accountancy approached as informing instrument, although it surpasses, as explicative value, the technical vision on accountancy, still has certain flaws, because it doesn't succeed in offering a complete image, not taking into consideration a series of important factors. In these conditions, there appeared the necessity of enlarging the perspective on accountancy to be also emphasized other facets of it, appearing the idea according to which accountancy is **an instrument of social brokerage**.

In this point of view, the measurement and the informing functions are passed in a second plan, and in the first plan are emphasized the consequences that the accounting information has on the social environment. In practice, there is made conscious the fact that the choice and the application of a certain accounting politics have especially important consequences on the redistribution of wealth and the risks between the different participants to the economical life. In our opinion, the social role of accountancy must be considered of priority, because it offers the possibility of establishing criteria according to which it is realized the reflection of reality and the informing of different categories of users, with the purpose of obtaining the desired economical-social effects.

The obtaining of the accounting information takes place as following the data processing and interpreting, through the use of some specific concepts and principles, being applied more methods and politics in view of reflecting the economical reality of and entity and the offering of the necessary information to those who take decisions or are interested in the respective entity.

The concept of modernism in an accounting sense

During its evolution, accountancy had to find solutions and to adapt itself to economical reality, fact that led to the use of some notions and accounting terminology, as to the appearance and the application of rules and conventions in view of obtaining information. Thus, accountancy has become today a complex technique of registering and reflecting the economical-financial reality of an entity, an informing system adapted to the users' needs, and instrument of administration and communication that assures the integration and the dialogue of the enterprise with its external environment (4).

The modern enterprise and its accounting informational system constitutes subjects that are intensely debated in the specialty literature, because there are distinguished two opposite directions of action that aim, on the one hand, at the desire of the enterprise to rally to the current of informational globalization and, on the other hand, to the restrictive demands imposed by the science and the practice in the field.

At a first view, it may be thought that many of the charges and the functions of classical accountancy were transferred to the informational system, arriving, at an end, to a so-called modern informational accounting system. Still, we consider as being relevant the opinion according to which barely now there can be made a clear distinction between the part of accounting technique and the one of accounting science, because now there can be let to the computer all aspects that make from accountancy a technique, through the development of some informational programmes that comprise all rules, procedures, methodologies and techniques necessary to the obtaining of the financial situations and implicitly to the information about an economical entity, so the human factor may occupy himself to its scientifically side (5).

In the situation in which we assist, at the present moment, to an emphasized information of accountancy, there appears, inevitably, the question in what measure the accountant is still given the chance to reason or, in other words, how much from the work made by the accountant is technical, imposed by the application of some algorithms specific to the used informational applications and how much represents the professional reasoning. In our opinion, the actual software products used in the financial-accounting field, through the way in which they are conceived, although they induce a certain degree of automatism in making the specific works, doesn't put aside what we call professional reasoning.

Besides, we think that the approach of the concept of modernism in accountancy doesn't have to be realized only through the report to the aspects that concern the information of this science, as following the use of the modern equipments of gathering and data processing, and also of the specialized informational applications. This is the reason why we consider that the actual tendencies, manifested at international level in the field of accountancy, under the impulse of the globalization phenomenon, are the expression of some profound changes in tight correlation with the economical and political evolutions that we notice regional and planetary level. So, we think that between the information of accountancy and the necessity of using a common language in this field, at word level, through the appeal to specialized standards for accountancy, there is a direct connection. Modern accountancy is also characterized through the fact that the politics applied in this field tend to become more and more complex, which imposes that, on the one hand, the appeal to the professional reasoning become an all-important condition and, on the other hand, the use of modern equipments and irreplaceable specialized soft wares.

In mustn't be omitted the fact that the development of accountancy, from all points of view, was determined and accompanied the ample process of development of the human society. In evolution of the informing needs, imposed by the evolution of the natural, economical and social systems, determined the development of the informational system and, implicitly, of its accounting component. In these conditions, the demand of accounting information has continuously changed its angle of interest, at present this aiming, more and more, for the spectrum of the events and phenomena about to manifest themselves and their predictable evolution, the user's urgent needs rather finding their answer in the future cash flows than in the accounting profit of this period.

In our opinion, the study of the concept of modernism in the field of accountancy, in the actual moment, imposes the analysis of an accumulation of elements, of which we consider that the most significant refer to the implementation of the informational technology in the context of the development of a complex process of reglementation in the financial-accounting field, the assurance of monitoring/convergence of accountancy at world level, the re-consideration of the role and the importance of the accounting profession, and also the influence exercised by accountancy on the social environment.

We consider that the process of financial communication and the tendencies manifested in this field at international level, under the impulse of the globalization phenomenon, represent dominant characteristics of modern accountancy. In the year 1973, there were put the bases of the International Commission of Accounting Norms – IASC (the actual IASB), without anyone could, at that date, to estimate the particular impact of this organism and of the norms that it created on what we call now financial communication through a common accounting language. The evolutions that took place in the plan of the international accounting normalization can be consider the more remarkable if we take into consideration the conceptual arguments that existed in the field of financial communication at international level (through the system of norms IAS – IFRS) and, respectively, at the level of the European Community (through directives), arguments that at present we can say that, in a certain measure, attenuated as following the process of re-consideration that the European accounting directions pass through. We have in mind the fact that the states members of the European Union have decided the implementation of the International Standards of Financial Reporting, according to the stipulations of the Regulation (CE) no. 1606/2002 of the European Parliament and of the Council from the 19th of July 2002 concerning the application of the international accounting standard. According to this regulation, the states members apply IFRS in the consolidated financial situations, précising that certain states in the Union allowed the application of the international norms also in the annual financial situations (individual) of certain types of entities but, most countries have chosen the maintaining of national accounting standards in view of creating the annual financial situations the information of which are used for taxation necessities.

In the context of the expressed ideas, we formulate few questions that, in our opinion, can constitute the basis of a discussion having as theme the concept of modernism in the field of accountancy:

- Could be considered this state of fact the beginning of the end in the case of some tight delimitation between the two big accounting orientations?
- For how long we would be able to speak of the accounting model of the continental Europe and the Anglo-Saxon model, in the conditions in which, today, the word of order is "globalization"?

In a futuristic vision and in the context of what we presented so far we think that the approach of the idea of modernism in the field of accountancy will reveal, in a not so far future, the breaking of the informational barriers manifested at present through the existence of most of accounting references.

Conclusions

Having in mind the role of social brokerage instrument that accountancy fulfills, it can be said that this influences, in its turn, the evolution of society. Accountancy does more than facilitating the application of the economical analysis. The aspects connected to measurement can bring into discussion the credibility of the data developed by accountancy, thus emphasizing the relation between the micro-economical process and the instrument that allows its functioning.

The character of social science, acquired by accountancy, correlated to the major mutations that were produced in the normalization and the convergence in the field what we now call, the accounting practice more than a simple application of a specific methodology. Modern accountancy represents not only an instrument through which there is assured the realization of the informing and assisting function of the decisional process but, in the actual context, having in mind the products that it provides, also the form that these take today, it must be viewed as in important factor of influence of the economical-social environment.

ABSTRACT: Enterprises frequently expend resources, or incur liabilities, on the acquisition, development, maintenance or enhancement of intangible resources such as, scientific or technical knowledge, design and implementation of new processes or systems, licences, intellectual property, market knowledge and trade-works (including brand names and publishing titles). Examples of items encompassed software, patents, copyrights motion picture films, customer lists, fishing licence import quotas franchises customer or supplier relationship, customer loyalty market shore and marketing rights.

Keywords: financial reporting, intangible assets, just value

Introduction

For financial reporting at the just value of the non-current intangible assets and not only, an important role is held by the economic information which is essential for the decision making of the users of financial information (managers, investors, creditors etc.) . It can be said that the market for accounting information has an increasingly international quality because its users are more and more pretentious, and for the accounting profession this is a challenge.

The just value is a highly debated concept, being a consequence of a principle: true and fair value. No one has interpreted the just value as the faithful value, being translated into different languages as: just (juste) in French; real (reele) in Dutch; the value attributable (beizulengender zeitmert) in German; fair value without any translation in Italian.

According to the International Standards of Financial Reporting the just value is defined as being "the sum at which an asset can be transacted or a liability can be discounted,

willingly, between parts acquainted with the subject, in a transaction where the price is determined objectively" [1].

The just value contains the market value and is prone to cover all the values born out of the estimations based on economic calculations. It is opposed to the principle of prudence and of evaluation at the historic cost. The just value presents a series of qualities such as: comparability, restricted complexity and neutrality.

When there is not sufficient market information at the evaluation data as a result of the nonexistence of an active market, instead of the market value, for the assets outside exploitation a net replacement cost will be determined (NRC). For the estimation of the just value we consider we will be needing the aid of some informational sources such as:

a) IAS 38 – current intangible assets (Active necorporale);
b) IFRS 3 – entities' combination (Combinări de întreprinderi);
c) IAS 36 – depreciation of assets (Deprecierea activelor);
d) European Directives – in what measure the just value is accounted for;

e) IVS (International Valuation Standards) treatments recommended for the evaluation destined for financial reporting, especially GN 4-Evaluation of intangible assets.

The accounting treatment and the manner in which the financial information regarding non

current intangible assets is presented are included in IAS 38 „Intangible assets". A non-current intangible asset is defined as a non-monetary non-current asset without material substance.

According to IAS "Intangible assets", a non-current asset fulfills the criteria of identification from the definition of a non-current intangible asset when „it is separated, that is it can be separated or divided by the entity and sold, transferred, authorized, rented or exchanged, either individually or together with a contract , an asset or a correspondent liability; or it comes from contractual rights or of any other legal provenience, no matter if those rights are transferable or separable from the entity or from other rights or obligations"[1].

Evaluation of intangible assets

Economic entities frequently invest in resources or attract liabilities for the acquisition, development , maintenance or extinction of intangible resources such as scientific or technical knowledge, designing and implementing new technologies, licenses, intellectual property, software, patents, copyright, trademarks. But not all the elements previously enumerated satisfy the definition of a non-current intangible asset, respectively the recognizable qualities, the control over a resource and the existence of future benefits. If an element from an applicability area of this standard does not comply to the definition of the non-current intangible asset, then the expense for obtaining or internally generating it is recognised as cost in the moment of its occurence. If that certain element is obtained through a combination of entities, it represents a part of the commercial fund recognised at the date of the acquisition.

As about the recognition of the current intangible assets - it is made only when certain recognition criteria are fulfilled:

- they are likely to generate future economic benefit
- the cost of the current asset can be credibly evaluated.

Starting with the second financial exercise, current intangible assets can be evaluated separately in order to be recognised in financial situations presenting a series of particularities such as:

1. Determining the total value of the current intangible assets – residual extent
2. Determining the report between the value of the invested capital (VIC) and that of the invested net cash-flow (INCF)
3. The order of the evaluation of separate current intangible assets
4. The addition of the fiscal benefit resulting from the amortisation of separate current intangible assets
5. Other particularities
6. Recognised methods of evaluation

The fixing of the current intangible assets' residual extent's total value, typical of the acquisitions of entities, is made through the following series of calculus:

To the price paid for the acquisition of all current assets plus the overtaken short-term debts, we add the overtaken long-term loans and thus obtain the corrected acquisition price. Out of this price we substract the just value of all current assets found in the balance (except for that of current intangible assets), thus obtaining the total value of current intangible assets.

The evaluation of separate current intangible assets is made in a certain order, and the main criterium is the credibility degree of the evaluation hypothesis:

1. Computer programmes
2. Internally applied intervention patents
3. Products' marks
4. Instructed labour force
5. Licenses

6. Unpatented technology
7. Unfinished research-development projects
8. Commercial fund

The evaluation of current intangible assets is made at their just value which, according to IFRS 2007, is a concept similar with that of market value. An intangible element, reported as a current expenditure, cannot be later on recognised as a part of a current intangible asset's cost. Following expenditures, performed with a current intangible asset, will increase the cost of that current intangible asset only when those expenditures allow the current intangible asset to generate future economic benefits that surpass the initially predicted performance and if they can be credibly evaluated. We must mention that set-up costs, professional development costs, publicity and promotion costs, moving or activity reorganising costs and internally generated commercial funds are not admitted as separate current intangible assets.

IFRS insists that, in case of entity combination, the owner should recognise as many separate current intangible assets as possible so as to ensure a more precise reflection of the entities' patrimony. Experts should especially pay attention to the current intangible asset called **"instructed labour force"** which cannot be admitted as a separate current intangible asset yet it is separately evaluated so as to ensure the accuracy of the evaluation techniques of the other separate current intangible assets. The explanation is that, due to the entities' incapacity of controlling the benefits brought about by such a current intangible asset, the value of the instructed labour force is included in the commercial fund when transposed in the accounting balance.

Identifiable current intangible assets, bought as a part of entities' combination, is registered at the just value of the acquisition date provided it fulfills the recognition criteria. The most credible estimation of a current intangible asset's just value is the acquisition price of other similar or identical current intangible assets from an active market. IAS 38 also mentions the possibility of estimating the current intangible assets' just value , current intangible assets that were obtained as a result of entities' combination, through indirect estimation techniques, which consist of

a) either some multiplying coefficients used on some forms of income
b) either the use of net due economic actualisation method
c) either the actualisation of the following net cash-flow that might be generated by a current intangible asset.

As about the evaluation methods used for the current intangible assets, they present a series of particularities, such as:

- In case the current intangible asset is evaluated with respect to its costs (for instance a computer programme), we must take into account the amount we save when the profit tax is levied (fiscal benefit)
- When two or three landings to value are used, the result is that obtained from the most credible landing, without making the arithmetical mean.
- If two procedures of the same evaluation method are used and we obtain two different but close values, we may suggest as a final value the arithmetical mean of the two results
- The result that relies on information collected directly from the market is always the most credible one.

The landings in the evaluation of current intangible assets are:

a) Landing through sales' comparison
b) Landing through income
c) Landing through cost.

Landing through sales' comparison

The determination of a current intangible asset's just / market value through this approach refers to:

- transaction prices of identical or similar current intangible assets, or
- through "evaluation multiples" implied in the transaction price of identical or similar current intangible assets.

An “evaluation multiple” is a multiplying coefficient computed as a report between the transaction price of a current intangible asset and a financial indicator such as the business figure generated by the current intangible asset, the profit generated by the current intangible asset after the deduction of the expenditures related to the use of the current intangible asset. These indicators may be from this year, the previous or the following one. The evaluation multiple is then applied to the financial indicator of the evaluated current intangible asset.

The market current intangible assets are transacted on may be:

1. **an** extremely small **active market** [2]**;** in IAS 38, fishing and cab licenses are called non-current intangible assets. In this particular case, when current intangible assets are identical, their transaction prices may be adjusted only so as to reflect the type of transaction and the shifting of prices between the moment of the identical current intangible assets’ transaction and that of the evaluation of the current intangible assets.

2. **an inactive market** on which similar current intangible assets are transacted. In this case either transaction price or evaluation multiples’ adjustments are required.

As a result of the reduced number of transactions with current intangible assets on an inactive market, the adjustments of the similar current intangible assets’ prices or multiples is extremely hard to justify and as a result the setting of the just/market values through this landing is quite rare. We notice the IAR 38’s firm position, stating that the current intangible assets’ reevaluation is only allowed for those which appear on an active market.

Landing through income

The value of a current intangible asset using this landing equals the updated value of the profit, of the cash-flow or of the savings that could be obtained by the participants in the market, owners of these current intangible assets. The income flow that may be attributed to a current intangible asset could come from several sources, from all the owner of the entity’s activity areas.

There are three methods used for the landing through income of a current intangible asset:

a) Economy method / due exemption method – primary method used for the evaluation of products’ marks, invention patents, franchises, licenses and technical documentations. Its credibility degree is high as it relies on due rates found on the market for similar current intangible assets.

b) Supplementary profit method (economic profit) – consists of the estimation and update or capitalization of the profit or of the supplementary cash-flow that may be obtained by the participants in the market that use a current intangible asset, besides those obtainable without the use of that current intangible asset.

c) Net profit method / exceeding periodical net cash-flow method is constructed on the prevision of the net cash-flow from that entity’s exploitation who uses a current intangible asset, out of which we substract the cash-flow allocated to ensuring the profitableness demanded by the other current assets that contribute to generating the entity’s net total cash-flow.

Landing through replacement cost

The essence of this landing consists of determining the cost of an identical or potentially similar current intangible asset: either by identifying the replacement price of an identical or similar current intangible asset, or by determining the internal generation cost of a similar or identical current asset. The evaluated current intangible asset needs to be transactionable at a price that is equal with its replacement cost in order for the result of this method to reflect the just/market value. The landing through net replacement cost is the only method registered through landing through cost just as the International Standard of Evaluation GH8 demands (the net replacement cost for financial reporting).

Landing through cost has greatest relevance for the evaluation of:

- instructed labour force
- computer programmes
- distribution system

However, several prestigious authors also sustain the possibility of applying the cost landing for the evaluation of other current intangible assets such as marks, invention patents, technological documents.

In order to highlight the relevance of this approach we propose a case study regarding a separately acquired invention patent.

Case study

An economical entity has bought from a foreign invention patent owner a patent for a procedure, for 200,000 Euro. The seller made a discount of 5% of the selling price of the invention patent. Customs duties rise to 20,000 Euro. You are asked to determine the cost at which the patent will be accounted in the initial accounting balance.

Solution: the cost of the patent = 200,000 – (5%*200,000) + 20,000 + 5,000 = 165,000 Euro, and this value will be initially written in the balance.

The values determined from the just evaluation are economical values found through expertise and diagnostic by professionals in the field.

The dependency between the stock exchange and the reevaluation reserves has been proven to take place by studies performed in the domain of evaluation through tests baring statistical significance on efficient markets. This dependency appears as a result of the use of the just value for the reevaluation of non-current assets.

The quality of the accounting information depends on the way the just value is estimated through the credibility and neutrality criteria. Professional experts have a significant role in the process of estimation of the just value, when evaluating the current assets. One of the requirements of some useful services is the proper knowledge and interpretation of the International Evaluation Standards (IVS), and of those of accounting (IFRS), as well as national accounting norms.

a) homogonous transaction elements

b) the permanent existence on the market of a considerable number of interested buyers and sellers

c) the availability of prices to the public.

ASPECTS REGARDING THE APPLICATION OF DIRECT-COSTING IN TAKING THE MANAGERIAL DECISIONS

Abstract: Direct-costing represents a method of calculation which, although can not be used in financial reporting, represents a very strong instrument of analysis within reach of enterprise's management. The method direct-costing requires the delimitation between the variable and fixed costs and including in the cost of production of the variable costs, the fixed costs being considered costs of the period. Another important aspect is the difference between the methods of absorbent costs and the method direct costing. The making of rational decisions that can permit the obtaining of optimum results can be made only if it is taken into account the correlation between the fixed costs, the variable costs, the volume of activity and the price of selling of the products, correlation given by the specific indicators of the method direct-costing.

Key-words: direct-costing, variable cost, fixed cost, cost of sub activity

Direct-costing represents a method of calculation which, although can not be used in financial reporting, represents a very strong instrument of analysis within reach of enterprise's management, because "the model direct-costing" is oriented to future; it permits the elaboration of some forecasts and simulations that emphasize the main factor of benefit or of lose of the enterprise: the volume of activity or the volume of sales (Nadia Albu, Catalin Albu, 2003).

Elaborated and applied by Jonathan N. Harris in the economic practice in U.S.A. in 1934 and later by G. Carter Harrison in 1935, the method direct costing was preluata and applied by a series of European countries, like Germany, France, England, Italy and others.

In the opinion of Robert W. Lentilhon, the method direct-costing determines a decrease of the value of the stock because the fixed costs are not taken into account at the calculation of the unitary cost of the product (Robert W. Lentilhon, 1964). The fixed costs are considered expenditures of the period. In the same time, R. Lee Brumet considers that the method direct-costing requires at first a study of the trends of cost and a separation of the fixed and variables elements (R. Lee Brumet, 1955). This study can be of incommensurable help in knowing the cost at all the levels of responsibility and in appreciating the complicated problems of planning and controlling the cost. Robert E. Seiler considers that direct-costing attributes to products only the variable costs and treats all fixed costs as costs of period (Robert E. Seiler, 1959). The variable costs will include only those that the enterprise considers that are occasioned by making the planned production.

Direct-costing can offer the manager of the enterprise information that has a special importance in taking decisions regarding the future activities. This method will offer a basis for the forecasts of the cost, for the study of the effects of planned changes in the volume of production, determined by the change of the economic conditions or some open actions of the management, such as price changes, the increase or decrease of costs, or special promoting activities.

The moment of sell is the most favorable for recognizing the revenue. In the case that sells are constant, the fixed total costs and the unitary variable costs will not change, and the volume of production will vary (James Don Edwards, 1958). If the price of selling is constant, in periods with small sells, the enterprise can obtain bigger profits, because when the level of activity increases, the unitary cost of production decreases, because the same value of fixed costs is apportioned to a bigger number of products obtained. This situation can appear if there is production on stock. In the periods with high sells, the enterprise obtains lower profits, because when the level of activity decreases, the unitary cost of production increases, because the same value of fixed costs is apportioned to a smaller number of products obtained. Thus, the total value of fixed costs imputed to a unit of product is inverse proportional to the quantities obtained. For eliminating the influence of the absorption of fixed costs by the complete costs and for an easier supervising of other causes of debates, it was elaborated the method of rational elaboration of fixed costs.

In order to establish the level of activity there can be taken into account the volume of production, the hours of functioning of equipments or the degree of using the capacities of production. There can be two types of activities, respectively capacities of production: the normal capacity of production and the real capacity of production.

The normal capacity of production represents the production estimated to be obtained in medium, over a certain number of periods, in normal conditions, taking into account the loss of capacity resulted out of the planned maintenance of the equipment.

The real level of the activity is represented by the production obtained and the normal level of activity is represented by the normal capacity of production.

If the level of the activity decreases comparatively to the normal level, the cost of production obtained will be more decreased than the real activities of the enterprise. Thus, it will appear a surplus of fixed costs that will remain unapportioned and that represent a “cost of sub activity”. In the oppose situation, there will appear costs apportioned in plus, named “prima of supra activity” or “gain of supra activity”. The cost of sub activity can be determined by the relation: Csact = Fixed costs x (1 – Real capacity/Normal capacity).

The method direct costing puts the accent on the promoting of sales. The difference between the price of sale of the product and the variable cost represents a margin of commercialization for recovering the fixed costs. The analysis will show the limit at which these costs can be covered from selling the products.

In essence, this method requires the net separation of the production costs and selling costs depending on their behavior towards the variation of the physic volume of production and sale in variable and fixed costs and taking into account at the calculation of the unitary cost of product only the variable costs. The fixed costs are deducted from the gross financial result of the enterprise.

An important aspect is the difference between the using of the method of absorbent costs and of the method direct-costing. At conceptual level, the justifying of using one of the two methods is based on the conception over the notion of asset. Thus, an asset represents a resource controlled b the enterprise, that comes from passed events and that is bearer of future economic advantages that must be benefice to the enterprise. This concept of future advantages is on the basis of the delimitation between the two methods of calculation of cost: the problem is the accuracy of capitalizing a part of the fixed production costs supported by the enterprise, under the form of recording in the assets (at stocks) the products made and not sold. The sustainers of using the method of absorbent costs consider that there is not anything wrong in delaying the recognition of a part of fixed costs by capitalization, because the stocks that had attached these costs are bearer of economic advantages benefic to the enterprise by obtaining some revenues; in plus, it would be as impossible the obtaining of production without employing the fixed production costs, as it was in the absence of supporting the variable costs, being necessary the affixation of the two categories of costs to the cost of stocks.

The sustainers of the method direct costing consider that a cost is bearer of future economic advantages only if it succeeds, by the employing in the current period, in avoiding the future supporting. There is 1judged the character of being benefic through the prism of future avoidance: any cost whose supporting in the current period does not keep down its supporting in the future periods can not be bearer of future advantages for the enterprise and it can not be capitalized (under the form of an asset). The supporting of some fixed production costs in the current exercise does not prevents the supporting of the same costs in the future periods; these costs do not accomplish the criterion of future avoidance of the cost and can not be recorded in the balance sheet. If the supporting of the cost will not influence in any way the ulterior supporting of the same cost, it is regarded as not having relevance through the prism of future events. This cost can not generate in any way a future advantage.

The so-called fixed costs of production do not accomplish the criterion of avoidance: the employment of such costs in a certain period will not eliminate its employment in the next exercise. Because of this fact, the fixed costs of a period can not be considered as significant for the future events, and will not bring further benefits or services. The sustainers of the method direct costing consider that any portion of the fixed production costs should not be reported in the balance sheet under the form of including in the value of the stocks.

Thus, the method of absorbent costs requires the calculation of cost of production as a sum of all the costs implied by this process and the appliance of the method direct-costing requires the imputation in the cost of those expenditures that vary direct proportional to the volume of production.

The arguments for this differential behavior applied to the variable and fixed costs are related to the consequences of using the method of absorbent costs over the determination of result, many authors proving, by practical examples, the difficulties of using this method. The most significant difficulty is that of anticipating the future profits by capitalizing a part of the fixed costs in the value of stocks, so the delaying of their recognition until the moment of selling. In the logic of direct costing, the fixed costs do not represent capitalized costs because they do not represent the consequence of unfolding the activity of production, being supported for maintaining the enterprise in a functional state. The delaying of recognizing these costs until the moment of recognizing the revenues obtained by selling the products (resulted from the worry of observing the principle of connecting the costs to the revenues) seem to falsify the result obtained, this being influenced more by the volume of production than the level of sales.

1The difference between the calculations of costs in the two methods can be exemplified as shown below:

There are known the following information:

Explanations	Bread of rye 500 g	Bread multicereals 500 g
Quantity (pieces)	14.000	13.000
Price of sale (lei/piece)	2,4	2,8
Direct materials (lei/piece)	1,4	1,6
Direct manpower (lei/piece)	0,3	0,4
Unitary variable cost (lei/piece)	1,7	2,0
Direct costs of capacity (variable) (lei)	6.000	8.500

Table 1. Initial information.

The fixed indirect costs are of 3.000 lei, the general costs of administration are of 500 lei and the costs of selling are of 300 lei.

During the period of administration there are sold 13.500 pieces of bread of rye and 12.600 pieces of bread multicereal. The work in progress at the end of the period of administration is of 500 pieces of bread of rye and 400 pieces of bread multicereals.

The basis of apportioning for the indirect costs is the direct manpower and for the costs of selling is the cost of production.

The calculation of the complete commercial cost can be showed as follows:

The method of absorbent costs	Bread of rye 500 g	Bread multicereals 500 g	Total
Sales	32.400	35.280	67.680
Direct materials	19.600	20.800	40.400
Direct manpower	4.200	5.200	9.400
Variable costs	23.800	26.000	49.800
Direct costs of capacity (variable)	6.000	8.500	14.500
Indirect costs of capacity (fixed)	1.344	1.656	3.000
Total costs	31.144	36.156	67.300
The work in progress at the end of period	1.110	1.112	2.222
Cost of production	30.034	35.044	65.078
General costs of administration	240,27	259,73	500
Costs of selling	150,17	149,83	300
Complete commercial cost	30.424,44	35.453,56	65.878
Gross result	1.975,56	- 173,56	1.802

Table 2. Calculation of costs in the method of absorbent costs. - lei -

The cost of work in progress at the end of period can be determined as follows:

- for Bread of rye: 500 pieces x (31.144 lei / 14.000 pieces) = 500 x 2,22 = 1.110 lei
- for Bread multicereals: 400 pieces x (36.156 lei / 13.000 pieces) = 400 x 2,78 = 1.112 lei

Advanced direct-costing	Bread of rye 500 g	Bread multicereals 500 g	Total
Sales	32.400	35.280	67.680
Direct materials	19.600	20.800	40.400
Direct manpower	4.200	5.200	9.400
Variable costs	23.800	26.000	49.800
Margin regarding the variable costs	8.600	9.280	17.880
Direct costs of capacity (variable)	6.000	8.500	14.500
The work in progress at the end of period	1.065	1.060	2.125
Cost of production	28.735	33.440	62.175
Contribution of covering	3.665	1.840	5.505
Indirect costs of capacity (fixed)	1.344	1.656	3.000
General costs of administration	229,88	270,12	500
Costs of selling	143,68	156,32	300
Complete commercial cost	30.452,56	35.522,44	65.975
Gross result	1.947,44	- 242,44	1.705

Table 3. Calculation of costs in the method direct-costing. - lei -

The contribution of covering is determined as a difference between the total sells and the cost of production.

The cost of the work in progress at the end of period can be determined as follows:

- for Bread of rye: 500 pieces x (29.800 lei / 14.000 pieces) = 500 x 2,13 = 1.065 lei
- for Bread multicereals: 400 pieces x (34.500 lei / 13.000 pieces) = 400 x 2,65 = 1.060 lei

We can see that in the two cases the gross result differs depending on the way of including the fixed costs in the cost of production and on the evaluation of the work in progress at the end of the period.

In order to eliminate the influence of fixed costs depending on the variation of the volume of activity, it can be used a "coefficient of rational imputation" (K_R). For a normal production of 28.500 pieces, the coefficient of rational imputation can be determined as follows:

$$K_R = \frac{Qr}{Qn} = \frac{26.100}{28.500} = 0{,}92$$

where: Qr = the real level of activity;

Qn = the normal level of activity.

The fixed costs that are taken into account are given by the relationship:

$Chf_i = Chf_r$ x K_R = 3.000 x 0,92 = 2.760 lei

where: Chf_i = fixed costs imputed;

Chf_r = real fixed costs.

It is calculated the difference to be imputed $D_{IR} = Chf - Chf_i$ = 3.000 – 2.760 = 240 lei.

In this case, there appears a cost of sub activity of 240 lei that can not be included in the cost of products, but it has to be reflected in the profit and loss account.

Based on these relationships, it can be determined the Cost of normal activity (C_{An}) or the rational cost:

a) The method of absorbent costs: $C_{An} = Chv + Chf_i$ = 62.878 + 2.760 = 65.638 lei
b) Direct-costing: $C_{An} = Chv + Chf_i$ = 62.975 + 2.760 = 65.735 lei

The making of rational decisions that can permit the obtaining of optimum results can be made only if it is taken into account the correlation between the fixed costs, the variable costs, the volume of activity and the price of selling of the products (Sorin Briciu, 2006). This correlation in the method direct-costing is expressed by using the following indicators:

1. The point of equilibrium (Pe) - is the point where the revenues cashed from the production sold cover all the variable costs of the production and the fixed costs of the period, so that the enterprise do not obtain any profit or losses. Any increase of the level of the production sold brings more revenue to the enterprise and any decrease of the volume of sales brings losses to the enterprise.

In the e1xample forementioned, when the enterprise obtains more products and is based on a certain structure of production, the point of equilibrium is calculated by taking as a base the medium gross contribution that is calculated as follows:

$$P_e = \frac{ChF}{\overline{c}_a} = \frac{3.000}{0{,}21} = 14.285{,}71 \text{ pieces}$$

$$\overline{c}_a = \frac{C_a}{\sum_{i=1}^{n} q_i} = \frac{5.505}{26.100} = 0{,}21$$

where: Ch F – fixed costs;

C_A – the total contribution of covering;

q_i – the quantity made and sold of each product.

The weight of Bread of rye in the total production obtained and sold: $\frac{13.500}{26.100} = 52\%$

The weight of Bread multicereals in the total production obtained and sold: $\frac{12.600}{26.100}$ = 48%

The point of equilibrium: - Bread of rye: 14.285,71 x 52% = 7.428,57 pieces

- Bread multicereals: 14.285,71 x 48% = 6.857,14 pieces

The point of equilibrium represents the quantity of product that the enterprise must make and sell for the purpose that the cashed revenue to cover the variable costs and the total fixed costs so that the profit or loss to be equal to zero.

2. *The factor of covering* (F_A) – is calculated by reporting the gross contribution to the volume of sales at price of selling, as follows:

$$F_A = \frac{C_a}{D} \times 100 = \frac{5.505}{67.680} = 8{,}13\%$$

where: F_A – factor of covering;

C_A – total contribution of covering;

D – volume of total sales at price of selling.

For Bread of rye: $F_A = \frac{3.665}{32.400} \times 100 = 11{,}31\%$

For Bread multicereals: $F_A = \frac{1.840}{35.280} \times 100 = 5{,}22\%$

This indicator shows how many percents of the volume of sales are necessary for covering the fixed costs and obtaining profit. The enterprises must orient their policy of fabrication and sell to the products with the highest factor of covering.

Knowing the factor of covering, it can be determined the volume of sale at the level of the point of equilibrium:

$$d = \frac{ChF}{F_A} = \frac{3.000}{0{,}0813} = 36.900 \text{ lei}$$

3. *The dynamic coefficient of safe* (Ks) – is calculated by reporting the difference between the total sales and the sales at the level of the point of equilibrium to the volume of the total sales and multiplying with 100:

$$K_S = \frac{D - d}{D} \times 100 = \frac{67.680 - 36.900}{67.680} = \frac{30.780}{67.680} = 45{,}48\%$$

This indicator shows how much can decrease the sales relatively for the enterprise to reach the point of equilibrium. Any decrease under this coefficient makes the enterprise to enter the area of losses.

4. *The interval of safe* (Is) – known under the name of distance or road of safe. This indicator is calculated in absolute figures as a difference between the volume of total sales and the volume of sales at the point of equilibrium:

I_S = D – d = 67.680 – 36.900 = 30.780 lei

This indicator shows how much can decrease the sales absolutely so that the enterprise will not enter the area of losses.

The appliance of the method direct costing has some limits, such as:

- the relativity of dividing the costs in variable and fixed because some costs are not strictly variable or strictly fixed, but they are oscillatory from a period to another and the economic financial result can not be established with accuracy;
- the margin of covering has a complex character including the fixed costs and regarding the gross financial result it must be shown that not always the production with the biggest contribution of covering has the biggest profit.

The positioning of the Romanian capital market within the national, international and European context was and currently is a continuous challenge for public and professional institutions in this field.

The legislation regarding the Romanian capital market was developed in a couple of stages, its benchmarks being the privatization law, the stock exchange law, the set up of the National Commission for Marketable Securities (CNVM) and the start-up of authorizing and controlling the capital market.

The aim of our study is to present a picture of the Romanian capital market in compliance with the EU Directives adopted between 2004 and 2006, but also in 2007. This article shall ascertain the impact of Romania's accession to the European Union on the national capital market, by means of integral harmonization with the European Aquis.

Keywords: capital market, EU accession, accounting regulation

1. Introduction

The capital market aims to transform a state's economy into a progressive one. The Romanian capital market can and has to undertake the role of financial accelerant and engine of economic development. But, therefore it should offer financial products of interest for companies in the viable economic sectors, which would use them for obtaining the financing necessary for development and creation of added value.

All efforts should aim to develop the capital market, to identify the disturbing agents and the solutions for vitalizing the Romanian capital market, and the legislative aspects governing its activity. The general organization and presentation framework for financial products should represent the mentioned accelerator for attracting sources in production and investments, and the means for harmonization with the western requirements in the context of Romania's accession to the European Union.

An efficient legal regulatory framework is a necessity for a stable climate, favourable for the activity of all participants in the economic life, able to attract investments in economy's real sectors. The institutional and regulatory efforts before and after accession were and still are oriented towards the connection to the European exigencies. Here we can mention the following: outsourcing of post-transaction services, set up of the central depository (authorised by CNVM and previously by NBR), set up of the investors' compensation fund, set up of the corporate governing institute and of the compensation fund for operations with derivatives at BVB.

The reform of the capital market legislation and the adjustments for its actual needs and for the compliance with the European Economic Communities standards are a must. Romania's accession to the EU brings some elements, which naturally will improve the forecasts related to the economic future and will bring a significant increase in transactions on the capital market.

2. The European Directives from the point of view of the law regarding the Romanian capital market

The adoption of Law no. 297/2004 regarding capital markets represented a critical moment for the future of the Romanian capital market from the point of view of Romania's accession to the European Union.

Law no. 297/2004 aimed to consolidate the existent legislation regarding capital markets and to adapt it to the provisions of the union's legislation. Law no. 297/2004 ensures the development of the legislative framework necessary for the creation of new institutions, the access of mediators on the Romanian capital market to the unique European market, as well as the set up of a viable capital market, which would allow the transaction of modern financial instruments.

We would like to highlight here the activity of the National Commission for Marketable Securities for lining up the national regulations with the European Directives, achieved by enacting the Regulation for Amending the C.N.V.M. Provisions (December 2006), in order to implement certain provisions of the following European Directives:

1. Directive no. 49/2004/EC regarding appropriateness of the capital of investment companies and lending institutions;
2. Directive no. 109/2004/EC regarding harmonization of the transparency requirements related to information on entities whose marketable securities are admitted for transactions on a regulated market, which amends Directive no. 34/2001/EC;
3. Directive no. 25/2004/EC regarding public takeover bids;
4. Directive no. 72/2004/EC regarding implementation of Directive no. 6/2003/EC related to the accepted market policies, definition of privileged information regarding financial derivatives for merchandise, preparation of the list with the persons who detain privileged information, notification of the transactions made by the management and notification of the suspect transactions;
5. Directive no. 39/2004/EC regarding markets in financial instruments;
6. Directive no. 71/2003/EC regarding the booklets published when marketable securities are made public or when they are admitted for transactions; it amends Directive no. 34/2001/EC;
7. Directive nr. 97/9/EEC regarding the investors' compensation schemes;
8. Directive no. 85/611/EEC regarding the legal, regulatory and administrative provisions related to certain investment trust companies for marketable securities (OPCVM).

The Regulation for amending the CNVM provisions in order to implement certain stipulations of the European Directives brings a series of novelties like the following:

- detailed provisions regarding cross-border operations included in the CNVM Regulation no. 1/2006; it is expressly stipulated that for issuers of marketable securities for which Romania is the origin member state, CNVM will approve the booklets for public takeover bids or for the acceptance to be transacted on a regulated market;
- reports of the issuers whose marketable securities are accepted to be transacted on a regulated market, prepared according to the provisions of Law no. 297/2004 and of CNVM; these reports will also be sent to an official archiving system (set up at national level);
- provisions regarding reporting duties for all issuers whose marketable securities are accepted to be transacted on a regulated market (not only for trading companies issuing shares and bonds);
- annulment of certain articles included in the CNVM Regulation no. 1/2006, which referred to some provisions of the European Commission Regulations no. 809/2004 and no. 2.273/2003, because starting with 1 January 2007 they became directly applicable in the national legislation.

3. Compliance of national regulations with the European directives and regulations

The law of capital markets enacted in 2004 marked the foundation of a regulation package, which should ensure a unitary approach in this field from the view of obtaining the European passport after Romania's accession to the European Union. The national legislation undertook a series of directives related to capital markets, issued by the European Union before 2004, during 1985-2004.

In 2004 CNVM started to prepare a series of regulations based on the law regarding capital markets and on the European Directives.

In October 2004 CNVM approved and enacted two regulations of special importance for the Romanian capital market: Regulation no. 8/2004 regarding the authorisation and functioning of the Investors' Compensation Fund and Regulation no. 9/2004 regarding the appropriateness of the capital of financial investment companies.

The Regulation regarding the authorisation and functioning of the Investors' Compensation Fund (20 October 2004) established the conditions and principles for the set up, authorisation, organisation and functioning of "S.C. Fondul de compensare a investitorilor S.A". The new entity aims to compensate the investors when the Fund's members are incapable to reimburse the money and/or financial instruments owed to or belonging to the investors.

According to the Regulation, the mediators authorised to provide financial investment services on behalf of the clients and the investment companies administrating individual investment portfolios, which develop activities in Romania, are pledged to participate in the set up of the Fund's financial resources.

The Regulation undertakes elements from Directive no. 97/9/EEC regarding the investors' compensation schemes and, according to CNVM's fundamental objectives, it aims to promote the investors' trust and interests in the regulated markets, in the investments in financial instruments, as well as to ensure their protection against unfair and abusive practices or fraud.

The Regulation regarding the appropriateness of the capital of financial investment companies (22 October 2004) reflects the provisions of Directive no. 93/6/EEC regarding the appropriateness of the capital of investment companies and lending institutions. This regulation introduces new reporting requirements for financial investment companies. They must correlate the undertaken risks with the level of own funds to be hold. Thus, the regulation describes the assessment of the position risk, settlement risk, counterpart risk, credit risk, exchange rate risk, concentration risk, merchandise risk and the calculation of initial capital and own funds to be hold by each financial investment company.

In December 2004 CNVM approved some regulations with particular implications on the activities of entities active on the capital market. They came into force on 01.07.2005. These regulations changed the legal framework valid until 2004 and adjusted it to the provisions of Law no. 297/2004 and of the European Directives.

We refer below to the most relevant changes:

1. The Regulation regarding financial investment services (no. 12/2004) undertook some provisions from Directive no. 39/2004/CE regarding the financial instruments markets, as following:

a) the procedures necessary for developing cross-border operations;

b) the minimum content of the mediators' internal procedures;

c) the guidance principles, which should be respected by mediators in their relationships with the clients;

d) the rules regarding fulfilling orders;

e) the eligible counterparts;

f) the requirements regarding transparency and integrity of transactions with financial instruments;

g) the mediators acting as domestic operators;

h) the distance contracts and the internet transactions;

i) the margin transactions;

j) CNVM's co-operation with qualified authorities in member states and third states.

2. The Regulation regarding the appropriateness of the capital of financial investment companies (no. 9/2004) reflects Directive no. 93/6/EEC regarding the appropriateness of the capital of investment companies and lending institutions. This regulation introduces new reporting requirements for financial investment companies. They must correlate the level of undertaken risks with the level of own funds to be hold. The regulation presents the assessment of the position risk, settlement risk, counterpart risk, credit risk, exchange rate risk, concentration risk, merchandise risk and the calculation of initial capital and own funds to be hold by each financial investment company.

3. The Regulation regarding issuers of and transactions with marketable securities (no. 13/29.12.2004) includes in a complex and unitary framework legal provisions related to various topics previously approached in different regulations: the public takeover bid, the public offer for subscription, the continuous and periodical informing through the issuers of marketable securities, etc.
4. The Regulation regarding regulated markets and alternative transacting systems (no. 14/2004) establishes the legal framework applicable to market and system operators, to markets regulated by financial instruments and to alternative transacting systems. The drafting of this regulation considered the new provisions of Directive no. 39/2004/EC regarding markets in financial instruments, as following:

- integrity requirements for the shareholders of the market operator, which organises and administrates the regulated markets; considering the necessity of insuring a prudent administration of the regulated markets, CNVM can deny the shareholder quality if it estimates that the respective persons could affect the good functioning of the regulated markets or their supervision;
- qualification and professional experience conditions to be fulfilled by the administrators and managers of the market operator;
- proper technical endowment of the market operator for managing the risks to which the regulated market is exposed;
- requirements regarding the mediators' access to the regulated market;
- acceptance, suspension or withdrawal of instruments for/from being transacted on the regulated market;
- requirements regarding pre- and post-transaction transparency on the regulated markets and on the alternative transaction systems;
- compliance with the rules of the regulated market and of the alternative transaction systems.

5. The Regulation regarding authorization and functioning of investment management companies, investment trust companies and depositories (no. 15/2004) reflects Directive 85/611/EEC regarding the legal, regulatory and administrative provisions related to certain investment trust companies for marketable securities. The regulation contains provisions for investment trust companies in marketable securities, for other investment trust companies (AOPC) registered with CNVM, as well as for financial investment companies (SIF). The regulation contains provisions related to the following:

- authorization procedures for investment management companies (SAI), for open-end investment trusts and for investment companies;
- conditions to be fulfilled by the shareholders of an investment management company, rules for calculating the net assets;
- transparency and advertising rules for investment trust companies in marketable securities, development of the activities regarding management of individual investment portfolios on a discretionary basis;
- conditions and procedures for registration with CNVM, rules regarding the minimum content of the by-laws of a financial investment company, rules regarding the administrators of a financial investment company; and
- authorization procedure for depositories of assets hold by investment trust companies;

The Regulation regarding the authorization and functioning of the central depository, of the compensation body and of the central counterparty (no. 13) came into effect in 2005. Subsequently it was amended through Regulation no. 17).

According to the Regulation, the central depository performs all depositing operations for marketable securities and any other operations in this respect, as well as the compensation operations, respectively settlement of the transactions with marketable securities. The compensation body performs all compensation operations and settlement of transactions with derivative financial instruments and any other operations in this respect and calculates the net positions of the mediators, of a possible central counterparty and/or of a possible settlement agent. The compensation body acts as central counterparty.

The central counterparty is the interface between the mediators in the system and acts as exclusive counterparty in respect to their transfer orders. The same entity can be authorised to act as central counterparty both for derivative financial instruments and for other financial instruments.

A new Regulation regarding financial investment services (no. 15/Dec. 2005) was elaborated. The previous one was annulled (Regulation no. 12). The new regulation contains authorization conditions, organisation and functioning conditions for investment companies, but also authorization and authorization withdrawal conditions for financial investment agents, traders and consultants from third countries.

Year 2006 – the year before accession – marked a new stage in restructuring the regulations, which complete the legislative framework of the financial market and, by default, of the capital market. This stage resulted in regulations' annulments, changes and amendments, determined by the Union's rules.

The Regulation regarding financial investment services (no. 15) was amended by Regulation no. 6 (28 Dec. 2006) and by Regulation no. 31 (applicable since 4 Jan. 2007), which refer to the authorization, organization and functioning of financial investment companies, of financial services agents, traders and consultants in the member states.

We should underline that Regulation no. 31/2007 amends the Regulation regarding the issuers of and the operations with marketable securities, thus reflecting the directive, which shows the current European trend in the field of issuers of and operations with marketable securities, as following:

- booklets published when marketable securities are offered to the public or accepted for transactions (Directive 7/2003);
- harmonization of the transparency requirements regarding information related to issuers whose marketable securities are accepted for transactions on a regulated market (Directive 109/2004);
- public takeover bid (Directive 25/2004);
- form and content of the bid booklets, inclusion of the most important information, as well as their publication (Regulation no. 809/2004, issued for the application of Directive 7/2003/EC);
- distribution of advertising materials (Directive 6/2003), definition and publication of confidential information, definition of market manipulation (Directive 124/2003);
- accurate presentation of investment recommendations and disclosure of the conflicts of interest (Directive 125/2003), exceptions regarding the buy-back programmes and stabilization of the financial instruments (Regulation 2.273/2003);
- accepted market practices, definition of confidential information, preparation of the list of persons holding confidential information, notification of the transactions made by administrators, as well as of the suspect transactions (Directive 72/2004).

The amendments brought to the regulation tried to consider the community's regulations and to adjust them (more or less) according to the specific and dynamics of the Romanian capital market, respectively to the complex field of issuers and transactions with their marketable securities. The regulation also introduced and developed new or updated concepts, approached in Law no. 297/2004, as following: acceptance for being transacted on a regulated market or on an alternative transaction system, public takeover bid, qualified investors, and exceptions from the issuance of offer documents, procedure for the shareholders' retirement / withdrawal from a trading company.

There were changes in the Regulation regarding the authorization and functioning of the central depository, the compensation bodies and the central counterparts (Regulation no. 2 applicable as of April 2007). Its elaboration was necessary in order to gather all changes for compliance with the new content of company law (Law no. 31 applicable as of the end of 2006), with some European Directives regarding authorization, organization, functioning and equity of entities on capital markets (appropriateness of the equity size until 2008).

