Abstract: In the current context of economic globalization, financing through the capital market has become a modern alternative against financing through the monetary market, therefore investors shall be the main users of financial information.

Financial analysis has to be able to offer also to this category of users of financial information the adequate instruments to fundamental decision making of investing on the capital market through the so-called market ratios1.

Market ratios are the most comprehensive means of measurement of a company as they reflect the corroborated influence of risk and profitability financial ratios.

This paper issue the main market ratios calculated by the investors on the market capital by help of two types of analysis methods (fundamental and technical methods).

Keywords: Market ratio, investors, fundamental analysis, technical analysis, market capital.

I. Introduction. General approaches regarding the financial analysis on the capital market.

Market ratios are the most comprehensive means of measurement of a company as they reflect the corroborated influence of risk and profitability financial ratios.

These ratios are more important because they reflect the general confidence and trust of the **market** in a company's management, but said confidence and trust depends upon many economic, social, and political factors. Therefore, when investors fundament their decisions, they take into consideration a variety of indicators, not only internal performances achieved by a company, and established by analyzing the information reflected in its financial statements.

When choosing a certain type of investment, the factor that determines investors' decisions depends on the *horizon of interest* pursued in a certain company. Therefore:

- If the company's **development prospective** is pursued, respectively the **long-term horizon**, potential investors (or majority shareholders, in case of existing investors) shall be interested in the operating result that would generate an increase in the value of shares in the future.

[1] In related literature they are also called "profitability ratios of capital investments" – Bătrâncea I. Coord. "*Balance Sheet Based Financial Analysis"* Published by Presa Universitara Clujeana, Cluj-Napoca, 2001, pg.158, or "stock market yield ratios" –Buglea Al. "*Analysis of the Company's Financial Statements*", Published by Mirton, Timisoara, 2004, pg.160, or "investors' indicators" – Gaskin T. "*Perfect Financial Indicators*", Published by National, 1998, pg. 62.

- If **immediate gain** is pursued, obtained in a horizon of less than 12 months, i.e. a gain in the form of dividends distributed and gains from the differences in quotations, potential investors (or minority shareholders, in case of existing investors) shall be interested in the level of this type of gain.

II. Types of financial analysis on the capital market methods.

In either case of decision to invest on the capital market, current and potential investors as well as capital market professionals use two categories of analyses, namely: **fundamental analysis and technical analysis**

a)Fundamental analysis

This is made through a comparative study of ratios obtained by analyzing the financial statements. The end goal of this analysis is to select the shares that have an intrinsic potential to grow, thus creating the premises for the market to recognize in the future the real value of said company (the one resulting from the analysis) and consequently the price would rise.

It involves a calculation of market ratios by investors and capital market professionals in order to assess the company's potential to grow. Among the most widely used ratios can be mentioned:

1. Market capitalization (MC) is calculated by multiplying the current market price (CMP) of a share by the total number of shares issued by the company (NS), with the formula:

$$MC = CMP \times NS$$

Market capitalization represents the market value of a listed company and it reflects the public opinion on the net worth of the company, and it is a basic determinant in evaluation of shares. It does not always reflect the real worth of the company, as in case of take over and acquisition offers, when the company is assessed based on several factors that give value to its business.

Market capitalization is one of the best liquidity indicators; it reveals how easily can the company's shares be traded, especially from the prospective of an investor who invested large amounts of money in shares and whishes to know how easily can a counterpart be found if he wishes to sell said shares. This feature becomes extremely important when selecting the securities in a portfolio according to their market capitalization. From this point of view, companies are divided in three large categories: large companies (large-caps), medium companies (mid-caps), and small companies (small-caps).

Market capitalization is also the first indicator taken into consideration when the size of a stock exchange is in discussion, in which case it is referred to as the sum of market value (market capitalization) of all the companies listed on an organized market. Hence, market capitalization is one of the basic indicators characterizing a capital market.

2. Earning per share (EPS) indicates the net result produced by a share during the financial period.

$$EPS = \frac{\text{Net profit}}{\text{Number of shares}}$$

Investors can do the **interpretation** of the **EPS** indicator as follows:

- A ***high level*** of this indicator may reflect:
  - investors' trust in the company's management, or
  - a lack of investors' trust in the company's current management, but it is estimated that there is a possibility to transfer the company's assets to another company with a more reliable management.
- A ***low level*** of this indicator may reflect:
  - may indicate a lack of trust in the current management, or
  - the management is dealing with issues that cannot be easily overcome.

If the net profit is reinvested the indicator must show an increasing trend because the profit retained by companies are used to generate a higher profit.[2]

[2] Gaskin T., *Perfect financial indicators*, National Ed., 1998, page 64

Interpretation of this indicator and its significance in market analysis has certain **limitations**.

- *Measuring the performance in time:*
  - The indicator relies on historical profits. The management might have taken certain decision in the past in order to foster an increase of the current profit on account of future growth, such as reducing research and development investments.
  - This is the reason why reliable forecasts regarding the company's future growth rate cannot be based on EPS growth.
- *Measuring the performance in space:*
  - Profits are influenced by decisions of the management of different companies regarding accounting policies (e.g. depreciation method)
  - Earning per share is influenced by the capital structure of different companies (e.g. changes in the number of shares by issuance of shares with a premium)

3. Price-to-earnings ratio (PER or P/E) indicates how much are investors willing to pay per a monetary unit of earnings. It is calculated as the ratio of the company's current share price (or market value per share MVS) compared to its per-share earnings (EPS).

$$\text{PER (P/E)} = \frac{\text{MVS}}{\text{EPS}}$$

The PER indicator estimates the number of years during which the investment can be recovered assuming that the entire profit is distributed to shareholders as dividends (its is relevant especially when dividends are paid in cash).

The PER indicators show how much has an investor to invest in order to obtain a monetary unit from the company's profit.

Investors can do the **interpretation** of the **PER** indicator as follows:

- A relatively ***low PER*** indicates a cheap share, therefore adequate to be purchased.
- A relatively ***high PER*** indicates an expensive share that can also be overvalued.

Interpretation of this indicator and its significance in market analysis has certain **limitations**.

- In case of a static approach it is obvious that a share with a low PER is preferred against a share with a high PER. But the owner of a share is entitled to future incomes to the same extent as to current ones, and the current profit generated by the security can be very different from its future profits. In such a case, it is possible that a *share with a higher PER to be more profitable than a share with a lower PER* if there are possibilities for the profit and dividends to grow rapidly during the following operating periods. In such a case, a higher indicator level can be explained through the expected higher growth rate or a reduced risk.
- Therefore, in the PER analysis one also has to take into account the increase or decrease of the share prices in the future. Because investors are interested in the future achievements of a company, the historical PER becomes unimportant, and the *PER based on forecasts of future earnings becomes more interesting*.

4. Price-to-Book Ratio (P/B or PBR) is the ratio of the company's current share price (or market value per share -MVS) compared to the book value per share (BVS). It is another important ratio because it indicates the value conferred by financial markets to a company's management. It is calculated with the formula:

$$\text{PBR} = \frac{\text{MVS}}{\text{BVS}} \qquad \text{where,}$$

BVS = Equity capital / Number of shares = (Total assets – Debts) / Number of shares

Investors can do the **interpretation** of the **PBR** indicator as follows:

- If PBR ***is less than one***, it reflects a "safe" investment in that company, because it says that the book value is a "support" level of the market price. The book value is considered the level below which the market price shall not fall, because the company shall always have the possibility to liquidate or sell its assets at their book value. It is considered that ***a low PBR*** can ensure a “safety margin”, that is why many analysts avoid shares with a high PBR in the first stage of building a portfolio. They rely on the idea that if all other conditions remain similar for two different shares, than the share with lower PBR is safer.

- If PBR ***is above one***, i.e. the book value is lower than the market price, it might be an indication that the shares are overvalued, which is a signal to sell, that shall incur an adjustment by falling prices.

5. Price-to-Sales Ratio (P/S or PSR) reflects the ratio between the market value per share (MVS) and the net turnover (NTS) per share or is defined as the ratio between market capitalization (MC) and the company’s turnover (NT).

$$\mathrm{PSR} = \frac{\mathrm{MVS}}{\mathrm{NTS}} = \frac{MC}{NT}$$

For investors the **interpretation** of PSR come to complete the interpretations of the other indicators, as follow:

- In practice it has been proven that this indicator is more useful to identify non-profitable investments rather than discover profitable ones. Moreover, analysts who use this ratio state that it is especially useful in assessing companies with low profit or with no profit, especially because in such cases the PER indicator cannot be calculated.
- This indicator is useful when other indicators cannot be used, either because the company registered losses or because its profitability or margins are extremely low. Turnover based evaluation is relevant in situations when a company’s estimation is intended at a certain moment when it registers very small or negative margins, but it is expected that it will return to its normal activity or it will be taken over by another company.

As **limits** of PSR we can invoke:

- It is not recommended to compare PSR between different industrial sectors; instead it is useful to compare the ratios of companies with very similar activity or with the average of the sector.

Below are the average values of the most important market ratios for different business sectors from Romania:

Business sector	Average PER	Average PBR	Average PSR
Banking	30.54	3.31	1.63
Consumer goods	14.48	2.02	1.59
Chemical industry	30.06	1.27	1.14
Equipment	22.77	2.06	1.33
Pharmaceutical industry	27.25	2.54	4.06
Materials	15.03	2.21	1.20
Oil industry	12.43	1.28	1.10
Energy services and equipment	34.26	2.59	1.46
Tourism	35.83	1.74	8.05
Others	36.15	1.27	1.77
Financial investment and services	15.84	0.76	-
BVB average	20.08	2	-

Table 1: Average PER/PBR/PSR for the main business sectors from Romania

Source: authors’s adaptations after www.bvb.ro

From the table below one can see that PER is very high for tourism, energy services and equipment, banking, and chemical industry. In other words, investors' trust in these sectors is quite high. The opposite side is represented by the oil industry, consumer goods industry and materials sector, which have a low PER indicator.

When considering the PBR ratio, the highest value is approached by the banking sector, where the market value per share is three times the book value per share. The pharmaceutical industry and energy services and equipment have a PBR ratio of about 2.5. Upon analyzing the PSR ratio one can notice that tourism is above 8, followed at a great distance by the pharmaceutical industry with a ratio just above 4, whereas for the other fields this indicator is between 1 and 2.

b) Technical analysis

This type of analysis aims at gain targets obtained by investors on the short-term (within a few weeks or up to one year). It relies on identifying the collective behavior of buyers and sellers based on price charts based on which the immediate evolution of shares is estimated. Therefore, technical analysis does not strictly rely on the real intrinsic performances of a company but on the daily results offered by the ratio between the daily trading price and the volume of shares traded in that day. More exactly, these results consist in a series of measures determining trends, support thresholds, resistance thresholds, price averages for different time periods, issues that shall be referred to in this paper.

III.Conclusions

In practice, these two types of analysis are used simultaneously. Fundamental analysis gives information about a company's financial situation, whereas technical analysis indicates the most appropriate moment to buy. One can consider technical analysis a practical application of the fundamental analysis. In other words, fundamental analysis helps us **to select the securities** that we want to have in our portfolio and which are valuable from fundamental point of view, and technical analysis allows us **to determine the right moment** to buy those specific securities. These two categories of analysis are completely independent one from another, and their indications differ. Therefore it is more desirable to make a decision to buy when the indications of both categories converge.

A very synthetic presentation of the decision scheme to invest on the capital market is as follows:

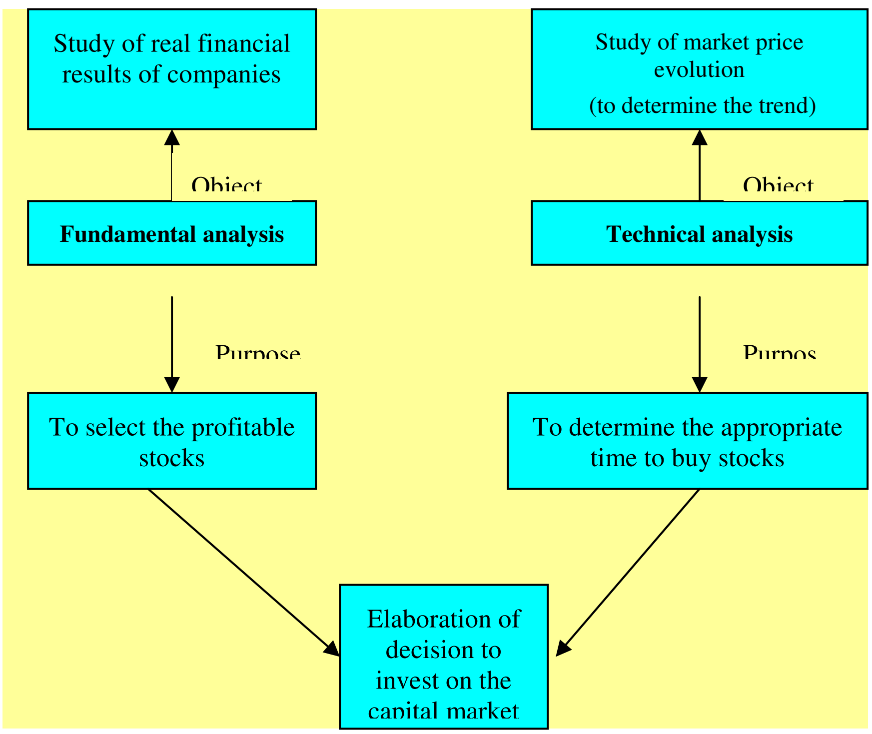

Figure 1: The scheme of the analysis of decision to invest on the capital market

THE INFLUENCE OF THE TAXATION POLICY ON THE ECONOMIC AGENTS ON THE EUROPEAN VIEW. THE DIRECT TAX – VALUE ADDED TAX

Antohi Valentin Marian

Galați, str. Tecuci, nr. 6, bl V5, ap. 22, Universitatea „Dunărea de Jos"Galați, Facultatea de Ştiințe Economice, valentin_antohi@yahoo.com, 07312210001

Abstract: The fiscal system acts upon all the enterprises, so, the influence upon the economic - financial performances appears at all the levels of the econimic agents. At first sight, the tax action upon economic - financial performances manifests in the same modality, regardless of the company which refers to. This standardisation of the way the tax policy acts upon the economic - financial performances of the companies starts from the idea that the law is the same for everybody. Really and truly , but not everybody understands the law in the same manner, not everybody can take advantage of some facilities (not always very easy to remark) offered by the law.

Key words: the taxes, the value added tax ,fiscality, economic – financial levers.

1. The use of the taxes as economic – financial levers

The state aims to collect financial funds for the budget instituing of the taxes. If we refer to economic agents, taxes, representing a drawing of financial funds from their disposal at state's disposal, have as effect the decrease of economic - financial performances. Leving taxes is, in conclusion, one reality of the contemporary economy. If we start from this idea, how is it actually posible that the taxes act as a factor of dynamic increase of the company's performances? One answer to this question can be given by the economic – financial levers point of view. These actions are taken by the state, and their goal is to fulfill some economic functions, contributing to solving some problems on economical bases rather than conditions in which would be appealed to administrative methods. Instauration of some legislative regulations in the fiscal area, which has a positive influence upon certain aspects of the economical activity becomes an economic lever.

Fiscal levers used for acting upon the increase of the economic - financial performances of the company don't have an imperative character for all the economic agents, but they don't enclose their possibility to benefit of them. To do this, economic agents have to fulfill certain conditions or to accomplish certain activities.

In the following lines, we will present a series of fiscal measures which had the role of economic – financial lever in Romania.[3]

Income tax represents one part of the company's profit which is transfered at state' disposal. However, through one series of regulations which were adopted during the last period of time, the income tax has the role of economic – financial lever, too.[4]

Allowing cutting down or exemption from income taxes aimed at a double benefit both for the state and for the economic agents, accordingly:

- allowing exemption from profit taxes for a certain period of time from the setting up of the company (starting with 1991 until 2006) intended, from the state point of view, to develop the private ecomonic field which can develop their activity, the tax being recovered afterwards, indirectly, as a result of increased taxation of some future profits. The benefit at the company was having at their disposal all the profit achieved, in this way providing additional cost-free financing.
- by cutting down with 50% of the amounts spent from the profit for the investment financing, which are meant to develop and modernize the manufacture technologies or to protect the environment (from 1991 until 2006), the state meant to influence in a positive way the

[3] Vacarel, I. si colectiv, Finante publice, 3rd Edition, EDP, Bucharest, 2004, p. 82

[4] Nemec Juraj, Wright Glen - Finanțe publice - teorie şi practică în tranziția central europeană, Ed. Ars Longa, Iaşi, 2000, p. 157

investment behavior of the economic agents and to make the invest towards environment protection. They meant to increase the competitivity between the economic agents, to increase the investments nationally, to protect the environment. The possible tax losses of the state could be made up for indirect taxes due to the increase of the expenditure (through acquisitions), for taxing future profits (increased as a resoult of the growth of the economic agents profitability), diminishing the expenses of environment protection. The economic agents benefit, through the decrease of the tax to be paied, from a additional, cost-free means of finance. In addition, the support of the investments, retechnologisation were meant to encrease the economic-financial performance of the economic agents.[5]

- cutting down the income tax for the economic agents who created jobs for the handicap persons, is for the state an economic-financial lever which can get to the integration of the handicap person in the professional environment (the benefit of the state is the reduction of the costs for their social protection). [6] As a result of these jobs the economic agents profit of an additional finance sourse, and by diminishing of the income tax the profitability rose.
- the practice of a low tax rate for the profit got as a result of customs taxes was a economic-financial lever by which the state wanted to increase the export and to bring foreign money currency into the country. The economic agents who exported goods could benefit after this facility with additional financing (the difference between the normal share and the reduced share) or with the possibility to establish low delivery prices
- allowing exemption from profit taxes for the economic agents which made important investments in economy and the state meant to increase capital invested in Romania, especially foreign resources, so thet the taxes were brought back indirectly from the taxes for salaries from the new jobs, from future taxes from well developed business.
- allowing exemption from taxes for agriculture was meant to develop the agricultural area in Romania, the development of the investments in this area, the economic agents benefting from a tax cut back.

Other economic levers which acted in the profit tax area were the possibility to choose one or the other method of liquidation, especially in profitable investments or the possibility to choose between profit tax, income tax (tax for the income of small enterprises), building free area of poor areas.

By using tax profit as a economic-financial lever, the state wanted to ensure a viable economic climate, the increase of investments, making new jobs, the development of export, the development of certain fields of activity, of certain geographic regions, left behind form the economic point of view.

The econimic agents'advantages were especially the possibility to benefit by additional source of autofinance, encrease of profitability, as a result of both the recuction of the profit tax to be paid and the creation of development premises as a result of new technology and means of production acquisition.

Still, we have to mention the fact that the tax reduction is diminished a lot nowadays because of the EU requirements to renounce to give tax reduction so that Romania can be a part of EU. [7] Also, the tax regime must be similar for all the economic agents.

Other categories of taxes have also been used as economic – financial levers. Thus, establishing some taxes excise on certain products categories has as a goal, beside collecting incomes for the budget, influencing consumers' behavior.

Practicing high customs duties has the goal to protect some branches of the national economy as consequence of prices increase at which the products can be commercialized in the country in which they are taxed (after 1990 there have been made pressures upon the Government, specially by the alimentary producers, for the customs duty increase in case of import products because they were comercialized on the intern market at lower costs than the intern products and, in this way, the effect could be the crush of the intern economic agents).

2. The use of regulation in the fiscal domain as administrative methods of influence on the economic agents performances

The intervention of the state through taxes upon economic – financial performances of the economic agents manifested as a consequence of adopting some administrative measures. Among other administrative methods with incidence upon comany's fiscality which acted or are still acting in Romania, we can remember: financial – fiscal control and the punishment of the tax dodging, applying some estimate methods established by state for fixed means, establishing a fixed means depreciation system**,** without taking into considerantion the specific characteristics of economic agents, granting exemption from taxation, prices reduction, postponings, spreadings of the tax paid for certain economic agents, making grants (negative taxes) etc.

Securing one efficient financial – fiscal checking can have as effect assuring a competitive climate from a fiscal point of view. Thus, economic agents who carry on their activity abiding the law can acquire higher financial – fiscal performances as a result of diminishing disloyal and illegal competition from economic agents who are not abiding by the law.[8]

Establishing some evaluation methods which doesn't take into consideration the profitableness brought by certain fixed means**,** but only their physical characteristics can lead in some economic agents case at overestimation, and in others' case at underestimation. In this way, influences on companies' economic – financial performances appear as a result of using reevaluation as an administrative method.

Making exemption from taxation, price reduction, spreading out again**,** postponing deadlines for paying taxes, making grants only for certain economic agents represents an administrative measure with positive effects on some economic agents, but with negative effects on business environment.

3. Grands regarding indirect taxes in European Union

3.1. Indirect taxes

Indirect taxes harmonization was one of the main objects of the European Union in the fiscal domain. Thus, the 93rd article of the constitution treaty of European Community asks to harmonize the turnover tax**,** excise and other indirect taxes.

3.1.1. Value added tax[9]

Value added tax was introduced in 1970 in European Economic Community by 1st and 2nd directives. It replaced different taxes on production and conpsumtion which burden commercial exchange between states. In 1977, through the 6th directive the foundation of value added tax harmonization in the EU states is established. Through this directive[10] a common assiette for this tax is established in the EU states. Also, this directive is no less than a law for the VAT foundation in the European Union.

As a result of the 6th directive the foundation of a working program towards the elimination of the borders for the VAT is established. The 6th directive was lately modified[11] to eliminate the fiscal borders and to adapt the VAT to the exigence of a gorder-less market. The changes established a VAT transitory system.

The elimination of fiscal borders required the harmonization of the VAT tax rate[12]. According to new stipulations establishd by 92/77/CEE directive, the EU members could apply the following VAT rate: normal tax or two reduced taxes. It was established that the normal VAT share should not be less that 15%, and the reduced shares should not be lower that 5%.

[12] Directive 92/77/CEE /19 October 1992

The reduced taxes can be applied to the products from Annex H in the 6th directive[13]. The increased taxes for VAT are removed, but in a transitory manner are still maintained: zero tax or super-reduced tax (lower that 5%). Also, it was established that for certain products (except the ones in Annex H[14] and for which the reduced tax is applied from 1st of January 1991) to be applied a reduced tax which should be lower that 12% (parking tax).

The Value Added Tax level in European Union on 1st of September 2004 is shown in Table 1.

Ungaria	-	5/15	25	-

Source: DGTAXUD, DOC/2008/2004 – VAT level in EU member states on 1st of September 2004

Compared to the European Union' forsights, Romania respects the regulations regarding taxing level: normal level 19% and reduced level 9%.

VTA taxing principle at European Union' level is the one of comsuption (goods' destionation), meaning the value added tax is gathered on delivery of goods and carrying out services in the state in which they are consumed. There are also tax obeied the importaions. This principle is regulated by Romanian legistaion[15].

In 1996, July, The Committee presented an acceleration programme[16] of passing from the transitory regim of VAT to final commom regime. There have been established one series of measures regarding VAT, basis tax, exonerating, national law principle etc. After the reticence of the member states regarding the suggested measures and the manner in which they can be approved, it was decided, in 2000, to be established a new long term strategy which would hint to ameliorate the VAT system functionality in the Common Market' cadre. This strategy regarding VAT[13] vises simplifing, modernizing, the unifrom application of the existing rules and a better administrative cooperation. In 2003 balance sheet[14] of the action programme achievements has been done (proposed in 2000).

Among the programme achievements there have been mentioned:

- annulment, after 1st of January 2003, of the possibility for the member states to impose to the intra-community operators the obligation to designate one fiscal official for the operations effectuated in other member states beside the ones in which they are settled;
- after 1 January 2003 all the tax payers (resident and nonresident) have the right to hand in a VAT statement in electronic form; it has been established the legal frame for electronic invoicing and electronic invoice storing;
- to carry out a proposal regarding the standardization of VAT reduced level and its sphere of activity;
- Romania, in the European Union integration context, intended to adopt a legislation according to EU' recommendation. In this way, true to European Union' negotioations, there have been adopted regulations regarding value added tax which come into effect at the date Romania integrated.
- The main reason for the introduction of these new regulatios is the following[17]:
- standardization of the legaslation with the one in the EU regarding intra-community agreements;
- to put in order the right to VAT deduction;
- to introduce the special regime for the agricultural producers, simultaneous with the remove of exemption from VAT for this activity;
- to introduce the special regime for the art objects, collection or antiquity, second hand goods, goods sold by public auction;
- special regime for gold investment;
- introducing new stipulations for VAT pay-back for the acquisitions made in Romania by taxable persons from the EU community and third party countries, elimination of exemption from taxes which are not conformable to the stipulations in the 6th directive of CEE (77/388), meaning: exemption for non-repayable founds given by international organism or foreign gouvernments; VAT exemption for commodity exchange; VAT exemption for veterinary medical care; VAT exemption for river transport for the citizens from the Danube Delta and from the areas of Orşova-Moldova Noua, Brăila - Hârşova, Galați – Grinda; exemption with the right of deduction of religious buildings; VAT exemption for the activity of research, development and innovation;

[15] See Law no. 571/2003 regarding Fiscal Code, later amended and completed
[16] This program has been carried on in five stages between 1996 and 1999. ; COM (2000)348. ^ COM(2003)614-Balance sheet of VAT stategy achievements
[17] www.mfinante.ro - establishment note amended Fiscal Code from 22 December 2004

- introducing tax exemptions allowed by the directive which are not stipulated in the national legislation, such as: VAT exemption for the construction delivery which are seen as new and land delivery; VAT exemption for the services carried out and deliveries of secondary goods made by the public mail service; VAT exemption for the teaching lessons carried out by teachers to help the scholastic or university environment; VAT exemption for postal stamps used inside the country.

For the good functioning of the VAT system in the European Union it was necessary to create a common information exchange system between the EU member states. This system is necessary especially in the case the provider of the goods and the ones who purchase the goods are in different states[18]. According to this system each member state must create a main department whose sole purpose should be the contact with the other member states and information exchange between them.

This department belonging to a member state can require to any other similar department of any other member state information necessary to a correct VAT evaluation. In the case the authorithy who was required information consideres necessary to make investigations in the VAT area, the representatives of the authority who required information can take part in these invastigations.

Also, the representatives of the departments of the states involved can take part in the common check-up when it is considered necessary that the investigation is made by the representatives of the authorities of both countries, rather than by the representatives of only one member state.

To make the information exchange more efficient every state member it must have an electronic data base which contains the information kept for a period of at least five years after the end of the financial year in which the events happened.

Having its roots in the French practice at the end of the 7th decade, 20th century, the value added tax is, nowadays, a fiscal lever which operates in all the European Union states, as well as in many countries outside the EU territory.

From the fiscal point of view, VAT has certain specific rules, which applies downstream upon the operation of the enterprise with its clients and the VAT exemption is admitted due to the upstream transactions with its contractors, while from the accountant point of view, VAT is neutral for the enterprise.

European Union directions are transposed in the Romanian laws through law 343/2006, and to change and complete law 571/2003 – Fiscal Code and intends to introduce the terms: intra-community good acquisition, intra-community delivery, intra-community transfer and intra-community non-transfer.

VAT is nowadays, one year after the adheration, an equation with „n" variables for the majority of the tax payers. This situation is maintained by the unstabile and hazy legislation, on the one hand, and by the persons responsible for giving the right answers, on the other hand.

PENSIONS INSURANCE SYSTEM IN ROMANIA AND IN EUROPEAN UNION'S STATE MEMBERS

Antohi Valentin Marian

Galați, str. Tecuci, nr. 6, bl V5, ap. 22, Universitatea „Dunărea de Jos"Galați, Facultatea de Ştiințe Economice, valentin_antohi@yahoo.com***, 07312210001***

Abstract: The actual socio-demographical and economical context of Romania - the ageing of the population, the reduction of the active population, macro economical problems and so; transforms social protection and pension system's efficient administration into a fundamental challenge not only for the actual governments but for the future ones. This unfortunate context becomes an alarming situation for the countries in a transition period, like Romania - incapable of finishing a pension reform, lack of vision and coherent strategies in field-, and also for the developed countries which are confronting with a growth lack of balance between available resources and those necessary for pension insurance.

Key words: pensions, reform, European, socio – demographical context.

1. Romanian pensions system

Social protection has lately become a sensitive subject in Romania, and also in European Union's member states. The actual problematic connected with slow economical growth, the spreading of unemployment, ageing, the lowering birth-rate, the reduction of active population and so, generate a powerful pressure upon the pension insurance system and also upon it's financing; social labor conscription can be regarded from different perspectives building itself as a crossroad area of pressures from many directions[1]:

- -derived pressure from social labor constriction's main function, that of population or its specified categories protection in front of some social risks; represent the main reason of the entire system;
- -derived pressure from the demands and standards of ensuring a balance at the macro economical level;
- -pressure from the productive sector, companies and employees, that carry the burden of social cost and labor; considered of affecting companies competitively and real employees incomes but also the labor market functioning.

Romania has a long life tradition in what concerns social- insurances, those being implemented since the beginning of XXth century, being among the first European countries that introduced at that time a compulsory insurance system.

Before 1989, the pension system in Romania situated itself at a comparable level with employee's incomes, except of farmer's pensions which were very low; the great majority of population was covered.

By pension system which was working without major financial problems, in the conditions of pensioner's dependence rate towards the low active population

After 1989, pension quantum was established proportional with the size of every citizen's contribution, using PAYG system that assumes a certain redistribution based on social solidarity principle between generations and between pensioners categories; but this redistribution(through establishing an extreme limit of pensions)disadvantaged the persons with high incomes.

[1] Maria Poenaru, „Prestațiile sociale în țările membre ale U.E. şi în România; Academia Română,2003

As a consequence among public pensions, now called the first pile which also exists in the European countries, social solidarity principle is maintained and compulsory contribution payment, even though their importance has decreased in favor of private pensions, the distortion between contribution proportions and those of the pensions being unjustified. This inequitable method has been preserved until 1st April 2001, when law 19/2000 has been adopted, law which represents the beginning of a late Romanian's pension system reform.

The main causes which determined these unbalances are made of:

- the low rate of economical activity and the alarming increasement of unemployment through out government's inefficient capitalization politics and the selling of many companies that represented the productive segment;
- the reduction of the liable to pay duties through the increase of unemployment and the establishment of social laws which assure different social professional systems without social insurance contribution payment;
- the increase of the number of pensioners due to the early retirement by avoiding the increasement of unemployment and also through laws resembling electoral and political capital;
- artificial increase of the number of pensioners due to the invalidity in suspect conditions, fraudulent or undiscovered;
- the inefficiency of contribution collecting system;
- the growth of tax dodging;
- the increase of inflation that that produced the cracking of pension's benefices;

All these causes, and also the inefficient politics adopted after 1989 inducted important financier unbalances in necessary resources for pension's allocation, and the Romanian pension system has confronted with series problems during the transition period[2]:

- the injustice of calculating retired person's pensions in different period of time;
- the postponement of pension system reform and its legislation instability;
- the reduction of liable to pay from over 8 million to approximately 4,5 million in present;
- the alarming increasement of retired persons (from 3, 5 millions in 1990 to over 6 millions after 2004);
- low collecting rate (the non-payment of some employers);
- undeclaring real incomes;
- low rate of covering the active population with pension insurances;
- postponing the introduction of some complementary solutions of collecting contributions;

Practically, because of the increase of elder population and of diversifying its specific needs.

A new balance between pension resources and other social insurances/other costs is needed through the increase of allocated resources and the reduction of exits, pension demands, and number of pensioners.

2. The necessity of reforming the Romanian pension system

Law 19/2000 marked the beginning of the Romanian's pension system reform. This new law has restriction the access at benefit by modifying the retirement age to 60 years for women and 65 for me (gradually until 2013), and the needed labor period of time: 30 years for women and 35 for men; the

[2] *Marian Preda, et al.-„Sistemul de asigurări de pensii în România în perioada de tranziție: probleme majore şi soluții", Institutul European din România, Bucureşti,2004.*

introduction of a more drastic control concerning infirmity pensions, early retirement restrictions, clear definition and the delimitation of working places in dangerous conditions

Nicholas Barr (World Wide Bank, 1995) adopts in 1995 the following conclusions regarding pension systems in the former communist's countries from Central and Eastern Europe:

1. *State pension reform in these countries is vital* since the actual PAYG system's costs will induce more accentuate financier deficits. We should take into consideration that systems, PAYG and those based on funds do not totally resolve problems. If in the first situation the social pressure is oriented towards pension quantum's increase, the second, as the experience from Latin America has proved us, refers to a problem based on the cracking of funds by the inflation
2. *The reform has to be as simple as possible.* Operating methods of financial markets and private pension funds management must have a high operational expertise and one of adjusting the system. Though former communist's countries are still on one hand, in lack of

these high qualified human resources in domain, on the other hand there are compulsions caused by limited institutional capacities. All these make the simplification of pension system's reform program necessary.

3. *Private pensions need a settlement system well organized.* The management of pension funds stands up complex technical problems which are poorly understood even by the west consumers. In this way, fund adjustment mechanisms and institutions are taken as they are by the countries which are reforming their pension systems, although developed countries as U.S.A or England are changing in present, after the appearance of some financial scandals connected with these funds.
4. *Private pensions require protection against inflation.* The problem of inflation represents a threat for the west doing the fact that it is more profound in Eastern Union where the experience of financial market functioning is low. So, the intervention of the state as guaranty becomes of great importance, the state being the one able to offer both direct guarantee but one based on the emission of indexed obligations. This intervention is based on the principle of horizontal justice: pensioners do not have to endure the risk of inflation more than employees should.
5. Western countries experience show us that the social pressures are more powerful for the state intervention in the direction of guaranteeing these funds and the pressures become even stronger when the funds are confronting difficulties.
6. *Reform requires political options.* The political decisions regarding the adjustment and the functioning of these funds provoke a series of questions and principle options concerning: social solidarity measure, the size of redistribution (minimal/maximal), the actors that endure the risks and risk division (employee fund and state), the adjustment system compulsion degree (how much liberty has the employee to chose?) and so.
7. *The introduction of reform* implies the development of institutional capacity: the involvement of specialists and functionary from the system's design phase, computerizing the records.

The system based on funds cannot be taken into consideration as a short term adjustment of budget crisis, but as a long term reform for the protection of elder persons.

Nicholas Barr previsions have proved themselves real referring to Romania and Eastern pension systems and they are current, the Romanian pension system must be reformed considering the actual characteristics and system's institutional possibilities, Romanian beneficial profile and also Western countries experience or that of neighbor countries.

In the actual demographical context, the ageing of population, the reduction of birth-rate, the financial pressures on pension systems lead to the search of new alternatives for the public pension system on medium and long term for guaranteeing financial sustainability and assuring higher pensions.

According to a study of "Social and Economical Affair Department", in O.N.U (2006) the population of Romania will have with a 17,5% proportion an average of age over 65 years in 2020, and in 2050 30% of the population will have over 65 years , as a consequence the necessity of expanding the actual pension system with two more pension sources(Pillar II and Pillar III) was born, supplementary at public state pension (Pillar I); that are built through participants individual contributions, being administrated by private companies, not like the old system based on generation solidarity of " pay as you go" type.

Alternative pensions have a serial of attracting characteristics as flexible retirement age individual's freedom on choosing, increasing life-hope, high capacity of handling risk and incertitude.

3. The integration of Romanian pension system in the European pension system

The actual reform of Romanian's pension systems must gather European Union's legislative tendencies. It is confronting in present with difficulties in its own pension systems that have as determinisms social and economical factors, which have lead in European Union at establishing a long and medium term of common measurements. As a consequence of Romania's demand of joining European Union, European Commission imposed to Romania several demands concerning the perspective of Romanian's pension systems in joining the European one:

- the increase of contribution collecting degree;
- the reduction of the system's financial crisis;
- the increase of PIB percentage destined for social insurances;
- the reduction of inequalities from the system generated by applying special pension laws for some socio-professional categories;
- the growth of coordinating capacities with E.U.'s social insurance systems;
- the actualization of social insurance laws concerning the transfer of rights and social insurance benefits in Romania and other states;
- the development of institutional capacities;

At the meeting which took place at Lisbon in 2000, The Europe Council has decided to form a Commission able to realize a study about member states pension system's sustainability and to propose solutions for resolving the unbalances (the Lisbon Strategy)[3].

A series of short term (2010) or long (2050) common measurements concerning the following strategic points were adopted:

1. The delivery of adequate pensions:

- assuring a decent life style for the retired persons;
- promoting solidarity among generations;
- supplying individual's access at public or private pension systems;

2. System's financial sustainability:

-public expenses with pensions are assumed to grow with 3-5% of PIB in most of EU's countries "between years 2000-2050" (15-20% of PIB in 2030) the following measures concerning system's sustainability were proposed:

- economical growth;
- the growth of skilled labor occupying rate from an economical growth of 3% from PIB, the medium employment rate should get until 2010 to 70% from the total active population (60% for feminine population) and to 83% until 2045- if the skilled labor occupying rate will grow according to this strategy, until 2010, the growth of public pension's expenses are to be reduced at a third in 2050;
- the growth of elder population's occupying rate (55-64) from 38, 5% to 50% until 2010 (retirement postponement);
- bringing qualified labor from countries in course of developing or under-developed ones;
- attraction women to enter and re-enter the labor market after a break of time period;
- the system's flexibility to allow women to work and to take care of the youngsters (the attempt of stimulating the growth of fertility);
- the recognition of years when the woman ends her work in order to take care of the new-born as bonus to the pension (2, 3 years);

[3] Adequate and sustainable pensions, Lisabona, 2000, www.en.int.org.

- adding one year to the pensioning age will absorbed approximately 20% of the medium forecasted growth of pension expenses from 2050;
- the harden of beforehand retiring conditions;
- the growth of retiring age with 5 years until 2010;
- equalizing the age of retirement for men and women to 65 years until 2020;
- adopting reserve funds in order to support the baby-boom generation's retirement;
- the growth of access for obtaining supplementary pension reducing in this manner the pressure upon public system;

- finding other financial resources for the public pension system, like eco-taxes;
- insuring the citizens that a long term contribution to the system will lead to higher benefits (to encourage the elder ones to remain on the labor market);

3. Re-newing pension systems as a response to the changing needs on the labor market:

Improving Pillar II system in order to enlarge the covering of mobile workers concerning the working place and the territorial one.

4.Conclusions

Analyzing Romanian pension system, as a consequence of diversifying its specific needs a new balance of pension resources and the reduction of system's problems through:

- enlarging resources allocated by PIB and attracting new supplimentary financial resources;
- the reduction of retirement demands, of infirmity and early pensions ,and the number of retired persons;
- creating and adopting long and medium term strategies regarding the assurance of life hope for elder persons;
- organising complete and efficient informational data bases;
- introducing a correct monitorising statistic indicators system, necessary for a highly competent analysis of pension system;
- a demographical politics based especially on the groth of birth rate;
- an adequate politics of immigration from certain areas and emigration towards some regions;
- recalculating the raports concerning fiscal burden; is needed.

No matter the type of the reform and the chosen solutions, we must find all the important measures to equilibrate the system through the participation of the entire Romanian and European society.

FISCAL AND ACCOUNTING ASPECTS REGARDING THE RELIGIOUS UNITS IN ROMANIA

Antonescu Mihail

University Spiru Haret, Faculty of Financial and Accounting Management Craiova, Mihail.Antonescu.DJ@mail.mfinante.gv.ro, 0740.223.764

Buziernescu Radu

University of Craiova, Faculty of Economy and Business Administration, radu@profcons.ro, 0722.350.573

Abstract: Taking into account the important role of the religious cults in the social life of a nation, the state, besides subsidizing from the state budget the activities unfolded as public use authorities, sustains the cult units by granting them certain fiscal facilities.

Thus, the religious cults acknowledged by law are exempted from paying the profit tax for revenues obtained from the production and capitalization of objects and products specific to cult units, but also for certain revenues obtained from unfolding economic activities. The capitalization of religious cult objects is also VAT exempted, as well as the payment of the tax on certain buildings and land in their patrimony.

For the unfolded economic activities, with some exceptions, the cult units are treated like the other economic operators.

Key words: religious cults, fiscal facilities, fiscal obligations, accounting activity

According to legal provisions[19], the religious structures with juridical personality are **cults** and **religious associations**, and the structures without juridical personality are **religious groupings**.

The cults recognized by law are juridical persons of public use. They are organized and function according to the law and on the basis of constitutional provisions, autonomously, according to their own statuses and canonic codes.

The component units of the cults are also juridical persons, as they are mentioned in their own statuses and canonic codes, if they comply with the requirements foreseen by them.

The state supports the cult units by granting them fiscal facilities, within the law conditions. The state also promotes the support granted to citizens of different cults by deductions from the income tax and encourages sponsorships towards different cults.

1. Fiscal facilities the cults units benefit by:

Religious cults are exempted from the payment of profit tax for the following incomes: incomes obtained from the production and capitalization of objects and products necessary for cult activity, incomes obtained from rents, other incomes obtained from economic activities, incomes from cash compensation, obtained as a result of reparatory measures stipulated by the laws regarding the reconstitution of the right of property. These incomes are tax-exempt on condition that the respective amounts are used, during the current year and/or in the following years, for the maintenance or functioning of cult units, for construction, reparation or consolidation works of cult places and of ecclesiastic buildings, for education, for supplying social services, for specific actions and other non-profit activities of religious cults.

Cult units are exempted from profit tax and for revenues from economic activities realized up to the level of the equivalent in lei of 15000 euros, in a fiscal year, but not more than 10% of the total revenues obtained from activities without patrimonial aim exempted from profit tax.

From the point of view of VAT, the delivery of religious cult objects (liturgical vases, metallic of lithographic icons, crosses, crucifixes, little crosses and medallions with religious images specific of the cult, religious calendars) are not considered economic activities. Decorative objects and objects for marriages or christenings are an exception from these provisions.

Services and/or deliveries of goods furnished by the members of the cult units in their collective interest are also tax-exempt, according to their own organization statuses and according to canonic codes.

---

[19] Law no 489/2006 regarding the religious freedom and the general cult regime, Off. M.11/08.01.2007.

There is also tax-exempt the furnishing of staff by the cult units in view of the following activities:

- hospitalization, medical care and other related operations, unfolded by authorized units for these activities, irrespective of their organization forms, such as: hospitals, sanatoria, centers of rural and urban health care, surgeries, medical laboratories, health care and diagnostic units, treatment and recovery centers, emergency stations and other authorized units to unfold this kind of activities;
- education, professional adult training, as well as services and deliveries of goods linked to these activities, unfolded by public institutions or by other authorized entities;
- deliveries of services and/or deliveries of goods linked to the assistance and /or to social protection, unfolded by public institutions or by other entities acknowledged as having a social character, inclusively those delivered to old age homes;
- deliveries of services and/or deliveries of goods linked to child protection and young people's protection, unfolded by public institutions or y other acknowledged entities having a social character.

Any energetic product purchased directly from the economic operators who are also tits producers, importers or distributors, used as fuel for heating the cult units, inclusively furnishing natural gas, is tax-exempt. The exemption is granted directly on the basis of the authorization of final user issued the territorial fiscal authority at which the cult unit is fiscally registered.

Cult units are also tax-exempt for:

- the buildings, which by destination, constitute cult places, except for the ones that are used for economic activities;
- buildings which constitute the patrimony of confessional education units and institutions, except for the places that are used for economic activities;
- funeral buildings from cemeteries and crematories;
- buildings retroceded to the Romanian cult units, according to the law;
- buildings used for humanitarian social activities, according to the local county's decision;
- any land of a cult unit acknowledged by law and any land of a local cult unit, with juridical personality;
- the land afferent to retroceded buildings, according to the law, during the period for which the owner is obliged to maintain the affectation of public interest.

By the syntagm buildings that, by destination, constitute cult places, we understand churches –places for prayer, houses for prayer – and their annexes. The term "lăcaş"/"religious place" is a variant of the word "locaş" (place).

The annexes of churches refer to any precincts that has constitutive elements of a building, the property of any cult officially acknowledged in Romania, such as: the steeple, the parish office, the holywaterfont, the mortuary chapel, the parish house and its outbuildings, destined as home for the priest/servant priests/serving personnel, the precincts for lighting candles, the table for selling candles, the crucifix, the warehouse for different cult objects, the social-charitable place, the xenodochium, the cell, the refectory, the precincts for unfolding administrative-religious activities, the kiriarhos' residence, as well as other activities linked to them; by social-charitable place we understand child care center, the old age asylum, the social refectory or any other precincts destined for similar activities.

2. The support granted to cult citizens

The tax payers who obtain incomes from wages or incomes assimilated to wages, can dispose on the destination of an amount up to 2% of the tax due in a fiscal year, for sustaining cult units.

The tax payers who obtain incomes from independent activities, incomes from yielding a good's use, incomes from agricultural activities determined on a real system, as well as the transfer of securities, from operations of buying-selling foreign currency at term can dispose on the destination of a sum representing up to 2% of the tax due in a fiscal year, for sustaining cult units.

The obligation of calculation, retention, and transfer of the 2% amount is incumbent to the fiscal agent within the area of activity of whom the tax payers have the fiscal residence, on the basis of the option exerted by the annual income declaration, respectively on the basis of the request of tax-payers who do not have the obligation of the annual income declaration.

3. Fiscal obligations of the cult units:

Cult units must pay a profit tax for the part of income subject to taxation that surpasses the exemption limit of 15000 euros or the part of the profit subject to taxation that corresponds to incomes other than those who are not subject to taxation. The incomes that are not taken into account for establishing the profit subject to taxation are the following:

- dues or members'registration fees;
- cash contributions or nature contributions of the members;
- registration taxes established according to the legislation in force;
- donations or cash or goods received by sponsorship;
- dividends and interests obtained from placing the disponibilities resulted from tax-exempt revenues;
- the resources obtained from public funds or from grants;
- exceptional incomes resulted from yielding corporal assets in the property of the cult units, other than those which are or have been used in an economic activity;
- the sums received as a result of non respecting the conditions in which the donation/sponsorship was done, according to the law, under the reserve that the sums in question are to be used in the current year or in the following years, for the achievement of the aim and of their objectives, depending on their own statuses and canonic codes, according to the case;
- the incomes obtained from compensations from insurance companies for damages produced on their own corporal assets, other than those which are used in the economic activity;
- the sums received from the income tax due by physical persons;

At determining the profit subject to taxation we must take into account the following elements:

1. the establishment of incomes that are not subject to taxation enumerated above;
2. determining the incomes that are not subject to taxation from economic activities, by following the next steps:
   - the calculation of the equivalent in lei of 15000 euros by the use of the average exchange rate EUR/ROL communicated by the National Bank of Romania for the fiscal year in question;
   - the calculation of the revenues which are not subject to taxation as being the least value of the amounts previously established;
3. the establishment of incomes that are not subject to taxation by adding sums from point 1 and 2;
4. determining the incomes that are subject to taxation by deducting from the total incomes those from point 3;
5. the calculation of the profit subject to taxation corresponding to the incomes subject tot taxation from point 4, taking into account the following:
   - the establishment of expenses in order to achieve the incomes subject to taxation from point 4. For this, it is necessary to use adequate keys to distribute common expenses;
   - the establishment of the deductible value of expenses determined according to the provisions of Article 21 from the Fiscal Code;

Cult units must declare and pay the annual profit tax, till the 15^{th} of February inclusively of the year following the one for which the taxation is calculated.

B. As regards to the value added tax, the cult units may be classified as being partially taxable persons, in case they perform simultaneously economic activities submitted to VAT and activities which are outside the VAT scope.

As partially taxable persons, the cult units may be registered for VAT purposes or may be exempted from the registration as being small enterprises on the grounds of art. 152 from the TAX CODE, in so far as their annual turnover is inferior to the limit provisioned at this article.

Cult units that unfold economic activities, whose annual business turnover is inferior to the limit of 35000 euros, are VAT-exempt. The equivalent in lei of the limit is established the exchange rate communicated by BNR at the date of Romania's integration into the EU. Cult units that begin an economic activity during the year and estimate that they will achieve a turnover inferior to the exemption limit can choose the application of the normal taxation regime. After being founded, if the turnover achieved during the year is inferior to the exemption limit they can choose at any moment the normal taxation regime.

If during the year the cult units achieve or exceed the exemption limit, they must request the registration with VAT aims in 10 days from the end of the month during which this limit was surpassed.