The Regulation regarding regulated markets and alternative transaction systems (14/2004) was annulled and replaced by Regulation no. 2 in March 2006. The latest was also amended (through Regulation no. 14/Aug. 2006 and Regulation no. 32/Feb. 2007 regarding financial services) in order to comply with the content of some European regulations, like Directive no. 39/2004/EC and the latest EC regulation regarding transactions with marketable securities (1.287/2006/EC), voting rights of the market operators and lining up of the equities of the Bucharest Stock Exchange and the Sibiu Commodity and Derivative Instruments Exchange, during the period 2007–2008.

We do not claim to have presented all the events in the evolution of the regulations regarding capital markets in the context of Romania's accession to the European Union. However, we tried to point out some of them, which we considered representative and with impact on the development of the Romanian financial and capital market.

6. Year 2007 and Romania's major objectives for the next period regarding the financial instruments market and, by default, the capital market

New regulations, with new contents, in compliance with the Union's framework, came into effect in 2007. The first CESR Guide (Committee of European Bodies for Marketable Securities) regarding the unitary implementation of the Directive regarding market abuses was also drafted in 2007. Starting from this guide and considering also the comments, proposals and suggestions gathered during the debate period (up to 20.04.2007), CNVM will implement the directive.

In the context of Romania's accession to the European Union (1 January 2007), the latest Regulation regarding the authorization and functioning of the Investors' Compensation Fund was annulled, replaced and amended in order to comply with the European Directives. The new Regulation (no. 10) reflects the provisions of Directive no. 97/9/EC regarding investors' compensation schemes and it implemented some incident provisions to the European Directives through Regulation no. 31/2006 (applicable since Jan. 2007), as following: appropriateness of the capital of investment companies and lending institutions (Directive no. 2006/49/EC); harmonization of the transparency requirements regarding information related to the issuers whose marketable securities are accepted to be transacted on a regulated market (Directive no. 2004/109/EC, amending Directive no. 2001/34/EC); public takeover bids (Directive no. 2004/25/EC); accepted market practices, definition of privileged information regarding derivative financial instruments for merchandise, preparation of the list of persons holding privileged information, notification of transactions made by the management and of suspect transactions (Directive no. 2004/72/EC regarding implementation of Directive no. 2003/6/EC); markets in financial instruments (Directive no. 39/2004); booklets published when marketable securities are offered to the public or accepted for transactions (Directive no. 2003/71/EC, amending Directive no. 2001/34/EC).

2007 started with the expiration of Romania's deadline for complying with the Directive regarding the financial instruments market. Among the 27 EU member states, only three, inclusive Romania (together with Great Britain and Bulgaria), accomplished this as of 1 January 2007.

From the historical point of view, in the last 15 years, the financial services in the EU did undergo a complex continuous adjustment process. A first programme, introduced in 1992 through the Directive for financial services, was subsequently adapted and amended. It came into effect in 2005. In 1999 EURO was introduced as account currency and in 2002 as physical currency. In 2005 new accounting standards emerged. The new Directive for markets in financial instruments, short - MiFID (Market in Financial Instruments Directive), started to be applied on 1 November 2007.

MiFID aims to liberalize the services circulation, to create a unique capital market in the EU, to increase the competitiveness of financial companies: stock exchanges, investment banks, brokerage companies, assets administrators and other providers of financial services.

Its objectives are the following:

- increase of competition between and inside the European financial markets;
- annulment of the concentration rule (which limits the transactions with securities on the stock exchange of a country) and of the principle regarding the best execution of orders (stipulating that investment companies should take all measures for obtaining the best possible execution results, considering not only the price, but also a complex of other agents); subsequently, this principle will depend on the client's order; should the client not have any specific instructions, the operator will chose „the best possible execution";
- option for a high harmonization level, with precise provisions regarding contract execution, transaction transparency, clients' eligibility, conflict of interest and internationalization of transactions with shares, bonds and derivatives;

- introducing of the so-called unique passport, which authorizes financial companies to operate in the whole European Union based on the consent of the competent authorities in their home countries;
- creation of the conditions for negotiating shares and bonds within a couple of structures, regardless of stock exchanges or investment companies;

The costs for applying the directive are of EUR 4 – 20 thousands for an operator on the financial market (and for a large operator they can reach even EUR 106 thousands). These costs arise from the fact that the financial companies will have to change their computer systems and control procedures. However, financial services in the EU still remain competitive, meaning that benefits exceed costs. High costs lead to a greater concentration. Large companies absorb the smaller ones, as we can notice in Romania too.

As an impact on the markets, MiFID could announce the end of the Balkan capital markets, being the greatest challenge for the financial services field in Europe in the last years.

Expectations are related to changes of negotiation procedures for shares, bonds and derivatives in the European Union, by means of market liberalization. MiFID will have an immaterial immediate impact on traditional markets, but a long-term impact. Instead, investment companies will be the first affected.

The effects are related to competition increase on the value titles market, which will change the business environment. The transactions volume will continue to increase as a result of a greater market transparency. On the other hand, as the European capital markets integrate, the companies' nationality becomes more and more ambiguous and stock exchanges will compete predominantly on a unique market. It is expected that the increased transparency imposed upon investment companies will attract more investors on the bonds market.

The beneficiaries of the application of the directive will be the operators with available adapting resources and with sufficient financial capacities for bearing the costs, but provided that they act as soon as possible. Also it will be a benefit for stock exchanges, which prepared for MiFID in due time, and for future administrators of pension funds, which are in a continuous growth. Less flexible and offhand companies will lose and suffer.

The professionals, who analysed the directive, highlighted the existence of certain ambiguities related to the following:

- voidance of a clear definition of „best conditions" in executing express orders for clients; accordingly, there are interpretations;
- no accurate method for estimating the transaction costs;
- evasive wording and stuffed text, creating confusions (e.g. financial investment companies are wrongly assimilated sometimes with stock exchange operators);
- despite the presented critical matters, MiFID has material consequences on the Romanian developing financial instruments market, related to:
- facilitation of the Romanian operators' intra-community activities, possibility of performing operations outside the stock exchange – which will increase competition and reduce transaction costs; and
- investors' protection by means of imposing upon the Romanian institutions on the market to adopt structures and practices for a better protection, a better information and the possibility the make transactions anywhere in the EU, based on the same regulations; the Romanian investors benefit of the same type of services, for the same price, for the Romanian shares and bonds, as for the foreign ones; internet transactions will be facilitated;

We have to highlight Romania's headmost position in complying with MiFID, marked by dynamic structures and transposition discipline, which brings a fresh breath on the financial instruments market. Unfortunately, its unitary application in all member states is not possible. Up to 1 January 2007, out of the 27 member states, only 3 accomplished the transposition (Great Britain, Bulgaria and Romania).

For Romania, 2007 represented the beginning of the "cohabitation in a new house", with a new dimension, with new and many obligations in various fields. The adoption and implementation of the EU directives regarding the financial instruments market is a priority in the current ascension and development stage of the Romanian financial market.

The architecture of the "new European house" is far from being finalized. Thus, at EU level, the perpetual ideas collation regarding the European construction would benefit if, within the administrative-institutional structure, the fifth market dimension would be more noticeable. The fifth market dimension is the financial instruments market, with the same primary objectives than the first four: barrier elimination, norms simplification, fighting the national preferences and discrimination, penalization of unfair competition practices and especially, harmonization of rules and functioning of national regulatory bodies, in a unitary cogitation flow, as a result of the European Union's multinational polychromic and abundance.

Gathered into a unique reservoir, the European economic thinking could feed the other four dimensions of the domestic market with a medium and long-term business vision. The European Union marks out through its unique formula for harmonizing the countries' interests, despite the polychromic cultures and even the political nuances. The European Union's force in the world consists in the suasion force of its ideas.

Au niveau international, le processus de la normalisation comptable peut être plutôt déductif, matérialisé par l'utilisation des cadres comptables conceptuels, ou plutôt inductif, matérialisé par l'utilisation du plan général des comptes. La préférence pour l'un ou l'autre des algorithmes de normalisation dépend des facteurs de l'environnement, mais également des ceux économiques et politiques qui agissent dans un système comptable à un moment donné. C'est connu le fait que dans le milieu comptable continental on retrouve la tendance d'une normalisation comptable surtout inductive, tandis que dans le milieu anglo-saxon, on préfère une normalisation comptable ayant à la base les cadres comptables conceptuels. Pour l'esquisse d'un trend de la future normalisation comptable en Roumanie, notre projet est structuré sur deux dimensions: la mise en évidence de quelques repères historiques de la normalisation comptable en Roumanie et l'analyse du contexte international.

Des mots clés: *la normalisation comptable, le plan général des comptes, le cadre comptable conceptuel*

1. Des repères historiques de la normalisation comptable en Roumanie dans des différents contextes économiques et politiques

Le problème de la réglementation de la comptabilité en Roumanie a résulté à la suite des besoins pratiques. Ainsi, à la fin des années '30, les préoccupations pour la normalisation ont commencé à se concrétiser sur la forme des publications sur ce thème-ci. Les idées principales étaient centrées sur l'adoption d'un plan comptable et d'un cadre comptable. Apres le début des démarches de normalisation comptable, on saisit des exposés des sujets traités, comme le projet antérieur sur la normalisation comptable. A cette époque-là, on avait deux points de vue différents sur la normalisation comptable – Calu (2005):

La normalisation de la comptabilité – points de vue:	
Juridiques (patrimonial) – Sp. Iacobescu	**Economique – I. N. Evian**
• *Le cadre général* sur des grandes groupes des comptes pour *toutes les entreprises;* • Au niveau de *branche* ou *domaine: des plans des comptes propres;* • *Les documents de synthèse* (le bilan et le compte de profit et perte) uniformisés au niveau de la branche (l'industrie, le commerce, les banques et les assurances); • Ce sont des positions juridiques prévues, comme les comptes d'*ordre* et d'*évidence;* • *Il n'implique pas des problèmes des calcules des coûts et d'évaluation.*	• *Le plan unitaire des comptes* (pour tous les types d'organisations); • *Des formulaires types* pour *les documents de synthèse* (le bilan et le compte de profit et perte) pour *toutes les catégories d'entreprises;* • Il est *« contre » les comptes d'ordre et d'évidence;* • Dans le cadre du plan des comptes projeté, *le calcul des coûts était inclus.*

Des points de vue sur la normalisation de la comptabilité dans la période d'entre les deux guerres, en Roumanie

Même si les discutions sur la normalisation comptable reflétaient les tendances internationales, au moment de l'apparition de l'économie de type socialiste, ces problèmes ont étaient abandonnés ; suite à ce-là, les essaies de normalisation comptable par les propositions des doctrinaires roumains ont continué sur une autre forme: la normativité de la comptabilité. Conformément à l'opinion de Leonte (1948), la normativité représente « *l'établissement de la norme unitaire pour les enregistrements comptables* [s.n.] des entreprises provenant d'une branche d'activité », les objectifs suivis étant les suivants : l'unification de la terminologie comptable (par la précision du contenu de chaque compte) et la systématisation de la comptabilité. Celle-ci a débute au moment de la constitution d'un *Conseil Permanent de la normativité comptable*, en 1947. Les membres du conseil ont élaboré, pour chaque secteur représentatif d'activité, un cadre général (une matrice qui était à la base de la systématisation et représentation symbolique du plan des comptes), ayant à la base le système décimal – Dewey. Ainsi, on a élaboré 5 cadres générales, pour les domaines suivantes : l'*industrie, le commerce, les assurances, bancaire et des offices industrielles.*

La période 1960-1966 est caractérisée par Rusu (1977) comme étant marquée des « efforts pour approfondir le processus de généralisation théorique ». En ce sens, une question a surgi : est-ce que l'harmonisation des plans des comptes déjà existants est préférable à l'adoption d'un cadre général des comptes pour l'ensemble de l'économie ou non ? Comme dans le cas de toute dilemme, on a eu des supporteurs des deux côtés. Ainsi, Mărculescu & Puchiță (1965) soutenait « l'approfondissement et le perfectionnement de l'harmonisation des plans des comptes en vigueur », prenant comme repère le modèle des plans des comptes de l'industrie, tandis que Demetrescu & Nişulescu (1967) ont soutenu l'institution « d'un schéma unique de classification et d'ordonner les comptes, un cadre général des comptes pour l'ensemble de l'économie – la base des plans des comptes uniques sur chaque branche ». Le deuxième avis, suivant la même longueur d'onde avec le trend de la normativité de la comptabilité dans les pays socialistes, a connu une forme concrète et pratique débutant en 1971[307]. Le passage à un cadre unique des comptes dans les années '70 a été précédé par des modifications similaires qui ont eu lieu dans le cadre des pays de l'ancien « bloc communiste »[308], des modifications qui, que ce soit ou non une coïncidence, ont eu lieu sur une scène politique spéciale[309].

C'est intéressant à mettre en évidence l'élaboration en 1984 d'un matériel qui visait la réglementation potentielle de la comptabilité en Roumanie. C'était le résultat d'une collaboration entre l'Institut de Finances, Monnaie et Prix et le professeur M. Ristea, d'un côté, et la doctrine comptable française, d'un autre côté. Même si seulement au niveau théorique, dans le cadre de ce projet-là, on fait une présentation de l'architecture du système comptable français et des éléments conceptuels de ce cadre.

Après 1990, la normalisation comptable en Roumanie a connu plusieurs étapes : a débute avec l'adoption d'un système comptable inspiré de celui français (1993) et a continué avec l'élaboration d'une réglementation ayant comme but de le rendre compatible avec les Standards Internationales de Rapport Financier (IFRS) et avec les Directives comptables européennes (1999). Quand la Roumanie a adhéré à l'Union Européenne, les IFRS ont devenu obligatoires pour la consolidation des comptes de group des sociétés cotées, pour les autres situations en appliquant les normes comptables nationales.

Au niveau conceptuel, on a aussi les premières représentations comparatives des types de normalisation comptable. Ainsi, Feleagă (1995, 1996, 1997, etc.) présente d'une façon tantôt explicative, tantôt interprétative, le cadre théorique global de la comptabilité financière dans les domaines divers référentiels comptables ; il présente aussi « l'architecture » du système français de comptabilité, offrant des repères importants sur la situation existante au niveau international. Parallèlement, M. Ristea (1995, 1997, etc.) pose le problème de la normalisation comptable au niveau international, tout en présentant ses points de

[307] Le signal de commencer a été donné par l'URSS, où, « a partir de 1960, on applique un plan des comptes unique pour les entreprises industrielles, de construction et montage, agricoles et des services » – RC (1971/4).

[308] En URSS il y avait eu lieu ce genre d'unification il y a un décennie, un trend qui avait était suivi aussi par la R. P. Bulgarie (1968), R.S. Tchécoslovaquie şi R.S.F. Yugoslavie. Il y avait quand même des pays dans lesquels on utilisait des plans des comptes élaborés pour chaque branche d'activité, qui avait à la base le système décimal des symboles (R. P. Pologne, R. P. Hongroise) - RC (1971/1: 30-38).

[309] Les années '60 ont représenté une période de relaxation suite à des mouvements sociales dans certains pays communistes (les événements de Hongrie et Pologne en 1956, Le Printemps de Prague, 1968).

vue sur l'avenir de la normalisation comptable en Roumanie. Après les premières publications dans cette direction, le problème de la normalisation comptable a été largement abordé, la majorité des auteurs qui ont publie des ouvrages sur la comptabilité financière, traitant plus ou moins ce problème.

2. Directions de la normalisation comptable existante au niveau internationale

Au niveau international, le processus de la normalisation comptable peut être plutôt déductif, matérialisé par l'utilisation des cadres comptables conceptuels ou plutôt inductif, matérialisé par l'utilisation du plan général des comptes (Ionaşcu, 1997). La préférence pour l'un ou l'autre des algorithmes de normalisation dépend des facteurs de l'environnement, mais également des ceux économiques et politiques qui agissent sur un système comptable à un moment donné. C'est connu le fait que le milieu comptable continental on retrouve la tendance d'une normalisation comptable surtout inductive, tandis que dans le milieu anglo-saxon, on préfère une normalisation comptable ayant a la base les cadres comptables conceptuels. Le mode de normalisation comptable surtout déductif se retrouve aussi au niveau international, dans le cadre IASB.

Les différences existantes au niveau international en ce qui concerne le processus de normalisation comptable représentent les points de départ de l'homogénéisation des informations fournies par la comptabilité. Jusqu'en 2000, il n'y avait pas une unité en ce qui concerne les voies d'atténuer les dissensions informationnelles générées par des pratiques comptables différentes. Les principaux organismes impliqués dans ce processus ont été un organisme supranational et un autre non gouvernemental. Ainsi, d'un coté on a essayé l'harmonisation au niveau de la Communauté Economique Européenne (CEE)[310] par le biais des directives comptables européennes, et de l'autre côté, on a émis les Standards Internationales de Comptabilité (IAS) par International Accounting Standards Committee (IASC) – le Comité des Standards Internationales de Comptabilité[311]. Mais, il y avait encore le problème des divergences existantes entre le point de référence de la comptabilité internationale et de FASB (Financial Accounting Standards Board – Le Conseil des Standards de Rapport Financier), exigé sur le marché boursier des Etats Unies. Dans ce sens, entre les représentants IASB et ceux FASB on a signé en 2002 un Accord de convergence. Dans le cadre de cet accord-ci, les deux parties « ont pris l'engagement de déposer tous les efforts pour : (a) agir de façon que les standards de rapport financier déjà existantes soient compatibles le plus vite possible et (b) coordonner leurs programmes de travail futures, pour que la compatibilité, une fois obtenue, soit maintenue » – www.fasb.org. Cet accord sur la convergence des situations financières a été reçu d'une façon favorable par la Commission Européenne, qui, un an plus tard, a adoptée les Réglementations d'approbation des standards internationaux de comptabilité.

Tandis que pour les entreprises cotées, l'application des réglementations internationales est obligatoire, pour les petites et moyennes entreprises des divers pays on appliques les normes nationales. Dans ce sens, au niveau des divers pays, les préoccupations portant sur la normalisation comptable nationale sont devenue une priorité.

Ding, Jeanjean & Stolowy (2005) étudient le rôle des valeurs culturelles et du système juridique en ce qui concerne les différences existantes entre les réglementations nationales des divers pays et les standards internationales de comptabilité de l'année 2001. Ceux-ci identifient deux directions en ce qui concerne les différences existantes entre les différents normalisations, internationaux et nationaux : (I) la divergence (tous les deux types de normalisation comptables couvrent les mêmes thématiques, mais les traitements comptables prescrits sont différents) et (II) l'absence (les standards nationaux ne couvrent pas certaines situations réglementées par IASB).

Un premier exemple dans ce sens c'est la France, qui, dans le cas des petites et moyennes entreprises, a des réglementations comptables propres. C'est intéressant a remarquer le fait que, dans leur cadre, on essaie d'harmoniser le spécifique national avec les tendances internationales. On rappelle la redéfinition récente

[310] Après ce moment-la, la dénomination de CEE a été changé en Union Européenne (UE)

[311] A présent, l'organisme a change sa dénomination en IASB ; les réglementations émises par celui-ci sont appelées des IFRS.

des actifs, intégrée dans le Plan Comptable Général Français (http://www.plancomptable.com/titre-II/titre-II_chapitre-I_section-1.htm). Un autre pays latin qui a fait des démarches récents dans la direction de l'élaboration d'un Plan Comptable National c'est l'Espagne. Les recherches ont eu comme résultat un projet sur un nouveau plan comptable national "un nuevo Plan General de Contabilidad (primer Borrador)"- (http://www.icac.meh.es/BPGC.pdf).

Toujours sur la ligne des nouvelles tendances de normalisation, le Japon a élaboré un cadre conceptuel propre. Dans le cadre de ce document, le normalisateur Japonais présente sa propre position en ce qui concerne le processus d'amortissement comptable ; également, on présente des éléments originales, spécifiques au milieu économique, politique et culturel. Street (http://www.iasplus.com/resource/gaap2002.pdf, 2002) a étudié les tendances d'adoption des IFRS en plusieurs pays. A la suite de cette investigation, il a constaté que trois pays (le Japon, l'Arabie Saoudite et Islande) n'envisage pas renoncer aux standards nationaux pour les IFRS.

Ces préoccupations pourraient être dû au phénomène de cosmopolitisme, qui, sur le plan économique et politique, a la tendance, conformément a certains spécialistes (Yegenoglu, 2006), de prendre la place au phénomène de globalisation. La conséquence, pour la comptabilité, serait de faire basculer l'accent d'homogénéisation des pratiques vers la préservation de l'identité culturelle.

3. La normalisation comptable en Roumanie : Quo vadis?

La présentation antérieure a eu le rôle de mettre en évidence, d'un coté, les plus récentes tendances au niveau national en matière de normalisation comptable en quelques pays, et, de l'autre côté, les préoccupations antérieurs dans le domaine, pour l'identification des certaines particularités existantes au longue du temps et d'une corrélation entre le processus de normalisation comptable et le milieu économique et politique. Suite à la courte rétrospective, on a pu voir le fait que l'apparition d'un milieu économique et politique restrictif (l'économie de type socialiste, dans le contexte d'une gouvernance communiste) a eu comme conséquence l'application des « modèles » prédéfinies sur la normalisation comptable, dans le sens que la réglementation de la comptabilité avait à la base un modèle soviétique.

La chute du régime communiste en Roumanie en 1989 a mené à la diversification des préoccupations sur la ligne de la normalisation comptable. Ainsi, on a vu le fait que, dans une première étape, en Roumanie, on a choisi un conseil sur la filière française en ce qui concerne la reforme comptable en Roumanie, fait justifié dans une certaine mesure par la collaboration antérieure dans cette direction. En utilisant comme source d'inspiration l'expérience française dans le domaine, on a réalisé aussi une adoption implicite des directions proposées par les Directives Européennes. En plus, on peut constater que la Roumanie a été réceptive aux tendances manifestées sur le plan international. Dans ce sens, on remarque le début du Programme de développement de la comptabilité en Roumanie en 1997, par lequel on introduit des éléments des standards de rapport financier.

Faisant l'analyse de la dimension historique de la normalisation comptable en Roumanie, on peut observer le fait que, dans les moments de scission historique, on a eu des modifications radicales de la vision sur le processus de réglementation comptable, l'approche étant différent. Les prédictions pour l'avenir de la normalisation comptable en Roumanie se basent sur le trend existant au niveau international. Si pour les entreprises cotées sur les marches des capitaux, l'avenir semble d'être relativement sur du point de vue des réglementations comptables à cause des exigences internationales, au niveau des petites et moyennes entreprises, on note la nécessité du développement des réglementations comptables autochtones, qui tiennent comptes des particularités nationales, comme en France et Espagne. Dans ce sens, il faut créer soit un plan des comptes national, soit un cadre conceptuel propre.

Faisant la synthèse des éléments présentés, le « panoptique » de la normalisation comptable en Roumanie peut être vu de la façon suivante :

LA NORMALISATION EN ROUMANIE:

<table>
<tr>
<td>

LA NORMALISATON INDUCTIVE

(PLAN GENERAL DES COMPTES)

(étude de début: 1941-1947)

(1990 – présent): on n'a pas eu une forme « classique » qui puisse inclure le plan des comptes, des réglementations spécifiques, des principes et un mixe de définitions, mais une forme « adaptée »

- OMFP 1752/2005[312]

LA NORMATIVITE (1947-1989):

- *L'unification de la terminologie comptable*
- *La systématisation de la comptabilité*

</td>
<td>

LA NORMALISATION DEDUCTIVE

(CADRE CONCEPTUEL)

(1999 – 2005)

La traduction du cadre conceptuel IASB a été incluse dans les suivantes réglementations comptables:

- OMF 403/1999
- OMF 94/2001
- OMF 306/2002

</td>
</tr>
<tr>
<td colspan="2">

PERSPECTIVES DE LA NORMALISATION COMPTABLE EN ROUMANIE:

- Pour les entreprises cotée : l'application des IFRS;
- Pour les petites et moyennes entreprises: l'élaboration d'un cadre conceptuel propre ou d'un plan comptable général.

Abstract: Information technology (IT) has a pervasive influence and it is a critical factor in many organizations. As such, it's often one of the most valuable assets an organization owns and uses as a cost-effective tool to attain their goals. But IT can also be a failure factor if the strategy used in designing, deploying and maintaining the IT architecture doesn't meet or converge with the overall strategy of the organization and it's continuous need for information. Enterprise architecture incorporates the main enablers an entity needs to achieve this convergence. From the internal audit's function perspective this can raise a wide range of challenges due to business strategy amendments that has an influence on the information system and the supporting technical architecture. The aim of this article is to set off the way an enterprise's architecture influences the work of the internal auditor in performing an IT audit.

Keywords: internal audit, IT audit, enterprise architecture

Introduction

In a dynamic business environment with harsh competition an organization cannot secure it's survival without a constant adaptation to the requirements such a market poses. External factors has to be "internalized" by the managers who have to rethink the organization's strategy which is supported by the business processes and operations and guided by information and decisions. An effective enterprise architecture is needed that must facilitate the flow of information regarding the initial state and position of the organization and also the desired or achieved status in comparison with the objectives predefined. Also, such an enterprise architecture must be adaptable, dynamic in order to cope with the future changes in cost-efficient and reliable manner.

Having this in mind we have to consider any organization as being a system which is „ ...a set of different elements so connected or related as to perform a unique function not performable by the elements alone" (Rechtin Eb., 1991, pg.7). Indeed an organization consists of several different elements such as departments, compartments, functional structure, that connected and related to each other by a formal or informal communication networks that permits the flow of data, information and decisions among them, but none of these elements or communication networks cannot assume and accomplish the function the organization does as a whole.

The influence of management reaction to change on the enterprise architecture

„Defining an enterprise architecture is complex, because it encompasses the systems within the context of the whole enterprise. To simplify this, an enterprise architecture is typically structured by considering a business or system as a series of components (or services) with inter-relationships, without having to consider the detailed design within the individual components." (Macaulay A., 2004, pg. 2)

Zachman J.A. (1987, pg. 276-277) attempted for the first time to define what system architecture is. But he came to the conclusion that at the time being there was „little consistency in concepts or in specifications of <architecture>". Also he notes that there was little chance that various definition would emerge. Still there are several definition of the term architecture generally accepted in the existing literature. One of them is stated in the ANSI/IEEE Standard 1471-2000 as: 'the fundamental organization of a system, embodied in its components, their relationships to each other and the environment , and the principles governing its design and evolution'. (Macaulay A., 2004, pg. 1)

Enterprise architecture allows organizations to build foundations they need to survive and adapt to present and future business challenges. Sound enterprise architecture supports the ability to stay agile, provides for increased return on investment, and creates a framework for making future technology decisions. It identifies the main components of an organization and how components in the organization's nervous system function together to achieve defined business objectives. These components include personnel, business processes, technology, financial information and other resources. If decisions about components and their interrelationships are uncoordinated, minimally effort and resources will be duplicated, performance and management problems will arise.

Enterprise architecture has also a role in the ability of the organization to align and coordinate its business strategy reflected by the business architecture and the corresponding an supporting information systems reflected by the technical architecture. Existing literature supports to a great extend this particularization. Wagter R. et. all (2005, pg. 39) considers that the various architectural domains can be grouped in: business architecture, information architecture and technical architecture. We considered above information architecture and technical architecture as a whole. Somehow in the same direction we can note the areas identified by Morgan T. (2002): business architecture, technical architecture and component architecture. Here to we can conclude that technical architecture and component architecture can be converged if we approach the architecture perspective of the enterprise from a more general perspective. Macaulay A.(2004, pg. 2) considers only these two components: business architecture and technical architecture.

Wagter R. *et. all* (2005, pg. 39) considers that „business architecture sketches the contours of the way in which an organization can be structured to effectively pursue its business objectives. Business architecture consists of three domains: the products and services offered, the processes responsible for producing these products and services and the organizational structure required to carry out these processes." Morgan T. (2002, pg. 40) states that "business architecture is a way of describing businesses and what they do or intend to do in the future"

„Technical architecture sketches the design contours for the provision of information within an organization. It consists of two domains: the data that is important for the correct functioning of the organization and the applications that ensure that this information is correctly distributed within the organization." (Wagter R. et. all, 2005, pg. 39). Morgan T., (2002, pg. 40) considers that "technical defines the technology that can be used to create specific information systems"

In a constantly changing environment strategic decisions regarding the organization have to be made more and more frequently. These decision made in the present time are based on information provided mainly by the organization's information system. In order to be reliable the business architecture must be aligned and coordinated with technical architecture. Present time decision have an influence on the organization's structure and behavior in the future which changes the entire enterprise architecture. In order to cope with these rapid changes enterprise architectures must be agile but still coherent.

A report issued by GAO (2003, pg. 1) recognizes that „the importance of developing, implementing, and maintaining an enterprise architecture is a basic tenet of both organizational transformation and IT management. Managed properly, an enterprise architecture can clarify and help optimize the interdependencies and relationships among an organization's business operations and the underlying IT infrastructure and applications that support these operations." (GAO 2003)

The role of the internal audit function in a changing organization

A modern and competitive organization, as a system, is inconceivable without using the advantages and benefits information technology has to offer in processing data, communicating information and decisions, interconnecting heterogeneous processes and departments in a reliable, flexible and time-efficient way. But we cannot omit the fact that information technology beside the benefits it brings it can be subject to risks the organization faces if it doesn't uses IT in proper way.

In order to assure that the use of information technology doesn't exposes the organization to undesired risk, there is a need for a fully capacitated internal audit function that can perform information technology audits as part of it's mission. The Institute of Internal Auditor's Definition of Internal Auditing states: " Internal auditing is an independent, objective assurance and consulting activity designed to add value and improve an organization's operations. It helps an organization accomplish its objectives by bringing a systematic, disciplined approach to evaluate and improve the effectiveness of risk management, control, and governance processes." (IIA, 2008).

The scope of internal auditing covers all of an organization’s activities, without regard for internal boundaries or geographical restrictions. Their work is based on the risk assessment and encompasses the adequacy and effectiveness of governance, risk management and internal control processes in identifying and responding to the risks facing the organization. A professional internal audit activity will be able to support risk management in two ways. Firstly, it will provide objective assurance to the board and to management that the risk management framework as a whole is operating effectively and that specific risks are being managed to the expected level. Secondly, it will invest its time and effort in consulting activities, which contribute to the establishment of sound risk management processes across the organization.

Therefore, we can say that the role of the internal audit is to report internal control issues to the audit committee and senior management. The real value comes when issues are addressed and problems are solved. In other words, reporting the issues is a means to an end. In this context, the end is to improve the state of internal controls at the company. Reporting them provides a mechanism by which the issues are brought to light and therefore receive the resources and attention needed to fix them. Therefore, the real mission of the internal audit department is to help improve the state of internal controls at the organization. Admittedly, this is accomplished by performing audits and reporting the results, but one must remember that these acts provide no value in and of themselves. They only provide value when the internal control issues are resolved.

An effective internal audit department considers the audit to be a partnership with the rest of the organization and not a policing function. An effective audit department is involved year round with key functions and does not just swoop in and out when performing audits. The audit should be just an occasional event in an ongoing relationship.

In a constantly changing environment the internal audit function faces a series of challenges it must cope with in order to prevent the materialization of risks emerging from changes an organization faces. „Without adequate control and visibility, an organization can spend money and effort on unneeded or low-priority changes while neglecting more important initiatives. Poorly designed or ill-considered changes can cause disruptions that must be addressed after the fact, or the changes must be “backed out.” IT changes to one component can disrupt the operation of other components.” (IIA GTAG 2, 2005, pg. 4)

The IIA’s GTAG no.2 (2005, pg.5) Change and Patch Management Controls: Critical for Organizational Success stresses that internal audit can assist management and the board of directors in their change management by: understanding the objectives of the organization regarding, confidentiality, integrity and availability of IT processing, identifying risks that could arise from changes and determine whether such risks are consistent with the organization’s risk tolerance, looking for and foster a culture of disciplined change management, including promoting the benefits of good change management.

Auditors are aware of the tight relationship between change and risk. IT assets seem to be in a state of constant change. According to Davis C. (2007, pg. 20) the technical areas in which an IT auditor might have constant preoccupations are:

- *„Entity-level controls.* The controls that are pervasive across the organization and provide the basic foundation for the control environment at the company. Examples of standard entity-level controls are company policies and mechanisms for complying with regulations such as Sarbanes-Oxley.
- *Physical facility.* The physical building and data center housing the computer equipment on which the system in question resides.
- *Networking and communications infrastructure.* They allow other systems and users to communicate with the system in question when they do not have physical access to it. This layer includes basic networking devices such as firewalls, switches, and routers.
- *Operating system.* They provides the basic operating environment on which the higher-level application runs. Examples are Unix, Linux, and Windows.
- *Middleware.* This is software that provides additional integration between two separate "programs" that were not originally designed to communicate with each other (e.g., between a database system and a web server or between an application and a database that it was not originally designed to access).

– *Database.* This is the tool that organizes and provides access to the data being run by the end application.
– *Application.* This is the end application, which actually is seen and accessed by the end user. This could be an *enterprise resource planning* (ERP) application providing basic business functions, an e-mail application, or a system that allows conference rooms to be scheduled."

This is not intended to be an exhaustive list of potential subject areas and technologies that could be reviewed by an IT auditor. It is instead intended to illustrate some of the more common layers that might be reviewed during an audit. The stack of potential auditing subject areas could be made significantly more complex and granular if desired, spiking out topics such as storage and web servers. "

Conclusions

During this article we stressed that the environment in which an organization operates has a pervasive influence on it. As a resultant of this influence the organization needs to assimilate the most effective and efficient technologies. But this leads to a reshape in the business architecture.

The increasing complexity of a business information systems that is the foundation of an enterprise architecture poses a wider range of threats and risks an organization is exposed to due to extensive usage of information technology capabilities. This leads to a need for a flexible and adaptable internal audit function and it's component the IT audit team.

IT auditors ensure that the core infrastructure supporting the company's systems has the proper security and controls. These audit teams generally consist of IT professionals who understand how to use application systems. In addition, the IT auditors might help to review some of the general application controls, such as change controls and overall system access administration.

THE REFLECTION OF THE DUALITY IN THE PUBLIC ACCOUNTING OF THE BUDGETARY INCOMES AND EXPENSES

Cenar Iuliana

University „1 Decembrie 1918"of Alba Iulia, Faculty of Science, Alba Iulia, N. Iorga, nr. 11-13, cenar_iuliana@yahoo.com, Phone 0766-662948

The public institutions accounting remains a budgetary accounting, because the central axe in which she builds the accounting information is the budget. This is the legal document, which establishes also in nature and in measure of the mobilized incomes to the state as well as the way volume of the budgetary allocations, which will be lead by the state for the finance of different activities during a year. The paper „The reflection of the duality in the public accounting of the budgetary incomes and expenses" presents the real accounting way of the budgetary incomes and expenses at the level of the state treasury in it's quality of cash collector of the public sector, and also at the level of the public institutions through which are realized operations which are supposed by the budgetary execution.

Key words: Accounting, Treasury, Public Institutions, Incomes, Expenses.

The contextual frame for the public institutions accounting

The public institution represents that organizatory structure of public nature through which the state and the administrative territorial units produce the social utilities, administrative, for the justice, public order, national defense and others. Accidentally the subunits of the public institutions can realize and produce units and services of economic nature.

The public accounting can perceive that the total amount of the principles that must be followed in order to realize complete evidences on the staff of the operations regarding the patrimony elements from the frame of the public institutions.

It has the evidence of the goods and incomes from the entering to the way out from the public patrimony; the evidence of the works and services taken by the public authorities till the end of those; the control operation regarding the way in which is managed the public finances resources and their way of use.

The public institutions accounting makes a logical subsystem integrated and coherent which reflects in the valor expression the interdependences between the sources of feeding of the public funds and their way of assignment and which presents the necessary competences for the economic operation control exercise generated by the different economic, social and politic phenomena's.

At the level of the public institution we notice (with delay) the opening to international of the accounting, through the approving of some accounting regulations, which promotes the accounting "principle" of engagements and generates the accounting in double part.

The accounting dimension of the budgetary incomes and expenses at the level of the State Treasury

The public treasury has the hole resources that the state have the instrument through which this creates the possibility to establish and apply the incomes and expenses politic, organizing its financial activity both at central level and in the territory.

The financial execution of the public sector is unrolled through he public institutions and the public finances treasuries, of which accounting makes the base of the informational system from the first till the last level of the national economy.

The house execution principle which stays at the base of the organization of the state treasury accounting which assures the registers of en-cashed operations and payments in the accounts of the incomes and expenses open on budgets, credit nominators, and subdivisions of the budgetary classification established by the Ministry of Economy and Finances.

The incomes en-cashed by the treasury are followed and distinct pointed out on budgets: state budget, local budgets, the state social assurances budget and others. In the frame of each budget is assured the evidence of the incomes realization on the incomes resources- chapters and subchapters from the budgetary classification, and also on the payers: economic agents, public institutions, tax payers- physical person.

The way of the forming of the incomes accounts in the treasury accounting is represented in a scheme like this:

The codification of the incomes accounts in the Treasury accounting

The codification of the incomes accounts in the Treasury accounting

The code of the synthetic account of the income[313]

The code of the income chapter

The code of the budget

The code of the subchapter of the income

The fiscal code of the payer

The instrumental accounting of the incomes in the frame of the treasury is realized like this:

The Town hall A puts in the cash of the treasury, with paper of the payment – the receipt, of the sum 3.654 lei, representing the tax encash on the building by the juridical persons.

10	=	2107020102	3.654
„House"		„Tax buildings juridical persons"	

The account 2107020101 formed like this:

2.1. – the synthetic account of the incomes from the local budget from the account plan specific to the treasury

07.02 – the budgetary chapter *Taxes and land taxes (*02 represent the budgetary account for the local budget)

07.02.01 – the budgetary subchapter *Taxes on buildings*

07.02.01.02- the article *Taxes on buildings from the juridical persons*

✎ SC. SIM SRL, fiscal code 1656838, pays by the collecting point of the treasury the sum of 297 lei, representing the contribution of the employer to the unique national fund of the social health assurances.

10	**=**	**26**200503*1656838*	2.970
„House"		„Contributions of social health assurances due by the employers	

The account **26**200503*1656838* formed like this:

26 – the synthetic account of incomes to the budget of the unique national fund of the social health assurances from the account plan specific to the treasury

20.05 – the budgetary chapter *The employers contributions* (05 represents the budgetary code fro the unique national fund of the social health assurances)

20.05.03 –the budgetary subchapter *Contributions of social health assurances due by the employers*

1656838- the fiscal code of the payer

The credit authority of the "budgets" is authorized to employ, to liquidate and order the expenses during the budgetary exercise, in the limit of the approved budgetary credits.

The way of forming of the expenses accounts in the treasury accounting is represented in a schematic way like this:

The expenses accounts forming in the Treasury accounting

The codification of the

The code of the synthetic expense account[314]

[313] The codes of the synthetic accounts of the budgetary incomes in the accounting of the treasury are the next: 20 - state budget incomes; 21 – local budget incomes; 22 – social state assurances budget incomes; 26 – the incomes of the budget of the Unique national fund of social health assurances 28 – incomes of the budget for the unemployment assurances.

[314] The codes given tot he expenses in the treasury accounting are the next: 23 – expenses of the state budget; 24 – the expenses of the local budgets; 25 - social state assurances budget expenses; 27 - expenses of the budget of the Unique national fund of social health assurances; 29 - expenses of the budget for the unemployment assurances.

expenses accounts in the Treasury accounting

The code of the expense chapter

The budget code

The code of the expense title

The fiscal code of the public institutions

The accounting transpose of the operations that generates the expenses for the different budgets is realized like this:

with the purpose to discount the expenses on the pupils transport the Town hall of the village C takes based on the cheque the sum of 11.580 lei.

24650220*4562028*	=	**10**	11.580
„The expenses of the local budgets”		„House“	

The numeric component of the account **24**650220*4562028* is explained like this:

24 – the symbol of the synthetic account *Expenses of the local budget*

6502 – the code for the chapter of expenses *Education*

20 – the expenses title *Goods and services*

The district house of alimonies deposits by cash order the sum of 195.000 lei representing the lab our conscriptions of the alimonies due to the pensioners:

25680357*4562028*	=	61	195.000
„The expenses of the state social assurances budget”		„The correspondent account of the treasury”	

The account **25**680357*4562028* formed like this:

25 – the expenses of the state social assurances budget;

6803 – the chapter of the social assistance and assurances budget;

57 – the expenses title– *Social assistance*;

4562028 – the fiscal code of the alimony house

So in the decode of the resorts of the treasury accounting to the public institutions are essential the finance ways the budgetary source of the funds source, the typological knowing of the special funds and others.

Some accounting references from the level of the “public institutions[315]”

The incomes of the state budget, the local budgets, the state social assurances budgets the health social assurances budget, the unemployment assurances budget are made out of the taxes, contributions and other incomes approved from the economic agents and from the tax payers and also from the payment of the public institutions and other incomes approved by budgetary law by the Parliament.

The incomes are registered in the public institutions accounting on the documents which certifies the creation of the claim right (the fiscal declaration or the decision sent by the fiscal authority), expedition notification, bills and other legal papers made or in the effective moment of the encash in the situation in which there does not exist previous documents to the encase in order to register the claim.

The structure of the accounting account of incomes to the public institutions has the next elements: the symbol of the account from the accounts plan; the budget of which the income belongs: the chapter; subchapter and the budgetary article.

The forming of the incomes account to the public institutions

The codification of the incomes accounts in the accounting of the public institutions

The symbol of the account from the accounts plan

The income source

The budgetary chapter

The subchapter

[315] Less the State Treasury

The paragraph

The registration of the District House of Health Assurances of the contributions to the unique national fund of social health assurances due to the physical persons or juridical which employ persons:

4665.20.05.03.01 = **7453.**20.05.03.01 2.970

The claims of the unique national fund of social health assurances — The contributions of the employers for the social health assurances. Contributions from the juridical or physical persons, which employs persons

The signification of the numeric symbol of the incomes account is the next:

7453 - - the symbol of the synthetic account Contributions of the employers for the social health assurances

20.05 – the budgetary chapter entitled *The employers contributions*

20.05.03 – the budgetary subchapter *Contributions of social health assurances due by the employers*

20.05.03.01 – the paragraph Contributions from the juridical or physical persons that employs persons

at the Town hall is pointed out in the accounting the budgetary claim represented by the tax on the buildings due by the juridical persons:

464 = **734.**07.02.01.02 3.654

The claims of the local budget — Taxes on property. The tax on the building from the juridical persons

The numeric structure of the account **734.07.02.01.02** has the next signification:

734 - the symbol of the synthetic account Taxes on property

07.02 – the budgetary chapter Taxes on property

07.02.01 – the budgetary subchapter Tax on buildings

07.02.01.02 – the paragraph Tax on buildings from juridical persons

At the public institutions the expenses accounts are developed in analytic on budgetary classification structure.

The symbol of the analytic account is made like this:

The forming of the analytic account of expenses at the public institutions

The codification of the expenses accounts in the accounting of the public institutions

The symbol of the account from the accounts plan

The source of finance of the expenses

Subchapter

Title

Article

Paragraph

at the district house of alimonies is pointed out the obligation of payment to the pensioners in sum of 195.000 lei.

676.57.01.03 = 4221 195.000

Social assurances — Civil pensioners- debt alimonies

The codification 676.57.01.03 has the next signification:

676. – the symbol of the synthetic account Social Assurances

57 – the title of the expenses from the economic classification entitled Social Assurance

57.01 - the budgetary article Social assurances

03 – the code of the budget of the state social assurances

the Town hall of the village is taking the evidence of the expenses with the pupils transport in sum of 11.580 lei which it will be paid lately from the financed account:

624.20.01.07	=	401	11.580
Expenses with transport of goods and personnel		Suppliers	

The analytic accounting "of the budgetary incomes and expenses" is imposed by the juridical norms to assure units of content of the budgetary incomes and to facilitate the indicators obtain at the macroeconomic level. In this way the accounting is proving again the capacity tot produce inform nations which to respect the norms with the purpose to assure the qualities such as the relevance, credibility, clearness and comparing.

Conclusions

The objectives related to the devoted and opportune reflection of the way of realizing the incomes and the expenses and also to supply through the budget the information's regarding the realization of the incomes, level, structure and the expenses dynamic, justifies the role extremely important of the budgetary information in the frame of all the public institutions.

So as we notice the accounting dualism to which we refer in the tile of the paper regards the double manner, the dual accounting instrumentation of those categories of budgetary incomes and expenses by reporting them to the different public entities: the public institution which notices/encash the income or the expense and the state treasury with its role of cash collector of the public sector. For the reflection of the accounting in the Treasury of the budgetary incomes and expenses is used a plan of accounts different from the one used by the other public institutions. At the level of the public institutions is applied the engagement in order to recognize the budgetary incomes and expenses when in the treasury accounting is used the base accounting on cash in order to recognize the same elements that generates the result.

The budgetary classification assures the link between the two categories of entities reported to the budgetary execution with the meaning that both public entities symbol of the numeric accounts of expenses includes the code title specific in the economic classification. Also the code of the chapter of incomes is found also in the structure of the incomes of the public institutions and of the Treasury.

CONSEQUENCES OF THE INFLATION OVER THE CONTINUITY OF ENTERPRISES` ACTIVITY

Cozma Ighian Diana

Universitatea de Nord, Facultatea de Ştiințe Economica, str. Victor Babeş, nr. 62/A , Baia Mare, județul Maramureş, Telefon: 0262-218922, Fax: 0262-276153

In conditions of inflation, the historical costs accounting, related to a basic principle of accountancy, that is the caution principle, lead to the enterprises decapitalization, with serious consequences over the continuity of the activity in conditions of economic efficiency. Therefore, finding new alternatives which could lead to the removal of this deficiency in the traditional accounting model, in conditions of inflation, is an imperative. In this context, the major objective of the firms that carry on their activity in an inflationist environment is to maintain their capital, as well as to secure a profit which can ensure the maintenance of the capital, the continuity of the activity depending mainly of its fulfillment.

Key words: inflation, financial capital, physical capital

The inflation is a self sustained phenomenon of an overall price increase, which affects the economy of a state, having important implications not only at an economical level, but also to the social one. The inflation has as effect the corrosion in time of money value, as well as the sustained price growth in economy.

In most countries, the financial statements are produced on the basis of the historical costs, without taking into account the changes of the overall price level or the individual change of the owned assets prices, except for the fixed assets, that were reassessed. Thus, the assets elements, the capital accounts, the debts, the incomes and the expenses are expressed in accordance with the value existing at the date when these elements appeared. The impact of the inflation is consequently ignored.

The inflationist phenomenon distorts the accounting information presented through the financial statements in two ways:

- it diminishes the accounting information's capital accounts;
- it over valuates the results of the accounting period;

In conditions of inflation, the historical costs accounting, related to a basic principle of accountancy, that is the caution principle, lead to the enterprises decapitalization, with serious consequences over the continuity of the activity in conditions of economic efficiency. Therefore, finding new alternatives which could lead to the removal of this deficiency in the traditional accounting model, in conditions of inflation, is an imperative. In this context, the major objective of the firms that carry on their activity in an inflationist environment is to maintain their capital, as well as to secure a profit which can ensure the maintenance of the capital, the continuity of the activity depending mainly of its fulfillment.

The distinction between profit and capital is extremely important in inflationist conditions. As long as the source of obtaining the profit is the capital, this one can not be consumed without affecting the future profits. So, the capital must remain intact in order to be able to produce the same profit level.

"In general terms, an enterprise maintained its capital if at the end of the period, it has a capital that is equal tot the one from the beginning of the period. Any other supplementary value besides the needed one in order to maintain the level from the beginning of the period is considered to be profit."[316]

"*The concept of capital preservation decides the extent to which an enterprise can allot the accruals obtained during the year without prejudicing its future*[317]*"*.

Consequently, the profit is the maximum value that an enterprise can allot during the year, so that it can preserve intact the capital owned at the beginning of the period.

[316] General Framework for the Preparation and Presentation of Financial Statements issued by the International Accounting Standards Board, pct. 107, overtaken in OPFM no. 94/2001 (O.G. no. 85/20.02.2001)
[317] Lavinia Olimid, Măsurarea rezultatului contabil, Economic Publishing House, Bucharest, 1998, page 60

Within an economy which is not affected by inflation, the profit obtained at the end of the period represents the real profit, and it can be consumed entirely, without the fear of impoverishing the capital. The capital is expressed in the same monetary units as at the beginning of the period and remains intact during all this time.

But in an inflationist environment, taking into account the fact that the incomes are expressed in real monetary units (in terms of the value of money from the moment of their recognition), and the expenses which are to be connected to these incomes are expressed in nominal monetary units (in terms of the value of money from the moment of achieving the assets which generated the expense), in order to find the real profit and to compute an unitary result of the activity, the expenses must be expressed in real monetary units.

The overall expenses adjusted to inflation will represent the sum of the value of expenses expressed in nominal monetary unit, and the price variations between the real monetary unit the nominal one due to the assets which generated the respective expenses.

Therefore:

$Cr = Cn + v$ where:

Cr – expenses expressed in real monetary units,

Cn – expenses expressed in nominal monetary units;

v – price variations due to the assets.

The real profit will be:

$Pr = V – Cn - v$

The historical costs profit (Pci) will represent the sum of the real profit and this price variations, which is in fact the gain resulting from the owning of the assets that generated the expense.

$Pci = Pr + v$

This owning gain represents the sum that needs to be invested in the enterprise, so that the capital level stays the same. In other words, the existence of the owning gain determines the issue of the capital preservation concept.

The question is: *this owning gain must be regarded as a constitutive part of the profit which is to be distributed later on, or as an element of the capital account under the form of a resource?*

The answer to this question can be found depending on the means of capital measurement. From the point of view of the desired objective of the enterprise, there are two perspectives regarding the capital measurement:

- the owner's (shareholders)
- the enterprise's

1. The owner's capital (financial) and its maintain

The owner's capital is found in the specialty literature under the name of financial capital. The paragraph 102 from the Conceptual Framework IASB defines the financial capital: "the financial capital is synonym with the net assets or with the entity's capital account".

The concept of financial capital maintain is defined in the paragraph 104 from the Conceptual Framework IASC[318], where it is specified that "according to this concept, the profit is secured only if the financial value of the net assets at the end of the period is higher then the financial value of the net assets from the beginning of the period, after the exclusion of all distribution towards the owners and of any contributions of the owners during the analyzed period."

In other words, the increase of the assets value, which exceeds the overall price increase, is to be recognized as profit.

The preservation of the financial capital can be measured in nominal monetary units, by using the concept of nominal financial capital or stable value of money, through the real financial capital.

[318] General Framework for the Preparation and Presentation of Financial Statements issued by the IASC Board and adopted IASB, International Financial Reporting Standards, page 54, CECCAR Publishing House, Bucharest, 2005

When the prices are stable, we can talk about the preservation of the nominal financial capital. The sharable profit represents the difference between the capital accounts existing at the end of the period and those from the beginning of the period, taking into account the possible capital increases or decreases which appeared during the year due to the owners` contributions or withdrawals.

When the prices are variable, the term of real financial capital becomes operational. As the preservation of the nominal capital becomes insufficient, the capital accounts from the beginning of the accounting period are adjusted according to the variation of the overall price index in order to preserve the real capital.

The financial concept of the capital must be adopted if the users of the financial statements are concerned mainly with maintaining the invested nominal capital or maintaining the value of the invested capital.

According to this concept, the profit is recognized only after the value of the capital accounts is maintained. All the adjustments that need to be done to the financial statements, so that the enterprise's financial capital (capital account or the net assets) stay stable, are the objectives of the conversion based methods (methods based upon the current value of money). This methods aim to adjust the financial statements expressed in nominal unitary methods, with the purpose of expressing them in stable monetary units , and also the quantification of the result owned to the national currency depreciation.

In order to exemplify the above mentioned, let's take the following hypothetical example:

At the beginning of the N accounting period, an enterprise has a share capital of 300 m.u., representing a building with the value of 200 m.u., stocks in value of 80 m.u. (40 pieces * 2 m.u./piece) and money supply in value of 20 m.u. The building is subjected to a straight-line amortization for a remaining period of 20 years. At the end of the N accounting period, the enterprise sells 20 pieces of stock at the price of 3m.u./piece.

During the N period, the overall price increase was of 20%.

(Historical costs) Balance sheet at the 1st of January N

Table no. 1

Fixed assets Stocks (40 pieces*2 m.u./piece) Money supply	200 m.u. 80 m.u. 20 m.u.	Share capital	300 m.u.
Total assets	300 m.u.	Total liabilities	300 m.u.

Loss and gain account at the 31st of December N

Table no. 2

Elements	In historical costs	In historical costs modified depending on the evolution of the overall value of money
Sales incomes - the cost of the sold stocks - the building amortization Losses from owning monetary elements (money supply)	60 m.u. (20*3 m.u.) -40 m.u. (20*2 m.u.) -10m.u. (200*5%/year)	60 m.u. (20*3 m.u.) -48 m.u. (40*1,2) -12 m.u. (10*1,2) -4 m.u. (20*0,2)
Profit	10 m.u.	-4 m.u.

The balance sheet from the end of the N accounting period expressed in current value of money will be:

Balance sheet at the 31st of December N

Table no. 3

Gross fixed assets (200*1,2) - amortization Net fixed assets Stocks (40*1,2) Money supply (20 + 20*3 m.u)	240 m.u. -12 m.u 228 m.u. 48 m.u. 80 m.u.	Share capital (300*1,2) Profit/Loss	360 m.u. - 4 m.u.
Total assets	356 m.u.	Total liabilities	356 m.u.

The real profit computed as a difference between the capital accounts from the end of the accounting period and the capital accounts from the beginning of the accounting period adjusted with the overall price index is:

Pr = 356 m.u. – 300 m.u.*1,2

Pr = -4 m.u.

The monetary elements (cash assets and debts) stay recorded at their nominal value in the financial statements from the end of the accounting period. The difference between them will determine the gain/loss from owning monetary elements, which will appear as a different position in the loss and gain account.

In what concerns the non monetary elements, these will be recorded in the financial statement at their new value adjusted in counter trade with an element of expenses or incomes, from case to case, for the adjustments of the current year, and a resources account for the adjustments of the previous years.

In conclusion, the adjustment of the financial capital, with the purpose of its maintenance, will be done through the overall prices index. This perspective admits the effect of the inflation over the patrimonial monetary and non monetary elements as a component of the enterprise's result.

2. The enterprise's capital (physical) and its maintain

The general framework IASB defines in the paragraph 102 the concept of physical capital or "the exploitation capacity" as it follows: "*the capital represents the production capacity of the enterprise expressed, for instance, in production units per day"*.

The concept of maintaining the physical capital is defined in the paragraph 104 as it follows: "*according to this concept, the profit is secured only when the productive physical capacity (exploitation capacity) of the enterprise at the end of the period surpasses the productive physical capacity from the beginning of the period, after the exclusion of all distribution towards the owners and of any contributions of the owners during the analyzed period*."

The profit determined on the basis of the historical cost does not make the distinction between the profit resulting from exploitation and the profit resulting from owning goods whose current cost is higher than the cost to which they were achieved. These owning gains are not gains obtained during the maintenance of the goods in enterprise's possession, and when they are to be sold, they will be entirely recognized in the gains and losses account, even if they are due to more accounting periods.

The concept of maintaining the physical capital decides the extent to which these gains are included in the sharable profit. With the purpose of maintaining the productive capacity of the enterprise, the increase of the assets value, and the latent additional value, will be recorded in the resources category, in a distinct account "adjustment reserves". The maintenance of the enterprise's physical capital is possible only if these reserves are not sharable.

With the purpose of establishing the production capacity which needs to be maintained, the goods that are used within the production process (fixed assets and stocks) must be expressed in current values, and also in values into which they can exchange at a certain point using real basis.

Among the assessment bases which can be used in the assessment of the financial statements (historical cost, current cost, realizable value and present value), the current cost, the realizable value and the present value can be considered as forms of the current value.

As it is determined based on some objective values (book value, specific price index), the current cost is the assessment base used the most often in order to express the present value of the goods. *The current cost* is the delivered cost of an equivalent new good, to which a rectification for depreciation is applied. The current cost can also be determined by multiplying the book value of the good with a price index specific to that category of goods.

Starting from the previous numerical example and knowing that, at the end of the accounting period, the stocks replacing cost is of 2, 5 m.u./piece (it grew with 25% from the beginning of the period), and the replacing cost of the fixed assets is of 240 m.u. (it grew with 20% from the beginning of the period), the financial statements will be retreated with the purpose of maintaining the physical capital as it follows:

Loss and gain account at the 31st of December N

Table no. 4

Elements	In historical costs	***In current costs***
Sales incomes - the cost of the sold stocks - the building amortization	60 m.u. (20*3 u.m.) -40 m.u. (20*2 m.u.) -10 m.u. (200*5%/year)	60 m.u. (20*3 m.u.) -50 m.u. (20*2,5 m.u.) -12 m.u. (240*5%/year)
Profit	10 m.u	-2 m.u

Determining the capital gains

Table no. 5

Realized yield from the sold stocks owning (20*(2,5-2))	10 m.u.
Realized yield from the building owning – interest from yearly amortisation ((240-200)*5%/year)	2 m.u.
Unrealized yield from the unsold stocks owning (20*(2,5-2))	10 m.u.
Unrealized yield from building owning ((240-200)-2)	38 m.u.
Total owning income	60 m.u.

The balance sheet of the N period, expressed in current costs is:

Balance sheet at the 31st of December N

Table no. 6

Gross fixed assets -amortization (240*5%/year) Net fixed assets Stocks (20*2,5 m.u) Money supply (20+20*3m.u.)	240m.u. -12 m.u. 228 m.u. 50 m.u. 80 m.u.	Share capital Profit/Loss Reserves of capital maintaining	300 m.u. -2 m.u. 60 m.u.
Total assets	358 m.u.	Total liabilities	358 m.u.

The real profit, computed as the difference between the capital account from the end of the accounting period and the capital accounts from the beginning of the accounting period, adjusted with specific price index of the non monetary assets, is:

Pr = 358 m.u. – (200 m.u. * 1, 2 + 80 m.u. *1, 25 + 20)

Pr = -2 m.u.

The non monetary assets are presented in the balance sheet at present value, and the profit will be recognized by the enterprise only after its operational capacity was maintained.

The adjustments made to the financial statements with the purpose of maintaining the enterprise's production capacity, represent the objectives of the assessment based methods (current costs based methods). These methods are oriented towards the usage of the specific index for the value correction of different categories of goods, of the amortisements and of the sales cost.

In conclusion, the maintenance of the enterprise's physical capital is done through the specific price index of the non monetary assets, recognizing the profit only after the capital was maintained.

3. The maintenance of the owners' and enterprise's capital

As resulting from those mentioned above, the adjustments made in order to maintain the financial capital do not take into account the fact that most prices of certain goods can surpass the overall price changes, and this prejudices the maintenance of the physical capital.

Moreover, with the purpose of maintaining the physical capital the inflation impact is quantified only in the case of non monetary assets, without taking into consideration the influence that the inflation has over the monetary elements of the enterprise, and this way, the complete maintenance of the financial capital is not ensured.

In order to maintain the financial capital, as well as the physical capital, the profit must be corrected with the gain or with the loss from monetary elements owning and diminished with the gain owed to the value increase of the non monetary assets over an overall price increase.

In the balance sheet, the non monetary assets are to be presented to an adjusted value, adjustment made through the overall price index or through the specific price index, depending on which one id higher, and the non monetary liabilities are to be adjusted through the overall price index. The monetary elements will stay recorded in the balance sheet at their nominal value.

The gains resulting from the non monetary assets owning, whose specific price index surpasses the overall price index, will be recorded under the form of non sharable reserves, which will rise the enterprise's capital accounts.

With the purpose of preserving the financial and the physical capital, the capital accounts from the beginning of the accounting period are to be adjusted with the overall price index, except for the non monetary assets whose prices are higher than the overall prices increase, which are to be adjusted through the specific price index to the respective assets.

Starting from the same numerical example, the financial statements adjusted with the purpose of maintaining the financial capital, as well as the physical capital, are as it follows:

Loss and gain account at the 31st of December

Table no. 7

Elements	In historical costs	In historical costs adjusted with the purpose of maintaining the physical capital and the financial capital
Sales incomes	60 m.u. (20*3 m.u.)	60 m.u. (20*3 m.u.)
- the cost of the sold stocks	-40 m.u. (20*2 m.u.)	-50 m.u. (20*2,5m.u.)
- the building amortization	-10m.u. (200*5%/year)	-12 m.u. (10*1,2)
Losses from owning monetary elements (money supply)		-4 m.u. (20*0,2)
Profit	10 m.u.	-6 m.u.

Determining the capital gains

Realized yield from the sold stocks owning (20*2,5-40*1,2) Unrealized yield from the unsold stocks owning (20*2,5-20*2*1,2)	2 m.u. 2 m.u.
Total owning income	4 m.u.

Table no.8

Balance sheet at the 31st of December N

Table no. 9

Gross fixed assets	240m.u.		
-amortization (240*5%/year)	-12 m.u.	Share capital(300*1,2)	360 m.u.
Net fixed assets	228 m.u.	Profit/Loss	- 6 m.u.
Stocks (20*2,5 m.u)	50 m.u.	Reserves of capital maintaining	4 m.u.
Money supply (20+20*3m.u.)	80 m.u.		
Total assets	358 m.u.	Total liabilities	358 m.u.

Pr = 358 – (200*1,2+80*1,25+20*1,2)

Pr = -6 m.u.

The capital accounts from the end of the accounting period expressed in real monetary units are of 358 m.u, and those from the beginning of the accounting period, adjusted with the purpose of expressing them in real monetary units are of 364 m.u., the difference between them representing the real loss, of 6 m.u.

If we compare the historical costs accounting system with the three accounting systems which have as purpose the maintenance of the capital in inflation conditions, we can see that historical costs profit is of 10 m.u., which is equal to a 4 m.u. loss if the financial capital is maintained, a 2 m.u. loss if the objective was the maintenance of the enterprise's production capacity and a 6 m.u. loss if the objective was the maintenance of the owners` capital, as well as of the enterprise's capital.

The choice of one of the capital preservation concepts is motivated by the requirements of the accounting information users, as well as their interest in maintaining the financial power of the invested capital or the operational capacity of the enterprise.

The maintenance of the financial capital is mainly preferred by owners, as it leads to the attainment of a maximum profit and to the maintenance of the capital value.

The physical concept of capital preservation is more attractive for an enterprise' managers and employees, which can consider that the objective of an enterprise is to perpetuate its existence, by providing future goods and services similar to those in the present.

Even if the enterprise's main objective is to maintain the physical capital, as the prices increase, the physical capital needs a higher financial capital, and this capital can be achieved by reinvesting the profit from the previous years or it can be brought by shareholders.

We can conclude that the objective which should be followed is to maintain the owners` possession in an inflationist environment and to maximize it, and this objective is also in compliance with the employees` requirements (jobs availability, safe wages, etc). This thing is to be achieved by the implementation of the inflation adjustment procedures of the enterprise's financial statements items.

Abstract: *The objective of IAS17 Leases is the prescribed for lessees and lessors, the appropriate accountancy policies and disclosure to apply in relation to finance and operating leases.*

This Standard applies to agreements that transfer the right to use assets even though substantial services by the lessor may be called for no other brand, this Standard does not apply to agreements that are contracts for services that do not transfer the right to use assets from one contracting party to the other.

Keywords: *leases, lessors, finance leases, operating leases*

CLASSIFICATION OF LEASES

The classification of leases adopted in this Standard is based on the extent to which risks and rewards incident to ownership of based assets to with the lessor or this lessee.

Risks include the possibilities of lessees from idle capacity or technological obsolescence and of variations in return due to changing economical conditions.

A lease is classified as finance lease if it transfers substantially all the risks and rewards incident to ownership. An operating lease is a lease other than a finance lease. A non-cancelable lease is a lease that is cancelable only:

a) upon the occurrence of some remote contingency;
b) with the permission of the lessor;
c) if the lessee enters into a new lease for the some or an equivalent assert with the some lessor;
d) upon payment by the lessee of an additional amount such that, at inception, continuation of the lease is reasonably certain" (1)

The inception of the lease is the earlier of the date of the lease agreement or of a commitment by the parties to the principal provisions of the lease.

The lease term is the non-cancellable period for witch the lease has controlled to lease the asset together with any further terms for witch the lesser has the option to continue to lease the assets with or without further payment, which option at the inception of he lease it is reasonably certain that the lessee will exercise.

Minimum lease payments are the payments over the lease term that the lessee is, or can be required, to make excluding contingent rent, costs for services and taxes to be paid by and reimbursed to the lessor.

Fair value is the amount for which an asset could be exchanged or a liability settled, between knowledgeable, within parties in an arm's length transaction.

FINANCE LEASES

LEASES IN THE FINANCIAL STATEMENTS OF LESSORS

Lessors should recognize assets held under a finance lease in their balance sheets and present as a receivable at an amount equal to the net reinvestment in the lease.

Under a finance lease substantially all the risks and rewards incident to legal ownership are transferred by the lesser, and thus the lease payment receivable is treated by the lessor as repayment of principal and finance income to reimburse and reward the lessor for its investment and services.

The recognition of finance income should be based on a pattern reflecting a constant periodic rate of return on the lessor's net investment outstanding in respect of the finance lease.

A lessor aims to allocate finance income over the lease term on a systematic rational basis. This income allocation in based on a pattern reflecting a constant periodic return on the lessor's net investment outstanding period, excluding costs for services, are applied against the gross investment in the lease to reduce both the principal and the unearned finance income. As asset about finance leases why is classification whereupon for sale in conformation with IFRS fixed assets whereupon for sale and worth interruption should be registering in conformation with IFRS. For registration in bookkeeping the type sell leases, is necessary as lessors to determined following elements:

1. gross investment
2. assets fair value
3. the cost

The entity should be count and sum's rest necessary bookkeeping:

The leases debt = Wholesale

Assets sale cost = Stocks

The financial income unfulfilled respectively:

2678	=	701
Other Assets debts		Income solve finish products
711	=	%
Stocks variety		345 Finish products
		472 The financial income unfulfilled

Manufacturers or dealers often offer to customers the choice of either buying or leasing an asset. A finance lease of an asset by a manufacturer or dealer lessor gives rise to two types of income:

- the profit or loss equivalent to the profit or loss resulting from an outright sale of the asset being leased, at normal selling prices, reflecting any applicable volume or trade discounts;
- the finance income over the lease term.

The cost of sale recognized at the commencement of the lease term is he cost, or carrying amount if different of the leased property less the present value of the non-guaranteed residual value. The difference between the sales revenue and the cost of sale is the selling profit which is recognized in accordance with the policy followed by the enterprise for sales.

Lessors should, in addition to the requirements in IFRS7 "Financial Instruments", make the following disclosures for finance leases (2):

a) a reconciliation between the total gross investment in the lease of the balance sheet date, and the present value of minimum lease payments receivable. At the balance sheet dates.

b) the entity should disclose the total gross investment in the lease and the present value of minimum lease payments receivable at the balanced sheet data, for each of the following periods:

1. not later than one year
2. later than one year and not later than five years

3. later than five years
4. unfulfilled finance income
5. the non-guaranteed residual values arriving to the benefit of the lessor
6. the accumulated allowance for uncollectible minimum lease payments receivable
7. contingent rents recognized in income
8. a general description of the lessor's significant leasing arrangements.

CONCLUSION

IAS17 Accounting for leases applies to agreements that transfer the right to use assets even thought substantial services by the lessor may be called for in conversion with the operation or maintenance of such assets.

This standard does not apply to agreements that are contracts for services that do not transfer the right to use assets from one contracting party to the other.

Abstract: Starting with the first days of the year 1990, there were created groups of interests specialized in contraband operations, both for exportation and for importation, in operations of speculation with scarce products, in performing some services of transport-taxi, public alimentation, etc. There were the first component elements of the black economy that appeared and developed in Romania, the incomes of which were important in most cases and constituted the necessary capital for initiation in legal organized businesses. Among the component elements of black economy, the most spread in our country were the activities performed without registering, tax dodging and black labour.

Key words: fiscal fraud, black labour, formal sector, informal sector

The transition of Romania from the planned economy to the market economy favourized the appearance and the manifestation of the black economy. Corruption and activities characteristic to the black economy are realities to which all states fight against, including the transition economy of Romania.

The National Statistics Institute estimates the value of hidden economy at approximately 20 billions euro annually taking into consideration only black labour, the TVA fraud and the domestic industry, the weight being held by the first two. In Romania, black labour assures the necessary living incomes for over one million people. It is the effect of the economical development; the mass of the accumulated capital surpasses the absorption capacity of the unofficial sector so that the new rich from black activities officialize their role and new status through their penetration in illegal activities.

In the transition period, Romania implemented the national accounts in the Romanian statistical system starting with the calculation year 1989. The European System of National and Regional Accounts, version 1995/(SEC95) has applied in Romania starting with the year 1989. The methodology SEC95 is obligatory for the Countries Members of the European Union, being the compatible and coherent background at the international level with the revised of the National Accounts System 1993 (SCN93) used by the big international organization. The data obtained in the European System of National and Regional Accounts are used for:

* giving subventions to the regions of European Union through structural funds for which the expenses are estimated on the data of the regional accounts;

* the control and the orientation of the European monetary politics starting from the data provided by the assembly of the national accounts (public debt, public shortage, PIB, etc.);

* the calculation of resources proper to the European Union on the basis of the data provided by the national accounts of the member states, thus:

- the totality of the resources of the European Union is determined as percentage from the gross national products of the member states;
- the contribution of every state to the third resource proper to the European Union (also called TVA) is much influenced by the national accountancy;
- the relative contribution of every member state to the forth proper resource of the European Union is based on the national gross proper product.

In the methodology of national accounts elaborated by SNC 93 and SEC 95 are used the following concepts and terms concerning the hidden economical activities of the production units: illegal, hidden, informal.

The essential factors that allowed the exacerbated development of black economy can be, mainly, the following:

- legislative uncertainties which accompanied the economical mutations;
- the uncontrolled economical division, the appearance of some small enterprises with speculative, temporary activity;
- decentralization, division of power through the distribution of responsibilities, thus increasing the number of compatible individuals;
- the tolerant attitude, both of the authorities, and of the population to the breaking of regulations, a certain reserve to the discipline;
- the immediate junction realized by the representatives of the parallel market existent in the socialist period with circles of similar preoccupations to those in the neighbouring states and, in this way, the connection to the international structures of the black economy.

The problems referring to the black economy were noticed and made public by the American P. Gutmanu, who, in the year 1977, appreciated that the statistically unregistered economical activity can not be further considered a negligible entity. To the same problem V. Tanzi expresses himself and sees the development of black economy as product of two big categories of factors: those connected to the desire to avoid taxes and those connected to the desire to avoid the governmental rules and restrictions.

In the speciality literature, there appeared a multitude of definitions, wider or more reduced, as following the diversity of activities that black economy reunites but also a series of particularities in space and time of this one.

We can define under the concept of black economy those activities the existence of which is not officially known (bookkept) and the incomes of which don't make the object of fiscal statements.

The definition given by Pierre Pestieau: the black economy represents "the ensemble of economical activities that are realized outside penal, social or fiscal laws or of those which escape (massively) to the inventory of national accounts" – is considered by specialists the widest definition of the black economy.

The definition that circulates on the international level and which is also adopted by the countries in the European Union, classifies the activities connected to the sphere of the black economy in:

1. **Undeclared licit (legal) productive activities** (the black economy) including activities that are not registered at the level of state through the system of national accountancy (domestic activities, volunteer labour, community service activities, etc.) and those that are not declared at the financial administrations (fraud and tax dodging, black labour, tips, etc.) and
2. **Illicit Productive Activities (illegal) of goods and services** (the production and the narcotic trade, the gun running, etc.) of course undeclared.

The System of National Accounts SNA from 1993 and the European System of Accounts ESA from 1995 are using the next concepts, which refer to the "invisible" economy:

- illegal production
- underground economy
- informal sector

Pierre Rosanvallon makes another classification of the activities of the underground economy, distinguishing between the underground economy and the secret economy like this:

* The autonomous economy classifies the not tradable underground activities in: the domestic work (self-consumption, taking care of children, housekeeping and gardening etc.)., helping services between neighbors, friends, family, voluntary work for physical persons, legal persons, or communities in general;

* The secret economy speaks about the tradable underground activities, like:

- undeclared legal activities: the production of the illicit enterprises, diminish reports of the production of the official enterprises, paid wages or undeclared or declared but diminished wages.
- delinquent activities: pimp activity, prostitution, gambling, swindle, corruption, bribery, insurance frauds, narcotic trade, usurious interest, money falsification, etc.

– illicit activities: work under the table, fiscal fraud, trade of labor force, etc.

Considering the divers definitions written in the specialized literature, and also knowing, for classification criteria, the report with the national accountability, the underground economy can be divided in two large sectors:

– a sector of the uncountable activities, because are hidden by those who practice them (illegal, illicit), and of course activities of fiscal fraud and criminal activities.
– a sector of legal activities, known, but which are not included in the national accounts: domestic activities, including self-control, secretariat work., etc.

Lippert and Walker made in 1977, a grouping of the assimilated activities of the underground economy concept, principally having the coinage and the legacy of the respective activities at the base:

Grouping of the assimilated activities of the underground economy concept

Type of activities	**Monetary transactions**		**Not monetary transactions**	
Illegal activities	Trade with stolen goods, narcotic trade, prostitution, gambling, smuggling and fraud, etc.		The exchange of narcotics, smuggling, production or cultivating drugs for self-consume, robbery for the self-consume, etc.	
Illegal activities	Illegal tax dodging (the undeclared incomes of those who become employed, the payment with cash or in nature goods from an undeclared job, bound to the deliverance of goods and legal services, etc).	Illegal tax dodging (the deductions given to the employees, the untaxed advantages received above the fee, etc.)	Illegal tax dodging (the exchange of goods and legal services, etc.)	Legal tax dodging (domestic activities, the help given to the neighbors, etc.)

Table 1

Source : Lippert O., Walker M., "The underground economy: Global evidence of its size and impact", The Frazer Institute, Vancouver, 1997

In the creation process of the Gross Domestic Product, we can see in Romania a special given attention to the estimations of the unnoticed market economy. From the point of view of the national systems of accountancy, the SCN/93/SEC95 from the unnoticed economy we understand the sum of economical activities which are hidden from the statistical observations, comprehending that is about something else than the illegal and hidden economy. According to The System of National Accounts SNA and the European System of Accounts ESA the production is defined like an activity where the entries are used to produce outcomes.

The issue regards of course the identification and the estimation of the illegal production and of the hidden economy which are not current in the national accounts but they are influencing the economy of a country, member of the European Union and who misinterprets the international comparisons.

The “illegal” concept mentioned above, it refers to the illegal activities (productive activities and unproductive activities) for which do not exists a general methodology accepted by the states of the European Union. The measuring and the introduction of those situations in the national accounts is different from a state to another. It’s important to exactly delimitate the activities which can be illegal in an economy and who blocks the compatibility assurance of the production between countries.

We can mention some illegal activities: the production of drugs and the narcotic trade; prostitution; illegal trade with tobacco, bootlegger, illegal trade with stolen cars, gun running; gambling with no license;

corruption, usurious interest; money falsification; robbery of art masterpieces, jewelers, banks; fraudulency and kidnapping; legal activities productive and unproductive made by unauthorized persons.

Some of those activities can be found at the border of the production, according to the national accounts and they are not included in the estimation of the production from practical reasons and from lack of dates.

The hidden economy is represented by the activities legally made, but which are intentionally hidden by the public authority for reasons like: the non-payment of the contributions to the social insurances, the non-payment of the income taxes, of the value added tax VAT or other taxes, avoidance of administrative procedures like the filling in of the statistically printed form or of other administrative documents. The hidden economy contains activities intentionally hidden in the purpose of reducing the production costs ("hidden" from an economical point of view) but also unnoticed activities cause of the deficiency from the statistically system.

From a statistically point of view, in the unnoticed economical sphere can be included: unregistered activities; under-report; non-answer; default of the actualized informations.

To identify the hidden economy and its integration in the process of valuate the value added tax and the next aspects must be respected:

- the existence of some procedures which permit values for the total production for a specific activity without separately identifying the different types of the hidden economical activities.
- the efficient utilization of the known dates and using also additional dates, obtained separately
- the estimation should be based on specifically adjustments and detailed using available sources and normal bounds between indicators
- the insurance of the results reliability using alternative estimations which can be compared and analyzed
- the insurance of the ideas and the assumption reliability which are important for the estimation procedures and must be periodically revisioned and explicitly presented.

For the identification of the unnoticed economy it is made the classification of the entire economy in two sectors: formal and informal. In the estimation of the unnoticed economy must be used that method which respects the evaluation of the sources of the existent dates and of the practice of estimations, of the efficiency rise of the date collection and of the answer level to the statistically investigations existing in the system and also the utilization of the available dates for the estimation of the unnoticed activities with some indirect techniques and of the adjustments and the development of new date sources.

According to the national accountancy, statistically dates covers only a part of the production. For the estimation of the unnoticed activities, on the international level we can not find standard methods which can be applied in all the countries and in any case. In Romania, the Statistically National Institute has improved each year the method used for the estimation of the unnoticed economy, according to the new dates, existing because of the investigation of different possible ways, the methodology is the same and assuring the comparability of the dates.

The formal sector of economy characterizes:

- the under report
- the estimation of the black market of labor by

a) the evaluation of the labor force supply
b) the evaluation of the labor force demand

the estimation of the tax evasion, of the **Value Added Tax fraud**

The non-financial societies, like institutional units from the formal sector are press hard by the National Institute of Statistic by the realized estimations of the under-report of the value added tax obtained using the underground force labor or using the tax evasion in the domain of the Value Added Tax.

According to the International Organization of Labor, the informal sector reunites the production units who represents a small authorized capital, a reduce level of organization and it's work relations are based on the family relations than on steady contracts. These units appear in the ménage sector, and their owners are totally responsible by the financial and non-financial obligations imposed by the production activity.

In SNA and ESA, the “informal sector” represents units that belong to the institutional sector “ménage” that contains developed activities, generally, by the members of the same family, artisans, craftsmen, etc. The owners of these units are totally responsible for the financial obligations relative at the production process. However, the activity of those units is, deliberately, hidden, entering in the sphere of the underground activities (the hidden economy from an economical point of view).

According to the European system of national accounts, the informal economy includes only the work under the table and the fiscal fraud.

From a statistic point of view the estimation of the unnoticed economy it is being made for all the activities realized by the family associations and workers from their own. An important category of the unnoticed economy is being represented by the activity realized by the unregistered units from the informal sector and there we can find: house painters, plumber, tailor, mechanics, teachers that give private lessons, persons that land their house during the holiday, etc.

The unnoticed economy from the formal and informal sector is being calculated and estimated according to the informations about the economical and social phenomenon, using statistic methods previous mentioned to determined the rate of these activities in the added value and in the Gross Domestic Product.

Resume: The new Labor Code adopted in 2003 in order to adjust the legislation to the European regulations brought significant changes in what regards the employment contract that also affected the accountancy related to it.

At a glance, one could say that accountancy of the damages caused by the employee to his employer couldn't arise any real difficulties. Nevertheless, the new labor Code completely removed the old form of the civil responsibility of the parties of the employment contract, meaning the material responsibility, which generated in our opinion significant changes in what regards the accountancy of the damages caused by the employees to

Their employer. In this paper, by an interdisciplinary approach, we are going to present certain difficulties that could be found in practice with a view to the registration of such debts in the accountancy of the commercial societies (firms) submitted to the provisions of the Law 82/1991 – the accountancy law.

Key words: Civil responsibility,Damages, Employment contract, Accountancy, Debtor, Debt recovery, Guarantee, Deduction

Since 1 March 2003 Romania has a new Labour Code[319], adopted as an absolute necessity to adapt the Romanian legislation to the *aquis communautaire*, to the socio-economical realities of the market economy and the transition period that characterizes our country.

From all the juridical institutions regulated by the Labour legislation, the most radical changes of all have been observed to the regard of the reparatory responsibility of the parties of the employment contract. If in the past there existed the material responsibility of the employees as a specific responsibility form that characterised Labour law, on the basis of which the recovery of the damages was accomplished by the issue of the imputation decision by the employer or through a payment statement signed by the employee, both of them being executory titles[320], nowadays the recovery of the damages caused by the employees to their employers can only be accomplished by an amiable agreement or a trial in court.[321]

Thus, according art. 270, first paragraph of the Labour Code, the employees bear the patrimonial responsibility, on the basis of the norms and principles of the civil contractual responsibility, for the damages they cause to their employer as a result of their guilt of in connection with their work.

In the same time, the employee who cashed from the employer a sum that he wasn't entitled to is mandated to pay it back. If the employee received goods of services that he wasn't entitled to he is obliged to bear their cost.

Taking in consideration that according to art. 164 of the Labour Code damages that the employee caused to the employer cannot be deducted form the salary by the employer unless they are settled by a final and irrevocable judgement, the doctrine[322] showed that, under the rule of the actual provisions, the only legal ways for the employer to recover the damage caused by an employee are for the last one to assume a

[319] Law 53/2003, published in the Official Romanian Journal, part I, no. 72 of 5 February 2003

[320] Art. 102 - 110 of the old Labour Code – Law 10/1972 regarding the Labour Code, published in the Official Romanian Bulletin, no. 140 of 1 December 1972

[321] Art. 270 – 275 of the new Labour Code

[322] **E. Lipcanu**, *Consideraţii critice în legătură cu o opinie aberantă referitoare la recuperarea de către angajatora prejudiciului pe care salariatul i l-a cauzat (Considerations about an aberrant opinion with a view to the recovering of the damages caused by an employee to his employer)* , in „Law Journal", no. 4/2004, pp. 78-80

written payment statement or for the employer to obtain a final and irrevocable judgment that orders the employee to pay the damage.

In the same time, nothing stops the parties of the employment contract to convene by mutual agreement on the extent of the compensation and the recovering procedure, according to the norms of the usual civil law, completed by the special labour law regulations.[323]

At a glance, one could say that accountancy of the damages caused by the employee to his employer couldn't arise any real difficulties. Nevertheless, the new regulations of the Labour Code regarding the patrimonial responsibility of the employees had an important impact over the accountancy of this kind of debts.

As in most of the cases the heads of the accounting departments are the ones that deal with the damages caused by the employees to their employer there have been many times that problems appeared in the practice, related to a very knowledge of the labour law legislation in this field, we consider that the present subject has a high importance both theoretical and practical.

In this paper we are going to present certain actual difficulties that could be found in the registration of such debts in the accountancy of the commercial societies (firms) submitted to the provisions of the Law 82/1991 – accountancy law.[324] Thus, we would also refer only to the damages caused by the employees hired by an employment contract on the basis of the Labour Code, by the companies mentioned above.

According to the provisions of art. 1, first paragraph of the Law 82/1991, as amended by the Law 259/2007,[325] the commercial societies, the national societies/companies, the administrations, national institutes of research and development, the cooperatives and other entities are obliged to organise and conduct their own accounting, meaning financial accounting according to the present law and the assets management accounting specific to their activity.

In the same time, according to the provisions of art. 43 of the same normative act, realising inexact accounting registrations with the intent to do so is forbidden.

Even more, according to the provisions of art. 43 of the same normative act, realising inexact accounting registrations or the omission to make the proper accounting registrations with the intent to do so, having the consequence of altering the incomes, expenses, the financial results and the active and passive elements reflected in the balance, constitutes the crime of intellectual forgery and is punished according to the law.

Therefore, the accounting registration of all the damages caused by the employees is mandatory, as they represent accounting operations as intended by the accounting law.

In order to realize the accounting registration, as expected, within the company certain acts are required, by which the employer takes account of the damage and the employee guilty of producing it. According to the provisions of art. 95 of the Collective Labour Agreement Unique at National Level for the years 2007 – 2010, the signing union confederations recognize the right of the employers to establish, under the conditions of the law, the disciplinary or patrimonial responsibility of the employees guilty of breaching the labour discipline norms or that cause damages to the employer. No reference is made regarding the way in which the responsibility of the employee would actually be determined.

Art. 6 of the Law 82/1991 stipulates that any economic-financial operation must be registered in the moment of its performance in a document that will be the basis of the accounting registrations, giving to the document the quality of a justifying act.

[324] Published in the Official Romanian Journal, part I, no. 48 of 14 January 2005, as amended

[325] For the amendment and completion of the Law no. 81/1992 – Accounting law, Published in the Official Romanian Journal, part I, no. 506 of 27 July 2007

According to the provision of the Order of the Ministry of Public Finances no. 1850/2004[326], the justifying acts must have the following principal elements:

- name of the document;
- name and headquarters of the issuing institution/company;
- number and date of the act;
- mentions regarding the parties that participated in the act (when the case);
- the content of the economic-financial operation and, when needed, the juridical basis of it;
- quantitative and value data related to the economic-financial operation performed;
- first and last name, and signatures of the persons in charge to perform the economic-financial operation, of the persons in charge of the preventive financial control, and the persons having the right to approve the respective operations, given the case;
- other elements destined to ensure the complete registration of the performed operations.
- The documents that serve to the accounting registrations can be given the quality of a justifying act only under the conditions that they provide all the information required by the legal provisions in force.

We consider that art. 95 gives to the employer the possibility to issue all kind of acts, that according to the law can be justifying acts in order to serve as basis for the accounting registrations of the damages caused by the employees to their employer. The provisions of art. 95 of the CAUNL must be interpreted as giving the employer the right to determine by its own ways both the identity of the employee that damaged him and the quantum of the suffered damage without permitting it to proceed to salary deductions and without any obligations in what regards the court's own settlement, unless the employee himself admits the evaluation realized by the employer. This is a preliminary phase in determining the patrimonial responsibility of the employee oriented to the acceptance of the employee of the established damage and to recovering the damage amiably, or, in the contrary, to obtaining a sum of proving elements to be used in court.[327]

The character of act usable to make accounting registrations regarding the damages caused by the employee to his employer also depends of the moment in which the registration should take place.

Taking in consideration the recent orientations in the practice of the courts, that of conditioning the proof of the damages incurred by the accounting registrations (that corresponds completely to the provisions of the Law of accounting, mentioned above), it means beyond any reasonable doubt that at the moment of the claim starting the trial against the employee the accounting registrations should have already been realised. Therefore, the judgement issued on the basis of this claim, and by which the employee is ordered to pay the damages, cannot serve as a justifying act for the first accounting of this damage, as the registering must have already been made before this moment. On the contrary, the acts that served for the accounting of the damages caused by the employee would be used as proofs in the trial against the employee, if the last one doesn't pay by his own the compensation, or the same acts would serve to the drawing up of an expert valuation that could be required by the court during the trial.

The following acts can serve as justifying acts on the basis of the mentioned provisions, the enumerating not being limited:

- Control acts (statements) issued by the financial and fiscal control organs of the state (Financial Administration, Financial Guard, Court of Auditors).
- The acts issued by the judicial organs that contain mentions regarding the damage (the resolution of non-prosecution, the judgement by which the court rejected the claim started by the employer against an employee on the grounds that another employee is guilty of producing the damage, etc.).

[326] Regarding the financial and accounting registers and forms, published in the Romanian Official Monitor, part. I, no. 23 bis of 07/01/2005

[327] **D. Crumpănă**, *Aspecte privind modalitatea de constatare a prejudiciilor cauzate de salariat angajatorului său – Aspects regarding the acknowledgement of the damages caused by the employee to his employer*, in „Romanian Labour Law Journal", no. 2/2007, pp. 108-109

- Acts issued as a result of the internals audits of the company, by the assigned control organs.
- The act issued by the commission of disciplinary investigation or by the commission assigned according to the provisions of art. 77 of the Collective Labour Agreement, Unique at National Level, for the years 2007 – 2010, in order to evaluate the employee professionally unfitted, if in during the proceedings a damage caused by the employee is also established.
- The decisions issued by the management of the company according to the provisions of the Law 31/1990, to serve the good functioning of the company by which there are acknowledged damages and the employee guilty of producing them. We do not mean by these acts to the imputation decisions issued under the regulations of the old Labour Code, as they can no longer be issued legally, and couldn't serve as basis for salary deductions, as they aren't executory acts anymore.[328]
- The act (convention – o.n. - C.D.) containing the agreement between the employee and the employer regarding the damages produces by the employee and the procedure of recovering it.
- The act – statement - by which the employee assumes the damage he produced and its quantum, with the amendment that this act isn't an executory deed and cannot serve as basis for salary deductions.[329]

Accounting of the damages produced by the employees and their recovery

The accounting registrations regarding the damages produced by the employees involves going through the following steps:

- establishing the patrimonial elements missing of destroyed and their value.
- Deleting from the registers the destroyed of missing assets.
- Establishing the guilty persons and imputing the damages.

Establishing the patrimonial elements missing or destroyed results from the inventory.

The inventory has the principal purpose of establishing the real situation of all the active and passive elements of every unit and the assets and valued held in any way, belonging to other persons or entities, in order to draw up the yearly financial reports that should offer a correct image of the financial position and performance of the company during the respective financial exercise[330].

Deleting from the registers the assets destroyed or missing is usually registered in the accountancy in the debt of an expenses account and in the credit of the account corresponding to the assets missing or destroyed.

Establishing the guilty persons and imputing the damages

The guilty persons are determined on the basis of an internal investigation within the company that suffered the damage.

The following acts are concluded:

- Explicative notice.
- Decision issued by the manager of the company by which there are determined the facts, the guilty persons, the disciplinary sanctions and measures to be taken in order for the damage to be recovered.

---

[328] As we affirmed before this kind of decisions are valid as long as they don't breach any imperative provision of the labour law - **D. Crumpănă,** *Aspecte privind modalitatea de stabilire şi recuperare a daunei cauzate de salariat angajatorului său (Aspects regarding the establishment and recovering of the damages caused by the employees to their employers),* in „Romanian Journal of Labour Law", no. 3/2005, p. 105

[329] For explanations that the new Labour Code doesn't preclude the employee form assuming a written payment statement plese refer to **I.T.Ştefănescu, Ş. Beligrădeanu**, *Prezentare de ansamblu şi observaţii critice asupra noului Cod al muncii (General overview and critical observations regarding the new Labour Code)* , in „Law Journal", no. 4/2003, p. 76

[330] Order of the Public Finances Ministry no. 1753/2004 regarding the approving of the norms referring to the organising and realising the inventory of the active and passive elements.

– The employee's written payment statement, if the case.

In case a judgement is obtained to oblige the employee to pay the damages, salary deductions can be performed to the limit of 1/3 of the salary. If the salary deductions are meant to cover several debts (alimonies, damages to a third person, damages to the employer, financial debts, etc.) altogether they couldn't be larger than ½ of the salary.

Examples of accounting of the damages:

I. On the basis of the inventory missing staples of 2.000 lei is acknowledged:

1. The missin staples are downloaded from the administration:

601	**=**	**301**	**2.000**
"staples expenses"		**"staples"**	

2. On the basis of the decision of the manager mentioned above the debt of the administrator is accounted.

4282	**=**	**%**	**2.380**
"Other credits related to personnel"			
		7588	**2.000**
		"Other activity incomes"	
		4427	**380**
		"collected VAT"	

3. Cashing the debt on the basis of the receipt or the salary grid – as a result of a judgement:

5311	**=**	**4282**	**2.380**
"Cash register in lei"-cash or		**"Other credits related to personnel"**	
421			
"Personnel salary owed"-for salary deductions			

If the administrator employed had a guarantee deposit:

Registering the guarantee of 3.000 lei:

4281	**=**	**5311**	**3.000**
"Other debts related to personnel"		**"Cash register in lei"**	

Deduction as a result of the recovering of the damage:

4281	**=**	**4282**	**2.380**

"Other debts related to personnel"		**"Other credits related to personnel"**

II. Example of accounting of the damages produces to a car property of the firm, resulted from a car accident. The registering value is of 30.000 lei, amortized 40%.

1. Deleting the destroyed asset from the register:

%	**=**	**2133** **"Transport means"**	**30.000**
2813 **"Amortisement of the transport means"**			**12.000**
658 **"Other exploitation expenses"**			**18.000**

2. The credit against the administrator is registered on the basis of the decision of the management.

4282 **"Other credits related to personnel"**	**=**	**%**	**35.700**
		7588 **"Other incomes from exploitation"**	**30.000**
		4427 **"collected VAT"**	**5.700**

Deduction as a result of the establishing of the damage and guilt, if the employee produces another car evaluated at 40.000 lei:

2133 **"Means of transport"**	**=**		**40.000**
		4282 **"Other credits related to personnel"**	**35.700**
		4281	**4.300**

The doctrine[331] showed that, in what regards the responsibility of the employee towards the employer it is usually inadmissible the granting of moral damages. Certain specific cases are excepted provided that the exception is stipulated by the law, as for example, the cases regulated by the Law no. 11/1991[332] regarding the combating of the unfair competition, in the case of damages resulted from crimes committed by the employees or in the case of the employees guilty of organising an illegal strike.

Nevertheless, we emphasise that such damages shall not be recovered from the employees on the basis of the Labour Code or on the basis of the contractual liability, but according to the norms and principles of torts, meaning on the basis of art. 998 – 999 of the Civil Code and other provision of special laws.

Abstract: *Any credit represents an anticipation of some future cashing. From this perspective, by cash flow, any credit contains the risk that these cashing isn't achieved totally or partly. This risk is also called insolvency risk of the creditor; it is essential in the banking activity due to the fact that the main function of a bank represents the granting of credits. The exact appreciation of the credit risk is, thus, of major importance for the bank. Being easier to prevent than to cure, for the minimization of the risk exposal, the most important stage of the crediting process is the choosing of the credit demands. In this stage, the behaviour of a bank might be presented as follows: a credit is granted only if there might be estimated that the probability of reimbursement exceeds the one of non – reimbursement. The appreciation of this reimbursement capacity might be done if it has at its base different procedures, according to the debtor: economic agent, private person, State. The determining elements for the administration of the lend risk are: payment capacity, character of the debtor – his wish to pay, the capital – wealth of the debtor, the guarantee (real or personal), all based on book information.*

Keywords: *lend risk client, book information, cash flow.*

General conditions regarding the reliability of economic agents in the crediting activity

Accounting information is an important component of the credit granting process. Accounting information establishes the monitoring relationship between the borrower and lender, affects accounting choices made by the borrower, and influences perceptions of the riskiness of the borrower and lender. Using inappropriate accounting information, particularly those that are too restrictive, are noisy signals that could have economic consequences for borrowers and lenders. In this circumstaces, professional loan officers analyzed financial and nonfinancial information of candidate borrowers and set preferred levels of collateral and covenants while their decision processes were captured using computerized process tracing.

The strategy of the Bank regarding the lend risk is included in the Crediting Regulation filled in with the General Strategy of the Bank for a short, average and long term, approved by the Board of Administration. The target group of the Bank, in the case analyzed in the present material, are **Micro-enterprisers and small and average enterprises (IMM's)**, category where are also included the micro, small and average private business, that are involved in the production or marketing of goods and services and which is active in Romania. We suppose, as well, that the Bank might finance also authorized natural persons that act as entrepreneurs and any other persons which are involved in entrepreneurial activities. Further on, the term "enterprise" makes reference to any form of business according to the above mentioned. In case of natural person, the main income source (during season, in case of season activities), must result from the development of some entrepreneurial activities.