Cult units that request the registration in VAT aims will be given a registration code only for the activity for which they have the quality of tax payer, while for activities without patrimonial aim they will be given another fiscal registration code. Once it has been granted the registration code with VAT aims, this will be valid for any other operations subject to taxation, tax-exempt or without right to deduction that it will realize in the future.

Cult units that are registered in VAT aims for the whole activity unfolded till the 27th of March 208 must request the attribution of a registration code with Vat aims different than the fiscal registration code.[20]

The position of partially taxable person also generates particularities regarding the practical application of the VAT tax deduction right. Therefore, for the operations which don't belong to the VAT application scope, the cult units don't have the right to deduce the VAT aferent to the acquisition of goods and services.

In proportion to the nature of operations which constitutes the economic activity of the cult units, concerning the practical application of the right to deduce the VAT for the acquisitions of goods and services, the following situations stand out:

- the cult units have the tax deduction right for the acquisitions of goods and services designated to the taxable operations and exempted with tax deduction right
- the cult units don't have the tax deduction right for the acquisitions of goods and services designated to the operations exempted without the tax deduction right

Practically, it may lead to the situation when, for the economic activity, if it develops both operations exempted without tax deduction right and taxable activities and exempted with tax deduction right, the cult units may be considered mixed taxable persons. The mixed taxable person deduces on a pro-rate basis, the VAT aferent to the acquisitions of goods and services whose destination is unknown (respectively if they shall be used in order to accomplish operations which offer a tax deduction right or for operations which don't offer a tax deduction right) or for which it can not be determined the proportion in which are or shall be used for operations which offer a tax deduction right and operations which don't offer a tax deduction right. The partially taxable person may require the application of a special pro-rate if it can't keep separate records for the activity developed as taxable person and for the activity for which it hasn't the position of taxable person, on terms regulated by standards.

4. Organization and management of the accounting activity:

Cult units must organize and manage the accoutning of activities unfolded according to te accounting settlement s approved by the Ministry of Economy and Finances.[21]

Accounting settlements refer mainly to activities without patrimonial aim, inclusively activities with special destination, unfolded by juridical persons without patrimonial aim, and in subsidiary, to economic activities unfolded, according to the law, by these juridical persons. For unfolded economic activities, these settlements are completed with the accounting Settlements according the the IVth Directive of et European

[20] GD no 1579/19.12.2007 for the change and completion of the Methodological Norms of application of Law no 571/2003 regarding the Fiscal Code, approved by GD no 44/2004, Official Monitor 894/28.12.2007.
[21] OMFP no 1969/09.11.2007 published in the Official Monitor no 846 bis/10.12.2007

Economic Communities, approved by the Order of the Minister of Public Finances no 1752/2005, with changes and ulterior completions.

Cult units which also carry out economic activities must draft annual financial reports that comprise:

- the balance sheet;
- the account of the result of the exercise;
- explanatory notes to financial annual reports.

The accounting of incomes is carried out by types of activities, respectively activities without patrimonial aim, activities with special destination according to the law and economic activities, and within the framework of these activities on types of incomes, according to their nature.

The accounting of expenses regarding the unfolded activitiesis done on types of expenses , according to their nature, such as follows:

- exploitation expenses;
- financial expenses;
- extraordinary expenses.

Expenses with commissions, depreciation and adjustments for depreciation or loss of value, as well as the expenses with the profit tax and other taxes, calculated according to the law, are emphasized distictly, depending on their nature.

Within the framework of categories of expenses according to their nature, the expenses accounts are developed compulsorily in distinct analitics on types of activities, respectively activities without patrimonial aim, activities with special destination according to the law and economic activities.

Cult units that carry out exclusively activities without patrimonial aim manage the accounting in simple party. These units do not have to draw annual financial reports.

Conclusions: Even if cult units benefit by numerous fiscal facilities, we consider that these must be extended, taking into account the important role of the cults in social life. We first think of the exemption from the payment of the tax on the profit used in charitable or humanitarian activities. The VAT-exemption could be extended also for the delivery of other goods or services, as well as the tax-exemption within certain limits applied to products subject to taxation obtained from the processing of fruit and grapes from the orchards detained in the cult unit's patrimony.

Universitatea din Oradea, Facultatea de Ştiinţe Juridice, B-dul Magheru, nr.26, e-mail:diana.cirmaciu@rdslink.ro, tel.0359.407.256

Abstract: The local taxes and fees represent an important financing source of the local public needs. Indeed under the reform conditions of the local public administration, of the economical, social and cultural institutions, for the accomplishment of a real local; autonomy, a major objective is to assure sufficient financial resources, in proportion to the competences of the local and district councils.

Key-words: local taxation, building, taxable value, inventory value

The actual (ordinal) incomes of the local budgets from those countries, that have an economy based on liberal principles, are realized through some local taxes and fees.

The local taxes and fees (in generally, taxation upon belongings) are frequently used in all developed European states (for example in England, France, Germany, even if the specific "local" fiscality of this states is not free from tough critics towards the "poll-tax"/taxation upon citizens in England or towards "Gewerbesteuer" – GewST/the professional taxation, which represents approx. 50% from the local incomes in Germany).

It is asserted, for the controlled fiscality of the local budgets, that those taxes show usability and efficiency, which do not imply complicated fiscal procedures, those which present a high level of stability of the encashment by the respective budget.

The model of the local taxation used in Hungary has its legal basis in the fundamental regulation of the Constitution of the state. Thus it is estimated that the levy and collecting of the local taxes and fees represents the basic instrument to realize the local autonomy and implicitly the financial autonomy (to create and apply an own fiscal politics of that certain administrative-territorial unit).

According to the Romanian legislation[22] the following financial sources integrally represent the incomes of local budgets of the different administrative-territorial units (communes, cities, towns, the sectors of Bucharest, districts):

- Taxation upon buildings;
- Taxation upon lands;
- Taxation upon vehicles;
- Taxes for certificates, notifications and authorizations;
- Taxes for use of advertising and publicity;
- Taxes upon shows;
- Hotel taxes;
- Special taxes;
- Other local taxes;
- Amendments and penalties for the earlier mentioned local taxes and fees
- Interest for the late payment of the local taxes and fees mentioned in part I.

Different taxes and fees controlled by: Law No. 146/24.07.1997 regarding to judicial timbre tax, published in the Official Monitor of Romania No. 173 from 29.07.1997, with the ulterior modifications and

[22] Title IX "Local taxes and fees", art. 248 and Law No. 571/22.12.2003 published in the Official Monitor of Romania No. 927/23.12.2003 with the ulterior modifications and replenishments

replenishments; Law No. 117/30.06.1999 regarding to the extrajudicial timbre taxes, published in the Official Monitor of Romania No. 321 from 06.07.1999.

In our country, those persons who own buildings placed in Romania must pay every year the tax for these buildings.

According to the legal definition building is "any construction placed on the ground and/or under the ground, whatsoever name or utility it has, and which has one or more rooms, which can be used as shelter for humans, animals, objects, products, materials, installations, equipments and other things, and the structural elements of it are walls and roof, irrelevant what materials are these constructed from. The room represents the space from the interior of the building[23]". There are some buildings that that are free of this taxation, as follows:

- the buildings which are propriety of the state, of the administrative-territorial units or of any public institution, except those buildings which are used for economical purposes24;
- the buildings, which by the law are classified as historical, architectural or archeological monuments, museums, memorial houses, regardless of who the owner of the property or administrative right is, except those buildings which are used for economical purposes;
- buildings that through their destination are cult-houses, owned by religious cults approved officially in Romania, except those buildings which are used for economical purposes;
- the buildings that are the inheritance of the educational units and institutions belonging to the state, to religious cults or private units, which have provisional authorization or which are accredited, except those buildings which are used for economical purposes;
- the buildings of the public health units, except those buildings which are used for economical purposes;
- the funeral buildings from the cemeteries and the crematories;
- the buildings which are the inheritance of the Romanian Academy, except those buildings which are used for economical purposes;
- the buildings used for social-humanitarian activities by associations, organizations and cults, according to the decisions of the local council, etc.

In the Hungarian system, the taxable object is the building, so the tax is paid for the buildings. The notion "building" implies art objects too – monuments, etc., which can't be taxable object.

The object of the taxation is only the construction itself, the interior court with roof is considered to be construction too.

At the same time, taxable objects are considered to be the annexes too.

The Hungarian legislator underlines too the importance of classification of buildings from the point of view of the obligation to pay taxes. Also we have the followings: ♦ buildings designated for housing, residence is considered to be that building, which according to law can be classified in comfort groups and exists in the immobile evidences as residence; the notion of residence is important in case of remission of taxes, because the majority of the local public administrations foresee the tax remission for the residence – and ♦ the buildings for other purposes as residence, like offices, commercial centers, factories, garages, etc.

The Romanian law from the point of view of taxation makes a difference between the evaluation method of the buildings which are owned by private persons and those which are owned by juridical persons, so that:

- In case of private persons the tax is calculated with the use of a taxation level of 0,1 % of the *taxable value*[25] of the building.

---

[23] Art. 249 paragraph 5 from Law No. 571/2003 regarding to the Fiscal Code

[24] Through the notion "used for economical purposes" we understand all the places used in commercial purposes, how these are defined in the content of article 3 of the Romanian Commercial Code.

[25] The taxable value of the building, established in RON, is calculated through the multiplication of the constructed surface, established in square meter, with the taxable value established in RON/m² in the content of article 251, paragraph 3 of the Fiscal Code.

– In case of juridical persons, the building tax is calculated with the use of the *taxation level*[26] upon the *inventory value*[27] of the building.

The same way like in the Romanian law, in the Hungarian law, the subject of the building taxation is the owner – that private or juridical person which exists in the evidences of the National Land Register and Immobile Publicity Office as owner. In case of attaining the building through succession, the successor must pay the tax beginning with the next year after the decease of the testator. In case of co-owners, the society of owners supports the costs of the building taxation, according to the percent of property (rule introduced by Chapter XII, article 141 from the Hungarian Civil Code).

The categories of tax remissions are established in a different way in the Hungarian legislation, considering some remissions of certain residences or remissions offered according to the person of the tax-payer. In the first category we can give as example: tax remissions for the residence of some social categories which have financial difficulties – which have suffered in a disaster, etc. when these are existing in the registers in such way; residences without comfort in smaller locations, which are not considered locations for repose, treatment, being placed in small human locations, which have no more than 500 inhabitants – for these residences is offered a tax remission for 100 m². In the second category we can mention the tax remission offered to public authorities, religious cults for the churches.

The Hungarian local administration had established two different ways to calculate the building taxation. This way we have: ♦whether the calculation of the used surface established in m², upon which it is applied a level, which maximal limit is 900 ft/m², ♦ or the taxation with 3% of the stated value of the building or construction[28].

In Romania, the annual taxation upon buildings must be paid in two equal rates, until the dates 31 March and 30 September, to the local budget of the administrative-territorial unit, where the building is located. For the advanced payment of the whole amount of the building taxation until 31 March, it is offered a discount of even 10%, established by the decision of the local council. The annual building taxation under the value of 50 RON inclusively, must be integrally paid until the established legal term.

Finally, we must stop upon a particularity of the Hungarian legislation from the studied domain, which consists in the possibility to request the abeyance/postponement, even for an unlimited period of time of the payment of building taxes. This postponement is conditioned by the final payment of some interests, the quantum of which will reflect the interest rates of the central banc. This option can be chosen by the aged persons with low incomes, persons with handicaps – owners of immobile, used as residence. The total value of the tax will be finally paid, in case when the immobile is sold or when the owner deceased – case in which the costs must be supported by the successors, or whenever the owner request it.

As a conclusion, the building taxation is levied in the majority of the European states, in most cases by the local communities.

[26] The level of the taxation is established by the decision of the local council and it can be between 0,25% and 1,50%.

[27] Through the notion "the inventory value of the building" is expressed the value of the building when it was obtained, registered in the accounting system of the owner, being referred whether to the buying costs for the buildings obtained with onerous title, or the cost of production, for the buildings constructed by juridical persons.

[28] Taxation system rarely used, in this moment approx. by 5 administrative-territorial units is used

DECISIONS REGARDING THE FINANCIAL STRUCTURE OF THE COMPANY

Abstract: The paper presents the relevant aspect regarding the analysis of entity's decisions in the conditions of equilibrium. The authors show the importance of using the indicators in the context of elaborating financial decisions.

Key words: financial policy, leverage effect, financial profitability

1. Introduction

Creating the financial policy, organizing and leading the activity in this field, implies the elaboration of the leadership strategy and a direct practical activity.[29]

Elaborating the general strategy and on areas of financial policy is concludes by adopting certain decisions with normative character, highly strategic, while the leading of the financial activity itself is made through strategic, tactic and operational decisions.[30]

Framing the financial decision in the broader process of financial policy, Professor Constantin Tulai believes that, in the field of finances, *decision* represents an option with executive character make to ensure the transformation of the strategic solution chosen in direct action. Its object is the formation of financial funds, they repartition according to each destination, their rational use and, in the case of economic agents, also the distribution of profit.[31]

2. Method and Results

In our opinion, in the decisional process regarding the financial structure of the company, an important role is held by the leverage effect through which we understand the positive or negative financial result obtained by the company, as a result of using credits as capital. This effect is obtained by comparing the economic profitability of the company (R_e) with the cost of borrowed capital (d).

If $R_e > d \rightarrow$ positive or favorable leverage effect;

If $R_e < d \rightarrow$ negative or unfavorable leverage effect.

$$Leverage\ effect = \frac{Debts \times (Re - d)}{Shareholders'\ equity}$$

So, the leverage effect finds itself in a direct relation both with the financial structure and the difference between profitability ratio (R_e) and interest ratio (d), on the one hand and with the borrowed capital with on the other hand.

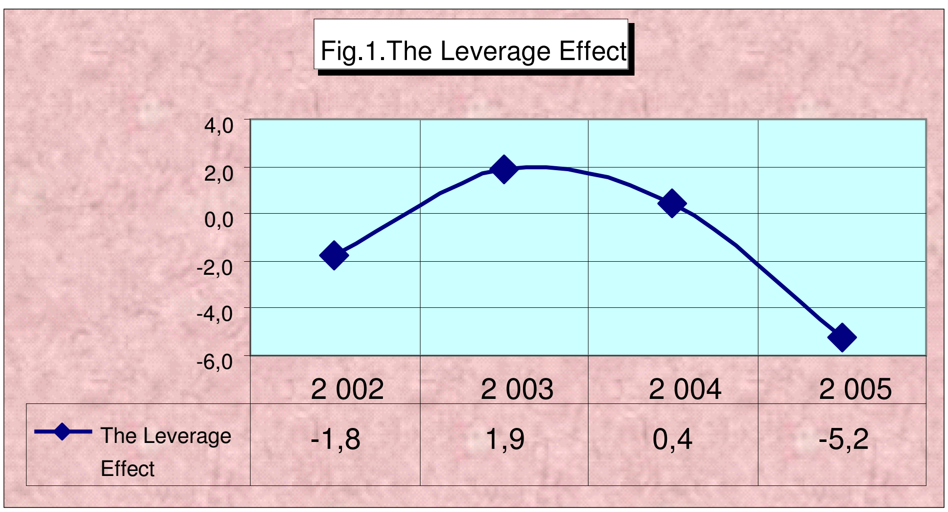
Leverage Efect	-1,8	1,9	0,4	-5,2

Table 1 - The Evolution of the Leverage Effect with SC MARA SA



Both from the above table and from above figure we may notice the effect produced by the leverage on SC MARA SA. In the financial periods 2002 and 2005, the leverage effect transformed in boomerang effect negatively influencing the financial standing of the company. During 2003-2004, leverage was benefic, contributing to the improvement of the financial situation of the company, as well as of its performance.

Adopting a decision regarding the financial structure of the company refers to two coordinates:

- On the one hand, determining the report between permanent capital and short term capital and

– Determining the proportion of each source of permanent capital (shareholders' equity and long term credits) in the total of the balance sheet liabilities (capital structure), so that it would enable the maximization of the company's value.

So, the capital structure signifies the composing elements of permanent funds available to a company. The importance of the capital structure results from the role *leverage* has on the financial profitability (Rf) that is *the profitability of shareholders' equity*, as well as on *the financial risk of the company*, as results from the model below:

$$B = Re *A - d *D = Re(C_p + D) - d*D$$

$$Rf = Re + (Re - d)\, D/ C_p$$

$$\text{But } r_L = D/C_p$$

Then:

$$Rf = Re + (Re - d)\, r_L$$

The leverage effect can be extracted from the above relation as follows:

$$E_L = (Re - d)\, r_L$$

where:

Re = Economic Pprofitability (Benefits/Total assets);

Rf = Financial Pprofitability (Benefits/Shareholders' equity);

A = Total Assets (from the Balance Sheet);

B = Profit generated by the company;

C_p = Shareholders' Equity;

D = Total Debts of the company;

d = Interest Ratio at a monetary unit (d/100);

r_L = Financial Leverage Ratio;

E_L = Financial Leverage Effect

Indicator	**2 002**	**2 003**	**2 004**	**2 005**

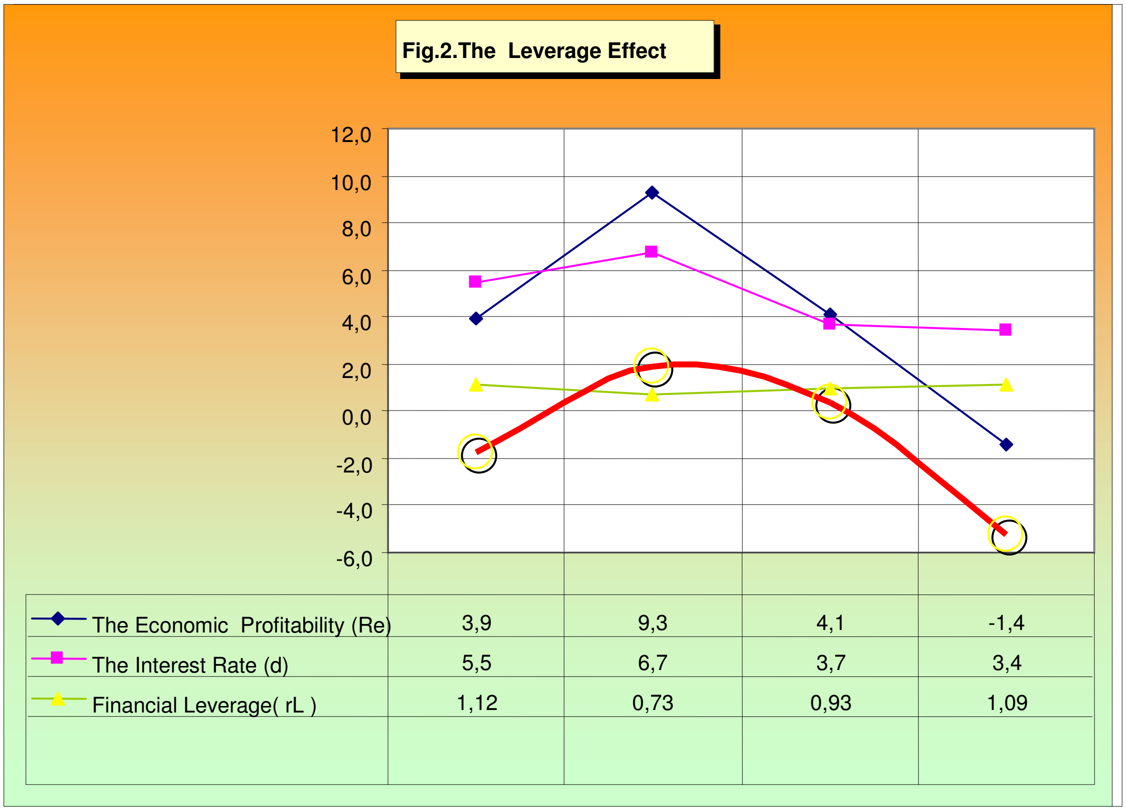
Financial Leverage Ratio ($r_L = D/C_p$)	1,12	0,73	0,93	1,09

The Financial Profitability $Rf = Re + (Re – d) r_L$	2,10	11,20	4,47	-6,64

Indicator	2 002	2 003	2 004	2 005
Economic Pprofitability (Re)	3,9	9,3	4,1	-1,4
Interest Ratio (d)	5,5	6,7	3,7	3,4
Financial Leverage Ratio (r_L)	1,12	0,73	0,93	1,09
Leverage effect (EL = (Re – d) rL)	-1,79	1,90	0,37	-5,23

Table 2 -The Evolution of Financial Pprofitability with SC MARA SA



From the graphic representation above we may notice that due to a higher interest ratio in 2002 and 2005, the leverage effect with SC MARA SA recorded negative values, an aspect that we believe to have created a financial instability from the point of view of the investors.

3. Conclusions

The decision regarding the financial structure depends on each company, on its objectives of economic growth, on the foreseen profitability level and on the risk that the company agrees to assume, but also on third parties, that is shareholders, banks and other creditors, on the state as well as on the economic circumstances (position of the financial market, oscillations of the interest ratio, monetary devaluing etc).

At same time, we consider that a negative leverage effect will create financial instability, a lack of financial autonomy and a non – financial equilibrium on the short run.

Abstract. In this paper, the authors present the method of evaluating the effect of taxation on the financial equilibrium of the company.

Key words: working capital, working capital requirement, net treasury, net standing.

1. Financial diagnosis- the evaluation method of the company's equilibrium

The financial diagnosis is a group of instruments and methods which enable the appreciation of the financial standing and the performances of a company.

The purpose of the financial diagnosis is of evaluating the financial standing of the company. Basing on this diagnosis, there takes place the creation of a new strategy of maintaining and developing in the local economic environment. In a general sense, the finality of the financial diagnosis consists of providing financial information both to those inside the company and to the interested ones from outside the company.

When the issue of the diagnosis occurs inside the company (internal financial diagnosis), the users may be the leaders, current shareholders or employees. The objective is, in this case, to detect the possible situations of financial instability and to adopt new decisions concerning the administration of the company. These decisions are based on the identification of the origins and causes of the lack of balance and, on the other hand, on the determination of the curative measures.

When the issue occurs outside the company (external financial diagnosis), the users may be financial analysts, potential shareholders, banking and financial institutions or even the state. The objective pursued is the company's financial capacity of generating profit, the company'c capacity of paying its short term or long term obligations (the liquidity nad solvability of the company), as well as the company's value.

External users usually require a financial diagnosis either for crediting the company (especially banks), or for making the decision of entering the capital of a company (potential shareholders or other companies).

Both the internal and the external analysis have the objective of appreciating the performances of the company and the risks it faces and they refer to: profitability analysis, risk analysis and company's value analysis.

Irrespective of the results obtained by the company or of the unfolding of the events, the making of a financial diagnosis has to take place on a periodical basis. The financial diagnosis identifies the favorable and unfavorable factors that will influence the future activity of the company.

The information resulting from the financial diagnosis often have to be completed with information referring to the external milieu of the company (standing of the economy, of the industry), information referring to the technical and human potential, commerical and juridical potential , the company's management (information depending on companies). All these elements influence the financial performances of the company and determine its competitive nature.

The information required for making the financial diagnosis are taken from the simplified financial statements that include: balance sheet, profit and loss account, annex to the balance sheet.

2. The double meaning of taxes in the case of the economic unit

From the definition there can be extracted the following characteristics of taxes:

1. the compulsory nature of paying taxes and, in relation to this, their legality and legitimacy;
2. tax is a take over without equivalent and, in relation to this, there occurs the issue of the reversibilty of taxes and their redistributive role;

3. taxes’ fundament and measure is the contributive capacity of each tax payer;
4. the double quality of taxes: resources for covering public expenses and fiscal leverages used by the state.

Stating that tax has as main purpose the overing of public expenses and to sustain the primary nature of its financial purpose implies the explict determination of al least four things:

- tax has a financial purpose: obtaining the necessary resources for covering public expenses;
- tax also has other purposes, also referring to the fulfillment of certain economic or social objectives;
- its objectives may be contradictory, therefore they must be harmonized;
- among its different objectives, the most important is the financial one.

Taxes have a double quality as far as the financial equilibrium of the companies or tax payers is concerned. Under this hypothesis, taxes represent, on the one hand, an expense for the companies or tax payers and, on the other hand, they represent their debt or obligation.

The development of the company is related to the ensurng of the economic equilibrium expressed as a value. The financial equilibrium expreses the equality and correlations between the required financial resources and the possibility of collecting these resources. The financial equilibrium of the company implies the covering of all the operational expenses out of own or borrowed incomes, of the expenses not shown in costs, of the development and modernization expenses, of the expenses with personnel and shareholders incentives, as well as of the contractual and financial obligations towards banks and state budget.

The activity of a company has to be performed so that there is ensured an equality among financial resources (R) and their use (F), so that R=F.

The financial resources (R) of a company may be made up of incomes resulting from the basic activity and from other activities (V), financial incomes (Vf), extraordinary incomes (VE), liabilities of operation and those from the investment sector (Pe), bank and other financial institutions credits (C) and new cash contributions of shareholders and other resources (Ar), so that:

$$R = V + Vf + VE + Pe + C + A + Ar$$

The uses of resources can be represented by clients inventories and assimilates (S), expenses with personnel and other salarial rights (Ce), expenses with investments and modernization (Ci), research and development expenses (CE), non deductible expenses (Cn), payment of obligations to the state as taxes and the contributions to the social insurance budget (imp), payment of credits and corresponding interest (Rc) and other expenses (Ac), so that:

$$F = S + Cp + Ci + Ce + Cn + Imp + Rc + Ac.$$

Taking into account the financial resources and their use, the financial equilibrium of the company is presented through the following equality:

$$V + Vf + VE + Pe + C + A + Ar = S + Cp + Ci + Ce + Cn + Imp + Rc + Ac$$

Taxes may influence the financial equilibrium of the company. Taxes represent a factor of influence over the financial stability of a company as far as the two aspects analyzed – expense and debt- are concerned.

3. The effect of taxes on the net standing

The net standing calculted as difference among total assets and total debts provides a first (accounting) evaluation of the company at the end of the financial period. This fundametal equation of the balance sheet represents the net wealth of the shareholders, respectively the asset not engaged in debts.

Indicators	Period			
	S_1	S_2	S_3	S_4
Total assets	10.000	10.000	10.000	12.000
Debts	3.000	4.000	2.000	3.000
Out of which taxes	1.000	2.000	500	1.800

Net standing	7.000	6.000	8.000	3.000
Variation of net standing	x	6.000	- 2.000	1.000

NET STANDING = ASSET – DEBTS

The net standing presents an increase or decrease in timpe, a fact that signifies the increase or decrease of shareholders' equity.

Analyzing the due taxes, we may say that the increase, respectivley decrease, of the taxes included in total debts influences with a positive or negative effect the net standing of a company and, consequently, its financial equilibrium.

During the S_2 period with increased debts on the account of taxes, the net standing of the company decreases. Under these circumstances, the debts and expenses of the company increase and we may notice a fiscal pressure.

Net statement S_2 = 10.000 – 4.000 = 6.000

During S_3 period with the decrease of debts on the account of taxes, THE NET STATEMENT of the companies increases. Under these circumstances, the expenses and the debts of the companies decrease and we may notice a fiscal relaxation.

The net statement S_3 = 10.000 – 2.000 = 8.000

During the S_4 period, when the value of the asset is determined by other factors but from total debts we notice a increase of taxes. Under these circumstances, even if the net standing records an increase, we may say that the fiscal pressure is positive as compare to S_1.

Net statement S4 = 12.000 – 3.000 = 9.000

4. Working capital, measure of the financial equilibrium

In order to accomplish the financial equilibrium of the company, it is necessary to respect the principle of maturities parity according to which permanet allocations (intangibles) have to be financed on the account of permanent sources (shareholders' equity and long term credits) due to their slower rotation; cyclical allocation (non current assets) are financed on the account of the temporary sources (short term liabilities).

The higher permanent sources are as compared to permanent requirements of funds allocation, the more the company enjoys a security margin, which protects it from unforeseen events.

This surplus of permanent resources, resulting from the financing cycle of investments, may be rotated for renewing inventories and account receivable. This potential use is responsible for its name, which is working capital. It expresses the long term financial equilibrium and its contribution to the accomlishement of the equilibrium of short term financing.

WORKING CAPITAL = PERMENENT SOURCES – PERMANENT ALLOCATION

Working capital = (Shareholders' equity + Financial debts) – Net amortization non current assets.

INDICATORS	S1	S2	S3	S4
SHAREHOLDERS' EQUITY	790.000	802.000	925.000	1.123.000
FINANCIAL DEBTS	0	0	0	12.000
NET NON CURRENT ASSETS	800.000	839.000	972.000	1.160.000
WORKING CAPITAL	- 10.000	- 37.000	- 47.000	- 25.000
WORKING CAPITAL VARIATION		- 26.000	- 10.000	22.000

FR S1 = (790.000 + 0) – 800.000 = - 10.000

FR S2 = (802.000 + 0) – 839.000 = - 37.000

FR S3 = (925.000 +0) – 972.000 = - 47.000

FR S4 = (1.123.000 + 12.000) – 1.160.000 = - 25.000

FR VARIATION S2/S1 = - 37.000 - (-10.000) = - 26.000

FR VARIATION S3/S2 = - 47.000 - (-37.000) = - 10.000

FR VARIATION S4/S3 = - 25.000 - (-47.000) = 22.0000

The negative value of the working capital reflects the absorbtion of a part of the temporary resources for financing certain permanent needs, contrary to the principle of financial administration: to permenent needs there are allocated permanent sources, so that long term allocations are finances by short term resources. These situations may be less unfavorable if the company leads an investment policy – an orientation towards development. At any rate, a negative working capital has serious effects on treasury and payment capacity.

During the S_4 period, there may be noticed a tendency of improving this long term lack of balance, thw working capital, even if still negative, is half the value of that of the preceding year; the company better administers the resources attracted from shareholders or creditors.

5. The need of working capital – way of reflecting the financial equilibrium.

It is the expression of the short term financial equilibrium, of the equilibrium between the requirement and use of operational capital.

NFR = CYCLIC ALLOCATIONS – CYCLIC SOURCES

NFR = (INVENTORIES + ACCOUNTS RECEIVABLE) – OPERATIONAL DEBTS

INDICATORS	**S1**	**S2**	**S3**	**S4**
INVENTORIES	75.000	49.000	27.000	54.000
ACCOUNTS RECEIVABLE	88.000	820.000	71.000	61.000
DEBTS	330.000	653.000	1.053.000	963.000
NFR	- 167.000	- 522.000	- 955.000	- 848.000
NFR VARIATION		- 355.000	- 433.000	107.000

NFR S1 = (75.000 + 88.000) – 330.000 = - 167.000

NFR S2 = (49.000 + 82.000) - 653.000 = - 522.000

NFR S3 = (27.000 + 71.000) – 1.053.000 = - 655.000

NFR S4 = (54.000 + 61.000) – 963.000 = - 848.000

NFR VARIATION S2/S1 = - 522.000 - (-167.000) = -355.000

NFR VARIATION S3/S2 = -955.000 - (-522.000) = -433.000

NFR VARIATION S4/S3 = - 848.000 (-955.000) = 107.000

NFR is negative. There is a surplus of temporary resources, this standing is accepted only if it results from the increase of the rotation speed of current assets and the engagement of debts with more relaxed due times. Otherwise, it implies the inadequate administration of inventories.

6. Net treasury – form of reflecting the monetary resources of the company

Net treasury represents the difference between the working capital and the required working capital.

Net treasury is the most conclusive expression of the unfolding of a balanced and efficient activity. It indicates the quality of the general equilibrium of the company both for long and short term.

TN = WORKING CAPITAL – REQUIRED WORKING FUND

INDICATORS	S1	S2	S3	S4
WORKING CAPITAL	- 10.000	- 37.000	- 47.000	- 25.000
WORKING CAPITAL VARIATION		- 26.000	- 10.000	22.000
REQUIRED WORKING CAPITAL	- 167.000	- 522.000	- 955.000	- 848.000

REQUIRED WORKING CAPITAL VARIATION		- 355.000	- 433.000	107.000
NET TREASURY	157.000	458.000	908.000	823.000
NET TREASURY VARIATION		- 328.000	423.000	- 85.000

Net treasury is positive for all the years, showing that the financial periods ended with a monetray surplus, the real expression of net profit from balance account liability anf other monetary accumulations. The increase of net treasury in S_3 as compared to S_2 and, respectively, the decrease in S_4 as compared to S_3 represents the cash flow which goes to the shareholders as dividends to be cashed and/or profit to be reinvested.

7. Intermediary administration balance account – modalities for reflecting the company's efficient activity

TRADE MARGIN = GOODS SALE – COST OF THE SOLD MERCHANDISE

INDICATORS	S1	S2	S3	S4
GOODS SOLD	2.000.000	1.999.000	3.250.000	3.761.000
EX. WITH MERCHANDISE	1.300.000	1.200.000	1.695.000	1.642.000
TRADE MARGIN	700.000	799.000	1.555.000	2.119.000

PRODUCTION OF THE PERIOD = PRODUCTION SOLD +/- PRODUCTION RETAINED + INCOMES FROM PRODUCTION OF NON CURRENT ASSETS

INDICATORS	S1	S2	S3	S4
PRODUCTION SOLD	12.431.000	14.000.000	1.985.000	25.650.000
PRODUCTION RETAINED	0	27.000	116.000	117.000
INCOMES FROM PRODUCTION OF NON CURRENT ASSETS	2.195.000	3.286.000	3.700.000	3.546.000
PRODUCTION OF THE PERIOD	14.538.000	17.313.000	23.401.000	29.313.000

ADDED VALUE = TRADE MARGIN + PRODUCTION OF THE PERIOS – CONSUMPTION FROM THIRD PARTIES

The added value expresses the increase in the value resulted from the use of the production factors, especially work and capital, over the value of the materials, energy, services purchased from third parties. This added value represents the source of monetary accumulations out of which there is made the remuneration of the direct and indirect participants to the economic activity of the company: personnel, state, creditors, shareholders and company through the capacity of financing itself.

INDICATORS	S1	S2	S3	S4
TRADE MARGIN	700.000	799.000	1.555.000	2.119.000
PRODUCTION FOR THE PERIOD	14.538.000	17.313.000	23.401.000	29.313.000
CONSUMPTION WITH THIRD PARTIES	6.989.000	7.555.000	8.617.000	9.834.000
ADDED VALUE	8.849.000	10.557.000	16.338.000	21.598.000

GROSS SURPLUS

FROM OPERATIONAL ACTIVITIES (EBE) = ADDED VALUE

+ SUBVENTIONS

- EXPENSES WITH THE PERSONNEL

- TAXES

INDICATORS	S1	S2	S3	S4
ADDED VALUE	8.849.000	10.557.000	16.338.000	21.598.000
INCOMES FROM SUBVENTION	0	0	0	0
EXPENSES WITH TAXES	79.000	237.000	992.000	1.342.000
EXPENSES WITH THE PERSONNEL	1.298.000	2.325.000	3.922.000	3.730.000
EBE	7.472.000	7.995.000	11.424.000	16.526.000

EBE expresses the gross accumulation from the operational activity, taking into account the fact that anortization and provisions are only expenses calculated, not paid. EBE expresses the potential capacity of self financing investments (from amortizations, provisions and profit), paying the debts to the state budget and remuneration of capital investors (shareholders and creditors).

The self financing capacity expresses a financial surplus resulting from the profitable activity of the company. It has only a potential character if not sustained by effective financial means. The monetary surplus resulting from the increase of net treasury during the most recent financial periods shows that the largest part of this self financing capacity is sustained by an available treasury.

8. Conclusions of the tax effects on the financial equilibium

The finances of the companies represent the main, basic link of the entire financial and credit system. This statement bases on the fact that most of the monetary funds formed on different levels result from the incomes created in the basic cells of the economy through taxes. The financial phenomenon emerges from the realtions that the company has with all the companies, the state and other institutions.

On a overstructural level, the finances of the company appear as a branch of financial science, which analyzes the mechanisms and processes of procuring and administering financial resources, their sources and destinations, in order to satisfy the different needs and to obtain profit.

In a company there may be created numerous funds, among which: fixed asset fund, working capital, reserve funds, scientific research funds, funds for training, rewarding and including employees in the profit disctribution. These funds that ensure the financial equilibrium of the company are conditioned by the total amount of taxes to be sustained.

The fiscal pressure may cause a state of financial lack of balance, respectively fiscal relaxation may generate financial equilibrium. Companies, through financial mechanisms and their specific methods may proceed to the formation and administration of capital.

The investment process implies, at a certain point, an amount of financial resources in a direction that might produce incomes during several successive periods of time.

Investments represent expenses that are made for obtainingfixed assets. For the financial manager, investment is, first of all, a decision of making capital intangible for the purpose of obtaining a future profitability. If the budgetary constraint of taxes is a strong one, the company cannot get the used funds.

The payment capacity expresses the possibility that a company should cope with due payments towards suppliers, employees, bansk, state budget, social insurances budget and social protection.

Payment capaicty refers to the report between a certain part of liquid assets – main liquidities - and due time payment obligations.

Under the circumstances of an exaggerated fiscal pressure, taxes have a negative influence over the financial stability of the companies, expressed as financial balance. NET STANDING, WORKING CAPITAL, REQUIRED WORKING CAPITAL, NET TREASURY and by intermediary administration balance accounts: TRADE MARGIN, PRODUCTION FOR THE PERIOD, ADDED VALUE, GROSS SURPLUS FROM OPERATIONAL ACTIVITIES, NET RESULT, SELF FINANCING CAPACITY, LIQUIDITY, SOLVABILITY.

Fiscal pressure via taxes negatively influences the administration rates. Under the circumstances of fiscal relaxation, taxes have a positive influence over the indicators of financial balance.

An effect of taxes is also held by the concordance between the measure of taxes and the paying capacity of the companies.

Abstract. In the paper the authors show a new method of computing and a system of indicators in order to analyze the cash-flow statement of a company.

Key words: cash-flow, current assets, debts, current liabilities

1. Introduction

The cash flow statement is made by analyzing the effects of each transaction on cash. Because of the large number of transactions made by a company and registered in accounting, even for a short period of time, this procedure is seldom used. However, the statement of cash-flow is usually made by comparing the values from the balance sheet for the beginning of the year and end of the year and analyzing the changes in monetary assets account that occurred during that period.

2. Method and Results

The aim of the cash flow statement is of showing the nature of the cash changes occurring throughout the year. A change in cash equals the net change in all the balance sheet accounts, others then cash. This can be shown by transforming the basic accounting equation, as below:

Basic equation:

$$\overbrace{(N + AC + AI)}^{\text{Assets}} - \overbrace{(DTS + DTL)}^{\text{Liabilitie}} = \overbrace{SN}^{\text{Net}}$$

From which the transformation: $\mathbf{N = SN + DTS + DTL - AC - AI}$

So:

Cash flow statement will be: $\Delta N = \Delta SN + \Delta DTS + \Delta DTL - \Delta AC - \Delta AI$

where:

N = cash

AC = current assets other then cash

AI = non current assets

DTS = short term debts

DTL = long term debts

SN = net statement

The last equation demonstrates that a change in cash (the left part of the equation) equals the net change in all the balance sheet accounts, others then cash (the left part of the equation). It can be noticed that, besides the changes in current assets, others then cash and the changes in non current asstes, each component from the right side of the equation is preceded by plus „+". The sign minus „–„ associated to the changes in assets, others then cash, show the fact that these changes are opposed as direction to the changes in cash. (for example, an increase of investments in real estate notes generates a cash decrease). On the other hand, the changes of all the other components from the right side of the equation (shareholders' equity and debts) have the same direction as cash changes.

Flows	x	x	-2 981 808	x	2 538 327	x	- 828 969

Table 1 - The Evolution of Cash –Flow at SC FELEAC SA

From the data presented in table 1, there results that negative cash flows in 2003 were due to certain decreases in both short term and long term credits, while the increase of share capital was not able to finance all the increases in non current assets and current assets, other then cash. As a result, between 2002 and 2003 there were recorded negative cash flows of 2,981,808 RON.

During 2003-2004, the financing sources of asset increase recorded a higher level then theirs, a fact that led to the obtaining of positive cash flows of 2,538,327 RON.

During 2004-2005, the decrease of shareholders' equity and long term financing was not able to compensate for the increase of current assets, thus generating negative cash flows of 829,939 RON.

Besides the indicators presented above, in the analysis of cash flows there can also be used other indicators:

1. Cash flows per share;
2. Cash flows from operational activities as percent from the total cash flows;
3. Cash flows from operational activities as percent from long term debts;
4. Cash flows from operational activities as percent from investment expenditures.

Table 2 - The Evolution of Indicators at SC FELEAC SA

Cash flow per share

Since 1973, the Commission for Securities and Exchange from USA has forbidden companies the reporting to the number of shares of cash flows. The committee believes that the investors accustomed to the data supplied according to earning per share, could be mislead to considering the cash blows based on shares as a measure of the companies welfare. Today, the position of FASB is the following: the reporting of cash flows per shares will incorrectly indicate the fact that cash flows, or one of its components, equals or is even higher then earnings as indicator of the performance or alternative of earnings per share.[32]

Limits of indicator "cash flow per share". The high concern of market analysts and investors with the cash flow per share does not imply the fact that this replaces profit in measuring the performance of a company. Both of them are important for financial analysis and their importance depend on certain circumstances. As previously noticed, the cash flow generated by operational activities excludes, in the case of the direct method, amortization and the transactions made but not cashed or paid. As a result, the harmonization of expenditures and incomes made according to the traditional method (which uses as starting point in earnings forecast) can not be found in the calculation of cash flows. Many companies obtain, during certain time intervals, negative cash flows that are not necessarily important in the future. High tech companies such as IBM or XEROX usually have, during the first years of activity, negative cash flows (caused by the intensive research and development expenses) that are not relevant for the future cash flows generated by operations.

In the case of SC FELEAC S.A., there can be noticed negative values of the indicator in 2003 and 2005 and positive values in 2004.

Cash flows from operational activities as percent from the total cash flows

When a significant part of the cash flow derives from other sources then operational activities (share issuing, long term debts or non current assets sale), the liquidity of the company is doubtful. Thus, a low percent of the cash flow resulting from operational activities usually signals a serious financial crisis. In fact, in 2003 and 2004, SC FELEAC SA the recorded negative levels of the indicator were close to triggering company’s bankruptcy.

Cash flows from operational activities as percent from long term debts

The cash flows from operational activities as percent from long term debts is usually called covering debts. It is a key indicator of liquidity used in appreciating shares and long term bank loans and shows the necessary time interval in which current cash from operational activities should cover long term debts. The balance sheet of SC FELEAC SA shows on the 31st of December 2003 long term debts of 29.7 million Ron, while the cash generated from operational activities was of 10.9 million RON. As a result, the required period of time for covering the debt was 2 years and 7 months. In 2004, the required period of time for covering the debts was 6 years and 2 months, and in 2005 the period of time for covering the debts was 2 years.

Cash flows from operational activities as percent from investment expenditures

On long term, a company has to generate sufficient funds from operational activities in order to finance the development and renewing activity and to satisfy shareholders. Even on short term, when development expenses are beyond the funds generated by operational activities, the liquidity problem can be solved. From the analysis made at SC FELEAC SA, we noticed that the development expenses of the company were, in 2003 and 2005, 60.7 million RON, while the funds resulting from operational activities were 32 million RON (52.7% from capital). This means that the company had enough funds from financing investments.

3. Conclusions

Cash flow statement is a report in order to help foreseeing the company’s capacity to sustain (or to increase) the cash from current operations. For this purpose, the statement provides several objective information ob:

---

[32] *The plan of exposing the statements proposed by FASB, „Cash Flow Statement”*

- the capacity of a company to generate cash flows from the operational activities;
- tendencies in the components of cash flows and the investment and financing decisions consequences over cash;
- Management's decisions regarding the critical areas as well as the financial policy, dividend policy and investments for obtaining the economic growth of the company.

Both cash flow statement and profit and loss account alone contain enough information in the process of decision making. The data from the profit and loss account and from the balance sheet have to be combined with cash flows in order to create a profound analysis of the company's capacity of investing in assets basing on reported profits and of paying the debts resulting from the engaged expenses and, thus, to help the analyst in introducing other relevant evaluation measures.

The data contained in cash flow statement may be used for:

- Over viewing the individual elements of cash flows for the analytical significance of cash movements;
- Examining the tendency of different cash flow components in time and their relation to elements corresponding to the profit and loss account;
- Considering in time the relation between cash flow components;

Generally speaking, cash flows from operational activities should be positive and to increase over time, since they provide resources for covering debts, for investing in assets and for remunerating shareholders.

Even if the profit and loss account and the balance sheet are imposed as parts of financial statements, cash flow statement is not required in many countries.

Cash flow analysis represents, in our opinion, an important instrument for international comparisons, due to the significant accounting differenced among countries. Cash flows are less susceptible then profit to variations resulting from the differences in accounting methods. Nevertheless, the differences in accounting methods influence the classification of cash flows. Thus, comparison on international scale requires the adjustment of reported cash flows.

Abstract. In the paper the authors show the different models of analyzing the company's solvency, taking into account many ratios with different importance.

Key words: general stability, financial solvency, reimbursing capacity

1. Introduction

The status of financial solvability is multi-criteria approached by local specialists and from abroad.

The International Accounting Standards mention the fact that solvency refers to cash availability for a greater period of time during which the due time financial engagements ought to be covered[33].

In our opinion, solvency has to be analyzed from the point of view of its function and the time horizon it implies. That is why we believe that solvability expresses the capacity of an economic agent of reimbursing on due time (larger then 1 year) the current rates towards banks and other financial institutions.

At the same time, we believe that solvability is a state of financial equilibrium measuring the value of the capital, as compared to the patrimony's size.

2. Method and Results

Solvency can be shown through many models. They are presented below.

– The analysis of general stability

The indicator of general stability (ISG) shows the degree in which the total assets of the company are able to cover the total debts of the company. This indicator shows the degree in which debts can be covered using assets.

$$ISG = \frac{Total\ asset}{Total\ debt}$$

The minimum level acceptable is of 1.66 (even if it should be at least 2.00). Under this level, the company faces the danger of payment incapacity. The optimum level is 3.00.

The general solvency report (RSG) indicates the amount of the net accounting asset in total asset:

$$RSG = \frac{Net\ Accounting\ Asset}{Total\ asset}$$

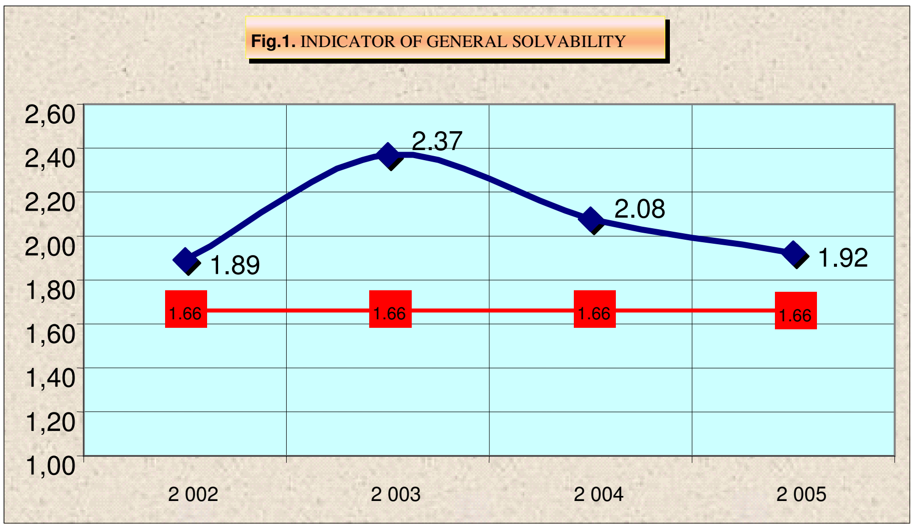
The minimum level acceptable is of 35%, but the optimum one is of at least 50%.