Generally, there are used two criterions for the segmentation of the target group of the Bank: the number and employees and the rate of turnover.

The turnover criterion is determined in order to establish the type of client but, in exceptional situations, according to the profile of the business and the number of employees, the client might be framed in another category than the initial one.

In any case, the Bank shall not finance enterprises that develop as main activity one of the activities included in the List with Exclusions for Environmental Problems.

The Bank engages itself to observe the policies of a prudent lend, according to the international banking practice. This thing supposes that there shall be granted credits only to clients with reliability. The reliability is established according to:

- Personal aspects;
- Current and future financial situation of the solicitor, including the competition situation, the future perspective for the business type in which the solicitor is involved, and the currency exchange risks;
- Future payment capacities – according to previsions of the cash flow of the borrowed or to the estimated situation of the income.

The data base of the Central Office of Banking Risks (CRB) must be consulted for debtors and co-debtors for all credits. The Credit Officer/ Credit Director of the Subsidiary/ Agency/ the Credit Coordinator/ the Deputy Director of the Subsidiary/ the Director of the Subsidiary/ Agency might ask the consultation of the CRB also in case of guarantees and/ or associates/ administrators of the enterprise and/ or other economic entities considered in the frame of the risk valuation process for the debtor/ co-debtor.

The access to the data base of CRB for debtors and co-debtors mustn't be older than 1 month at the moment of granting the credit and to the moment of granting each installment, if the credit is granted in installments.

The data base of the Credit Office (**CredIT**) might be consulted in case of Credits for enterprisers for main owners of the respective company, only when the Credit Officer/ Credit Director of the Subsidiary/ Agency/ Deputy Director of the Subsidiary/ Credit Coordinator/ Director of the Subsidiary/ Agency considers that the loan fulfills all conditions for being approved and the access is performed for granting the loan. However, for any debtor or co-debtor, natural person, there must be signed the agreement for the consulting of the Data Base of the Credit Office.

The data base regarding the payment incidents (CIP) shall be accessed for debtors and co-debtors, for all credits, excepting natural person with activity in agriculture and authorized agricultural producers (in this case consultation shall be done only at the request of a member of the credit board). The Credit Officer/ the Credit Director of the Subsidiary/ Agency/ the Credit Coordinator/ the Deputy Director of the Subsidiary/ the Director of the Subsidiary/ Agency might request its consultation, also for other person involved in the business and/ or for guarantees and/ or for other economic entities considered in the frame of the risk valuation process for the debtor/ co-debtor.

The bank classifies the credits granted to enterprises in Micro, Small and Average Credits.

Analysis and processing of information for the risk valuation of the client

Information obtained and checked might be processed by the Credit Officer such as to offer an exact image of the generally current financial situation of the economic unit.

Generally, at *microfinancing*, the relation between families and business is very important. The balance issued by the Credit Officer, that reflects the current situation of the enterprise, shall include all actives used in the activity, even if the juridical owner is one of the family members. The private debts of the family, as well, made for covering the needs adequate to the economic activity, must be included in the balance presented by the credit officer.

In the case of *small and average enterprises* the accent is put on the financial analysis of the economic unit, generally there exists no close connection between the economic unit and the family of associates/ shareholders.

However, the Credit Officer must identify in both analysis types the active and the debts that are bound from juridical point of view to the business owners, that are used in the activity or that are owed to it and that might influence the reimbursement capacity of the crediting enterprise. The active and the passive whose book value doesn't reflect the reality (because of inflation or of other reasons) must be valuated by the credit officer according to their market value, the probable investment cost, the depreciation, the replacement cost, etc. (or according to the contractual and juridical clauses in case of debts).

The average cash flow presented in the analysis forms is an important indicator regarding the present and future payment capacity of the client. It considers the influence of the credit on the activity (replacement of expenses with rents, reduction of expenses bound to fuel or consumable materials, etc.) and neglects the incomes or expenses that shall clearly disappear during the credits' reimbursement (cease of the leasing or crediting contracts, temporary incomes, stopped activities, etc.). The foreseeing of the development of the clients' activity has also an important role in establishing the cash flow.

The cash flow shall include incomes that come from economic activities, including future estimation and those that come from other sources (salaries, etc.), as well as monthly expenses and obligations of the enterprise and the family, replacing the projection of the cash flow.

The historical cash flow shall be presented in the analysis form or in analytical book documents supplied by the client in case that the Crediting Board decides it is a representative and useful element for taking the decision of granting the credit and for Average Credits there might be done a **projection of the cash flow,** that shall include the duration of the credit.

In case of Small and Average Credits, the valuation of the Credit Officer might additional include precise information regarding the juridical status of the enterprise, the financial situation issued and checked by the Credit Officer, the historical cash flow and projections that show the probable impact of the credit on the future of the business.

The Credit Office shall do its best to obtain the most exact information possible as base for the performance of the credit analysis. The Credit Officer might use following sources:

- A general discussion with the owner of the business regarding its general, specific features and recent development. The truthfulness of the supplied information must be certified by crossed checking.
- Inspections at the headquarters of the business in order to obtain qualitative information (for ex. Management and administration capacities of the potential client) and in order to collect and check data for the financial and economical analysis (stocks, fixed assets, account receivables, debts, cash, banking accounts), including relevant documents such as contracts, invoices, etc.
- Information regarding the market quota of the enterprise, the situation of the competition, currency exchange risks, etc.
- Collecting and checking the official documents of the enterprise.
- Information regarding other business unfurled by the solicitor.
- Inspection of goods that might be considered as guarantee.
- Estimation of the moral integrity of the future client (references).
- Information regarding the location of the business headquarters and of the client's dwelling (for the facilitation of the future monitoring).
- Comparing the conclusions in case of repeated visits.

In case of average enterprises, considering the complexity of the business and implicit of their relation with the bank, there shall be put a greater accent on financial and legal aspects of the business.

These credits do have usually longer maturities and thus there exists a bigger probability for the apparition of some changes in the activity and evolution of the enterprise. As a result thereto, the Credit Officer must estimate the opportunities and risks associated to these changes. This means that, the aim for which the credit shall be used, plays a much more important role in the valuation of the reliability made by the credit officer than in the case of Micro Credits.

In the performance of the analysis for small and average credits, the Credit Offices must use following additional information sources:

- A discussion with different persons in the management of the enterprise. The correctness of information must be checked by crossing.
- The analysis of the documents of the enterprise.

- The analysis of the documents regarding the participation to other companies, affiliation to groups (if it is the case) and a consolidated and explanatory analysis of these participations (if it is the case).

Conclusions

The risk that appears at the moment that one credit client or counter-party can't or doesn't wish to observe his contractual obligations, resulting an adverse effect on the profits and capital of the bank, represents the *client credit risk*.

The administration of the credit risk starts from the credit officers. Thanks to the detailed analysis made by them, to the adequate guarantee level and to the conservator crediting practices, we reduce the lend risk even at the beginning of the crediting cycle, for example, from the moment the credit demand is received and processes. The decisions regarding credits must be based on the analysis of documents brought by client, on the entire and prudent valuation of the economical – financial situation of the client, on the analysis and valuation of the impact provoked by the use of the credit on the activity of the debtor, inclusively on the valuation of guarantees. The key of the high quality level of our analysis is the intense formation of which our credit officer benefit and the rigorous analysis of the cash flow and of the book balance. The demands regarding the guarantee must be defined as integral part of the credit decision and the credit can't be integrally granted but when there were passed the registration steps of the requested guarantee. Additional demands, such as the composition of the credit boards and the adhering to the rules regarding the levels for approving the credits, create efficient mechanisms for the administration of lend credits during the credit granting and for the reduction of the fraud risk. The mechanisms for the approval of credits are described I detail in the crediting procedures of the bank. The good relations with clients, according to the mission of the bank, are an important instrument in avoiding the delay cases and in the identification of problems bound to the credit, even from its beginning phase. The bank revises half – annual the scoring of the client, according to the demands of NBR and performs, if necessary, the adequate changes in the system. The bank has procedures that define the steps to be followed when the capacity for the fulfilling of credit obligations by a client begins to give deterioration signs.

The crediting and monitoring standards, together with the demands regarding the guarantees and the monitoring of the problem situations bound to credits, tend already to "remove" the potential problem clients. It is important that the bank avoids the creation of an image as a "neglecting creditor".

The monitoring of the quality of the credit portfolio is constantly done by using the risk portfolio indicator, defined as the credit volume in development that has at least one rate delayed with more than 30 days, as basic unit for the measurement of the quality of the actual portfolio.

In all these analysis the book information is the main data source.

ACCOUNTING APPROACHES REGARDING THE FACTORING BUSINESS

David Delia

"Vasile Goldiş" Western University of Arad, Faculty of Economics, address contact: Arad, str.Iustin Marşieu, nr.16, bl. A, ap. 10 ; e-mail address: david_delia2003@yahoo.com***; phone: 0722336885***

Factoring is a modern technique of financing that is done especially in the countries which are developed from an economic point of view, the most important markets being the United States, Italy, Great Britain and Japan. In Romania, three- four years ago, factoring was a notion which was not too much utilized, but nowadays it tends to become a customary practice due to the needs of financing of the commercial societies.

This paper has as its goal a short presentation of the factoring operation and of the implications that these operations have upon the accounting of the factor but also of the adherent.

Key words: factoring, factor, factoring client, factoring debtor, cession of debts.

1. The description of the factoring operation

Factoring represents the operation of financing of the bills in order to rapidly get cash.At the basis of the factoring businesses there is the factoring contract, which is concluded between the adherent or the supplier, that owns a package of debts, and the factor, which in exchange for a commission which is received from the adherent takes on the obligation of paying the equivalent of the debts which are surrendered by the contract.

According to the criteria of classification, we distinguish the following types of factoring:

a) a) depending on the right of recourse that the bank can exercise upon the adherent, we distinguish:

– non recourse factoring – the factor pays the adherent the accepted equivalent of the bill, usually 80%, immediately after having been issued, and 20% in 180 days since the date of payment of the bill, even if it does not collect (totally or partially) one or more of the bills. In the interval of 180 days from the date of payment of the bill, the bank tries to recover the sums from the debtors or perhaps from the ensuring- reinsuring society to which it was ensured against the risk of non-collecting. The factor does not turn to the adherent in order to recover the equivalent of the bills, not having the right of recourse upon it.

– -recourse factoring – in the case of not paying, the factor will recover the sums which were not collected from the adherent, by exercising the recourse right, through the debiting of the current account of the adherent or through the capitalization of the security.

b) depending on the participants in the factoring operation, we distinguish:

– domestic factoring – at the basis of this operation there is an internal contract that takes place inside the same country and within it there is only one factor.

– international factoring – supposes the existence of an international commercial contract within which there intervene two factors (the import factor and the export factor). The export factor buys the debts of the exporter (also called the adherent) upon the importer, then surrendering them to the import factor.

The international factoring appeared as a consequence of the development of the national factoring, the important characteristics of the two forms being:

a) In the case of the national factoring, the undergoing of the contract supposes the participation of three parties:

– The supplier – it can render services or execute works, or a producer that delivers merchandise that according to the contract becomes a *factoring client* or an adherent.

– The beneficiary – it is the one that purchases the merchandise from the producer, benefits from the executed works or the rendered services and that according to the factoring contract will pay the bill directly to the factor. It is called a *factoring debtor.*

- The factor (usually a banking society) – buys the debts and finances the supplier. The factor, the supplier and the buyer undergo the transaction according to the national legislation of the country in which the operation takes place.It gets from the supplier a commission in exchange for which it pays the value of the package of surrendered debts, either totally, or partially in falling due instalments. The commission of the factor consists of agio and the security commission. Currently, in addition to these sums, the factor also holds back from the adherent the security of collection risk that is paid back to the adherent after the collection of the bills from the debtor clients. The factor performs the operation of financing in the local currency.

b) b) A contract of international factoring implies the participation of four parties:

- The supplier (exporter) – that delivers goods or renders services.
- The export factor (FE) – the one that performs the financing operation in the currency in which the exporter made the delivery of the good or the rendering of the service. This is exposed to the risk of exchange variations. We mention the fact that the supplier and the export factor are situated in the country of the exporter.
- The import factor (FI) – is responsible for the monitoring and the collecting of the funds from the importer.
- The buyer (the importer) – that purchases the delivered goods or the services which are rendered by the exporter.

The import factor and the buyer (the importer) are situated in the country of the importer. The export factor and the import factor collaborate on the basis of a code of rules regarding the international factoring.

2. Accounting aspects regarding the taking place of the factoring operation

The accounting treatment of the factoring operations will be different depending on the position of the factor in relation with the risk of cashing of the debt. As mentioned above, if the factor takes on the risk of cashing the debt, we speak of an operation of factoring without recourse (RPF), otherwise we speak of an operation of factoring with recourse.

In order to be able to discuss the accounting aspects of the factoring operation, it is necessary to clarify, according to the legal provisions and the current practice, who will do the bookkeeping and will present in the balance sheet the debts towards the factoring debtor.

a) In the case of the factoring contracts without recourse, the specialized literature considers that the factor has the right of property upon the debts which were taken over. By becoming the rightful owner of the debts which were taken over, the factor has the obligation of comprising them in the balance sheet.

The adherent (the factoring client) will eliminate from his bookkeeping the debts towards the factoring debtors, the debts which come from the delivery of goods or from the rendering of services. The factoring client will accentuate in his balance sheet only the debts towards the factor that will be maintained until they are settled by it.

In the accounting of the factor:

DEBIT (ACTIVE)		CREDIT (PASSIVE)
Debts which are bought towards the factoring debtors	=	Debts which are expressed in the buying price towards the factoring client(the sums which are paid in advance are subtracted)

In the accounting of the adherent (the factoring client):

DEBIT (ACTIVE)		CREDIT (PASSIVE)
Debts towards the factor to pay the selling price/ analytic factor (the sums which are paid in advance are subtracted)	=	

b) the case of the contracts of factoring with recourse is discussed in the specialized literature in a controversial manner. This is because there is still no concrete answer to the question: Who must keep the books and in whose balance sheet should it appear? Some specialists claim that the debts which are surrendered and taken over must be registered in the accounting and the balance sheet of the factor. Other groups of specialists uphold the theory according to which the lack of services of the factor leads to the marking out in the accounting of the adherent of the operations which are the object of the factoring. Because the opinions are divided and the normative acts of our country do not comprise exact and detailed provisions in this regard, it remains for the problem to be treated taking into account the specific character of each factoring contract.

The factoring operation presents accounting implications in the accounting of the factor, as well as in the accounting of the adherent. So we will take on the problem distinctly for each of the two parties which are involved.

The taking place of the factoring operation has the following succession: receiving the bills from the factoring client; separating the approved bills from the un-approved ones; financing the debts which come from approved bills; retaining the security of the risk of cashing; cashing the commissions; cashing the debt; giving back the security; cashing agio.

a) a) In the accounting of the factor:

The bills which are taken over by the factor are classified into two groups:

- bills which are approved, that generate the available term of factoring. These bills are available immediately under the form of credit in the account of the client, based on the presentation of some ensuring documents of the bank.
- bills which are unapproved or unavailable that generate the unavailable term of factoring. These bills are not approved until the cashing of the debts or until their contractual date of payment.

The factoring society can function from the point of view of the form of organization both as ***conventional societies of factoring*** (outside the banking societies) and as ***factoring societies that belong to banking societies.***

The conventional factoring societies will have to adapt the general plan of accounts which was approved by OMFP 1752/2005 modified through OMFP 2374/2007 to the specific of the factoring operation. In her book, which is called *The accounting of the operations of external commerce*, (Ed. Economică, Bucharest, 1997, p.224), Margareta Traşcă underlines an adaptation of the account plan to the operation of factoring. Keeping in view the changes which were brought to OMFP 1752/2005 modified through OMFP 2374/2007 the accounts which are utilized in the operation of factoring are the following:

- - the taking over of the debts from the adherent will be done utilizing the 2678 "Other immobilized debts" account and the 269 "Payments to be made for financial immobilizations" account.

The 2678 "Other immobilized debts" account will present three analytic accounts that will be utilized according to case:

2678.1 "Other immobilized debts/ available factoring"

2678.2 "Other immobilized debts/ unavailable factoring"

2678.3 "Other immobilized debts/ securities to the factoring operations"

The 269 "Payments to be made for financial immobilizations" account will be developed according to case:

269.1 "Payments to be made for financial immobilizations"/ approved bills

269.2 "Payments to be made for financial immobilizations"/ unavailable factoring.

I would like to mention the fact that there are on the market societies of accounting consulting that suggest for the financial brokering societies the use of other accounts than those which are presented above and namely:

4111 "Clients" – the nominal value of the debts which is taken over from the cessionary

401 "Suppliers" – with the value that is owed to the releaser of the debt.

- the management commission and the interest will be initially registered in the 472 “Incomes which are registered in advance/ factoring operations” account, going to be monthly marked out in the accounts from class 7. We are talking about accounts 766 “Incomes from interests”/ agio factor and 704 “Incomes from executed works and rendered services”/ commission factor.
- for the commission and the interest which is collected by the factor, the provisions of the Fiscal Code which was effective on the 1st of January, 2008, specify the compulsoriness of paying the Value Added Tax to the state budget, in a percentage of 19%, marked out in the 4427 “Collected Value Added Tax” account. The security will be taken in the 2678 “Other immobilized debts” account.

The factoring societies that function within the banking societies are usually the main societies that perform factoring operations. The plan of accounts which is specific to the banking societies, in accordance with Order no.5 from 22.12.2005 for the approval of the accounting Regulations which are in accordance with the European directives, which are applicable for the institutions of credit, modified and supplemented by Order no. 24/2006 and Order no.11/2007 provides special accounts for the taking place of the factoring operations. Thus we distinguish the accounts:

- at the signing of the contract the equivalent of the bills which are taken over from the adherent is registered outside the balance by using the accounts:

90319 “Other commitments in favour of the clientele” and 999 “The trade-off”

- the factoring debt implies the utilizing of the accounts:

20.112 “Factoring” – in which the nominal value of the mobilized debts and of the 25211 “Available factoring accounts” respectively 25212 “Unavailable factoring accounts” accounts is registered

- the management commission and the interest will be registered in the 70212 “Interests to the factoring operations” and 7029 “Commissions” income accounts
- the security for the risk of not cashing will be marked out in the 25336 “Other collateral deposits” account.
- the Added Value Tax which is afferent to the value of the commission and the interest will be marked out in the 35327 “Collected Added Value Tax” account.

b) in the accounting of the adherent (factoring client):

The general plan of accounts which is approved by OMFP 1752/2005 modified through OMFP 2374/2007 does not provide special accounts through which the adherent can mark out in accounting the taking place of a factoring operation. According to the specialized literature, in the accounting of the adherent there are two variants of bookkeeping of the operations of factoring:

1. The first variant (Vişan, “Accounting in external commerce”, Bucharest, 1999, p.82) supposes the taking place of the registering in accounting thus:

- the delivery of merchandise (and the issuing of the commerce bill with the specification that the beneficiary is really the factor, the commerce bill that is accepted by the importer not being given back to the drawer of the exporter but to the beneficiary):

4111” Clients/ Factoring debtor”	=	%	V
		707” Incomes from the sale of the merchandise”	
		708”Incomes from various activities”	
		766”Incomes from interests”	
		472” Incomes which are registered in advance”	

- the transfer of the debts of the factor, in order for it to pay the equivalent of the bills:

4111”Clients/ The factor” = 4111”Clients”/The importer V

- the cashing of the debts from the factor (the equivalent of the bills), excluding the value of the interest and of the commission:

5124” Accounts at banks in devices” = 4111” Clients” /The factor V-(C+D)

- registering the commission and the interest:

668 „ Other financial expenses” = 4111”Clients”/ The factor C+D

2. The second variant of reflecting in the accounting of the adherent (Margareta Traşcă – *The accounting of the operations of external commerce,* Ed. Economică, Bucharest, 1997, p. 224) presents itself like this:

– the debt which is accepted by the factor will be closed through account 2678 “Other immobilized debts” until the date of the collecting of the sums from the factor:

2678 “Other immobilized debts” = 4111 “Clients” / importer V

– cashing the debts from which the managing commissions and the interest held back by the factor are held back in the 622 “Expenses with the commissions” account, respectively 666 “Expenses regarding the interests” and Added Value Tax 19%.

%	=	2678”Other immobilized debts”	V
5124”Accounts at banks in devices”			Ci
622” Expenses with the commissions”			C
666” Expenses with the interest”			
4426”Deductible Added Value Tax”			D

– the value of the security which is held back by the factor will be registered in the 2678 “Other financial immobilizations” to a distinct analytic 2678.3 “Other immobilized debts/ securities to the factoring operations”.

5124 “Accounts at banks in devices”= 2678.3 “Other immobilized debts /securities to the factoring operations”.

Where : V – the nominal value of the approved bills ; Ci- the value which is cashed by the adherent; C- the value of the managing commissions; D- the interest

By analyzing the two variants we can state that the last variant would be preferred if we think that the external commerce society does not deliver merchandise to the factor but sells bills. Applying none of the two variants is not rigorously imposed but in practice the first variant is more utilized. We specify that for the registration of the income and the commission which are held back by the factor, according to the current legislation, it is recommended to use the 622 respectively 666 accounts.

In the end I would like to make some references to the cost of the factoring operations on the Romanian market. The collected cost for the factoring operations is divided into the tax for the managing of the transaction and a separate tax for the actual financing of the operation. Thus, there is a factoring commission and a financing one. The factoring commission is applied to the nominal value of the paid-for bills and represents 0.5-1% for the internal factoring services (in lei) and 1-2% for the export factoring services (in foreign currency).The financing commission is applied to the financed value, respectively to 80-90% of the equivalent of the bills, during the taking place of the contract. This is comparable to the interest which is applied to the short term loans (in lei or in foreign currency) and can be negotiated according to each transaction.

3. Conclusions

Factoring is an alternative to the classical models of financing, especially the operations of exterior commerce, that brings the clients the advantage of getting the financing in the shortest possible time, compared to the classical loan. It also allows the development of the business without immobilizing the actives of the societies in material securities, ensuring, at the same time, an efficient management of the debts. As we can see from the presentation of the paper, in the case of the banking societies, the bookkeeping of the factoring operations is ensured by registering into accounts which are especially provided for this operation. We cannot say the same about the accounting of the conventional societies of factoring (other than banking societies) and about that of the economic agents. The plan of accounts does not provide any special account for this type of operation, and the accounting legislation makes no concrete reference to the way of marking this out. If special accounts were introduced, each of the three parties which are involved could correctly and distinctly register in the bookkeeping the movement of the surrendered debts from every point of view. There are opinions of some specialists in this area, regarding the taking place of the factoring operations, to which I actually made a reference in this paper, but a legislative provision would clarify things, especially that during the last three, four years, the factoring operations in Romania increased.

UTILIZING THE OPERATION OF FORFEITING AS A TECHNIQUE OF FINANCING AND UNDERLINING THE IMPACT WHICH THIS OPERATION HAS ON THE ACCOUNTING OF THE EXPORTER

David Delia

"Vasile Goldiş" Western University of Arad, Faculty of Economics; address contact: Arad, str .Iustin Marşieu, nr.16, bl. A, ap. 10 ;e-mail address: *david_delia2003@yahoo.com****; phone: 0722336885***

Romanian integration into European Union brought about a series of changes, including the domain of banking activities.The first operations of forfeiting appeared in Switzerland , and today they are used all over the world's financial centres.Forfeiting strongly developed durong the 1990s as a result of opening of new markets in Central Europe and Eastern Europe due to the existance of enough buyers of goods but lack of financial resources for their aquisition.This paper has as its goal a short description of the forfeiting operation and the advantages which it offers in relation with other techniques of financing which are utilized in our country, such as: bank loans, bank rating, leasing, factoring. The flux of records in the accounting of the exporter which utilzes this technique of financing is also presented.

Key words: forfeiting, debts, commercial effects, contract, accounting records.

1. The description of the forfeiting operation

The term *forfeiting* comes from the French expression "a forfeit" and means giving up certain rights. The forfeiting operations developed to a great extent in the period of the years 1950 – 1960, as a result of the increase of the importers' demands for longer and longer periods of loan with a view to ensuring the necessary financial resources for the payment of the acquired goods or services. As a result, there was an increase in the need of the exporters of goods and services to mobilize their financial resources which were placed in the exports which were made and had a longer and longer term of payment. As a consequence of the opening of new markets in Central and Eastern Europe, in the 90s, the forfeiting operations underwent a significant growth, because on this market there are enough buyers of goods and services but insufficient financial resources for their acquisition. The first forfeiting operations were initiated in Switzerland and nowadays they take place in almost all the worldwide financial centres. London is the most important centre from the point of view of the volume and of the value of the forfeiting operations. At first, the forfeiting operations were done only by specialized financial institutions, but nowadays the banks have developed departments which are specialized in these operations.

"Forfeiting represents a technique of financing in the phase of post-delivery/ rendering goods/ services, by the sale- buying without recourse to the exporter or to the beneficiaries of some falling due debts, incorporated in loan bonds (bill of exchange or promissory note), guaranteed or not by a third party, or debts which can be paid through ensuring methods of payment (the documentary letter of credit or the letter of guarantee)." [333]

The main element that differentiates forfeiting from bank rating is the transfer from one owner to another, without recourse, of the debt and consequently of all the rights and risks that the transaction debt implies until the date of payment. The term "without recourse" assumes that any buyer takes on the risk of loan of the debtor's and/ or the guarantor's, if it exists, as well as the vis major risk that can stop the making of the payment.

Forfeiting offers the exporters/ sellers the following possibilities: removing the risks which are related to the sale, offering loaning terms to their clients, improving the situation of their cash flow.

The simplicity of the solicited documentation is one of the most important advantages of forfeiting. This fact facilitates the rapid conclusion of the transaction. The client will present to the bank, in order to initiate

[333] Mihaela Rovenţa - Introducere în forfetare &factoring. Tehnici moderne de finanţare a activităţii de export Editura Economică,2002-pag.160

the forfeiting operation, the loan bond along with a forfeiting request which will comprise, along with the identification information of the beneficiary: the issuing date of the bond, the date of payment of the bond, the mention by which the beneficiary undertakes to acquit to the bank, in exchange for the rendered service, the forfeiting tax and the afferent commissions, will present the bond to the bank with a view to forfeiting at least 15 working days prior to the date of payment.

The development and implementation of the forfeiting product have been generated by the supplier loan, perfected between a supplier and a buyer, by which the supplier accepts to be paid by the buyer at a later date for the delivered goods or the rendered services, usually in a period of time of up to 5 years.

Forfeiting refers to the buying/ selling of the debts which are materialized in bills of exchange or promissory notes, which come from delivering goods and services, with fixed dates of payments. The banks buy these bills of commerce from the supplier or their owner, usually without recourse to the seller, in exchange for the holding back of a forfeiting tax and the collection of a commission.

The forfeiting tax is the tax which is collected by the bank or the specialized institution, according to the risks which it undertakes: the country risk, the transfer risk, the exchange risk, the commercial risk, the interest risk. The forfeiting tax is determined by taking into account the value of the bond, the number of days between the date of forfeiting and the date of payment and the level of interest for the respective currency. When establishing the forfeiting tax, one also takes into account a global risk margin which is calculated according to the conditions of the import-export contract, while keeping in mind the commercial, economic and political risks.

The calculation formula:

$$TF = \frac{VN*(D+M_r)*n}{100*360}$$

where:

TF= the forfeiting tax which is due to the bank

VN= the nominal value of the bond which is inscribed on the especially reserved rubric on the front of the bond

D= the level of LIBOR interest which is afferent to the respective currency

Mr=the risk margin

N= the number of days until the date of payment

2. The advantages of the forfeiting operation in relation with other techniques of financing:

Studied in relation with other techniques of financing, the forfeiting operation presents some specific advantages. I will mention some of the particularities that make the forfeiting operation differ from other techniques of financing:

The bank loan is any obligation to pay a sum of money in exchange for the right to be reimbursed the paid sum, as well as the payment of an interest or other expenses which are related to this sum, or any extension of the date of payment of a date and any obligation of acquiring a bond that incorporates a debt or another right to the payment of a sum of money. In comparison with the bank loan, the forfeiting operation has the following differences:

- the fluctuation of the interest: the banking societies give credits, getting interests in exchange, all through the duration of giving the loan. The value of these interests fluctuates depending on the variation of the basic rate of the interest of that currency. The basic rate of the income is established according to the LIBOR or EURIBOR level for various terms. The resorting of the exporter to a bank loan in order to mobilize the financial resources which are afferent to the loan deliveries can be a decision with a negative impact on his financial situation if the rate of the interest evolves in an unfavourable way. The unexpected increase of the interest rate and its long-term maintaining inevitably determines problems in the activity of the one that took out the loan. The bank loan is distinguished in the accounting of the one that took out the loan in specific loan balance sheets, affecting its solvency indicators.

- the constituting of guarantees: in the case of the banking loans, the banking societies usually solicit guarantees under the form of mortgages or deposits and all the costs of evaluating and constituting are the task of the one that took out the loan. As a result, this process is costly for him, and his access to loans is limited because his patrimony can be insufficient.
- the risk of not collecting at the date of payment: the exporter may be in the situation of not paying the loan instalments. This fact can lead to a re-spreading out of the payments of the debts by the bank but this facility is temporary and implies additional costs for the one that took out the loan. If the bank decides to execute the constituted guarantee, major problems in the activity of the exporter are created. In the case in which the exporter resorted to an insurance policy with a view to cover the risk of not collecting, his budget would be affected. Practically, the insurance of the risk of not paying generates costs that affect his budget.

Leasing – is an operation through which a Locator places at a User's (locating client) disposal a good which is bought from the supplier, in exchange for the periodic payment of some leasing instalments by the user to the locator. The leasing operations are regulated by the Government Ordinance no. 51/ 1997, republished, which classifies them into two types: financial leasing and operational leasing. This financing technique is exclusively used for the deliveries of goods of capital: equipments, tools and other similar products. As a result, it cannot be applied to the deliveries of the goods of consumption or services.

Bank rating is a technique of financing by which the owner of a commercial bond gets from the bank, by cession, the equivalent of the bond, diminished by an agio, before the date of payment. The agio represents the sum between the interest and the commission which is collected by the bank. The differences between the two methods of financing are the following:

- the bank rating action is done on short terms, up to 90 days, while the forfeiting can be done on medium or even long periods of loan.
- the financing in the case of bank rating is done only based on bills of exchange and promissory notes, while the forfeiting has as goal the financing of the debts which are incorporated in loan bonds of both the type of the bill of exchange and the promissory note and of the debts which can be paid through insuring methods of payment, with a date of payment.
- usually, the bank rating operation is based on transactions which are made inside a country, between partners which are situated in the same country. The forfeiting finances debts which come from international commercial transactions, between partners that are situated in different countries.
- bank rating is an operation with recourse upon the beneficiary of the loan bond, while forfeiting is an operation with no recourse upon the latter.

Factoring represents the operation of financing the bills to rapidly obtain cash. The main differences between the factoring operation and forfeiting are the following:

- the duration of financing: in the case of factoring we speak about a 30-80 days financing, and in the case of forfeiting, a long and medium term financing.
- the factoring operation is specific to the delivery of the consumption goods and services (the capital goods are excluded), while forfeiting is usually practiced to finance the deliveries of the capital goods. We specify that by forfeiting one can also finance the deliveries of consumption goods/ the rendering of services.
- the financing by forfeiting ensures the mobilization of the debt, 100% of its value, while factoring does not allow the mobilization of the entire value, only of a part of it.
- in the case of the factoring operations, the cost of the operation is totally the exporter's obligation, while for the forfeiting operations, almost all the financing costs are transferred to the importer, by their inclusion by the exporter in the value of the commercial contract.

3. The registering in accounting of the forfeiting operation by the exporter

Although the forfeiting operations give multiple advantages to the users, in country resorting to such a technique is manifested in a reduced manner. The accounting plan which is afferent to the financial accounting approved by OMFP 1752/ 2005 does not provide accounts with a specific name regarding the taking place of the forfeiting operation.

In the exporter's accounting the 413 "Bills to collect" account for the value of the accepted bills of exchange and promissory notes, the 667 "Expenses regarding the given bank rates" account for the value which is held back by the bank at the granting of the bank rate loan to the exporter are used.

The flux of the entries regarding the operation of forfeiting which is reflected in the accounting of the exporter is the following:

- making the bill of delivery of the merchandise to the importer:

4111"Clients" = % V

707" Income from the sale of the merchandise"

708" Income from various activities"

766" Income from interests "

- the emitting of the commerce bill (the debt bond) :

413 „ Bills to receive" = 4111 „ Clients"

V

- the extra-accounting bookkeeping is done at the same time:

8028 „ other received bills " V

- the bookkeeping of the billing of the forfeiter's debts, at the same time sending him the endorsed commerce bills:

4111" Clients „/Forfeiter = 413 „ Bills to receive V

- collecting the equivalent of the forfeiter bills, excluding the forfeiting tax and the collected commissions:

5124 „ accounts at banks in devices" = 4111" Clients" /Forfeiter V -TF – C

- registering the forfeiting tax and the commissions which are due to the specialized institution:

a) if the forfeiter calculates the forfeiting tax and commissions in a global way, the bookkeeping operation will be:

668" Other financial expenses" = 4111" Client /Forfeiter" TF + C

b) if the forfeiter distinctly calculates the forfeiting tax and the commissions the bookkeeping entry will be:

% = 411 „ Clients / Forfeiter" TF

667" Expenses regarding the given bank rates" TF

627"Expenses with the banking and assimilated services " C

where : V– the value of the right of debt upon the importer

TF – the forfeiting tax

C- the commission which is collected by the bank

Conclusions

The globalization of the world economy and of the financial market have determined the banking societies to orient themselves towards the utilizing of new techniques of financing. Due to the complexity of the operations which take place between the clients and suppliers, the financers have had to look for new forms of financing, which are different from the classical ones.

In the end I would like to synthesize advantages which are given by using the forfeiting operation:

- the foreign currency liquidities of the exporter are improved, the “on term” transaction becoming a “transparent” transaction;
- the possibility of the total financing of the transaction (up to 100%);
- the transfer of the risk of not paying, in a 100% percentage (there is no regress upon the exporter, once he has sold the documents, with the exception of the fraud cases);
- structuring the transaction according to the solicitations of the owner of the debt;
- eliminating the risk of fluctuation of the interest, of transfer, of not paying;
- eliminating the costs of managing and monitoring the payment;
- fixed interest till the date of payment;
- no real guarantees are solicited (mortgages, deposits, etc.);
- ensuring the confidentiality, according to the wish of the participants to that respective transaction;
- relatively simplified documentation.

Popa Ioan

Babeş-Bolyai University, Faculty of Economics and Business Administration, Teodor Mihali Street, No. 58-60, 400591, Cluj Napoca – Romania,

Our paper represents a pleading for fair value in the specific case of valuating inventories. The real significance and implications of fair value can only be seen after analyzing the topic from different points of view concerning all involved actors. Therefore we have based our scientific demarche on analyzing the trade literature and comparing the foresights of international regulations given by both the accounting setting bodies and the valuation setting bodies. Moreover we have followed two of the three moments which require valuation and for these moments we have selected those cases which require the using of fair value. Our opinion regarding the findings of the research is expresses by giving practical examples for the specific application of fair value and the way to reach it.

Key Words: Fair value, inventories, recognition, market value

Introduction

Any commercial, industrial or service providing entity must purchase goods and services on a regular basis. A purchasing policy must be established consisting in finding the best supplier in order to reach the optimum profitableness. More precisely we are talking about: the suppliers' competences, technical qualities of the products, delivery terms and prices.

From the accounting point of view, purchases (acquisitions) are first debated in the form of inventories bought by the entity or of the services used, and then in the form of their consumption within the different processes of creating new products or offering new services.

Our study deals with inventories and their value in different moments from their entrance within the estate of the entity until the exit. The possible destinations for inventories consist in productive consumption or sales in the same form.

Valuation of inventories from the accounting point of view is being made in three major moments, corresponding to initial valuation (entrance within the estate of the entity) and the subsequent valuation (the moment when the inventories exit the entity or the closing of the financial period) (Matiş et al., 2007). Our opinion differs from the classic presentations regarding the moments for inventories valuation which talk about entrance within the estate of the entity, the stock taking of assets, closing of the financial period and exit. We believe that the moment of stock taking coincides with the one of closing of the financial period when the patrimonial elements, including inventories, are being valued from the qualitative point of view by comparisons with their specific market.

Main objectives of the paper and research methodology

Among these accounting valuation moments, we will present and debate valuation of inventories at entry within the estate of the entity and valuation of inventories at the closing of the financial period. One of the reasons which made us choose these moments are the discussions that go beyond the historical cost as a basis for valuation, since they require estimating some values or they imply making some calculations and allocations of costs, through reference to the needs of the market. All these cases lead to fair value, accounting concept which corresponds to other valuation basis than the historical cost (the current cost, the reachable value and the current value).

The current accounting regulations (OMFP nr. 1752/2005) restrain the using of fair value. It is only explicitly foreseen in the case of revaluation for tangibles when dealing with consolidated financial statements and also in the case of financial instruments still within consolidated financial statement. Even though we believe that fair value is implicitly necessary in an indirect manner in other situations. Moreover, some entities apply mandatory or optional IFRS. With these having been said, we will present some considerations regarding the use of fair value in Romania in the specific case of inventories.

The paper has a theoretic character with some technical aspects. It is based on the normative accounting theory, both the one that uses the general chart of accounts and the one which relies on the conceptual framework, considering the fact that in Romania the two approaches coexist. We actually connect the classic accounting concepts and principles to the reform in the field of valuation – the fair value. In order to achieve these objectives we have analyzed the normative documents (valuation standards for assets and accounting standards) and also the trade literature. The comparison method and case studies were extremely helpful in demonstrating our opinion towards the moments when the fair value should and is being used and also its optimum utilization.

Valuation at the moment of entry within the estate of the entity

We believe that the values of inventories at the moment of entry within the estate of the entity, are both the ones proved through documents which show their source and fair values, in some special situations. These special cases will be discussed in the following part of the paper.

Fair value is conceptually presented as being a valuation basis, a convention or an accounting principle or an objective of the valuation (Obert, 2004; Casta, Colasse et al., 2001; Tournier, 2000; Holmes et al., 2002).

From the practical point of view, as an application, we consider that fair value can be reached through the three used approaches for valuation of assets or business': cost, income and market comparisons. The first approach leads to the net replacements cost, the second to the continuing utilization value and the third to the actual market value (Deaconu, 2004).

The case of inventories obtained free of charge

When we say free of charge inventories we understand receiving some inventories as a donation or having positive differences at the stock taking moment. In these situations the valuation is being done at the identified fair value for the moment of entry within the estate of the entity for that particular inventory. Across history, Romanian accounting regulations have also used some other names to refer to fair value, such as utilization value or current value. Generally, for assets, a certain type of consensus exists when talking about the value which they receive as being donated. Both the Romanian and International regulations refer to a certain form of fair value. Regarding the plus of stock taking, sometimes no express mentioning is being done and some other times we find some references to fair value. It is our opinion that in the case of inventories obtained free of charge their fair value must be determined, consisting in their market value as we will show within the 3rd section of our paper.

The case of acquisition/production of coupled inventories

It is sometimes possible that some acquisitions/production processes regarding inventories to be made at a global cost, corresponding to more coupled inventories. In this case it is necessary to determine the acquisition/production cost for each product separately, the accepted method being proportional to the corresponding market value (Blin, 2005:24). Other trade literature specify the using of the net realizable value (Epstein and Mirza, 2005: 170). Anyway we consider that it is the case for a value in correspondence to the market conditions at the valuation moment, with or without deduction of supplementary corresponding afterwards costs.

Case study no.1:

A batch of materials is being bought at a global acquisition cost of 5.000 lei. After the sorting, ferrous materials, copper and aluminum are being separated. An estimating market value of 3.000, 2.000, and

1.000 Lei at the date of acquisition is being considered for the three distinguished products. Consequently the global acquisition cost will be assigned to each inventory separately, proportionally to its market value, as follows:

- acquisition cost for ferrous materials: 5.000 x 3.000/6.000 = 2.500 Lei
- acquisition cost for copper: 5.000 x 2.000/6.000 = 1.666 Lei
- acquisition cost for aluminum: 5.000 x 1.000/6.000 = 834 Lei.

The case of determining the cost for the harvest agricultural production from biological assets

Inventories in the case of agricultural production which is being harvested by the entity from its biological assets are treated from the determination of costs point of view within IAS 41 "Agriculture".

At the moment of initial recognition for these type of inventories, in other words at harvest time, the valuation is being done at fair value less the estimated costs at the selling point at harvest time.

We should also mention that according to IAS 2 "Inventories" the fair value, even diminished with the harvest costs is different from the net realizable value, which is specific for inventories. Our own point of view referring to these aspects will be presented below.

Valuation at the moment of closing the financial period

It is the case for determining the net realizable value at the moment of closing the financial period. The aim of the valuation is analyzing some eventual impairment of inventories and presenting the minimum between their cost and their net realizable value within the balance sheet.

We consider that calling the above mentioned value a fair value consisting in net realizable value leads to the realizable value as valuation basis. Appling this valuation basis represents the actual market value.

The way to reach the market value is presented and developed within the valuation standards and also within the accounting standards. Among the accounting standards, the most complex in clarifying this matter, in our opinion, are the ones comprised within the FASB's project "Fair value measurements" and which aim the market value. The project offers o hierarchy of value which groups the inputs which should be used in order to estimate the fair value at three levels. Among these we have selected the first 2 levels:

a) Level 1 of estimations, which uses market references and which requires the observation of the active market with immediate access for the entity;
b) Level 2 of estimations, in the case when market prices for identical assets can not be found. In this case market prices for similar assets are being used by adjusting them for differences if such information is available.
c) More precisely, in order to obtain the net realizable value to compensate it with the accounting value of inventories and eventually record some adjustments for impairments, the following stages are distinguished:
    1) *Estimating the current selling price on the market, in other words the market value*

In our opinion, the market value must be understood in the exact sense of its name, using prices which are already met on the market for identical or similar inventories.

We appreciate that inventories subscribe to the above presented procedures with the observation that when some selling contracts exist the contractual price can also be used as an equivalent of the market value for the corresponding quantity of inventories. Even without an actualization clause for the prices comprised in the contract, because of the high rotation speed of inventories on the market, there is no significant risk for the prices in the contract to "get old".

The used market information will represent the most sustainable data available at the moment of valuation, concerning the events which occurred after the closing of the financial period, if these confirm the existent conditions at the end of the period.

2) *Deducing some elements meant to transform the market value into a net value, specific for the considered inventory*

Therefore the following are taken into consideration: usual commercial discounts, administration and distribution expenses which were afterwards made, and also production expenses which will be made forward for the products in progress. The profit percent isn't deducted on product, as the benefice wouldn't exist for the sellers of inventories.

The International Accounting Standards, through IAS 2 "Inventories" subscribe to the above presented aspects regarding the net realizable value. We consider it to be useful to also underlie three aspects mentioned within the standard, among which we agree with the first two of them. On the other hand we dare to comment upon the third.

Therefore:

- Considering the mentioning within the accounting standard, we appreciate that at the moment of estimating the net realizable value, the aim of holding the inventories is also taken into consideration. This influences their value as follows:
  - for raw materials and consumables - held for consumption – it is recommended to determine the replacement cost;
  - for finished products, semi finished products and commodities – destined for trading – it is appropriate to determine the market value and to deduct the corresponding elements in order to obtain the net realizable value, as described above.
- Also, the international accounting regulations referring to inventories mentions that normally, the net realizable value must be determined for each inventory element taken individually. Some exceptions are still admitted for global valuation of some assembling elements, which are linked to each other, and therefore can be correctly valuated even if taken together. As an example, products lines with assembling utilizations, made and traded within the same geographical area are mentioned (Feleagă and Malciu, 2004: 164).

Besides the above mentioned case within the international standards there are also some situations stipulated within the American accounting standards. We should mention that the US GAAP accept the recognition as revenue for the gains, even if there aren't achieved yet. Therefore the valuation at net realizable value for a whole group of products is accepted if for some elements an unrealized gain appears (the net realizable value being higher than the accounting value), and for other an unrealized lose (the net realizable value being smaller than the accounting value), finally the two of them compensating each other and reducing the net lose.

- Finally, IAS 2 "Inventories" underlies the fact that the net realizable value which is being determined for inventories, with the aim of analyzing some eventual impairment is different from the fair value. The net realizable value would refer to the net sum which the entity would expect to obtain by selling inventories during the normal development of its' activity (IASB, 2007). The fair value would reflect the sum for which the same inventory could be exchanged on the market, between buyers and sellers who are interested and well informed. It is mentioned that the first is a value which is specific to the entity while the second isn't. It is also shown that even though fair value would be diminished by the selling costs, it wouldn't be equal to the net realizable value for inventories.

As for where we are concerned, we do not accept these differentiation and these arguments. In our opinion fair value can take the shape of an historical cost, a market value, a replacement cost, an actualized value. It does not have to be looked at unilateral, just as a market or exchange value. If so, the net realizable value, based also on a market value or seldom on the replacement cost, is equal to fair value which takes into consideration all the required deductions that might appear in a particular situation for valuation an inventory.

We believe that the accounting standard wants to differentiate the way to determine fair value, term used in a generic manner, for the whole category of inventories – it is the case for net realizable value – and particular inventories such as biological assets or inventories held by brokers on the stock exchange – for which the fair values/current values are being determined considering the specific conditions.

More precisely, after analyzing the trade literature and the spirit of IAS 2 "Inventories" and also of the connected standards such as IAS 41 "Agriculture" we understand that there are two exceptions from applying the historical cost as a basis for valuation of inventories. These require applying other valuation basis for initial recognition which would lead to fair values. We refer here to: biological assets until the moment of harvest, according to IAS 41 "Agriculture" (since afterwards IAS 2 is being applied and therefore a valuation based on costs) (1); inventories that belong to brokers on stock exchanges in accordance to IAS 2 (2).

In order to continue our arguing for the equivalence between the net realizable value and fair value diminished with the specific costs of finishing or selling the inventories we also offer the case, also stipulated within IAS "Inventories", of initial valuation of inventories at the so called net realizable value. These would apply in the exceptional case of inventories of agricultural and forest products, agricultural products after harvest, mineral and mining products for which we can not determine the cost, but the price of the day is available (again the realizable value is just a market value). When inventories are valued over the cost, revenue will be recognized in advance of the selling (anticipated). In conclusion, the net realizable value used to directly record these inventories whose cost can not be determined, is actually a fair value, another basis for initial valuation than historical cost. We therefore find ourselves in the case of biological assets and inventories held by brokers on the stock exchange, which are initially valued at fair value.

The international valuation standards (IVS), conceived in close correlation to the accounting ones, restate the definition for net realizable value comprised within IAS 2 "Inventories", but mention that it is a value which can be used only in the context of IAS 2 for properties held with the purpose of selling within the course of the normal activity of the entity (IVA 1 "Valuation for financial reporting") (IVSC, 2005). In the context of valuation for financial reporting, the valuators should respect this accounting presentation /requirement following the market value (from which the cost related to the selling are being deducted) if and only when all the demands within the definition given by valuators for market value are carried out. The valuation standard also mentions that the term "net realizable value" is equivalent to the one of "net selling price".

An important remark taken from Annex A "Accounting fundaments for IVA 1" of IVA 1 is the one referring to the definition of current assets and their connection to tangibles and intangibles assets on which the valuation standards generally focus. It is shown that for current assets they refer to elements which are effectively owned as a commercial inventory which is to be sold during the exploitation cycle of the entity, usually one year. Dwellings built and sold by the constructors are given as an example and it is concluded that current assets (we must underlie again that they are only understood to be non current assets own with the purpose of being sold) should not be valuated in the context of their connection and meaning for accountancy and financial statements.

We conclude that it is recommended to apply the valuation methodology for investment properties in order to identify their market value and therefore their net realizable value.

Also, we consider that the valuation standard (IVA 1) is reductive, it does not understand inventories different from commodities and only includes in this category non current assets held for trading. Its' contribution still consists in underlying the fact that the net realizable value is actually an accounting term, specific for inventories valuation, which is determined by starting with the market value. Obviously that the net replacement cost, which might be used in the case of some raw materials and consumables, it is not mentioned since this type of inventories doesn't even exist within the standard. The connection to fair value isn't done, but it is also presented as a market value (with the exception referring to the case when there is no market information available, therefore appealing to other valuation models). Moreover the connection with the net realizable value is easy to be done.

Case study no.2:

An entity owns for selling an inbuilt land, with a surface of 1000 m2, situated in an industrial area. At the valuation date, the prices on the market for comparable lands had values between 50 and 80 Eur/m2. The values were determined through expertise, by using the direct comparison method, applying corrections for: ownership rights, legal restrictions, financing conditions, selling conditions, location and other comparison criteria. The valuator opted for the value of 60 Eur/m2, by using the standard with a few corrections. Therefore a value of 216.000 Lei was determined.

Conclusions

Fair value gains more and more field as a principle used in valuation. Promoted by the American accounting regulations and then by the International ones, it seems to be more required in Europe by each day. In order for it to applied, fair value must be understood as a concept and technical implications. Our study presents the moments and cases which impose the using of fair value for inventories. We consider that accounting valuation is being done in three moments, among which we have presented the moment of entry within the estate of the entity and the closing of the financial period in the case of inventories. For these moments we have selected those cases which require the using of fair value. We have expressed our opinion regarding the specific application of fair value and the way to reach it by giving some examples. Therefore we have based our scientific demarche on studying the trade literature and the professional standards. We consider that in the case of inventories, very often, it is followed the market value and as an exception the replacement cost. These applications are required in the case of inventories which are obtained free of charge, coupled inventories, inventories with a specific nature (like biological assets or investment property owned for selling), and also in the case of estimating adjusting for impairment at the closing of the financial period.

SYSTEM OF ACCOUNTS SPECIFIC TO THE MANAGEMENT ACCOUNTING IN WHOLESALE TRADE

Deju Mihai

University of Bacău, Faculty of Economic Sciences, 1 Constantin Muşat Street, Bacău, Email: comatbacau@zappmobile.ro, Telephone: 0722 – 208.411

According to the Romanian accounting norms, management accounting is organized at the level of each patrimonial unit according the specificity and information needs; and they have the possibility to create and use their own system of accounts, adapted to the viewed aims.

In this paper we present a system of account specific to the organization of the management accounting on responsibility centres in wholesale trade units.

Key-words: system, accounts, management

The organization of accounting, referring to the ***separation of the confidential information from the public information***, has generated ***the dualism in accounting***[334], concept based on the organization of accounting on two interrelated branches: the financial accounting and the management accounting. This concept supposes the distinct processing of expenses and incomes by the two accountings by separate information flows (circuits), each of them aiming the realization of their specific objectives, that is the drawing up of financial situations at the end of the accounting period, by the financial accounting and, the calculation of production costs, the establishing of results and return of the developed activity, the following and control of results, by the management accounting. The latter uses specific accounts, grouped separately from financial accounting system of accounts, by means of which the following objectives are met:

- the taking-over of expenses from the financial accounting for their collection and repartition on destinations;
- the calculation of costs according to the technical-productive characteristics of the developed activities and to the information needs of the decision-taking factors;
- the taking-over from the financial accounting of incomes for the settlement of afferent costs and establishing of analytic results;
- the realization of the management control on the deviations from the pre-established costs (in the case of standard costs use);
- internal budgetary control on budgetary expenses and incomes.

The management accounting is also useful for the establishing of unitary tendencies of economic phenomena and processes, for the substantiation of programmes and the elaboration of previsions regarding the expenses and incomes to be realized[335].

In fact, as Michel Capron concludes, the management accounting is an instrument used by the enterprise management to fill their information needs and to direct their decisions and that, unlike the financial accounting, is not liable to some common conventions of all enterprises, and the supplied information is not public.

In accordance to the Romanian accounting norms, the management accounting is organized at the level of each patrimonial unit according to its specificity and information needs, and they have the possibility either to use a system of specific accounts, or to develop the financial accounting accounts or to organize cost calculation by means of the technical-operative record.

---

[334] N. Feleagă, I. Ionaşcu, *Contabilitatea financiară (Financial Accounting)*, vol. I, Economic Publishing House, Bucharest, 1993, p.13

[2] M. Capron, *Contabilitatea în perspectivă (Accounting in the future)*, Humanitas Publishing House, Bucharest, 1994, p.57

The use of accounts, as well as their symbolizing is realized so that the stocking and accessing system of the obtained results should be flexible and allow a wide range of options. The list of management accounts can be adapted according to the viewed aims, respectively: the prominence of the cots flow, the determination of the costs afferent to stocks, the determination of incomes and results according to the generating-activity, previsions etc.

As within the management accounting there is followed only the determination by accounts of production costs, the expenses taken for re-treatment from the financial accounting refer only to the operating expenses and to a part of financial expenses with depreciations and provisions[336].

The procedures and techniques used in the management accounting are established in accordance with the qualitative characteristics of the information required by users, as well as with the characteristics of the developed activity[337].

We suggest here a system of accounts appropriate to the management accounting in the wholesale trade sector.

Taking into account the characteristics of the wholesale trade enterprises, operating expenses and incomes recorded in the financial accounting on different types according to their economic nature, are taken in the management accounting on expense places or responsibility centres, as we have defined them, divided in profit centres and cost centres using the 9th class accounts with the following adjustments:

- group 90 – "Internal settlements accounts"
  - 901 "Internal settlements on commercial activity expenses";
  - 902 "Internal settlements on commercial activity incomes";
  - 903 "Internal settlements on results".
- group 92 – "Calculation accounts"
  - 921 "Main activities expenses";
  - 922 "Auxiliary activities expenses";
  - 923 "Indirect expenses";
  - 924 "General administrative expenses";
  - 925 "Selling expenses"
- group 94 – "Operating incomes"
  - 941 "Commercial activity incomes".

We have to make the following observations to the system of management accounts, proposed for a wholesale trade enterprise:

- within group 90 "Internal settlements accounts", the account 903 "Internal settlements on results" gets another economic content than that established by the accounting norms.

This account helps to record the results on profit centres as well as to take the expenses afferent to the period (general administrative expenses, subactivity cost, selling expenses) according to the way the result is established on the commercial activity cost or on the total commercial cost.

Taking into consideration the lack of finished production in the wholesale trade activity, this account loses its signification of reflecting the differences between the pre-established cost and the effective cost of production, the way it functions in other sectors of activity.

- - group 93 "Production cost" will no longer be used, taking into consideration the lack of finished production and of manufacturing production, so that the two accounts 931 "The obtained production cost" and 933 "The manufacturing production cost" remain without objects.

---

[336] Budugan D., *Contabilitate de gestiune (Management accounting)*, Pro Juventute Publishing House, Focşani, 1998 p.222

[337] Ministry of Public Finances. Mentions on some organization and management measures of the management accounting, approved by Order 1826/22nd December 2003, published in Monitorul Oficial no. 23/12.01.2004

– from reasons of reflecting the result afferent to profit centres, obtained in the selling process, we suggest the introduction of *group 94 "Operating incomes" that, by account 941 "Commercial activity incomes", will take from the financial accounting the incomes afferent to profit centres, offering thus the possibility to determine the afferent results.*

We have to demonstrate here that, in fact, the system of management accounts regulated by the Romanian accounting norms allows only the calculation of effective costs on costs holders and the record of differences from the pre-established cost, leaving unsolved the problem of the products selling results reflection.

In order to organize the calculation on responsibility centres by using the suggested system of accounts, it is necessary to take the financial accounting expenses into the management accounting, on expenses places and calculation items, as follows:

– the direct expenses that can be charged directly to the responsibility centres, will be taken to the debit of the account 911 "Main activities expenses" on profit centres and calculation items;
– the expenses afferent to the auxiliary activities will be taken by the debit of the account 922 "Expenses afferent to auxiliary activities", with development in analytical on appearance places (auxiliary activities) and on expense elements;
– indirect expenses, meaning those expenses that cannot be charged directly to the profit centre will be taken from the financial accounting by the debit of the account 923 "Indirect expenses" with deduction on analytic on appearance places (operational or functional structures-deposits or auxiliary sections) and expense elements;
– the general administrative expenses will be taken from the debit of the account 924 "General administrative expenses" on appearance places and types of expenses;
– the selling expenses will be taken by the account 925 "Selling expenses" on types of expenses and appearance places;
– the incomes from the selling of goods will be taken by the credit of the account 902 "Internal settlements on commercial activities incomes", analytically on profit centres, in correspondence with the account 941 "The commercial activity incomes".

The determination of results on profit centres requires the collection of incomes on places of appearance, calculation and settlement of the auxiliary activities costs, the repartition of indirect expenses and the calculation of the main activities cost. The necessary stages and the afferent book entries can be represented synthetically as follows:

1. The collection and entry of direct expenses afferent to responsibility centres (main activities and auxiliary activities).

%	=	**901 "Internal settlements on expenses"**	10,000,000
921 "Main activity expenses"			8,000,000
analytic xx.xx.xx[*]			
922 "Auxiliary activities expenses"			2,000,000
analytic xx.xx[*]			

2. The collection of indirect expenses on responsibility centres (main activities, auxiliary activities and general activities).

[*] The explanation of analytical accounts is presented at the end of this paragraph.

%	**:**	**901 “Internal settlements on expenses”**	2,000,000
923 “Indirect expenses ”			1,500,000
analytic xx.xx*			
924 “General administrative expenses”			500,000
analytic xx.xx*			

----

3. The settlement of mutual carrying-outs between the auxiliary sections, as well as by the other enterprise activities.

---   **--**

%	**:**	**922 “Auxiliary activities expenses”** analytic xx.xx*	2,000,000
922 “Auxiliary activities expenses”			500,000
analytic xx.xx*			
923 “Indirect expenses”			700,000
analytic xx.xx*			
924 “General administrative expenses”			500,000
analytic xx.xx*			
925 “Selling expenses”			
analytic xx.xx*			300,000

----

4. The repartition of indirect costs on profit centres and the establishing of the effective cost for each profit centre.

921 “Main activities expenses” analytic xx.xx.xx*	**:**	**923 “Indirect expenses”** analytic xx.xx*	2,200,000

----

5. The taking of incomes from the financial accounting, analytical on each profit centre.

---   **--**

941 “Commercial activity incomes”	**:**	**902 “Internal settlements on commercial activity incomes”** analytic xx.xx*	1,500,000

----

6. The settlement of the effective costs of the profit centres on incomes and the establishing of the gross results, afferent to each profit centre, according to the commercial activity cost, and

* The explanation of analytic is presented at the end of this material.

the costs of the period (general administrative costs, selling costs, sub-activity cost) will be charged directly to the result account.

Variant A

902"Internal settlements on commercial activities incomes" analytic xx.xx*	**921"Main activities expenses"** analytic xx.xx*	10,200,000

902 "Internal settlements on commercial activities incomes" analytic xx.xx*	**903 "Internal settlements on commercial activities results"** analytic xx.xx*	4,800,000

903 "Internal settlements on commercial activities results" analytic xx.xx*	**%**	<u>800,000</u>
	924 "General administrative expenses" analytic xx.xx*	500,000
	925 "Selling expenses" analytic xx.xx*	300,000

7. The settlement of the general administrative expenses and of the selling activity on the responsibility centres account, with the determination of results on profit centres according to the total commercial cost:

Variant B

921 "Main activities expenses" analytic xx.xx*	**%**	<u>800,000</u>
	924 "General administrative expenses" analytic xx.xx*	500,000
	925 "Selling expenses" analytic xx.xx*	300,000

902,, Internal settlements on commercial activities incomes" analytic xx.xx*	**921"Main activities expenses"** analytic xx.xx *	11,000,000
902,, Internal settlements on commercial activities incomes" analytic xx.xx*	**903,, Internal settlements on commercial activities results"** analytic xx.xx*	4,000,000

8. The settlement of total expenses on incomes with the view to close the internal settlements account on expenses.

901"Internal settlements on the commercial activity expenses"	**941 "Commercial activity incomes"**	11,000,000

9. The closure of the commercial activity results and income account.

903 "Internal settlements on commercial activities incomes"	**941 "Financial activity incomes"**	4,000,000

The use of the two variants requires further elucidations:

- **in the case of Variant A:**
- the results obtained by each profit centre are supplied by the analytic record of the account 903 "The commercial activity results" and are established according to the incomes resulted from the selling of goods and the commercial activity cost;
- the administration and distribution cost affects the result of the whole activity and is supplied by the two accounts: 924 "General administrative expenses" and 925 "Selling expenses".
- **in the case of Variant B:**
- the result obtained for each profit centre is calculated according to the total commercial cost – established for each profit centre by means of the account 921 "Main activities expenses" and is found in the crediting turnovers of the analytical of the account 903 "Commercial activities incomes", before closure, as a difference between the incomes obtained from the selling of goods and their complete cost.

After these two entries, all accounts are balanced.

In order to give the possibility to collect expenses and incomes on responsibility centres, so as to determine the commercial activity cost as well as the results afferent to each profit centre, the synthetic management accounts have been developed on analytic accounts, as follows:

921 - is divided on three categories of analytic accounts:

921.xx. - 1st degree analytic accounts, corresponding to level I profit centres (storehouses);

921.xx.**xx** - 2nd degree analytic accounts corresponding to level II profit centres (managements);

921.xx.xx.**xx** - 3rd degree analytic accounts, corresponding to calculation items

(01 – „Merchandise purchase cost";

02 – „Salary expenses";

03 – „Social insurance-supplementary pension";

04 – „Indirect expenses";

05 – „Bank interests";

07 – "General administrative expenses").

922, 923 - developed on two categories of analytic accounts,

924, 925 as follows:

922.xx - 1st degree analytic accounts – afferent to responsibility centres

923.xx (profit centres and costs centres)

924.xx

925.xx

922.xx.**xx** - 2nd degree analytic accounts on types of expenses symbolized with two figures

923.xx.**xx** representing the completion of the expenses accounts from the 6th class

924.xx.**xx** financial accounting, respectively 6**00**, 6**01**, 6**02**, …, 6**81**.

925.xx.**xx**

902, 903 - are broken down on two categories of analytic accounts:

902.xx - 1st degree analytic accounts representing level I profit centres

903.xx (storehouses, auxiliary activities);

902.xx.**xx** - 2nd degree analytic accounts representing level II profit centres

903.xx.**xx** (managements and auxiliary activities).

MANAGEMENT ACCOUNTING ORGANIZATION IN WHOLE SALE TRADE - CHARACTERISTICS

Deju Mihai

University of Bacău, Faculty of Economic Sciences, 1 Constantin Muşat Street, Bacău, Email: comatbacau@zappmobile.ro, Telephone: 0722 – 208.411

The characteristics of management accounting organization in wholesale trade enterprises are based on their unstandardized character, fact that gives enterprises the possibility to establish an independent management accounting system, conditioned by the following factors:

- *the specificity of the goods supply and selling activity;*
- *the organizational structure of wholesale trade enterprises;*
- *the concept of cost used in establishing the results and performances of responsibility centres;*
- *the system of economic and financial indicators of return analysis and control.*

Key words: characteristics, accounting, management.

The characteristics of management accounting organization in wholesale trade enterprises are based on their unstandardized character, fact that gives enterprises the possibility to establish an independent management accounting system, in accordance with their own specificity and information needs.

In fact, in approaching the specific aspects of each enterprise, we should start from the fact that management accounting information "represents a component of the enterprise's information system that helps realizing independently the operating analytical accounting, respectively of expenses and results from the point of view of value holders and organization's subdivisions – responsibility centres, as well as the internal budget audit, with the purpose of supplying confidential information necessary for the substantiation of the patrimonial unit"[338].

Taking into consideration all the aspects mentioned above, we can conclude that the organization of the management accounting is conditioned by:

- the specificity of the goods supply and selling activity;
- the organizational structure of wholesale trade enterprises;
- the concept of cost used in establishing the results and performances of responsibility centres;
- the system of economic and financial indicators of return analysis and control.

a). The specificity of merchandise supply and selling activity

In accordance to the classified list of economic activities, used in European Union countries wholesale trade enterprises are considered: *"units wholly or mainly employed in reselling, in partnerships, goods to retailers or other wholesalers, producers or other users with a view to further processing, conditioning, packing, disassembling. Generally, the wholesaler's role involves, on the one hand the storage of goods and, on the other hand, the deed of property or the right of disposing of the respective goods"*[339].

This definition covers, in general, the traditional role of wholesale trade, supply, storage and selling of goods by the different beneficiaries (not consumers). Yet, in practice the existence of wholesalers is justified by the services they offer to their customers and the assumed risks:

---

[338] V. Pătruț, *The attempt of the management accounting conceptual delimitation*, „Finances, Credit, Accounting" Journal, no. 11,12/1999

[339] NACE – The Classified List of Economic Activities in the European Community, endorsed by the Regulations of European Economic Community Council no. 3037/9th October 1990.

- the physical purchase of goods for anticipated storage in order to meet the clients' operative needs, fact that makes wholesalers more preferred than producers (by getting closer to beneficiaries, varied selection lines and efficiency);
- in order to cover the supply and storage costs, wholesalers charge a reasonable addition share, inferior to the expenses the beneficiaries would have if they supplied directly from the producers;
- the purchased stocks financing for which the wholesalers invest their funds as well as a high volume of loans (bank credits);
- clients' financing by selling on commercial credit;
- risk assumed from the moment of supply and storage of goods of keeping a certain unsold merchandise fund (the registration of damages, degradations which are not imputable to the staff, the change of selection lines demanded on the market etc.).

From all those mentioned above, one can see the complexity of the activity developed by these enterprises and we can notice at the same time that these units do not have production activities that would necessitate the collection and repartition of expenses with a view to determine the product cost what makes the management accounting object be centred on the determination of the commercial activity cost on responsibility centres, according the decisional factors' information needs regarding the obtained results and the determination of influence factors.

The main categories of expenses concerning the trade activity refer mainly to:

- storage and keeping expenses;
- salary expenses;
- goods selling expenses (packing, sorting, batching, retailing, loading etc.);
- expenses concerning auxiliary activities (transportation, transport facilities maintenance and repair shops, loading machinery and internal transport maintenance and repair shops, general repair an maintenance shops);
- general administrative expenses (managerial activity, financial accounting activity, information processing, security, firemen etc.).

b). The organizational structure of wholesale trade enterprises

The organizational structure of a wholesale trade enterprise contains, just like any other profit-generating patrimonial unit, an operating (production or operational) structure and a managerial (functional) structure.

The operating structure of wholesale trade enterprises refers to the activities developed in operational subdivisions, organized as managements, specialized in the supply and selling of certain groups of products. Managements themselves are classified according to certain technical-economic criteria, in organizational structures, called storehouses. Within the operating structure, there can also be included the auxiliary activities whose object is the execution of works or providing services in order to normally develop the main operating activities (the supply and selling of goods) and the general administrative activities, such as:

- the transport activity using their own transport facilities;
- yard track transport activity;
- the mechanization activity of loading-unloading, stowage works (cranes, motolifts, gantries, truck scales etc.);
- car and machinery maintenance and repair shop;
- the maintenance and repair activities of machinery under operating standards checking (scales, truck scales, gantries);
- general repair and maintenance shop;
- power station, if need be.

The functional structure refers to those activity compartments where the general functions of a lucrative enterprise take place, respectively: the management, commercial, financial-accounting, finance, marketing, administrative function, etc.

Both the activities developing within the operational (operating) structures, and the functional ones are generating expenses that all constitute the whole cost of the commercial activity. In order to locate and follow the reduction of expenses caused by operational-functional links, **we suggest that they should be organized in *responsibility (analysis) centres*** *that, according to the direct contribution to the turnover and profit, can be divided in* ***profit centres*** *where turnovers and financial results are realized and* ***cost centres*** *when incomes cannot be associated to the expenses caused by these structures.*

The grouping of activities on responsibility centres, divided in profit centres and costs centres for a wholesale trade enterprise, is as follows:

- profit centre:
  - **managements** – specialized in the trade of some groups of goods with the same characteristics of consumption destination, grouped in organizational structures at a storehouse level;
  - **transport activity** – developing both transportation for the main activity (supply of goods) and tariff transportation to third parties.
- costs centres:
  - on the structure of auxiliary activities:
    - maintenance and repair shop for transport facilities and machineries;
    - general repair and maintenance shop;
    - handling devices mechanization shop (loading, unloading, stowage, etc.);
    - power station.
  - on the structure of general administration activities
    - management activity (commercial, financial-accounting);
    - information processing activity within a computing office;
    - administrative activity (cleaning, security, firemen, telephone exchange).

In a wholesale trade enterprise the organization of income and costs accounting on responsibility centres, is strongly influenced by the specificity of the activity object, that is *supply-selling* of goods that requires the main activity to be represented by the administrative structures of the merchandise fund, that is *storehouses* and, within them, the *managements of goods*. Within these organizational links the process of supply, storage and selling of goods takes place.

The *managements of goods* are *profit centres* as the expenses caused within them are associated the incomes obtained from the selling of goods, so that a result account can be drawn up for each centre.

Profit centres, *managements of goods*, respectively, represent the object of *cost calculation* characteristic for the commercial activity and the establishing of afferent results. In the management accounting, the collection of expenses and the cost calculation are realized by means of a synthetic account developed on analytic accounts corresponding to each profit centre.

In order to ensure the appropriate conditions for the *supply-selling* functions by the operational structures (management of goods) within the enterprise, there are organized a series of auxiliary activities that perform works or provide services for them, but sometimes for third parties, as well. It's the *transport* sector that performs both carryings out for the main activity and transportations for *clients'* interest, as well as *the mechanization activity of supply and selling works* (AMLAD), which sporadically provide services for third parties.

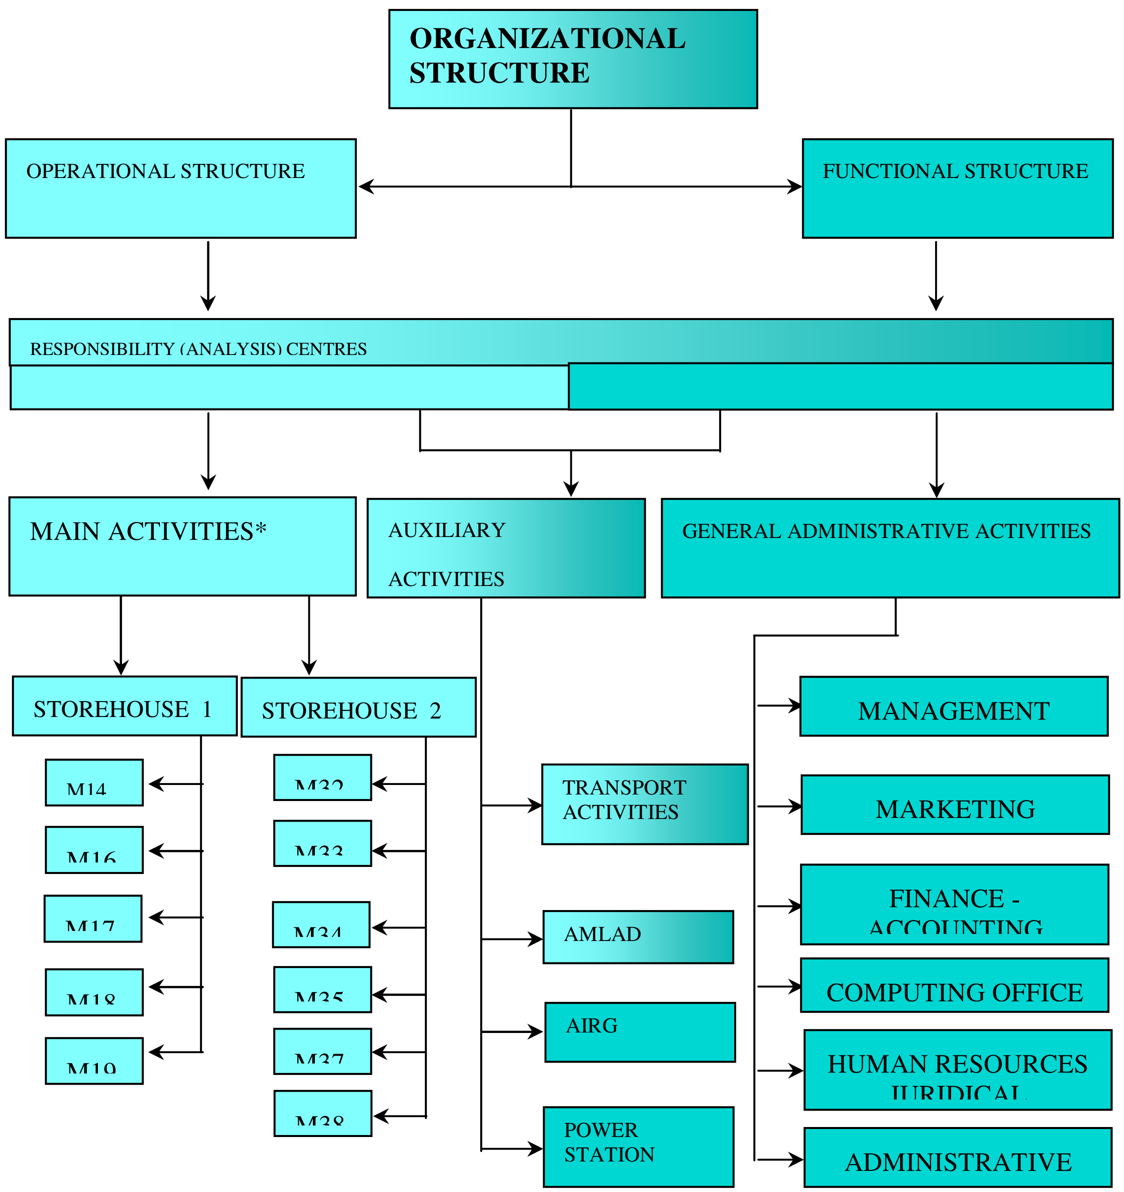
Due to the random and insignificant character of the carrying-outs accomplished within the *auxiliary activities* by third parties, we consider that it is not necessary to organize a calculation concerning the determination of these carrying-outs effective costs. In order to avoid the repartition of the cost afferent to the carrying-outs supplied to third parties on the main activities, we shall separate them by a method of indirect estimation, according to the planned return margin which is part of the used tariffs. Thus determined, the costs of the carrying-outs tariffed by the auxiliary activities of the different third parties will be charged to the incomes collected for the respective activities.

Taking into consideration that the incomes from the auxiliary sectors are insignificant, these expenditure zones appear as *cost centres*. The role of management accounting, as far these structures are concerned, is that of establishing the deviations of real costs from budget costs. The auxiliary activities costs, collected by means of a specific account deducted on appropriate analytic accounts, are settled on profit centres and cost centres.

In order to collect the indirect expenses that are to be found in profit centre costs only after the realization of some repartition and charge calculations (such as the expenses at storehouse level), there are used specific accounts analytically developed on responsibility centres and on expenses elements.

At the level of the enterprise functional structure, within the management accounting there are constituted distinct expenses areas that act as cost centres, grouped on the comportments accomplishing the general functions of the enterprise (management, financial, administrative, etc.).

The organization on responsibility centres of wholesale trade enterprise activities is presented in the following figure:



Structure model on responsibility centres of wholesale trade enterprise activities

c). The concept of cost used in establishing results

The management accounting collects expenses from the financial accounting so that it would be possible to determine both the commercial activity cost and the total commercial cost on profit centres, in the following structure:

- merchandise purchase cost;
- direct expenses;
- indirect expenses;
- bank interest expenses [x]

Circulation expenses

TOTAL COMMERCIAL ACTIVITY COST

- general administrative expenses [xx]
- selling expenses [xx]

TOTAL OR COMMERCIAL COST

The simultaneous presentation of the result, calculated according to the commercial activity cost and the total or commercial cost, in the conditions of a determined selling price, is as follows:

<table>
<tr><td colspan="3">900</td><td colspan="3">270*</td><td>1170</td></tr>
<tr><td colspan="3">Commercial activity cost</td><td colspan="3">Profit*</td><td>Delivery price</td></tr>
<tr><td>600</td><td>100</td><td>200</td><td>150</td><td>50</td><td>70</td><td>1170</td></tr>
<tr><td>Merchandise purchase cost</td><td>Direct expenses</td><td>Indirect expenses</td><td>General administrative expenses</td><td>Selling expenses</td><td>Profit</td><td>Selling price</td></tr>
<tr><td colspan="5">TOTAL OR COMMERCIAL COST</td><td>PROFIT**</td><td>DELIVERY COST</td></tr>
<tr><td colspan="5">1100</td><td>70**</td><td>1170</td></tr>
</table>

Note:

* *The profit is determined according to the realized income expressed in delivery prices, and the expenses were collected at a commercial activity cost level.*

The general administrative and selling expenses are considered costs of the period and influence the result on total operating activity and not on profit centres.

*** In the second variant, the profit is determined according to the total of commercial cost (which includes the general administrative and selling expenses rate distributed to each profit centre) and the income expressed in delivery prices.*

---

[x] As a trade characteristic, we consider relevant the inclusion of expenses with the interest afferent to the financing of circulating assets (stocks) within the activity cost. [x x] Taking into account that the determination of results on profit centres is made according to the commercial activity cost, the general administrative expenses and the selling expenses are considered expenses of the period.

d). The system of the return analysis indicators

Among the indicators used for the return determination and analysis in the wholesale trade, we can enumerate the following:

- gross margin (trade mark-up);
- commercial activity cost on profit centres;
- commercial activity cost on cost centre;
- total commercial cost on profit centres;
- the result on profit centres;
- rate of return afferent to the consumed resources.

In the process of expenses collection and repartition on profit centres, such as they have been proposed in our paper, one has to take into account the obtaining of these indicators necessary for the setting and control of the respective profit centres return.

THE QUALITY OF THE BOOK-KEEPING INFORMATION – ESSENTIAL CONDITION IN ORDER TO MAKE EFFICIENT DECISIONS

Diaconu Elena

Universitatea Spiru Haret, Facultatea de Contabilitate şi Finanțe, Rm. Vâlcea, str. G-ral Praporgescu, nr. 22., Email :diaconuush@yahoo.com, Tel. 0723941248

Summary: The accountancy, as language of business, must keep up with the evolutions which have been registered in the fields of economical life and the need to promote unanimously accepted concepts prove its usefulness more and more.

The contribution of the accountancy in the achievement of managers' strategic objectives manifests itself under the form of the assurance of necessary information in order to gain control and to determine the degree of responsibility and of the effect at different jobs. This thing allows the tracking down of internal reserves, of non-economical expenses and of losses.

In other words, the book-keeping information constitues the most important source, the „data base" of the leadership in the process of making decisions. Thus the accountancy becomes needful in the leadership activity of economical entities, indifferently of the activity which they develop.

Key words: book-keeping information, qualitative characteristics, relevance, users, decision

The relationships between the econimcal unities and the background where they develop their activity generates the need of relevant and objective information whose satisfaction demands an appropriate offer. The production of book-keeping information is assured by professional practitioners in this field within the informational book-keeping system of the entity. This type of information must accede to certain demands so that it can be useful for everybody who uses the accountancy products. That's why we consider that their dissemination must take place in a dynamic and rational process as a result of the negociations and compromises between the enterprise and the external factors.

Nevertheless, we have to notice that the growth of the number of users who apply to book-keeping information determined both the growth of the volume of requested information and the exertion of a constant pressure during the dissemination process. At the same time we witness an intensification of the entity's responsibilities towards the quality of the product.

The book-keeping information in the decisional process is useful to the partners of trading companies only if it accomplishes certain attributes called qualitative characteristics.

The need of qualitative book-keeping information has appeared in the United States after the economical, financial and stock market crisis from 1929 when the investors didn't have enough information. The first step in this direction was to establish financial rules for companies which were making out negotiable titles.

The users take advantage of the support of the generally accepted conventionswhich have the goal to simplify the interpretation of financial situations. FASB enumerates the following generally accepted conventions: the comparability and and the permanence of methods, the relative importance, the prudence, the good information and the reliability, which influence the quality of information transmitted to the users. This thing is also noticed in the figure below.

Intelligibility

The decision factors have to be able to interpret the book-keeping information

Conventions which make interpretation easier:

-comparability and permanence

-the relative importance

-prudence

-good information

-reliability

Usefulness

The accounts have to provide useful information in the process of making decisions.

External financial reports of general use

The relevance

-the image value of the past

-the prevision value

-the opportunity

The reliability

-the faithful representation

-the possibility to check or to be checked

-the neutrality

Figure 1. The relationships between the qualitative characteristics of the financial information and the generally accepted conventions

Though they have the same objective, the qualities of the book-keeping information vary in different ways according to the body which nominates them.

According to the General framework of IASB (International Accounting Standards Board), in order to elaborate and present financial situations, the qualitative characteristics of book-keeping information, seen as symbols which determine their utility, refer to: intelligibility, relevance, credibility and comparability**.**

Intelligibility is presented as the main characterstic of financial information. The paragraph 25 stipulates that "the information delivered by the financial situations must be easy to understand by the users". In order to reach this goal the articles and the book-keeping elements are aggregated and clarified in the most adequate way. They must assure a balance between the book-keeping knowledge, that concerning the businesses and the economical activities, on one hand, and their interest to study the information reflected in the financial situations, making the necessary efforts, on the other hand.

Obviously, not all the information are accessible to all the categories of users. There is complex and relevant information which appear in the financial situations even if all the people don't understand it. To assert that any book-keeping information with a complex character may be understood any time and by anybody means, in our opinion, to deny the necessity of qualification and perfecting of human ressources in this field.

We think that the information regarding the complex problems which influnce the users' economical decisions must be included in the financial situations even if they prove to be more difficult to understand to a part of the users.

The relevance represents the quality of financial information to influence the users' economical decisions, supporting them to evaluate past, present or future events, confirming or correcting their previous evaluations. For instance, the balance sheet and the profit and loss account offer to the users information related to the financial postion and to the performances of the enterprise from the past financial budgetary year but they also help them to make previsions regarding the financial position and the future performances in other fields of great interest such as: the payment of dividends, of wages, the capacity of the enterprise to honour its falling due obligations.

In the theory of speciality, the relevance of information is present under two forms: spatial and temporal.

The spatial relevance of information supposes its selection and processing according to the needs of a beneficiary while the temporal relevance supposes the bringing up-to-date of the information.

The two forms of the relevance are found in the General Framework of IASB under the deonomination of "the nature and the threshold of significance" and represent the influence factors of the relevance and of the opportunity of information.

In some circumstances, the nature of the information is self-sufficient in order to determine its relevance. For instance, the information regarding the creation of a new activity sector in an enterprise is sufficient in order to measure the risks and the opportunities of the enterprise, indifferently of the results registered within the new activity sector during the report period. In other circumstances, the nature of the information is not self-sufficient in order to determine its relevance, both of them being necessary. For instance, the information related to the debts of a society must be completed taking into account their falling due terms.

An information is appreciated as being significant if its omission or its wrong presentation changes the economical decisions of the users taken on the basis of financial situations. The threshold of significance depends on the size of the element or of the error which is judged in the specific circumstances of the omission or of the wrong presentation. As a consequence, the threshold of significance represents more a limit than a main characteristic of the information in order to be useful and relevant. It's worth being mentioned that we notice quite frequently that the published book-keeping information is affected from the point of view of the relevance characteristic because it has a subjective character which results from the expression of the individual's opinions in what concerns the methods and the practise of the commitment book-keeping. The book-keeping documents do not deliver raw information but information which have suffered some processing or retreatment whose meaning depend on the utilization and interpretation of book-keeping principles. There are certain limits due to the fact that rules and principles can not predict everything, leaving also freedom of action to the enterprise in order to book-keep some operations or economical phenomena.

In conclusion, we can assert that the book-keeping information is relevant when it helps the users to evaluate correctly the past, present and future events, confirming or correcting their evaluations.

The credibility of financial information refers to its lack of error, partiality or distorsion so that the users can trust that it represents the reality in a correct and reasonable way. In other words, the book-keeping information must be neutral and complete. It also must represent the events faithfully and reflect mainly the economical substance of operation, not only its legal form.

In its book-keeping framework IASB imposes neutrality as a characteristic of financial situations, stating that "in order to be credible, the information included in the financial situations must be neutral and must lack influence. The financial situations are not neutral if through the selection and the presentation of the information influences the decisions or the formulation of a reasoning in order to reach a result or a pre-determined goal".

The IASC book-keeping framework stipulates that: "In order to be credible, the information must represent the transactions and other events they are supposed to represent or which could reasonably be expected to represent. For instance, the balance sheet must represent in a credible way the transactions and other events which are being concretized in current assets, debts and stocks in-trade of an enterprise at the report date and which accomplish the recognition demands".

Nevertheless, being credible supposes also being prudent, cautious in what concerns the exertion of professional reasoning (the current assets and the incomes should not be underevaluated while the liabilities and the expenses should not be overevaluated).

The complexity of the contemporary activity makes us question about the credibility of book-keeping information. This characteristic of being credible is fully satisfied only when the whole truth is reflected in accountancy and when the user is sure of the trustworthiness of the information.

The comparability represents the quality of book-keeping information which can be compared by the users.

The comparability of book-keeping information must be assured both in time and in space. By comparing book-keeping information of a company in time, the decisional factors can identify the evolution of the financial position and of the performances obtained by the company. The comparability of book-keeping information in space offers to the users the possibility to make decisions through the comparaison of financial situations of different companies.

One of the important implications of comparability is that the users should be informed about the book-keeping policies used to elaborate financial situations, their changes and their effects. Besides, the users should be able to identify the differencies between the book-keeping policies used in transactions and other similar events used within the same enterprise at diiferent periods of time or those used by other entities.

The necessity of comparing the information doesn't have to lead to uniformity and doesn't have to constitute an obstacle in what concerns the introduction of improved accountancy standards. It's not in the advantage of an enterprise to continue its book-keeping in the same way for a transaction if the adopted method doesn't maintain the qualitative characteristics of relevance and credibility. Besides, it's not indicated for a company to leave its book-keeping policies unchanged when there are more relevant and credible alternatives.

The general framework IAS also presents a series of limitations which can restrict the quality of book-keeping information even if all the desiderata mentioned above have been accomplished. The opportunity of presenting / publishing the information is essential because a "perfect" information which has become degraded because of the passage of time can no longer be relevant though it's credible. On the other hand, an incomplete information may be relevant but not credible.

The Romanian scientists agree with the IASB opinion according to which "the application of the main qualitative characteristics and of adequate book-keeping standards has normally as a result the elaboration of financial situations which reflect a faithful image of the enterprise situation".

However, there are some questions related to different aspects which don't have anything to do with the normalization process but which influence the quality of the book-keeping information. In that regard, we can mention several aspects:

- can we talk about the relevance of book-keeping information when there are a lot of users who have at their turn a big diversity of users?
- which is the unanimously accepted degree of intelligibility?
- how objective is the book-keeping information? Is there a conflict of interests between the economists and other categories of people who use book-keeping information?
- The quality of book-keeping information is being appreciated according to the economic reality (as long as this reality, depicted, on one hand, by the economical, social and political climate in which the Romanian enterprises develop their activity and, on the other hand, by the economical and financial situation of each enterpise) and is being characterized by insecurity, non-productivity, reduced performances, etc. We can expect nothing but a painful "book-keeping truth" and we suppose that under these circumstances we may assist to a distortion of the book-keeping image.
- Is there a comparability if there are standards which limit the options but do not exclude diversity?

We think that the satisfaction of the informational needs of the users in making economical decisions imposes the achievement of a balance between relevance and credibility.

- The rapport cost-benefit has as a premise to consider the financial information as a "resource of the enterprise". The benefits obtained through the use of information must be superior to the costs which are necessary to its delivery.
- The balance between the qualitative characteristics is, generally speaking the condition sine-qua-non in order to achieve the objective of the financial situations. The achievement of this objective becomes more difficult when the relative importance of qualitative characteristics is a problem of professional reasoning which belong to the producers or users of information related to financial situations".
- The faithful image or the faithful presentation, the performances and the changes of the financial position must be a reality, not an idea.
- In order to be useful in mking economical decisions, the book-keeping information must have all the qualitative "standards". That's why, some "situations of conflict" may frequently appear between them. The most commonly encountered situation is between the relevance and the credibility because the growth in what concerns the relevance of information decreases its credibility. We can assert that to impose some qualitative characteristics to the book-keeping information is a necessary nut not sufficient condition to have the guarantee of its quality.

Due to its importance, the problem of quality criteria has been in the center of multiple theoretical and empirical studies. Such a study has been made by the researcher Morton and has had as an objective to check if the qualitative characteristics mentioned in the conceptual framework are correctly understood in practise and if they form the basis of making a correct decision. The conclusions enunciated by Morton have been the following: the qualitative characteristics are subjective while the intelligibility and the relevance are two qualities which depend on each other. As a consequence, the information which is less intelligible but relevant are not taken into account by the users when they make economical decisions.

We can draw the conclusion that in the economical unities the book-keeping information plays a very important role in the knowledge and the multilateral analysis of phenomena and processes and it constitutes, in fact, the basis of making decisions. They have imposed both through their increased cognitive value and through the importance they have in the total volume of economical information.

The efficiency of the decisions and of the aactivities undertaken in the leadership process is influenced by the quality of book-keeping information and by the way this information is understood and applied. This category of information allows the leadership of economical unities to realize the way in which the activities must be developed and to compare the efforts which have been made with the results which have been obtained.

THE PARTICULARITIES OF TOURISM AND PUBLIC FEEDING PROCESSES AND THEIR INFLUENCE UPON THE ACCOUNTING MANAGEMENT

Diaconu Elena

Universitatea Spiru Haret, Facultatea de Contabilitate şi Finanțe, Rm. Vâlcea, str. G-ral Praporgescu, nr. 22., Email :diaconuush@yahoo.com, Tel. 0723941248

Summary: The importance of the two fields of activity – tourism and public feeding – within the national economy frame, constitute the first reason as regards the choise of the research theme.

The second reason that we had in view, as important as, the first one, is the place and the role of accountancy in the managerial process.

The implications concerning the particularities of the two types of the activities upon accountancy are multiple, but we only kept in mind some of these considered more important by the specialists.

Key words : tourism, public feeding, distinct features, system of accounts, accounting technique.

Tourism is situated, within the national economy, in the third section – of services, together with trade , transport, public feeding and other activities that do not produce material goods.

Two famous specialists in the management and marketing field, namely Kotler and Armstrong state that : "services are facilities with immaterial form given by the supplier to a beneficiary, without the latter,as a buyer, to get the right of ownership .Usually the services are connected to a material good, although this is not a compulsory condition."

Specialized literature reveals the fact that the individualisation and the limiting of services from the other components of the economic and social activities is based on the specific features of these activities.

As an activity of providing services, tourism means a series of specific features coming out from the particular way of carrying on the activity, of its own nature of production and work in this field. Some of them are the same with all the components of the third section – which emphasizes on the tourism membership to this section - having only distinct character, others are specific only to tourism services and are determined by the tourism supply and demand.

In the following part, out of the multitude of features common to all the services, we bear in mind only those that specialists consider as being more important:

- Unstockability – due to its inmaterial feature, touristic services can not be stocked and kept for a future consumption. Some authors in the field name this feature perishability. It can generate a series of drawbacks, especially in ensuring the equilibrium between supply and demand and the effective accomplishment of the touristic services. Therefore, the services once offered on the market, but not used determine losses of human and material means (for example, the offer of places for accommodation) but they can not be kept.
- The simultaneousness of production and consumption – the accomplishment of the touristic services imposes the presence in the same place of the provider and of the beneficiary, the concomitance of their carrying out and their consumption
- The inseparability from the person of the provider – the touristic services cease to exist from the moment of ending the action of the provider.
- The high weight of the expenses with the human work – the presence of the worker in tourism both due to the specific of the activities and the consumer - tourist psychology, is required.
- The lack of ownership means at the same time, in some specialists opinion, a feature of the tourist services. Thus, the tourist is offered a satisfaction without the result of the transfer upon any object. Within this context, touristic service providers should make special efforts for their clients to become faithful to them, by offering different incentives to their consumers.

In their turn the features specific to touristic services mainly refer to the following issues :

- The personalization of services – due to the differentiated behaviour of the tourists regarding each component of the carrying out of the touristic services, they should be particularized both at the group level, and the individual level.
- Temporary fluctuation - the result of the oscillation of the tourist request, of its concentration in certain periods of the calendar year.
- Complexity – the result of different combinations between the elements that come out of the natural and anthropic conditions specific to each touristic destination and the services provided by the organizers
- Dissimilarity – the result of the touristic services being dependent on material endowment and the provider's personnel
- Replacement – results of the multitude of opportunities of the combination and the substitution of the elements constituting the touristic offer, allowing the accomplishment of a large range of touristic products.
- The participation of a large number of service providers to the accomplishment of the final product - this feature comes up as a conquence of a great number of economic activities comprised in the structure of touristic service (accommodation – meals, transportation, entertainment, production and selling of goods specific to tourism, services connected to the organization of tourism).

In the context of those presented so far, we can declare that those particularities influence, to a certain larger or smaller extent, the way of organizing and managing the accountancy of the economic units that develop activities in tourism.

The implications of these particularities upon accountancy are multiple, but we keep in mind only few of these, considered by the specialists as being more important:

The variety of services ensured to the tourist all the way of his trip (accommodation, meals, transport, visits etc) determines the complexity of the touristic activities

If these services are comprised within a programme determined in time and space, for a certain touristic action (holiday programme trip etc) they form the touristic action (holiday programme, trip etc.)

In order to determine the efficiency of the activity carried on, globally or partially, the accounting limitation of expenses and incomes on activities, types and kinds of touristic activities, types and kinds of touristic services, as well as the suitable detaliation of the analytical accounts of the accounting management, are required.

a) Each touristic action is entrusted to a specialized agent who receives mandate to making the expences required by its accomplishment.

Handling various valuables (money, traveling tickets, etc) the travel agent becomes debter until the moment of justifying the received valuables, at the end of the action.Special attention should be payed to the material guarantee, issued on the name of the travel agent, since he uses large values sometimes.

The registration of the expenses in the accounting process takes place after concluding the touristic actions, since the agent keeps himself the documents containing the expences during the trip period.

In the accounting management process, the expences reimbursed by the travel agent have the effect of a direct expense given the touristic action, their reflection being justified into each of these . From the practical point of view, due to the large number of touristic activities, the analytic pursuing of these can be possibly done by the help of the technical – operative book keeping and the analytical accountancy of the direct expences to be done into the inner management accountancy only on activities and on types of touristic actions. These difficulties can be easily surpassed if electronic means are used in the process of treating the accounting data, when by suitable enconding, only one a complex data processing is possible both for the financial accountancy and for the management one.

b) The short period of time of the touristic actions, which makes a touristic action initiated within a month time to end in that particular month, being a direct connection between incomes and expenses in the same management period. If the actions are in development, they are not looked as expenses the documents being held by the travel agent, and if some payments are done, they are treated in advance using number 471 account: “Expenses registred in advance”.

c) Touristic services are usually collected in advance regarding the total utilization of the capacity of the technical and material basis.Guaranteed means of payment can also be used.