Indicator	2 002	2 003	2 004	2 005	Simbol
Total Asset	183 763 008	213 169 364	289 944 108	305 777 818	At
Total Liability	97 217 073	89 964 477	139 336 362	159 570 651	Dt

[33] *O.M.F.P. no. 1752/2005 – Q work.*

Net Accounting Asset	86 545 935	123 204 887	150 607 746	146 207 167	Anc
Indicator of General Sovency	1.89	2.37	2.08	1.92	Lsg = At/Dt
Growth Indicator	100%	125%	88%	92%	Iclsg = lsgn/lsgo
Variation of the indicator	0.00	25%	-12%	-8%	dlsg = (Δlsg)/lsgo
Minimum value acceptable	1.66	1.66	1.66	1.66	Min
General solvency report	47.10%	57.80%	51.94%	47.81%	Rsg=Anc/At
Minimum value acceptable	35.00%	35.00%	35.00%	35.00%	Min

Table 1 - General Solvency at SC AMPELUM SA



During the entire analyzed period, the level of the general solvability indicator is over the normal limit, even if slightly descending during 2003-2005. The descending tendency of the indicator is due to the more rapid growth rhythm of total debts, as compared to total assets. Nevertheless, from this point of view SC AMPELUM SA is safe during the entire period of analysis, a fact that means that it is able to cover all its debts basing on assets. The same conclusion results from the analysis of general solvability report.

– The analysis of financial solvability

The indicator of financial solvability (ISF) shows the degree in which the total assets of the company are able to cover total financial debts.

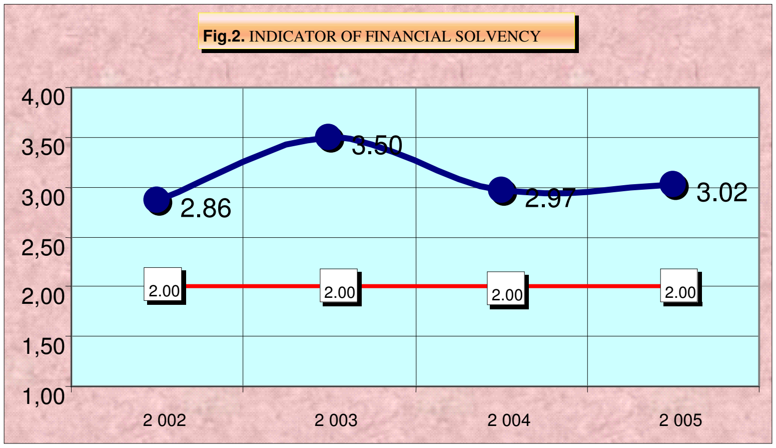
$$ISF = \frac{Total\ asset}{Total\ \ financial\ debt}$$

The minimum level acceptable is of 2.00. Under this level the company faces payment incapacity.

Indicator	**2 002**	**2 003**	**2 004**	**2 005**	Simbol
Total Assets	183 763 008	213 169 364	289 944 108	305 777 818	At =Ai+Ac
Total Financial Liabilities	64 325 931	60 831 920	97 621 346	101 417 082	Dft = Dtml+Cbts
Financial	2.86	3.50	2.97	3.02	IsF = At/Dft

Solvency					
Minimum value acceptable	2.00	2.00	2.00	2.00	Min

Table 2 - Financial solvability with SC AMPELUM SA



During the entered period analyzed, the value of the indicator is over the average limit, even if in 2004, as compared to the previous year, the value decreased. The descending tendency of the indicator is explained by the more rapid growth of financial debts, as compared to total assets. However, from this point of view, SC AMPELUM SA is safe during the entire period of analysis, a fact that shows the capacity of the company of covering all its financial debts basing on assets.

– The analysis of debt reimbursing capacity

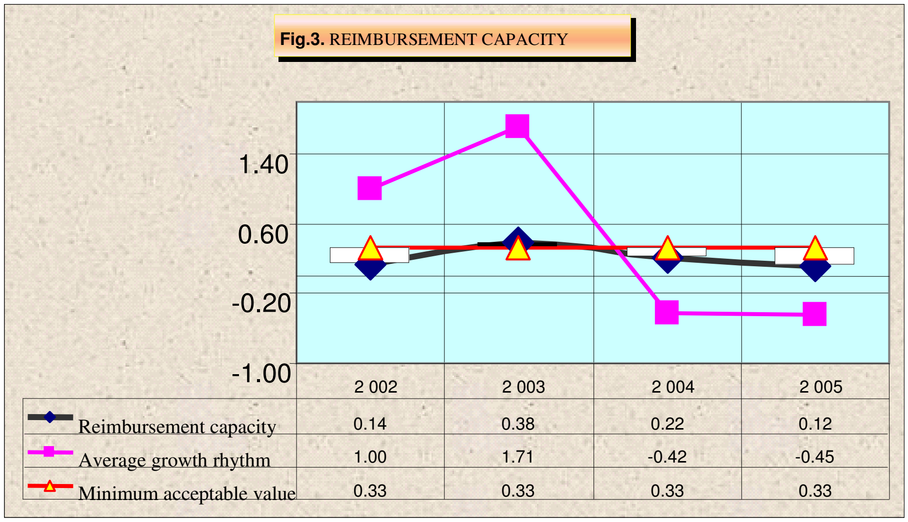
Debt reimbursing capacity (CRD) shows the degree in which the potential sources of self financing resulting from the activity of the company can cover total debts.

$$CRD = \frac{Self\ \ financing\, debt}{Total\, debt}$$

The minimum level acceptable is of 0.33 (corresponding to the covering of debts in a period of 3 years). If the level is under 0.33, the company faces payment incapacity and the optimum level is 1.00.

Indicator	2 002	2 003	2 004	2 005	Simbol
Self financing capacity	13 383 951	34 284 540	30 191 651	18 975 448	Caf
Total debts	97 217 073	89 964 477	139 336 362	159 570 651	Dt
Reimbursement capacity	0.14	0.38	0.22	0.12	Crd = Caf/Dt
Growth indicator	100%	271%	58%	55%	IcCrd = Crdn/Crdo
Variation of the indicator	100%	171%	-42%	-45%	dvlCrd = (ΔCrd)/Crdo
Average growth rhythm	1.00	1.71	-0.42	-0.45	Rmc
Minimum acceptable value	0.33	0.33	0.33	0.33	Min

Table 3 - The Capacity of Reimbursing Debts at SC AMPELUM SA



In 2003 the value of the indicator was over the minimum level; as compared to the previous year it increased by 171%. The tendency of the indicator is descending. From this point of view, SC AMPELUM SA has an acceptable financial security during the analyzed period.

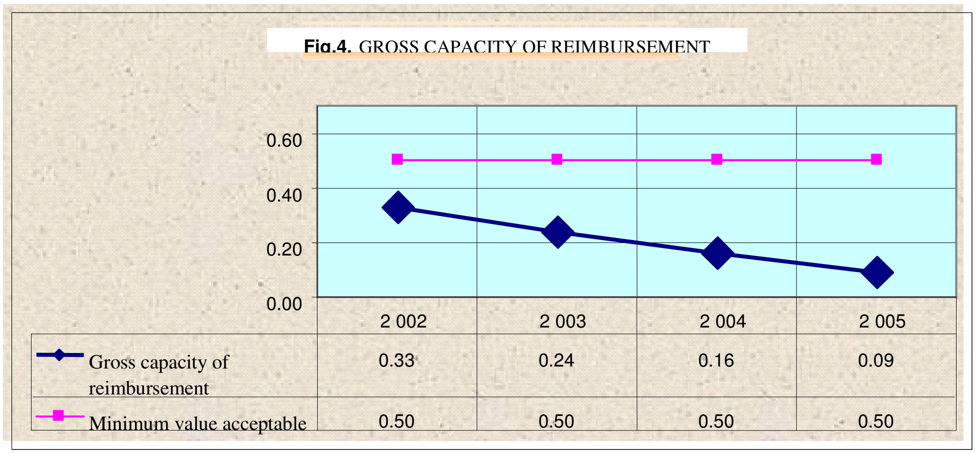
The gross capacity of reimbursing debts (CBRD) shows the degree in which the potential sources of self financing resulting from the operational activity of the company are able to cover the total debts of the company.

$$CBRD = \frac{Gross\ surplus\ from\ operational\ activities}{Total\ debts}$$

The minimum acceptable level is 0.50 (corresponding to covering debts in a 2 year period), under this level the company faces payment incapacity. The optimum level is 1.00.

Indicator	2 002	2 003	2 004	2 005	Simbol
Gross surplus from operational activities	32 451 335	51 338 829	45 515 107	28 734 234	Ebe
Total liabilities	97 217 073	213 169 364	289 944 108	305 777 818	Dt
Gross capacity of reimbursement	0.33	0.24	0.16	0.09	Crd = Caf/Dt
Minimum value acceptable	0.50	0.50	0.50	0.50	IcCrd = Crdn/Crdo

Table 4 - Gross Capacity of Reimbursing Debts at SC AMPELUM SA



For the entire period analyzed, the value of the indicator is under the minimum value acceptable. As compared to the previous year, it shows a tendency of constand decrease. Ther general tendency of the indicator is descending. From this point of view, the company is not safe as far as its payment capacity is concerned.

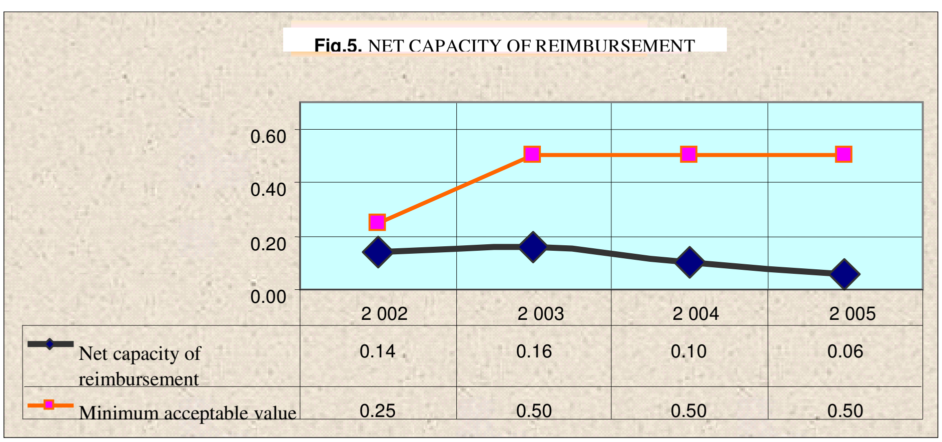
b) Net capacity of reimbursing debts (CNRD) shows the degree in which net self financing is able to cover the total debts of the company. It indicates a report between own sources and borrowed ones.

$$CNRD = \frac{Net\ self\ \ financing}{Total\ debts}$$

The minimum acceptable level is of 0.25 (corresponding to covering debts in a 4 year perios); under this level the company faces payment incapacity. The optimum level is 1.00.

Indicator	2 002	2 003	2 004	2 005	Simbol
Net self financing	13 383 951	34 284 540	30 191 651	18 975 448	Afn
Total liabilities	97 217 073	213 169 364	289 944 108	305 777 818	Dt
Net capacity of reimbursement	0.14	0.16	0.10	0.06	Cnrd = Afn/Dt
Minimum acceptable value	0.25	0.50	0.50	0.50	Min

Table 5 - Net Capacity of Reimbursing Debts



During the entire analyzed period, the value of the indicator was under the average limit. During the last year, the value of the indicator significantly decreased, as compared to the preceding year. The general tendency is of continuous decrease. From this point of view the company is in a state of financial instability.

- The analysis of financial expenses requirements

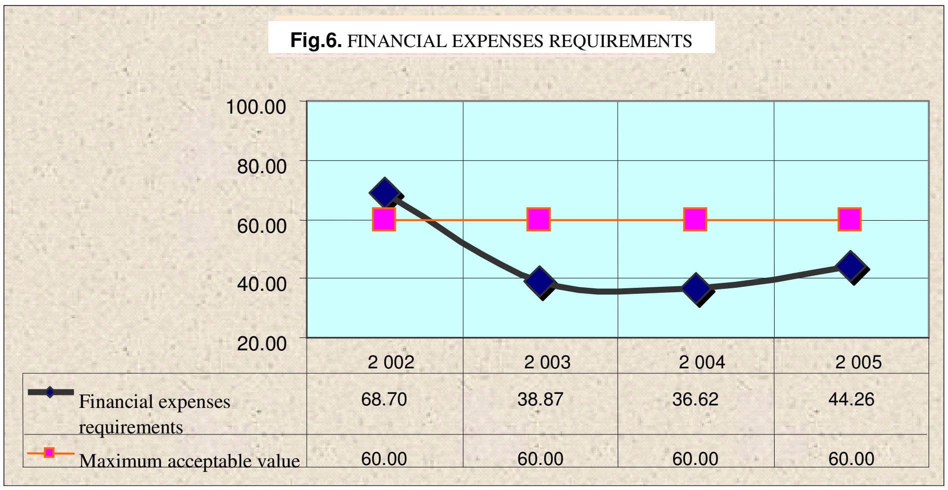
The ratio of financial expenses requirements (RPCF) shows the degree in which financial expenses consume cash from the gross accumulations of the operational activity.

$$RPCF = \frac{Financial\ expenses}{Gross\ surplus\ \ from\ exploitation}$$

The maximum level acceptable is of 60%; over this level the company faces the danger of negative cash.

Indicator	2 002	2 003	2 004	2 005	Simbol
Financial expenses	22 293 955	19 954 458	16 668 688	12 717 525	Chf
Gross surplus from exploitation	32 451 335	51 338 829	45 515 107	28 734 234	Ebe
Financial expenses requirements	68.70	38.87	36.62	44.26	Rpcf = Chf/Ebe
Maximum acceptable value	60.00	60.00	60.00	60.00	Max

Table 6 - The Ratio of Financial Expenses Requirements



During the first year, the value of the indicator was within normal limits, but it increased, as compared to the previous year. The indicator has a general descending tendency, both basing on the decrease of the financial debts, which generate expenses with interests, as well as basing on the decrease of the surplus from operational activities. Nevertheless, from this point of view the company is not safe during the analyzed period.

3. Conclusions

Taking into account the above said, we may draw the conclusion that the solvability SC AMPELUM SA is adequate. The leverage level of the company does not generate significant risks with continuing the activity. However, we noticed that there is a tendency of depreciation of the solvability indicators in the last part of the time interval analyzed.

Abstract. In the paper the authors show the importance of capital structure and the financial structure in the company financing taking into account the owner's capital and the borrowing capital.

Key words: capital structure, debts, leverage

1. Content of the financial structure of the entity

The financial structure of the enterprise is determined by the structure of the entire liability of the balance sheet and we believe it shows the role of capital in financing the company. Comparing to the structure of the capital, the financial structure additionally includes the capital borrowed on short term basis.

We also believe that the financial structure include the capital structure of the company. In this sense, by financial structure we understand the report existing between the short term financing and the long and intermediary term financing of the company.

$$\textit{The financial structure of the company} = \frac{\textit{Short term financing}}{\textit{Long term and Intermediary term financing}} = \frac{\textit{Treasury resources}}{\textit{Permanent capital}}$$

The financing requirements emerge both in the line of operating, respectively production activity, as well as on the line of certain operations non-specific to operating.

The treasury resources are formed by short term banking credits, as well as by commercial credits and cover a part of the circulating assets.

Permanent capital is formed by the own funds of the company and intermediary and long term loans and covers the non current assets, as well as a part of the circulating assets seen as the working fund.

Indicator	**2 002**	**2 003**	**2 004**	**2 005**
Non current assets	130 191 372	146 704 676	180 674 661	179 735 454
Circulating Assets	53 557 906	66 459 041	109 256 641	124 800 912
Advance Payments	13 730	5 647	12 806	1 241 452
Current Assets	53 571 636	66 464 688	109 269 447	126 042 364
Total Assets	183 763 008	213 169 364	289 944 108	305 777 818
Due (intermediary and long) term debts	29 730 177	28 603 328	33 712 286	29 594 985
Owners'Capital	86 545 935	123 204 887	150 607 746	146 207 167
Permanent Capital	116 276 112	151 808 215	184 320 032	175 802 152
ShortTerm BankCcredits	34 595 754	32 228 592	63 909 060	71 822 097

Commercial Credits	32 891 142	29 132 557	41 715 016	58 153 569
Treasury Resources	67 486 896	61 361 149	105 624 076	129 975 666
Total Liabilities	183 763 008	213 169 364	289 944 108	305 777 818
Long Term Financing	63.28	71.21	63.57	57.49
Short Term Financing	36.72	28.79	36.43	42.51

Table 1 - The evolution of resources and allocations at SC ELBA SA

From the table above there results that during the entire analyzed period of time, over 60% of the resources have been allocated for the investment activity and a bare 40% of the resources have been allocated for the operational activity.

The leverage of the company may occur by using banks and other specialized financial institutions or bond financing.

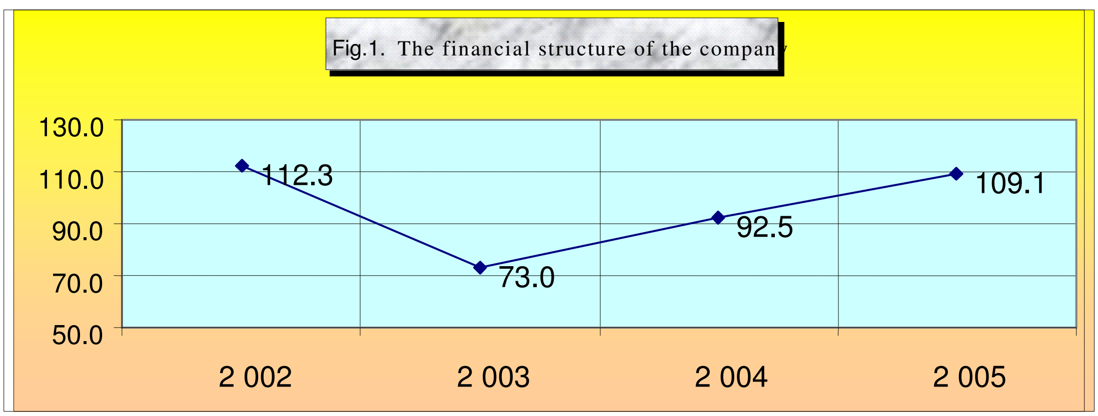
In a simplified way, *the financial structure of the company* can be appreciated according to the report:

$$\frac{\textit{Total debt}}{\textit{Shareholders' equity}}$$

Reflecting the amount of financing based on borrowed resources, as compared to own resources.

Indicator	**2 002**	**2 003**	**2 004**	**2 005**
Total debt	97 217 073	89 964 477	139 336 362	159 570 651
Shareholders equity	86 545 935	123 204 887	150 607 746	146 207 167
Financial structure of the company	112.3	73.0	92.5	109.1

Table 2 -The Evolution of the Financial Structure at SC ELBA SA



From this graphic representation, we may notice that foreign financing resources are larger then the own resources in 2002 and 2005 with 12.3%, respectively 9.1%. This is important since it influences negatively the financial autonomy and independence of SC ELBA SA.

The choice of a certain financial structure represents an important *financial policy decision*. If the financial covering through short term obligations provides a certain flexibility for the entreprizer, in the sense that he/she may develop or reduce operatively the volum of the activity, the financing through permanent capital is less expensive, therefore more profitable. Even if the profitability criterion is a very important one, the decision regarding the financial structure also takes into account other elements, such as the total volume of the needs to be financed, as well as the nature of the various capital uses.

The financial structure is a variable that does not depend solely on the company, its economic growth objectives, foreseen profitability or the risks it agrees to assume. The financial structure is influenced, and often determined, by shareholders, bank or other financers, by the state, as well as by the economic-financial context: the situation of the financial market, the oscillations of the interest rate, monetary devaluations etc.

Last but not least, the adoption of a financial structure is also determined by the creditors taking into account the risk to which they are exposed when crediting the respective client. Creditor's risk may be a risk of capital loss when the debtor can no longer reimburse the contracted loan; it can be an interest risk when the debtor can no longer reimburse the due interest, but it can also be an non current risk, which can emerge even when the debtor pays his/hers due time obligations. This means that the creditor blocks his/her capital in different assets (inventories, receivables) thus being forced to re-finance himself/herself under crcumstances of interest and time that may be unfavorable.

In order to prevent these risks, the creditor (the bank) acts by creating insuring collaterals and, at the same time, imposes the participation of the debtor with own capital to the respective financing. If the profitability is low, the debtor has to provide a larger participation with own funds in order to protect the creditor, and vice-versa. In the case of an unsatisfying profitability, the financing through leverage stresses the insolvability and lack of liquidity risk.

2. Criteria in choosing a financial structure

In order to choose a certain financial structure, managers have to take into account several criteria, presented below:

- The criterion of profitability in choosing a financial structure

Both shareholders equity and the borrwed capital imply risks. The fundamental difference between the cost of shareholders equity and borrowed capital is represented by the fact that shareholders equity is not remunerates unless the company makes profit, while borrowed capital has to be remunerated irrespective of the company's profitability.

An enterprise with highly levered (over 50%) will permanently have high financial expenses (principal plus interest), a fact that diminishes its possibilities to finance itself. Therefore, the respective company will have to use new credits in order to cover its financing needs, credits which will increase financial expenses. This is possible when the profitability rate is higher then the interest rate, this making possible and desirable the use of credits, as compared to the alternative of waiting the gradual formation of own funds for financing a project.

The leverage effect is obtained by comparing the economic profitability of the company with the cost of the borrowed capital. This:

- if economic profitability is higher then interest rate, there results a positive or favorable leverage effect;
- If economic profitability is lower then interest rate, there results a negative or unfavorable leverage effect.

Supposing, for example, that the economic profitability (R_e) is of 16%, and the interest rate (D) is 12%, the company is interested to *finance through leverage*, since it makes a profit with 4% higher then the borrowed capital ratio. The profitability ratio of the shareholders equity is as high as the report borrowed capital/shareholders equity is higher.

- The criterion of sources destination in choosing a financial structure

The non-current assets, which represent permanent needs, may be covered with permanent capital, while circulating assets (the expenses of the operating cycle) mainly formed by goods inventories and other material values, by receivables over clients and short term financial investments, may be covered, if possible, with the own working fund – which represents a part of permanent capital – but also with short term debts formed by treasury credits and obligations towards suppliers.

For every company it it important to adapt its financing decision according to the permanent or temporary character of the financing needs.

As previously presented , there results that *the financial structure of a company* is expressed not only as report between *leverage and shareholders' equity*, but also as a report between *short term financing and long term financing*.

Financial structure = Short term financing/Long term financing = Treasury resources/Permanent capital

Indicator	2 002	2 003	2 004	2 005
Treasury Resources	67 486 896	61 361 149	105 624 076	129 975 666
Permanent Capital	116 276 112	151 808 215	184 320 032	175 802 152
Financial Structure	58.0	40.4	57.3	73.9

Table 3 - The Financial Structure at SC ELBA SA

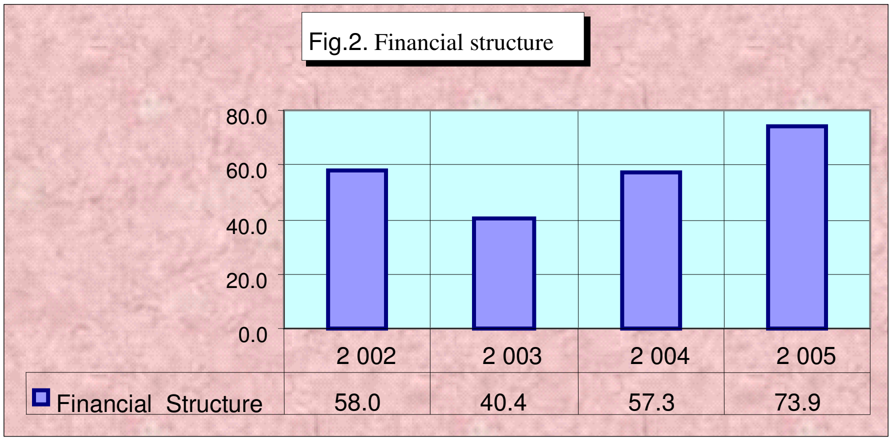


Fig.2. Financial structure

From the graphic representation above there can be noticed that treasury resources, as compared to permanent resources has the following values: 58% in 2002, 40. 4% in 2003, 57%3% in 2004 and 73.9% in 2005.

– Leverage capacityis is another criterion

Taking into account the importance of the financial structure for any company both for evaluating its own situation and for expressing it in the relation with the bank, it is useful to determine, in the case of *financial analysis*, certain *indicators* that would show *the usage degree of shareholders' equity*, as compared to long and intermediary term loans or with total loans.

If we state that **the asset** of a company is formed by non current assets, goods investories and other material values, clients discount and other liquidities, and **the liability** is formed by permanent capital (shareholders' equity, long and intermediary term debts) and by short term debts (suppliers, treasury credits), we may use as *analysis instruments of the financial structure* the following indicators:

Global leverage coefficient

$$\frac{\textit{Total debts}}{\textit{Total liability}} \leq \frac{2}{3}$$

$$\frac{\textit{Total debts}}{\textit{Shareholders' equity}} \leq 2$$

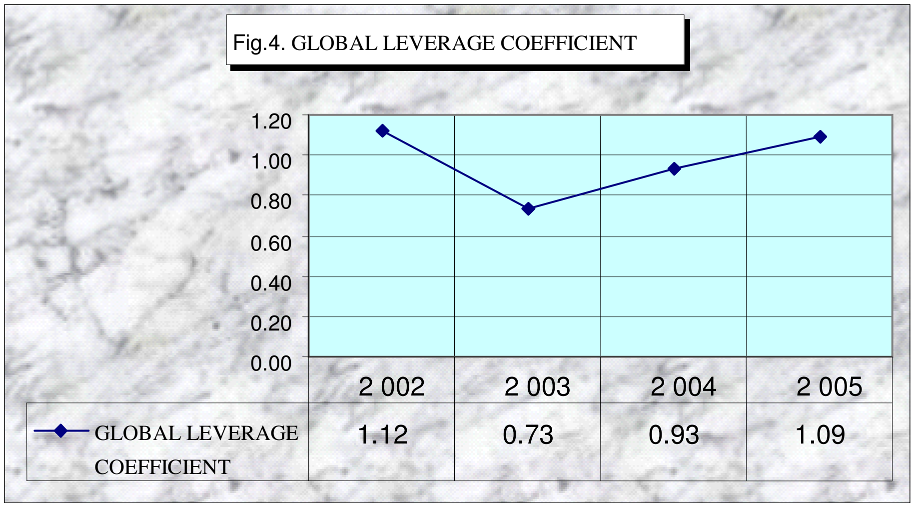
Indicator	2 002	2 003	2 004	2 005
Total debt	97 217 073	89 964 477	139 336 362	159 570 651
Total liability	183 763 008	213 169 364	289 944 108	305 777 818
Global leverage coefficient	0.53	0.42	0.48	0.52

Table 3 - The Evolution of the Global Leverage Coefficient at SC ELBA SA

From the graphic representation above we can notice that SC ELBA SA is situated in a gry area, with a leverage ratio between 30% and 50%. This is a negative aspect from the point of view of the suppliers and creditors, who, in the case of insolvency, would record bigger losses then the company's owners.

Indicator	2 002	2 003	2 004	2 005
Total debt	97 217 073	89 964 477	139 336 362	159 570 651
Shareholders' equity	86 545 935	123 204 887	150 607 746	146 207 167
Global leverage coefficient	1.12	0.73	0.93	1.09

Table 5 - Evolution of the Leverage Ratio at SC ELBA SA



The evolution of this indicator was: 1.12 in 2002, 0.73 in 2003, 0.93 in 2004 and 1.09 in 2005.

In our opinion a leverage ratio over the unit endangers on short term basis the financial autonomy of the company, and, on a long term basis, th capacity of reimbursing the loan.

The indicator „global leverage" is expressed above in two ways, but we believe that it suffices the approach of an unique model when referring to the analysis of the financial structure or the solvability of the company. Analysis favor *the second calculation method of the indicator* since it refers to the usual banking norms, according to which total debts *can not be twice as shareholders' equity*. These limits may be reconsidered by the banks. In the situation in which these leverage limits are reached, the leverage capacity is seen as *saturated* and the company can no longer obtain long or intermediary term financing sources through leverage.

3. Conclusions

The indicators presented above express essential elements that characterize the financial standing of the company, but, in order to maintain normal relations with the banks, they are concerned with their clients' situation also in the sense of their capacity of reimbursing the contracted credits. Banks are interested to know beforehand whether the reimbursement of the loan and the payment of the corresponding interest can be fulfilled by the clients in normal circumstances, without creating major financial difficulties. For this purpose, there can be used come indicators presented above, expressing the possibilities, which may be accepted by the banks, for fulfilling the obligations of the debtor clients towards the credit institution.

From a fiscal point of view, it is believed that a leverage ratio smaller then 1 provides the possibility that the company completely deducts the expenses with interests and net loss related to the foreign currency exchange. If the leverage degree equals 1 or is higher then 1, the amount of expenses with interests and net loss related to the foreign currency exchange is deductible only in the limits of the following sums: the income from interests plus 10% of the other taxable incomes, less: income from interest, income from foreign exchange, income recorded in 711, 721 and 722 accounts, as well as the other incomes resulting from operations having as aim the increase of this limit[34].

THE INTERNET AND THE CREDIT INSURANCE

Bențe Corneliu

Universitatea din Oradea, Facultatea de Ştiințe Economice, Str. Carpați nr.1B, PB 36, ap. 9, Oradea , Bihor, România, Tel: +40-259-408.401, Email: corneliubente@gmail.com

Abstract: Credit insurance provides companies with coverage four outstanding commercial recivables, protecting against risk of buyer default or insolvency. In adition to managing credit risk, credit insurance supports financing needs: by reducing the risk of non-payment of trade recivables, a firm can borrow at lower interest rates.

keys: e-marketplace, e-business, internet

1. Introduction

The outlook for credit insurer is promising. Credit insurers enjoy a significant competitive advantage due to their vast expertise in credit risk management and their proprietary databases on millions of companies worldwide. This expertise and information on trade recivables is the basis for underwriting credit risk. It can be used to provide new services to credit departments, in addition to credit insurance.

Credit insurers are beginning to provide new products an to unbundle existing products by separately providing information and risk coverage. Related services such as invoicing and debt collection, are providing additional sources of earnings.

The internet is facilitating these developments by providing a less expensive distribution channel and high-speed communication to support services such as claims adjustment. The explosive growth of business to business internet transactions is providing an opportunity for credit insurers and other credit service companies. By providing lines of credit to buyers on the internet, credit insurers are enhancing their fee-based revenue by leveraging their proprietary information of the credit worthiness of buyers. Finally, the growing market for derivates and asset backed securities presents opportunities and challenges for credit insurers. Credit insurers can provide asset specific credit enhancement, particularly for the underlying assets of the asset backed commercial paper of the trade recivables.

The internet provides new opportunities and challenges to credit insurers.

Currently, credit insurance companies are utilizing the internet in three different ways. First, they can use the communications features of the internet to improve client communication and reduce costs. Second, they can market, sell and manage their traditional credit insurance via the internet. Third they can provide new products for the rapidly growing volume of e-commerce, particularly business-to-business(B2B) internet sales.

2. New technologies are helping to reduce costs

Besides being an important information and communication medium, the internet has developed into a powerful distribution channel, which can improve client communication and reduce costs.

The internet can help insurance companies deliver high quality, personalized information to their clients. It can also help in reducing paper work and other costs related to processing information and forms by doing the work online. The increasing use of the internet by insurers is expected to improve efficiency in underwriting, distribution, administration and claims settlement, which will be reflected in lower costs for insurers. According to a recent study [35] on e-business, its greater use could lead to about 9% costs savings in commercial lines. We expect that the cost saving for credit insurance could be about the same. There is some potential for extraordinary savings for credit insurers on underwriting, but only after a large amount of expenditure on information technology.

3. Traditional credit insurance can be provided via internet

Providing traditional credit insurance via the internet is fairly straightforward, though it faces potential technical and regulatory hurdles. It is technologically feasible to match a company's customer to a credit

[35] Swiss Re, " *The impact of e-business on the insurance industry: Pressure to adapt-chance to reinvent*", Sigma No 5/2000.

rating database and provide some indicative pricing on a credit insurance policy. The data needed from the credit insurance client are company identification, value of sale and data of sale. Unknown companies would need to be eliminated from the price of the credit insurance. In addition, credit insurers can use the internet to enhance the quality of their services, for example by improving communications with clients and speeding the claim process. For many years now, technological developments have been improving the electronic exchange of information between the insurer and the insured.

However, there will remain frequent personal interactions between the policy holder and the insurance provider.

The credit insurance companies are devising new and innovative solutions for the growing volume B2B transactions over the internet. Internet sales of products in the B2B market have been growing rapidly. The turnover of internet trading between companies was estimated to be USD 150 billion worldwide in 1999, and USD 7,3 trillion by 2004.

The growth of internet B2B sales has accompanied by a growing number of anonymous transactions on e-commerce marketplaces (e-marketplaces), substantially increasing credit risk. Credit insurers has recognized this and devised differing business models to mitigate the risks associated with the extension of trade credit on the internet .

4. Two business strategy

Credit insurance companies bundle two similar and related services for their clients. The first service is the provision of information on buyers. The insurance companies have collected huge amounts of information on the credit worthiness of business all over the world. This information is used by the insurers to price premiums and is also supplied to clients to help them manage their trade recivables. The second service provided by the credit insurers is the risk coverage that protects the sellers against default by the buyers. These two services can be packaged together or separately, providing two strategy or models.

The first strategy relies more on the credit insurer’s information advantage. In this model, the insurers unbundled their services and provide information separately from their information product. The credit insurers’ rate firms included in their databases and sell these ratings to their clients and e-marketplace. Lesser known, or new, firms can pay a fee to an insurer to be rated. Since the insurer continue to provide insurance products, the clients can choose whether they want to buy information services alone or information bundled with insurance.

Large business seeking for self-insure and to reduce the cost of monitoring theirs costumers or suppliers will only purchase information services from the credit insurers. Small firms that find credit insurance too expensive may also buy only ratings from the insurer. The emphasis in the business model is on providing information services to a larger market than is currently interested in credit insurance. Though, not necessarily related to the internet, this business model lends itself to providing other unbundled services, such as invoicing and debt collection, to support credit departments.

In the second model, instead of providing information risk coverage separately, these services are provided together. Normally, in this model the credit insurer insures the entire e-marketplace with which it has a relationship. All transactions on the insured e-marketplace are covered. This is similar to traditional credit insurance, which generally covers the whole turnover of large clients with a diverse portfolio of buyers.

In e-business the credit insurer extends credit limits to buyers in the e-marketplace. The size of the firm does not matter as long as it is doing business at an e-market place covered by the insurer. This business model has a lot in common with the consumer credit card market. The e-marketplace brings buyers and sellers together, deriving its revenue from fees added on to sales. For example, the e-marketplace might be a conduit for sellers of automobile parts to vehicle manufactures and the auto parts after-market.

Alternatively the e-marketplace site might sell only one’s company product line to many buyers, as in a computer parts company selling to computer manufacturers. Buyers are accepted if they have a credit limit set by the credit insurer or other acceptable firm. The financial firm that provides the credit line and guarantees the sell receives a portion of the sales fee from the e-marketplace, in much the same way that credit cards companies receive a portion of all sales involving use of their credit card. The financial firm, such as credit insurer, can work with the e-marketplace to provide Credit Certificates to all customers using the site for purchases. A payment guarantee ensures that the seller will receive even if the buyer defaults.

Alternatively, the financial firm could work with buyers, providing credit limits directly to them for use on any site affiliated with the financial service.

In either case, buyers are also assigned a spending limit, based on data to be provided by buyers and credit information agencies. The credit providing agency will also monitor payments, deducting the value of a transaction from the credit limit after a purchase, and adding it back after the invoice has been paid. This product involves information on the buyers and risk coverage for the sellers.

Though there is a great overlap in company strategies, the large credit insurers have somewhat different approaches to the internet. Coface is using the internet to enhance its relationships with important clients, and a large proportion of their credit limit requests and policy amendments are now handled online, improving service and reducing costs. In January 2000, Coface launched an internet-based commercial debt rating system called @rating which markets information about buyers to sellers. Coface's ratings are based on its database of payment recordsfor over 32 million companies. Coface has trading partenerships with Wisekey, a leading internet service provider, and Tradecard, an online payment and settlement software company. Coface also sells insurance to clients and e-commerce marketplaces.

Euler's e-commerce strategy consists of servicing existing clients as well as providing insurance for internet transactions. For internet services, Euler primarily uses its Online Information Service (EOLIS) to manage the insurance policies of their clients. Customers can check outstanding limit on existing clients, track claims field, check information on potential customers and even get automatic responses to requests for extensions in credit limits.

For internet transactions Euler provides insurance for all transactions of an e-marketplace.

Gerling Kredit provides insurance for the entire selling chain. In addition to the electronic business-to-business transactions it also offers insurance for the electronic business to consumer transactions. Within the electronic business-to-busines segment, Gerling Kredit provides online service to its existing clients by Net&Serve and has recently created Trusted Trade GMBH, a new company aimed at insuring business-to-busines transactions. Trusted Trade provides credit insurance for entire e-marketplaces. In addition Trusted Shops, another company affiliated to Gerling Kredit, protects online consumers form a company's failure to deliver goods or damaged delivery of goods.

NCM provides its online services through an affiliated company, eCredible.com. eCredible.com's offering consists of two elements: credit management services and the eCredible Payment Guarantee. The key element of credit management services is the credit certificate that is issued to the sellers current customers or new prospects to authenticate the buyers credit worthiness. Buyers are also assigned a spending limit, based on data provided by buyers as well as from credit information agencies or NCM's database. NCM also updates the balance on the buyer's account, deducting the value of a trasnsaction from this spending limit and adding to the limit the value of payments on the accounts. The eCredible Payment Guarantee ensures that the sellers will receive payment if the buyer defaults.

5. Competitive issues

Some firms, such as Dun&Bradstreet, compete with credit insurers by providing company credit information. In November 1999, Dun&Bradstreet launched its electronic joint venture, eccelerate.com, with internet trust services provider VeriSign. The group facilitates e-commerce trading by providing unique, secure identifiers and access to credit checks. Digital certificates, similar to the Payment Guarantee provided by eCredible.com, contain a company identifier and pre-qualify a firm to conduct e-commerce on a range of exchanges, online auctions and procurement sites.

The internet has made access to vast amounts of information easier and less costly than previously. The ease of access and competitive pricing may pose a significant challenge to credit insurance companies which have always exploited the value of their company databases. Some company information is publicly available- this is how information service providers like Dun&Bradstreet hve built their databases- and can be supplemented with information solicited directly from companies. The credit insurers have a vast amount of proprietary information based on actual transactions, which should prove to be a better source of information on future payment practices. The credit insurers can leverage this proprietary information to their advantage. Also, credit insurers have experience in underwriting transactions and debt collection which can provide significant value to credit management departments.

Abstract: Bancassurance, the provision of insurance services by bank, is an established and growing channel for insurance distribution. However, bancassurance is applied heterogeneously around the world. Regulatory considerations, as well as cultural and socio-demographic factors, could explain some of this variation. Despite this heterogeneity, overall bancassurance penetration has increased in recent years, particularly in emerging markets.

keys: distribution agreements, joint ventures, integrated operations

1. Introduction

Successful bancasurance models have thus far primarily involved selling simplified products over the counter to customers who make on-the-spot decisions. Bancassurance products tend to complement existing bank products, which can in turn lead to additional selling opportunities. Worldwide, insurers have been successfully leveraging bancassurance to gain a foothold in markets with low insurance penetration and a limited variety of distribution channels. It is believed that the ability to integrate banking and insurance can help to lower costs and maximize synergies.

The economics behind integrated operations, however are being increasingly challenged by regulatory changes. New regulations have eliminated many of the capital advantages previously enjoyed by bancassurance. At the same time, the quest for additional growth has led some bancassurance to explore alternative business models. Some, for example, are beginning to focus exclusively on distribution, and are employing multi-supplier and multi-channels strategies. The marketing of more complex products has also gained ground in certain countries, alongside a more dedicated focus on niche client segments and the distribution of non-life products. In many of these situations, significant re-engineering of existing marketing and back-office process is needed, particularly in areas such as claims management, due to higher claims frequency of non-life insurance products.

Over the last two decades, bancassurance has become a key distribution channel in many insurance markets. Its prevalence is most pronounced in Southern Europe, but its use has also spread to other regions, in particular emerging markets.

2. Determinants of bancassurance

Bancassurance has achieved remarkable success in some markets. In Europe, it is not uncommon to find over half of life insurance business being transacted by banks. For example, in France, Portugal and Spain, banks handle over 60% of life insurance business. Banks and insurers are attracted to the idea of bancassurance for different reasons, which also influence the way their cooperation takes place.

The following will briefly summaries the determinants of bancassurance from the perspective of various stakeholders- banks, insurers, consumers and regulators.

2.1. Banks

Retail banks earn their income from the spread between the rates they charge on lending and those they pay for deposits. Growing market competition, however, weighing down heavily on banks' interest margins while credit risk is always a headline concern. As a result, banks are increasingly looking to commissions and fees from selling insurance products to supplement their core earnings. Some banks are eying bancassurance as a step to the formation of financial supermarkets where one institution serves all the financial needs of its customers. A potential benefit is the reduction in the volatility of return on equity due to the lack of synchronization between insurance and banking profitability cycles[36].

From the perspective of banks, bancassurance is attractive because banks can>

- Secure an additional and more stable stream of income through diversification into insurance and reduce their reliance on interest spreads as the major source of income;
- Leverage on their extensive customer bases;
- Sell a whole range of financial services to clients and increase customer retention;
- Reduce risk-based capital requirement for the same level of revenue;
- Work towards the provision of integrated financial services tailored to the life-czcle of customers;
- Access funds that are otherwise kept with life insurers, who sometimes benefit from tax advantages.

2.2.Insurers

The benefits to the insurers are equally convincing. The ability to tap into banks' huge customer bases is a major incentive. The extensive customer base possessed by banks is considered to be ideal for the distribution of mass-market products. On the other hand, insurers can make use of the wide reach of bank customers to categorise potential clients in detail according to their needs and values. With increasing sophistication on bancassurance operations, some insurers can focus on the high-net-worth segment, which offers greater potential for wealth management business.

Apart from the ability to tap into new customers groups, escaping from the high cost of captive agents is another reason prompting insurers to look into alternative channels. In some cases, teaming up with a strong bank can help to fund new business development and boster public confidence in the insurer.

In a nutshell, insurers are attracted to bancassurance because they can:

- Tap into a huge customer base of banks;
- Reduce their reliance on traditional agents by making use of the various channels owned by banks;
- Share services with banks;
- Develop new financial products more efficiently in collaboration with their bank partners;
- Establish market presence rapidly without the need to build up a network of agents;
- Obtain additional capital from banks to improve their solvency and expand business.

There are different organizational structures under which banks can work together with insurers, including distribution agreements, joint ventures ore some integrated operations. It is then only logical to presume that different motivations will drive the choice of different organizational models

[36] Swiss Re, Sigma No. 7/2001, "World financial centers: New horizons in insurance and banking ", p.25

Table 1: Benefits of bancassurance

Benefits to banks	Distribution	Joint ventures	Integrated operations	Benefits to insurers	Distribution	Joint ventures	Integrated operations
Secure an additional and more stable stream of income through diversification into insurance and reduce their reliance on interest spreads as a major source of income	x	x	x	Tap into the huge customer base of banks	x	x	x
Leverage on their extensive customer bases	x	x	x	Reduce their reliance on traditional agents by making use of the various channels owned by banks			
Sell a whole range of financial services to clients and increase customer retention		x	x	Share services with banks		x	x
Reduce risk-based capital requirement to the same level of revenue	x			Develop new financial products more efficiently in collaboration with their bank partners		x	x
Works towards the provision of integrated financial services tailored to the life cycle of customers		x	x	Establish market presence rapidly without the need to build up a network of agents			
Access funds that are otherwise kept with life insurers who sometimes benefits from tax advantages		x	x	Obtain additional capital of banks to improve their solvency and expand business		x	x

2.3. Consumers

Unlike with banks and insurers, where benefits of bancassurance will have to be weighted against business risk, the positive impacts on consumers are unequivocal. Part of the lowering of distribution costs will be passed on to clients in the form of lower premium rates. In addition, it is likely that new products will be developed to better suit client needs, which otherwise may not be available if banks and insurers worked independently. Examples are overdraft insurance, depositors' insurance and other insurance covers sold in conjunction with existing bank services. The convenience offered by bancassurance should also increase customer satisfaction, for instance, when it is possible to pay premium as well as to withdraw and repay cash loans backed by life insurance policies through bank's ATM s. Just as important, is more than often a strategic step of financial service providers to shift from being product-oriented and to focus on distribution and customer relations.

2.4. Regulators

Bancassurance poses major challenges to regulators. The ability of financial institutions to diversify into others sectors should help to lower the level of latent systemic risk. Banks will benefit from lower income volatility while insurers could potentially obtain additional capital to bolster their solvency levels.

3. Overview – keeping up with the strong growth tempo

The popularity of banassurance remains strong although regional disparities persist as can be observed from table 2 bellow. Europe has the highest bancassurance penetration rate, with life bancassurance accounting for more than half of premium income in many markets. In North America, the penetration of bancassurance is much lower in both the US and Canada, partly reflecting the previously restricted regulations on banks' distribution of insurance. The market of bancassurance was fully liberalized in Japan by the end of 2007; therefore penetration has remained low.

In contrast, Australia has a high level of bancassurance penetration in the life sector, due to the acquisition of many life companies by banking groups. Emerging markets have very diverse bancassurance penetration rates depending on the local regulatory frameworks, the level of foreign participations and other social and cultural considerations. Bancassurers have generally made significant inroads in penetrating the Asian markets, many in the life insurance sector. At the same time, successes have also been reported in Central and Eastern Europe as well as in Latin America.

Table 2: Share of bancassurance distribution in selected markets

Source: Swiss Re, Sigma **No. 5/200***7, " Bancassurance: emerging trends, opportunities and challenges ", p. 11*

While the lack of consistent and comprehensive data have made it difficult to quantify how bancassurance penetration has developed in recent years, anecdotal information largely confirms that bancassurance has continued to gain importance in most regions.

In continental Europe and Oceania, bancassurance penetration in the life insurance sector has stabilized at a relatively high level with the exception of Germany since 2000. Non –life distribution is gaining in popularity, albeit from a low level. The US and Canda have yet to fully embrace bancassurance although some of regulatory hurdles have been removed. In Japan, bancassurance did not exist in 2000, but has since become a competitive channel. Further liberalization is likely to see bancassurance gaining market share.

Among emerging markets, bancassurance has a developed robustly in the life markets of Latin America, Central and Eastern Europe (CEE) and Asia, many from relatively low levels. Activities in the non-life sector generally remain limited. However, in Latin America, non-life distribution has actually preceded life distribution for bancassurers. In comparison, bancassurance has not flourished in the Middle East of Africa where penetration has remained low over the last few years.

We should be aware that the generalisation of regional trends could conceal significant developments in individual markets.

THE FINANCING OF THE FIRM BY BONDS

Berceanu Dorel

Faculty of Economics and Business Administration, University of Craiova, Romania

Through this present paper there are presented a few aspects concerning one of the instruments of medium and long term debt which can be used by companies, and that is the bonds credit.

So that, after a short presentation of the framework in which this debt method can be used, there are presented the conditions that have to be fulfilled so that a company could have access on the bonds market. Then there is briefly presented a parallel between the mechanism of forming the capital through the issue of stocks and bonds. A large space is occupied by the parameters of the issue of bonds. Also, there are widely presented the elements included in the prospect of emission. After a short presentation of the conditions which have to be fulfilled in order to have access to a certain category of listing and emphasizing the six emissions of bonds quoted on the Bucharest Stock Exchange, in march 2008, finally, there are presented the advantages and disadvantages of appealing of this method of debt.

Key words: bonds, credit, firm, share, capital market

The financing through the capital market represent an efficient and flexible option for dinamic firms.

Together with the equity and the financing by means of bank loans, important sources of financing from outside the company are attracted appealing to the public savings that is the bond financing.

For any company, in some situations, the equity is insufficient to cover the financing needs, and its growth (by new cash subscription or by the incorporation of the reserves) may encounter difficulties, not only from the juridical point of view but mostly from the inherent risks related to the potential investor's trust in the issuer of shares and those related to the possibility of loosing control for the old shareholders. In addition to that, contracting bank loans implies for the company, sometimes, more restrictive conditions to be fulfilled. These are the reasons that determine the companies, especially the big ones that are marketable, to apply to bonds financing.