Since the effective value of the services is different than the one collected in advance or the touristic reflection of the collection coincides with the incomes, being made evident en number 472 account: “ Incomes registred in advance”.

The various conditions of engaging touristic services determine differentiation in the way of settling the services and the emphasizing of incomes and expenses.This settling in the organized tourism is done between the contracting units through the agency of banks.In the unorganized tourism, the practice of tourist paying in advance is frequently encountered and as a consequence, the received amount of money is to be regularized or the money connected to the unprovided services is to be reimbursed.

In the organized tourism the expenses and the incomes are emphasized only by the contracting unit even it the performing units also participate to its accomplishment.

In the unorganized tourism, the expanses and the incomes are reflected in the accountancy of the unit that organizes and collects the money from the touristic services.

The expenses that the providing units made , are not emphasized as the expenses of the touristic activities, but in the form of the expenses from the touristic service activities, being recovered from the requesting unit. The incomes also come from the touristic service activities.

In the case of the accomplishment of a touristic action, more units participate, one of them palying the part of the organizing unit and the others being performing units .This situation determines the emphasis of incomes and expanses from tourism activities only in the accounting of the organizing unit and the recovery of the price of the touristic services by the performing unit from the organizing unit (usually from the travel agents). The performing units receive an errand for some services, out of which they cover their own expenses and they ensure their own profit.

The content and the particularities of the travel activity determine, from the accountancy aspect, the utilization of a certain system of accounts and a suitable technique of entering in the accounts of economical – financial operations. Both in the specialized literature, and in the practical activity the specialists deal with different forms entering in the accounts of the touristic activities, more accounts being used, of which the following can be mentioned :

- 472 “ Incomes registered in advance “ – reflects the price of services of medical attendance and leisure, received in advance. These returns are constituted into incomes in the same financial exercises, at the beginning of the holiday periods, corresponding to the fully used places.
- 704 “ Incomes from the work performed and the services done” – reflects the incomes constituted at the beginning of the holiday
- Expense accounts – used to collect the expenses of the organizing unit.
- Treasury accounts – for defraying of the expenses
- 121 account “ Profit and Loss Account “ – to emphasize the result got from the performed activity .

According the way of engagine of touristic performance, direct relations of the travel unit with the outside companies and with the tourists, can be reflected by using 419 account “Clients – Creditors” or 462 account – “Various Creditors”

We choose to use 419 account “Clients – Creditors” that can be detailed on types of touristic actions or on types and kinds of touristic performance.

In order to offer information regarding the constitutive elements of costs and results, one can use the management accounting, using the 9th class accounts of whose content should be adapted to the specific character of the touristic activity. On the other hand, according to the real situations we consider as necessary the introduction of accounts adapted to the specific character of the touristic activities, as follows :

- 901 " Internal settling up of accounts regarding expenses " which ensures the process of taking over the expenses from the financial accountancy into management accountancy.
- 904 " Internal settling up of accounts regarding the performance done", detailed on inner tourism, international tourism, medical attendance and leisure tikets etc.
- 903 " Internal settling up of accounts regarding the Differencies of Price with development in analytical way, similar to 904 account. Having in view the explanations previously given regarding the specific features of the touristic units the amounts registred in 903 account will have the meaning of incomes from the performed activity and not differences upon costs.
- 921 " Basic activity expenses " whose name can be "Expenses of the basic Activity in Tourism ", developped in the analytical way for the inner tourism international tourism, medical attendance and leisure tikets, visa granting etc for expenses that can be identified according to the respective actions or touristic services.
- 924 " General Epenses of Mnagement ", with modified name and content, which to take over, from the financial accountancy, the indirect expenses given the types and ways of actions on touristic services.Due to the complexity and the variety of touristic activities, the sums registred in 924 account will have to be distributed according to the types of activities, having in view the above mentioned way of analytical detaliation, the basic of distribution being the value of direct expenses stipulated in the price precalculation.
- 941 " Service Peformmed Cost" which is detailed for the inner tourism, the international one selling of medical attendance and leisure tikets, visa granting etc.
- in close connection with the touristic activity in the public feeding activity, which can function withen this one's frame, but also independently, as a specific unit.

The particularities of the activity that develops in the public feeding field, such as: the complex aspect of the activity (production activity and goods circulation), different types of restaurants and the wide range of types of goods have a direct influence upon the way of organizing the accountancy of operations from these units.

The most important particularities regarding the organization of accountancy, consist in the impossibility of separation of this activity of production from the circulation activity, to the joint operative units of public feeding.

The activity of production, should normally be followed by the help of the expenses account specific to this activity, calculating the cost according to products, and finally the financial results of this activity shoud be able to be established.

The activity of circulation, on the other hand, should be distinctly followed by the help of accounts corresponding to goods, differences of prices on goods, expenses and incomes.

The distinct following of the two cathegory of activities is not possible, due to the tight combination of production expenses with the circulation expenses.The majority of the expenses that occur in these units have a mixed character, referring to both cathegories, and we can exemplify here : the salaries of the managerial personnel and the auxiliary one, the redemption the fixed means, the expenses generated by the electric power etc.

The content and the particularities of the activities of public feeding determine, in the accountancy aspect, the utilization of a certain " system of accounts and a suitable technique of entering the economical – financial operations into accounts .Both in the specialized literature and the practical activity , the specialists use various forms of accounting of the public feeding activity. There are different points of view regarding the accounting in the operations done in the confectionary and pastry laboratories such as :

- Some authors encourage the giving up of the utilization of the 345 account " Finished Products" and 711 " Stock Variation" because 345 account does not usually reflect real management, the confectionary and pastry products being delivered right from the laboratories, and 711 account does not justify its utilization from the same reason of quick circulation of products, the high degree of perishability does not allow their stocking.

Other authors consider that, due to the fact that in the confectionary and pastry laboratories an activity of production is developed, the two accounts that reflect the production results should be used.

As far as we are concerned we agree with the second point of view for the following reasons :

- The utilization of 701 account : " Incomes from the finished product selling " implies the registration of finished product in the debit of 345 account and in the credit of 701 account.
- There are deliveries between third persons that are not directly done from the laboratories and the products are stocked within the validity limit.

Regarding the management accounting of the goods circulation in the public feeding, it can be accomplished by the specifiction of accounts in the 9th class : "Management Accounts".We are for the setting up of groups of expenses and incomes so that to establish the profitability according to places and to groups of products or even to products.

THE INFORMATIONAL VALENCES OF THE FRENCH FINANCIAL STATEMENTS' SCHEDULE

Doinea Ovidia

Universitatea din Craiova, Facultatea de Economia si Administrarea Afacerilor, Str. Capitan Romulus Lepri nr. 98A, Drobeta Turnu Severin, ovidiad@rdslink.ro, telefon 0745090010 – 0352.316058

The schedule to the French financial statements is completing and commenting at the same time the information given by the balance and the result account, representing an essential instrument for the reflection of the true image of the enterprise's patrimony, financial statement and result.The schedule is defined as a document including the explanations necessary for a better understanding of the other synthetic documents and completes or presents under another shape the information within those.The structure of the schedule depends on the size of the enterprise, having two formats: simplified schedule and basic schedule.Besides the compulsory information stipulated by the legislation, other information considered necessary and relevant for the achieving of the true image will be recorded as well.

Keywords: schedule, synthetic documents, true image, basic schedule, simplified schedule

The schedule is a document of English origin, corollary and instrument to put in practice for the principle of true image/description.

It had been introduced in France by GAP, becoming in 1982 a compulsory document, beside the balance and the result account in the structure of the annual statements.

From the general point of view, we consider **that the schedule has the role to give the information and the explications necessary for a better understanding of the other synthetic documents, to complete or present under another shape the information within those.**

As an argument in favor of our opinion we mention the art.9 from the Commerce Code saying: **the schedule completes and comments the information given by the balance and the result account.**

It becomes therefore an essential instrument for reflecting the **true image** of the enterprise's patrimony, financial statement and result.

So if the application of an accounting prescription is not enough for revealing a true image, supplementary information must be given in the schedule.

The Commercial Code also stipulates: "*if, in an exceptional case, the application of an accounting prescription is improper for revealing a true image of the patrimony, the financial account or the result, a derogation must exist; this derogation is mentioned in the schedule and seriously motivated, pointing out its influence on the the enterprise's patrimony, financial statement and result*"[340].

The same legislative act is referring to the contents of the schedule, as following:

- the total amount of the enterprise's obligations regarding the retirement funds is indicated in the schedule;
- the balance, the result account and the schedule must include as many columns and situations as necessary for reflecting the true image of the enterprise's patrimony, financial statement and result.

In consensus with the stipulations of the Commercial Code, the Accountancy Law also stipulates a series of information that must be given by the schedule, such as:

a) presentation of significant information;
b) presentation of some balance positions in detail;
c) explications of sums that are object of the records from the regularization accounts;

[340] Neag R. – Reforma contabilității românești între modelele francez și anglo-saxon, Editura Economică, București, 2000.

d) commentaries on various situations like: expenses related to the society's formation, the research-development expenses, the commercial fund, other non material fix assets etc.

And, last but not least, the GAP defines the schedule as: "**a document that includes the explications necessary for a better understanding of the other synthetic documents and completes, when is needed, or present under another shape the information within those. No presentation in the schedule can not generally represent a substitute a normal registration stipulated by the General Accounting Plan in other synthetic documents."**

GAP also includes the necessity to mention in the schedule the accounting methods and rules used, the information complementary to the balance sheet and the result account, as well as other informational elements.

Considering the fact that financial statements must present a true image of the enterprise's patrimony, financial statement and result and the incidence of the fiscal norms bring about important subterfuges in accountancy, our expressed opinion is that **"schedule has an important role in presenting supplementary information, commentaries and explications that will allow access to other perspectives, different from the juridical one in the accountancy domain.".[341]**

We consider justifiable to point out the perspective of Claude Perochon who succeeds in synthesizing the informational significance of the schedule in regard to the application in practice and the achievement of the objective **true image** – an opinion we sustain.

The role Claude Perochon gives to the schedule is found in its presentation, as mentioned above:

1. **a complementary document** to the balance and the results account; it has no double utilization with these two, only brings its information in addition to those to complete them;
2. **an open document** in which all information susceptible to influence the judgment of the annual accounts reader on the matter of the enterprise's patrimony, financial statement and results must be recorded.
3. **a document meant for the principle of importance**, because there are no compulsory standards for the schedule like in the case of balance sheet and profit-loss account;
4. **a document for the accounting side but also for the extra accounting side:**

   1.**accounting**, for the elements given directly by the accounts and verifiable in those

   2.**extra accounting**, for the qualitative or quantitative elements that are not expressed in the accounts.

5. **a document modulated according to enterprises' nature and size**, modulation that is not the identical with the limits stipulated for the use of basic or arbitrary systems, as follows:
   - **juridical persons:**
     - over 50 employees – **basic schedule**
     - until 50 employees – s**implified schedule**
   - **physical persons:**
     - more than 3.500.000 F from the business turnover - **simplified schedule**;
     - less than 3.500.00 F – **no schedule.**

The schedule is guided after the same principles as the other two financial statements, the balance sheet and the result account.

In consequence, the information stipulated in the schedule must be as reliable as the ones in the balance sheet and the result account, which means they can be verified by confrontation/comparison with the documents attesting their accuracy, and are comparable from an financial exercise to another or from an enterprise to another by application of the same methods of calculus and presentation.

Related to the schedule's contents, the GAP gives an **indicative list** of the information that are presented in the schedule only **if they are significant**.

Considering the above paragraphs on the matter, the conclusion is that **the most important information part of the schedule's structure are generally referring to:**

- the accounting methods and norms;
- the image/description of fix assets, amortizations and provisions;

[341] Perochon C. – Presentation du plan comptable français (PCG'82), Les Editions Foucher, Paris, 1983.

- the image/description of settling days and debts;
- liabilities and debts represented by commercial effects;
- explanations on the difficult accounts, respectively: formation expenses, commercial fund, regularization accounts etc.;
- information on the credit-bill operations.

We notice the large importance shown to the information that are object to detailed presentation in the schedule. We can group these, generally, in three sections:

- information related to accounting methods and norms, if they are considered significant;
- supplementary information related to balance and results account, if they are considered significant;
- other significant information, other than the already presented ones.

Because of the details degree of schedule's information, we consider obvious the higher and higher role and importance those have within the assembly of the documents done at the end of the financial accounting exercise.

The detailed presentation of the information considered significant in the decision taking process expresses a new vision on the users of the accounting information, that is also found in the methodology for the elaboration of the financial statements to be compulsory presented by the Romanian enterprises.

In conclusion, the information structured in the schedule must assure the satisfying of the informational needs of the various category of users.

The structure of the schedule is differentiated depending on the enterprises' size and has two formats:

- simplified schedule
- basic schedule

The compulsory information that must be presented in the simplified schedule are referring to: commercial effects, expenses to pay and incomes to receive; the expenses and incomes discovered in advance; leasing and the clause of property reserve.

For the **basic schedule**, the legislators have not imposed **a compulsory standard presentation,** and have only defined the information it must offer, information already presented when their classification was pointed out in a general manner.

In regard to the accounting norms and methods that are presented in the schedule, we consider necessary to be mentioned the general conventions applied, and in the case of derogation from the above the reasons for which the method was changed indicating the direct influence on the patrimony, financial statement and results.

The French enterprises present the following informational valences regarding the **information complementary to the balance and the result account**:

- the situation of the fix assets;
- the situation of amortization;
- the situation of provisions;
- the situation of the claims' settling days and of the debts at the closing of the financial accounting exercise after the criterion **under 1 year, between 1 – 5 years** and **more than 5 years;**
- the variation of the reevaluation differences within the exercise and their repartition;
- the situation of the financial obligations;
- information about leasing;
- the modality of accounting the commercial fund and its depreciation;
- the accounting treatment of the non material fix assets, of expenses and incomes imputable to other exercises and of the exceptional expenses and incomes;
- the distribution of the business turnover on sectors of activity and geographical markets;

- the affiliation of the income tax to exceptional elements and other elements in order to point out the current result after taxation;
- information concerning the consequences of applying the fiscal dispositions on the exercise result;
- mentioning the increase or decrease of the future taxation debts that derive from the temporal difference between the fiscal process and the accounting treatment of the incomes and expenses;

In the category of **other various information** are included:

- the image of the result affiliation that presents the modality used for the result's repartition;
- the image of the result and other specific enterprise elements during the last five financial accounting exercises;
- the list of subsidiaries and participations;
- the number and nominal value of shares;
- the identity of all enterprises setting consolidated accounts;
- the medium number of employees on categories etc.

Besides the compulsory information stipulated by the legislation, other information considered necessary and significant for achieving the real image will be also recorded in the schedule.

While analyzing the problems of schedule, we may notice the special informational valence given to it, an approach found also in the romanian schedule, the difference being that the legislators in Romania impose a more restrictive character of the information presented in the explicative notes and, more than this, standardizing the format of some of situations such as:

- the situation of provisions(Note 2);
- the situation of profit repartition(Note 3);
- the situation of the exploitation result analysis(Note 4);
- the situation of claims and debts(Note 5).

This paper wants to reveal the importance of Sustainable Development (SD) as a new concept and also the measurement of sustainable development indicators (SDI) on a capital approach. Capital approach is a new concept for SDI measurement so that the research team considered that it is interesting to present this approach. The team's preoccupation was human capital (HC) as a concept and valuation and also some possible contributions that make clear this concept and how organizations must act and how accounting must provide information.

Key words: sustainable development, sustainable development indicators, human capital, accounting.

Introduction

Sustainable Development (SD) was defined by The Brundtland Report of the World Commission on Environment and Development as follows: "Humanity has the ability to make development sustainable – to ensure that it meets the need of the present without compromising the ability of future generations to meet their needs". This definition clearly reveals two fundamental aspects: one is based on present needs or intergenerational equity issues and the other has to do with future generation or development in time.

So that SD may be considered as a temporal concept, a never-ending process where development must be forever in the benefit of the sustainability.

What kind of development may be accepted for a long period of time? Is this in relation with a long-team policy? When is a development good or bad? Why a development is considered as a good or bad one?

These are some questions that were arisen during the period when the research team was studied SD and SDI and also the accounting's position in this context.

Sustainable Development and Sustainable Development Indicators

The concept of development (economic development) was analyzed during a long period of time, on a capital base of societies as an important force behind development. Capital as a base that explains development consists on more than money and assets (produced capital), such as human, natural and social capital. Consequently, development may be explained by produced capital; human, natural and social capital.

Sustainable development is a dynamic concept, is about the development of social welfare over time. Also development over time requires savings that can be invested in various capital types.

SD, as a new concept, was analyzed by a lot of researchers, such as A. Knut, M. Greaker, A. Geir etc. Pears and Atkinson (1993) considered that SD might be a weak or a strong sustainability. Strong or weak sustainability is a concept based on the interrelation between different types of capital, the substitution between the various stocks of capital.

Sustainable development from a capital approach was characterized as follows in the UN handbook and System for Environment and Economic Accounts (SEEA 2003): “Sustainable development is development that ensure non-declining per capital national wealth by replacing or conserving the sources of the wealth: that is stocks of produced, human, social and natural capital”.

Capital approach to measuring SD was often analyzed by different institutions and organizations implied in SD policy but also by a lot of researcher interested by a theoretical outline of the capital approach. Some arguments in the favor of this concept are the following:

- welfare may be considered as a function of how assets are distributed so distributional rules can be viewed as a manifestation of social capital;
- production and consumption can be seen as a function of capital, of how capital was allocated through the working of societies institutions (Dasgupta, 2001).

By contrast Czesnay (2007) considers that capital is not the most appropriate term to be used because of a misleading connotation between different forms of capital.

Total National Wealth (TNW) may be defined as the sum of different types of capital. But to give a value to TNW each form of capital must be valued based on an accounting price or shadow price, which are defined as the welfare effects of a marginal change in the corresponding types of capital.

Human capital (HC) and accounting

Human capital is not a traditional type of capital such as financial assets and physical capital. Human capital in its current meaning is what used to be called human potential or human resources. HC may be defined also as an individual’s collection of human resources including personal abilities, knowledge, skills, time, and energy. Other some definitions of HC are as follows:

- the stock of economically productive human capabilities (Bahrman and Taubman in World Bank, 2006,p89);
- the knowledge, skills, competencies and attributes embodied in individuals that facilitates the creation of personal, social and economic well being (OECD, 2001).

Czesnay (2007) analyzed the relation between HC and the enhancement on the other forms, such as:

	Private benefits	Public benefits
Economic benefits	I	II
Wider social benefits	III	IV

Human capital theory was based on private economic benefits because an better-educated people are economically active and also potential sources of higher earnings. In other way, investment in HC may yield benefits to the economy at large.

A study that was made by OECD shows us that a rise in HC by 10 percent leads to an increase in output per capital between 4 and 7 percent. So that, in the last years, researchers tried to identify the effects of education on economic growth in order to show that HC in general and education in special, have on important impact on national wealth.

In order to calculate SDI, on the capital approach is necessary to establish a measurement frameworks. What does this mean? In this context a measurement framework “is a practical set of data and organizational rules that translate a conceptual framework into policy relevant information in the form of a sustainable development indicators set” (Working Paper, Economic Commission for Europe Conference of European Statisticians, 2007, page 40).

The instruments used for a measurement framework are considered national accounts. In 2003, UN made an extension of the Standards for National Accounts (SNA) to cover natural resources and this was done in the Systems of Environmental and Economic Accounting (SEEA). But, regarding HC and SC such extension does not exist. In this context, a part of HC may be estimated based on national accounts, using some data from those accounts.

Regarding HC, in literature, there are two points of view: the first consider HC composed by three elements: raw labor, education and skills and the second identifies HC with education and skill.

The value of HC was calculated not only to evaluate SD but also for other three reasons:

1. to evaluate education policy;
2. to evaluate what determine employment;
3. to understand economic growth (Stroombergen, Rose and Nana, 2002, Review of Statistical Measurement of Human Capital).

How to calculate the value of HC? This was a challenge for many researchers. An intensity method for HC valuation was conceived by Stroombergen, Rose and Nana. They identified three categories for HC valuation such as:

a) the cost based method that estimate HC from the input side;
b) the revenue generating method that estimates HC from the output side;
c) the current stock characteristics method.

a) On the cost based method from the input side, HC is estimated by all expenses that contribute to HC formation such as education expenses; on job training expenses and employer financed outside job courses. Also some depreciation may be considered due to the period when people leave the work, or stay unemployed, or they begin a new trade.
b) The revenue generating method from the output side supposes to estimate the expected wages obtained on a labor market. In this method the economic point of view is important.
c) The last method consist in a separate measurement of average years of schooling in the population, unemployment rates, the health status of the population and to translate them in monetary units to the stock of HC.

Because a lot of investments in HC are made, HC may be valued at the discounted sum of expected returns.

Pearce and Atkinson (1993) discussed for the first time about an indicator called Genuine savings for SD. After this moment a lot of researchers developed this indicators. In 2005 World Bank, in a book presented a model of how to calculate genuine savings (GS) as follows:

$$GS = NIPC + EE - RR - DE$$

where: NIPC – net investment in physical capital

EE – expenses for education; wages paid to teacher, but excluding investment in buildings

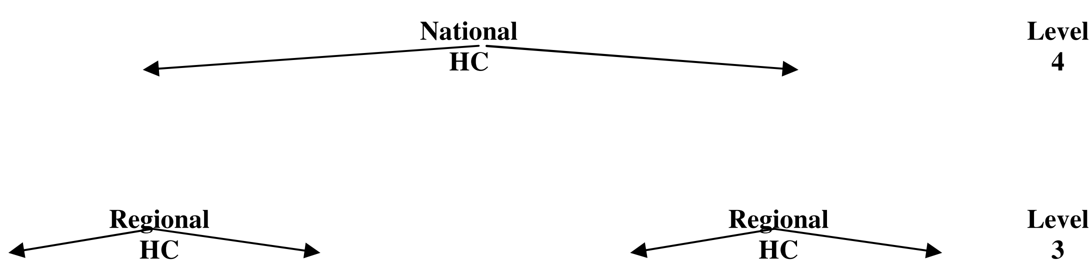
RR – resource rents in non-renewable natural resource sectors

DE – damages to environment from particulate matter and carbon dioxide.

If GS is non-negative that means that consumption is sustainable. This indicator also expressed changes in HC component with expenses to education for a particular period of time.

In the last years the growth literature has tried to ensure HC from the output side, because HC from the input side was largely debates in literature. So that Becker (1975), Jorgenson and Traumeni (1989,1992), Hui Wei (2004), Ervik, holmay and Hargeland (2003), based on the measurement of HC from output side, calculated rates of return to education by looking at wages differentials between workers with different levels of education and also they calculated the HC component.

One important conclusion arises from this presentation: that is not easy to measure HC in order to calculate SDI. In our opinion HC may be analyzed at different levels such as:



Local HC	**Local HC**	**Local HC**	**Local HC**	**Level 2**
		Organization's HC		**Level 1**

The measurement of HC at different levels must be something specific based on procedures and methods considered as appropriate for each level and also for the general target that is the calculation of SDI on capital approach.

From the organization's points of view in order to ensure the participation to the preparation of a HC measurement framework is necessary some information to be periodically transmitted to a higher level so that organizations must prepare a few statements where some indicators regarding HC and HC components are to be presented.

Those indicators may be:

- number of employees classified by different level of education and wages received;
- training expenses in order to help employees to gain a particular job skill and techniques that help them contribute to achieve the organization's strategy;
- development expenses involving on-going education to help prepare employees for future jobs;
- on-the-job training expenses for new employees in order to accumulate enough experience to achieve a predetermined performance.

Those indicators may be calculated based on accounting information, especially from managerial accounting where a network of budgets is prepared and HC budget is an important part of the budgeting system. In order to calculate national HC two elements are necessary: (1) information from other levels and (2) own procedures and information (statistical investigation). So, two kinds of accounts are basically used: organizations accounts and national accounts. The research team considers that for organizations the measurement of HC may be ensured from output side and for other levels of HC from both methods.

SDI on the capital approach

In the report from the Joint UNECE/OECD/Eurostat Working Group on Statistics for SS was presented a list of SDI based on capital approach such as:

1. real per capita economic wealth
2. real per capita produced capital
3. real per capita human capital
4. real per capita natural capital
5. real per capita social capital
6. a physical indicator of climate
7. a physical indicator of air quality
8. a physical indicator of water quality, quantity
9. a physical indicator of ecological integrity
10. a physical indicator of biological integrity
11. a physical indicator of soil productivity
12. a physical indicator of educational attainment

13. a physical indicator of health status.

This set of indicators clearly reveals two policies: (1) to optimize the social welfare in relation with a given stock capital and (2) to limit or reverse the depletion/degradation/depreciation of capital stocks through investments of savings.

An important advantage of this set of indicators is the possibility of international comparison (benchmarking) between different countries. On the other hand, another advantage is the opportunity to invest in different types of capital and use these capitals.

SDI calculated on capital approach operates with a long period of time, because the effect of different actions is not immediate.

In our opinion organizations must contribute with a set of specific indicators to the calculation of SDI. So, these indicators are obtained by the contribution of different organizations and areas.

General conclusions

(1) SD as a new and important concept must be known by people and organizations in order to act consequently;
(2) SDI ensure the measurement of SD;
(3) SDI may be calculated on different basis;
(4) Capital approach is now considered as an appropriate base to measure SD because of some advantages such as:
    a. Solid theoretical base;
    b. Harmonized solution across countries;
    c. Comparability; work in cooperation;
    d. Reduce political manipulation;
(5) HC is a specific form of capital difficult to be measured, but some theoretical methods were created and applied in practice;
(6) HC may be analyzed at different levels in order to calculate the real value;
(7) Accounting must have an important contribution to the preparation and presentation of appropriate information for HC calculation;
(8) HC policy, in our opinion, must be a national policy and each region and organization has to ensure the application to the general human resources policy.

Starting from the reality according to which, from the objectives of the management accounting, for the model adopted in Romania, ***the objective regarding the stocks management lacks – this one being realized through the financial book-keeping*** *– a main objective of the study is represented by the presentation of two models of book-keeping which allow* ***the passage of the actual model based on the analytic calculation of the costs, to the model centered on the analytic calculation of the result, pattern oriented at the same time towards the stock management****. Also, we appreciate that in the profit and loss account we must renounce to the conflict between the analysis of the expenses by nature and destination.* ***The solution proposed – that of the passage from the results account by nature to the results account by functions –*** *constitutes the second objective of the study and it is based upon the reclassification or the re-composition of the expenses depending on their function and destination.*

Key-words: the analytic calculation of the costs, the analytic calculation of the result, monist conception versus dualist conception, nature-destination conflict.

The existence of a pattern centered on the analytic calculation of the result and oriented at the same time towards the stock management, has as motivation the need to insure, for now in the transition period, through a standardized and obligatory system, the evidence and the control of the stocks integrity. Of course such a variant can be discussed, practically being appreciated that the analytic evidence of the stocks cannot be standardized, the methods and the techniques used being details.

Being given the pattern adopted in Romania, regarding the management accounting, the problem will concern the calculation of the costs and the analytic results. Proceeding in this manner, we are in the same consensus with the fact that within the calculation process, the central problem is represented by that of the costs. By cost it is expressed the consumption having as destination the resources, and by this way we can find answers regarding the allocation of resources to maximize the profitableness.

In what follows we present three solutions regarding the perfecting of the management accounting, this way:

1.The pattern proposed regarding the calculation of the analytic result

A variant which we submit to the attention is **that of the evidence and the calculation of the analytic result without the presence of the stocks accounts.**

The pattern proposed is based on the development of the 9th **class "Management accounts"** on the following structure:

90 Internal reimbursements: 901 Internal reimbursements regarding the expenses; 902 Internal reimbursements regarding the production obtained; 903 Internal reimbursements regarding the price differences; 904 Internal reimbursements regarding the internal circulation; 905 Internal reimbursements regarding the sales

92 Calculation accounts: 921 The expenses of the base activity; 922 The expenses of the auxiliary activities; 923 The indirect expenses of production; 924 General expenses of administration; 925 distribution expenses

93 The production cost: 931 The cost of the production obtained; 933 The cost of the production now being executed; 935 The cost of sold production

95 Accounts of analytical results: *951 Analytical results*

The cycle of accounting registering is presented this way:

1. The taking over of the initial stocks of finite products (**931 = 902** and **902 = 901)**

2. The collection of the effective stocks: (**92x = 901**)

3. The gaining of finite products during the month, evaluated at the standard cost: (**931 = 902**)

4. The sale of the production registered at the sale price: (**905 = 951**)

5. The calculation and the reimbursement of the production costs:

5.1. The effective cost of the unfinished production (**933 = 902**)

5.2. The effective cost of production of the total production (finite and unfinished): (**902 = 92x)**

5.3. The calculation and the registration of the price difference between the effective cost and the standard cost of the obtained production: (**903 = 902** and **931 = 903**)

5.4. The reimbursement of the effective cost of production of the sold production: (**935 = 931**) and with the same value, (**951 = 905**)

5.5. The reimbursement of the period cost:

951	=	**923**
		924
		925

6. The establishment and the registration of the analytic result and the closing of the account **951 "Analytical results"** through the account **905 "Internal reimbursements regarding sales"**: positive result (**951 = 905**) and negative result (**905 = 951**)

It can also be used the variant in which the account **903 "Internal reimbursements regarding the price differences"** is credited by the debit of the account **901 "Internal reimbursements regarding the expenses"**. In this way, in the accounts **931 "The cost of the obtained production"** and **935 "The cost of the sold production"**, the production is evaluated and registered at standard price. Altogether, when taking over the initial stock of finite products the registration takes place:

931	=	**902**
903		

7. The interface cost production-occasional costs

901	=	**905**
		931
		933
		935

2. Alternative – the developed pattern of the management accounting

The new system of accounting, adopted within the reform, circumscribes the management accounting only to the collection and the calculation of the costs of activities, sections, phases of fabrication and products, works and services. For now, it does not propose to keep the evidence of the stocks, the determination of the analytical results, the foreseeing of the costs and incomes through the internal network of budgets, the costs and budget control through deviations. At the same time, the accounting settlements do not exclude, depending on the enterprises' option, the adoption of the developed variant, on the structures above, of organizing the internal management accounting.

In the spirit of those mentioned above, in what comes next it is presented the developed variant of analytic accounting which proposes as objectives: *the analytical evidence of the stocks and the analytical calculation of the costs and of the results on value carriers (products, works and services). The places of the delimited costs presented under the form of activities, sections, phases, of fabrication and of other structures of calculation are used only as intermediary steps in the delimitation and the calculation of the costs concerning different types of products, works and services.*

The adoption of the developed variant imposes the reconsideration of the actual class 9 "**INTERNAL MANAGEMENT ACCOUNTS**", in the structure presented below:

90 Internal reimbursements: 901 Internal reimbursements – initial stocks; 903 Internal reimbursements – buying; 904 Internal reimbursements – expenses and donations; 906 Internal reimbursements – obtained production; 907 Internal reimbursements – sales; 908 Internal reimbursements – analytical results; 909 Internal reimbursements – collector account

92 Costs accounts: 921 The expenses of the base activity (9211 The expenses of the base activity – normalized costs and 9212 The expenses of the base activity – deviations); 922 The expenses of the auxiliary activities (9221 The expenses of the auxiliary activities – normalized costs and 9222 The expenses of the auxiliary activities – deviations); 923 Indirect expenses of production; 924 General expenses of administration; 925 Distribution expenses; 926 Circulation expenses.

94 Inventory accounts: 940 Inventory – commodities and materials (9400 Commodities, 9401 Consumable commodities and 9408 Price differences of the commodities and of the materials); 942 Inventory – inventory objects and compounds (9421 Inventory objects, 9422 The wear of the inventory objects, 9423 Compounds and 9428 price differences of the inventory objects); 943 Inventory - the production now being executed (9431 Products now being executed, 9432 Works and services now being executed and 9438 Price differences of the production now being executed); 944 Inventory – products (9441 Goods in process, 9445 Finite products, 9446 Residual products and 9448 products price difference); 945 Inventory – stocks hold by third parties (9451 Commodities and materials hold by third parties, 9452 Inventory objects hold by third parties, 9453 Products hold by third parties, 9456 Animals hold by third parties and 9457 Goods in custody or in junk shop hold by third parties); 946 Inventory – animals (9461 Animals and birds; 9468 Price differences at animals and birds) 947 Inventory – goods (9471 Goods and 9478 Price differences at goods);948 Inventory – packing (9481 Packing and 9488 Price differences at packing); 949 Adjustments – stocks and production now being executed (9490 Adjustments – commodities, 9491 Adjustments – consumable commodities, 9492 Adjustments – inventory objects, 9493 Adjustments – production now being executed, 9494 Adjustments – products, 9495 Adjustments – stocks hold by third parties,9496 Adjustments – animals, 9497 Adjustments – goods and 9498 Adjustments – packing).

97 Incorporation differences: 971 Non-incorporable differences and 972 Added differences (suppletives)

98 Analytical results: 981 Sales results; 982 Intermediary results; 983 Results obtained after renouncing at the assets; 984 Results obtained from the taking back of the provisions; 985 Results obtained from inventory differences; 989 Other analytical results.

From the comparative analysis of the 9th class of accounts – the actual variant and the proposed variant – can be noticed the introduction of three groups: **94 "Inventory accounts"**, used for the evidence and the analytic management of the stocks, **97 "Incorporation differences"**, for the delimitation and the accentuation of the non-incorporable and suppletive differences; **98 "Analytical results"**, for the calculation and the analytical evidence of the results. It hasn't been created a separate group for the evidence of the incomes, due to reasons of simplification. All incomes created by sales and other operations are accentuated directly, through the credit of the accounts from group **98 "Analytical results"**. Also, by creating the account group for the stocks accentuation, the accounts in the actual group **93 Accounts regarding the production cost** loose their content and accounting function. For the production obtained, their role and function are taken over by the accounts in group **94 "Inventory accounts".**

For the definition of the function of the accounts in the 9th **class "Internal management accounts"** in the proposed variant, we present in what follows the cycle of accounting registrations for the base operations and significant operations.

The functioning of the accounts in group **97 "Incorporation differences"** is inspired from a common principle: **It debits** when the internal management accounting registers fewer expenses and more incomes than the financial accounting; **It credits** in the opposite case; **It sells off** through the transfer to the account **98 "Analytical results"**

In what concerns the adjustment accounts for depreciations regarding the stocks and the production now being executed, **it credits** through the debit of the cost accounts in the case of the increase of the adjustments calculated upon inventory at the closure of the exercise and **it debits** at the diminishing or resumption of the adjustments through the **credit** of the accounts **98 "Analytical results."** In what follows it is presented the cycle of accounting registrations:

1. The taking over of the initial stocks, at the effective cost, (**94x = 901**)

2. Buying of stocks at the price of acquisition (**94x = 903**)

3. The collection of the primary costs, the effective cost of the used production factors

92x = **94x** • stocked consumptions, inclusively unfinished initial production

903 • non-stocked consumptions

904 •personnel expenses, amortize

4. Cost determined by the internal circulation, inclusively the distribution of the indirect costs of production (**92x – place of receiving costs = 92x – place of supplying costs)**

5. The production obtained at registration price, inclusively the unfinished production,

94x = **906**

981

6. The production sale at sale price (**907 = 981)**

7. The reimbursement of the production costs regarding the obtained production (**906 = 92x**)

8. The establishment and the registration of the difference of price,

9438 = **906**

9448

981

9. The reimbursement of the production costs regarding the sold production, the registration price plus the price differences

981 = **9445**

9448

10. The reimbursement of the analytical result

- result-profit (**981 = 908**)
- result-loss (**908 = 981**)

11. The closure of the calculation accounts regarding the costs left outside the production costs

982 = **923** (the under activity cost)

924

925

12. The clearance of the account when closing the financial exercise

- for the accounts with debtor balance

901 = **909**

903

904

908 (debtor balance)

– for the accounts with debtor balance

909 = **94x**

907

908 (debtor balance)

3. The solution of the passage from the results account by nature to the results account by Functions

The solution of the decomposition or the passage regarding the passing from the results account by nature to the results account by functions, even though it appeals to the principle of relativity of the information, it is generator of supplementary efforts. In order to surpass this situation, it can be adopted the solution of the modification of the Plan of the General Accounts respectively of the classes of accounts meant for the accentuation of the expenses which are able to allow the supply of information for the elaboration of the profit and loss account in both variants. The variant proposed is based on the reclassification or the re-composition of the expenses depending on their function or destination. In this way in class 6 "expenses account" is created a distinct group **69 "Cost accounts on destinations"":** *691 The base production costs; 692 The costs of the auxiliary activities; 693 The indirect costs of production; 694 The distribution costs; 695 The general costs of administration; 696 Other exploitation costs; 697 The production cost now being in process; 698 The sales cost.*

According to the above modifications, the registration types regarding the re-composition of the expenses, the permission and the sale of the production are:

1. The re-composition of the costs depending on the expenses destination (**69x = 60x, 61x, 62x, 63x, 64x, 65x**)

2. The production cost of the obtained products (**34 = 697**)

3. The production cost now being executed (**33 = 697**), and at the opening of the period: (**697 = 33**); and it can be effectuated the registration too (**691 = 33**) or (**692 = 33**)

4. The cost of the production and of the sold goods

4.1. Sold products: (**698 = 34**)

4.2. Sold works and services (**698 = 697**)

4.3. The cost of the sold goods (**698 = 607**)

5. The collection at the closing of the period of the costs included in the production cost of the products and services:

697 = **691**

692

693

694

695

696

The costs of the period unknown as the element of the product cost remain as debtor balance of the accounts above.

7. The recognition in the profit and loss account of the costs connected to incomes (**121 = 69x)**

For the debtor balance of the costs accounts, and for the account **67 "The production cost under way"** for the debtor or creditor balance, by the case.

The above mechanism regarding the bookkeeping of the expenses allows the creation of joint account of result, which represents a combination of the two, nature and functions, which has as center of reference the production sold which has the decomposition of the expenses on functions and within them on natures. The pattern of such profit and loss account is presented this way:

	20-X	20-1

Incomes Sales cost **Gross margin** Other exploitation incomes Distribution costs Administrative expenses Other exploitation expenses **Exploitation profit** Financial costs Incomes from partner enterprises **Profit before taxation** Expenses with taxation on profit **Profit after taxation** Interest pertaining to a minority **Net profit from current activities** Extraordinary elements **Net profit of the period**	X (X) X X (X) (X) (X) X (X) X X (X) X (X) X X X	X (X) X X (X) (X) (X) X (X) X X (X) X (X) X X X

Table 1 The profit and loss account

Generally, the concept of management control is associated to the production companies more than to the distribution ones. That is why, the research team considers that creating a management control model for the distribution companies should interest especially the practitioners. In this paper we will present the steps to be followed in the elaboration of a management control model based on the targets set by the company and on the reports that must be prepared for showing the way those targets are achieved. The model proposed will be elaborated based on the identified activities performed in a distribution company and on its responsibility centers.

KEY WORDS: Management control, distribution, performance, reports, responsibility centers

Introduction

Generalizing a reflection on strategy and management control within the Romanian companies is rather recent. The environment changes and especially the changes in the nature and the dimensions of the markets due to the globalization and normalization raised real questions for companies, generated a strategic thinking and made the appearance of an efficient management control compulsory.

The main mission of the management is to integrate as well as possible the external and internal complexity especially by searching for a temporary balance between coordination and anarchy by elaborating procedures and organizational structures that take into account the expectations of the personnel. But this mission won't be fulfilled unless the system called *enterprise* is subject of control.

The managerial accounting corresponds to the adoption of a new way of structuring the expenses in order to obtain a cost of a specific object such as the functions, processes, activities and in the end the finished goods produced and sold. The costs obtained are useful for the managerial decisions concerning the markets, distribution or the analysis and the evolution of the operational processes such as, for instance, the productive processes. Each cost method involves an accounting modeling of the company, a simplified face of the reality we wish to follow and control. This reality corresponds to operational acts that target producing a good or a part of it that fulfills the clauses of a distribution relationship (Sole, 2006).

Nowadays, the economic reality is characterized by uncertainty and strong competition asking from the entities that want to survive the same concern about their mission and vision, their stability in time, their adaptation to the changing conditions. How can you know if the entities follow the correct direction in order to achieve their targets; if they didn't miss their aim; if the instruments they use were well selected and applied? The answer has to be checked in control in general and in management control in particular.

The management control is a domain that interests the managers as they want to find out if the targets were achieved, with what effort, with what failures, why, who is responsible? How do you have to act in the future? We try to answer these questions in this article, which is concerned with the distribution and its characteristics, wishing to obtain adequate solutions.

Literature review

The concept of management control and the models of presentation for specific types of companies was studied by other authors throughout the time.

Mann R., Mayer E. (1996) have presented in their work a new concept of management: management control. Their work was based on a case study for a production company.

Bruggeman W., Everaert P., Levant Y. (2005) were among the first researchers that presented an innovative "method of cost modeling": the time-driven ABC method. In this article they presented examples of time equation and they could even formulate a rule to be used in order to build these equations in general. Their case study was conducted within a distribution company and they consider it is a research as they were pioneers.

The impact of the financial structure on decisions was studied by Saulpic & Tanguy (2004) on the example of burgundy wine merchants.

Research methodology

In order to explore real-world implementation of a management control model, we used the fundamental research (for the literature review) and we conducted case study research at distribution companies. A case study is the most appropriate research method to explore the reasons for a particular accounting practice (Scapens, 1990; Otley & Berry, 1994). As such, this case study represents a preliminary investigation of an innovative management control model, which is intended to generate ideas for testing at a later stage.

Since the purpose of our study was to learn from practice, we conducted interviews. Rather than assuming that the existing literature had covered all aspects of management control models we tried to uncover new concerns as much as possible. Therefore, the direction that every interview took was unique. Complete access was given to the activity databases. The authors approached these companies because of a business contact between one of the authors and the company. In a sense, these companies selection was not random, although it helped tremendously to overcome one of the biggest practical difficulties of conducting case study research, i.e. gaining access to companies (Baxter & Gua, 1998). These companies are attractive because they are some of the biggest companies in its area.

Management control for the distribution companies

Do the entities in the distribution area in Romania have a management control organized as a distinct department with functions and relationships with the other departments?

We can give a negative answer without being afraid to be wrong. However we still have to admit that some objectives of management control are achieved by other departments, without being identified as the attributes of the management control. As a consequence we can only suggest the organization of a distinct department that will have to pursue, analyze and report the information needed for the support of the managerial decisions concerning the achievement of the targets fixed on a short term as a step in reaching the strategic objectives. For this we consider that the information related to the costs is welcomed as it allows the computation of margins and results both at the level of the entity, groups of products and clients. As the generally accepted objective of each entity is customer's satisfaction it is normal for the management to have complete information about the clients they interact with.

As a consequence, we suggest two types of analysis adapted to the distribution companies especially because of the diversity of customers they operate with. A first analysis is a global one, at the level of the entity and on the warehouses, connected to achieving the performances: turnover, cost of sales, gross margin, profit or loss, breakeven point, standard and real.

For this, a model of such a report could be presented in the following manner:

Table 1. The report for the global/warehouse analysis

ElementS	Real	Standard	DIFFERENCES		CauSeS
			-	+	
1. Turnover	X	X´			
2. Cost of sales	X	X´			
3. Gross margin (1 -2)	X	X´			
4. Other variable expenses	X	X´			
5. Total variable cost	X	X´			
6. Margin on total variable cost (3-4)	X	X´			
7. Fixed expenses	X	X´			
8. Profit or loss (6-7)	X	X´			
9. Profit or loss/Turnover	X %	X´%			
10. Gross margin/Turnover	X %	X´ %			
11. Margin on total variable cost/Turnover	X %	X %			

The data source for fulfilling this report can be: the budgets network, the financial and managerial accounting. If the total of the expenses according to their nature is offered by the financial accounting, for function and behavior classification we have two options, meaning: a development of the financial accounting or the managerial accounting as suitable. The situation presented is also functional at the level of the warehouses, because each warehouse corresponds to a center of profit, so it can present an elementary profit or loss account.

In case an entity is split into different area, the report will be fulfilled for the total company and for areas. The effect is connected to the adapting the price politics to the specific of each area in the circumstances of achieving the objective of global and zonal profitableness.

At the level of the groups of products, the computation and analysis of the profitableness imposes detailed information concerning the full cost, which are rarely, but not impossible, computed in the distribution.

As the cost of goods sold can be easily computed, the managerial accounting has to focus on the other expenses in order to find a reasonable absorption rate.

In this case the recommended situation could include the information presented in Table 2:

Table 2. The report for the analysis of the profitableness on groups of products

ElementS	Real	Standard	DIFFERENCES		CauSeS
			-	+	
1. Turnover on groups of products	X	X ´			
2. Cost of sales on groups of products	X	X´			
3. Gross marginon groups of products	X	X´			
4. Other expenses	X	X´			

5. Full cost	X	X´			
6. Profit or loss on groups of products (3-5)	X	X´			
7. Gross margin ratio (3/4 x 100)	X	X´			
8. Profit or loss ratio (6/1x100)	X	X´			

Nowadays, the literature presents two types of enterprises (Kotler & Armstrong, 2005):

- some orientated towards the competition;
- other concentrated on clients.

Obtaining a good product with a low cost is not everything; finding the right customer for your product completes the process. The concept of the client profitability splits the performance obtained by the economic entity in categories of clients or groups of clients, building a hierarchy. It starts from the premises that there are not profitable products, only profitable customers and not all the customers bring the same profit. It is necessary to delimitate the part of the profit that corresponds to each client or each group of clients in order to identify properly the consumers which participate the most in profit obtaining and to formulate some future strategies for the profit maximization. And the use of the financial reports cannot be avoided. Manufacturing a product only generates costs while selling it determines the profit.

"Our client our master" should be the guiding line of the companies nowadays. "The scope of an enterprise consists in creating and keeping the client" (Lynch, 2002). The companies owe their prosperity to the customers that choose their products.

By the profitability analysis on customers the customers which contribute in a more significant measure to the enterprise profit can be identified, as well as the customers who are completely not profitable (Curpăn, 2007). According to the "20-80" rule it is possible for 80% of the company's profit to be provided by 20% of the total number of customers. Sherden proposed to change this rule with the following: "20-80-30", first 20% of customers (according to the value of their orders) contribute with 80% to the enterprise profit and half of these profits are used to cover the enterprise losses generated by the last 30% of the not profitable customers (Sherden, 1994).

In the case of the analysis of the profitability of clients appears the problem of computing the cost on client. What does this cost include? The elements would be: the cost of goods sold, the specific cost for the customer (transport, sales agent expenses, telephones, service etc.), the administrative expenses quota. All this components offer the possibility to compute margins and results, allowing a management through margins. Such a report of the profitability of clients is presented in Table 3.

Table 3. The report for the analysis of customers' profitableness

ElementS	Client A	Client B	Client C	Total FOR THE ENTITY OR FOR THE AREA
1. Turnover	X	Y	Z	X+Y+Z
2. Cost of goods sold	X	Y	Z	X+Y+Z
3. Gross margin (1-2)	X	Y	Z	X+Y+Z
4. Costs for the client . client visits . telephones . transportation . invoicing	X	Y	Z	X+Y+Z

5. Client cost (2 +4)	X	Y	Z	X+Y+Z
6. Margin on client (3 – 5)	X	Y	Z	X+Y+Z
7. Administrative expenses quota	X	Y	Z	X+ Y+Z
8. Full cost for the client	X	Y	Z	X+Y+Z
9. Profit or loss for the client (1-8)	X	Y	Z	X+Y+Z
10. Gross margin ratio (3/1x100)	X%	Y%	Z%	average
11. Margin on client's ratio (6/1x100)	X%	Y%	Z%	average
12. Profit or loss Ratio (9/1x100)	X%	Y%	Z%	average

The grand total of the report has to correspond to the totals on entity or area. The report above has to include all the discounts allowed for the customers according to certain criteria, such as: faithfulness, seriousness, satisfaction, etc., in order to analyze the impact of discounts on the profit and thus on the future price politics.