For the countries where this means of capital mobilization is an usual practice, the issue of bonds, as a means of attracting the public savings, is preferred mostly by small and middle companies unquoted on this market section, and the issue takes place by the association of these firms to contract bank loans in common name. In the latter case, the issue takes place by the association of many firms that guarantee the loan together, by means of some institutions and collective emplacement agencies, that allocate the attracted capital as loans for the issuing firms. There are situations when even the big firms use this technique, especially when they have relatively reduced financial needs and they don't wish to spend the confidence capital to the public through individual credits, reserving this option only to attract large amounts of money from the market.

At first sight, one might appreciate that a total capital growth by means of the issue of bonds has a bad influence on its financial structure toward the growth of the balance of debts in the total capital. But, in fact, such a procedure has a series of benefic effects over the firm because it connects it, in a durable way, to the capital market, with serious implications in the dynamic adjustment of the capital cost, in the dynamics of the capitals and in the transparency of the external image offering in the same time, new values to the programming of the production activity and to the investments.

There are several *conditions* to be fulfilled in order to have access to bonds financing market:

- it has to be a joint-stock company;
- the firm has to have at least two or three years of activity reflected in the balance sheet approved by the shareholders;
- the issue of bonds by public offer is made on the basis of a prospect of issue;
- the value of the subscribed bond financing has to be completely subscribed.

These requests are specified in the 31/1990 law regarding Commercial Firms republished and modified.

The bonds can be issued in a material form, on paper, on an abstract/unembodied form, by account subscription.

Therefore, as a specified form of the loan, the bonds loan supposes the materialization of the debentures over the issuing firms as securities called bonds.

Therefore, we can define the **bond** as a **securities** that proves that a medium or long term loan that the issuer obliges to repay in a determined period of time, that gives the right to its owner (the creditor of the firm) to a certain annual interest, during the whole period, no matter the economic or financial situation of the issuer.

In the sense of a better understanding of the mechanism of forming the capital through bonds and the financial consequences of the issue of bonds, there can be made a parallel with the mechanism of forming the capital through the issue of stocks. The shareholder of the company is the owner of a part of the company and he takes the risks and perspectives of profit. The bondholder, on the contrary, borrows the company for a definite period of time with an interest settled at the time of the issue, and in case of its bankruptcy, he prosecutes the recover of his rights. The shareholder has the right to vote at the General Shareholders' Meeting concerning the administration of the company and sharing the profit for dividends and/or capitalization, while the bonds' owner deliberates within the bonds' owners meeting, concerning his rights. So that, bonds give to their owner no power of decision within the respective company, and neither permit him to benefit from the company's growth, as it happens in case of stocks. Bonds' owners meeting, legally constituted can name a representative of the bonds' owners and one or more substitutes, with the right of representing them in front of the company and in the court law. Usually, the cost of procuring the bond credit is smaller than the subscriptions at the stockholders' equity.

The issue of bonds is settled by the general shareholders' meeting and not by the council of administration or by the company's manager, so that the legislator wanted to protect the bonds' subscriptors against the commercial companies that do not offer all guarantees necessary for the loan reimbursement. Besides, the legislator asks for maximum of information to be given to the future bondholders for him to take the decision of buying the bonds with full knowledge of the facts.

The public offer of selling the bonds takes place in a similar way with the stocks' selling. Just like the stocks, the bonds are emitted through public offer only through a specialized company of mediation, called Society of financial investments services (SSIF).

This has the role of coordinating all operations bond through financing through stocks:

- elaboration of the issue prospect based on the parameters established in accordance with the issuing company and with the data received from it;
- coordination of bonds' selling operations;
- elaboration the closing offer report;
- listing the bonds.

The issuing company of the bonds establishes, through consulting with the mediation company and based on the its own needs of financing the characteristics **(parameters) of the issue:**

- ***the par value of the bond*** equals the part of the landed amount/stock, represented by each bond. The par value, as mentioned before, is established by law. The bonds from the same issue must be of an equal value, to give the owners equal rights. *The par value of one bond cannot be smaller than 2.5 RON,* except for the par of the bonds convertible in stock, that have an equal value with the stock. The convertible bonds can be turned/changed in shares of the firm that issued them, in the conditions established in the public offer prospect. A small par value presents the advantage to bring foreword the transactions and the inconvenience of complicating the commercial data processing of the debts.
- ***the issue price*** represents the amount paid by the buyer to become the owner of the bond. In some cases, the issue price equals the par value, and in other situations, as, for example, the need to speed up the bond sale, there is a difference between the par value and the issue price (the par value may be bigger than the issue price), called *issue premium*. Sometimes, to make the bonds more attractive, or when the period is big, they are returned when due time at a bigger price than the par, the difference being called *returning/repayment premium* (returning premium - par).

The issuing and returning premiums, the payments concerning the bond issuing and the remuneration for the personnel that ensures the bond sale, decide a cost of the credit higher than the nominal interest.

When the issue of bond financing is *underpar*, and its return is at a higher value than the par, both a issue premium and a returning premium will appear.

- the numbers of bonds;
- the total amount of the bonds financing, is obtained by multiplying the issue price with the numbers of bonds, i.e., practical, the amount which is financed the firm;
- the data of use is the date when the interest begins to flow;
- the data of regulation is the date when the investors deposit the amounts for the bonds financing;
- the amount of the interest. The issuer remunerates the borrowed amounts, with a periodic interest on a detachable bond coupon. The interest is determined by multiplying the par value (V_N) with the rate of interest established by the issue process (d). So, the average calculating operation is:

$$\text{Interest}=\frac{V_N \cdot d}{100} \quad (1)$$

- the life period, the frequency of payments and the returning modalities.

In the financial practice, there are used many returning ways. A bond may have one or more specifications for amortization. Generally there are:

a) the normal amortization of the loan;
b) the amortization with specifications for the return with anticipation.

a) The normal amortization is always presented as a table, and can be made according to many methods, the most used being:

a_1) in equal portions (constant amortization);

a_2) constant annuities;

a_3) full amortization at maturity date.

The **annuity** of a loan is the total annual amount made up of interest and the credit rate (the amortization) that the issuers use to pay the debt.

a_1*) Equal portions amortization* infer the return of an equal number of bonds each year.

In this situation, the annuities are given by the relation:

$$A_i = \frac{D}{n} + D_i \cdot d, \qquad i = \overline{1,n} \quad (2)$$

where:

A_i = the annuity to be returned in the “i” year;

D = the value of the bond credit;

n = the period of the credit;

$\frac{D}{n}$ = the credit rate (amortization)

d = interest rate (the percentage);

D_i = the value of the bond credit remaining to be reimbursed in the beggining of the year “i”.

a_2) The amortization in constant annuities

The annuity value is determined according to the formula:

$$A = D \cdot \frac{d}{1-(1+d)^{-n}} \quad (3)$$

where:

A = the annuity to be returned, that, in this case is the same for every year.

The constancy of the annuities is established by the decreasing variation of the debts and, compensatory, the on growing amortization variation (the credit rate)

a_3) *Full amortization at maturity date* is the most frequent case. The issuer returns the entire loan at the maturity date.

In this case, the annuities are determined according to the formula:

$$A_i = D \cdot d, \quad i = \overline{1, n-1} \quad (4)$$

$$A_n = D + D \cdot d \quad (5)$$

By using the amortization methods a_1) – a_3), the returning is made, generally, by parity, and the bonds to be returned are, in the most cases, established either by the drawing of lots of the series and numbers of the bonds, or they are bought back on the bond market at an equivalence of no more than half of the amount of amortization.

The reimbursement on stock exchange is interesting for the debtor firm when the quotation is inferior to the refund value.

b) The anticipated amortization

The reimbursement may be done anticipated, if this right was provided on issue. In this case, sometimes the firms covers the loan by another loan with a lower interest.

According to art. 176, law no. 31/1990 regarding the firms modified and republished, in our country, the bonds are reimbursed by the issuer at maturity date.

Before the maturity date, the bonds from the same issue and with the same value may be reimbursed, by drawing of lots, at a higher value than their par value, established by the firm and openly announced, with at least 15 days before the drawing of lots.

- ***the sale period of the bonds and their type (convertible or non convertible)***. The convertible bonds may be changed in shares at the firm of issue, in the conditions established in the public offer prospect.
- ***the warranty modality and the quotation on the organized market***

Based on these characteristics and on the information received from the issuing company, SSIF elaborates an official document of presenting the issuing company and the bonds that are to be sold, called **prospect of issue**

Through the elements included in the prospect of issue of the bonds there are:

- presenting the companies and the persons that have participated at the prospect elaboration;
- the informations about issuer (the name, the headquarters, and the duration of the society; the other issued bonds; the share capital and the reserves; the date of the publication in the Romania's Official Monitor of the completion of the registration and the modifications that were made to the constitutive document; the situation of the shareholders' equity after the last approved balance sheet; the categories of shares issued by the corporation; the assignments that are imposed on the tangible assets of the corporation);
- the informations about issued bonds and the attached rights (the numbers of the issued bonds, the par value of the bonds, the issue price, the means of repayment, the payments, their interest, to point out whether they are bearer or registred bonds, and weather they are convertible from a category to another or in shares, the warranty modality, the listening, the offer and the destination of funds);
- the informations about the activity of the issuing (operations, economical-financial performances, head quarters, research and development, law procedures, wage earners, investments, financing sources);
- the informations about the management, future perspectives, risk factors;
- the date when the decision for the issue of bonds of the extraordinary general assembly was published

The issue prospect has to be approved by the Romanian National Securities Commission (CNVM). Analog with stocks, bonds cannot be offered to be sold if this procedure had not been done. Also, according to the regulations in force it is recommended the bonds' guarantee with actives, especially in the case of new issues.

After the approval there takes place the official publicity of the offer, meaning its presentation in national newspapers and through other methods.

During the development of the offer, bonds are put on sale at distributors' head quarters – companies of financial investments services and banks with which the issuing company has concluded distribution contracts.

After the successfully closing of the offer, bonds are registered at CNVM, and after that these can be listed at Bucharest Stock Exchange(BSE).

The listing al BSE will be done in the sector "Credit titles" at one of the three categories. Fitting in a certain category will be done on the basis of the following conditions (table 1):

Table 1

Conditions\Category	**Category 1**	**Category 2**	**Category 3**
Corporative bonds must be public distribute at least	1000 persons	100 persons	-
The total value of bonds credit	>200.000 EUR	>200.000 EUR	>200.000 EUR

Source: BSE

Bonds credits that are not emitted by entities from Romania fit in "International" and have to have a value greater than 200.000 euros.

At the time being (March 2008), for the financial instrument "Corporative bonds" we have four issues of the companies from Romania and two international ones. These are presented in table 2

An issuing company of bonds, through public offer, will have to fulfill a series of obligations of reporting to the institutions of the capital market and to the investor public: financial reports, communiques with the events that affect the bonds' owners, interests' payments etc.

Resorting to the bond financed has both advantages and a series of limits:

As *advantages* we can cite:

- it allows the procurement of some important amount of money to make some large scope investments;
- putting aside the banks and the expenses to remunerate them in the process of getting the equity for production;
- obtaining a bigger net result than the one that would have been obtained if the bond financing value had been the result of the shareholder's equity growth (the gain of net profit equals the savings from the income tax for the interest paid for the bond financing, that are deductible), with direct implications over the relative cost of the bond financing;
- the debt cost is absolutely limited, and the creditors do not take part of the profit growth except for some situations;
- the bonds give the holder no power of decision inside the enterprise, the shareholders not being forced to share the control when they use the debt financing;
- the possibility to withdraw the old bonds, when the possibility of a new bond issue with a lower interest rate;
- the possibility to ransom on the exchange markets their own bonds at the market price (if the ransom price is lower than the par, the enterprise would gain profit).

The *limits* refer to:

- no matter the firm situation, the debts from the bond financing are a fixed expense, the firm paying periodically the interest obligatorily;
- it has a higher risk than other financing forms;
- the annuities that have to be refunded have an exact maturity date, a moment when the enterprise might be caught on the wrong foot as far as liquidities are concerned, and even if they do exist their diminution inevitably takes place;
- in the case of an economic recession, the bond financed firm would have big difficulties to make the payments as compared to the case of share issue financing;
- the contractual relation on a short and medium term inherent to a bond issue imposes much more restrictive specifications in comparison with the share issue or the case of the short term loan/credit;
- the risk of not subscribing the bonds, and, as a consequence, the loss of the investment opportunities might drive, sometimes, to difficulties for the enterprise and, why not, to its bankruptcy.

As for Romania, we consider that we can speak only theoretically about a bond market, because :

- the securities market where the bonds are issued and circulate is insufficiently developed, having a lot of syncope, not functioning continuously as a very active market in this direction;
- people's lack of trust in firms, because even firms that believed themselves to be very solid were bankrupt;
- the people's habit to work with banks (more than that, there is the guarantee of collecting an amount of money as refund in the established guaranteed limit if bankruptcy occurs) and the temptation of currency investment and state titles in the last few years. But, once with the drastic deflation of the deposits interest rates and with the sinuous evolution of the exchange rate we can also expect a sense of direction of the firms and natural person towards the types of investment like shares and bonds.

Abstract: In the context of European Union integration, the effort of European Union countries is oriented on reaching the same occidental standards in local public administration. Therefore, the reforms of local public administration are concentrating on local public investments, and especially on infrastructure projects and the sources of financing them. This paper presents these sources of financing local public investments in Romania and other new EU countries from Central and Eastern Europe.

Key words: European Union, local infrastructure investments, budgetary revenues, EU grants, private financing

1. Necessity of local infrastructure investments and the role of local authorities in financing them

The scientific literature admits the existence of a direct relationship between the level of investments in infrastructure (transport, telecommunications, environment etc.) and the performances of economic growth of a country. In this context, the increasing of investments is recommended as a precondition for sustaining the potential of a state's economic growth.

The necessity of massive infrastructure investments is specific not only to European states, but to the international level, too. At this level, it is manifested in a context characterized through three historic importance phenomena as follows: globalization, which imposes to create a competitive infrastructure, the decentralization process, which sometimes is not accompanied by authority or resources transfers and urbanization, which imposes the assurance of some basic services withought precedent.

In the European context, big infrastructure investments are important especially for the new member states of EU (from Central and Eastern Europe) for sustaining the real convergence program. A study made in 2005 estimated the necessary of investments in infrastructure in the new EU member states in 1995 – 2010 at 505 billion euro (44 billion for roads, 37 for railways, 63 for telecommunications, 180 in the water/sewage sector, 110 in the energy sector and 71 in environment) [Brenck and others, 2005].

The lack of investments in infrastructure, especially in transport, is a reality for Romania too. In accord with Ernst & Young Research „Investments attractivity in S-E Europe in 2008", although Romania is the main destination of investments in South-Eastern Europe, improvements are still necessary, from the foreign investors perspective, in some areas such as communications, transport, logistics, social environment and the quality of life.

In this context, the financing of investments in infrastructure, in EU countries and on international level, too, seems to be "one of the most important challenges of the millennium" [Sierra, 2005].

The decentralization process generates the implication of local authorities in local infrastructure investments, as a result of exclusive competences and, so, the necessity of ensuring the financing sources for them. At the same time, the statute of EU member state imposes restrictions on local authorities, but, also, offers them the opportunity to access new financing resources for local infrastructure projects.

2. Financing local infrastructure investments through budgetary revenues

In the traditional way, the financing of local investments projects in infrastructure should be made only with *ordinary resources of local budgets*. From this point of view, article 9 of the European Charter of Local Self-Government suggests, at least implicitly, that the structure of local authorities' resources should be broken into two broader concepts as follows: *own resources* and *transferred resources* or *financial transfers*.

The own resources, of which they may dispose freely within the framework of their powers, are from the local community territory and mean: local taxes, fees. Transferred resources are financial transfers from central budget with the help of tax-sharing system. The own revenues in accord with Romanian Local public finances Act [Act of local public finance, Art. 5 (1)] are: local taxes, contributions, quotas from income tax (in total amount of 82%) and others. Another source of financing are the transfers from the state budget or other budgets, but as a rule of local financial autonomy, it is indicate this amount to be smaller. The transfers from state budget have the form of sums from VAT and subventions.

If the ordinary resources are insufficient, a solution for local investments in infrastructure is *local indebtedness* using borrowings, as *extraordinary resources of local budgets*. There are two main possibilities that local government can use in borrowing: bonds and loans from commercial banks.

The Romanian local public finance Act stipulates that local councils, counties councils and the General Council of Bucharest County can contract internal and external loans, short, medium and long-term, for local public investments and for refinancing local public debt. An important prudential rule is that “annual debts representing the due installments deriving from contract loans…shall not exceed 30% of own revenues of the local budgets…” [Act of local finance, Art. 63 (4)].

However, prudence is recommended when employing local indebtedness, for Romania and other EU member states, because of the nominal convergence criteria which says that the ratio of government debt to GDP must not exceed the benchmark value of 60%. The practice of local indebtedness in the context of a big central government debt stock can generate the unfulfilment of the convergence criteria. For Romania and the other Central and Eastern European countries the situation is not a worrying one because they have a low level of total public debt, much less than 60% (Hungary being an exception).

If the public deficit ratio to Gross Domestic Product (GDP) exceeds the reference value of 3% (convergence criteria of The Treaty of Maastricht, also stipulated in the Stability and Growth Pact), no project will be financed from the Cohesion Funds, until the deficit problem will be solved. So, it is necessary to practice a prudent local indebtedness for not limiting the access to EU funds. In 2007, Romania was very close to the government deficit limit (2,7% of GDP).

The low level of funds available for local public administrations and real impossibility (and not legal) to raise local taxes for bigger revenues of local budgets, makes the money look insufficient for infrastructure investments, even for small investments. Local borrowing must be used prudently for not generating budgetary deficit over the limit, although it looks like a viable solution. In this context, it is necessary to find alternative sources of financing, such as European Union funds or public-private partnership.

3. EU funds for financing local infrastructure investments

The EU integration offers to the member states new opportunities to obtain financial resources for financing the development projects, inclusively local infrastructure projects. Starting with the moment of accession, the states benefit by non-reimbursable financial assistance through the funds allocated in accord with the European Union policies.

The fundamental policy of EU is the Economic and Social Cohesion Policy, whose implementation is realized with the help of three structural instruments, as structural funds (European Regional Development Fund – ERDF - and European Social Fund - ESF) and the Cohesion Fund - CF. The actions financed by these funds and the categories of eligible member states are presented in Table 1.

EU Fund	Supported actions	Eligibility
Cohesion Fund (CF)	- Transport infrastructure projects - railways, road traffic, inland waterways, civil air transport, etc. - Environment projects - energy efficiency, renewable energy and transport projects	EU Member States whose GNP per capita is below 90% of the EU-average
European Regional Development Fund	- Direct aid to investments in enterprises (focus on SMEs) to create sustainable jobs - Infrastructures related to research and innovation, telecommunications, environment, energy and transport	All 27 EU Member States

(ERDF)	- Support via financial instruments such as capital risk funds, local development funds, etc. for regional and local development and encouragement of cooperation between cities and regions - Technical assistance	
European Social Fund (ESF)	- Lifelong learning and adoption of workers and enterprises - Integration of unemployed, women and migrants in the labour market - Fighting discrimination in the labour market - Reforming education system and improving human capital	All 27 EU Member States

Table 1: Eligible Member States and supported actions from EU Funds

For the 2007–2013 period of time, the intervention objectives of the Economic and Social Cohesion Policy are:

- Convergence – for the regions where GDP/inhabitant is under 75% of the EU average (financed by the ERDF, the ESF and the Cohesion fund);
- Regional Competitiveness and Employment – for regions which are not eligible for the Convergence objective (financed by the ERDF and the ESF);
- European Territorial Cooperation – for regions, counties and transnational zones (financed by the ERDF).

In accord with their stage of economic development, the new EU member states from Central and Eastern Europe, inclusively Romania, can benefit by all three funds. For the period of time 2007 – 2013, Poland benefits by the biggest amount of funds (67284 mill. Euro, almost 19,37% of total funds), followed by the Czech Republic (7,68%) and Hungary (7,28%) (Figure 1)

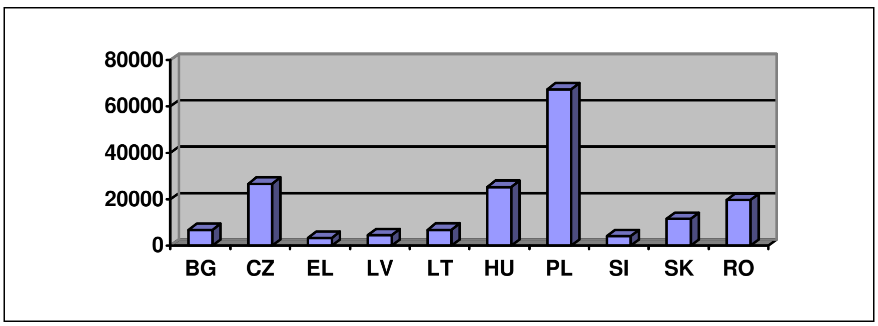

Figure 1: Cohesion policy 2007-2013: Indicative financial allocations for the new EU Member States (million Euro, current prices)

Source: European Commission

The total amount of Cohesion and Structural Funds allocated for Romania for 2007-2013 is 19668 million Euro, representing 5,66% of the total funds. 12661 million Euro are allocated through Structural Funds in the „Convergence" objective, 6552 million Euro are allocated through Cohesion Fund and 455 million Euro are allocated to the "European Territorial Cooperation" objective. The distribution of Structural Funds – Convergence objective- and of the Cohesion Fund for Operational Programs makes evident the priority of infrastructure projects in transport (23,8%) and environment (23,5%) (Figure 2)

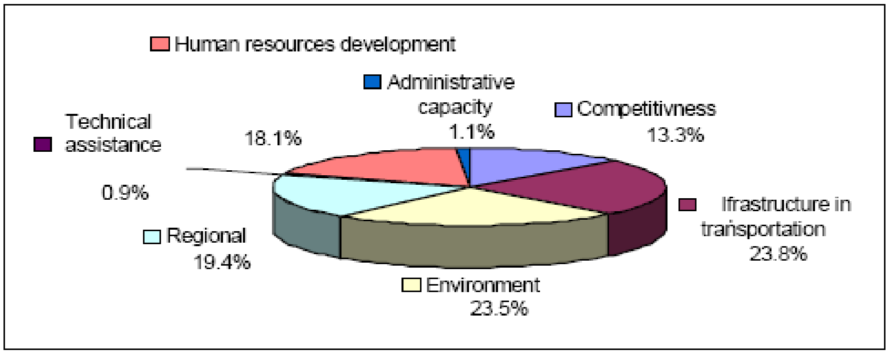

Figure 2: Estimative allocation on operational programs for Romania, 2007-2013

Source: The Romanian National Strategic Reference Framework (RNSRF) 2007-2013

Resources from Cohesion and Structural Funds represent an opportunity for the new member states, because they offer the possibility to make big investment projects, also in local infrastructure, withought using ordinary resources and without affecting the level of consolidate budgetary balance. The differences between borrowing and EU funds are as follows: the funds are not reimbursable and don't suppose interest rates.

Though, there are two aspects which must be taken into consideration. First, the rules of Cohesion and Structural Funds impose the necessity of co-financing by the member states. The maxim level of EU contribution is established by the Council Rules no.1083/2006, according to the EU financial perspectives for 2007- 2013.

Romania can benefit by a maximum communitarian financing rate at the level of OP of 85% for all three funds: ERDF, ESF and Cohesion Fund. The RNSRF allocation within the "Convergence" objective needs a national co-finance estimated at 5.07 billion Euro, proceeded from public sources (2/3 from the total of co-finance) and from private sources (1/3). The public co-financing will be assured from the state budget by the Romanian Government and from the local budgets of the public authorities which will apply structural instruments for financing.

Considering the lowest financial capacity of many local authorities to assure this co-financing, the Romanian Government decided to reduce as far as possible the local budget contribution. Thus, the principle which will be applied in the operational programs tell us that the personal co-financing which the local authority need to assure for a project will be in general 2% from the eligible value, a major exception being the projects which generates incomes. Consequently, the approved contribution of the local authorities is under 5% from the total of national co-finance.

Secondly, the new EU member states, and Romania in particular, don't have the capacity of absorption of these funds because of the inadequately institutional and legal framework, although the volume of cohesion and structural engagements is considerable.

In the first two years after the integration of the ten countries in the EU in 2004, the absorption rate has been under expectation (Poland, Hungary and Czech Republic). Only Latvia registered some performances. Also, Romania encountered the same problem in 2007. A study published by the National Bank of Romania in March 2008 pointed out that the level of European funds absorption by Romania in the first year as a EU member state (21,7%) was at the half of the level registered by other countries as Czech Republic, Poland (42,8%), Hungary (42,9%) and Slovakia. In this context, Romania became a net contributory to the European Union budget. Unless such a problem is properly addressed, it may result in de-commitments and the opportunities offered by EU funds would never materialize.

4. Financing local infrastructure projects through private participation (Public Private Partnership)

Public Private Partnership, as an alternative of financing the public investment projects, is applicable in the local infrastructure field, too. The mobilizing of available resources of both parts, public and private, presents a big advantage: it creates the possibility of local public administration to make big projects, which would be impossible without private partnership. Respecting the restrictions imposed by The Treaty of Maastricht and the Stability and Growth Pact on fiscal criteria, the Public Private Partnership is an alternative to make big local investments in infrastructure without practicing supplementary pressure on local budget. On the contrary, the relief of local budget from the obligation to entirely finance the local investment projects creates the instrument to reduce budgetary deficit and to rise other categories of current expenditures.

An analyze of the employment of Public Private Partnership in the European Union countries demonstrates that this instrument of financing is relatively new. Only The Great Britain has been using the Public Private Partnership as an alternative of financing public investment, for over 15 years. This financing alternative is familiar in Great Britain and Portugal. In the other countries of EU, the amounts of Public Private Partnership contracts are low.

The same situation is present in the Central and Eastern European states of EU, including Romania. The legal framework of Public Private Partnership was developed only recently and so, its employment is still at the beginning. The legal framework of PPP in Romania started with Act no. 219/1998 on concession regimes and Government Ordinance no. 16/2002 on public-private partnership contracts. The harmonization with the European directive on public acquisitions and concessions determined the new legal framework in 2006, GUO no. 34/2006 (approved by Act n. 337/2006) on public acquisition contract, equipment and services concessions contracts.

Country	Number of projects 1990-2006					Value of projects 1990-2006 (million USD)				
	Total	Energy	Telecom	Transport	Water and sewage	Total	Energy	Telecom	Transport	Water and sewage
Bulgaria	22	13	5	3	1	7133	3566	2881	534	152
Czech Republic	67	27	14	6	20	21186	5165	15216	390	415
Hungary	58	26	17	6	9	24362	5903	13817	4437	206

Table 2: Private participation in infrastructure projects in the new EU Member States

Source: World Bank, Private Participation in Infrastructure Database

The incipient stage of development, from this point of view, registered in the new member states of EU from Central and Eastern Europe, can be presented using the number and the value of infrastructure projects financed by private participation (Table 2). Romania registered only 20 projects with a total value of 9563 million USD, after the Czech Republic, Hungary and Poland. The most important fields are telecommunications and energy. On the contrary, participation of private capital for financing transport projects is very small.

Being a European Union member state, Romania is expected to register a significant development of this financing mechanism in the next period of time, thus Public Private Partnership is an important option for future infrastructure local projects.

LABOR MARKET DEVELOPMENTS IN THE EU

Boglea Vanina

Universitatea "Aurel Vlaicu" din Arad, Facultatea de Ştiinţe Economice, Arad, B-dul Nicolae Titulescu, Bl. 308 Sc. A, Ap. 6, e-mail: vanina.boglea@yahoo.com, phone: 0744496289

Abstract. Labor market performances in the region have further improved with unemployment rates reaching historically low levels and employment rates increasing. Real wage growth is slowing in most countries in the region, but remains strong especially in Latvia and Romania. Despite the wage moderation, unit labor costs continue to rise in much of the region.

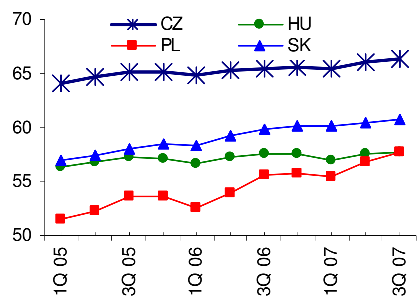
Keywords: labor market, unemployment rates, real wage growth, regional differences, educational systems.

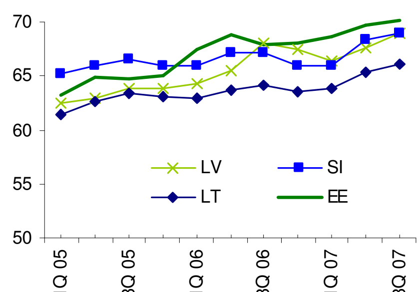
1. Unemployment Rates

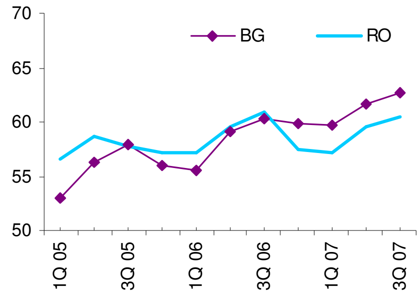
With the exception of Hungary unemployment rates in the EU8+2 are now at the lowest level since 1Q 2000. While in 1Q 2000 unemployment rates across the region ranged from 7 to 19%, and the average rate was at almost 13%, in 3Q 2007 unemployment rates were in single digits in all countries but Slovakia (11.3%). Poland has made the most significant progress by reducing the unemployment rate by half within the past 3 years.

Lower unemployment rates result mainly from higher demand for labor and go hand in hand with higher employment rates (Chart 1). Still, only the Baltic countries, Slovenia, and the Czech Republic come close to the Lisbon Strategy target of a 70% employment rate. Significantly, three out of these five countries (Estonia, Slovenia, and the Czech Republic) are the best performers in the PISA assessment in the region. Although labor market performance is improving in the remaining countries too, their employment rates remain 10 percentage points or more below the Lisbon target.

Chart 1. Employment rates, %







Source: Eurostat, 2007

Educational attainment and quality of education are significant determinants of employment rate differentials within countries. Tertiary education gives at least an 80% guarantee of employment in all EU8+2 while employment rates of those with primary and lower secondary education vary strongly across the region (from 15% in Slovakia to almost 50% in Slovenia). In the Baltic countries, the Czech Republic, Slovenia, and Bulgaria, 70% or more of the labor force with upper secondary and post secondary education is employed (Table 1). People from this category and those with higher education contributed positively to overall employment growth between 3Q 2006 and 3Q 2007 in all countries with the exception of Estonia and Latvia (Chart 2).

PISA 2006 reveals that 15-year old students in the region generally perform below the OECD average. Only young Estonians and Slovenians performed above the OECD average in science, reading and mathematics. The Czechs performed better than the OECD average in two areas, while Poles and Hungarians did in one (reading and science, respectively). The remaining five countries in the region scored below the OECD average in all three areas (Chart 3). The very sizeable gaps for Romania and Bulgaria are particularly disturbing.

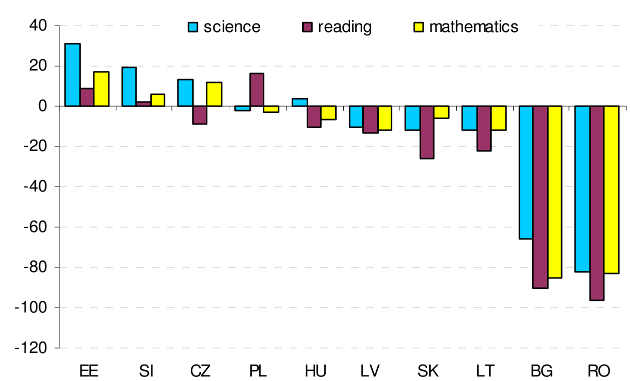
2. Performance of the EU8+2 and Croatia in PISA 2006

PISA (Program for International Student Assessment) was launched in 1997 by the OECD. It represents a commitment by governments to monitor the outcomes of education systems in terms of student achievement on a regular basis and within an internationally agreed common framework. PISA has now become the most comprehensive and rigorous international program for assessing student performance and providing data on the student, family and institutional factors.

The first PISA survey was conducted in 2000 and focused on reading literacy. PISA 2003 focused on mathematics and PISA 2006 focused on science, but also examined student attitudes towards science and their awareness of the opportunities that science competencies may bring, and of science learning opportunities and environments offered by their schools. It also placed student performance in the context of other factors, such as gender, socio-economic background and school policies and practices, providing insights into how they influence the development of knowledge and skills at home and at school and analyzing what the implications are for policy development.

Chart 3. A distance of the national score from the OECD average, points

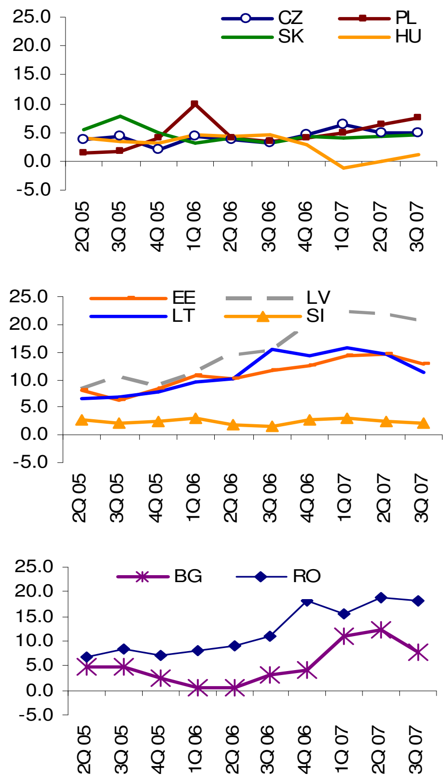


Notes: Positive distance stands for better than OECD average performance.

Source: OECD (2007).

Labor markets are tightening as labor shortages become more evident. The resulting increase in real wages in 3Q 2007 varies considerably across the region. Wage pressure remains high in the EU8+2, and even the where there has been some moderation of real wages (Baltic countries, Bulgaria, and Romania) it results largely from an acceleration of inflation rather than deceleration of nominal wages. Unit labor cost dynamics in the Visegrad countries and Slovenia still remain moderate as compared with the Baltic countries, Bulgaria, and Romania (Chart 4). The persistence of wage pressure may undermine countries' competitiveness and weaken their prospects for high and sustainable economic growth.

Chart 4. Real wage growth, yoy, %



Note: Data in line with CSO methodology

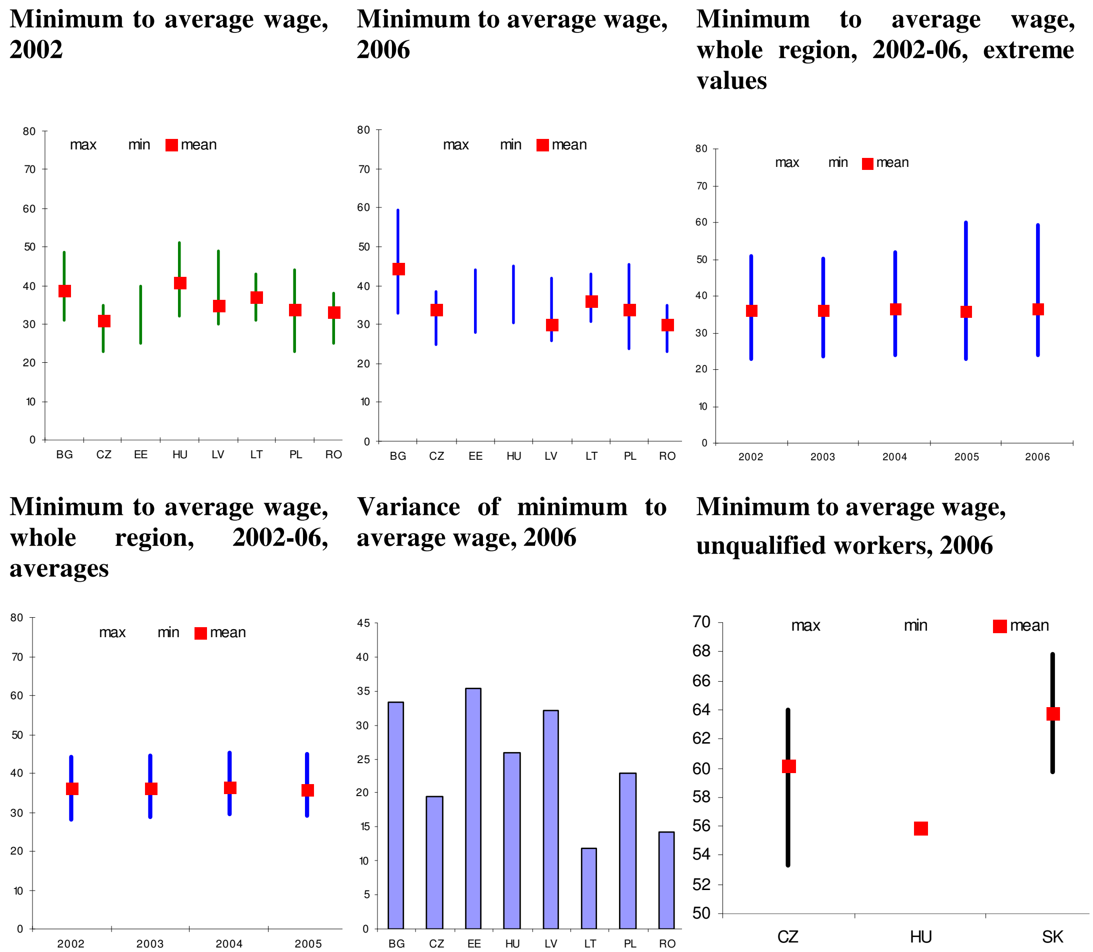
Source: CSOs

3. The minimum wage may be too high for unqualified workers in lagging regions

Regional differences within individual EU8+2 countries are considerable and may interact with country-wide minimum wage rates. These regional differences are also related to educational attainment as people with lower education levels are overrepresented in lagging regions. Hence, uniform economy-wide minimum wages may prevent the local labor market from clearing at a lower level of wages.

Twenty EU member states have a statutory national minimum wage despite the potentially negative impact on employment. While on average the minimum wage is too low – compared to the average wage – to affect a significant number of workers in the economy as a whole, it could affect unqualified workers in lagging regions.

Chart 5. The minimum wage for unqualified workers



Source: CSOs,

Note: in %. Romania only 2002-05, Lithuania 2003-2006. Source: Eurostat, CSOs and WB staff.

Regional data for EU8+2 from 2002-2006 indicate that the ratio of the minimum to the average wage is low in the regions surrounding capital cities, but is as high as 59% in some regions of Bulgaria. The ratio is falling in almost all countries, but especially in Hungary and Latvia. Bulgaria, is one of a few countries where the ratio increased, on average by 3.4 percentage points every year. More importantly, the variance of regional ratios has fallen in half of the countries – in Estonia, Hungary, Latvia, Romania and Slovenia.

The ratio of minimum to average wages for unqualified workers is much higher than the economy-wide average. It reached 64% in the Czech Republic in 2006 and 68% in Slovakia in 2005. Unfortunately, regional figures are not available for more countries, but it seems reasonable to assume that the ratio for unqualified workers could be at about 60 to 80% of the economy and nation-wide average. This could drive unqualified workers in lagging regions out of the formal labor market.

Conclusions

Frequently less than a fifth of public spending on active labour market programmes is in programmes targeted specifically at youths facing difficulties in the labour market, but partial data for EU countries suggest that up to two-fifths of participants in these programmes, including subsidised apprenticeships, are aged under 25. Strategies of early intervention and diverse pathways in education and training are described, and recent labour market policy experience is reviewed under headings of activation strategies; broadly-targeted employment programmes; dual systems; and “safety nets” for school leavers. New or greatly expanded youth programmes, introduced by a number of countries since the mid-1990s, have had a visible impact on youth unemployment rates in some cases. Youth labour market outcomes are sensitive to general economic conditions, but additional structural features that are often associated with good outcomes in international comparative terms include active public management of the transition-to-work process, involving youth unemployment benefits combined with activation measures and backed up by a "safety-net" approach, and early contact with the world of work through apprenticeships or student jobs.

The European Union development is an irreversible and complex process which enforces the deep reorganizations, reforms, especially for the countries which want to be integrated, and for the countries that are member big expenses, but it will assure the growth of the economic and human potential of E.U. Transport is particularly important for developing links between Romania and the E.U., but he road network is one of the least developed in Europe. Two thirds of the total surface of the road infrastructure from Romania must be rehabilitated. Beside the absence of grounds, the authorities don't dispose of experts who are able to develop viable projects which to attract European financing. The access to the structural funds is not an easy one, because is a bureaucratic organization, and in combination with our bureaucracy has a negative result for our country.

Key words: road infrastructure, rehabilitation, European funds, projects

Currently European Union follow the creation of a space of freedom, of security, of justice and integrates the accumulations resulted from previous collaboration of the second states, which will carry on (continue to) consolidate it self on fundamental principles of freedom, democracies, man` s law and stat` s law rightful. A prime interest is that binded of the realization of unique market on the background custom union, an economic dynamic space, bank on the common rules and equal condition of competition, the harmonization of taxation methods, reciprocal reconnoiter of diplomas and the freedom of all access to the professions in the respective countries. Therewith involves the enterpriser's freedom to establish themselves in the communitarian's areas, what presupposes the juridical harmonization settlements concerning the freedom of capitals, economic goods, and cetacean's movement.

Another communitarian objective is that considering the agrarian politic commune intended to harmonize the distinct national mechanisms and let them establishes the commune custom barriers for the merchandises extra communitarians, followed by industrial politics. This is adverted to:

- The simplification and the update of existing settlements in the profitable sense of the relation cost - profit, envisaging also the risk factor and environment;
- The Assurance of competition efficient frame in the sectors where the monopoly of the state is not justified (energy, telecommunication, and mail);
- Massive investments in the priorities sectors – future sectors of the economies (scientific research, projection, technology) beginning with the preparation of the necessary work forces until labor exploitation;
- The concentration of scientific research and its collaboration with the priorities areas (information and communication, industrial technology, environment, energies).

Another E.U.` s aim of creation and operation is the economic union and monetary union, and an important component is the politics of competitions, having in sight the mechanism of competitive economies from its terms of reference, and also outwardly its. In this sense there are the following areas of action:

- The elimination of the competitions restrictive agreements and abuses of dominant arrangement;
- The check of firms` s fusion in the aim of preventing the formation of a dominant firm;
- The liberalization of the sectors with monopoly arrangement (energy, telecommunication);
- The closely pursuit of stat` s subventions.

The E.U. development is an irreversible and complex process which enforces the deep reorganizations, reforms, especially for the countries which want to be integrated, and for the members countries big expenses, but it will assure the growth of the economic and human potential of E.U. Romania had a temporally series of different agreements with European Economic Community in diverse areas, as: mercer, metallurgy, industrial products. Beginning with February 2000, our country initiated the process of integration in E.U., on the strength of an application enunciate in this sense and respecting the requirement of economic order and politic enforced.

The adhesion requires profoundly process of economic reform considering the economic convergence and which foresees as much the macroeconomic stability, quotient and the financial one. Romania` s process in this sense follows:

- The economically breed supported on the strength of internal investments and also external resources in the shape of direct investments, in conditions of transparency;
- The assurance of economic transparency on the strength of a budgetary tolerable deficit (about of 33 from PIB), managing public debts adequately and reducing gradually the inflation;
- The promotion of a coherent politics concerning the improvement of economic structure, the vivification of competitive activities, the capitalization of agricultural and touristic potential, the amplification of financial services;
- The creation of legal settings necessary promoting the environment of competitive businesses;
- The development and the modernization of public services in the interests of citizens and national economies as much as possible nearer the E.U.` s standard.
- Long-term programs concerning ecologic accidents, levels of environment pollution.

Nevertheless, it does warn there is a need for more rapid adaptation to shifting economic trends and fresh thinking about the role of social policy in adjusting to new sources of competition – whether due to technological change or the other effects of globalization.

The warpath and objectives fixed by competent organs from Romania, for the period 2001 - 2004 and 2004 - 2006 there are subordinated in total amount to " National Strategy of Economic Development of Romania on average term", but also concordantly with the negotiations from the E.U.` s terms of reference concerning at the real and durable growth of P.I.B., in the conditions of competitive economy.

The transport sector has great importance for the Romanian economy. Transport is particularly important for developing links between Romania and the European Union. The railway network is extensive but the road network is one of the least developed in Europe. The long-term objectives of the program are to help prepare the transport sector for accession to the European Union through support for developing appropriate legislation, institutions, regulatory systems, human resources and infrastructure support market reforms in the transport sector aimed at contributing to overall economic development.

An enormous main road rehabilitation program has begun in Romania. One vital route is the Budapest to Bucharest route (1053 km of roadway from the Hungarian border to Pitesti, North Bucharest). The project to bring the road up to European standards began in 1994 and will be completed in 1998. Romanian, and European Union Private contractors have won contracts for the work with international experts supervising the construction on behalf of the Romanian government. Phare funding of 21 MEcu is 35% of the total. The remaining 65% is being financed by the European Investment Bank.

Two thirds from the total surface of the infrastructure from Romania must be rehabilitated. Many international studies show that the bad condition of the roads and the absence of investments in this segment represent a major impediment in the path of economic development. In these conditions, the development of the infrastructure as like the European standard is one of the national priorities for the period 2007-2013. Otherwise, the infrastructure is principal beneficiary of the E.U.`s backgrounds of cohesion. Romania has to retrieves a very big shifting in the infrastructure area, against the remainder countries from E.U. For instance, from the network almost 80 hundred km of roads, just 20 per cent represents national roads. The remainders are country and earth roads which degree of utility had diminished dramatically in last years, this because only 21 km from those roads had been repaired. The state of detritions is big also because the number of highways from Romania remained the same about ten years. The highways from touristic areas became extravagantly agglomerated in seasonally periods. Related with its surface, Romania has the smaller density of roads from all states which are member of E.U., meaning 33, 5 km to 100 of square km.

A report of World Traveling of Tourism Council (WTTC), consider that bad state of roads represent a major impediment in the path of development Romanian `s tourism, in the conditions in which most foreign visitors come in Romania on terrestrial path. The WTTC `s representations support that the roads are an essential elemental not only for tourism, but also for the development of the country. There are necessary strong investments in the principals route to Black Sea, and towards town as Brasov, Sighisoara or Sibiu, as the like as the north of the Bucharest. Project concerning improvement of road infrastructure represents an important segment on the buildings market from Romania, it shows in a study of Polish companionships of PMR `s consultants. The PMR `s specialists estimate that two thirds from the total surface of road infrastructure from Romania must be remade. The considerable funds allocated by European Union for the remaking the infrastructure project offers Romania the opportunity for resolving the infrastructure problems. Considering the PMR `s statistics, no less than four billions of Euro, representing irredeemable funds, were allocated for Romania by E.U. for infrastructure project. The biggest part of those funds, 60 per cent will be used for the main axis 1, which carries the visa of a development transport incident to network system of roads and freeways of E.U.

Likewise, 34 per cent from funds will be fated to modernization and development of national infrastructure. Romanian transport strategy is based in the main time to network transport construction, what means new freeways and the finalization of those which are in building. For the national and county roads, the strategy is based on their rehabilitation. Until the year 2013 is advisable that Romania to have almost 2. 000 of km of freeway. For the construction of freeways in the period 2007 - 2012 is necessary a yearly finances of 1, 86 billions of Euro, according National Company of Freeways and National Roads from Romania. The value represents an average of 11, 8 per cent from the incomes of state's budgets for the year 2007.

For the infrastructure development, up to the adhesion date, the most important European funds were allocated through ISPA and Phare programs. Opening with year 2007, financial assistance through ISPA is changed automatically with solidarity funds. Otherwise, all financial support will continuum to grow for three or four times more then ISPA fund in the moment of adhesion. From all the European funds allocated to Romania, 19, 7 billions of Euro represents the structural and cohesion funds. Almost 60 per cent from sum will go to basic infrastructure. Money will be allocated to the projects from the basic infrastructure area. Also, through the ISPA program, Romania beneficiated of important funds for infrastructure. In the period of 2000-2006, Romania covered 95, 9 per cent from the financial parcel of 2 billion of Euro allocated through the ISPA program. Romania received between 20 and 26 per cent from the annual budget available for ISPA facility on the period 2000-2006, so that becoming the second country after Poland in what looks the help granted. Romania also beneficiated of important funds through Phare program - component of Regional Infrastructure. For the period 2004 - 2006 were anticipated funds of 152 of millions of Euro.