The analysis on areas and distribution channels can be made for all the types of entities but especially for the ones that activate in the en-gross sector.

M. Ristea et al. (2007) proposes another model for the customer analysis.

Table 4. Customer profitability analysis

	The net turnover specific to the client "I" (assessed based on the sale price of the products)
-	Cost of sale specific to the client "I" (based on the products costs)
=	Gross margin (commercial) on sales
-	Specific costs to the clients (for example the marketing costs with the client "I")
-	Indirect costs allocated to the turnover (for example cost for maintaining the enterprise on market segments)
=	Profit/loss obtained from the commercial relationships with the client "I"

Such a formula should not be applied to all the situations. As the literature shows (Dumitru, 2006), "Exhaustive allocation of all the costs on the whole clients portfolio is very risky, preventing the managers to make right decisions. For example, the decision to renounce to a client, which apparently is not profitable based on a complete analysis of costs can determine the disappearance of a descendent spiral, in which the lost turnover not to be covered by a comparable reduction of costs. For this reason it is necessary to understand well how an enterprise operates, starting from the cause-effect relations, in order to have a just repatriation of costs on the costs objects. Cost objects can be products, services provided to the clients, costs with enterprise maintenance on a market segment".

CONCLUSIONS

The management control becomes a necessity for the entities including the ones with a distribution activity, because in spite of the characteristics everybody's objective is to assure and control the performance. The way to deploy the management control depends on everybody's knowledge about the quantity and quality of the information asked by the managers.

The reports that communicate the information to the managers have to be flexible, prepared in due time, adapted to the requests even if you cannot use a standard format (which could create problems).

The content of the reports is very broad, including both the financial and nonfinancial (qualitative measures) side of the business. An efficient management control keeps under pressure the entity and helps it to enroll and stay on the right course, in order to arrive to the point it aims.

FINANCIAL IMPLICATIONS OF THE IAS/IFRS ADOPTION ON THE CIRCULATING ELEMENTS OF THE LIQUID ASSETS TYPE

Dumitru Mihaela

Universitatea din Piteşti, Facultatea de Ştiinţe Economice, Piteşti, jud. Argeş, str. Brădet, bl. B20, sc. D, ap. 1, contabweb@yahoo.com, 0749017052

Within this article one presents some aspects regarding the affectation of the liquid assets both in leu and in currency by the International Standards of Financial Reporting. Regarding the liquid assets in currency we gave some precisions related to their presentation within the financial situations, and regarding the liquid assets in leu we made some appreciations regarding the synthesis document – the situations of the treasury flows.

Key words: cash-flow, transactions in currency, non-monetary elements, monetary elements, cash equivalent

Since the 1st of January 1999, the beginning of the coming into force of the Economic and Monetary Union (EMU), euro has become a currency with its own rights, and the exchange rates between the euro and the national participating currencies have been irrevocably established, i.e. the risk of the subsequent exchange differences of these currencies being eliminated starting with this date. IAS 21 Requirements – The effects of the exchange rates variation, regarding the conversion of the transactions in currency and the financial situations of the operations abroad must be strictly applied to the passing to the euro. The same reasoning is applied to the exchange currency rates when the countries adhere to the EMU in the subsequent stages.

This means that, especially:

- the assets and the monetary debts in currency resulting from transactions will continue to be converted in the functional currency on the closing rate. Any differences of the resulting exchange rates will be immediately recognized as incomes or expenses, excepting the case in which an entity will continue the applications of its accounting policies existing for the gains and losses relative to the covering of the exchange rate risk in case of a forecast transaction ;
- the differences of cumulated exchange rates afferent to the conversion of the financial situations for the operations abroad will be further classified as stockholders' equity and will be recognized as incomes or expenses only in what regards the giving up to the net investment in the operation abroad;
- the differences of the exchange rates resulted from the conversion of the debts expressed in the participating currencies won't be included in the accounting value of the afferent assets.

IAS 21 – The effects of the exchange rates require that the monetary elements of the currencies (as they are defined here) should be reported using the closing exchange rate on each date of the balance-sheet. As we mentioned above, the differences of the exchange rate which appeared in the conversion of the monetary elements must be recognized, in general, as incomes or expenses in the period in which they appear.

The beginning of the coming into force of the EMU after the date of the balance sheet does not modify the application of these requirements on the balance sheet data. According to IAS 10 –The events subsequent to the balance sheet date , it is not relevant if the closing exchange rate can fluctuate or not after the date of the balance sheet.

On the basis of *the treasury flow situation* one can make appreciations by the users regarding the capacity of the enterprise to generate cash and cash equivalent, the necessities of using the treasury flows. When it is used with the rest of the financial situations, the situation of the treasury flows provides information which permits the users to evaluate the modifications in the net assets of an entity, its financial structure (inclusively its liquidity and solvability), as well as the capacity of the enterprise of influencing the value and the moment of the treasury flows apparition, in the view to adapting to the ever changing circumstances and opportunities.

The information referring to the treasury flows are useful for the establishment of an entity capacity of generating cash and cash equivalent and give the possibility to the users of developing models of evaluation and comparison of the updated value of the future treasury flows belonging to different entities. Also, this information raises the degree of comparativeness of the results reporting form exploiting between different entities, since they eliminate the effects of using different accounting treatments for the dsmr transactions and events.

The information referring to the treasury flows is often used as an indicator of the value, the apparition moment and of the certitude of the future treasury flows. This is very useful in checking the exactitude of the former evaluations of the future treasury flows, as well as in examining the relationships between profitability and treasury net flows, and of the impact of price modification.

The cash equivalents are detained more with the view to fulfilling the liabilities in cash on a short term, than for investments or on other purposes. To classify a placement as a cash equivalent, this one must be easily convertible in a cash pre-established sum and to be subject to an insignificant risk of changing the value.

Consequently, an investment is normally qualified as a cash equivalent only when it has a low maturity, for let's say three months or less since the date of purchasing. Investments in the shareholders' equity are not considered cash equivalents, excepting the case when they are in their economic fund, cash equivalents, for instance in the case of the preferred stocks during a short period before their falling due and with a date of specified compensation.

Generally the bank loans are considered financing activities. Anyway, in certain countries, the overdrafts which are reimbursable at sight make an integrant part form the management of entity cash. In these circumstances, the overdrafts are considered a component of the cash and cash equivalent. A characteristic of these banking arrangements is the fact the sold frequently fluctuates between positive and negative.

The treasury flows exclude the movements between the elements which constitute cash or cash equivalents, because these components are part of the cash management of an entity, and not from the activities of operation, investment and financing. The management of the cash presupposes the placement of the cash surplus in cash equivalents.

An entity presents its treasury flows from the activities of operation, investment and financing in a manner which correspond best to its activity. The classification on activities provide information that allow the users to establish the impact of the respective activities on the financial position of the entity, as well as the value of the cash and cash equivalent. This information can also be used, to evaluate the relations that appear between the respective activities.

A single transaction can include treasury flows that are differently classified. For example, when the reimbursement in cash of a loan includes both the interest and the borrowed capital, the interest element can be classified as an operation activity, and the capital element, as a financing activity.

The value of the treasury flows which come from activities of operation is a key-indicator of the measure in which the activities of the entity generated sufficient treasury flows in order to repay the loans, to maintain the capacity of functioning of the entity, to pay dividends and to make new investments, without resorting to external financing sources. The information regarding the specific components of the treasury flows from operations, together with other information, are useful in the forecasting of the future treasury flows from operations.

The treasury flows coming from operation activities are derived, in the first place from the main income producing activities of the entity. As a consequence, they result, in general, from the transactions and other events which enter into the determination of the profit or of the loss.

The separate presentation of the treasury flows coming from investment activities is important because the treasury flows represent the extent to which the expenses served to the obtaining of the resources meant to generate future earnings and treasury flows. The separate presentation of the treasury flows coming from financing activities is important because it is useful in predicting the future treasury flows expected by the financers of the entity.

The treasury flows coming from the transaction effectuated in currency will be recorded in the functional currency of an entity through the application of the exchange rate between the functional currency and the currency, on the value in currency, on the date of the treasury flow. For the treasury flows afferent to a branch abroad will be converted on the exchange rate between the functional currency and the currency, on the date of the treasury flow.

The unachieved profit and losses that come from the variation of the currency exchange rate are not treasury flows. Anyway, the effect of the variation of the currency exchange rate on the cash and the cash equivalents, detained or owed in currency is reported in the situation of the treasury flows in order to reconcile the cash and the cash equivalents at the beginning and at the end of the period. This value is presented separately from the treasury flows coming from activities of operation, investments, financing and includes the differences, if they exist, of those treasury flows which were reported to the exchange rate at the end of the period.

In the case of the interests and dividends cashed or paid, the treasury flows will be presented separately. Each of these ones will be classified in a consequent manner from a period to another, as being generated either by operation activities or investment or financing. Both the paid interest and the cashed interest and dividends are classified by the financial institutions as treasury flows form operations.

Anyway, there is no consensus regarding the classification of these treasury flows by other entities. Both the paid interest, and the cashed interest and the dividends can be classified as treasury flows from operations, because they enter into the determination of the profit or of the loss. Alternatively, the paid interest and the cashed interest and dividends can be classified as treasury flows from financing and respectively from investment, because they represent costs of the attraction of the financing sources or of the investments.

The paid dividends can be classified as treasury flows from financing, because they represent cost of the attracting the financing resources. Alternatively, the paid dividends can be classified as a component of the treasury flow from activities of operation in order to help the users to determine the capacity of an entity of paying dividends from treasury flows of operation.

The treasury flows coming from the profit tax will be presented separately and will be classified as treasury flows from operation activities, with the exception of the situation in which they can be allocated specifically to the activities of financing and investment.

The separate presentation of the treasury flows which represent increases of the capacity of operation and of treasury flows necessary to the maintenance of the capacity of operation is useful, offering the possibility to the users to determine if the entity invests adequately for the maintenance of the operation activity. An entity which does not invest adequately in the maintaining of its operation capacity can prejudice its profitability in the future for the current liquidity and the allocations towards shareholders.

In a hyperinflationist economy, the reporting without conversion of the results of operation and of the financial position in the local currency is not useful. The money loses its purchasing power to such an extent, so that the comparison of the sums that result from transactions and other events that took place at different moments, in the very moment of the same accounting period, induces in error. One didn't establish an absolute rate from which level the hyperinflation is considered. The date of the moment on which the conversion of the financial situations becomes necessary is a problem of professional reasoning.

The hyperinflation is indicated by characteristics of the economic environment of a country, which include, but do not limit to the followings:

- most of the population prefers having the fortune in non-monetary assets or in a relatively stable currency, the sums detained in the local currency are immediately invested in order to maintain the purchasing power;
- most of the population appreciates the monetary values as compared to a relatively stable currency and not with the local currency, the prices can be expressed in the same currency;
- the sales and the purchases on credit are done on prices that compensate the expected loss of the purchasing power during the crediting period, even if the period is short;
- the interest rates, the wages and the prices are related by an index of prices;
- the accumulated rate of the inflation on three consecutive years gets close or exceeds 100%.

In most of the countries, the financial situations are drawn up on the basis of the historical cost, without considering the changes on the general level of the prices and the increase of the prices specific to the detained activities, excepting the case in which the corporal immobilizations and the financial investments can be reevaluated .

Some entities present anyway primary financial situations based on the method of the current cost, which reflect the effects of the price modifications specific to the detained activities. In a hyperinflationist economy, the financial situations based either on the historical cost model, or on the current cost one, are useful only if they are expressed as the unity of current measure since the date of the balance sheet.

The sums of the balance sheet which are not expressed as against the unity of the current measure on the balance sheet date are conversed through the application of a general index of the prices. The monetary elements are not conversed, since they are already expressed as against the current monetary unity on the balance sheet date. The monetary elements are the pecuniary reserves and the elements to cash or pay in money.

The assets and the liabilities bound through a contract of price modification, the way the bonds and loans are, which are indexed, are adjusted in conformity with the contract for establishing the basic value on the date of the balance sheet. These elements are recorded at this adjusted value in the converse balance sheet. All the other assets and liabilities are non-monetary. Some non-monetary elements are recorded at current values on the date of the balance sheet, as, for example, the net achievable value and the market value, so they are not conversed. All the other non-monetary assets and liabilities are conversed.

The most non-monetary elements are recorded at the cost or cost minus depreciation: consequently, they are expressed at current values on the purchasing date. The conversed cost or the cost minus depreciation conversed for each element is determined through the application of the historical cost. The conversed cost or the cost minus depreciation for each element is determined through the application of the historical cost and of the depreciation cumulated to the variation of a general index of the prices to the date of the balance sheet.

As a consequence, corporal immobilizations, financial investments, stocks of raw materials and goods, commercial fund, patent, trademarks and similar assets are conversed since the date of their buying. The products stocks in course of execution and of the finished products are conversed since the date of the apparition of costs of acquisitions and processing.

The conversing value of a non-monetary element is diminished in conformity with the requirements of the Standards, when it exceeds the recoverable value from the future utilization of the element (inclusively the selling or other form of giving up). That’s why, in such cases, the conversed values of the corporal immobilizations, the commercial fund, the patents and the trademarks are diminished at the recoverable value, the conversed values of the stocks are diminished at the net achievable value, and the conversed values of the short term investments are diminished till the market value.

The impact of inflation is usually acknowledged in the costs of the leverage. The conversion is inadequate during the same period of capital expenses financed through borrowings and of the capitalizations of the part of the leverage costs which compensate inflation, during the same period. This part of the costs of leverage is acknowledged as an expense in the period in which the costs were supported.

In an inflation period, an entity which detains a surplus of monetary assets compared to the monetary debts loses purchasing power, and an entity with a surplus of monetary debts as compared to the monetary assets gains purchasing power, if the assets and the debts are not related to a level of prices. The gain or the loss of the net monetary position can derive as a difference resulted from the correction of the non-monetary assets, the shareholders’ equity and the elements of the profit and loss account, and of the adjusting of the assets and debts related by an index. The gain or the loss can be estimated through the application of a general index of the prices to the average of the difference between the assets and the monetary debts of the respective periods.

The gain or the loss of the net monetary position is included in the net income. The adjusting of the respective assets and debts bound through a contract by the variation of the prices is compensated with the gain or the loss of the net monetary position. Other elements from the profit and loss account, such as the incomes and the expenses from the interests and the exchange rate differences afferent to the invested or borrowed funds are, also associated with the net monetary position. Although such elements are separately presented, the presentation in the profit and loss account can be useful, together with the gain and loss of the net monetary position.

APPRECIATIONS REGARDING THE FINANCIAL IMPLICATIONS OF THE IAS/IFRS ADOPTION ON THE ELEMENTS OF THE PROVISIONS TYPE

Dumitru Mihaela

Universitatea din Piteşti, Facultatea de Ştiinţe Economice, Piteşti, jud. Argeş, str. Brădet, bl. B20, sc. D, ap. 1, contabweb@yahoo.com, 0749017052

The present paper contains appreciations regarding the contents and the effects of the IAS/IFRS adoption on the elements of the provisions type within the financial reporting carried out by the enterprises. Assimilated will be also the elements considered to have a contingent character: assets and liabilities (element of novelty for the Romanian accounting system).

Keywords: contingent assets, contingent liabilities, provisions, restructuring, financial position.

According to the Conform IAS 37 dispositions– Provisions, contingent liabilities and assets, the provisions are defined as being uncertain from the point of view of the exigibility or value. A provision will be acknowledged in accounting when, and only when:

- an entity has a current liability generated by a passed event;
- a coming out of resources might affect the economic benefits necessary to honour the respective liability; and
- one can give a credible estimation of the liability value. The standard states that only in very rare cases it is not possible a credible estimation of this one.

In rare cases, for instance, in the situation of a process, it is likely not to be obvious if there is a current liability. In these situations, a passed event can generate a present obligation if, taking into consideration all the available proofs, there might be a current liability on the date of the balance sheet. An entity acknowledges a provision for a present liability if other criteria of acknowledgement are fulfilled. If it is more likely not to exist than to exist a present liability, the entity will report a contingent liability, excepting the situation in which one eliminates the possibility of a coming out of resources generating economic benefits.

One must not acknowledge the provisions for future losses from the operation activity. The predicting of such losses indicates the fact that some operation assets can de depreciated. In this case, the entity tests these assets for depreciation in conformity with IAS 36 – the Depreciation of assets.

Within the financial situations one will find at the end of some reporting periods its financial position, so one cannot acknowledge those provisions for the categories of costs which will be supported by the entity – only during the future exercises.

The dispositions of the present standard are specific to provisions in general and to those for restructuring in special: the selling or the ceasing of the activity of a part of a business, the closing up of the headquarters in a region or a country, the movement of an activity from a country or region into another one, modifications in the structure of the board, fundamental reorganizations with significant effects in the nature and the aim of the entity activities (one also includes here the provisions for the interrupted activities). Also within the framework of the standard one defines and states regarding the contingent elements (assets and liabilities).

The standard defines a contingent liability as being:

- a possible liability which appeared as a consequence of some passed events and whose existence will be confirmed only by the apparition or non-apparition of one or several uncertain future events, which cannot totally be under the control of entity; or
- a current liability which appeared as a consequence of some passed events, but which is not acknowledged because: it is not likely that some resources comings out will be necessary, which incorporate the economic benefits for the solving of this liability or the liability value cannot be evaluated credibly enough.

The standard defines the contingent asset as being that potential asset which appears as a consequence of some previous events and whose existence will be confirmed only through the apparition or non-apparition of one or several uncertain future events, which cannot totally be under the control of entity (a debt which constitutes the object of a process in which the entity is involved, whose result is uncertain). An implicit liability is the liability which results from the actions of an entity in the case in which:

- through the establishment of a previous practice, through the written policy of a firm or from a declaration sufficiently specific, the entity indicated to its partners that it assumes certain responsibilities;
- as a result, the entity induced the partners the idea that it will honour those responsibilities.

The provisions distinguish themselves from other debts, as the debts from commercial credits or accounting obligations, due to the fact of incertitude related to the exigibility or the value of the future expenses necessary to the sinking of the debt. Unlike these ones:

- the debts from the commercial credits constitute payment obligations of the goods or services which were received or sent to by the suppliers and which were invoiced or whose payment was officially convened with the suppliers;
- the accounting duties are payment obligations for goods and services which were received from or sent to by the suppliers, but which were not paid, invoiced or whose payment was officially convened with the suppliers, inclusively the employees' wages (the sums afferent to the paid leave). Although it is sometimes necessary an estimation of the value or exigibility of these debts, the incertitude element is in general more reduced than in the case of the provisions.

Another factor of differentiation appears at the moment of presentation of these elements: the duties are presented as part of the debts resulted from commercial credits or from other activities, and the provisions are reported separately.

In a large sense, all the provisions are contingent because they are uncertain from the point of view of the exigibility or value. Although, the „contingent" term is used for liabilities and assets which are not acknowledged because their existence will be confirmed only by the apparition or non-apparition of one or more future uncertain events, which are not in totality under the control of the entity control. Besides, the „contingent debt" term is used for the debts which do not fulfill the acknowledgement criteria.

One makes difference between:

- provisions – acknowledged as debts (if the estimations are certain) being current obligations and some resources may be necessary which to incorporate economic benefits for sinking the obligations;
- contingent debts - are not acknowledged as debts, being possible obligations, but for which one has to confirm if the entity has a current obligation which can generate a reduction of resources which incorporate economic benefits or current obligations which do not fulfill acknowledgement criteria (either it is not likely the reduction of the entity resources which incorporate economic benefits for the sinking of the obligation, or one cannot achieve a sufficient credible estimation of the obligation value).

In case one estimates that a part or all the expenses necessary to the sinking of a provision will be reimbursed by a third part, the reimbursement will be acknowledged only when it is sure to be received if the entity honours its obligation. The reimbursement will be considered as a separate asset, and the acknowledged value for reimbursement will not exceed the value of the provision.

In the profit and loss account, the cost related to a provision can be presented at its value diminished with the value acknowledge for reimbursement.

Sometimes, an entity can request to another party to pay a part or all the expenses necessary to the settling up of a provision (in a contract of insurance, the clause of damage or of the offered guarantee). The other party can either reimburse the value paid by the entity, or effectuate the payment directly.

In most of the situations, the entity remains responsible for all the sum, so that, in the case in which from a reason of another the third party does not effectuate the payment, the entity is the one which has to pay. In such situations, the entity will acknowledge a provision for the entire value of the debt, and a separate asset for the foreseen reimbursement is acknowledged when it is certain that the reimbursement will be received in the case in which the entity honours the debt.

A provision afferent to the restructuring will include only the direct costs generated by the restructuring, i.e. those which are simultaneously generated in a necessary way by the restructuring process and are not related to the continuous development of the entity activity. A provision for restructuring must not include cost as those related to: re-qualification or the movement of the permanent staff, marketing, investments in new systems and distribution networks. These expenses referring to the future administration of the activity do not represent debts of restructuring on the date of the balance sheet. Such expenses are acknowledged on the same basis if they appear independently from restructuring.

In the case of the existence of an onerous contract (the unavoidable costs involved by the sinking of the obligations assumed through a contract exceed the economic benefits estimated to be obtained from the respective contract), the current contractual obligation is acknowledged and evaluated as a provision (it is about the minimal cost between the fulfillment of the contract and any compensation or penalty generated by the non-fulfillment of the contract). There is the possibility that when canceling such contracts no penalty is paid, from where no obligation results, but the existence of some events is possible, which to transform such contracts in contracts with onerous character, from where the applicability of the IAS 37 dispositions results.

In general, the value of a provision will represent the actualized value of the expenses estimated to be necessary for the sinking of the obligation. Thus, the provisions afferent to some comings out of the resources that appear after the date of the balance sheet, are of a high onerous level, compared to those afferent to the resources comings out of the same value which appear much later. So actualization is done when the effect is significant.

In the case of the utilization of the accounting value of a provision will increase due to the passing of the time, increase acknowledged as a cost of the leverage.

There are future events which can affect the sums necessary to the sinking of an obligation and implicitly the value of the provision (with the proofs necessary to the apparition of these events). One has to keep in mind that at the foreseen giving up of the assets, the resulted earnings will not be taken into consideration (they will not affect the value of the provision).

The revision of the elements of the provisions type will be done at each reporting date, and afterwards one effectuates their adjusting for offering the best possible estimation. In the case in which it is not probable the coming out of some resources concomitant with the obtaining of some economic benefits, with the view to canceling an obligation, the provision is canceled.

Regarding the provisions classes each entity will present the following categories of information:

- the accounting value at the beginning and at the end of the period;
- the supplementary provisions appeared during the period, inclusively the increases afferent to those already existing;
- the values used during the period which lead to the diminution of the provisions;
- the values non-used and retaken during the period;
- the modifications during the period, due to the time factor and reutilization of the updating rate;
- a short description of the obligation nature and an estimation of the period during which one will record comings out of economic benefits;
- the degree of incertitude regarding the value or the moment of appearance of these comings out;
- eventual predicted reimbursements.

Any provision will be used only on the purpose for which one initially made the acknowledgment. The expenses initially acknowledged will be used for the subsequent canceling (or respectively the value found according to the evaluations). A subsequent canceling of these expenses for a provision which was used on any other purposes than those established on the constitution, is an event of a distinct nature.

NEEDS OF ADAPTING THE COMMITMENTS' ACCOUNTING SYSTEM OF PUBLIC INSTITUTIONS

Dragu Gabi

University 1 Decembrie 1918, Valahia Târgovişte, Faculty: Accounting, Adress: 31 Colentina Street, Bl. R48, Scara B, ap. 57, Bucureşti, e-mail: gabi.dragu@mfinante.ro, Tel:0751/29.21.19

Throughout this work, the stages mentioned in Omfp (Order of the Ministry of Public Finance) 1792/2002 are presented. The attempt is to bring clarifications with respect to delicate aspects: delegating competencies, delegation incompatibility, specialty compartment, manner of processing the annexes to the financial situations, individual/global commitment, proper determination of the available resources before making the payments, calculation of the available resources in case of payments made in currency, the need of a budget for commitment credits.

Key words: Global commitment, Budget for commitment credits, Processing undertakings in the annexes to the financial situations, Green stamp fee.

Responsibilities on the organization of commitments' accounting

All public institutions, irrespective of the subordination and the manner of financing the expenditures, have the obligation to:

- - organize the accountancy of the legal and budgetary commitments;
- - observe the procedures for going through all the 4 stages of the expenditures' budgetary execution, respectively the commitment, clearance, authorization and expenditures' payment.
- - organize, run the accountancy and the report of budgetary and legal commitments starting with the budgetary year 2003, based on the normative act of the Order of the Ministry of Public Finance no. 1792/2002 for approving the Methodology norms on the commitment, clearance, authorization and expenditures' payment of public institutions, as well as the organization, clearance and report of budgetary and legal commitments.

The budgetary execution is based on the principle of ***separating the attributions*** of the people that have the capacity of credit release authority from the attributions of the people that have the capacity of accountants.

Credit release authorities for the budgets mentioned in art.1 para.(22) in Law no.500/2002 are authorized to commit, clear and authorize expenditures throughout the budgetary exercise, within the limit of the approved budgetary credit, while the payment of the expenditures is carried out by the people that, according to the law, bear the general title of accountant.

The specific operations of commitment, clearance and authorization of the expenditures fall in the competence of the credit release authority and are carried out based on the specialty compartments' permits of the public institution according to art. 53 para.(3) in Law no. 500/2002 regarding public finances.

According to the legal frame, the unit leaders/managers may delegate competencies to the people with whom they collaborate, may designate people within the respective unit to carry out certain tasks, with the observance of the legislation in force, of the organization and functioning regulations.

The need to have a clearer definition of certain aspects can be notices, especially regarding:

- *delegation of competence*

  this represents the transfer of competence to people in the organizational structure that may, based on the delegation act, commit the institution by legal acts with patrimonial consequences or may order the elimination of the obligations undertaken by the respective public institution by means of these legal acts.

- *the empowered/ designated persons , incompatibility situation;*

  the manager of the "economic directorate" cannot enter the category of "other empowered persons" because it is the leader of an operational organizational structure which in the process of the budgetary execution fulfills the attributions and competencies of a "specialty compartment" leader; the structure involved in certifying reality, regularity and legality of the created or asserted patrimonial operations, depending on the pertaining tasks from the Organization and Functioning Regulation

– *defining the specialty compartment:*

  “represents the organizational structure of the public institution where payment obligations based on public funds are created (in case of administrative acts or contracts) or are asserted (in case of laws, Government decisions, agreements, court orders)”.

In case of salary, benefits or corresponding contributions expenditures, the specialty compartment is the one that has attributions in calculating the salary rights and the corresponding contributions that draft the clearance documents (collective or individual payrolls), as well as Payment credit release.

Applicable in practice when the human resources service is divided in compartments/ offices/ designated to draft payrolls/personnel recruiting, filling out labor registers, etc., or this is carried out in crossed combination in case of small units).

It is necessary to have the involvement of the legal specialty compartment in controlling, in a preventive manner, the legal aspect of the administrative acts, by the prior consulting notice, both exclusively for certain administrative documents and before exercising the preventive financial control visa. The consulting notice is part of the category of documents prior to adopting the legal deed, whose request is obligatory, but it does not involve the obligation to comply.

With respect to the specification on the preventive financial control part, it is necessary within the Omfp.1792/2002 to replace the phrase “person empowered to perform the preventive financial control” with "the person designated to perform the proper preventive financial control" and to replace the phrase "preventive financial control visa" with "proper preventive financial control visa".

The budgetary authorization is not global. This requires a **specialty** of the credit based on expenditures’ categories.

Credit specialty is regulated by art.12 and art.2 in Law no,500/2002, according to which: "...budgetary expenditures are registered and approved in the budget by expenditures’ categories, grouped according to their economic nature and their end use, according to the budgetary classification”, provision harmonized with the Financial Regulation no.1605/2002 of the Council “the credits are specialized on titles and chapters, the chapters are subdivided in articles and positions.

The more detailed the budgetary specialty and the credit transfers are conditioned by prior authorizations of budgetary bodies, the more rigid the budget organization is and the resource oriented management.

Mutually, the more globalized the credit, and the interventions of a budgetary authority throughout an execution are more reduced, the more flexible the budget organization is and the more objective-oriented the management.

Committing expenditures

Commitment represents the stage in which the institution creates legal obligations to third persons (legal commitment) and reserves the necessary budgetary credits for covering these obligations (budgetary commitments). Committing any expenditure has two aspects: legal commitment and budgetary commitment.

a) The legal commitment represents, according to the definition included n Law no.500/2002 at art.2 para.(3),"...any legal deed resulting into or that could result into an obligation based on public funds"
b) The budgetary commitment represents the deed by means of which necessary amounts for covering certain expenditures are reserved from the budgetary credits. Consequently, the approved budgetary commitments cannot exceed the approved levels of budgetary credits.

   The budgetary commitments may be:

   - individual budgetary commitments;
   - global budgetary commitments.

For compliance with the approved annual credit limit, it is mandatory to reserve the committed budgetary credits for the payments that will be carried out in that budgetary year. The budgetary commitment by means of which the public funds were reserved for a certain use, within the limit of the approved budgetary credits, precedes the legal commitment. Thus, the value of the legal commitments **cannot** exceed the value of the budgetary commitments and that of the approved budgetary credits by the incomes and expenditures budget.

The *individual budgetary* commitment represents the operation of reserving the budgetary credits necessary to cover the expenditures generates by **new** operations that are to be performed during the budgetary exercise, which were not initially included in the provisional budget, and do not have a repetitive nature.

Salaries of the personnel included in the payroll positions annexed to the approved budget and their corresponding obligations, pensions and social assistance benefits established according to the laws in force, as well as expenditures with interests and other expenditures pertaining to the public debt are considered to be *individual* legal and budgetary commitments *at a global level* starting with the 1st of January of each year with the entire amount of the approved budgetary credits.

Reporting commitments of this nature is done each year, even from the first quarterly report.

The global budgetary commitment is used in case of operations that occur again during the same budgetary year and generate current administrative expenditures (repetitive operations).

Thus, in title II "Goods and services" commitment is carried out individually when the beneficiary or the exact amount are unknown.

- in case of utilities where there is **no** contract with a definite amount, the commitment is carried out individually, invoice per invoice,
- when the beneficiary of the contract is known, the amount, the commitments is carried out at the level of the contract.
- in case of direct acquisitions mentioned in the procurement plan, the order represents the basis for the budgetary and legal commitment,

The budgetary credit represents a payment authorization, and the commitment credit represents a commitment authorization which, in part, may generate payments in the future exercises as well.

It is necessary that the budget ceases to be a planning act strictly limited to a budgetary exercise, and to allow it to become of the commitment credits due to the existence of specific activity sectors, so as not to be in contradiction with the principles of commitments' accounting.

Thus, the specific activity sectors are envisaged, such as: the sanitary sector where, considering the provisions of art.250 para.(2) in the Law regarding the health reform no.95/2002 according to which "deducting the medical services and medical equipments pertaining to the month of December of the current year is done in January of the next year, estimating that the medical services and equipments cannot be considered expenditures in December unless these are made and, implicitly, committed before January in the next year (contracts for paying hospitalization days, medical analyses, etc.).

Because the law specifically states that payment of services and equipments pertaining to December are carried out in January of the following year, in the current year, practically, no budgetary credits can be estimated in order to cover the payments made in January for the medical services and equipments used in December.

Similarly, in December, salary commitments and the corresponding contributions can only be highlighted within the limit of the budgetary credits. These are registered in the corresponding expenditures accounts in view of observing the basic principles of the commitments' accounting, which leads to differences.

Clearing expenditures

Clearing expenditures is the phase in the process of the budgetary execution where the existence of the commitments is checked, the reality of the due amount is determined or checked, the contingent liabilities of the legal commitment is checked based on justifiable documents attesting the respective operations. The operations of clearing expenditures are carried out by the credit release authority.

A special aspect that occurs in case of clearing the global service provision contracts is that the invoice is issued for a global service without detailing it on types of activities, case in which there can no longer be an exact assertion of the strict observance of the contract, complying per budgetary articles. As a conclusion, it is necessary to draft an invoice offering the necessary information requested in art. 155 in Law no.571/203 regarding the Fiscal Code.

In case of drafting the deduction for plane travels, in case of issuing it electronically, it is necessary to present documents established by internal procedures (boarding tickets, activity reports, especially when accommodation is not provided by the unit).

Authorizing payment expenditures

Authorizing expenditures represents the phase within the process of the budgetary execution when there is a confirmation that the delivery of goods existed or that other accounts receivable were checked and payment can be carried out.

Authorizing payment is the internal documents by means of which the credit release authority orders the manager of the Financial-Accounting Compartment to draft the expenditures' payment instruments. This operation does not reflect in accounting, being strictly a managerial action.

On filling out the available resources in column 1 at the moment Annex no.3 "Payment Authorization" is drafted, it is recommended for the specificity of the data to take into account the budgetary commitments highlighted in account 8066 "Banking commitments" (former 950) but also the payment made in account 770 "Budget financing" (former 700) or in other available resources' accounts as the case may be; but also the expenditures that were committed, cleared and authorized before that did not appear as deducted in the bank statement at the moment of the draft, the amounts erroneously entering the account, the amounts undergoing clarification.

If the Payment authorization is drafted for buying currency necessary to make external payments, the amount in lei or the equivalent in lei of the currency payment obligation is calculated at the exchange rate set by the National Bank of Romania valid on the date of the transfer of the amount for buying currency, with an additional insurance margin covering possible exchange rate differences for the period starting from the day of the transfer and the date of the external payment to the suppliers and to the other creditors, as well as possible commissions and other due costs.

Expenditures' payment

Expenditures' payment is the final phase of the budgetary execution by means of which the public institution is free of its obligations to third parties-creditors.

The unit manager does not have attributions in this phase, it no longer grants the first signature unless in small units, only those financed from the local budgets [art. 54 para.(7) in Law 273/2006 regarding local public finances] No payments regarding several subdivisions of the budget approved in one payment can be included, even if it is made for a sole supplier.

The accountancy of the available resources before making the payment shall be affected by the provisions of Art.8 (1) in the GEO 37/2008 for regulating certain financial measures in the budgetary domain "The amounts coming from the budgetary financing of the previous years which is reimbursed under the provisions of the budgets' law they were granted from is highlighted in execution at a position other than budgetary expenditures".

Up to now – the amounts representing payments in advance that cannot be justified by delivered goods, works performed and services provided by the end of the year *were recovered* by the public institution that granted the deposits and were given back to the budget they were granted from, with the corresponding *interests and delay penalties,* according to the law. This aspect shall be clarified on entering into force of the application norms of GEO no.37/2008.

It is necessary to correlate the amount paid in lei with the committed amount, because it was made as the equivalent in lei of a currency, for exemplifying the application of Law 315/2006, regarding the incentive of books or electronic educational programs' procurement, necessary for improving the quality of the didactic activity, in the pre-university educational system.

Reporting Commitments

It is necessary to revoke annex no.4 in Omfp 1792/2003 because it is found entirely in annex 7 "Execution account of the public institutions' budget - expenditures" in Omfp 616/2006.

In view of eliminating confusions on filling out the expenditures' execution accounts (i.e., annex 7), the title was changed from "Initial budgetary credits" to "Updated budgetary credits" for quarterly reports, in view of accurately filling out with the last *approved* budget at the end of each quarter.

Highlighting and the legal multi-annual expenditures' commitments with the "environmental fee" which will be paid in full according to the Government decision no.448/2005 regarding the electric and electronic equipments waste with the subsequent completions, for the assets that will be removed from use in the following future, the correlation of these amounts with the registration in ct.1518 "Other provisions" completing the function of account 151 "Provisions"

Presently, the green tax paid one purchasing inventory objects, bought fixes assets, representing a non-recoverable tax is included in their costs.

It is recommended to perform a continuous analysis of the available resources that can be committed and to carry out the necessary remedies.

Draft for Check list in view of applying Omfp 912/2004 for amending and completing the General methodology norms in reference to the execution of the preventive financial control, approved by Omfp 522/2003 with the subsequent amendments.

CHECK -LIST

OF PAYMENT AUTHORIZATION GRANTED TO THIRD PARTIES

Summary: We consider that the approach of the mentioned theme presents an interests for all the theoreticians and practitioners in the economic and financial domain for the fact that the activities of the nature of the bankruptcy know an ascending trend and they lead to accounting treatments and to specific insurance measures. We have considered that it is useful to debate the problems concerning the delimitation and the short definition of the bankruptcy situations, with national and European juridical references and especially, the implications of the operations that that they generate upon the accounting information. For the realization of the accounting registrations we have used the dates which are registered in the two obligatory balance sheets, the initial one and respectively the final one, this last one is essential for solving the examined problem.

Key words: accounting information bankruptcy, own capitals, specific procedures

Introduction

The economic and social factors, inclusively the market, normally influence the entities' activity, especially concerning their performance. As a reaction to these provocations, the entities use different reorganization ways which could allow the continuation of the activity, and in this case its cessation is produced as well as the realization of the liquidation operations.

From this perspective, in the practical activity we find many ways for the reorganization of the entities, determined by the decision taken by the competent organs concerning the continuation or the stopping of the activity. So, we use the fusion operations, in the situation when we decide the continuation of the activity, or the dissolution operations, in the case when we choose to stop the activities or to start the liquidation of the society. We mention that in the life of a society we can have some critical situations which generate the juridical reorganization and, finally, the bankruptcy.

Taking into consideration the complexity and the effects of such operations, we will further underline the connection between them and the entities' own capital and the operations of dissolution, liquidation and bankruptcy.

Definition of the bankruptcy

The bankruptcy is the juridical institution which is procedurally regulated with the aim of assuring the administration and the liquidation, in the interest of the common creditors, the patrimony of a juridical or physical person that has the quality of trader and that in the impossibility of paying his debts which have been assumed concerning the trade acts concluded in proper name. The procedure for the bankruptcy consists in certain rules for the forced execution of the goods from the debtor's patrimony for the payment of the debts towards the creditors, and its application has as an effect upon the cessation of the activity. In Romania, Italy or in Belgium only the traders- physical persons or trade companies can be declared as bankrupted, but in other countries, such as Germany and Netherlands, any physical or juridical person, without taking into account the nature of his activity, can be declared in a bankruptcy state, excepting the societies of public right. In Italy, for the insurance societies, for the societies of economies or for the cooperative societies, the is possible only the procedure of administrative liquidation. This diversity of solutions can lead to some conflicts of laws. So, the bankruptcy of a non-trader, admitted by his national law, cannot be declared in Romania, because the law of the forum is opposed, it reserves this procedure only for the traders.

Implications of the bankruptcy upon the accountancy of the own capitals

The bankruptcy of an entity supposes a different accounting treatment compared to the ones which have been presented before, because the money availabilities resulted after the liquidation can assure or not the payment of the debts. In case of bankruptcy the accounting operations are registered in the order settled by the liquidator and which is the one stipulated by the legal norms, with the difference that in the situation when, after the liquidation there has not resulted any profit, the operations of partition are not produced.

In order to take the operations on the total we finally take into consideration an example where after the liquidation there has resulted a satisfactory profit for the payment of the debts.

So, the situation of the tangible and intangible elements, according to the balance elaborated based on the dates from the accountancy and which have been agreed with the results of the inventory, are presented in the table below:

Item	Indicators	Details and determinations	Balance (in thousand lei)
1.	Immobilized assets		1.300,00
	Corporal immobilizations (ct. 212-2812)	(1.000.000-250.000)	750,00
	Non-corporal immobilizations (ct.208-2808)	(400.000-100.000)	300,00
	Financial immobilizations (ct.265)		250,00
2.	Circulating assets		700,00
	Stocks (ct.371)		500,00
	Debits (ct. 411)	(Sums which will be cashed after a period bigger than one year)	200,00
	Cash register and the accounts in the banks (ct. 5121)		0,00
3.	Debts (ct.401+404+419) which should be paid in a period of up to one year	(450.000+200.000+ 150.000)	800,00
4.	Debts (ct.162) which should be paid in a period of over one year		600,00
5.	Assets – Debts		600,00
6.	Own Capital		
	Subscribed and paid capital (ct. 1012)	500.000 shares x 1,00 lei /share	500,00
	Legal reserves (ct. 1061)		0,00
	Other reserves (ct 1068)	Made up of the repartition of the profit in the previous years	100,00

Table 1 The situation of the tangible and intangible elements corresponding to an entity entered in the bankruptcy procedure

In order to assure the money availabilities necessary for the realization of the specific operations of liquidation from the competence of the elder judge and of the liquidator, the computer programs have been sold with 250.000 lei compared with the net accounting value of 300.000 lei; the buildings with 900.000 lei compared to the net accounting value of 750.000 lei; the goods with cu 600.000 lei compared with the net accounting value of 500.000 lei; the participation tiles with 300.000 lei compared to 250.000 lei – as an acquisition cost. In the same time, the sum of 180.000 lei has been received from the clients, by offering a discount of 10% (18.000 lei); the loan with the sum of 600.000 lei and an interest of 100.000 lei has been paid; the sums towards the suppliers have been paid with a value of 450.000 lei, by receiving a discount of 5% (22.500 lei); the suppliers of immobilizations in sum of 200.000 lei and the advances received from the clients have been given back, being in sum of 150.000 lei.

For the realization of the liquidation operations there have been realized some expenses in a total sum of 800.000 thousands lei, from which for salaries 50.000 lei and as expenses for the auctions 30.000 lei.

These operations have been registered in the accountancy as it follows:

1. The capitalization of the computer applications

a) Sale of the programs

461	=	%	297.500 lei
		7583	250.000 lei
		4427	47.500 lei

b) Subtraction from the evidence of the sold computer programs

%	=	208	400.000 lei
2808			100.000 lei
6583			300.000 lei

c) Cashing of the value

5121	=	461	297.500 lei

d) Closing of the account for incomes

7583	=	121	250.000 lei

e) Closing of the account for expenses

121	=	6583	300.000 lei

2. Capitalization of the corporal immobilizations

a) Sale of the buildings

461	=	%	1.071.000 lei
		7583	900.000 lei
		4427	171.000 lei

b) Subtraction from the evidence

%	=	212	1.000.000 lei
2812			250.000 lei
6583			750.000 lei

c) Cashing of the value for the building

5121	=	461	1.071.000 lei

d) Closing of the account for incomes

7583	=	121	900.000 lei

e) Closing of the account for expenses

121	=	6583	750.000 lei

3. Capitalization of the goods

a) Sale of the goods

4111	=	%	714.000 lei
		707	600.000 lei
		4427	114.000 lei

b) Cashing of the value

5121	=	4111	714.000 lei

c) Subtraction from the administration

607	=	371	500.000 lei

d) Closing of the account for incomes

707	=	121	600.000 lei

e) Closing of the account for expenses

121	=	607	500.000 lei

4. Sale of the participation titles

a) Sale of the shares

461	=	7641	300.000

b) Cashing of the value

5121	=	461	300.000 lei

c) Subtraction from the administration

6641	=	265	250.000 lei

d) Closing of the account for incomes

7641	=	121	300.000 lei

e) Closing of the account for expenses

121	=	6641	250.000 lei

5. Cashing

a) Clients cashing

5121	=	4111	180.000 lei

b) Allowance of discounts

667	=	4111	20.000 lei

c) Closing of the account for expenses

121	=	667	20.000 lei

6. Payment of the creditors

a) Restitution of the loans

162	=	5121	600.000 lei

b) Payment of the interests

666	=	5121	100.000 lei

c) Closing of the account for expenses

121	=	666	100.000 lei

7. Payment of the suppliers

a) Payment of the suppliers of immobilizations

404	=	5121	200.000 lei

b) Payment of the suppliers

401	=	5121	427.500 lei

c) Registration of the discount

401	=	767	22.500 lei

d) Closing of the account

767	=	121	22.500 lei

8. Restitution of the advanced received from the clients

a) Restitution of the advance

419	=	5121	150.000 lei

9. Registration of the salaries and of other operations concerning the salaries

a) Registration of the rights

641	=	421	50.000

b) Registration of the tax

421	=	444	5.000 lei

c) Internal payment

581	=	5121	45.000 lei

d) Effective taking of the cash

5311	=	581	45.000 lei

e) Payment by the pay office

421	=	5311	45.000 lei

f) The payment of the tax

444	=	5121	5.000 lei

g) Closing of the account for expenses

121	=	641	50.000 lei

10. Realization of the auction expenses

a) payment of the expenses 6

628	=	5121	30.000 lei

b) Closing of the account of expenses

121	=	628	50.000 lei

11. Operations of VAT liquidation

a) VAT registration

4427	=	4423	332.500 lei

b) VAT payment

4423	=	5121	332.500 lei

The situation of the accounts 121 and 5121 before the realization of the partitions (in lei):

Account 121		**Account 5121**	
Debt	**Credit**	**Debit**	**Credit**

300.000	250.000	297.500	600.000
750.000	900.000	1.071.000	100.000
500.000	600.000	714.000	427.500
20.000	300.000	300.000	200.000
250.000	22.500	180.000	150.000
100.000			45.000
50.000			5.000
300.000			30.000
			332.500
Total		Total	
2.000.000	2.072.500	2.562.500	1.890.000
Sold	72.500	672.500	

From the facts presented above it results that from the liquidation operations it has been gotten a profit of 72.500 lei, which will be added to the social capital, in sum of 500.000 lei, and to the reserves that have been constituted before the liquidation, in sum of 100.000 lei, case when the assets resulted and registered in the account 5121 in sum of 672.500 lei will be covered. In the **partition balance**, the result of the liquidation, as an accounting information, is represented by the creditor balance of the account 121 „Profit and Loss".

After the confirmation of the balance, the liquidator realizes the operations concerning the restitution of the own capital towards the shareholders, operations which lead to the situation for the accounting registrations in the following way.

12. Operations concerning the social capital

a) Registration of the social capital

1012 = 456 500.000 lei

b) Restitution social capital

456 = 5121 500.000 lei

13. Taxation of the liquidation result

a) Registration of the profit tax

691 = 441 11.600 lei

b) Closing of the account of expenses

121 = 691 11.600 lei

c) Sending to destination

441 = 5121 11.600 lei

14. Registration of the dividends resulted from reserves and from the net result

a) Registration of the dividends

% = 456 160.900 lei

1068 100.000 lei

121 60.900 lei

b) Registration of the tax for dividends

456 = 446 25.744 lei

c) Payment of the tax

446	=	5121	25.744 lei

d) Obligation for the payment of the dividends towards the shares

456	=	457	135.156 lei

e) Effective payment

457	=	5121	135.156 lei

The conclusion that we considered to be motivated consists in the fact that the present work brings a plus of quality to the accounting information concerning the own capitals, by the fact that it allows a profound study of the problems of juridical nature and especially of the accounting problems concerning the bankruptcy and its financial and financial implications.

The companies (registered as VAT payers) that receive compensations from insurance companies are faced with the dilemma whether to collect or not the value-added tax related to these amounts. In other words, we can put the problem this way: "to collect or not to collect?". In the following pages we'll try to solve this problem, both from a tax and accounting point of view.