Taking count of the Romanian necessity of reducing economic and social development disparity comparative with others state members of European Union, as well as the fact that an efficient, durable, flexibly and secure transport system can be considered a prerequisite condition for the economic development, corroborate with the commitment of developed the network TEN-T 7 = Trans European Network Transport and main projects TEN-T 7, the world objective of Operational and Sectorial Transport Program (POST) is of promoted a durable transport system in Romania. This will facilitated the transport in safe seat conditions, speedster and efficient, for persons and the merchandises with a duty level to European standard, between and in the frame of Romanian regions. After modernization, transport infrastructure thus improved will go directly to the growth of products competitively and the jobs supply, from the key sectors of economies and in the regions from Romania. The global impact will go to the improvement of economic activity in Romania. For achieving the objective POST, the European Union` s funds and those from the state` s budget were anticipated for being allocated to the transport sector in sight of implementation the follower main axes:

- - The modernization and the development of main axes TEN-T 7 in the aim of a development of a durable transport system and its integration with transport networks of European Union.

- - The modernization and the development of national transport infrastructure situated out of main axes TEN-T 7 in the aim of a development of a durable national transport system;
- - The modernization of the transport sector in the aim of improving the environment protections, human health and safety of passengers;
- - Technical assistance.

Each main axis is financed either from the cohesion fund, or FEDR, but don't from both, and containing one or many operations. This area of intervention is addressed to only one beneficiary, National Company of Freeways and National Roads from Romania, which is the lessce of all the national road infrastructures from our country. Its intervention follows:

- finances of projects preparation in the road infrastructure situated on the route of axis TEN-T 7 and the national road one situated out of this route;
- finances of investment's works for the modernization of national roads, the building of circuitous variant and /or freeways on the route of axis TEN-T 7 and those situated out of this route

The axis TEN-T 7 presents on the territory of Romania two branches which continuations the follow routes: Northern branch: Nădlac – Arad - Timişoara - Lugoj - Deva – Orăştie - Sibiu - Piteşti - Bucureşti – Cenavodă - Constanța.

Southern branch: Lugoj - Drobeta Turnu Severin - Craiova - Calafat with a variant at Simian - Maglavit, rounding Craiova

We will present you the variant as a rough guide of financial allocation for the expenditures which follow to be registered in the period 2007 - 2013 for the modernization and the development of road infrastructure placed on the route of axis TEN-T 7.

Total	508.476.333	381.758.516	126.717.817	126.717.817

Financial allocation as a guide for the modernization and development of road infrastructure situated out of main axis TEN-T 7.

As you can see from both presentation, the most important participation is the one of European funds, because the participation of Romanian part is smaller then the first one. The difference can be observed better in the first example, that with the modernization and development of the road infrastructure out of the main axis TEN-T 7.

The requests of financing afferent to the preparation` s projects of the future investments or for the works `s projects that was not followed in exact way by the Authority of Management of Operational and Sectorial Transport Program can be deposits to the initiative of the National Company of Freeways and National Roads from Romania in the period 12. 07. 2007 - 31. 12. 2013, only that is recommended as the National Company of Freeways and National Roads from Romania to has been informative consulted with the Authority of Management of Operational and Sectorial Transport Program (AM POST) before the official prompted of financial requests. AM POST was constituted in the settings of Transports Minister, having the resposability to manage, administer and implementation of financial assistances allocated to the POST. Each project from this major area of intervention will do the object of impact evaluation of environment and the indicators be used-up for the monitoring of the programs` s implementation results.

The projects of finances from this major area of intervention will lead to the communitarian` s objectives accomplishment to decrease and/or eliminate the negative effects caused by the growing of traffics. The project of investment effectuated will generate new work places especially in the building phase. These will be accessible to all social categories.

In the case of projects from this major area of intervention is not applied the rule of state` s help, because the infrastructure which follow to achieve represents the infrastructure of public state and which will be managed by the National Company of Freeways and National Roads from Romania, the concessionaire of all the infrastructures of national roads and freeways from Romania. In the case in which is decided the reassignment of construction and maintenance to other companionship will be taken into account the national and communitarian rules concerning the public acquisitions.

Since the year 2000, respectively in the last seven years, Romania did not succeeded into expending for the road infrastructure more than 200 millions Euro from European funds, although the ISPA program allocated for this sector for the period 2000 - 2010 near 673 millions Euro. This one means that until the year 2010, the central and the local administration must expend for the roads and freeways 471 of millions of Euro, respectively across 70 per cent from the money, in just 33 per cent from the time granted to loan ISPA. The project suggested to be financed from ISPA` s funds attracted feather in currently 364, 5 millions Euro, from which only 200 of millions of Euro were spent, as the numbers given from National Company of Freeways and National Roads from Romania show. The reasons which caused the low degree of absorption are many and known, sauce as: the problem of expropriations, which have not been made on time and for which there are not money now, the lack of experts whom to manage the making and the carrying on of the projects, and, not at last, the acute absence of financing. The most big problem is the absence of available grounds for building the roads, the process of expropriation being made heavier by the lack of proper legislation and of a previous strategy of unlocking the passages on which carry on being built the highways and freeways. It would be better if in the beginning of years '90, those roadways were reserved. For instance on the freeway Bucureşti - Constanța, on the transom Cernavodă - Constanța, on Bucureşti - Ploieşti here are not free grounds, 100 per cent available ground is not anywhere and there aren't money for expropriations.

Beside the absence of grounds, the authorities don't dispose of experts who are able to develop viable projects which to attract European financing. The solution could be the employment of some big companionships specialized on the works of ruttier infrastructure, which to carry on a big part from the responsibility of National Company of Freeways and National Roads from Romania. So that, the administration of the roads will must conceives the package of project, for which management would organize auctions in order to place them in the carry of another specialized company.

They found a solution for incurred problems: 'Express - roads' instead of freeways -1, 2 billions of Euro will be used for building those roads, as an intermediate solution between freeways and national roads, which they will be building on the transoms Arad - Oradea, Turda - Sebeş, Piteşti - Craiova and Tetea - Satu Mare - Baia Mare, 380 of km, the project being finalized in a year and three months, and own execution will begin in the year 2009.

Because in the case of investments in the TEN project is a high risk in what concerns the incomes in the beginning of operational phase of the project, European Commission and European Bank of Investments signed an agreement of cooperation for settle the instrument of guarantee the borrowed for the projects concerning the European network of transport (LGTT). The instrument will encourage the participation of private sector for financing the transport infrastructure of European importance. LGTT, which is part of the program concerning the European network of transport (TEN-T) and the initiative of BEI" Action for development" will cover fractionally this risk, improving thus in significant way the financial viability of TEN-T investments. The contribution of capital, in value of 1 billion of Euro (500 of millions of Euro from Commission and 500 of millions of Euro from BEI), is meant to guarantee up to 20 of billion of euro from the investments of capital. In the case of some projects, the partnership of public sector with the private one could prove to be the most efficient path to be traced. The new instrument of warrant is an important middle of facilitates such a partnership.

In all one presented must exist and a negative part, that access to European funds represent a main problem, because it synthesized a whole series of dysfunctions. The access to the money arrives many times at the paradoxes, that zone most needy can let us access incomparably many such difficulty sources because their access means qualification, not poverty. Romania was entitled to funds of 2 billions Euro in 2007, from which succeeded the attracts only 440 millions Euro, respectively 21 per cent from sum put to disposal by European Union only on one area they accessed all money. After on year from adhesion at European Union, the degree of access is 21-22 per cent from which 32 per cent structural and cohesion funds and only 3 per cent funds for agriculture and rural development, mean while in the first year from cohesion Cehia had 41 per cent, Poland 42, Slovakia 41, Hungary 42, therefore round double. These countries attract successfully more than they paid to the communitarian found.

The access to the structural funds is not an easy one, because is a bureaucratic organization, and the combination among our bureaucracy and theirs has a negative result for our country. Because of the low degrees of access we were net contributors. The contributions aren't little, being in year 2007 of 1,2 per cent from PIB, that means 1 billion Euro contribution to the communitarian budget, and arrive in year 2011 to 1, 3 billion Euro, that means 0, 7 per cent from PIB. If the process of accessing will not be radically improved, Romania will remain in the position of being a poor developed country, clear contributor to the European budget.

ANALYSIS MODEL OF COMPANY TREASURY IN THE EUROPEAN THEORY AND PRACTICE

Bucătaru Dumitru

„Al. I. Cuza" University of Iaşi, Faculty of Economics and Business Administration, Address: Carol I Boulevard, No. 11, Building C, 6th Floor, C804, Email: dbucat@yahoo.com, Phone: 0232.201450,

Abstract: The paper approaches the financial analysis starting from the tenet that the treasury analysis represents the pivot of financial analysis, suggesting in this way the multiple aspects of this analysis for the corporate assessment.

In this regard, some cash-flow approaches are presented which can signify different analysis models of corporate cash-flows. The author presents some models reflected in the French financial theory.

Key words: corporate treasury,cash-flow; French theory.

French financial accounting is strongly marked by the concept of ownership. As a consequence, its main compulsory output has for a long time been the balance sheet. About two decades ago, however, proposals started to emerge to include a statement of changes in financial position (or a funds statement) as well in order to improve the accounting presentation of a business operation and its policies. Organizations such as banks, the associations of professional accountants and even the French accounting standard setters designed models of such statements which were discussed in numerous papers and monographs. Due to the work of professional accountants and financial analysts, as well as professors of accounting and finance, a debate arose out of these deliberations focusing on what is termed 'cash-flow accounting' in English-speaking countries. The French debate reflects this prior linkage rooted, as it was, in previous work on statements of sources and uses of funds.

Interest in the area was initiated in the late 1950s and early 1960s when a few banks and some French companies started to use funds statements, following the example of American firms. The statement only became more officially recognized in 1968, however, when a study group of the Ordre des Experts Comptables et Comptables Agrees (OECCA), the French legal association of accountants, proposed a model for the funds statement and recommended that it be presented in addition to the balance sheet and income statement. That recommendation became quite an influential one and French companies which included such a statement in their annual reports very often used it as a reference.

Another well-known model has been designed by the 'Centrale des Bilans' of the Bank of France, a statistical agency that utilized the model for its own statistical purposes. Proposed in 1975, the model was aimed at facilitating the analyses of corporate performances and policies by banks. Although this model had not been commonly used for either internal management or external reporting purposes, it nevertheless served as a reference point for the articulation of the optional model included in the 1982 Plan Comptable. In 1987, the Bank of France issued two new statements inspired by the French evolution of the last decade.

While emerging amid pragmatic influences, the concept of the funds statement has evolved since 1977 on the basis of proposals made by a number of professionals and academics. In the process, the concept was changed to become more of a form of cash-flow accounting. There is no doubt that the work of de Murard, a practitioner, played an important role in this transformation, given both his charismatic personality and the attention which the work attracted. In subsequent years, the ideas of a number of finance academics were also to be influential, no doubt reflecting the fact that initially cash-flow accounting had been regarded as an aspect of finance. It only became an accounting topic with the implementation of the 'new' Plan in 1984.

Although in the next section consideration is given to the conceptual and methodological characteristics of the various proposals, thereafter it is important to return to a discussion of the different rationales lying behind the various proposals. For already it should be evident that different emphases have emerged from different institutional contexts. While both the banker and the financial executive might incorporate social and economic, as well as financial concerns in their proposals, their interpretation of such environmental contingencies might be very different.

Only the most typical funds statements will be described in the following discussions. Although an attempt is made to avoid being too technical, the main features of each statement nevertheless need to be presented, not least because some of them are specific to the French context.

Designed to describe how the resources a company had at its disposal during the period under review have enabled it to meet its financial needs, the first part of the statement lists the uses of funds and the sources from which these were obtained. The resultant change in working capital is then analyzed in the next part of the statement which lists changes in all the individual working capital accounts.

The reporting format, although widely used by both large and small firms (the statement used by the Centres Agrees was of the same type), started to become obsolete for the purpose of financial analysis. It was proposed at a time when the concept of working capital and the distinction between short-term and long-term were important components of an analysis of the financial equilibrium of a firm. Additionally, the statement is closely related to the opening and closing balance sheets, its aim being to explain changes between the two.

The concept of 'working capital needs' (besoins en fonds de roulement) started to be articulated in 1970 and has been quite influential thereafter, allowing the analyst no longer to reason in terms of short- and long-term but rather to focus on the level of working capital in relation to factors influencing the need for it. Although the concept of need takes a normative form in planning, under this approach it enables a descriptive analysis of financial reports.

The idea was developed by three bankers, Meunier, de Barolet and Boulmer, and its success certainly reflected the particularities of the French context. The reasoning behind the concept takes the following form. At any given time, a firm must not only finance its inventories but it must also consider the credit it grants to its customers or clients, credit which can be particularly significant in France where it is customary to grant sixty or ninety days' credit. Of course, the firm itself is also a recipient of credit, the extent and conditions of which are negotiated with its suppliers. Taking account of both sides of the financial equation, a 'need' emerges which can, in some cases, be negative. In so far as inventories, accounts receivable and accounts payable are constantly renewed in a continuing activity, such needs are permanent and, according to conventional financial principles, must be financed by stable resources, i.e. be what is defined as working capital. The idea formulated by Meunier, de Barolet and Boulmer in order to facilitate the assessment of the financial equilibrium of a firm is expressed in the following equation which gives the 'cash situation', including short-term bank credits which are another peculiarity of the French system:

Cash situation = working capital - working capital needs

With: cash situation = cash less short-term bank credit

While the above equation is established either on the descriptive basis of the balance sheet or the normative basis of the financial plan, the equivalent concept applicable to the funds statement is as follows:

Change in cash situation = Change in working capital +Change in working capital needs

The concepts behind the latter equation subsequently had a marked influence on thinking about and models of funds statements. For, although the appearance might still be one of technical calculation, the approach is significant since it represents an attempt to interrogate and formulate accounting formats in terms of their subsequent analytical functions rather than in terms of their compatibility with traditional accounting statements. In this way, research was starting to provide a different basis for appreciating and changing the domain of accounting practice.

Conceptually the regulatory proposal is not as rich as the Bank of France matrix. Nevertheless it is an important step that the official text for French accountants now provides a model for the funds statement, not least because the transformation of this statement from being only a financial concern to being also one for accounting can only serve to improve French financial reporting. The structure of the proposal embodied in the Plan represents a compromise between the OECCA document and the now conventional French financial analysis equation articulated by Meunier *et al.*

Change in working capital = Change in working capital needs + Change in cash situation

Moreover, in its entirety, the model analyses two types of changes in working capital needs: those related to changes in business operations and those related to the non-operating changes.

Compared with previous approaches, that of Murard is a major conceptual and methodological change. It represents the completion of the evolution from a funds statement to cash-flow accounting. The structure of the proposal can be summarized in three parts. As can be seen from Table 1, the first part begins with a synthesis of the income statement which results in earnings before depreciation, interest and income tax, a figure which is also found in the Centrale des Bilans statement but not in the model of the Plan Comptable. Murard, who is a practitioner, then considers a sequence of dispositions or allocations which give a series of different types of results or surpluses. For instance, in the first part of the structure given in Table 1, the first disposition that Murard considers is the financing of working capital needs. An operating cash flow then remains, from which the financing of fixed assets is deducted giving a notion of surplus E (or 'economic'). It provides a measure of the ability of the firm to respond to the financial needs which come from its current operations as well as its capital expenditure programme.

The second part of the statement is independent of the first. It provides a measure of a specifically financial surplus (surplus F) which is seen as the difference between the change in total debt, on the one hand, and outflows related to debts, i.e. interest expenses and other necessary payments (income tax and dividends), on the other hand.

Table 1 1 The de Murard analysis

PART I		
_	Earnings before depreciation, interest and income tax Changes in working capital needs	
=	Operating cash flow	
-	Expenditures on fixed assets	
=	Operating surplus (or 'economic' surplus)	(E)
PART II		
-	Issuance of long-term debts less reduction of these debts Interest expense Income tax Cash dividends	
=	Financial surplus	(F)
PART III		
+	Operating surplus Financial surplus	
=	Current surplus (or global surplus)	(G)
+ ±	Disposal of fixed assets Issuance of additional capital stock Extraordinary items	
=	Change in cash	

Other flows are presented in the third part of the statement which begins by the addition of surpluses E and F to arrive at a global figure, surplus G. Other changes in cash flows are then acknowledged, resulting in the overall change in cash.

From a methodological point of view, two main differences from the other statements are apparent. First, it totally ignores the notion of working capital which was a traditional basis for statements of changes in financial position. Second, it considers a more global notion of capital expenditure since the surplus E is calculated after considering not only the acquisition of fixed assets but also changes in working capital needs. The structure proposed for the statement therefore reflects a very particular mode of analysing the financial policy of the firm. Not surprisingly, the statement has been widely commented upon. Academics, in particular, have discussed the particular structure, the proposed analysis of dispositions and the related surpluses, and have presented alternative models that are perceived to be more neutral. A consideration of one of these follows.

Charreaux's analysis, which was inspired by the previous work of Levasseur and Poncet and Portait, is based on six steps which enable an analysis of different aspects of a firm's policy. These steps are related to:

- industrial operations (surplus A)

- operations related to investments (surplus B)
- changes in cash (surplus C)
- operations related to equity (surplus D)
- long-term debts (surplus F)
- short-term debts (surplus G).

A further surplus, surplus E, is also included to represent the cost savings on interest expenses, a tax effect.

Some elements of the preceding analysis are to be found in the Charreaux statement, particularly the notions of earnings before depreciation interest and income tax, and operating cash flow. However, according to the author, the main originality of the proposal compared with that of Murard is that there are no specific dispositions or allocations: resources are not supposed to cover particular uses in a more or less arbitrary manner. As such, it differs from statements emanating from a more practical context, its coherence reflecting financial theory rather than practice (table 2).

Table 2 The Charreaux proposal, 1984

FIRST PART: REAL FLOWS	
	Earnings before depreciation, interest and income tax (EBDIT)
	Changes in working capital needs
	OPERATING CASH FLOW
	Theoretical calculation of taxes (no debt hypothesis)
A =	INDUSTRIAL FLOW
+	Transactions on investments
	Interest and dividends received
B =	INVESTMENT FLOW
C =	CHANGES IN CASH
SECOND PART: FINANCIAL FLOWS	
_	Issuance of additional capital stock Payment of dividends
D =	FLOW ON EQUITY
E =	COST SAVINGS ON INTEREST EXPENSES
	Change in long-term debt
	Interest expense on short-term debt
F =	FLOW ON LONG-TERM DEBT
	Change in short-term financial debt
	Interest expense on short-term debt
G =	FLOW ON SHORT-TERM DEBT
NB: A+B+C=D+E+F+G (Total real flows = Total fiinancial flows)	

If the Bank of France uses both statements in its financial studies of French firms, the public accountants (the OECCA) also issued two statements in 1988 but recommended a cash-flow format (Table 3).

The first, a funds statement, is quite close to the document of the 'plan comptable' although presented in a different manner. It is not developed here.

As to the second, a cash-flow statement, the application is obvious: it is strongly inspired by SFAS n° 95 from which it borrows the general structure:

Cash-flow from operating activities + Cash-flow from investing activities + Cash-flow from financing activities = Increase (or decrease) in cash + Cash at beginning of period = Cash at end of period

Table 3 The OECCA cash-flow statement, 1988

(A) NET CASH FLOW FROM OPERATING ACTIVITIES

* Net income

* Elements without effects on cash or not related to operations (depreciation, amortization, gains or losses on disposals of assets, etc.)

* Changes in inventories, clients, suppliers and other items related to operations (change in operating working capital needs)

(B) NET **CASH FLOW FROM INVESTING ACTIVITIES**

* Acquisition and disposal of fixed assets

* Transactions on investments

* Changes in accounts related to investing activities

(C) NET CASH FLOW FROM FINANCING ACTIVITIES

* Changes in capital stock

* Dividends paid

* Issuance and reduction of debt

CASH * Effects of exchange rates changes (D)

* Opening cash (E)

* Closing cash = (A) + (B) + (C) + (D) + (E)

It is noticeable that the conceptual content of the statement is not in line with some definitions of the Accounting Plan. The two main differences bear on the definition of cash (larger in the US and OECCA texts than in the PCG) and on the concept of operating activities (larger than in the PCG). The promoters of the document have clearly preferred the international (i.e. US) framework rather than consistency with the French tradition. This is altogether a testimony to the influence of international standards and a mark of independence of the French profession. If the Conseil National de la Comptabilite is still 'the' official French accounting standard setter, other bodies such as the OECCA have from time to time the willingness to assert their autonomy.

THE EFFICIENCY OF CAPITAL INVESTMENTS INSIDE COMPANIES

Burja Camelia

University '1 Decembrie 1918" Alba Iulia, Faculty of Sciences, Nicolae Iorga Street, no. 11-13, Email: cameliaburja@yahoo.com, Tel: 0258/811512

Abstract: Justifying the decisions regarding the investment projects that are going to be implemented by companies is based on a series of efficiency criteria which reflect the most important aspects of the investment process tied to the obtained results in accordance with the expenses. Considering the opportunity cost of the invested capital and the time's influence on value, making the investment decision is not an easy task. The paper presents aspects regarding two important criteria used in substantiating the economic efficiency of the capital investments: the net adjusted present value and the internal rate of return.

Key words: economic efficiency, capital investments, net adjusted present value, the internal rate of return, substantiating decisions

1. The net adjusted present value method

Because the investment objectives usually have a long exploitation period, naturally their economic parameters manifest differently in time and affect the efficiency degree and the economic viability.

The project's investors are the main capital suppliers who, by financing the project, give up a potential earning resulted from using the capital in a different business or on the capital market. They will be interested in the invested capital's opportunity cost and its value at different moments of time, which is important for substantiating the decisions regarding the proposed project. For the investors it means the expected rate of return which justifies giving up the chance to render profitable the capital in a different alternative of investment. For the entrepreneur the invested capital's opportunity cost represents the minimum profitability level, which must be guaranteed by efficiently managing the resources allocated for the desired objective.

In setting the invested capital's opportunity cost its influence factors intervene, such as: the incomes resulted from the project during its life duration, the investment's cost and the influence of the time factor.

For the investment projects, time is an important economic resource which leaves its fingerprint on each element involved in reaching the objective. Both the investment efforts' elements and the elements of the resulted effects have a bigger or smaller size when they are analyzed in comparison with the epoch outlook. Establishing the correct economic profitability, which means the earning brought by the project, implies a temporal approach of its economic parameters by using up-dating techniques.

For investment projects the most important moment is the launching of the objective's execution. From this moment the capital suppliers give up allotting their capital in other investment alternatives and pour their money into the project.

When analyzing the opportunity cost, the biggest interest is studying the economic-financial indicators specific to the investment's objective at the moment of substantiating the decision and at the start of the project's life cycle. When evaluating the project's economic efficiency we usually adjust the parameters at the m_o moment, but depending on the interests of the investors other scenarios can be used.

By placing the moment of the economic profitability's analysis in the phase of substantiating the investment decision, in order to compare different economic-financial indicators achieved in different time periods it becomes necessary to find out the adjusted present values of the efforts' and investments effects' parameters at the time of starting to implement the project (m_0).

The financial approach of the opportunity cost takes into consideration the liquid assets flows which are obtained in the future by exploiting the objective. These future earnings are evaluated through their present value.

When an S sum is invested in the project and the investment objective is reached in a number of years (d) and from its functioning result annual net earnings (P), the calculus formula of the net adjusted present value ($NAPV$) is:

$$NAPV = \sum_{h=1}^{n} \frac{P_h}{(1+a)^h} - \sum_{h=1}^{d} \frac{S_h}{(1+a)^h}$$

If we apply the formula for all the situations which imply making a net income or having investment expenses in any year of the objective's existence, the calculus formula is:

$$NAPV = \sum_{h=1}^{n} \frac{P_h}{(1+a)^h} - \sum_{h=1}^{n} \frac{S_h}{(1+a)^h}$$

or

$$NAPV = \sum_{h=1}^{n} \frac{I_h}{(1+a)^h} - \sum_{h=1}^{n} \frac{S_h + E_h}{(1+a)^h}$$

where: I_h şi E_h represent anual incomes and expenses for n years

The situation when the net adjusted present value is positive proves that capital suppliers can choose as investment to finance the project and thus have a comparative earning with the alternative to invest on the capital market. If the net adjusted present value is zero it means that allocating money for the project is not a good decision, because a superior fructification of the capital can't be guaranteed. In these conditions, the available financial resources can be directed towards the capital market with the same earning rate and with a lower risk, or towards financing a different, more profitable project.

In order to determine the net adjusted present value there are other calculus methods recommended by the methodologies of different financial institutions involved in monitoring funds destined for financing investment projects. They lead to approximately equal results.

An aspect which influences a project's efficiency is the capital's adjusting rate. It can be set at the level of the capital's opportunity cost, which depends on: the interbank bid rate (if the project is financed from long term loans), the inflation rate (to maintain the capital at least at the present level), the sector's or the economy's rate of return, etc. If the project is financed from own sources then the actualization rate is set depending on the average return of the company in which the project is implemented (set for the last 5-10 years) to which a certain risk premium is added.

For the actualization rate to guarantee a fair evaluation of the project, the rate should be set at the level of the weighted average cost of capital, which will lead to an earning regardless of the used sources of financing (own or lent). Because of the difficulties tied to establishing the cost of different capital components, in practice the actualization rate's size, which guarantees a reasonable profitability for a project, is at the return level of the money market and it corresponds to the opportunity cost of the long term capital. For the European money market the rate stretches between 5 and 10%. In Romania, for the 2000-2006 periods, the reference size recommended by specialized institutions for the adjusting of investment projects was 6%.

The rate's size also varies depending on the economic sector in which the project is set. For example, for agricultural investments the Ministry of Agriculture and Rural Development recommended a value rate of 8%, which covers the refinancing rate of the European Central Bank and the country risk margin.

2. The analysis of the internal rate of return

The analysis of the internal rate of return allows appreciating the future performance of the investment project, by offering information about the extent to which the project will ensure in a real manner the needed cash for its good functioning and won't be in the danger of being stopped.

The internal rate of return is an adjusting rate for which the total adjusted incomes resulted in a project is equal with the total adjusted expenses spent during the investment and its exploitation.

The rate's level shows the quality of the project, expressed through its capacity to recover the expenses caused by reaching the investment objective (the investment cost and the operating cost) and to create net income. Because it reflects the earning power of a project, in the case of multiple alternative projects, the chosen project will be the one which is characterized by a higher internal rate of return. A necessary acceptance condition for a project is for its internal rate of return to be higher than the capital's opportunity cost approximated through the adjusting rate, if this is an imposed regulation. In this case, the project offers the investors a higher financial yield than in the case of a different investment alternative (the banking system, papers, a different project).

The calculus algorithm of the internal rate of return is based on the idea of the net value's inversely proportional dependence to the adjusting rate. We must find that certain internal rate of return (adjusted) which when used to bring to present the net incomes derived from the project, can lead to a total adjusted income equal to zero. The economic significance of the indicator is at a low level of yield, a point when the total adjusted incomes equalizes only with the total adjusted expenses, thus, there is no profit. Over the level of the internal rate of return, the net adjusted value is positive (profit), and below its level there are losses. The steps of the algorithm are the following:

- in the beginning, the net value is adjusted to different adjusting rates;
- the size of the net adjusted value is established at >0 and has as correspondent the smallest adjusting rate a_{min};
- the first net adjusted value's level <0 is calculated and has as correspondent the biggest adjusting rate a_{max};
- the internal rate of return will be in the [a_{min}, a_{max}] interval, which must be lower than 5% and in the interjection.

The calculus relationship of the internal rate of return is based on the following formula:

$$IRR = a_{\min} + (a_{\max} - a_{\min}) \cdot \frac{NAV_1}{NAV_1 + |NAV_2|}$$

where: *IRR* is the internal rate of return;

NAV_1 – the positive net adjusted value;

NAV_2 – the negative net adjusted value.

3. Case study

Studying the profitability of an investment is illustrated in the case of a project which presents the following economic-financial indicators in table 1.

Indicators	**Years**									
	1	**2**	**3**	**4**	**5**	**6**	**7**	**8**	**9**	**10**
1. Annual expenses, as follows:	4576	14135	31753	28566	28284	29644	28644	28284	28284	28284
- Total investment	4576	6360	3903	320	-	1360	360	-	-	-
- Operating costs	-	7775	27608	27948	27948	27948	27948	27948	27948	27948
- Interests	-	-	-	32	32	32	32	32	32	32
-Taxes	-	-	242	266	304	304	304	304	304	304
2. Annual incomes	-	6000	23370	30100	30100	35218	36182	36265	36265	36265

Table 1. Financial indicators of the investment project, thousand lei

On the basis of the elements of expenses and incomes resulted from the investment objective's functioning it can be established which are the annual net income flows and what is their adjusted value. The results are presented in table 2.

Indicators	**Years**									
	1	**2**	**3**	**4**	**5**	**6**	**7**	**8**	**9**	**10**
1. Annual expenses	4576	14135	31753	28566	28284	29644	28644	28284	28284	28284
2. Annual incomes	-	6000	23370	30100	30100	35218	36182	36265	36265	36265
3. Net incomes	-4576	-8135	-8383	1534	1816	5574	7538	7981	7981	7981

(2-1)										
4. The $(1+a)^{-h}$ factor	0,926	0,857	0,794	0,735	0,680	0,630	0,583	0,540	0,500	0,463
5. The net adjusted income	-4237	-6972	-6656	1127	1235	3512	4395	4310	3990	3695
6. The net adjusted value	4399									

Table 2. The net adjusted value (a=8%), thou lei

The analysis made on the basis of the net adjusted value indicator shows that the project is acceptable and represents an investment opportunity. It guarantees that at an adjusting rate of 8% the total adjusted cash flow is 4399 thou lei, a sum which represents the real earning resulted from implementing the project.

In order to find the internal rate of return, first we must determine the interval in which the profitability of the project is placed. In the case of the studied project, it has already been observed that for an 8% adjusting rate the adjusted net value is positive, but we must know the turnaround, which is the level of the adjusting rate from which the adjusted net value starts to be negative. To find the size of NAV_1 and of the $NAV<0$, which is NAV_2, the adjusting rate must be increased successively.

Years	**Annual net incomes**	**Net adjusted incomes**	
		a=10%	**a=15 %**
1	-4576	-4159	-3976
2	-8135	-6719	-6150
3	-8383	-6296	-5508
4	1534	1048	877
5	1816	1128	902
6	5574	3144	2408
7	7538	3867	2834
8	7981	3723	2610
9	7981	3384	2267
10	7981	3077	1971
Total	**19311**	**2197**	**-1765**

Table 3. The net adjusted income used to calculate IRR, thou lei

On the basis of the results obtained in table 3 it can be seen that the internal rate of return is in the [10, 15] interval and its value is:

$$IRR = 10\% + (15\% - 10\%) \cdot \frac{2197}{2197 + |-1765|} = 12{,}8\,\%$$

At a level of financial profitability of 12.8% the project can be accepted. This profitability covers the rate of interest, the expected inflation rate and a certain safety margin.

Conclusion

The used methods of analysis allowed substantiating the opportunity of the investment decision, the purpose being the company's economic-financial development. The criteria which guided the profitability's evaluation for the project was economic and both of the decision criteria pursued especially to signal the critical aspects that could lead to the impossibility to cover the financial efforts and to a lack of an earning for the capital suppliers. The real evaluation of the investment's profitability must be made on the basis of a more complex system of criteria, which will target benefits not only for the economic perspective, but also for the local communities and for the environment.

Marcu Niculina

„Constantin Brâncoveanu"University, n_marcu@yahoo.com, 0724.00.63.49

The public local incomes and expenses have suffered important changes both as a consequence of the reform of public finances, in general, and of local finances, in particular, and due to the decentralization, who has added a whole series of expenses to the local budgets.

Out of the incomes of the local budget we provide the financing of expenses for the public services in the competence of the local public administration authorities. In fact, the public expenses from the local budget consist in buying goods and services necessary to the functioning of public services and institutions, by the local authorities, a series of services provided to the community.

Key words : strategy, public finance, local finances,management

The fundamental strategy, the planning and control of a local authority's actions are reflected in its budget. It represents the connection between the mobilization of fonds and the attaining of goals and objectives of the local authorities.

The public local incomes and expenses have suffered important changes both as a consequence of the reform of public finances, in general, and of local finances, in particular, and due to the decentralization, who has added a whole series of expenses to the local budgets.

As a consequence of the analysis of the budget of Pitesti Municipality for the period 2005-2007, we found its increase year by year. The total incomes of the budget of Pitesti Municipality have registered in 2007 an increase of 15.95% in comparison with 2006 and an increase of 69.88% in comparison with 2005.

In order to know the elements and factors which have led to this evolution, we have made an analysis of the income sources of the budget of Pitesti Municipality and of their evolution in time. But we have to mention the fact that, during the analyzed period, the budgetary classification has suffered major changes, and this is why the simple reading of the figures from the budgets of the years 2005, 2006, 2007 does not correspond to the conclusions we will refer to herein.

Analyzing the great categories of incomes, we may notice that:

The own incomes, also including the divided quotas of the revenue income, cashed on the territory of the Pitesti Municipality, which show, in fact, the potential and the development degree of the locality, have evolved from 48.22%, the percentage represented by this category of incomes from the total incomes of the year 2005, to 51.62% in the year 2006, while in the year 2007 it represented 53.16% of the total incomes of the local budget. This category of incomes has increased in value year by year, registering in 2007 an increase of 87,29% in comparison with the year 2005, and an increase of 19.41% in comparison with 2006.

Out of the total own incomes resulting from taxes and other local incomes, without calculating the quota on the revenue income attributed to the municipality, the incomes cashed from the taxes for buildings and lands and from the tax for the means of transport have the greatest weight. If in 2005 the weight of the three sources represented 46% of the total own incomes, in 2006 it represented 52% while in 2007 it represented 62% of the incomes resulted from taxes and other local incomes. We must mention the fact that during the analyzed period, the municipality has maintained a low level of the local fiscality, the level of local taxes being one of the lowest in the country. The registered increase was, in fact, influenced by the continuous development of the municipality, which has led to the capital accumulation both by the the inhabitants of the municipality and by the business environment who have invested both in car acquisitions and in building constructions.

Within the non-fiscal incomes, the concession and rental incomes as well as the disbursement incomes from the public institutions, on which the municipality has a direct influence by the way in which it administrates the public patrimony of the locality, represent the most significant sources in this category, namely over 70%. From the value point of view, in 2006 the three income sources registered an increase of 23% in comparison with the year 2005, and in 2007 an increase of 43% was registered in comparison with the year 2005.

The capital incomes have registered insignificant amounts, with the exception of the year 2006, because the municipality has not had a sales policy of some goods from the private domain of the locality

We may draw the conclusion that even if the municipality has not increased the level of the local fiscality, however, by offering some quality services, by creating the necessary infrastructure, it has influenced the development of the municipality and, implicitly, the increase of the own incomes of the budget of Pitesti Municipality.

With respect to the amounts of money from the state budget and the other amounts from other budgets attributed to Pitesti Municipality, we find out the fact that, even from the value point of view they have increased year by year, respectively with 112% in 2007 in comparison with the year 2006 and with 37% in 2006 in comparison with the year 2005, however, as a weight of the total incomes of the municipality's budget, they have registered a decrease in the analyzed period. The decrease of their weight is the effect of the increase of the own incomes of the local budget, which has brought about a greater degree of autonomy of the public administration authorities from Pitesti, in comparison with other municipalities in the country.

In the category of divided amounts of money, the greatest weight was represented by the amounts attributed for the partial insurance of the fonds necessary for the financing of some decentralized activities, namely for the preuniversitary education, for supporting the protection system of disabled persons, for the community services for registering the persons.

Some fonds were also attributed for the subsidy of the thermal energy supplied to the population in the centralized system or for financing some investments regarding the re-technologization of the system of supplying the thermal energy.

Pitesti Municipality made in 2006 a loan in value of 14.000 lei out of which it provided the partial financing of two major public investments and it was the beneficiary of some non-refundable funds which were used for developing the institutional capacity.

In 2006 and 2007, besides the incomes of the local budget, it provided the financing of some local public investments from the working balance, amounts which resulted from the budgetary surplus of the prior year.

The expenses of the local budget

Out of the incomes of the local budget we provide the financing of expenses for the public services in the competence of the local public administration authorities. In fact, the public expenses from the local budget consist in buying goods and services necessary to the functioning of public services and institutions, by the local authorities, a series of services provided to the community.

We also pay out of the budget the wages of the staff which provide these public services, as well as some rights of the disabled persons and of underprivileged families.

Another category of funds from the local budget is attributed as subsidy to the cultural institutions as well as for subsidizing a part of the tariff for supplying the thermal energy to the population in the centralized system.

For developing the services and ensuring the local infrastructure, we provide the necessary funds from the budget for the financing of capital expenses.

With respect to the expenses of the local budget, as well as to the other categories of budgets, the largest amounts of money have been attributed to the current expenses (staff expenses, expenses for goods and services, subsidies for covering the tariff differences for the thermal energy delivered to the population, the payment of interests for loans, transfers made to the local companies for carrying out some public investments, social security payments, scholarships and supporting the cults) and in a smaller proportion the funds have been directed towards investments (capital expenses).

Strategic objectives for drawing up, executing and controlling the local budget

From the inquiry of the civil society carried out in Pitesti Municipality, it resulted that the option of citizens with respect to the way in which the expenses of the local budget should be attributed in the next period, is the following:

- The increase of the expenses for health, education and social assistance;
- The increase of expenses related to the urban public services (sewage, green spaces, road infrastructure, handling the wastes);
- The decrease of the weight of expenses related to the gas and water supply.
- With respect to the financing sources of expenses (the incomes of the local budget), in the next years, they should, in the opinion of citizens, consist in:
- Concessions and rental incomes
- The profit tax from the economic agents
- Hotel taxes
- Land taxes.

In the same time, at the level of population, there is the opinion concerning the fact that among the financing sources of investments we should use the incomes from the privatization of public services, the loans (mortgage bonds or bank loans) and, as a last solution, the local taxes, with the observation that all sources have a score of over 50% (scores between a maximum of 3.77 and a minimum of 4, being thus above the median).

However, the observation referring to the way of financing the investing programs is in contradictory to the public opinion from Pitesti Municipality, regarding the privatization of some public services.

Thus, 45.3% of the respondents to the inquiry carried out in Pitesti Municipality have a bad or a very bad opinion (so they are rejecting such an orientation), 20% have a good and very good opinion (so they appreciate the privatization of some public services), and 34.7% are situated at the middle, between these two opinions.

Strategic directions proposed for the next period:

a. Ensuring the necessary funds for the quantitative and qualitative increase of public services in the competence of the local authorities having in view:

The maximization of the own incomes of the local budget by:

Creating an internal procedure for administrating the public patrimony as well as an efficient internal control.

Settling the level of local taxation, according to the short-term, medium-term and long-term objectives of the municipality but also with the condition of being bearable by the taxpayers, having in view the fact that in Pitesti Municipality the level of fiscality is one of the lowest.

Improving the activities of finding, observing, cashing and registering the local taxes in view of increasing the degree of cashing these incomes of the local budget by:

Evaluating the taxable mass;

Taxing the goods at their real value, and in this sense we should change the fiscal legislation;

The analysis and observation of the dynamic of debts for each debtor, so that there would be no debts older than six months.

The building of the budget must be made preponderantly out of incomes resulting from economic activities and provision of services;

Using the local public debt, namely the securities, the loans from commercial banks or from other credit institutions, supplier's credits, financial leasing; for obtaining supplementary fonds for financing some public investments;

Identifying some alternative solutions for supplementing the funds from the local budget:

Accessing non-refundable fonds, mainly those structural which cover a large range of domains, and in this sense:

- the development of the specialty service,
- the training of the staff in this domain,
- the identification of possible partners interested in carrying out some common projects, and
- the preparing of projects which are within the requests of the structural funds

are required.

Creating some public-public or public-private partnerships in view of providing some public services in common or in view of financing some public investments.

b. Improving the way of elaborating, executing, monitoring, controlling and reporting the local budget by:

- Developing the ability of elaborating the budgets on programs, the long-term budgets, a planning made for at least three years and giving priority to expenses;
- Elaborating some forecasts – in order to evaluate correctly the level of expenses which are to be made;
- Defining and monitoring the performance indicators – physical, efficience and result indicators – classified on directions, activities and actions for each tertiary credit release authority;
- Settling some quantitative and qualitative standards for the local public services;
- Creating a system for settling the priorities;
- Developing the internal control and the auditing procedures.

ORIGINES ET IMPACT DE LA CRISE DES SUBPRIMES

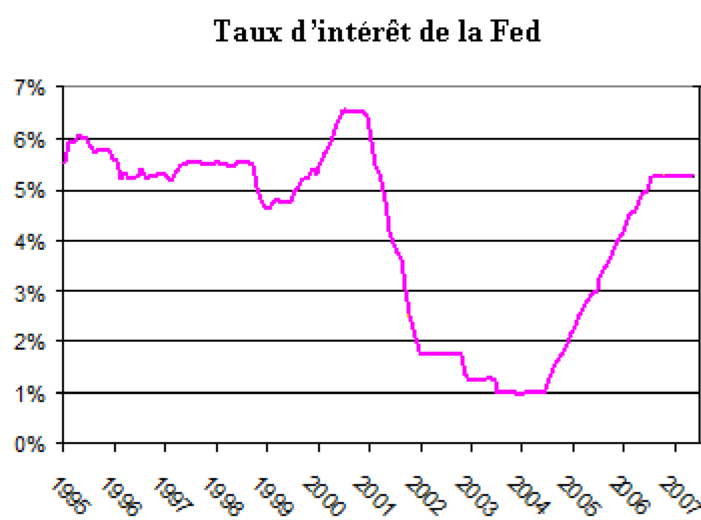
Abstract. The subprime mortgage crisis was made possible by the macroeconomical evolutions of the last years. An increase of the global liquidity, massively invested in the United States, caused a drop of the interest rates and the orienteering of the savings towards riskier investments (real estate) in search of a better return. The "subprimes" were encouraged to assume mortgages by the long-term trend of rising housing prices, hoping to be able to refinance at more favorable terms later. When the housing bubble burst, refinancing became more difficult and banks begun recording high default rates. The banks have used securitization to pass the risk to third-party investors and thus the crisis was transferred to the financial markets and to the global economy, notably Europe.

Key words: subprime, securitization, mortgage

La crise sur le marché américain des prêts hypothécaires à risques (« subprimes ») est apparue en 2006. Des prêts ont été consentis à des ménages aux revenus modestes et à faibles antécédents en matière de crédit, qui n'auraient pas normalement eu accès à un prêt hypothécaire classique. Les conditions d'octroi font peser un risque de solvabilité sur ces personnes : les mensualités de remboursement sont abaissées les premières années, les prêts sont consentis à des taux d'intérêt variables et de niveau élevé. En 2006, les crédits « subprime » ont représenté 24% des nouveaux crédits immobiliers octroyés aux Etats-Unis. En fin d'année, leur encours atteignait près de 13% du total des crédits hypothécaires aux Etats-Unis (10.200 milliards de dollars), contre 8,5% en 2001[37].

Le crédit hypothécaire, ou « mortgage », est le type de crédit le plus utilisé dans les pays anglo-saxons. Le bien acheté à crédit est hypothéqué auprès du prêteur, ce qui veut dire qu'en cas de défaut de paiement, la banque peut se payer en vendant la maison. Avec ce système, le pouvoir d'achat des ménages dépend très largement de la valeur du bien immobilier. Ainsi, lorsque la valeur de la maison chute et que les taux d'intérêt augmentent, les ménages voient leurs revenus diminuer car ils doivent rembourser plus.

1. L'éclatement de la bulle immobilière et la hausse des taux



La hausse des taux d'intérêt directeurs de la Réserve Fédérale[38] (Fed) a entraîné celle des taux des crédits immobiliers outre-Atlantique. Confrontées à un coût de l'argent plus élevé pour financer leurs besoins, les banques ont répercuté ces conditions plus sévères sur leur clientèle. Parallèlement, l'assèchement de la demande de biens immobiliers a tiré les prix de ces derniers vers le bas, entraînant du même coup une

crise. Les Echos, 26/12/2007

ain après une hausse continue des prix de

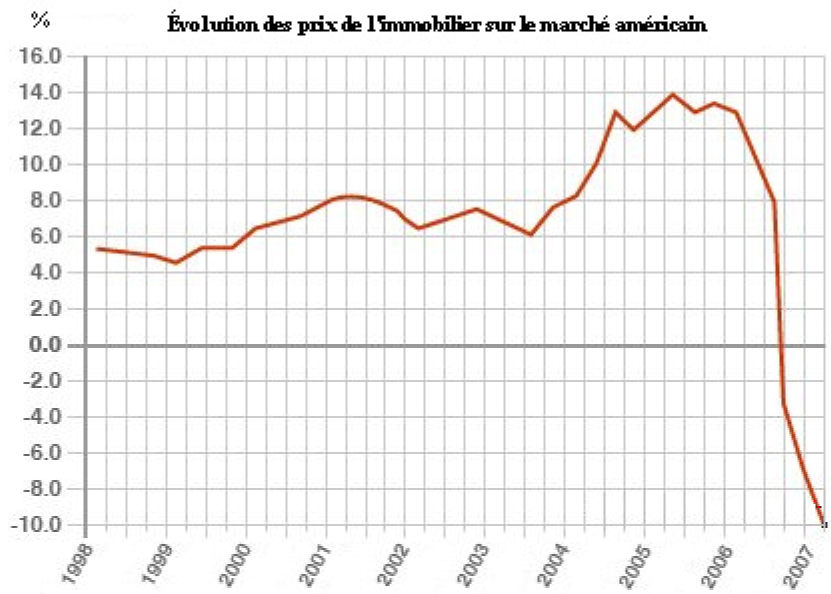
diminution de "l'effet richesse" des ménages - la valeur de leurs

Evolution du taux d'intérêt directeur de la Fed[39] appartements et maisons ayant baissé, leur richesse potentielle s'est amoindrie. La conjonction de ces deux évolutions défavorables a conduit à une hausse des défauts de paiement voire, dans certains cas, des situations d'insolvabilité de foyers.

Les ménages à faible revenu sont beaucoup plus sensibles à la hausse des taux. Comme ceux-ci ont donc augmenté, et comme, dans le même temps, les prix de l'immobilier ont chuté, les ménages les plus pauvres ont dû vendre, augmentant encore plus la baisse des prix sur le marché immobilier. Le résultat est que les banques ne peuvent plus se dédommager avec la vente de la maison d'où les problèmes voire les faillites de certaines banques.

La baisse des prix du marché de l'immobilier (graphique[40]) et le non remboursement par les particuliers de leurs prêts immobiliers ont provoqué la crise du marché immobilier américain qui après s'est diffusée au marché du crédit « subprime ». Le véhicule de transmission de la crise vers les marchés financiers à risque a été la titrisation. La titrisation est une technique financière par laquelle des créances traditionnellement illiquides (ou les risques de crédit y afférents) et gardées par leurs détenteurs jusqu'à l'échéance sont transformées en titres négociables et liquides. Par ce biais on réalise le plus souvent un transfert total ou partiel des risques de certaines institutions à d'autres.



La titrisation, véritable courroie de transmission de la crise

Les banques n'avaient pas donc de soucis pour intervenir sur ce segment de clientèle risqué car elles externalisaient leur risque grâce aux produits de titrisation. Ces créances risquées ne figuraient pas dans leur bilan. Elles étaient achetées par des agents ayant une faible aversion pour le risque comme les hedge funds.

La titrisation donne lieu à une émission de titres sur les marchés de capitaux, adossés aux actifs sous-jacents (crédits hypothécaires, par exemple) et regroupés par « tranches ». Certaines de ces tranches incluaient des crédits touchés par des défaillances ou défauts de paiement de ménages. Les investisseurs se sont alors retirés de ces produits qu'ils considéraient comme trop risqués. Conséquence : certains fonds n'ont plus pu être cotés. L'absence de demande pour certains titres contenus dans ces fonds a en effet empêché de calculer la valeur liquidative de ceux-ci - la valeur liquidative résultant de la confrontation de l'offre et de la demande.

Arrivés à ce point, il faut mentionner le rôle joué dans la crise par les agences de notation. Ces sociétés ont pour rôle d'évaluer le risque des placements grâce à une note. Les agences sont accusées d'avoir donné de trop bonnes notes aux « subprimes » et sont soupçonnées de conflit d'intérêt du moment où elles sont payées par les entreprises qu'elles notent et non pas par celles qui utilisent leur système.

La crise de liquidité et l’intervention concertée des banques centrales

Plus grave, la crise des « subprimes » a atteint aussi le marché monétaire avec une forte crise de liquidité, car les banques, ne sachant quelles institutions sont réellement exposées à des pertes liées aux subprimes, ne se font plus confiance et ne se prêtent plus entre elles.

La défiance vis-à-vis des produits de titrisation s'est propagée à d'autres segments de marché, notamment celui des « commercial paper » - titres de créances négociables émis par les entreprises sur le marché monétaire donc de court terme -, qui représentent d'énormes montants. Les investisseurs n'ayant plus confiance dans ces actifs, ils s'en sont retirés - pour se reporter sur des instruments qu'ils jugeaient plus sûrs. Conséquence : cette chute de la demande a entraîné un assèchement de la liquidité sur les marchés. D'où une crise de liquidité, une flambée des taux interbancaires, et un risque de durcissement généralisé des conditions de crédit, qui a contraint les banques centrales, en particulier la Fed et la BCE, à injecter massivement des liquidités sur le marché monétaire. Au cours de la seule première semaine d'août 2007, par exemple, les instituts d'émission américain, européen et asiatiques ont mené des actions concertées au cours desquelles elles ont fourni plus de 330 milliards de dollars aux marchés. Les autorités monétaires n'avaient pas autant infléchi leur stratégie de concert depuis les attentats du 11 septembre 2001. Elles avaient alors baissé leurs taux très rapidement de façon coordonnée tout en inondant les banques de liquidités.

La réserve fédérale américaine a pris une série de mesures pour augmenter la liquidité sur les marchés du crédit. Entre septembre 2007 et mars 2008, le taux directeur de la Fed a baissé de 5,25% à 2,25%. La banque centrale américaine a annoncé la création d’une nouvelle procédure qui va lui permettre de prêter jusqu’à 200 milliards de dollars de titres du Trésor à un groupe restreint de grandes banques. Elle a également annoncé qu’elle ferait passer de 10 à 30 milliards de dollars la ligne de crédit ouverte à la BCE.

Certains observateurs jugent qu'en réagissant aussi fortement, les autorités monétaires jouent un rôle de « pompier pyromane », et récompensent les investisseurs ayant pris des risques excessifs, en préparant ainsi la crise suivante.

Des conséquences à l’échelle mondiale

Les grandes banques européennes subissent l’effet de la crise

Les premiers trois pays les plus touchés par la crise des subprimes relativement à leur taille sont la Suisse, les Etats-Unis et l’Allemagne. Les banques américaines paient dans l’absolu le plus lourd tribut à la crise avec 47% de l’ensemble des dépréciations, 17% pour les banques suisses et 15 % pour les allemandes ; mais comparativement à leur taille et à leur capitalisation, les banques suisses sont de loin les plus touchées avec près de 40% de leurs actifs dépréciés quand les banques américaines et allemandes n’ont du déprécier « que » 15 à 20% de leurs actifs.

Pour la première banque suisse, UBS, la crise s’est aggravée en 2008 avec une perte nette de 7,6 milliards d'euros pour le seul premier trimestre en raison de dépréciations d'actifs de 12 milliards d'euros. Les banques allemandes ont été particulièrement touchées avec la Deutsche Bank, qui a annoncé 2,5 milliards d’euros de dépréciation sur le premier trimestre 2008, soit plus que sur l’ensemble de l’année dernière. Les banques britanniques, sauf le cas particulier de Northern Rock, nationalisée provisoirement par le gouvernement, n’ont procédé qu’à moins de 5% de dépréciations de leurs actifs, mais la situation pourrait se renverser avec le retournement du marché immobilier anglais. Les banques françaises résistent mieux même si, d’après Citigroup, elles devraient passer 4,2 milliards d’euros de dépréciations sur l’année 2008.

L’impact sur l’économie américaine

Les dépenses des ménages américains ont été extrêmement soutenues ces dernières années grâce à plusieurs facteurs positifs. Toutefois, l’un après l’autre, ces facteurs disparaissent. Tout d’abord, l’importance des gains enregistrés par les marchés d’actions et du logement ont accru la richesse des ménages et ont été utilisés afin de financer leurs dépenses : plus de 5 % des dépenses des ménages aux Etats-Unis au cours des deux dernières années provenaient des extractions hypothécaires. Toutefois, suite à la baisse actuelle des prix des logements, cette source de revenu n’est plus aussi facilement disponible.

Deuxièmement, les consommateurs ont augmenté leur endettement à des niveaux sans précédent en raison de la faiblesse des taux d’intérêt et de la disponibilité du crédit. Il est déjà devenu plus difficile pour les ménages les moins solvables sur le marché subprime d'accéder au crédit et ce durcissement des conditions d'accès devrait se généraliser à tous les types de prêts.

Troisièmement, la vigueur du marché de l'emploi a soutenu la confiance des ménages à l'égard de la sécurité de l'emploi, de même qu'elle s'est traduite par de solides hausses des salaires. Ce dernier facteur à l'origine du boom des dépenses des ménages reste dynamique, mais il montre néanmoins des signes de détérioration avec la récente modeste progression du chômage (en dépit d'un niveau qui reste faible) et la décélération de la croissance des salaires.

L'économie américaine semble donc sur le point de connaître des difficultés du fait d'un consommateur plus réticent

L'impact sur l'économie mondiale

Les taux de croissance au niveau mondial vont probablement ralentir si les ménages américains capitulent, mais les Etats-Unis ne constituent cependant plus le moteur de la croissance mondiale qu'ils furent autrefois. Selon les dernières données du FMI, c'est la Chine qui devrait désormais le plus contribuer à la croissance mondiale en lieu et place des Etats-Unis.

Ailleurs, les « nouvelles économies » d'Asie affichent certains des taux de croissance les plus élevés et les plus robustes au monde, soutenues en grande partie par l'évolution de leurs modèles commerciaux. Ces marchés sont aujourd'hui moins dépendants de la demande américaine afin de pérenniser leur développement et trouvent dans le commerce intra-asiatique le principal facteur de contribution à leur croissance économique. Les consommateurs asiatiques sont, de plus, beaucoup moins endettés et connaissent une hausse de leur revenu disponible.

Conclusion

La crise est en grande partie la conséquence de la politique monétaire de la Fed : entre 2001 et 2004 elle a procédé à une baisse de ses taux directeurs et à une injection massive de liquidité dans le système monétaire globale (notamment suite aux événements de 2000 – chute des valeurs technologiques du Nasdaq – et 2001 – les attentats terroristes).

Les investisseurs ont profité des taux bas pour spéculer sur le marché immobilier, ce qui à mené à une hausse des prix de l'immobilier. Les banques, elles aussi, ont prêté généreusement en prenant un risque soutenu car les prêts étaient gagés sur la valeur de l'immobilier. Les ménages américains à risque, les « subprimes », ont bénéficié des conditions d'octroi de crédit favorables : taux bas les premières années, mais puis indexé sur les taux du marché.

Après 2004, suite à une inflation devenue galopante, la Fed a procédé à un durcissement de la politique monétaire et à la hausse des taux, qui ont passé de 1% à 5,25% en quelques années. Sur le marché immobilier, les prix commencent à chuter, à partir de 2006. Les prêts étant à taux variable et l'immobilier ayant baissé sous sa valeur de garantie, les ménages les plus fragiles font défaut. Les banques saisissent les biens des emprunteurs insolvables et les stocks de logement augmentent, avec un impact sur le prix de l'immobilier qui continue de baisser.

La contagion de la crise des subprimes aux marchés financiers, à l'économie américaine et à l'échelle mondiale s'est produite par le biais de la titrisation. Le marché monétaire et obligataire a été frappé par une grave crise de liquidité : les investisseur en quête de liquidité et ne pouvant revendre ses actifs titrisés se sont tournés vers le marché des Commercial Papers. D'ici la crainte que les emprunteurs sur le marché monétaire soient détenteurs d'actifs titrisés.

La baisse du moral des ménages, de l'activité du secteur financier et le resserrement des conditions de crédit en termes de prix et de qualité ont mené à une baisse de la consommation des ménages et de l'investissement des entreprises qui n'ont plus les financements nécessaires et, en suite, à la baisse de la croissance et ralentissement de l'économie américaine.

Les impacts les plus importants à l'échelle mondiale se sont fait ressentir dans les pays développés, notamment en Europe. Toutefois ils restent limités du fait que les moteurs de croissance de l'économie mondiale ne sont plus les Etats Unis, mais les pays émergents comme la Chine et l'Inde, qui ont joué un rôle d'amortisseur dans la crise.

Abstract: L'adoption du traite de Maastricht a determine une preoccupation aigue pour la cible de deficit budgetaire de 3%. Les finances publiques des etats membres se sont concentrees sur l'elaboration des politiques destinees a assurer un controle ferme du deficit budgetaire. La litterature de specialite inclut de nombreuses discussions contradictoires concernant les deux composants des finances publiques – budgetaire et fiscale- capables d'assurer une gestion performante du solde budgetaire. Le dilemme de la concentration soit sur l'instrument budgetaire, soit sur l'instrument fiscal pour toucher a la cible de deficit budgetaire a detremine l'adoptation des mesures qui ont vise soit la diminution des charges pubiques (France ou Allemagne), soit la croissance des revenus fiscaux (le cas des pays emergens est europeens).

Ce papier se propose de mettre en evidence quelles sont les variables determinantes de la pression fiscale en Roumanie, tout en se concentrant sur les deux categories de politiques. Le defi c'est de relever de la direction de determination des deux variables –charges et revenus publiques.

Key-words: pression fiscale, politique fiscale, politique budgetaire

JEL Classification Numbers: G21, G30, G33

Introduction

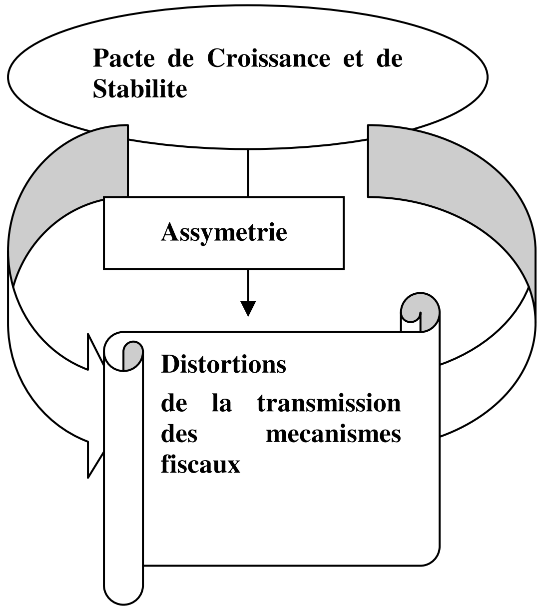
L'adoptation du Traite de Maastricht de 1992 et, ulterieurement, du Pacte de Stabilite et de Croissance, ont eu une influence importante sur les politiques fiscales europeennes dans la perspective des exigences etablies au niveau du deficit budgetaire et de la dette publique. Beaucoup de discussions contradictoires sont apparues autour des deux valeurs cle – 3% pour le deficit budgetaire et 60% pour la dette publique. On a demande frequemment des explications cocernant les principes qui par rapport auxquels on a mis le fondement numerique des deux criteres.

En fait, les deux valuers cible ont ete determinees par la moyenne enregistree au niveau des 15 etats membres. En1992, l'annee ou le traite de Maastricht a ete signe la moyenne du poids de la dette publique au PIB pour les 15 etats membres a ete 60,4%. Econometriquement, on a releve du fait qu'a un poids de la dette publique au PIB de 60%, c'est un deficit budgetaire 3% qui corresponde dans les conditions ou on enregistre un ecroissance economique nominale de 5%.

La validite de ces criteres a ete durement contestee ; la realite econimique a releve pour les etats membres, au niveau de l'annee 2006, une dette publique moyenne de 2 fois plus elevee que celle des etats qui se trouvaient en train d'etre integres (Blege, Grece Italie – 100%) tandis que ceux-la ont enregistre des deficits plus eleves (Pologne -20%).

C'est ainsi que l'assymetrie apparait et qui est determinee par les distortions enregistees au niveau de la transmission des mecanismes fiscaux.

Graphique no 1 – Assymetrie generee par les contraintes budgetaires

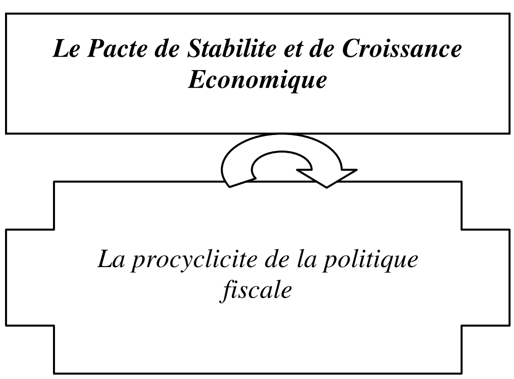


Source : traitement propre

On suppose qu'un pays enregistre des deficits eleves, non-soutenables a long terme. Dans ce cas, la prime de risque correspondante aux emissions obligataires gouvernamentales realisees par ce pays va augmenter. Si les deficits enregistrent des augmentations continuelles, le marche financiere interne et internationale va limiter les moyens de financement [1]. Ainsi, la prime de risque va devenir prohibitive et la perspective du blocage de l'acces au marche international de capital va diminuer les emissions obligataires, ce qui va determiner d'une maniere automatique la reduction de la dette publique, mais aussi du deficit budgetaire [2].

L'assymetrie impliquee par les prevoyances du Pacte de Stabilite et de Croissance se manifeste specialement dans le contexte des contredictions qui puissnet apparaitre entre la politique fiscale nationale et celle reglementee au niveau europeen[3]. Dans le cas d'une recession economique, les autorites fiscales ne peuvent pas operer des modifications sur les stablisateurs fiscaux. Ainsi, la politique fiscale devient prociclique pendant les periodes de recession parce le taux fiscale augmente et les charges publiques diminuent.

Graphique no 2 – La dimension restrictive du Pacte de Stabilite et de Croissance



Source : traitement propre

[3] Meltze Calmfors, Lars (2005). *What Remains of the Stability Pact and What Next*? Swedish Institute for European Policy Studies, Stockholm

Dalsgaard et DeSerres (1999) ont pris en consideration la perspective d'une politique fiscale prudente justement pour eviter cette procyclicite. La prudence va devenir possible seulement dans le contexte de la cosnstitution d'un surplus budgetaire qui va conferer aux stabilisateurs fiscaux la capacite d'operer automatiquement pendant les periodes de recession justement pour eviter les deficits publics au dela des limites imposees par le Pacte de Stabilite et de Croissance.

Ce projet se propose de mettre en evidence les determinants du solde budgetaire ai niveau de la Roumanie.

2.3 La perspective quantitative sur la pression fiscale par la modelisation econometrique des relations entre les variables fondamentales du systeme fiscal

L'accentuation du phenomene inflationniste est certianement un des effets negatifs de l'apparition et de la persistence du deficit budgetaire. Au fur et a mesure que le niveua des des charges publiques va augmenter, la demande aggregee va etre inflammee, ce qui va generer automatiquement l'augmentation des prix [4] et la baisse du pouvoir d'achat.

Le deficit budgetaire appparait dans le contexte du phenomene d'eviction (crowding out) ; la croissance des charges publiques est une modalite par laquelle les periodes de recession economique peuvent etre surmontees[5]. Les adeptes du Keynes promouvaient la necessite de de l'intervention de l'etat par l'augmentationdes harges publiques pendant les periodes de crise economique pour assurere a l'economie les ressorts necessaires pour remettre l'equilibre. Mais c'est justement dans ce contexte de relache fiscale que le deficit budgetaire apparait.

La litterature de specialite inclut de nombreuses discussions contradictoires concernant les causes du deficit budgetaire [6]. Les discussions contradictoires sont apparues a l'egard des deux composants determinants du deficit budgetaire – les charges et les revenus publics.

Source : traitement propre

Theoriquement, le deficit budgetaire apparait dans le contexte des charges publiques excedentaires par rapport aux revenus pubics. Cependant, quelques theoriciens considerent que le deficit budgetaire est impacte d'une maniere plus forte par le composant fscal, c'est a dire un niveau reduit des revenus publics.

Pour surprendre d'une maniere plus viable le mecanisme qui a determine l'apparition du deficit budgetaire dans le contexte actuel de l'economie roumaine, on va tester quelques hypotheses par la construction des regressions entre le solde budgetaire (SB), comme variable dependante, et le niveau des charges publiques (CHP) et des revenus publics (VP) comme variables independentes.

La base de donnees valorisee appartient a l'Institut National de Statistiques et comprend les informations concernant les valuers enregistrees par le solde budgetaire et des charges au long de la periode 1990-2007.

Tout en prenant en consideration la periode de transition, marquee par de profondes restructurations d'ordre economique et social, on va emettre l'hypothese par rapport a laquelle le deficit budgetaire a ete determine sous l'impact des charges publiques, la dynamique des revenus publics n'ayant pas d'impact important dans cette perspective.

Ainsi, les hypotheses testees sont:

1. Les charges publiques ont un impact important sur le deficit budgetaire
2. La dynamique des revenus publics n'a pas eu d'impact important sur le deficit budgetaire

En faisant usage de la methode des moindres carres pour estimer la regression, on remarque le fait que le solde budgetaire peut etre modele de la perspective des charges publiques, mais aussi de la perspective des revenus publics :

Tableau no. 2 La regression Solde budgetaire – Revenus publics

Dependent Variable: SB

Method: Least Squares

Date: 09/25/07 Time: 01:24

Sample: 1990 2007

Included observations: 18

Variable	Coefficient	Std. Error	t-Statistic	Prob.
VP	-0.139392	0.019941	-6.990076	0.0000
β	0.62412	0.002323		

R-squared	0.546836	Mean dependent var	-2302876.
Adjusted R-squared	0.546836	S.D. dependent var	2725989.
S.E. of regression	1835067.	Akaike info criterion	31.73701
Sum squared resid	5.72E+13	Schwarz criterion	31.78648
Log likelihood	-284.6331	Durbin-Watson stat	1.361468

Source : traitement propre

SB = -0,14*VP +0,62412

SB = -0.126905*CHP + 0.235476

ou

SB = solde budgetaire

VP = revenus publics

CHP = charges publiques

Tout en construisant les deux regressions, on remarque le fait que les statistiques correspondantes de la premiere equation de regression sont plus significatives que les statistiques de la deuxieme regression.

Dans ce cas, la premiere hypothese est acceptee tandis que la deuxieme est rejetee. Ainsi, du point de vue du coefficient R-squared, mais aussi de la somme des carres des residus et de la statistique Durbin Watson, on remarque le fait que la regression construite entre le niveau du solde budgetaire (deficit budgetaire) et le niveau des charges publiques exprime une relation beaucoup plus forte entre les deux variables que la regression construite entre le deficit budgetaire et les revenus publics [7].

Ainsi, tout en elargissant l'interpretation au niveau macroeconomique, on apprecie que le deficit budgetaire est apparu dans le contexte d'un niveau excedentaire des charges publiques par rapport aux revenus publics, plus precisement le composant budgetaire, de redistribution des finances publiques qui a ete plus fort que celui des prelevements.

Celle-ci est une particularite des economies emergentes ou l'etat s'implique par la croissance des charges publiques pour ameliorer les duretes du processus de transition de l'economie centralisee a l'economie de marche.

Mais a long terme, la persistence du defcit budgetaire a des influences negatives sur l'equilibre macroeconomique [8] .

C'est pourqoui les analystes se sont mis d'accord sur la necessite des options publiques equilibrees, qui impliquent l'interference equilibree du composant budgetaire et du composant fiscal.

On anticipe une augmentation du taux de la fiscalite en Roumanie a l'avenir, tout en prenant en consideration son integration a l'Union Europeenne et les pressions exercees par les taux de fiscalite beaucoup plus eleves des etats membres.

Dans ces conditions, il y a de nombreuses opinions par rapport auxquelles une potentielle croissance du taux de la fiscalite conduise d'une d'une maniere inevitable a l'uagmentation des pressions inflationnistes, ce qui representerait, en effet, un reel peril pour la stabilite macroeconomique[9].

[9] Alexandru F., "*Eficiență-echitate în materie fiscală*", Tribuna Economică, nr.22/31 mai 2000

Pour mettre en evidence la correlation entre la fiscalite et le niveau de l'inflation en Roumanie, on a construit deux regressions entre inflation, comme variable dependente, et les impots indirects et deficit budgetaire comme variables independentes.

Tableau no 3 Regression inflation – impots indirects

Les hypotheses formulees seront:

1. Le deficit budgetaire detrmine l'augmentation du phenomene inflationniste
2. Il y a une relation de proportionnalite entre le niveau des impots indirects et l'inflation

Les tests statistiques realises permettent la rejection des deux hypotheses. Ainsi, au niveau de la Roumanie on constate l'inexistence d'une correlation entre le deficit budgetaire et l'inflation, tout comme entre les impots indirects et l'inflation [10].

L'explication reside dans la cause de nature macroeconomique du processus inflationniste. La baisse du pouvoir d'achat, la reduction permanente des reserves en

devises de la Banque Centrale[11], la diminution de la capacite productive dans le

CHANGES IN FISCAL REGULATIONS REGARDING THE DIRECT TAXES, APPLICABLE IN 2008

Brote Ioana

FABBV, ASE, Bucharest, Address: Sibiu, str. Rahova, nr. 63, bl. 92, ap. 49, cod 550381, jud. Sibiu, Telephone: 0726/017771

Brief: The paper aims to highlight the major changes in fiscal regulations regarding the direct taxes, applicable in 2008. We treat the main direct taxes separately:

The dividend tax regulations, regarding the application, the taxation quota, the anticipated dividend payments.

The tax on income from investments (legal aspects, taxable income from interests vs. gains from transfer of securities, reporting obligations).

The profit tax (advance payments, contracts for provision of services, taxable base of fixed assets, ellimination of the declaration of payments for non-residents).

Keywords: fiscal regulations, direct taxes, dividends, tax on income from investments, profit tax

Romania has launched a major reforming process regarding taxation, in order to elliminate the fiscal differences and exempts, which have contributed to fiscal evasion and deferred payments, in the past.

The new Fiscal Code, meant to harmonise the legislation with the EU acquis, brings changes in the fiscal regulations, which will generate higher income for the state budget.

The dividend tax

Application

The Fiscal Code, Title I, Chapter III, art. 7 defines the dividend as „a distribution in money or in kind made by a legal person to a participant in the legal person, as a consequence of the ownership of participation titles in such legal person, except for the following:

a) a distribution of additional participation titles which does not modify the percentage of ownership of the participation titles of any participant in the legal person;

b) […];

c) a distribution in money or in kind made in connection with the liquidation of a legal person;

d) a distribution in money or in kind made on the occasion of cutting down the registered capital actually constituted by participants.''

If the amount paid by a legal person for the goods or services supplied by a participant in the legal person exceeds the market price for such goods or services, then the difference shall be treated as a dividend. Likewise, if the amount paid by a legal person for the goods and services supplied to the advantage of a shareholder or associate of the legal person is carried out for the personal benefit of the latter, than that amount shall be treated as dividend.

The declaration and witholding of dividend tax owed by companies

The article 36 from the Fiscal Code treats the witholding of tax on dividends:

1. „A Romanian legal person which pays dividends to a Romanian legal person shall have the obligation to withhold and to pay in the withheld tax on dividends to the state budget, […].
2. The tax on dividends shall be determined by applying a taxation quota of 10% on the gross dividend paid to a Romanian legal person.
3. The tax which must be withheld shall be paid to the state budget until the 25th of the month following the month when the dividend is paid. In case the allocated dividends have not been paid by the end of the year in which the annual financial statements have been approved, the tax on dividends shall be paid by 31 December of that year.

4. The provisions of the present article shall not apply to the dividends paid by a Romanian legal person to another Romanian legal person, if the beneficiary of the dividends holds a minimum of 25% of the participation titles in such legal person on the date when the dividend is paid, for a period of two years ending on the date when the dividend is paid. […].
5. The quota regarding tax on dividends provided in paragraph (2) shall also apply to the amounts distributed to the open investment funds.''

The declaration and witholding of dividend tax owed by people

Art. 65 from the Fiscal Code says that dividends shall be taxed with a 16% quota of the amount of such incomes. The legal persons shall be obliged to calculate and to withold tax on incomes in the form of dividends at the same time with the payment of such dividends to shareholders or associates. The time limit for the payment of the tax shall be until the 25th day inclusive of the month following the month when the payment is made. In case of distributed dividends which were not paid to shareholders or associates by the end of the year when the balance sheet was approved, the time limit for the payment of dividend tax shall be until 31 December inclusive of that year.

The comparative fiscal treatment of the dividend

Companies:

- the net dividend received from another company is non-taxable income;
- the gross dividend is non-taxable at source, if the beneficiary owns at least 15% in the paying company, or 10%, since 2009.

Natural persons:

- the dividend received from a company is taxable with a 16% quota;
- the witheld tax is final.

The differences in fiscal treatment

Companies

- the dividend received by a company that owns less than 15% (10% since 2009) is taxed with 10% at source; this is not a fiscal credit for the natural persons who own interests in the company that benefits from the dividend;
- there is a double taxation of the dividend:
  - 10% at the payment to the company that holds interests in the company that pays dividends;
  - the net dividend of the beneficiary company is taxed the second time with 16% at the payment to the natural persons (share-holders or associates).

Natural persons:

- they receive the dividend in less than 6 months from the approuval of the annual financial statements;
- they can receive the dividends during the fiscal year, according to the law:
  - provided there is profit;
  - the dividend distribution is the result of the approuval of the share-holders or associates.

The anticipated dividend

There is a possibility to make anticipated payments of dividends, which results from art. 67 Law 31/1990, modified and harmonised with the UE acquis:

1. The share of the profits to be paid to each associate represents a dividend.
2. The dividends shall be paid to the associates in proportion with their participation quota in the registered and paid capital, provided the constitutive act does not provide otherwise.
3. Dividends can be distributed only out of real profits.
4. Dividends paid with the infringement of the above mentioned provisions shall be reimbursed.

5. The right to sue for the reimbursement of the dividends is limited to three years since the day of their distribution.
6. The dividends due after the shares changed the owner belong to the assignee provided the parties did not agree otherwise.

The payment deadline of tax for the anticipated dividend is 25 of the month following the month the dividend is received.

The tax on income from investments

The tax on income from investments owed by Romanian legal persons

The companies are subject to tax on taxable profit obtained from any source, either in Romania or from abroad, with a 16% quota; fiscal losses can be reported for the following five years.

The tax on income from investments owed by non-resident legal persons

The non-resident companies are subject to tax profit for the income obtained from selling interests in a company, if:

- the owned company is romanian;
- a minimum of 50% of the fixed assets of the transactioned company is, directly or indirectly, real estate located in Romania.

The Fiscal Code says that gains obtained from investments, other than interests, obtained by a non-resident company are not taxable in Romania.

The Norms of application of the Fiscal Code say that the application of the Conventions for avoiding the double taxation is extended to gains obtained by non-resident companies from transactions with all kinds of stocks.

The internal taxation quota is 16%; the fiscal loss can be deferred for the following five years. The gain or loss is determined with the following formula:

Gain/loss = (no. of shares * market price) – (no. of shares * acquisition cost) – commisions, taxes, direct transaction costs

The deadline for the payment and declaration of the tax is 25 of the next month of the termester when the gain is obtained. For the gains obtained during the year, a declaration of profit should be submitted , until 15 April next year.

Any foreign company that obtains income from selling interests in a Romanian company has to pay profit tax and also to submit a profit tax declaration. These companies may assign a fiscal representative for these matters.

Exceptionally, the non-resident company does not have these obligations if its income is paid by a Romanian company, or by a permanent head-office of a non-resident company; in which case, the income payer has the obligation to calculate, to withold, to declare and to pay the tax.

The Conventions for avoiding the double taxation apply, provided that the fiscal residence certificate is presented either to the income payer of the transaction gains (if this one is a Romanian company, or a permanent head-office in Romania of a non-resident company), or to the fiscal representative in Romania of the non-resident company.

Most of the Conventions for avoiding the double taxation, settled between Romania and other countries stipulate that these gains should be taxed only in the benficiary's country. Exceptionally, some Conventions (e.g. France, Germany) stipulate that these gains should be taxed in the source-state, if most of the fixed assets of the transactioned company represent, directly or indirectly, real estate located in Romania.

The Fiscal Procedure Code says that any entity/person who is subject of a fiscal transaction should be registered and have a fiscal identification code. The contributors who don't have a fiscal residence in Romania but who should submit fiscal declarations, need to assign a representative that has fiscal residence in Romania.

The tax on income from investments owed by Romanian natural persons

The Romanian natural persons are subjects of the investment income tax, for the gain obtained from selling titles.

The tax is calculated for every transaction; the net annual gain is calculated only for investments transactions, others than interests and shares in closed companies.

The calculation methods vary according to the investment type:

- gain/loss from investments transfer, other than interests = no. of shares * (sale price – acquisition price) – transaction costs
- gain/loss from interests transfer = no. of shares * (sale price – nominal value/acquisition price)
- gain/loss from the transfer of interests in open investment funds = no. of shares * (repurchase price – acquisition/subscription price)

The gain from transactions with investments in closed companies and interests is taxed with a 16% quota. The yearly fiscal loss is not recognised nor deduced or reported. The taxable person is the one who earns the gains. The deadline for the declaration and payment of the tax is 25 of the next month from the income realisation.

Except for investments in closed companies and interests, the gain from investment transactions is taxed with a 1% quota if the shares were owned more than 365 days, and 16% if they were owned for a shorter time. At the end of the fiscal year, only gains of the same nature are compensated, and annual loss is not reported. The intermediary is obliged to withhold, declare and pay the tax, until the 25 of the next month from the income realisation.

The tax on income from investments owed by non-resident persons

According to art. 115, alin. 2 from the Fiscal Code, the gains earned by non-resident natural persons from the transfer of investments in a Romanian company and from the transfer of titles, other than interests, are taxed according to the regulations applicable to Romanian natural persons.

If the beneficiary presents the fiscal residence certificate, the gains are taxed according to the Conventions for avoiding the double taxation.

Just like for the companies, most of the Conventions for avoiding the double taxation, settled between Romania and other countries stipulate that these gains should be taxed only in the benficiary's country. Exceptionally, some treaties (e.g. France, Germany) stipulate that these gains should be taxed in the source-state, if most of the fixed assets of the transactioned company represent, directly or indirectly, real estate located in Romania.

Penalties

For not submitting the fiscal declarations, including the fiscal registration, there are fees of 1.000 – 5.000 lei for companies and of 500 – 1.000 lei for persons. There are 0,1% per day penalties for not paying the tax.

The profit tax

Anticipated payments

The contributors (other than Romanian banks and non-resident bank branches) should have applied the termestrial anticipated payments of profit tax, starting 1 january 2008.

The application of this system has been delayed until 2010.

Formal requirements for service provision contracts

The fiscal regulations valid during 2007 required that the contracts for provision of services should include information on execution terms, prices, the way prices are allocated and the total value of the contract. These requirements were stipulated in order to sustain the deduction of the expenses generated by the contract.

Since 1 January 2008, these requirements are not valid any more, the mere existence of a contract being a sufficient reason for deduction.

The registration of contracts for provision of services with non-residents

Only the contracts between Romanian companies and non-residents (persons or companies who activate in Romania) that could generate a permanent head-office should be registered with the authorities.

The fiscal base of fixed assets

The fiscal value includes the reevaluations of fixed assets, made on a legal basis. The reduction of the fixed assets value below the acquisition cost should not be taken into consideration for fiscal reasons.

The reduction of fixed assets value, subsequent of reevaluation, can not be deduced when calculating the profit tax. The fixed assets reevaluation should be recognised in Accountancy starting 1 January of the year following the reevaluation. Reevaluations made when the company is reorganised should not be taken into consideration for fiscal reasons.

The ellimination of the declaration regarding payments to non-residents. The Romanian contributors had to submit a declaration regarding payments to non-residents (both affiliates and others). This declaration is not required any more.

A similar, but not identical declaration should be submitted though, before the last day of February, in the year next to the one that payments were made (according to the regulations regarding the taxation of incomes earned by non-residents).

Accomodation and transport expenses

Accomodation and transport expenses were deduced when calculating the profit tax, provided they were made by the employees and administrators of the company.

Starting from 2008, the Fiscal Code stipulates that these expenses may be deduced also if they are made by persons assimilated to the employees (non-resident persons for delegations or temporary secondment in Romania, for business purposes, training, consultancy etc.).

The expenses made by the employees to and from their workplace are specifically mentioned as expenses that are made in order to obtain taxable income.

Technological loss

The technological loss included in the consumption norms of goods/services are expenses that are made in order to obtain taxable income.

Legal reserve

The Norms for the application of the Fiscal Code have been adjusted to the stipulations of the Fiscal Code regarding non-taxable income excempt from the calculation basis of the legal reserve, for fiscal purposes (the Fiscal Code, art. 20, lit.c).

If, subsequent to reorganisation, the legal reserve exceeds 20% of the social capital, the diminishing of the reserve is not mandatory.

Stock option plan

The difference between the market value and the preferential price of shares in stock option plan programs is defined as an expense in favour of the stock-holders (with an impact on profit tax and potentially on the dividend tax).

Sale and lease-back

The sale and leas-back operations should be considered a financing operation if the leasing operation qualifies as a financial leasing operation.

A coherent legislation on direct taxes is necessary, because there are more non-resident companies which make transactions on the Romanian capital market, and also, Romanian investors have access to titles issued on european markets.

Thus, we believe the permanent updating of the fiscal regulations will improuve the income collection for the state budget and will help create a healthy economical environment.

Abstract: The external vulnerability became an important issue as a result of recent financial crises. The debates focused on the external and public debt sustainability in order to identify the relationship between these two variables in order to investigate the degree of vulnerability of a country from the point of view of its international financial position and internal stability. So, the recent increase of external debt in Romania conduct to the necessity to analyze the debt sustainability for the external position and for the domestic debt. The aim of this paper is to investigate the relationship between public and external debt sustainability in Romania. Using monthly data from 1992 to 2007 we find evidence for weak form of Romanian debt sustainability.

Key words: public debt, external debt, sustainability.

1. Introduction

The external vulnerability became an important issue as a result of recent financial crises. The debates focused on the external and public debt sustainability in order to identify the relationship between these two variables and to investigate the degree of vulnerability of a country from the point of view of its international financial position and internal stability. So, external debt is sustainable if a country "is expected to meet its current and future external debt-service obligations in full, without recourse to debt relief, rescheduling of debts, or the accumulation of arrears, and without unduly compromising growth"[41]. This definition reveals the complexity of this concept which is analyzed using different variables and techniques in order to ensure long term debt sustainability without affecting the country's capacity to service external debt on long run. These variables that are taken into the consideration are economic growth, export, import and fiscal revenue.

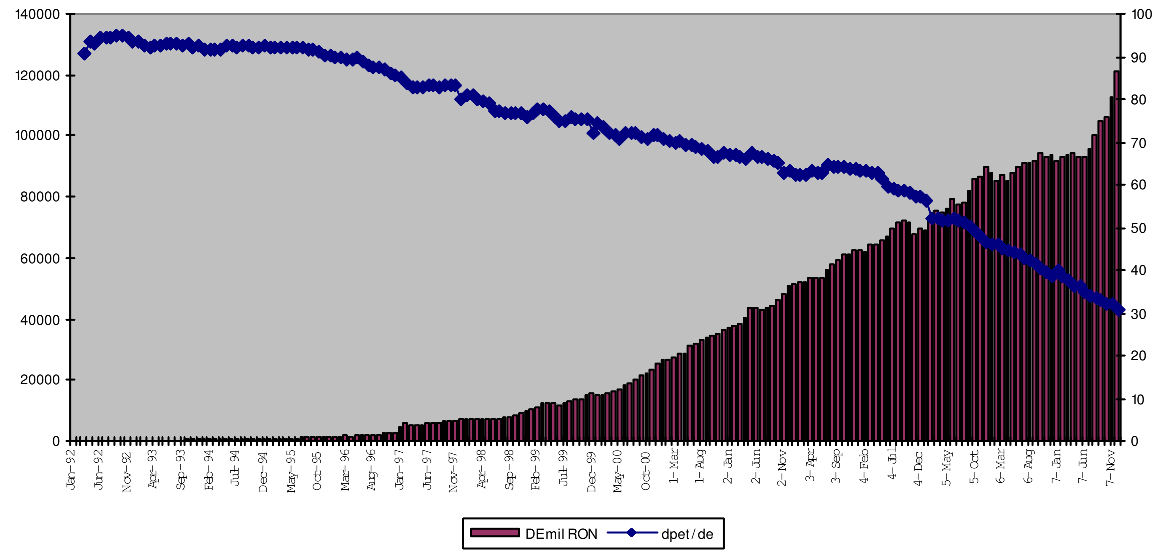
So, considering the relevance of external debt sustainability in relation with public debt sustainability, we find useful the investigation of this issue for Romanian case.

The study is structured as follow. After a brief presentation of the Romanian public and external debt (Section II) we investigate the literature on debt sustainability (Section III). Section IV highlights the results of the empirical tests to analyze the relationship between Romanian public and external debt sustainability. Section V discusses the policy implications of these findings.

2. Romanian external and public debt

External debt is the result of the country financial liabilities that is owed to creditors outside the country. In Romania, external debt has an increasing trend over the period 1992-2007 as a result to external indebtedness of public authorities and private entities. But public external debt has a decreasing trend starting with 2004, when the ratio of public debt to external debt became less then 50 percent. This ratio varies between 94.9 percent in October 1992 and 30.9 percent in December 2007, and shows the external vulnerability caused by private debtors (figure 1).

[41]IMF, 1997, pp. 17.



Source: data are from National Bank of Romania.

Figure 1 External debt and external public debt, 1992-2007

3. Review of selected literature

Sustainability of external debt is based on the intertemporal budget constraint which expresses aggregate income of the economy as a function of total expenditure, as follows:

$$Y_t + \Delta B_t + TR_t = A_t + rB_{t-1} + [N_t - (1+i_t)N_{t-1}] \text{ or } TB_t + \Delta B_t + TR_t = rB_{t-1} + [N_t - (1+i_t)N_{t-1}] \quad (1^{42})$$

where: Y- GDP during t period; ΔB- change of gross external debt; TR- net transfer receipts; A-total expenditure of domestic residents on goods and services; r- nominal interest rate; N- foreign currency reserves of central bank; i- interest rate in these reserves; TB- trade balance. These variables can be expressed as ratio of GDP or in real term.

If it is considered the expectation operator, the intertemporal budget identity became:

$$B_t = E_t \sum_{j=t+1}^{\infty} \frac{S_j}{\prod_{t=1}^{j-t}(1+r_{t+i})} \quad (2^{43})$$

So, the external debt at time t is equal to the present value of future net surpluses which is equivalent with external debt sustainability if: $E_t \lim_{N\to\infty} \frac{B_N}{\prod_{j=1}^{N-1}(1+r_{t+j})} = 0$ (3^{44})

Investigation of external debt sustainability may also take into the consideration: (i) current account sustainability focused on the composition of CA and on the methods used to finance the CA deficit through foreign direct investments or other. In this context it is useful the net external position (NEP) of a country (Lane and Milesi - Ferretti, 2005); (ii) domestic public debt underlined how it undermines the sustainability target for external debt (Abbas, 2005). Presbitero and Arnone (2006) analyze the external sustainability using domestic public debt because it became an important part of the indebtedness level and interest rates

[42] Gülcan and Utku, 2006, pp.671.
[43] Gülcan and Utku, 2006, pp.672.
[44] Gülcan and Utku, 2006, pp.672.

on domestic debt constrained the government spending and investment; (iii) economic growth (Bhattacharya, Clements, 2004; Presbitero, 2005); (iv) fiscal deficits and economy (such as consumption, investment) (Agenor, 2004).

External debt sustainability and it's incidence on other variables are investigated using different techniques and variables. The procedures are: (i) unit root test for external debt and trade balance or current account; (ii) cointegration regressions among external debt and trade balance or current account, or exports, imports, GDP, and interest rates (Hamilton, Flavin, 1986; Sawada, 1994); (iii) reaction function for external debt expressed by other explanatory variables. Unit root and cointegration tests are useful to analyze the implication of the intertemporal constraint on long run in order to identify if a government can sustain its domestic and external deficits without major adjustments imposed by intertemporal budget identity. Such empirical investigation begin with the study of Hamilton and Flavin (1986), and extended by Wilcox (1989), Trahan and Walsh (1991), Hakkio and Rush (1991), Buiter and Patel (1992), Tanner and Liu (1994), Liu and Tanner (1995), Tanner (1995), Wu (1998).

As a result of the empirical studies, investigation of external debt sustainability can be done by using accounting approach (Cuddington, 1997; Agenor, 2004; Burnside, 2005) and present value constraint approach. According to this last method the debt is sustainable when "NPV of debt (public and publicly guaranteed) to exports ratio and the debt service to export ratio are below certain country specific target levels within ranges of 200-250 percent and 20-25 percent respectively" [45]. These standard levels for different debt ratio are: (i) public external debt is 50 percent of GDP, 200 percent of exports and 250 percent of consolidated general budget revenue; (ii) public external debt service is 20 percent of exports, 25 percent of consolidated general budget revenue; (iii) interest on public external debt is 10 percent of exports and 15 percent of consolidated general budget revenue.

4. Relationship between public and external debt sustainability: evidence for Romania

In order to investigate the relationship between public and external debt sustainability in Romania we use unit root, cointegration and OLS regression for external debt and public external debt. The variables used are external debt (*ED*), public external debt (*PED*), export (*EX*), import (*IM*), trade deficit (*TB*) and current account deficit (*CA*) from January 1992 to December 2007. Unit root tests show that these variables are I(1) according to Phillips-Perron (table 1). As a result we may say that sustainability of external debt and external public debt is weak as a result of the equilibrium relationship on long run between external debt or public external debt and trade or current account deficit over the entire sample.

ariable	*t -Statistic*	*Test critical values*		
		1 % level	*5 % level*	*1 0% level*
Phillips-Perron				
(PED)	*-12.09523*	*-3.464827*	*-2.876595*	*-2.574874*
(ED)	*-8.919266*	*-3.464827*	*-2.876595*	*-2.574874*
(EX)	*-18.25251*	*-3.464827*	*-2.876595*	*-2.574874*
(IM)	*-17.76182*	*-3.464827*	*-2.876595*	*-2.574874*
(TB)	*-15.75528*	*-3.464827*	*-2.876595*	*-2.574874*
(CA)	*-15.55951*	*-3.464827*	*-2.876595*	*-2.574874*

Table 1 Results of unit root tests

[45]IMF, 1997, pp. 28.

The results of our tests are: (i) external debt determines import and export but there is a weak relationship between them; (ii) public external debt causes import and export and it is influenced by export. So, the regressions results are:

$ED_t = 286.8678 + 1.013162 ED_{t-1} - 0.130557 EX_{t-2} + 0.097598 IM_{t-2} + \varepsilon_t$, with R-squared = 0.998789

$PED_t = 180.7910 + 1.009919 PED_{t-1} - 0.024882 EX_{t-2} + 0.012117 IM_{t-2} + \varsigma_t$, with R-squared =0.998240

Investigation of public external debt and external debt using the standard level recommended by World Bank and International Monetary Fund shows that Romanian public external debt is sustainable because these ratios are below targets. For example we present these results, for 2005-2006, in table 2.

	2005	*2006*	*Standard level*
Public external debt (% of GDP)	14.4	10.4	50
Public external debt service (% of GDP)	2.5	1.8	
Public external debt (% of export)	43.9	39.4	200
Public external debt service (% of export)	7.7	6.5	20
Interest of public external debt (% of export)	2		10
Public external debt (% of consolidated general budget revenue)	50.1	34.2	250
Public external debt service (% of consolidated general budget revenue)	8.6	5.9	25
Interest of public external debt (% of consolidated general budget revenue)	2.3		15

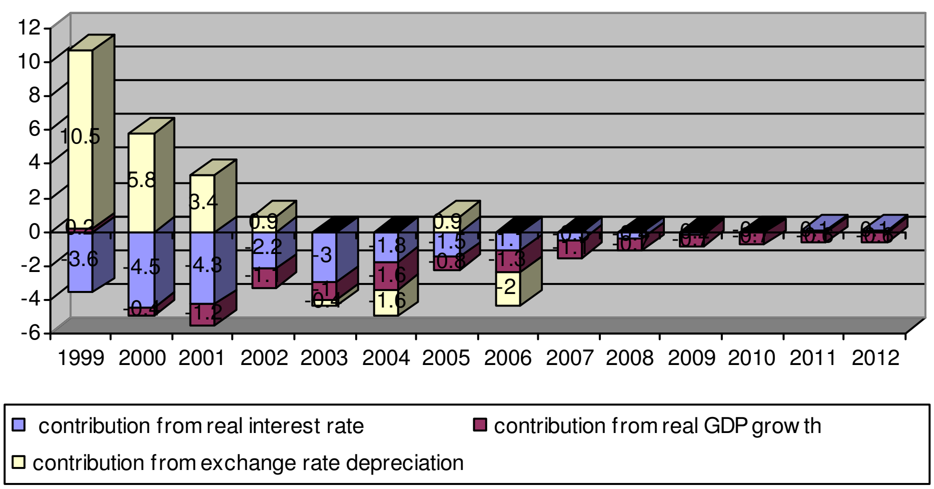
Table 2 Public external debt indicators

Another way to investigate debt sustainability is to use the IMF methodology using sensitivity tests for different macroeconomic perspective such as economic growth, GDP deflator, real interest rate on public debt, primary deficit and gross financing need. The results of these investigations for automatic debt dynamics[46] are presented in figure 2 and 3.



[46] Relations and data are from IMF, Romanian Country Report No. 04/221 and No. 07/219.

Automatic public debt dynamics is determinate using equation [(r-p(1+g)-g+ae(1+r)]/(1+g+p+gp)) times previous period debt ratio, with r = interest rate; p = growth rate of GDP deflator; g = real GDP growth rate; a = share of foreign-currency denominated debt; and e = nominal exchange rate depreciation (measured by increase in local currency value of U.S. dollar).

Automatic external debt dynamics is derived as [r-g- r(1+g)+ea(1+r)]/(1+g+r+gr) times previous period debt stock, with r = nominal effective interest rate on external debt; r = change in domestic GDP deflator in US dollar terms, g = real GDP growth, e = nominal appreciation (increase in dollar value of domestic currency), and a = share of domestic-currency denominated debt in total external debt.

Figure 2 Automatic public debt dynamics

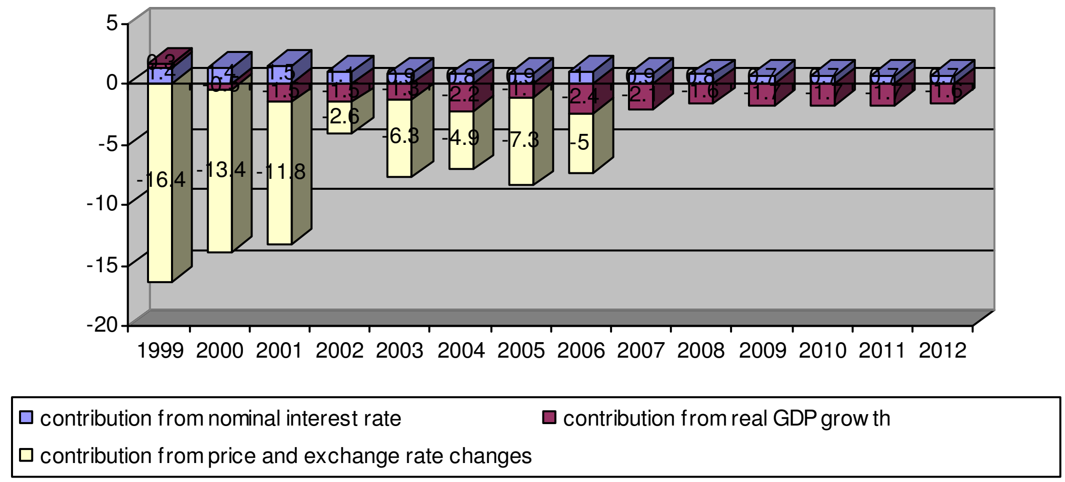


Figure 3Automatic external debt dynamics

Automatic public debt dynamics had positive value in 1999 and 2000 as a result of the contribution from exchange rate depreciation, and negative for 2001-2012. These negative value express al so the decreasing path of public debt at 11.6 percent of GDP in 2012 according to the IMF projections. For external debt, the automatic dynamics is negative for the entire sample especially as the result of price and exchange rate changes which will conduct to a level of external debt of 32.3 percent of GDP in 2012.