Keywords: compensation, value-added tax, accounting treatment, tax treatment

Introduction

The companies (registered as VAT payers) that receive compensations from insurance companies are faced with the dilemma whether to collect or not the value-added tax related to these amounts. In other words, we can put the problem this way: "to collect or not to collect?". In the following pages we'll try to solve this problem, both from a tax and accounting point of view.

Short history

For a start a short history is necessary. Until June 1, 2002 the problem was regulated by the Government Emergency Ordinance no. 17/2000 and its application norms which stipulate that the compensations also contain the value-added tax. Implicitly, the taxpayers registered as VAT payers had to collect the VAT for the amounts representing compensations received from insurance companies.

Therefore, in taxpayers' accounting records, the collection of insurance compensations in the amount of lei 1.190 was registered as follows:

5121 "Cash at bank in lei"	**=**	**%**	**1.190,00**
		7581 "Claims and compensations, fines and penalties"	**1.000,00**
		4427 "Output VAT"	**190,00**

Considering that the company did not record in the administrative period other taxable operations as concerns the VAT, based on the VAT return (with a pro rata of 100%), the VAT adjustment is reflected as follows:

4427 "Output VAT"	**=**	**4423 "Payable VAT"**	**190,00**

and the VAT payment to the state budget, according to the payment order:

4423 "Payable VAT"	=	**5121 "Cash at bank in lei"**	**190,00**

Tax and accounting treatment after 1 June, 2002

After 1 June, 2002, with the repeal of the Government Emergency Ordinance no. 17/2000, the regulations on the VAT related to compensations received from insurance companies are made in compliance with the Law no. 345/2002 on VAT and then with the Law no. 571/2003 on the Fiscal Code as the tax treatment was radically changed.

Therefore, as from 1 June 2002, taxpayers who receive insurance compensations are the recipients of VAT exempt operations (whereas insurance companies make, in accordance with the law, VAT exempt operations) and therefore they do not have to collect the VAT related to the compensations received.

The reasoning seems simple and can be compared to the one applicable to the interests received by companies for the cash accounts.

However, in practice, the accounting and tax professionals translate differently the issue of the VAT related to the compensations received, proceeding erroneously to VAT collection.

Accounting treatment exemplification

Next we shall present the correct solution for a situation frequently encountered in practice[342], that is compensations received for goods deteriorated or degraded from various reasons, including reasons of force majeure or natural disasters and which require repair work before being used.

For instance, SC X SRL receives a compensation of 1.190 lei from an insurance company for repairing a damaged transport means (which makes the object of an insurance agreement previously concluded).

The situation can be solved by also taking into account the aspects related to the manner in which the repair work is performed, which is in the repair shop of the owner, of the user or of the leasing company, or in the repair shop of an automotive service facility (other than owner, user or the leasing company).

Therefore, if the repairs are performed by the owner (user or leasing company) in their own repair shop (by themselves), the latter will deduct the VAT related to the purchase of goods and services necessary to make the repairs, receiving from the company insurance the compensation, exclusive the VAT already deducted upon the input operations. In the same time, the companies that make repairs in their own repair shops do not have the legal possibility to invoice these repairs to the insurance companies since services to the insurance company are not performed like this (the settlement is made based on the repair list which will not include the deductible VAT related to the purchase).

From the accounting point of view, here are the things:

- ✓ The purchase of spare parts necessary to make the required repairs is reflected in the owner's (user's or company leasing) accounting, according to the fiscal invoice and to the acceptance and difference inspection report, in the amount of 1.190 lei, including VAT:

%	=	**401 "Suppliers"**	**1.190,00**
3024 "Spare parts"			**1.000,00**
4426 "Input VAT"			**190,00**

- ✓ The payment of the spare parts supplier is reflected, according to the statement of account and payment order:

[342] The examples are purely theoretical, meant to point out the accounting and tax treatment, making some abstractions, such as bank charges etc.

401 "Suppliers"	=	**5121 "Cash at bank in lei"**	**1.190,00**

✓ The spare parts previously purchased are given to consumption, according to the consumption note:

6024 "Spare parts"	=	**3024 "Spare parts"**	**1.000,00**

✓ There is registered the payment of the compensation through transfer made by the insurance company, based on the list previously made for the repairs performed in one's repair shop, list that does not include the VAT previously deducted, according to the statement of account and payment order:

5121 "Cash at bank in lei"	=	**7581 "Claims and compensations, fines and penalties"**	**1.000,00**

✓ The VAT adjustment is reflected, according to the VAT return (supposing there are no other taxable operations related to VAT in that period):

4424 "VAT receivable"	=	**4426 "Input VAT"**	**190,00**

✓ The VAT receivable is received (making abstraction from the dispositions on the level of the VAT receivable amount):

5121 "Cash at bank in lei"	=	**4424 "VAT receivable"**	**190,00**

We can notice that after closing the income and expenses accounts related to the repairs and compensation (6024 and 7581, equal amounts) the accounting profit and taxable profit are not influenced, and as concerns the cash flow statements, as the amount received as compensations (1.000 lei) and the VAT receivable (190 lei) is equal to the amount due to the spare part suppler (1.190 lei), the operation is neuter (the account 5121 is balanced, balance 0).

The same reasoning is used if repairs are made in the repair shop of a specialized service facility (other than the owner, user or leasing company) and the latter invoices the repairs to the owner or to the user.

✓ The repairs invoiced by the service facility is registered, in amount of 1.190 lei, including VAT:

%	=	**401 "Suppliers"**	**1.190,00**
611 "Maintenance and repair expenses"			**1.000,00**
4426 "Input VAT"			**190,00**

✓ The service facility payment is reflected, according to the statement of account and payment order:

401 "Suppliers"	**=**	**5121 "Cash at bank in lei"**	**1.190,00**

✓ There is registered the payment of the compensation through transfer made by the insurance company, based on the invoice received from the service facility, according to the statement of account and payment order, if the insurance company accepts a copy of the service invoice; the compensation does not include the VAT which is deducted by the owner or user:

5121 "Cash at bank in lei"	**=**	**7581 "Claims and compensations, fines and penalties"**	**1.000,00**

The other operations related to VAT adjustment, payment of the VAT receivable from the budget, closing of the income and expenses accounts are identical to those presented for the case when repairs are made in the owner's repair shop (user's or company leasing), with the same effects.

You should notice, if the insurance company requires the service invoice in original, considering that the owner or the user will not be able to deduct the value-added tax related to repairs because it cannot be accounted for with the original invoice, the compensation will also include the VAT:

5121 "Cash at bank in lei"	**=**	**7581 "Claims and compensations, fines and penalties"**	**1.190,00**

and in the same time, the input VAT becomes non-deductible (it cannot be accounted for with the original invoice):

635 "Other taxes, duties and similar expenses"	**=**	**4426 "Input VAT"**	**190,00**

Therefore, the account 4426 "input VAT" is balanced and the VAT adjustment operation remains without object. Therewith, the effects are the same (the account 5121 is balanced, as liquidities are not influenced, the accounting and taxable profits are 0 and the expense accounts 611 and 635 compensate in amount the income account 7581).

If the insurance company pays the repair work directly to the third specialized service facility, without settlement and through the company which holds or uses the damaged/deteriorated good, then the latter shall not register any operation in its accounting, related to the damage and repairs performed.

Conclusions

In conclusion, currently in Romania, regardless whether the compensations received from the insurance company include the VAT (1.190 lei or 1.000 lei for the example presented), the recipient of the compensation (owner, user or leasing company) does not have to collect the VAT related to insurance (the account 4427 "Output VAT" will not be used).

Abstract: Goodwill represents a financial indicator which serves as an evaluation tool for the quality of the company's production structures. The evaluation and the recognition of the Goodwill raises may controversies, as for example: Is the Goodwill an asset or not? Is it kept within the assets part or is it subtracted out of the company owner's equity? Is it depreciated or it is sufficient to be included in the provisions? Therefore, the stakes for choosing one solution, or the other, should not be neglected. It is necessary to analyse the factors that influence the managerial decisions, when choosing a way to record the Goodwill. In this analysis we may use the theory of the Contract Costs. In its own path to eliminate the manipulation options for the published information, the international referential has supported within the past years, numerous revises and modifications regarding the Goodwill accounting treatment. Goodwill in the context of the international accounting convergence processes.

Keywords: Goodwill, accounting referentials, controversies, accounting convergence processes.

Theoretical Issues regarding the nature of the Goodwill:

Goodwill represents a financial indicator that serves as an evaluation instrument for the quality of a company's production structures. It is „the only asset that the competition cannot depreciate or destroy".[343] The specialty literature presents various methods for computing the Goodwill and the most important ones are as follows:[344]

A. Goodwill is determined as a difference between the real global value of an enterprise and the fair value of all its net quantifiable assets. This subtractive method, preferred by the accountants, is rather simple to be used, but has the major inconvenient that it does not explain the intangible components of owner's equity.

B. Goodwill is computed with the additive method, starting with the direct valorisation of its own components (registered marks, licenses, brands, distribution chains, s.o.). The additive method ignores though the interdependence of the asset component elements and its effects on the enterprise capacity, reasons for which it has been rarely utilised by the accountants.

C. Goodwill is determined on the basis of the estimations regarding the company's capacity to generate a result superior to the one which may lead to a non-risk participation of the invested capitals. From a practical perspective, this method imposes identifying the asset-generated cash flows, the upcoming cash flows for the shareholders (under the form of dividends), and the extra-added value brought by the company's sale.

C. Collette and J. Richard³ analyse the subtractive method for determining the Goodwill, through the light of the dynamic and actuarial accounting procedures.[345] Within this vision, the Goodwill represents the difference at a certain point in time, between the actuarial value of the owner's equity and its dynamic accounting value. In other words, the Goodwill is the difference between the linear cumulated results (according to the actuarial accounting procedures) and the cumulated „dynamic" results. Beyond the difficulties for evaluating the Goodwill, it is asked whether this represents a feasible indicator for measuring the intangible capital of a company. Obviously, the answer is negative. One of the main

343 "To goodwill, the one and only asset that competition cannot undersell or destroy." Marshall Field, Goodwill, web page.

344 P. Epingard

345

characteristics of the intangible capital is its indirect relationship with the enterprise performance in terms of profit or market share, and its value is linked to the qualitative characteristics of the organisation, its competencies and flexibility. Such aspects cannot be measured and quantified using the Goodwill, an indicator built to estimate the market value according to some financial logistics on the short-term that sustain the shareholders' rights.

Accepting the fact that Goodwill actually measures the immaterial capital of a company, means giving credibility to the market when it estimates the value of that company. In real life, the market-estimated value is based (as Keynes said in 1936) more on a „conventional evaluation, the result of a collective psychology belonging to a large number of ignorant individuals", rather than on a long-term performance measurement. In other words, as an asset-evaluation issue, one cannot be right if he opposes to a multitude of individuals, no matter how ignorant or blind those persons are.

The recognition and the evaluation of the Goodwill – Controversies:

The arising problem is whether Goodwill represents an asset in the legitimate context of this word. Briefly, it can be easily stated that within the specialty literature it has been demonstrated that the experts' points of view are far from being convergent in all the aspects. A first argument against recognising the Goodwill is the fact that this „element" does not satisfy the definition of the „intangible" assets, as it has been presented in the IAS 38 standard, as follows: it cannot be separately sold form the acquired enterprise, therefore it doesn't have a separable character, and being identifiable only as a remaining part. Also, incurring an expense is not automatically translated into the process of creating an asset. W.P. Schuetze offers an example as to illustrate the above mentioned issue – an example about the business managed by his sister in a small Texan city. We quote: „She has recently bought a concurrent society, paying an extra 100,000$ over the purchased identifiable elements of the net assets. In return for the extra 100,000$, the seller accepted not to be concurrent with her business for the next 5 years. I explained to her that this represented acquired Goodwill and that, in conformity with the General Accepted Accounting Principles (US GAAP), it should be recorded as an asset. She started laughing and replied: try to pay with this asset all the wages, the rent and the electricity bills, or the dividends. The 100,000$ is actually just an expense."[346] It should not be neglected that, within the international vision, an asset represents a resource controlled by the enterprise that was generated by past commercial events and which is susceptible to bring future economic benefits to the company. Obviously, the Goodwill generates future economic benefits (positive cash flows), because it has the capacity to create, together with other assets, cash flows, and further the economic entity controls these economic advantages (as a result to a past transaction, the operation of enterprise grouping).

Another argument against recognising the Goodwill notion, is the fact that this „element" cannot be feasibly evaluated, excepting the moment when grouping the enterprises. In other words, Goodwill satisfies the criteria for being recognized as an asset, at the moment of purchasing a company, but not also after that point in time. Consequently, it has been stated that, in the case when the Goodwill is recognised as an asset, afterwards it must be subtracted from the owner's equity. Therefore, the practical procedures for treating the Goodwill, is equivalent to rejecting the Goodwill's status of an asset.

We consider though that there are similar difficulties to be encountered in the case of other tangible assets, for which there is no active market (for example the highly-specialised equipment market). And, despite all these, the mentioned type of equipment is recorded as an asset, according to the transaction amounts (acquisition cost). The question raising from here would be: why Goodwill is not treated in the same way? Also, ignoring the Goodwill, allows the future recognition of some non-realised revenues. For example, selling an enterprise for the sum of 100 mil. m.u., that has been previously acquired for the same amount, through a sale of titles – recorded in the accounting journals, at the value of only 60 mil. m.u., due to eliminating the Goodwill part), will generate a sale revenue of 40 mil. m.u., in the conditions in which the selling price and the purchase price are equal as value. Moreover, if the enterprise is to be sold at the value of 90 mil. m.u., a 30 mil. m.u. gain would be recorded, while in real facts this transaction is translated in a 10 mil. m.u. commercial loss.

[4] Schuetze, W.P., *What are assets and liabilities? Where is True North? (Accounting that my sister would understand)*, Abacus, volume 37, no. 1, 2001.

In the case in which the Goodwill is recognised as an asset, questions are raised on how it will be depreciated along the time. The accounting practice and theory generally sustain four divergent solutions for the Goodwill accounting treatment, as follows:

- maintaining the Goodwill as an asset, without any amortisation or provisioning;
- subtracting the Goodwill from the owner's equity;
- the capitalisation of the Goodwill and making provisions for it - in the case in which the acquired assets have depreciated;
- the capitalisation of the Goodwill and its amortisation.[5]

a) Maintaining the Goodwill as an asset, without any amortisation or provisions. There are experts who sustain the fact that the value of the Goodwill does not decrease in time, but on the contrary it maintains its value or even grows along its economic life. In other words, „the Goodwill represents an investment and must be kept in the Balance Sheet without any amortisation"[347]. C. Collette and J. Richard both consider that such a solution is not acceptable because the Goodwill represents a virtual asset that leads to the misrepresentation of the real and net status of the assets and of the result.

b) The imputation of the Goodwill from the owner's equity. The creators of this solution had as a starting point the fact that a company accepts to pay an extra-price for acquiring the assets belonging to another company, when it is estimated that, by purchase, they will obtain future economic benefits under the form of future superior incomes. Because these future extra-revenues will affect the owner's equity, then they may be compensated through the extra-payment made at the acquisition moment. This solution is though contested, because it creates a false image of a higher profitability of the company group, than the real state of facts.

c) The capitalisation of the Goodwill and creating provisions for it, in the case in which the purchased assets have been depreciated. Such a solution leads to a similar image with the one generated by the first one.

d) The capitalisation of the Goodwill and its amortisation for a period equal to the useful life of the bought or consolidated assets, at the moment of acquiring an enterprise. Some specialists plead for the necessity of depreciating the Goodwill, due to its own elements' economic nature. Therefore, the Goodwill may contain identifiable intangible assets that support depreciation, and which are not separately recorded, because their value cannot be feasibly determined. Also, some components of the Goodwill, as for example the „managerial team" or the „collective intelligence of the team" do not have a definite economic life. Consequently, not amortising the Goodwill does not allow the creation of a real image of a company's financial status and economic performances.

C. Collette and J. Richard sustain that the only rational solution is to amortise the Goodwill during its investment period. The amortisation of the Goodwill significantly influences the prepared an disclosed financial results of the company. Consequently, most of the enterprises take advantage of all these ambiguities belonging to the various types and incertitudes of theoretical issues, in order to develop an opportunistic attitude that serves their own perspectives and targets. That is why B. Martorz and F. Verdier criticize the following situation (considered by us representative for this issue): „When IBM acquired, in 1995, the Lotus Development Corporation, with the total sum of 3.2 billion $, the amount of 1.84 billion $ (that is 57% out of the acquisition price) has been allocated to the R&D expenses still in progress. IBM recorded this issue into its own Profit and Loss Account, by applying the rule which states that the R&D expenses represent expenses for the current financial year. Why this artificial method? Well, the answer is that the immediate recording of the R&D expenses within the Profit and Loss Account, allows the elimination of a big part of Goodwill, which further leads to the ability of diminishing the future amortisation and significantly increase the published financial result for the company. Also, this operation decreases the total value for both the owner's equity and the total assets, creating the illusion of a higher profitability".[348]

[348] Martory, B. și Verdier F., *Comment traiter le goodwill? Pratique d'une théorie, théorie d'une pratique*, Comptabilité, contrôle, audit, tome 6, volume no. 2, september 2000.

Our opinion is not though the same with the one belonging to Professors C. Collette and J. Richard. Using a linear amortisation system, may lead to the creation of a false and deformed image of the enterprise, due to the fact that the Goodwill is a special asset with a relatively stable value on the short-term, and with potential spectaculars drops on the long-term. Most of the companies record the Goodwill in the Balance Sheet and treat it in the same way as for the Tangible Fixed Assets. Here, we must mention that while the value of the Tangible Fixed Assets rarely incur fast depreciation processes, on the contrast, the value of the Goodwill may disappear in only one second, if we reach the conclusion that the company paid too much on the Intangible Fixed Assets (for example, a registered mark is not „that original" as it has been considered at the beginning, or the demand for a new technology is very low). As an example, it is sufficient to offer the case of Financial Corporation of America (FCA), that paid in 1983, an extra 1.1 billion dollars in order to acquire also the company's Goodwill advantages. The duration for amortising the Goodwill has been settled at 30 years. In 1984, the FCA has recorded a 600 million $ loss, which in turn diminished its owner's equity with 75%. Between 1985 and 1986, the same company had profit, but again in 1987 it recorded a 470 million $ loss, generating a negative value for the owner's equity (minus 170 million $). At the end of 1988, American has been sold to another enterprise. At that moment in time, the FCA Balance Sheet presented a non-amortised Goodwill of 950 million $, not covered by the sale transaction. The need for transparency and avoiding the utilisation of an arbitrary accounting system, both represented reasons which laid the foundations for giving up to the Goodwill amortisation procedure presented in some performant accounting referentials.

The stakes for choosing one solution, or the other, previously analysed, should not be over passed. This is the reason for which it is absolutely necessary to analyse the influencing factors for the managerial decisions when choosing the accounting method as to record the Goodwill. In this analysis, we shall utilize the theory of *Contractual Costs.* Watts and Zimmerman have studied numerous case studies on the contractual costs. Some of these studies worth our attention, especially the *Agency Costs* matters.[349]

The analysis for the agency costs, worth identifying the agency relationships susceptible of influencing the accounting policies to be chosen. It is about settling relationships between: a) the managers and the shareholders; b) the shareholders/managers and the creditors; and c) the company and its external environment. Through the procedure of including within the contracts some compensatory plans, or some additional liability restrictions, the managers actually accept to link their interests to the ones belonging to the shareholders and to the ones of the creditors. Positive researches have emphasized that managers tend to have an opportunistic behaviour, that is to choose those accounting policies and procedures which maximise their remunerations, reduce or avoid the contractual restrictions and minimise possibilities of political interference. Using such results, within the Goodwill accounting analysis, intuitively leads us to the following conclusions:[350]

- in the case of the companies that already have such managerial compensation plans, it is preferred to apply an accounting method with no adverse effects upon the accounting financial result: i) maintaining the Goodwill in the assets part, with no amortisation or provisions, or ii) subtracting Goodwill out of the owner's equity side of the patrimony.
- in the case of those enterprises having no restrictions concerning the additional liability, or balance rate restrictions, it is preferred to apply a method which doesn't diminish owner's equity: i) the capitalisation and the amortisation of the Goodwill; or ii) the capitalisation and provision-making for the Goodwill.

Goodwill and the International Standards:

At international level, the treatment for the Goodwill is the object of the IFRS 3 accounting standard – *Groups of Enterprises.* This standard provides rules for recognising the Goodwill (positive or negative), generated from the acquisition of other enterprises. In the case of company-acquisition operations, any over passing of the acquisition costs, beyond the limit of the assets' fair value and of the acquired quantifiable liabilities, must be described as part of the Goodwill, as an asset.

[349] R.L. Watts, J.L. Zimmerman, *Positive accounting theory*, Prentice Hall International Inc, 1986.

[350] Also relevant is the 1998 analysis of P. Gore, F.M. Taib and P.A. Taylor, *"Accounting for Goodwill: what factors influence management preferences?"* – the web page. This paper represents an investigation of the British stock exchange companies, between 1993-1995, and tries to identify which one of the six mentioned accounting treatments foreseen within the project "Goodwill and other intangibles", is the best for managing the Goodwill.

The Goodwill generated through an acquisition process represents a payment made by the buyer, as a consequence to anticipating future economic benefits. These future economic benefits may result form the merger between the identifiable assets acquired, or from individually analysed assets that do not meet all conditions for being in the financial statements, but for which the buyer is willing to perform a payment within the acquisition transaction. There are situations in which the apparent existence of the Goodwill indicates the fact that the fair value of a significant identifiable asset, hasn't been correctly determined. For example, we may choose a company that has as object of activity the minerals extraction and their sale on a market with continuous price changes/quotations. In order to determine the value of the non-extracted minerals, there are evaluation methods based on the current market prices. Due to the aspect that the minerals reserves represent the only important/significant asset of that company, which in turn has its activity limited to the minerals extraction, then the value of those reserves essentially determines the value of the company. In the case in which a potential buyer would accept to pay for this enterprise a higher price than the conventional value of the reserves, then it means he estimates a greater value for the reserves than the conventionally-settled value. The payment excess, over the real value conventionally determined, must be added to the value of the reserves.[351]

At the purchase date, the acquired Goodwill, within a group of enterprises, is evaluated at its acquisition cost and also recognised as an asset. After its initial recognition, that Goodwill must be evaluated as a difference between its acquisition cost and the cumulated losses generated by the depreciation. In other words, the Goodwill is non-amortisable, but it bears a depreciation test which may lead to the recognition of some value losses.[352] If the share owned and controlled by the buyer, out of the total net asset at its fair value, overpasses the titles' acquisition cost, then the buying company must re-identify and revalue the assets, liabilities and potential liabilities of the acquired enterprise, as well as the revaluation process for the acquisition cost. The negative difference of acquisition may have one of the following causes:

- errors in the revaluation of the assets' fair value, of the liabilities and potential debts of the acquired company (for example, the future potential costs haven't been correctly emphasized within the fair value of the assets, liabilities and potential liabilities);
- revaluation errors for the titles' acquisition costs;
- the obligation provided by some accounting standard, as to revaluate an asset at another value than the fair one;
- an acquisition at a good price.

If, as a result of the revaluation, a negative purchase difference is still kept, then the Profit and Loss Account will be definitely affected. On the 10th of January 2008, IASB – International Accounting Standards Board has published a revised and modified form of the IFRS 3 standard, which becomes compulsory starting the 1st of July 2009. The revised accounting standard, allows an economic entity to choose on how it evaluates the minority interests (non-controlling interests), as follows: either using the *entire Goodwill method* – at the fair value; or by using the proportional *corresponding part out of the total net asset* of the purchased company. Under these circumstances, the Goodwill becomes measurable as a difference between the following items:

- the sum of: i) the transferred titles' fair value, at the acquisition date, ii) the value of minority interests, and iii) in the case of a company grouping operation, the fair value of the buyer's previously-held shares within the bought company's total social capital;

AND

- the net value at the acquisition date, for the purchased identifiable assets and liabilities, valued in conformity to IFRS 3.

Goodwill is measured at the date when the buyer gains full control over the acquired company.

This situation held a slight change comparatively to the current in-use-method, according to which the buyer separately evaluates the Goodwill for each transaction, by comparing the acquisition cost with the percentage of fair value belonging to the net identifiable assets, at the date of each acquisition.

---

[351] Pricewaterhouse Coopers, *Understanding IAS*, 2001, web page.

[352] In order to perform the Depreciation Test for the Goodwill, one should use the policies and procedures presented within IAS 36 – *Depreciation of Assets*.

To sum up.....

Summing up the analysis upon the accounting principles and practices regarding the treatment of the Goodwill, leads us to the following main conclusion: when the different types of regulations are ambiguous, with difficulties in settling frontiers, then the accounting rules become insufficiently developed and therefore the companies have an opportunistic type of behaviour.

Inevitably, under such circumstances, there is a continuous race between the authorities (wanting to develop and implement very detailed rules) on one side, and the enterprises that wish to explore those rules as to maximise their own utilities, on the other side. The Goodwill represents a residual value with extremely ambiguous characteristics. All theoretical considerations, avoid to compare between the computing the depreciation or the amortisation, while the stock exchange companies try to minimise the financial impact of their value losses. For this reason, some of the accounting referentials (including the Romanian one), provide the Goodwill amortisation solution, as a substitute when there's no better alternative.

The solution given by the international accounting referential seems to reconciliate the theoretical vision, with the accounting practice for the Goodwill issue, regulating both the transparency matter for the grouping operations towards their shareholders and creditors, and the future expense effects linked to this asset, over the company's financial result. The above described solution creates major inconvenients with some of the national accounting standards, in the matters of the initial recording of a group of enterprises, and also in the depreciation/amortisation issue for the Goodwill. It is very likely though, that most of these incompatibilities will disappear once the international accounting convergence processes are further developed.

ABSTRACT: Nowadays the participation of all states in the world economical circuit is an objective necessity. The complexity of global economy, the extremely strong incidence of technical progress, the diversification of the economic processes, the emphasizing of the interdependences between national economies, the extremely important advantages that can be obtained from international specialization (or the dangers to which those that prefer autarchy are exposed), are just a part of the causes and factors that have led to the generalization – at a planetary scale – of the international economical exchanges. In this field we include our study of analysis and presentation of foreign transactions, which have as a main characteristic the expressing in a foreign currency, can generate differences in the exchange rate between the time of the appearance of the external debt/liability and the time of recording or presentation in the financial statements of the unaccounted for until the end of the financial period.

KEYWORDS: import; export; accounting information; external price; risk (currency); financial statements; currency.

1. Introduction

1.1 Motivation and methodology

"Through the development of foreign trade and international economic cooperation – writes Ph. D, Professor. Alexandru Puiu – each country can increase its economical potential, respectively the possibilities capitalizing its material and human resources in the direction of the development of production forces, promoting technical progress, superior capitalizing of natural resources, creation of new products, raising work productivity, higher qualification of the work force." [1:715]

Given the complexity and importance of the foreign trade operations, they represent, for accounting as well, an extremely important special field of research and application. This much more because in import – export operations partners from different countries are joined together, consequently the sphere of accounting information users grows larger. In these conditions, obtaining and transmitting relevant, credible and comparable information that utilizes a common accounting jargon enabling communication between all users categories is vital to the business environment.

The content of the present paper will be based on the deductive approach, starting from theory to practice, with some tendencies of inductive research which consist of practical case studies meant to verify the degree in which certain theoretical aspects, mentioned earlier are validated from a practical point of view. Practically, the tools of the deductive research used are case studies, through the descriptive/narrative method, but also the work tool materialized in the analysis of documents, especially of synthesis accounting documents. We can specify in this case that we used the quantitative method simultaneously with the qualitative on in the investigation. And, for the gathering of data, the main method used was the observation method.

1.2 Literature review

The complexity of the problems that are raised by external trade and especially the quantification of its importance for the economy of each country, have led to numerous analyses and conclusions, which, although in large terms differ one from another, being hard to find a common denominator applicable in practice, still they constitute the support of a fundamental direction in the development policy and strategy of an economy and of its external commerce. In this way, in the national literature, among the main authors preoccupied with the importance of external commerce for the Romanian economy, we mention: Ciobanu G. [2], Popa I.[3], Popescu G.[4], and of the ones that gave attention to the risk that these transactions are subject to in the currency fluctuation conditions we notice Vişan D., Buruda C., Burtescu C., Luță D.[5]. These authors have started, however, directly from the premise that the currency fluctuations in which the import-export operations are expressed affect their efficiency and have suggested solutions for diminishing or even eliminating this currency risk. In the international literature, remarkable studies on this theme have been written by the following authors: Williamson J [6], Shapiro A. [7], Bartov E., Bodnar G. M.[8], Halpem L., Wyplosz C[9].

Financial instability is an international public bad, but not a classical one. Instability is not purely a technical by-product of the production of financial services. Rather, it is the outcome of market failures, for reasons not yet fully understood. [10:156] The Gordon M. Bodnar and Richard C. Marston model's demonstrates that foreign exchange exposure elasticities should be largest for pure exporting and importing firms, especially those with low profit margins. Exposure elasticities should be smaller for multinational firms that match their foreign currency revenues and costs [11:107]. Söhnke M. Bartram and G. Andrew Karolyi show that the reductions in market risk were concentrated in firms domiciled in the Euro area and in non-Euro firms with a high fraction of foreign sales or assets in Europe. The Euro's introduction led to a net absolute decrease in the foreign exchange rate exposure of nonfinancial firms, but these changes are statistically and economically small.[12:519]. In conclusion, Muller A. and Verschoor W.F.C said that „Assessing the sensitivity of firm value to exchange rate changes has been one of the most challenging issues in international financial management over the last two decades" [13:385].

2. The recognition of the differences in the exchange rate generated by the import-export operations in the financial statements

Preparing financial statements, as periodical reporting documents, mark the final stage of the annual data processing through which the activity of an economic entity that performs import – export operations is expressed. They are the result of applying hypotheses, assessment bases and principles specific to accounting and destined to reflect as precise as possible the financial position and the performances of an entity in order to serve the interests of a large scale of users of the accounting information. In economic literature, in order to reflect "the enterprise in financial terms" [14:22] at the end of the exercise different tools are used: balance sheet, accounting documents of synthesis, annual accounts, and financial statements. In the general sense, the documents of synthesis notion are used in accounting, to mark the fact that these statements assure the synthesis (syntax) of accounting information. [15:433]

At an international level, we find the problem of financial statements in the provisions of the international accounting norm IFRS 1"Presentation of financial statements", but also in other international accounting norms. Irrespective of the title under which we discover them in accounting or the normative act that regulates them, financial statements as accounting documents of synthesis represent for the users of the accounting information, the "data base" necessary in decision taking.

Thus, taking into account the users objectives and the decisions that these must also substantiate, financial statements demonstrate their utility through the following [16:386]: they represent a method of leading and analyzing, named as "the mirror" of the economic entity; they represent the main method of information of present and potential investors, business partners and the wide public, interested in the activity of the entity regarding the operations and transactions made in the reporting period and their effect on the financial equilibrium, on the registered financial results respectively; they constitute a calculation basis of the macroeconomic and sectorial indexes and of elaborating forecasts through the statistical date that it supplies regarding the patrimony and results of all economic entities.

In this paper we do not intend an exhaustive presentation of all the elements of an economic entity that can be comprised in the financial statements, but we will follow only those aspects relating to the specific of the import-export operations, to the modality of presenting them in the main components of the financial statements, respectively. As main components of the financial statements, we included, unarguably, the Balance sheet, Profit and loss account, and, also, the Cash flow statement.

The Balance sheet presents the balance of cash and cash equivalents of an entity at the end of the period. By examining the balance sheets referring to two consecutive periods, we can state if the cash and cash equivalents have risen or fallen within a certain period of time. However, the balance sheet does not indicate why the balances of the cash and/or cash equivalents have varied on the course of the exercise. The profit and loss account presents information of the incomes, expenses and results emitted from different activities types – "keys" regarding the sources and uses of cash and cash equivalents, but not even this financial statement explains why the respective elements have risen or fallen. Moreover, not few times, behind significant profits, the profit and loss account can hide critical cash problems of the economic entity.

The table of cash flows presents such flows, known under the name of cash receipts and cash payments, in the course of the period. In other words, it shows where the cash came from and how it was spent, explaining in this way the causes of their variation. [17:80] The Cash flow statement belongs to the flow tables family, extremely useful tool for financial analysis, business assessments, diagnosing the situation of the enterprise, forecasts and other papers of economic-financial facture that are based in a large extent to the data from the financial statements. The cash flow table must present the cash flows of the exercise classified into operating, investment and financing activities. This synthesis document together with the Profit and loss account represents two fundamental elements that indicate the accurate dimension of performance of the company.

An import-export operation carried out in a foreign currency must be registered, when it is initially registered in the national currency, by applying the exchange rate between the two currencies, at the date of the transaction, to the value of the operation. Afterwards, at each date of the balance sheet, according to O.M.F.P no. 1.752/2005, the balance sheet accounts shown in foreign currency are treated as follows: the monetary elements (liquidities and assimilated elements, such as the letters of credit and bank deposits, accounts receivable and accounts payable) shown in foreign currency must be estimated and reported using the exchange rate established by the National Bank of Romania at the end of the financial year. The advantageous or disadvantageous differences between the exchange rate at the date of the recording (initial account) or the exchange rate at which the foregoing financial reports were put forward and the exchange rate at the end of the financial year, are accounted for as financial gains or losses according to the case; the non-monetary elements purchased in a foreign currency and accounted for/registered at the historical cost (non-current assets, inventories) must be reported using the exchange rate from the date of the transaction; the non-monetary elements purchased in a foreign currency and accounted at the fair value must be reported using the exchange rate form the date of the related estimation.

Due to this stipulation exchange rate discrepancies can thus appear in the following situations: *At the foreign currency liabilities' and receivables' maturity*, when exchange rate differences appear be they advantageous or disadvantageous, according to case, between the "historical" exchange rate[353] and the exchange rate at the time of payment. These differences are considered financial gains or losses according to case. When the foreign currency receivable or liability is paid during the same financial year it appeared, the whole exchange rate difference is acknowledged in that year. When the foreign currency receivable or liability is paid during the following financial year, the exchange rate difference acknowledged in each financial year that appears until the year of payment is determined by taking into account the modification of the exchange rates from each financial year; a*t the end of the financial year* when the unpaid *foreign currency receivables and liabilities* are *updated* to the exchange rate at 31.12. The exchange rate differences generated by this update are treated, like in the previous case, as financial gains or losses, according to case. In this way "the historical exchange rate" of the unpaid receivables/liabilities until the end of the year becomes the exchange rate as of the 31st of December; a*t the end of the financial year, the update of the foreign currency liquidities* is made, compulsorily, at the exchange rate from the end of the year, so that a correct piece of information is shown by the financial statements. This update also generates exchange rate differences, hence financial gains or losses, according to case.

[353] The "historical" exchange rate is considered, according to the new approach of the prudence principle, the exchange rate from the date that the receivable or liability in the foreign currency appeared, if this happened in the same financial year, respective the exchange rate from the end of the latest financial year, in case the receivable/liability, or a part of it, appeared in the previous financial year.

From all of the requirements mentioned above it clearly results the way in which financial statements for the foreign currency transactions are presented. Thus, the monetary elements must be presented in the Balance Sheet at the exchange rate from the end of the financial year, and the non-monetary ones at the exchange rate from the latest registration. In the Profit and Loss Statement/Account, the differences resulted from the update of the monetary elements, or payment of foreign currency receivables/liabilities, are presented as foreign exchange gains and/or losses at “Other financial incomes” or “Other financial expenses” respectively. In the elaboration of the Cash Flow Statement tough, there is the issue of exchange rate differences like the ones mentioned above that can or can not be acknowledged as cash-ins respective payments.

The cash flows do not contain the change in liquidities or liquidity equivalents because they are part of the economic entity’s treasury management and a cash flow statement must show the incomings and outgoings of funds generated by the operational, investment and financial activities. Considering this we state our opinion that exchange rate differences that appear in the situations mentioned above can be viewed as unaccomplished according to the requirements on which the Cash Flow Statement[354] is based. . Of course that if the link with the transactions that generated them is considered, the differences may be accomplished, if they correspond with the payment of the transaction, or can be unaccomplished if they correspond with a transaction unpaid until the end of the year when the update of the foreign currency receivables, liabilities and liquidities takes place at the exchange rate from that time. However, we believe that no matter what transaction they are linked with (paid or not) the financial gains and losses from exchange rate differences do not generate cash and so they needn’t be recorded in the Cash Flow Statement.

For the operations of an economic entity made in a foreign currency, all the three situations generate an unrealized profit or loss. However, only the third situation, i.e. the update of cash and cash equivalents at the end of the year using the exchange rate from that time, is shown distinctively in the Cash Flow Statement. This is due to the fact that the other two situations (the payment of foreign currency liabilities and receivables and the update of the unpaid liabilities/receivables at the end of the financial year) do not influence directly, through the registrations, the treasury accounts. Even if they are not distinctively reported in the Cash Flow Statement, foreign exchange losses and gains related to these two situations do not influence the Statement because, through the way in which it is presented based on its logic, they and their equivalents are indirectly eliminated.

Conclusion

The distinct presentation of the exchange rate variation effect on the cash and cash equivalents group is needed for bringing together these elements at the end of the period, and it is done as follows:

- When applying the *direct method of reporting* the operating flows, but also the investment and financial flows that are usually presented on a gross basis, the cash-ins and payments generated by foreign currency transactions will be presented at the exchange rate at the date of the cash flow. In this way we directly consider the exchange rates from the date of the cash flows for foreign currency transactions, disregarding the other balance sheet accounts and the implicated results, and also the exchange rate differences that are incorporated. Thus the cash-ins and payments related to the foreign currency transactions during the period are obtained.
- When applying the *indirect method of reporting* the operating flows: the losses and gains that reflect the exchange rate differences related to the update of the cash and cash equivalents group are annulled from the net book result. In this way the exchange rate differences generated by the update of cash and cash equivalents are eliminated from the operational flows group; the liquidities are recorded in the last group of the Cash Flow Statement for their initial and final balance accounts, including, for now, the exchange rate differences that have no connection with cash (generated by the update of liquidity); these differences must be annulled for the respective balance accounts to reflect the cash existence. The way in which

[354] There are opinions that state the fact that the foreign exchange differences related to the transactions paid during the year must be considered accomplished when the Cash Flow Statement is made because they generate payments or returns.

this is done is presented in the standard, on a distinct line, in the cash and cash equivalents group, under “Exchange rate variation effect”.

Thus, the unaccomplished gains and losses that result from the variation of the exchange rate between the date of the flows and the end of the year are not cash flows. However, the effect of the exchange rate variations related to liquidities and liquidity equivalents owned or owed is presented in the Cash Flow Statement, in order to allow the comparison between the liquidities and the liquidity equivalents related to the beginning and the end of the year. They are presented separately from the cash flows generated by the operational, investment and financial activities.

QUALITY COSTS, AN IMPORTANT DIMENSION OF BUSINESS

Firescu Victoria

Universitatea din Pitesti, Facultatea de Stiinte Economice, B_dul Republicii, nr.71, cod 110014, Pitesti, jud.Arges, Telefon:0740035680, E-mail:firescu Victoria@yahoo.com

Abstract: Nowadays, many company leaders erroneously perceive quality assurance as a rule imposed from outside and as an administrative act .Quality is regarded as a socially desirable objective, but its contributions to the profitability of the company are considered marginal. In order to cope with the strong competition present in a market companies are forced to continuously manufacture high-quality products at prices as low as possible to create the conditions necessary to obtain benefits. It is not sufficient just to manufacture high-quality products. The costs necessary to achieve these goals must be carefully monitored, so that the long-term effect of quality costs on the company should be the intended one.

Key words: quality costs, evaluation, monitoring

Foreword

Quality costs are not different from the other types of costs. Much like the maintenance, project, production, sale costs and the costs of other activities, they too can be measured and analysed.Quality costs appear in each of the stages of the product life cycle, as well as at all the operational levels of the company.Traditionally, poor-quality costs are correlated with scrapped goods, rework, excessive effort spent on tests and trials. These costs are easily understandable but little reference is made to them in the account books of the company. Moreover, the poor management of quality costs leads to other costs that could be avoided.

Nowadays, several studies reveal that the non-quality costs as well as the prevention and appraisal costs amount to an average of 25% of the turnover of a company and to approximately 5-15% of the production cost. In Crosby's opinion, they would amount to a much higher percentage, up to 40% in the case of the service companies. The level of the quality costs represents an important instrument of quality valuation, a potential source of increasing the profit of the company. There is a possibility of identifying the ineffective activities and the critical points of the processes through costs thus providing a more reliable basis for corrective or improvement actions necessary in a certain sector of the company and the evaluation and monitoring of the effectiveness dynamics of the adopted measures. However, they do not represent an absolute measure of the performance of a company. They must be appropriately integrated into the management performance evaluation system.

1. Quality costs conceptual approaches

Quality costs represent one of the main topics debated in the specialized literature, being an important instrument that allows for the financial evaluation of the measures adopted in order to ensure performance. In his paper "Quality Control Handbook", Juran widely approaches the problems of quality costs, specifying that 11 categories of costs are necessary for the manufacture of products "fit for use".

In his approach of quality costs problems, Feigenbaum considers that four categories of costs are needed: prevention costs, appraisal and control costs, internal defect costs and external defect costs

Internal defects are defined as defects identified before the product delivery, while external defects are defects identified after the product shipment to the receivers (traders, dealers, customers).

In Crosby's opinion, quality is free, and he approaches quality exclusively through two categories of "prices": *the price of conformance and the price on non-conformance*. He prefers the word "price" instead of "cost", in order to highlight the fact that this price that is paid is not unavoidable; in fact, on the contrary, it can be reduced and even eliminated. He includes into the price of conformance all the expenses necessary to provide the product conformance with the requirements and into that of the non-conformance, the expenses incurred because the product is not in conformance with these requirements.

Kelada criticizes the traditional approach of quality costs, mainly because it only takes into consideration direct, tangible costs, and proposes the following distinct categories of costs:

– *direct quality costs* that are quantifiable and non-quantifiable;
– *indirect quality costs* that are, in their turn, also subdivided into quantifiable and non-quantifiable costs.

According to Tkaczyk, S. (2001) quality costs represent the main indicators on the basis of which the performance of the quality management systems can be evaluated. Quality cost (c_c) could be defined (Rusu, C. and others, 2001) as the difference between the actual cost (c_R) of a product or service and its reduced cost (c_r) if no service below standards and no failure or manufacturing defect would have occurred into the product manufacture.

According to international standard ISO 8402, quality costs represent the costs incurred to ensure the quality level of the products and services as well as the losses that occur when the satisfactory level of quality is not reached. To summarize, a typology of these costs can be made (Rusu, C. and others, 2001) so that they could be analyzed in the clearest possible way (figure 1). This typology is established by norm AFNOR X50-126 France. Nevertheless, this is not the only typology available on the market. Inspiring himself from Juran's and Deming's papers, Harrington proposes a slightly different approach (an approach adopted by ASQC) where we can find the same categories of costs.

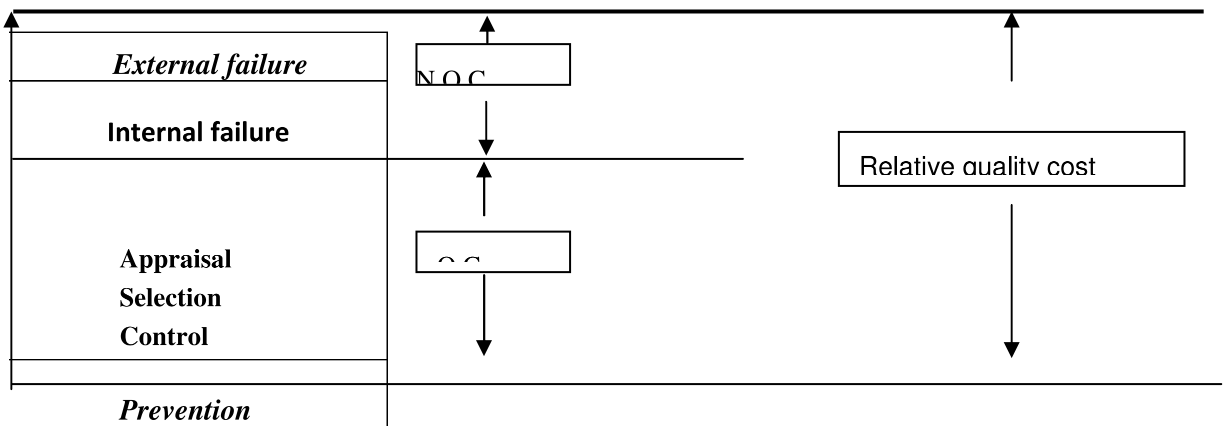

Fig. 1 Typology of quality costs (Rusu, C. and others, 2001)

NQC – non-quality costs; QC – quality costs/costs necessary to achieve quality.

2. Practical approaches of quality costs

Currently, the classic approach of quality costs, with its delimitation of the four categories of costs (prevention, appraisal, internal and external failure), is the most unanimously accepted one in the specialized literature, and especially in the economic practice. The European Organization for Quality – EOQ defines quality costs as costs representing *"the costs implied by the prevention and appraisal activities and by the loss caused by the internal and external failure ".*

The German Society for Management Systems (Deutsche Gessellschaft fur Managementsystemen) gives a similar definition: "quality costs represent the costs implied by the measures adopted in order to prevent defects, the quality appraisal and the internal and external failures ".

For a more convincing suggestion that these costs are avoidable, and that, in fact, quality "is free", lately, the usage of the expression "quality-related costs", instead of "quality costs". The new expression was also accepted in the 1994 amended version of the ISO 9000 family of standards.

Prevention costs represent the costs incurred with the efforts made to prevent the occurrence of defects. Costs implying the following are part of this category:

– product and process engineering;
– drawing up the quality management system and the quality system documents (quality planning, quality manual, quality system procedures, etc.);
– quality improvement programme;
– employee quality awareness and training;

- supplier evaluation;
- a comparative analysis of the quality of the company with that of the competitors;
- quality audit;
- process control (for example, by applying the statistical control methods);
- calibration of equipment;
- quality system implementation;
- other quality assurance measures.

The appraisal costs represent the costs incurred with tests inspections and checks performed to determine whether the specified requirements are met. A more suggestive definition of these costs is given by Vachette: "the appraisal costs represent all the costs incurred so that a non-conform product should not reach its internal of external client". This category comprises costs implying: inspections and tests of purchased materials and products, in-process inspections and tests, finished product acceptance, test equipment purchase and maintenance, laboratory tests, inspection and test documentation, inspection and test employees' wages, analysis of the inspection and test results, materials and products destroyed during tests.

The internal failure costs represent the costs incurred to correct all the non-conformities found prior to the product supply to the beneficiary. The costs determined by the following fall into this category:

- the volume of scrap;
- performing remedy, rework and repair operations;
- costs of reprocessing, re-treatment, repeating the tests;
- product downgrading costs;
- failure analysis, with the purpose of finding the cause;
- idle time (for example, downtime),
- non-conformance of raw material that was not found at its acceptance,
- additional operations to sort components in order to eliminate the non-conform ones.

The external failure costs represent the costs incurred for the remedy of the non-conformities found after the product supply to the beneficiaries.

The costs determined by the following fall into this category: customer complains , customer returns, product liability insurance premiums paid by the companies, damages, penalties for delays in deliveries, providing service and after-service, warranty replacements.

By definition, failure costs are caused by the non-conformance of products to the specifications, so they only represent material loss, but lately, there is an ever-increasing tendency of taking into account the immaterial losses even if they are more difficult to quantify.

3. Monitoring quality costs by means of key performance indicators