5. Conclusions

The external vulnerability became an important issue as a result of recent financial crises. The debates focused on the external and public debt sustainability in order to identify the relationship between these two variables in order to investigate the degree of vulnerability of a country from the point of view of its international financial position and internal stability. So, the recent increase of external debt in Romania conduct to the necessity to investigate the debt sustainability for the external position and for the domestic debt. In theoretical and empirical studies on this issue are developed many techniques in order to analyze the debt sustainability regarding the existence and the type of sustainability, and the incidence of economic variables on debt sustainability. These variables can be used to influence the dynamics of public and external debt in order to ensure the intertemporal budget constraint. Starting with these methods we find that Romanian debt sustainability is weak and there are evidences for long term equilibrium between debt and current account.

Abstract: The issues of assuring public debt sustainability and the impact of tax and budgetary policies on it were the subject of numerous studies both at national and international level, with complex approaches in the specific literature. Debt sustainability is al so important because of the need to ensure long term sustainability of public finances in the context of risk factors represented by rising longevity, falling fertility rates and the retirement of the baby boom generation (European Commission, 2006). In this context we find important to investigate the sustainable gap of public debt over 1990-2005 and the public indebtedness path over 2050 in EMU member states.

Key words: public debt, fiscal balance, primary balance, sustainability.

Introduction

The issues of assuring public debt sustainability and the impact of tax and budgetary policies on it were the subject of numerous studies both at national and international level, with complex approaches in the specific literature. They start with defining the sustainability and its the factors of influence, continue with identifying the type of sustainability and ending with the determination of the impact of public policies on the sustainability and the impact of sustainability on other macroeconomic variables (e.g. economic growth, inflation).

Debt sustainability is al so important because of the need to ensure long term sustainability of public finances in the context of risk factors represented by rising longevity, falling fertility rates and the retirement of the baby boom generation. These risks were identify by the European Commission (2006) based on the projections until 2050 taking into the consideration the incidence of population ageing on economic growth and public expenditure in order to avoid an excessive burden on future generations.

The purpose of this paper is to analyze the gap sustainability in EMU member states. This paper is structured as follows. Starting with empirical evidence on public debt sustainability in section 2 and sustainability model in section 3, section 4 presents the gap of public debt sustainability and risk factors (rising longevity, falling fertility rates and the retirement of the baby boom generation) effects on public debt path. Section V discusses the conclusions of our study.

2. Empirical evidence on public debt sustainability

In the studies that focused on the analysis of public debt, sustainability at country level there were used different methods (Blanchard, 1990; Buiter, 1995; Bohn, 1998, 2005), which lead sometimes to contradictory results. Thus, in the case of US economy, tests on the stationarity of deficit and public debt allowed to identify the existence of public debt sustainability, although data series differed among the studies, as follows: Hamilton and Flavin (1986), annual data series for 1962-1984; Trehan and Walsh (1988, 1991), annual data series for 1890-1983, 1960-1984; Kremers (1988), annual data series for 1920-1985; Bohn (2005), annual data series for 1792-2003. Wilcox (1989) used annual data series for 1960-1984 and stationarity tests on the public debt of USA. He concluded that there is a lack of sustainability, result confirmed Hakkio and Rush (1991), who used quarterly data series or the period 1950-1988 and cointegration tests between the budgetary revenues and expenses. These cointegration tests between the budgetary revenues and expenses of the USA were used for testing the sustainability in the works that followed. This time, the result was positive, although the data series were both annual and quarterly: annual for 1950-1989 in Tanner and Liu (1994) (except the year of 1982); quarterly for 1947-1992 in Quintos (1995) (sustainability until 1980); quarterly for 1950-1990 in Haug (1995); quarterly for 1950-1994 in Crowder (1997) (sustainability until 1982); quarterly for 1947-1992 in Cunado, Gil-Alana and Perez de Gracia (2003), who observed that public debt had a weak sustainability which meant that the adjusting processes are long lasting.

The studies developed on other countries had led to different results: (i) public debt is sustainable in Australia (Elliot and Kearney, 1988); Greece (Visaggio, 2004); Germany (Payne, 1997; Greiner, Koeller and Semmler, 2005); France (Monnier and Tinel, 2006); Japan (Doi, Ihori and Mitsui, 2006); (ii) public debt is not sustainable in Canada (Smith and Zin, 1991); India (Buiter and Patel, 1992); Greece (Makrydakis, Tzavalis and Balfoussias, 1999), Italy (Baglioni and Cherubini, 1993; Athanasios and Sidiropoulos, 1999; Galli and Padovano, 2005); Brazil (Issler and Lima, 1998; Giambiagi and Ronci, 2004; de Mello, 2005).

The determinants of the budgetary deficit and public debt were the subject of many papers meant to explain how the public policies can explain them. Analyzing the OCDE countries Tujula and Wolswijk (2004) have identified a series of factors, as the macroeconomic environment, interest rates, electoral cycles, integration in the Economic and Monetary Union. Some works are in favor of the importance of public debt management (maturity, instruments etc) in stabilizing of public debt to GDP ratio (Bacchiocchi si Missale, 2005).

The studies on the relation between the fiscal sustainability and the external sustainability show a strong correlation between the budgetary and current account deficits that lead to the concept of twin deficits. (Enders,1990; Raybaudi, Sola and Spagnolo, 2003; Ley, 2005).

The recent studies analyze the issues of assuring public debt sustainability through tax and budgetary policies on emergent economies. They use simulations for medium term projections of the impact of excess dept. Gupta, Baldacci, Clements and Tiongson (2003) study on 25 emergent economies the factors that influence the fiscal adjustment periods quantified by the variation of the ratio of fiscal deficits to GDP. Thus, based on the variables used (number of periods when the fiscal consolidation failed; the ratio of budgetary expenses to GDP; the ratio of budgetary revenues to GDP; the initial level of debt to GDP ratio; the exchange rate; the unemployment rate; corruption etc) they draw up a model of fiscal consolidation that emphasizes the importance of both budgetary deficits and public debt. They obtained results that concluded that the risk of fiscal adjustment decreases as the economy heads to a sustainable level of public debt (link between the dimension of fiscal adjustment and sustainability).

Through their study, Hostland and Karam (2005) show that tax and budgetary policies can prevent the excessive debt on medium term of the emergent economies only if they are flexible. Therefore, the governments of emergent economies have to make a trade-off between the management of the risks induced by the unsustainable debt and other fiscal and budgetary goals. These findings were confirmed also by Celasun, Debrun and Ostry (2006), Jeanne and Guscina (2006). Celasun, Debrun and Ostry (2006) demonstrate the role of tax and budgetary policies, and of the noise that they induce in economy on the risk of unsustainable public debt using the example of Argentina, Brazil, Mexic, South Africa and Turkey. Jeanne and Guscina (2006), analyzing the determinants of public debt sustainability on 19 emergent economies conclude that the sustainability of public debt can be assured by a mix of fiscal-budgetary policies, that have goals like reducing the budgetary deficit and increasing the primary surplus, and the monetary policy, that aims at monetary stability. Michel, von Thadden and Vidal (2006) give an answer to the question of the possibility of establishing the sustainable public debt level as a rule in drawing up all the instruments of tax and budgetary policies. They use a model of a closed economy with several generations and conclude that the answer to the above question depends on the long-term level of public debt at which the economy is stable

In Romania, the interest for the study of public debt sustainability and incidence of tax and budgetary policies has grown as these are among the objectives of the governmental policies needed to fulfill the five criteria for convergence to the European Union. Such studies were performed by Albu and Pelinescu (1999, 2002), Campeanu, (2007, 2006, 2005, 2003, 2002), Stoian (2007, 2006, 2005, 2004), Mosteanu, Catarama and Campeanu (2005), Obreja and Brasoveanu, (2005), Roman and Marin (2005).

3. Public debt sustainability according to the intertemporal budget constraint

Public debt sustainability is investigated especially by using intertemporal budget constraint which implies that public debt at the moment *t* (b_t) depends on primary deficit at the moment *t* (pd_t) and public debt at the moment *t-1* (b_{t-1}). Equation 1 indicates the budget constraint presented in many studies such as Blanchard (1990), Buiter (1995), Bohn (1998,2005):

$$b_t = pd_t + \frac{1+r}{1+g} \cdot b_{t-1} \qquad (1)$$

where: b_t is public debt to GDP ratio at the moment *t*; pd_t is primary deficit at the moment *t*; *r* is real interest rate of public debt; *g* = real growth rate.

Considering the expectations at moment *t* on equation (1), sustainability is achieved when present discounted value of public debt converges to zero, as follow:

$$\lim_{k \to \infty} E_t \left(\frac{1+r}{1+g} \right)^{-(1+k)} b_{t+k+1} = 0 \qquad (2)$$

The variables used in the model are in real terms and as GDP ratio, but real interest rate of public debt and real growth rate are considered constant in order to simplify the equation.

4. Public debt sustainability in European Monetary Union member states

The aim of our study is to investigate the public debt sustainability level using the equation 1 in order to see if fiscal policy is or nor on a sustainable path. The results of our study are presented in table 1, when we evidence the sustainability gap according to fiscal criteria established by Maastricht Treaty and to intertemporal budget constraint, and the effects of risk factors (European Commission, 2006) on public debt.

	Public debt according to limit imposed by Maastricht Treaty		**Sustainable public debt according to intertemporal budget constraint**		**Effects of risk factors on public debt**
	below 60% of GDP	**above 60% of GDP**	**indebtedness below the sustainable level**	**indebtedness above the sustainable level**	
EMU	1990-1994 (gda 51.1%)	1995-2005 (gda 76.2 %)	1998-2002 (sga - 2.6 p.p.)	1992-1997 (sga 4.1 p.p.), 2003-2005 (sga 2 p.p.),	Positive effect on public debt during 2010-2030, when gda will be 47.04%, except 2050, when indebtedness will reach 126.9%.
Belgium		1990-2005 (gda 118.5%	1990-2005 (sga - 9.9.p.p.)		Public indebtedness will decrease over 2010-2030 (gda 62%), so we may consider that these factors will have no effect on public debt
Finland	1990-2005 (gda 44.7 %)		1996-2005 (sga - 6.5p.p.)	1990-1995 (sga 8.5p.p.)	Positive effect on public debt which will be 18% in 2010, and - 39.5%, on average, during 2030-2050
Slovenia	1990-2005		1994 (sg -	1995 (sg 2.1.p.p.),	Major effects because

	(gda 24.9 %)		1.7p.p.),1996 (sg -1.2p.p.), 1998 (sg -0.2p.p.), 2005 (sg -0.9p.p.)	1997 (sg 1.1.p.p.), 1999-2004 (sga 1.7p.p.)	the public debt will increase from 67% in 2030 to 274% in 2050
Austria	1990-1992 (gda 56%)	1993-2005 (gda 65%)	1991-1992 (sga -2.3.p.p.), 1996-1998 (sga -3.8p.p.) , 2000-2005 (sga -3.3.p.p.)	1993-1995 (sga 3.5p.p.), 1999 (sg 0.6p.p.)	Public debt will decrease over 2010-2030 from 63.4 in 2005 to 42% in 2030. But in the next two decades there will be a return to 63%.
Netherlands	2000-2005 (gda 52.5%)	1990-1999 (gda 74%)	1991-1994 (sga -5.1p.p.), 1996-2002 (sga -6.8p.p.), 2004-2005 (sga -1.5 p.p.)	1995 (sg 3.1p.p.), 2003 (sg 1.3p.p.)	Positive effect because the public indebtedness will be, on average, 31% over 2010-2050
Luxembourg	1990-2005 (gda 6.2%)		1991 (sg -2 p.p.), 1993-2003 (sga -3.1 p.p.)	1992 (sg 0.5 p.p.), 2004-2005 (sga 0.9)	A major negative impact because public debt will increase from 10% in 2010 to 268% in 2050
Italy		1990-2005 (gda 112 %)	1992-2004 (sga -6.5 p.p.)	2005 (sg 0.9 p.p.)	There will be an influence on public debt which will be 261% in 2050, from 110% in 2010
France	1990-2002 (gda 51.2 %)	2003-2005 (gda 64.5%)	1991 (sg -1.2p.p.), 1998-2001 (sga -2.2 p.p.)	1992-1997 (sga 3.5 p.p.), 2002-2005 (sga 2.7 p.p.)	Yes, public debt will increase with 258.9%, in 2050 from 2005
Spain	1990-1993 (gda 48.3%), 2001-2005 (gda 49.4%)	1994-2000 (gda 64.1%)	1991-1992 (sga -0.03p.p.), 1997-2005 (sga -3.5 p.p.)	1993-1996 (sga 4.3p.p.)	Public debt will decrease in 2010-2030 (dga 4.5%), except 2050, when public indebtedness will reach 72%
Greece		1990-2005 (gda 104.4%)	1994-1999 (sga -7.3 p.p.), 2001-2002 (sga -0.9 p.p.)	1992-1993 (sga 8.5 p.p.), 2000 (sg 8.9 p.p.), 2003-2005 (sga 4.2 p.p.)	Yes, public debt will increase with 137.2% in 2050 from 2005
Ireland	1998-2005 (gda 37.1%)	1990-1997 (gda 85.8%)	1991-2005 (sga -6.4 p.p.)		Positive influence (gda 7.7%)
Germany	1990-1996 (gda 49.4%) , 2001 (gda	1997-2000 (gda 60.8%) 2002-	1996-2002 (sga -2.4 p.p.)	1992-1995 (sga 4.2 p.p.) , 2003-2005 (sga 1.9 p.p.)	Influence the public debt path which will increase during 2010-2050 (gda 152.7%)

	59.6%)	2005 gda 64.5%			
Denmark	1999-2005 (gda 46.8%)	1990-1998 (gda 69.4%)	1992 (sg -4.4 p.p.), 1994-2005 (sga -8.2 p.p.)	1993 (sg 4.1 p.p.)	Positive influence because public debt will decrease (gda - 84%)

Source: data presented in this table are determined by authors, as percentage of GDP, using official data from EUROSTAT for 1990-2005 and projected debt developments for 2010, 2030 and 2050 (European Commission, 2006).

Note: *gda* is gross public debt average expressed as percentage of GDP; *sg* is sustainability gap that expresses the difference between gross public debt and sustainable public debt; *sga* is sustainability gap average.

Table 1 Sustainability gap and effects of risk factors on public debt

Investigating the results of our research we may identify the period of sustainable public debt in EMU member states and the effect on risk factors on public debt. The findings are presented in the next section.

5. Conclusions

The risk factors (rising longevity, falling fertility rates and the retirement of the baby boom generation) identified by European Commission (2006) express the need to realize policy adjustments in order to ensure long term sustainability of public finances. In this context, we consider important to investigate the debt sustainability and the sustainability gap in EMU member states taking into the consideration the Maastricht Treaty limit for public debt and the intertemporal budget constraint. We use these techniques because of the short series data which not allows us to run econometric tests.

As results of our researches we find: (i) evidences on sustainability using Maastricht Treaty criteria and intertemporal budget constraint in: EMU, 1990-1991; Finland, 1996-2005; Slovenia, 1994, 1996, 1998, 2005; Austria, 1990-1992; Netherlands, 2000-2002, 2004-2005; Luxembourg, 1991, 1993-2003; France, 1991-2001; Spain, 1991-1992, 2001-2005; Ireland, 1998-2005; Germany, 1996, 2001; Denmark, 1999-2005; (ii) positive influences of risk factors on public debt path in Belgium, Finland, Netherlands, Spain, Ireland, Denmark; (iii) major influence of risk factors on public debt in Slovenia, Luxembourg, Italy, France, Greece, Germany.

This paper is an analysis of how the companies in building and constructions use tax liabilities in order to finance their assets. We start from the assumption that tax liabilities are an important source of financing their assets and, thus, the introduction of the new mechanism of "reverse charge" in the field of value added tax generated difficulties in their financing, difficulties that forced the companies to change their capital structure. Then we investigate whether or not they constituted in an interest system that determined the change of the law back to its initial state

Keywords: taxation, interest systems, capital structure, corporate governance

1. Introduction

This paper is trying to add a page to the answer to a fundamental question in financial economics: "What are the determinants of the firm's capital structure?" Among these determinants the most frequently mentioned are taxes, the cost of financial distress, agency costs, and the firm's product and input market strategies[47]. The relation between capital structure and taxes has been the subject of extensive theoretical analysis[48]. These analysis specify particular relations among the optimal capital structure, corporate tax rates, nondebt tax shields, and personal tax rates.

The first element that was considered by the theory was the corporate tax rate. Thus, Modigliani and Miller (1963) stated that the corporate income tax makes debt more attractive than equity in financing a company due to the deductibility of the interests, which will generate a decrease in the cost of capital.

Then, it was considered the effect of nondebt tax shields on leverage. DeAngelo and Masulis (1980) suggest that there is substitution between debt and other deductions in shielding corporate income from taxes

The effect of personal tax rates is viewed through the taxation of debt income or equity income (Miller (1977)). If debt income is taxed more favorable that equity income, than individuals will have more incentives in investing in debt instruments than in equity instruments.

We will investigate the possibility that an increase in tax accruals, due to VAT legislation changes may have an impact on the capital structure.

2. A short review on the financing sources of a company

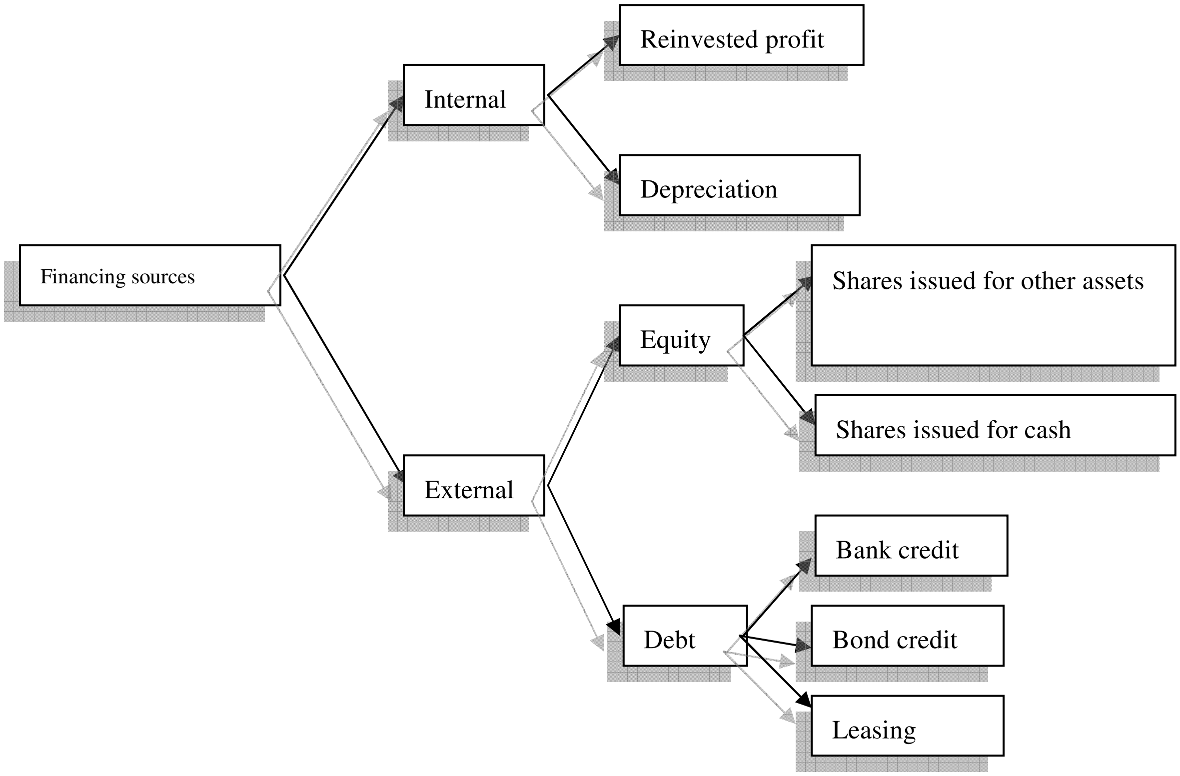

Fig. 1. The financing sources of a company

Source: Dragota V., Ciobanu A., Obreja L., Dragota M., (2003) "Management financiar", Editura Economica, Vol. 2, pag. 120

In order to analyze the capital structure of a company is necessary to identify the financing sources that a company may use in financing its asset. The theory identifies two main types of sources:

So, where do tax liabilities interfere? It is true that they can not be seen in this figure, as they are a part of the current liabilities of the company which are used to finance the current assets of the company.

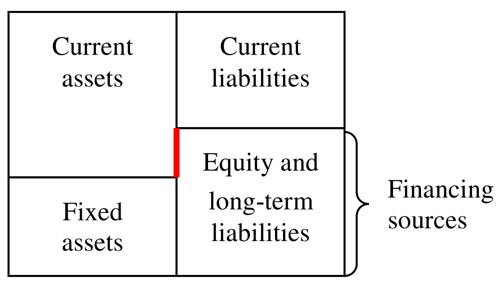

Fig. 2. The classical financial equilibrium of a company

In figure 2 it is shown how the financing sources are used in order to finance the fixed assets of a company and the net-working capital of a company.

3. The reverse charge system

The reverse charge system in the field of VAT was introduced in 2005 and means that the tax-payers that will apply it will no longer collect VAT at the sale of the product under this system but will have the right to deduct it. In order to apply this system both the seller and the buyer must be registered for VAT purposes. At the beginning of 2005 this was applicable to the sale of metal scraps, lands, buildings, wooden materials and live animals. After some changes in the list of goods for which this system shall apply in January 2007 the reverse-charge system was introduced for the selling of construction works[49]. This affected a large market that was estimated in 2006 to 10 bln. euros[50], and for which had a growth rate in 2006 of 23,5%[51].

So what happens when there is an increase in tax assets due to the increase of input value added tax (VAT) to be deducted, which does not turn into cash as there is no output VAT and the amount must be recovered from the state? So the question is what happens when a company is affected by a change in the taxation policy of the state by not collecting VAT anymore, but accumulating deductible VAT, as it happens in the case of the reverse charge system?

We illustrate this situation in the following two-stage example:

Company A is a company working in the building field. Before the introduction of the reverse charge system a typical transaction would have been:

- buy raw materials: 1.000 lei + VAT 190 lei
- sell building works: 2.000 lei + VAT 380 lei
- cash-in clients and pay suppliers

After paying the VAT liability, the company will remain with a profit of 1.000 lei turned into cash.

Cash 1.190 lei	Profit 1.000 lei
	VAT liability 190 lei

After the introduction of the reverse charge system, a typical transaction becomes.

- buy raw materials: 1.000 lei + VAT 190 lei
- sell building works: 2.000 lei + No VAT
- cash-in clients and pay suppliers

Cash 810 lei	Profit 1.000 lei
VAT accrual 190 lei	

After paying the VAT liability, the company will remain with a profit of 1.000 lei which is turned into cash only for 810 lei, and for the remaining 190 lei there is a tax accrual that should be cashed in from the state.

Normally, this tax accrual should not have a very important impact on the company's financing policy. It should require, at most, a short-term bank credit in order to finance the short-term cash gap until the VAT is recovered from the state.

In order to recover for this VAT a company must make an option on its VAT return. After making this option, according to the current tax laws[52] the taxpayer will be included in a risk category. There are three risk categories:

a) taxpayers with a low risk, for which the decision of VAT reimburse will be issued;
b) taxpayers with a medium risk, for which a documentary analysis is needed prior to VAT reimburse;
c) taxpayers with high risk, for which a tax inspection is needed prior to VAT reimburse.

In all cases the procedure should not exceed 45 days from the date of the VAT reimburse request. This is in theory, because if the Tax Administration needs any additional information, the period shall be prolonged with the time needed to provide the additional information[53].

Thus, in practice, the period in which a company may recover the input VAT may be more than 6 months. Taking into account that during this period new input VAT is accumulated we may conclude that this

---

[49] Law No. 571/2003 the Tax Code, published in the Official Journal No. 927/2003, with the subsequent changes

[51] Buletin statistic lunar, Nr. 2/2007, Institutul National de Statistica, pag. 59
[52] Law No. 571/2003 the Tax Code, published in the Official Journal No. 927/2003, with the subsequent changes, OMFP No. 967/2005 regarding the Methodology for solving the VAT returns with negative VAT sums with an option for return, published in the Official Journal No. 698/2005 with the subsequent changes, and OMEF No. 1857/2007 regarding the Methodology for solving the VAT returns with negative VAT sums with an option for return, published in the Official Journal No. 785/2007 with the subsequent changes
[53] According to the Tax Procedure Code, art. 70

system generates a level of the tax accrual that can be considered as a long term asset and not a short-term asset, for which the company must find financing resources.

4. The impact of the reverse charge system on the capital structure

For analyzing the impact of the reverse charge system on the capital structure we studied the case of a company working in the field of construction works.

Our company buys raw materials and sales construction works to other registered for VAT companies. Thus, in 2007 all its aquisitions will incur input VAT, but its sales will be made with the reverse charge system.

In the following table we present the situation of VAT in 2006 and then consider that in 2007 the value of VAT taxable aquisitions and supplies remains constant, in order to see the impact of VAT reverse charge system:

RON

	2006	**2007**
Aqusitions (VAT taxable)	13.158.000	13.158.000
Input VAT	2.500.020	2.500.020
Supplies (VAT taxable)	17.520.000	17.520.000
Output VAT	3.328.800	0
Tax liability	828.780	-
Tax accrual	-	2.500.020

Thus, in 2007, the company needs additional financing sources of 2.500.020 RON. Considering a short-term bank credit to finance this loan, at an interest rate of 15% p.a. this will generate additional interest expenses a a higher cost of capital. The cost of capital will increase with exactly 15% x (1-16%) x q, where q is the percent represented by the new short-term loan into total financing sources.

Of course that the company should analyze the posibility of not paying VAT to the supplier. In this case, if the penalty required by the supplier will be lower than the interest paid for the new loan, probably the company will have some incentives in not paying this VAT. Yet, this type of behaviour can generate serious commercial difficulties, so the company must thoroughly analyze wether or not to take this decision.

5. The interest system in the construction works field

An interest system may be defined as a „set of individuals or groups with common interests on the long term, which have the potential of generating pressure groups with methods specific to the goal persued and the force they have”[54]

We may say thet the antreprenours in the construction field may constitute an interest system which made pressures in order to change the reverse charge system. So this system was change with the begining of 2008. We fail to bring documented evidence on whether or not this interest system influenced tis decision. Taking into account the substantiation note of the Finance Ministry on the change of the reverse charge system for the construction works, the reason was „an unfavourable delay of receipts from VAT to the state budget", „the diffculties of the taxpayers to apply correctly this sytem” and „the increased number of requests for VAT reimburse”[55]

6. Conclusions

This paper tried to reveal the impact of a new system of tax rule in the field of VAT may influence the capital structure of a company. We gave evidence that this new system had an important impact and that this negative impact generated the change of the law back to its initial state. Thus, a sentiment of uncertainty in the tax field was created and we believe that the possible effects of such a system should have been more thoroughly analyzed before their implementation in order to avoid an uncertain situation.

ANALYSE OF THE LIQUIDITY TIDE (CASH-FLOW), A MODERN FINANCIAL CONCEPT

Căruntu Genu Alexandru

Universitatea Constantin Brâncuşi Tg-Jiu, Facultatea de Ştiinţe Economice, Str.Victoriei, Nr.24, Targu-Jiu, Gorj, Romania, cgenuc@gmail.com, 0740132713

For any manager, cash-flow must to represent a permanently science in order to adopt a financial strategy which can mentain the firm in dealings. If the balance sheet illustrates the company's wealth, the profit and loss inventory account illustrates it's the efficiency, the treasury flows demonstrate the modifications in financial situation of the firm.

Inside and outside enterprise's medium are formed a lot of tides, but the ones expressed in currency form detain an important role and place, due the fact that is related to capital formating, increasing, and paying. An economic society could be lucrative,could achieve profit, but could not be solvent, due the liquidity's lack, thanks to differences between incomes and payments made inside the frame of financial cycle.

firm's strategy, absorb of liquidity, cashing, payments

The liquidity tide's analysis (cash-flow) allows to firm's management and to affair partners(the banks, the investment persons) to check if the money-goods-money channnel of circulation are developing normaly, respectively if the firm has the money possibilities needed in order to support the payments, representing same time a real support/plinth in ordering the treasury forecasts(available currency).

By cash-flow analyse are gathering relevant informations regarding the cash inputs and outputs(payments) (inclusively their equivalents concentrated in treasury inventory accounts predicament/category).

In financial practice is useful that cash-flow method must be applied both to current situation analysis and to firm's strategy.The cash movements are grouping on three different activities:

- proceeding/operational activities (of exploiting);
- investment activities;
- financial activities;

In all these activity types, the liquidity analysis serves to:

- connection of profit (losses) with the cash;
- spliting of activities which imply cash versus the activities which don't imply cash;
- valuation of firm's capacity to fulfill the cash payment obligation;
- valuation of cash flows for future activities (strategical cash-flow).

In exploiting activities (A) is necessary that cash-flow method to illustrate the transaction effects/results which have measured the profit or losses and modify (addition or minus) of working balance.

In investment activities (B) by cash-flow analysis will illustrate the cashing or payments made for acquisition or sales of fixed assets, thus beeing the variation of fixed/capital assets.

In financial activity (C) are illustrated the modification of debts and own capital.

Exploiting treasury cash-flows (operational cash-flow)

The firm's legal competence to produce cash from exploiting activity illustrates the manner of firm's function. The exploiting cash-flow is considered a major indicator of real financial „health ” of the firm. The exploiting cash flow is focusing on finance and not on profit measurement and, in consequence is adequate for valuation and shot-term liquidity forecast. Are known two methods in order to measure the exploiting cash flow:

- the direct method;
- the indirect method.

The direct method assumes to record all gross cash inputs and outputs regarding the exploiting activity. In this way is offering the cash measurements for both sides (inputs and outputs) and is offering details regarding the cash movements, also is taking notices concerning the places(posts) to which is possible to supervene a cash need.

The direct method illustrates the net profit as well as it has been computed on cash bases. In this sense could mention the following computation pattern :

Exploiting activity cash – Payments for expenses cash = Cash income before tax – Cash payments for tax = Cash derived from exploiting activity;

It could be reach to cash income before tax through the following pattern (which could be considered an replacing element for direct method):

Sales – Increasing in receivables inventory accounts – (Sales goods cost + Costs increasing + Decreasing of suppliers inventory accounts balance – Paid Interests, Exploiting expenses (which from are decreasing the fixed assets amortisation and the debts etc = Cash income before tax .

The indirect methods starts from net profit and depreciation considered as flow resources and are making increasing and decreasing based on variations which intervene in positions from final balance sheets versus the initiate ones and influence the money availabilities(cash). Is the most used method in firm's practice, due the possibilities to apply it both in execution phase and in liquidity flow forecast, by estimating first the level of future incomes..

A major place is engaged by the analysis of working balance from asset elements point of view (stocks,receivables and other operational assets), also from the passive elements point of view (suppliers, advance payments from customers, and other current debts).

Increasing of stocks, receivables etc. illustrates an absorb of liquidity,whereas a decrease of these active elements conducts to a liberation of available money.

From evolution of pasive elements point of view –suppliers, advance payments to suppliers and other current debt-is obvious that an increase illustrates a resources atractiing which influence favourable the liquidities, whereas a decrease of these conduct to a liquidity decrease.

The liquidities exploiting flow pattern by indirect method is as follow: Net result of the period [profit (+) or loss (-)] + Depreciation and costs included provisions, suppliance miscellaneous, customers – Creditors and other current operational pasive (+/-) – Stocks evolution (+/-), claims and other effective operational assets (+/-) = Net liquidity from exploiting activity.

The investment activity assumes both the sums from sales and capitalize of fixed assets, and the expenses made for acquisition or own resources/funds execution of the assets.

In a syntetic manner, the investments influence on the treasury flows could be illustrate through the variation of fixed assets (comparison of situation from the period's end to situation from the period's start).

Regarding the finance activities is necessary to pay attention to:

- variations of loans and assimilated debts;
- variation of other debts;
- variation of registred capital.

By algebraic add of all three flows categories flows (A, B and C) we obtain the total treasury flow(cash flow), which will be the same as the difference between available (treasury) from the period's end and the treasury from the period's start illustrate in balance accounts.

In cash flow analysis based on these three types of activities, the results evaluation takes into account the following demands:

A>0 means that the cash-flow derived from exploiting activities must be positive with an important value , due the fact that illustrates the expeditious informations of the firm;

B>0 means that the cash-flow from investment activities is positive. Such a situation could illustrate the intention of reorganization the firm's activity, which makes available fixed assets or has major commercial credits, given by the fixed assets suppliers;

B<0 means that the cash flow from investment activity is negative and conduct to investment achievements with value compensate partially from fixed assets capitalization ;

C>0 situation when the cash flow derived from finance activities is positive and it's made from extra financed sources in order to complete those derived from exploiting activity;

C<0 situation when the cash-flow from finance activity is negative and means that were made payments concerning capital decrease, repayment of loans, payment of financial leasing obligations, interests payment etc.

The algebraic sum of those three flows categories is normal to be positive, illustrates the liquidity's result of exploiting activity , that means a normal evolution of economic channel of circulation (money-goods-production-money) and allows the current needs cover , the cover of long terms needs and a financial equilibrium.

The total calculate flow must to be identically with the cash and cash equivalents from period's end minus the one from the period's start.

Using cash-flow method in firm's management are conditions to achieve the various goals related to good admnistration, thus we could mention:

- illustrate firm's capacity to generate liqudity(treasury), which demonstrates the efficiency of firm's activity;
- follow the variables which influence the cashing and payments, also taking/adopting the adequate measures;
- settlement of compulsory drawing sizes which affect the treasury and settlement of tresury flows which remains to firm's disposal;
- using the available liquidity in order to investments proceedings, following firm's development policy(otherwise, the un-investment policy);
- attracting of foreign sources (loans or credits) in case that the available liquidity is not enough for development;
- analyse of potential risk in manner how the firm achieves and uses the liquidities (cash) taking into account the influence upon firm's rewardings.

The cash-flow method is used in firm's financial strategy elaboration. In strategy elaboration intervenes a serie of various features, first beeing the forecasts, so it is working with probably variables and no sure variables. Too, an errors serie which had been made in a previous period are not forecast(deviations from proper proccedings of money- goods-money cycle).

The liquidity flows table are framing in an ensemble of methods and forecast financial methods. Thus, we mention: incomes and expenses budget, prevision balance and designed progress of efficiency and administration indicators. The starting point in financial strategy elaboration is the sails figure/turnover, which is based on market studies.

As a conclusion, the cash-flow is a continous investment process of money in an affair, which has as goal to obtain a money surpluss, beeing a firm's financial estate, which illustrates both the money funds formation and it's using, estimating the financial gains which can be obtained by an enterprising/business man from an affair.

METHODS TO DETERMINE THE ENTERPRISE'S RESULT MEASURE/SIZE

Căruntu Genu Alexandru

Universitatea Constantin Brâncuşi Tg-Jiu, Facultatea de Ştiinţe Economice, Str.Victoriei, Nr.24, Targu-Jiu, Gorj, Romania, cgenuc@gmail.com, 0740132713

The enterprise's performances measurement is related first by profit measure. From practice activity point of view, the most important calculation pattern is the accounting/book-keeping pattern, due the fact that it has an official compulsory character.On these bases, profit has become known under the name of benefit and it is determined as difference between the incomes and expenses produced by commercial activity of one economic agent.

self-finance, cost, efficiency, amortization

The profit made from difference between total income minus production cost (total, option or opportuneness) is named economic profit and it is, as a rule, lower then legal obtained profit.

There is many methods to determine the enterprise's result size,such as:

a) Patrimonial method: by comparison the value of one enterprise, made at two different moments in time, using the same valuation methods.
b) Economical method: by substract the total expenses from total incomes, related to same period.
c) Financial method : by substract the depreciation from treasury net flows (this last measurement method is derived from the economic method).

From patrimonial point of view, enterprise method measurement proceed from the legal equation of balance sheet:

$$\text{ASSETS - LIABILITIE S} = \text{EQUITY}$$

Afterwards, by comparison of own resources of two successive periods, are determined the result :

EQUITY	-	EQUITY	=	RESULT
AFFERENT TO EXERCISE		AFFERENT TO EXERCISE		EXERCISE
N		N-1		N

Due the fact that this equation don't takes into account the possible changes of registered capital (basic element of equity) intervened during the exercise/period (capital increasing by cash contribution and by nature items contributions or due to debts exchange, decreasing of registered capital) also the fact that a part from profit could be distributed to associates as dividends, the equation which allows to determine the period' s result is :

$$\mathrm{Re} = Vcp - Ccs + Dd \qquad (1)$$

which:

Re = period's result;

Vcp = evolution of owner's equity between 2 successive periods (N şi N-1);

Ccs = Increasing of registered capital afferent to exercise/period N;

Dd = Distribute of dividends and, eventually, decreasing of registred capital afferent to exercise/period N.

Determined the result through the patrimonial method is criticazable in period of prices increasing, due the fact that adjustments brought to patrimonial elements, as a consequence of prices variation could be achieved by different methods, fact that conducts to supply of many measures/sizes for the result.

The economic method recognizes the period's result as difference between total incomes and total expenses :

TOTAL INCOME – TOTAL EXPENSES = EXERCISE/PERIOD RESULT

The result could be a positive measure, named profit or benefit, when the incomes are higher then the expenses, or a negative value, named losses, in oposite situation.

From financial point of view the exercise result appears as varition of enterprise treasury during a period by comparison of incomes flows and payment flows.

Due the fact that enterprise self-financed is ensured by exercise result (profit) and increase of amortization and provisions calculated expenses, un-generate payments, the equation which illustrates the result's size in this approach is :

$$\mathrm{Re}\,p = Ca - Cha$$

where:

$\mathrm{Rep} =$ Exercise/Period result;

$\mathrm{Ca} =$ Self Finance Capacity ;

$\mathrm{Cha} =$ Depreciation Expenses, provisions.

Theory and financial practice from our country take in account many methods to profit forecast, the most used beeing:

1. Syntetic method, which starts from taking into account of many syntetic indicators, with levels designed for future period, following the underneath methods :

a) Exploiting expenses measurement, as beeing the value of production for sales which from are deducted the value added tax, multiply by maximum level of expenses made to 1000 ron production, thus:

$$\mathrm{Ce} = (\mathrm{Qpv} - \mathrm{TVA})\,\mathrm{x}\,\frac{\sum \mathrm{Ce}}{Q}\,\mathrm{x}\,1000 \qquad (2)$$

which:

Ce =total exploiting expenses ;

$\mathrm{Qpv} =$ volume of production for sale, illustrated in sale prices:

$\frac{\sum Ce}{Q} \cdot 1000$ = maximum expenses made to 1000 ron production;

b) Profit establishment from sail of manufactured production, as difference relationship between gross sales which from has deducted the value added tax and exploiting activity :

$$\mathrm{Pi} = (\mathrm{Qpv}\quad \mathrm{TVA}) - \mathrm{Ce} \qquad (3)$$

which from:

$\mathrm{Pi} =$ the initiate profit from current exploiting activity;

c) Determine the stocks influence and the influence of invoices issued and unpaid from start and end of year over profit volume :

$$\mathrm{DP} = \mathrm{Pi} + \mathrm{Pf} \qquad (4)$$

Which from:

DP – difference ± of profit;

Pi – profit to year's beginig;

Pf – profit to year's end;

d) The volume of obtained gross profit :

$$\mathrm{PB} = \mathrm{Pi} \pm \mathrm{DP}$$

2. The direct method could be applied to enterprises with small number of products, due the fact that is necessary a large volume of calculus.In fact, is determined the profit on each product, and the profit/benefit calculation on every product are achieved by proceeding the following phases:

a) product profit, as difference between the value od production for sale less TVSA and exploiting expenses necessary to product's manufacture:

$$PQ = (Qpv - TVA) - qce \qquad (5)$$

Which from:

PQ – product profit;

Qpv – product value in selling price;

TVA – value added tax ;

qce – the exploiting expenses afferent to manufactured product dedicated to sell

b) The profit afferent to stocks and factors measured from the year's start and year's end for the respective product:

$$Dpq = pqi \pm pqf \qquad (6)$$

Which from:

Dpq –profit difference;

pqi – profit to year's start;

pqf – profit to year's end;

c) The total profit, obtaining as sum relation of profit for manufactured products and profit difference related to stock and unpaid invoices:

$$PB = PQ \pm Dpd \qquad (7)$$

În extended form, the profit calculate by direct method presents the following relation:

$$PQ = [(Q_{pv} - TVA) + (S_{iqpv} - S_{fqpv})] - [(Q_{ce} + S_{iqce}) - S_{fqce}] \qquad (8)$$

Which from:

Qpv – product express in sell price;

TVA – value added tax;

S_{iqpv} si S_{fqpv} – stock value to begin (i) and end period (f) of product, express in sell price without TVA;

Qce – product value express in exploiting cost;

S_{iqce} si S_{fqce} – stock from product express in exploiting cost, to period begin (i), respectively to period end (f).

3. The method reference to bases period is proceeding in enterprises with a large assortment of products, to which the direct method becomes useles/ inoperative through the large number of analytic calculations which imposed.

The succession of working phases in the frame of this method is as follow :

a) Establish of efficiency rate afferent to the previous year, as division between the total profit sum and the sum of exploiting costs for the goods selled:

$$\frac{\sum P_0}{\sum Ce_0} \cdot 100 \qquad (9)$$

consisting of :

$\sum P_0$ – the profit volume from the base period ;

$\sum Ceo$ – the sum of exploiting expenses from base period .

b) Determined of profit afferent to production of goods prognosed to be sell or cash in future year, accordingly to the efficiency rate from the previous year:

$$P_1 = \frac{Q_{pv1} \cdot R_{r0}}{100} \qquad (10)$$

Which from:

Q_{pv1} – value of goods production dedicated to sell in forecast period, expressed to sell price;

R_{r0} – the efficiency rate from the base period.

c) The measurement of increasing (decreasing) profit as effect of decreasing (increasing) of exploiting cost :

$$P_2 = Q_{pv1} \text{ x } I_{cel/0} \qquad (11)$$

which from:

$I_{ce1/0} = \dfrac{Q_{ce1} - Q_{ceo}}{Q_{ceo}} \cdot 100$ -value production index, express in exploiting cost

Q_{ceo}– production value, express in exploiting cost from base period ;

Q_{ce1}– production value, express in exploiting cost afferent to the presented period.

d) Modification of profit mass due to change of production assortment, calculated as deviation of prognosis efficiency rate versus the one from the base year, accordingly to product structure share in total goods production:

$$R_0 = \frac{(a_0 \cdot x) + (b_0 \cdot y) + (c_o \cdot z)}{100} \qquad (12)$$

Consisting of :

a, b, c – share of products (assortments)

$$R_{ri} = \frac{(a_i \cdot x) + (b_i \cdot y) + (c_i \cdot z)}{100} \qquad (13)$$

Which from:

x, y, z – the efficiency rate from the previous year to the assortments taken into account

from year:

$$DP_3 = \frac{Q_{ice0} \cdot (\pm DRr)}{100} \qquad (14)$$

Which from :

Q_{ice0} = the forecast goods production value express in exploting cost from the base year ;

$\pm$ DRr $=$ difference between the average rate of efficiency rate from the base year and the rate afferent to programmed structure of production from the next year.

e) Establishment of profit afferent to products which have not made in previous year (no comparable production) which are proceed accordingly to direct method:

$$P_4 = (Q_{ipv} - Q_{ice}) - (Sf_{pv} - Sf_{ce}) \qquad (15)$$

Consisting of :

$Q_{ipv} =$ the value of goods production express in sell prices;

$Q_{ice} =$ the value of goods production express in exploiting costs from the designed year;

$Sf =$ haunch of factors and stocks from year's end express in sell price, respectively the exploiting costs.

f) Establishment of total gross profit from current activity by adding the following elements:

$Pt = P_1 + P_2 + P_3 + P_4$, respectively: $Pt = P_{Rr0} \pm D_{Pce} \pm D_{PSp} + P_{pn} \pm D_{Ps}$ (16)

$P_{Rr0} =$ profit afferent to forecast goods production, calculated accordingly to efficiency rate from the base year ;

$\pm D_{Pce} =$ profit result from decreasing (increasing) of exploiting cost;

$\pm D_{PSp} =$ profit result from modification of assortment structure of production in conditions of mainteining the efficiency rate from the base period;

$P_{pn} =$ profit which will be obtained from manufacture, sell and cash of no comparison production;

$\pm D_{Ps} =$ profit which will be obtained from stocks and uncash invoices revaluate.

4. Other methods to forecast the profit mass : a) the method of direct costs and b) method of linear programme/schedule

a) Method of direct costs takes into account to determine the variable expenses on each product unit, and the constant expenses are taken under the form of a global sums, independently by production volume and marketing variation, that's mean in a simple relation : Pb = (P – Cv) x D, consisting of Pb = gross profit ; P = production price ; Cv = the various costs on product unit; D = sellings volume from the period considered.

b) Method of linear programme/schedule, the mathematical method, processes the economic-financial evidences included in a simple tabel related to costs, the maximum use of production capacities, the specific consumption, the assortments, the production quantities which could be manufacture and other elements.

"THE CLUSTER", THE WAY OF INCRESING THE COMPETITIVITY AND FINANCIAL CAPACITY OF THE ROMANIAN COMPANIES

Chirilă Emil

Universitatea din Oradea, Facultatea de Ştiințe Economice, 0259/408401

The certification for the professional qualification of the construction companies represents an official recognition of their competency based on a scientific criteria and assurance of their specialization in different fields of activities.

Creating a certification system would put at the disposal of the investors an official list of the companies for which is operating the presumption of being capable for realizing good quality works. The presentation of a certification is being compulsory in order to participate in biddings for public works.

Adoption of an adequate legal framework in the field of professional certification combined with formation of clusters will allow enhancing of the technical and financial competitiveness of the Romanian companies.

Key words – clusters- free association of juridical and financial independent companies, which through conventions are establishing the conditions for participating in common at the actions of adjudicating public works

The certification for the professional qualification of the construction companies represents an official recognition of their competency by the bodies recognized by the legal authority from the construction sector.

This certification is realized based on scientific criteria that classify the companies on fields, types of constructions, technical classes and competitiveness in design, execution, general consultancy, technical assistance, specialized services in construction, including technological services with specialized equipments etc.

The certification of all the categories of participants at the construction process ensures the presumption that the investments, the constructions, shall be realized according to the provisions of the Law 10/1995 regarding the quality in constructions.

There are 14 states in Europe that apply their own certification system of the companies: England, Belgium, Switzerland, France, Finland, Greece, Germany, Italy, Norway, Holland, Portugal, Poland, Spain and Sweden. In 5 of the 14 states, the presentation of a certification is compulsory in order to participate at biddings for public works: Belgium, Greece, Italy, Portugal and Spain.

All the states that have introduced a certification system for the professional qualification of the construction companies run these activities through certification bodies of private law, recognized by the coordinating authority in the sector of constructions from the respective country since they ensure the observance of the European norms regarding the independence, the impartiality, the non representation of individual or group interests, the implementation of non discriminating procedures, the transparency as well as the possibility of the applicants to access its services without imposing conditions about the size of the company or its affiliation to a certain group.

The process of certification for the professional qualification of the construction companies is controlled by the EU states, under the supervision of the central authority that coordinates the sector of constructions or at the level of the ministries of economy and finances, according to the European procedures, standards and norms regarding the criteria that must be fulfilled by the certification bodies as well as the imposed exigencies regarding the certification activities.

The certification system for the professional qualification of the construction companies ends with a correct scientific evaluation, with the publication and /or placing the official lists with the certified companies at the disposal of the investors/beneficiaries, with the compulsory presentation of a qualification certificate at biddings for public works (in Belgium, Greece, Italy, Portugal and Spain) and, in the near future, with obtaining mutual recognition of the certification papers among states.

In Romania, the first steps for implementing a certification system for the professional qualification of the construction companies started in 1992, when the first aspects regarding this action were presented to the MDPWH.

In 2003 the SR 13476-1 “General demands for the certification bodies” and the SR 13476-2 “Certification criteria”, the Romanian standards for certification for the professional qualification of the construction companies were elaborated and approved.

The last variants from the European standards EN 45000, EN 17000, ISO 9001 were adopted in the interval 2001-2006. The Emergency Ordinance regarding the assignment of contracts of public acquisitions, ensuring the alignment to the 2004/18/CEE Directive regarding the coordination of the actions of assigning the contracts of public works and services was also promoted.

In 2006 the Ownership of the Romanian Contractors promoted the law project regarding the certification for the professional qualification of the construction companies that is presently debated by the institutions that are involved or that coordinate the activities at national level in order to set up some points of view that can promote a legal act that meets the demands imposed to ensure the protection of human life and national wealth.

The main criteria established by the Romanian normative acts that correspond to the European ones are the following:

- Juridical and administrative criteria that establish the compulsory criteria regarding: registration at the Trade Register Office, providing documents regarding the professional morality, payment of taxes/duties, non affiliation to criminal organizations, corruption deeds, fraud, money laundry etc.;
- Economic and financial criteria that establish the proofs regarding the financial situation (excerpt of the last balance), declarations regarding the turnover, financial reports or any documentation that can probe the economic and financial capacity;
- Technical criteria regarding the evaluation of the technical capacity based on the information and on the performed evaluations that refer to satisfying the conditions of the ISO 9000 standards, to the experience in the sector that is to be certificated, to the qualification and competence of the personnel, to the technical endowment, to the endowment with measuring devices, to the implementation of a system of quality management, to the experience (performed works, execution certificates), to the information on the technical staff, equipments, installations and on the applied quality management.

Depending on the supplied and verified information, the certification body releases a certificate that permits the classification of the company on: sector of activity, types of performance, technical capacity, size of contract.

The classification of the construction companies presents several favourable implications, such as:

- providing eligibility conditions for the public biddings;
- reducing the volume of documents requested for biddings;
- allowing the association of several companies certified for the same sector or for adjacent sectors as well as for ensuring the norms regarding the size of the contracts (by sum of competences);
- allowing the competitive micro-enterprises and the SMEs to obtain a qualification that entitles them, by direct participation or in collaboration with other companies, to take over works according to their performances;
- eliminating the subjectivity of the bidding commissions in evaluating the performances and in assigning the work contracts;
- publication of the official list of the certified companies, thus facilitating the options of the investors or natural/juridical persons, who intend to build, by choosing a competitive company;
- allowing the certified companies to take over works in other countries by presenting a certificate that represents a guarantee and a competence acknowledgement.

Adopting a proper legislation in the field of professional certification of the construction companies, combined with the formation of clusters, shall ensure the construction companies a better participation in the competition for accessing structural funds.

The clusters represent free associations among legally and financially independent enterprises that, due to the acknowledged conventions, establish the conditions of common participation to the actions of assigning public works or from other funds. So, by summing up the held conditions regarding the equipment, personnel, experience, financial capacity, size of the past contracts, clusters can be assigned to perform works that single enterprises could not accede.

Clusters can be formed in all the economic sectors, at national or regional level. Called "poles of competitivity" in France and sustained by the European Commission, clusters play a key role in the European cohesion policy and in the absorbance of the structural funds.

In 2007, at EUROPA INNOVA, the European Cluster Observatory was set up. Its role is to collect all the statistic data, to set up indicators of quantifying the dynamism of the European clusters and to evaluate the impact of the national and regional cluster policy.

Within the cohesion policy, clusters represent one of the planning pillars for 2007-2013, promoting innovation as the main component of investments and sustainable development.

The cluster represents a territorial agglomeration of specialized and highly competitive companies. It represents a concentration or a special, territorial agglomeration of the SMEs specialized within the same or adjacent sectors that can become a leader on the market (even global market) of that specialized sector.

It can be located in any type of territorial community, from small ones (towns, communes, groups of communes) to state regions, state or cross-border regions.

The experience of the developed countries has shown that clustering processes serve as fundament for a constructive dialogue between the representatives of the entrepreneurial sector and the state, educational environments. The cluster has lead to an efficient growth of the mutual relationships within the innovation processes from the private and state sector, commercial associations, educational and research institutions.

Peculiarities of a cluster:

1. it is a form of regional economic activity limitted from the interior of the adjacent sectors, linked by certain scientific institutions (universities, research and innovation centres etc.);
2. it represents vertical production links (value chain); narrow specialized sectors where the common production stages constitute the core of the cluster (the chain "supplier – producer – dealer – customer");
3. there are industrial branches formed at a high level of aggregation (e.g. "the chemical cluster", "the agro industrial cluster").

Specific features:

- identical or adjacent sectors of activity;
- sectors may differ, the economic activity becomes dominant and highly performant;
- even if there is a competition between the companies and they are specialized on types, there appears a parallel phenomenon of cooperation, association in sectors, thus ensuring a plus of competitivity to all of them;
- rapid phenomena of innovation and of common innovation infrastructure appear among companies, where universities and technological centres play an essential role;
- association capacity of the companies and relations based on trust maintained by a proper supporting cultural environment that reduce the transaction costs and increase the competitive advantages;
- the cooperation sectors can be prepared professionally, management and marketing techniques, research and development and everything connected to enhancing the innovative capacity.

Functional strategies in choosing and elaborating a cluster:

1. spatial initiation of the economic activities clustered at local level (e.g. fruit growing in Holland);

2. horizontal: certain branches/sectors can enter larger clusters (e.g. the mega cluster from the Dutch economy);
3. vertical: within a cluster there can exist stages of common production process;
4. lateral: within the cluster various sectors can merge in order to ensure a global impact on the economy;
5. technological: the compatibility of the branches that use the same technology (e.g. the biotechnological cluster);
6. focus: cluster of companies that are concentrated around an enterprise-centre, a technological centre or around a teaching establishment.

General strategies within the cluster:

1. strategies oriented towards the increase of the level and applicability of the knowledge in the existent clusters;
2. strategies oriented towards setting up/ starting new cooperation systems within the cluster.

Figure 1 presents the functioning model of the clusters of construction units.

Abstract: The bankruptcy represents an absolutely normal market phenomenon, in our country it didn't reached yet to be part of "game's rule"; any investor wishes to know not only the manner of entering within a business, but also of going out of it, the business being carried out with a society which is at bankruptcy. The number of bankruptcy is an essential indicator on evaluating the functionality level of an economy. "The economists show that it is normally within a market economy with percent of 2-6% for all companies to suffer bankruptcy within a year".

keywords: financial decision, judicial reorganization, the insolvency, the bankruptcy, the creditors

1. Generaly terms

Within a company's economic life, certain recessive and of failure moments can appear, which lead to putting under financial supervision, reorganization/restructuring and finally to liquidation. The failure can be interpreted in more ways, depending of problems involved or not by the collapse and dissolving that company, associated with a loss in total investment of creditors. In this way, clarifying the following terms becomes necessary56:

- the economic failure signifies the fact that a company's incomes do not cover the total costs, including the capital's cost;
- the company's failure refers to any company which stop its activity, having as result a loss for creditors;
- technical insolvency. A company will be considered technically insolvable if it cannot respect the current observations on their becoming payable. A company being in this situation is considered in technical stopping of paying the obligations. The technical insolvability denotes the lack of financial difficulties to customers;
- the insolvency in bankruptcy appears when within an enterprise, the total of duties exceeds the real value of assets. This situation is much more severe than the technical insolvency, because it generated the company's liquidation.

Within the Romanian regulations for the judicial reorganization and bankruptcy procedure, distinction is made between the insolvency and insolvability. The insolvency (inability of payment) comes when the debtor do not have necessary liquidities for paying his real, liquid and due debts. The insolvency or debtor's stopping of payment has to be delimitated of so that called "financial constraint", which consists on just being lack of necessary liquidities for duties acquit. It is possible that, in short time, the debtor to cash the debts from his own debtors and to financially redress.

The insolvency doesn't mean insolvability, for as long as the debtors maintains in his patrimony goods which can be enforced executed, in the view of paying the duties towards the creditors. The insolvability consists on debtor's impossibility of respecting his obligations towards the creditors, both from liquidities' lack and other goods among which the creditors' debts have to be satisfied. Practically, the passive (duties) is bigger that the active (rights) of patrimony. In this way, the insolvability state regulated by the Romanian legislation is the same as the bankruptcy insolvability, while the insolvency is the same with technical insolvability, previously approached.

---

[56] Halpern, P. ş.a. ***- Finanţe manageriale,*** Editura Economică, Bucureşti, 1998, p. 882.

The economic failure of a company is caused by more factors, among which the following can be presented:

- incompetence and managing failure (60%);
- the unfavorable evolution of the market (about 20%);
- the natural phenomenon, fire, calamities, Earth quakes (10%);
- other causes (10%).

It can be observed that the main cause has in view the failures of managing processes and of knowing the market. Therefore, the managers have to identify in time the signals of deteriorating the financial situation of enterprise, such as:

- achieving the negative net financial results;
- existence of a negative working capital;
- the impossibility of reimbursement the credits to their normal date of payment;
- the bankruptcy of some providers or main customers for the enterprise;
- the reduced impossibility or non-availability of a manager;
- persistence of strikes.

2. The legal frame

The legal frame as concerns the commercial companies functioning, as well as the Law of enterprises' insolvability foresee the impossibility of declaring the bankruptcy state for the company, which is carried out, firstly by supervising activities, of reorganizing and restructuring-readjustment.

The bankruptcy is a judicial procedure in the view of reorganizing or liquidation of a company, when reorganizing or liquidation is organized by special courts. The bankruptcy can be of two types:

voluntary, when the bankrupted company presents to judicial instance a request and no order of supervising exists, and the manager of real patrimony/syndics is directly named;

involuntary, when the company's creditors presents to judicial instance a request and prove that the debtor do not respect the duties on date of payment. In this case, the instance institutes the order of supervision over the debtor and names the patrimony managers.

The creditors can anticipate the incapacity of debtor for respecting the obligations to date of payments, upon the basis of bankruptcy deeds, which this committed, being the following:

- the false pretences transfer represents a transfer of properties towards a third party, on inadequate conditions, with intention of prejudicing the creditors;
- the preferential transfer represents the money or assets transfer by a insolvable debtor towards a creditor, giving to creditor a bigger part of duties unto other creditors will receive to liquidation. The preferential transfer is also called "false pretences preference";
- hiding or removal. Hiding refers to hiding certain properties on intention of prejudicing the creditors; removing the properties also has in view the creditors' prejudicing;
- assignation. If a debtor makes a general assignation on creditors' benefit, there will be an act of bankruptcy. This will allow to creditors that do not trust within the assignation process to transform this transaction into an involuntary bankruptcy;
- sudden leaving. If the debtor disappears in the view of cheating or delaying towards the creditors, then a request of bankruptcy can be submitted;
- admittance to a creditors' meeting. The debtor will commit a bankruptcy act if at a meeting of creditors, he presents a declaration of assets and duties which show that he is insolvable or admits in write that is unable of paying the duties;
- communication towards the creditors. If the debtor communicates to any creditor that he suspended or will suspend the duties' payment, a bankruptcy act will take place;
- order of officer of the court. If the debtor do not redeem the goods that were sequestered by an execution order issued against him, there will be a bankruptcy act;

- the technical insolvability is the most commonly act of bankruptcy and takes place when the debtor is unable of respecting, in generally, the conditions of indebted contracts to date of payment.

At this moment, the creditors will have to take the decision of they dissolve the company by the liquidation procedure or will maintain it alive by reorganization. This decision depends upon determining the company's value in conditions of its rehabilitation towards its assets values, if these are separately sold. As a result, the creditors choosing will depend upon their financial pain severity, by the existing financial structure's complexity and of company's dimension.

The creditors will have three available options:

- the creditors, by negotiations with the company, either length the time duration for paying the interest and/or the load, either will reduce the interest rate to overdue duties. Both procedures will decrease the financial heaviness over the company and allow it to continue the exploiting; moreover, the creditors contract minimal costs of transaction and payment of lawyers. This option is chosen when the financial sufferance is temporary, the company having a good economic situation, and the managerial team will present trust towards the creditors. This option is used for the companies with simple structures of capital, which have a reduced number of creditors and which has as result voluntary reorganization of duties payment;
- establishing the supervising regime. This is a procedure more expensive towards the first option and is practiced in cases of more severe financial sufferance. In this way, after setting the syndic, the creditors have to decide if the company "values more dead than alive". If the value of market for the company which would continue the activity is less than the value of liquidation, the company has to be liquidated and encashment distributed in accordance to a n algorithm previously established. Contrarily, if the value estimated of the market maintained alive is greater than the value of liquidation, an economical restructuring plan has to be applied. It is also had in view the reorganization of financial arrangements, for reducing the company's duties, event if each class of creditors can loose a part of the initial investments. In many cases, the conditions of a successful commitment involves the replace of existing managing, liquidation of certain assets and emission towards the creditors of new immovable values, of whom efficiencies to be dependant of company's success.
- using the legal remedy offered by the bankruptcy law, by which the company is declared to be broke and liquidated, finally by applying the rules specified within this law.

If the creditors choose this option, it will be possible for the company's owners to make a last effort of saving the company. In this way, they can present to creditors a reorganization proposal. If they reach to conclusion that the company values more dead than alive, the proposal will be rejected and the company liquidated. That respective option is used especially to small companies.

As concerns the big companies, the owners have a certain influence within this process. Having at disposal financial resources, they can make appeal to accountancy and juridical consultancy; they can ask to judicial court a certain protection in the view of elaborating a new plan of reorganization, for presenting it both to creditors and justice. Concretely, the owners of great companies appeal to all kind of measures for stopping any activity of the creditors, which cannot enterprise anything in this duration. If the proposal is rejected, the company will be broke and liquidation will be carried out.

For establishing a financial decision in case of bankruptcy, the financial service proceeds on determining the most of financial information. At the beginning, by the legislation research as concerns the companies, the bankruptcy law and other judicial provisions, the methodological information is established. Upon their basis, the information as regards the financial expenses and financial incomes are determined. The information as concerns the financial expenses refers to expenditure made in the view of process managing of bankruptcy and to eventual organizations and restructuring, being thus determined by the procedure of quotation. The payment obligations refer to amounts payment towards creditors and their proportion, the payment of wages for the staff and to the level foreseen by the law of bankruptcy, the payment of taxes remained towards the central and local budget.

The information as concerns the financial incomes are determine by the market value of the asset sold by public auction by the bankruptcy process managing. The financial decision as concerns the bankruptcy makes part of the documentation that attaches the company's bankruptcy, being the last financial distribution in the name of economic agent in discussion.

Using the changing strategies represents a practice often met, both in countries with economy on functional market and those being in transition. Adopting these strategies is imposed both in crisis situations and also in those being favorable, when the enterprise is adapted to exigencies of business environment, but also wishing to consolidate the position, thus essentially changing the financing manner. Mostly, the changing strategies are regarded as avoiding solutions for affecting the financial situation and implicitly, of bankruptcy.

With all these advantages, within the mechanism of changing, both elements which determine the changing act, as well as elements that stop it. From the first category, the following take part: changing the conditions of work, changing the structure of work force; these elements offer tensions for changing. At their turn, the elements that stop the changing and form the resistance to changing is: the old mentalities, the fear of new, the fear of failure, the reduced level of professionalism and the mental blocking.

Mainly, an enterprise being in difficulty can apply the following strategies11 of changing, with great impact over the payment capacity of it and of its evolution on market:

- strategies of changing in conditions of temporary inadaptability;
- strategies of transforming and reorientation;
- strategies of recovering or of making efficient.

The first type of strategies is adopted by those enterprises being temporarily in an unfavorable situation thanks to certain unfavorable conjuncture phenomenon, but which can be surpass in the future, by adopting some objectives and concrete measures of activity. Adopting such a strategy is based upon issuing an adequate diagnosis, which is able to support certain vanguardist manifestations, of launching in business that can reward the courage by adopting certain decisions in risk and uncertainty conditions thus assuring the economic recovery.

At their turn, the strategies of transforming and reorientation can be adopted by those enterprises which achieve in present the adequate economic performances and are well adapted to existing economic context. But, upon basis of diagnosis strategically done, the enterprise observes that it should activate in the future to an environment totally different from that existing in present, under all views, reason for which it will perform to transformations to business organizing forms, of the property's structure, of the technical potential, strategies of supplying and sale, etc.

Finally, the recovering or making efficient strategies can be adopted when the enterprise achieves weak or unfavorable results, thus recording loss or it is not well adapted to the existing economic context, being absolutely necessary for the enterprises being on bankruptcy start; it needs a high spirit of responsibility form the managers, the future of enterprise having to be taken into consideration. Within the process, two strategic directions which have to be thought are aimed, meaning:

the strategy of business activity, where what, how and how much is supervised;

financial strategy, where how much is cached and what is the profit is taken into consideration. Therefore, the financial restructure is observed in Table:

Strategy of changing by business restructuring	Strategy of changing by financial restructuring
Organizational and dimensional restructuring	Liquidities management
Issuing of sector's and territorial strategies on short and mean term	Reducing of duties
Segmenting of business	Adequate using of economic – financial lever

Table : Strategy of enterprise restructuring

Successfully applying of changing strategies needs the following steps respecting:

- understanding the need of adopting the strategy and changing the mentality frame of enterprise. The mental frame represents a particular form of thinking which characterizes individuals that lived and worked in the same environment for long time, thus representing the result of a culture and specific structure. He has to become receptive to changing and to impose the steps necessary to changing;
- defining the objective of changing strategy, depending the nature and structure wished to enterprise's level;
- choosing the type of strategy, which is adapted the best to enterprise's problems;
- execution of strategy and evaluating the achieved results.

THE EVOLUTION OF INSURANCE MARKET IN 2006

Clipici Emilia

University of Pitesti, The Faculty of Economics Sciences, Adress: Pitesti, str. Fratii Catina, bl. C3, sc. E, ap. 6, cod 110324, Arges, Romania, Email: emiliaclipici77@yahoo.com, Tel. 0740254576

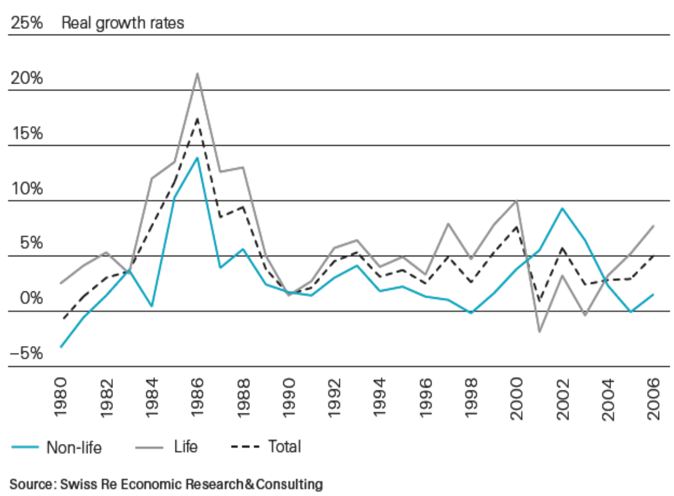
Abstract: Insurance and reinsurance act is a catalyst for economic growth. A dynamic insurance sector is at the heart of a strong economy. Which explains why the regulatory gaze is increasingly focused on our industry. Worldwide insurance premiums amounted to USD 3 723bn in 2006. This was split into USD 2 209bn in life and USD 1 514bn in non-life insurance. Total premium volume grew by 5%, in real terms,1 with life premiums increasing by 7.7% and non-life premiums by 1.5%. Profitability improved in both life and non-life insurance in 2006 compared to 2005. The macroeconomic environment during 2006 was characterised by solid economic growth and, in most geographical areas, moderate inflation, rising but still low interest rates and booming stock markets.

Key words: insurance, life insurance, Non-life insurance

The insurance manifests itself as one of the economy and business areas and is used as a possibility of compensating the damages incurred in case of occurrence of the insured case for all the production stages, thus providing for the growers' economic freedom and reducing their dependence on the influence of negative factors. The insurance is a factor of reducing the economic uncertainty and a means of resuming production after a temporary interruption or in the case of goods loss. The analysis of the insurance market highlighted the necessity of applying measures of improving the insurers' activity. Currently, one of the most efficient means of perfecting the insurance activity is the implementation of the marketing methods into the insurer's practice. Such concrete measures can be: the improvement of the company's image, the improvement of the service quality, granting additional services to the insurance holders, (including the insurance agreements into the general insurance policies, depending on the commercial operations), stimulating the conclusion of insurance contracts (including advertisements), adapting the insurance products to the market requirements.

In the developed countries the insurance has an important place in the national economy. The income of the insurance organizations coming from their activity contributes to the gross national product increase. Mention must be mad of the fact that in the developed countries of the Western Europe, USA and Japan the insurance rate in the volume of the GDP is 12-15%.

In 2006, total world premium volume grew by 5% in real terms, up from 2.9% a year before. Both life and non-life markets grew in real terms, although at 7.7% and 1.5%, respectively, the pace of development was somewhat divergent. Figure 1 shows the performance of the markets over the longer term.



Real growth rates

In 2006, global premium income amounted to USD 3 723 billion. Life business made up 59% (or USD 2 209bn), up slightly from its 58% share in 2005. The upgrade of Hong Kong, Singapore, Taiwan and South Korea added 5 points to the industrialised countries' share of business, bringing it up to 92%. Growth both in Western, Central and Eastern European life insurance helped Europe gain 1% of market share, while America and Asia lost 0.5% and 0.7%, respectively, on the back of comparatively lower growth in the US life sector and slipping premiums in Japan. However, the South and East Asia region alone gained 0.5%, and Latin America and the Caribbean 0.2%.

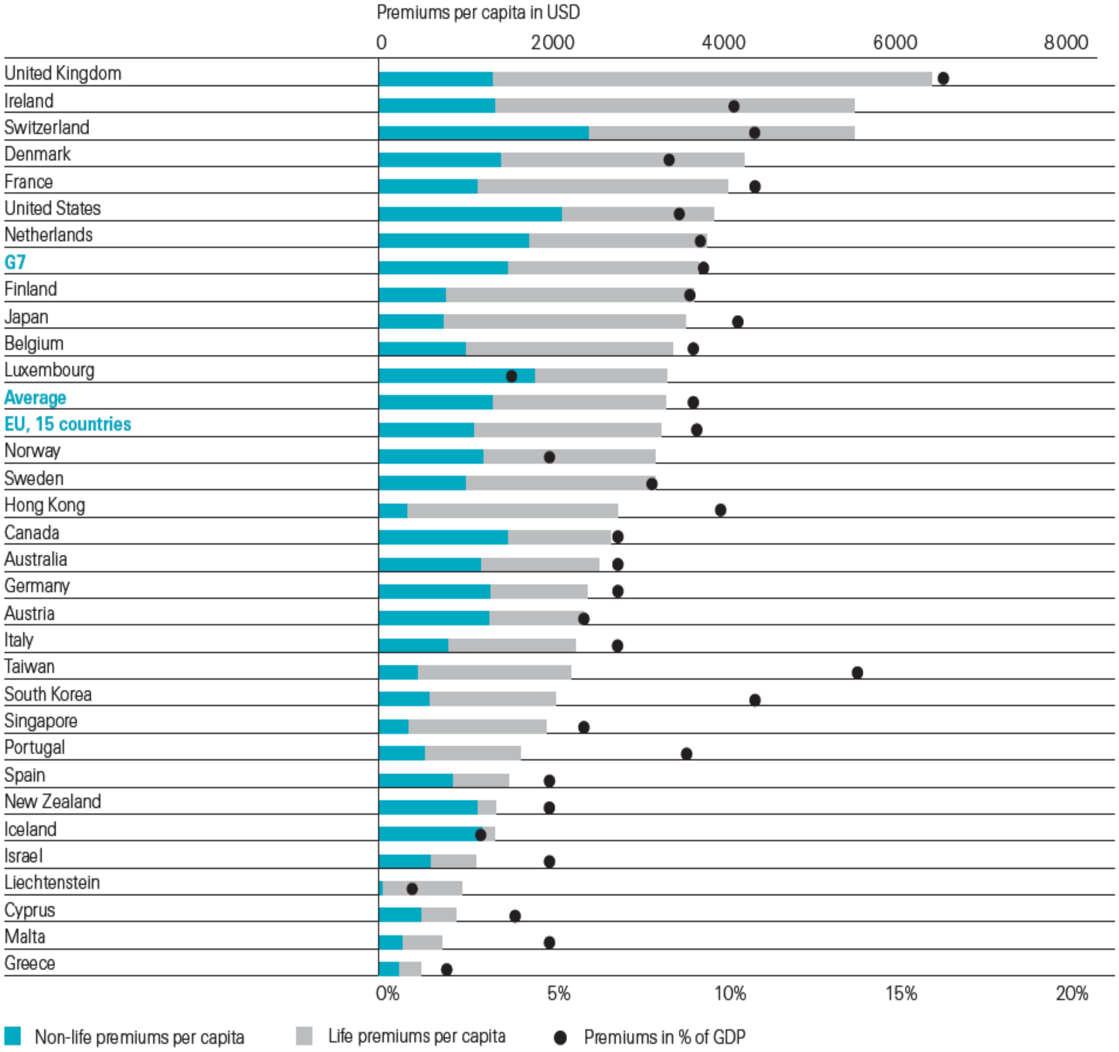
The industrialised countries, which generate 92% of world premiums, saw growth of 4% in real terms, to USD 3 390bn. This is more than 2005's 2.6% and above the 10-year average of 3.4%. Life premium growth drove overall premium level increases in the industrialised world.

In 2006, life insurance premiums in industrialised countries grew by 6.6%, up from 5.1% in 2005 and almost twice the long-term 3.8% growth rate. However, divergent performance was observed from country to country. While positive developments in the largest markets contributed significantly to overall growth, Japan actually saw premiums decline by 2%. Regulatory and fiscal changes drove increases in some industrial countries. The strongest growth was observed in the UK, up 30%, where changes in the pension regulations allowed increased contributions to funds. In contrast, life premiums in Belgium decreased by 21% as a result of the introduction of a new 1.1% tax on individual policies.

Non-life insurance premiums in industrialised countries rose slightly by 0.6% in 2006, having declined by 0.8% in 2005. However, 2006's performance lagged behind the 2.7% 10-year average. After substantial price rises in recent years, good profits have boosted insurance capacity, which in turn has heated up price competition, leading to lower prices and subsequently lower premium growth. Favourable economic conditions resulted in the strongest growth of 8.2% being posted by South Korea, which has only recently joined the category of industrialised countries.

The strongest decline was observed in the Netherlands, down 3.2%, where price competition in the largest lines of business, and in particular in the accident and health business following healthcare reforms, pushed the market down. On a per capita basis, an average of USD 3 362 was spent on insurance in industrialised countries in 2006 (see Figure 11); split into USD 2 026 in life and USD 1 336 in non-life insurance. Insurance penetration, measured as a percentage of GDP, remained unchanged at 9.2%. Life penetration averaged 5.5% and non-life business 3.7%.

Insurance density and penetration in the industrialised countries in 2006.



Source: Swiss Re Economic Research&Consulting

In the context of sustainable economic growth and of the expectations regarding the benefits of Romania's integration into the European Union, the insurance market in Romania showed significant growth of gross written premiums in 2006. Thus, the volume of written premiums reached approximately 1.7 billion euros in 2006, which accounted for an insurance penetration ratio 1.67% compared with 1.54 in the previous year, calculated as a percentage of the Gross Domestic Product, also on the increase. Most written premiums were accounted for by non-life insurance premiums (approximately 80%), especially by auto insurance, which shows that at least in the medium-term life insurance premiums are highly unlikely to account for an increased percentage of total premiums.

The forecasts for 2007 show that gross written premiums for the two categories of insurance business shall increase to approximately 8 billion lei (more than 2.4 billion euros), of which approximately 6.7 billion lei (2 billion euros) shall be accounted for by non-life insurance.

Credit insurance, guarantee insurance, property insurance as well as motor vehicle insurance and travel insurance are forecasted to account for a significant percentage of this amount.

With respect to life insurance, gross written premiums are expected to amount to more than 1.3 billion lei (400 million euros), accounting for 10% real growth compared with 2005, mainly as a result of the development of health insurance.

An insurance penetration ratio higher than 2% was estimated by comparing the estimated volume of gross written premiums for the two categories of insurance business to the estimated GDP for 2007 (390.3 billion lei, according to the Main macroeconomic indicator projections for 2007-2013 calculated by the National Commission of Prognosis in the spring of 2007).

There is multitude of factors that must be taken into consideration when trying to determine social and economic development. In recent years, one of these factors that had a growing impact was represented by natural catastrophes. Lately floods increased in intensity, frequency and were responsible for more losses than any other natural phenomena in Romania. At international level, managing the risk of floods became a top priority for insurance companies and governments alike. There are however a series of factors which make catastrophe risk unsuitable to be covered by traditional insurance. Within this article, we try to address a more suitable approach on the matter represented by catastrophe bonds.

Key words: catastrophe bonds, floods risk, securitization, financial innovation, ART

Catastrophe bonds – Rationale

In recent years, in Romania, the severity and frequency of floods have increased considerably due mainly to heavy precipitations and snowmelt during springtime. In 2005, as stated within the Guy Carpenter & Company Ltd's *European Flood Report 2005 –Central and Eastern Europe*, our country experienced the most terrible flooding in over 30 years with over 30 counties and 500 towns reported to have been affected, 69 people killed and over 13000 people constrained to abandon their homes. From a financial perspective, the Romanian government estimated that losses attained more than 1.5 billion euros, while only 10% of the households in the affected areas had flood coverage policies. In addition, as one can notice from the table-displayed bellow, for the period 1999 to 2008, the economic damage costs from the top ten natural disasters were determined mostly by the occurrence of floods.

Disaster	Date	Damage US Dollars (000's)
Flood	July-2005	800000
Drought	June-2000	500000
Flood	August-2005	313000
Flood	April-2005	200000
Flood	June-2001	120000
Flood	April-2000	100000
Flood	July-1999	50000
Flood	March-2001	15000
Flood	June-1999	10000
Flood	March-2000	500

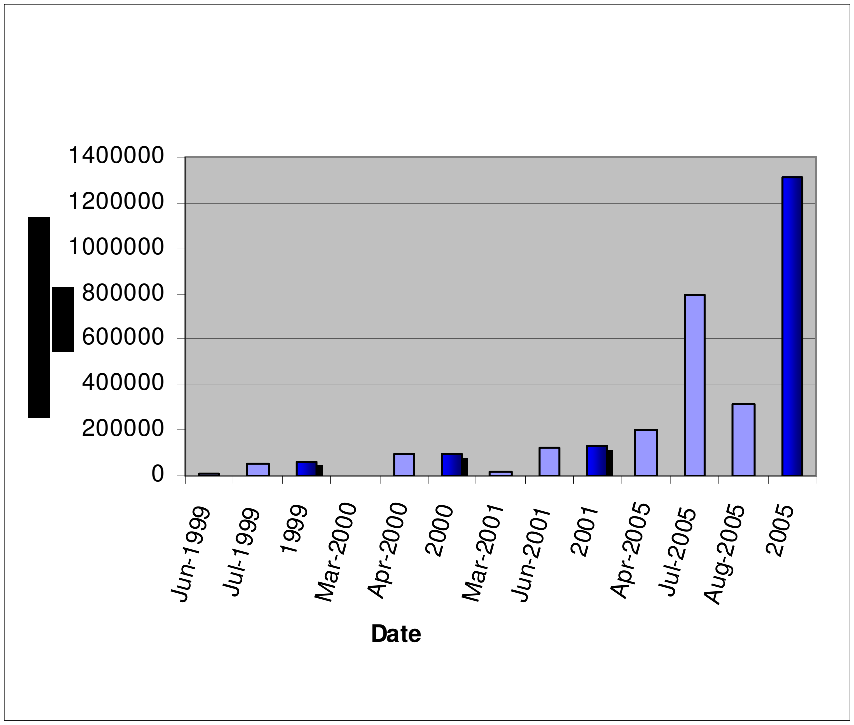
Natural disasters in Romania for the period 1999 to 2008

Source: "EM-DAT: The OFDA/CRED International Disaster Database

www.em-dat.net - Université Catholique de Louvain - Brussels - Belgium"

Besides the immediate losses caused by floods, such as damage to buildings, motor vehicles, infrastructure and persons, costs of clearing up and disposal, one can identify several indirect losses like the damage from business interruption and power failure, costs of transportation, assistance, accommodation, communications and storage as well as intangible losses like parting of the area at risk psychological impairments or losses of intangible values.[57]

Furthermore, in the end, all these damages transpose themselves into losses for the entire economy in the form of a decline regarding the economic growth. As we can observe from the following table, in Romania, the financial costs regarding the floods exhibited a growing trend in the last years. Al these facts lead to the conclusion that flood stand for one of the most important catastrophe risk factors in our country with a huge impact on the determinants of social development and economic growth.



Economic damage costs from flood (1999-2005)

While insurance companies cover the pure risks using the law of large numbers by holding a large portfolio of independent risks, in the case of catastrophes, in general, and floods, in particular, one can consider the location an impediment as, at the same time, the entire insured pool could be affected. Therefore, the incidence of these events is characterized by high correlations among the losses within one insurance company's pool. Furthermore, one should mention the frequency of these events: they do not occur quite often with respect to other events (such as a fire), making almost impossible the design of scenarios based on historical statistic data. In addition to all these, the occurrence of one catastrophe can lead to the emergence of other unfavorable events, like epidemics or fires.

At international level, as a consequence of the reduced financial capacity of the insurance companies with regard to the losses from natural catastrophes, the financial innovation phenomenon induced the emergence of market – oriented contracts. These ones are meant to `transfer and scatter the catastrophe risk (from natural catastrophes like earthquakes, hurricanes or floods or man-made catastrophes) towards the investors within the capital markets through well-defined mechanisms – *alternative risk transfer (ART)* solutions. In addition to all said, from a financial perspective, one can notice within this contracts the solving of the

[57] Hausmann, P. (1998), *Floods – an insurable risk?*, Cat Perils, Reinsurance & Risk division, Swiss Reinsurance Company

issue regarding the incomplete market through accessing the capital market resources. Therefore, the limits of insurability can be mitigated by designing innovative financial contracts such as those represented by the catastrophe bonds (*CAT bonds; Insurance-linked bonds; Act of God bonds*).

Basically, the contracts mentioned above are characterized by the fact that both the coupons and the principal can be modified or no longer paid in the case of occurrence of a natural catastrophe within a well-specified area. One could say that these contracts are financially indexed to natural catastrophes. Another aspect that should be mentioned relates to the fact that, in order to issue these bonds, there is used a very popular financial process, known as *securitization*. Through this technique, financial assets characterized by a low degree of liquidity (such as mortgages, commercial loans, credit cards) are transformed into new financial contracts, traded on the international capital markets. More thoroughly, the securitization technique consists in packaging financial promises and transforming them into a form whereby they can be freely transferred among a multitude of investors.[58]

Several aspects regarding the securitization of catastrophe risk

As far as the catastrophe risks are concerned, the securitization technique involves the presence of several economic actors, among which the following three ones are the most important:

- **The sponsor –** is the company that selects, pools together the catastrophe risks and cedes them to the special purpose vehicle. The CAT bonds could be seen as options or supplements of the reinsurance. The sponsor can be an insurance or reinsurance company.
- **The special purpose vehicle (SPV) –** acts as a "reinsurance company" in relation with the ceding company and finances the operation by covering the risks through issuance of securities (bonds) towards the capital markets. The payment relative to the coupons and / or the principal will occur only if one or more conditions related to the catastrophe event will or not are fulfilled, mainly if there are not registered damages over a certain trigger point, established within the contract. Therefore, the cash flows due to the investors will be transferred to the ceding company to pay policy claims in the case of surfacing of a catastrophic event. In addition, the loan funds are invested in a collateral account with. The main role of the SPV is represented by the fact that it insulates the investors and the sponsor / ceding company.
- **The investors –** stand for the last important participant of this market. They are those who invest in the CAT bonds issued by the special purpose vehicle. One can notice the importance of the SPV for the latter ones – if they were to buy the bonds directly from the ceding company, they would have had to face a double risk: first, the catastrophe risk and second, the default risk of the ceding company. As far as the motivations are concerned, for the investors they consist in the fact that there is no correlation between the catastrophe events and the risks connected to the financial securities. Therefore, for investors there is the opportunity to diversify their portfolios and to invest exclusively in the catastrophe risk when the presence of the SPV. In addition, one can think at the possibility of investing in a new asset class with al the advantages resulting, such as diversification within a portfolio formed by correlated corporate bonds that could be characterized by losses while qualms within the fixed income markets are present. Furthermore, taking into account the fact that this is relatively a new asset, this type of bond could offer a significant premium of novelty.

A very important aspect regarding the catastrophe bond contracts resides from the determination of the losses and the specific mechanism of trigger (mainly, when the coupons and / or the principal of the bonds should be paid partially or at all to the investors). Among the most known mechanisms are the following ones:

- **Indemnity trigger –** in this case, the trigger point is a function of the actual suffered losses of the ceding company and resembles a lot the reinsurance principle. The coverage offered by the CAT bonds is triggered when the sponsor company suffers losses above a certain level, known as *trigger point* and the latter one is indemnified for the registered damages due to the catastrophic events specified within the contract. For this type of mechanism, the financial

[58] Davidson, A., Sanders, A., Wolff, L-L., Ching A.; (2003); *Securitization Structuring and Investment Analysis*, John Wiley&Sons, Inc., Hoboken, New Jersey

literature has identified the presence of information asymmetry, through adverse selection and moral hazard phenomena. The former one can be detected when the insurance or reinsurance company (the sponsor within the securitization process) holds within his portfolio the appealing positions and cedes the risky ones. The latter one consists mainly in a reduction of policies regarding the indemnities, since the risks have been transferred to the investors.

- **Industry index trigger –** the trigger mechanism consists in the fact that the ceding company retrieves only a part of the total industry losses, above a level previously established. One can notice that the investment operation has a more transparent character as far as the investors are concerned as there is a third party to measure the trigger parameters of the industry losses. Through this mechanism, the sponsor faces the basis risk defined by the difference between the actual suffered losses and the indemnity received from the CAT bonds. Therefore, if the discrepancy is positive (and large) the sponsor finds itself in the position of being exposed to the catastrophe events. Contrary, if the difference is negative, the sponsor benefits from the transaction.
- **Pure parametric trigger –** while the last mechanism presented some transparency characteristics, this one, as the name says, is based only on the parameters of the catastrophe event, such as location or magnitude in case of an earthquake or flood depths in case of the floods. The main disadvantage is represented, as in the case of the industry index trigger, by the basis risk.
- **Modeled loss trigger –** for this trigger mechanism, after the occurrence of a catastrophe event, the values of its parameters are introduced within a well-defined model in order to generate the expected losses for the ceding company's portfolio. The result of the model will be compared with a certain level in order to determine the triggering of the bond.
- **Parametric index trigger –** this one differs from the pure parametric one through the employment of different categories and through the weighting of each category in order to reflect the exposure of the ceding company within a certain area.

With respect to the market of catastrophe bonds, this one has grown rapidly since its inception in 1997 regarding both the number of contracts, the perils covered and regarding the contracts designed. As far as the flood risk is concerned, the first catastrophe bond ever to be known was introduced with reference to river flood in Great Britain, by Allianz Global Corporate & Specialty through a Cayman Island-based company (Blue Wings Ltd.), fronted by Swiss Re. Besides the flood risk, the catastrophe bond is designed to cover earthquakes in Canada and the US excluding California. It is interesting to notice the fact that the mechanism used is a parametric index trigger, while the index is determined using the flood levels registered at over fifty locations from Great Britain As far as the earthquake risk is concerned, the bond uses a modeled loss trigger.

Further research

As one can notice the challenge of catastrophe events represent a significant part of the research studies and pragmatic solutions. Furthermore, for our country, the study of these events and their implications from a financial perspective, with reference to their management by shifting towards the capital markets through alternative risk transfer instruments (such as CAT bonds) could stand for an important field of research.

THE HEALTH SECTOR IN EASTERN EUROPE AND PROPOSALS FOR REFORM

Văidean Viorela-Ligia

Universitatea „Babeş-Bolyai" Cluj-Napoca, Facultatea de Ştiinţe Economice şi Gestiunea Afacerilor, Str. Teodor Mihali, No. 58-60, Cluj-Napoca, viorela.vaidean@econ.ubbcluj.ro, 0264-418654

This article describes the current state of the health sector in Eastern European countries. We have focused on similarities, although the health sectors, just as the political and economic systems, differ in many aspects not highlighted here. The first part of the paper presents considerations regarding the current state of the health sector, its financing, delivery, doctors' incomes and the widespread phenomenon of under-the-table payments. Furthermore, we have presented some guiding principles for reform in this sector, mainly focusing on the health system reform in our country.

Key words: health expenditure, health system financing, health system reform

The Current State of the Health Sector in Eastern Europe

In the Eastern Europe of the 1990s, the spending on social services, including health spending, generally decreased less than GDP. The majority of Eastern European countries spent less than 6.5 percent of GDP on health in 2007 (Albania 3.5%, Bulgaria 4.8%, Hungary 5.3%, Macedonia 6.1%, Poland 6.2%, and Romania 4.1%). Although population health depends on the combined effects of several factors, certainly if health sector performance improved, it would help to improve population health, ideally in conjunction with other favorable changes.

Financing

Compulsory social-insurance contributions finance the majority of health services in Eastern Europe. The contribution rates as a percentage of earnings vary significantly across countries, from the modest 3.4% in Albania to the alarming 23.5% in Hungary and the nominal distribution of the contributions between employers and employees ranges from 0 : 100 [%] in Poland to 100 : 0 [%] in Macedonia[59]. However, the central state budget continues to play an important role, through financing public health, specialized research and clinical institutions and, nevertheless, financing the deficits of the social insurance fund.

Private financing, through voluntary insurance and out-of-pocket (both legal and illegal) payments, plays a role in almost all countries in the region. Private medical insurance in Hungary, Poland, and other countries is increasing, but from a very small base. If proper account could be made of the extent of semi-legal "gratuity" payments to providers, the scope of private financing would most likely appear much larger than the official figures reveal.

Delivery

- Public Institutions

The legacy of socialistic planning is clearly evident in the region's health-care delivery system. Even though hospitals must mainly cover their expenditures out of their revenues, in practice, they repeatedly exceed their budgets. The outcome is usually a bailout by the central or local state budget. In Romania, the public hospitals' budget is strictly supervised by the Regional Health Insurance House that aliments them, together with local budget sources and own sources. The budget must not be overcome according to the frame-contract and the legal norms for applying it.

- Legal Private Activity

[59] The size of the health-care social insurance contributions and the nominal distribution of the contribution between employers and employees in Eastern Europe, at the beginning of the century.

The largest change has occurred among doctors practicing individually, in primary care and dental care. All the Eastern European countries legalized private practice in the early 1990s, and some undertook "privatization campaigns"[60]. Several—the Czech Republic, Hungary and Romania—"privatized" primary care, by converting doctors from state employees to self-employed professionals, working under contract with the insurer and the local (or regional) government, which provides the premises and equipment. Privatization of dental care is even more extensive, and pharmacies are overwhelmingly private nowadays.

The first nonpublic hospitals, clinics and other health-care providers have also appeared in the 1990s in most Eastern European countries. Some are nonprofit, owned and operated by churches and private foundations. Most are for-profit institutions. Still, in the Eastern European region as a whole, the nonpublic share in total service volume remains very small. Hungary also has a high private-sector proportion for certain special diagnostic and therapeutic treatments.

Purchasing and Payment

By the end of the 1990s, most countries had moved away from historical-cost budgeting—towards alternative payment methods (*see Table no.1*). Fee-for-service (FFS) predominated in some countries, such as the Czech Republic. In that case, real health care spending increased by almost 40 percent in two years, with health expenditures jumps as a percent of GDP, too. Private practice physicians paid on a FFS basis billed significantly more in every category of service than public (primarily salaried) providers did.

Country	Primary Care	Outpatient and Inpatient Care
Albania	Capitation	Global budget and salary Planned: FFS
Bulgaria	Global budget and salary	Global budget and salary
Czech Republic	FFS Planned: capitation	Global budget
Croatia	Capitation and FFS	FFS and salary
Hungary	Capitation	Case-based payment (DRG)
Macedonia	Capitation	Global budget and salary
Poland	Capitation and FFS	Capitation and FFS *and* case-based payment[61]
Romania	Capitation and FFS	Capitation and FFS *and* case-based payment[62]

Table no. 1 Payment systems in Eastern Europe, at the beginning of the century

Several countries have introduced supply-side cost sharing, such as capitation and case-based payment for hospitals. Capitation has already become the most common form of payment for primary care in Eastern Europe.

Doctors' Earnings and Gratuities

Another resemblance between the market-socialist period of the economy as a whole and the health sector is the tension apparent between legal and illegal (or semi-legal) earnings. One aspect of the phenomenon is the disproportionately low salaries of doctors, most of whom remain employed by public institutions. Although physicians are among the best paid professionals in the traditional market economies (3 to 4 times average earnings), in Eastern Europe, official medical earnings are only 1.3 to 2 times average. This relatively low proportion understandably embitters and annoys the medical profession in light of the widening differentiation of earnings in other fields.

[60] The Czech Republic in 1993 and Croatia in 1996
[61] According to the choice of the territorial fund
[62] Since 1999

The other side of the coin is the system of what are known as gratuities—under-the table payments made by a patient or relative to a doctor or other health-care provider for publicly-financed services. Experts on the subject consider that semi-legal payments to doctors are very widespread in Hungary, Romania, Poland and Bulgaria, and much less so in the Czech Republic and Croatia.

The two sides of the gratuity system—intolerably low official pay and the prevalence and astonishing size of the semi-legal gratuity payments—are inseparably linked. Certainly the majority of doctors accept gratuities; they have become part of their normal income, without which they could not balance their household budget.

Recommendations for Reform

Almost all the countries of the world are confronted with a discrepancy between medical services' demand and the available resources. This led to the research of different methods for upbringing the efficiency of resource usage, starting from the care process technology, up to perfecting the sanitary organization and the financing of health services. Changes within the health system, reached larger proportions at the end of the 1980s and the beginning of the present decade, their expansion embracing many countries from Europe and America. Changes focused to eliminate or reduce disturbances that turned up in democratic countries with a stable market economy, but also in countries that had an economy based on state monopoly and a centralized rigid planning system. An ideal perfect sanitary system doesn't exist anywhere.

Dissatisfactions that generated the process of health care system reform, appeared among tax payers, doctors, institutions, politic and administrative authorities. Discontents aimed increased costs of health, in an intolerable rhythm, without substantial improvement of health status, insufficiency coverage of population with services, the absence of an efficient insurance quality mechanism, exaggerated volume of daily work, inefficient management.

The need for a coherent politic, harmonized with European and internationals health objectives, assumes to complete the desideratum "health for everyone" established by the World Health Organization, based on:

- Universality, i.e. all community members must have access to health care, at a reasonable cost;
- Quality, i.e. the medical services administrated must fulfill legally standards;
- Existence of a complementary powerful and viable private sector;
- Possibility to choose;
- Efficient medical services, based on needs;
- Respect of privacy and personal dignity;
- Existence of a gathering data system used in programming, decision and reglementation;
- Facility of integration models and cooperation for the delivery of medical services;
- Initiatives of long term programs, to prevent sicknesses and to increase life quality.

Our recommendations are based on a proposed set of specific guiding principles for reform of social policies in economies undergoing post-socialist transition, further applied to the health sectors of Eastern Europe. Our main point is the ethical challenge of promoting individual choice and sovereignty while assuring social solidarity.

Guiding Principles	***Recommendations***
Sovereignty of the individual (choice)[63]	Sovereignty of the patient's choice of provider (at least for primary care); choice of insurer for individual supplementary and later for basic care; mechanisms for patient appeals and complaints; etc.
Solidarity[64]	Risk pooling at broadest level for basic care; risk

[63] The transformation promoted must increase the scope for the individual and reduce the scope for the government to decide in the sphere of social services.

	adjustment of payments to insurers and providers to assure risk solidarity, with complementary policies (mixed payment, high-risk pooling); etc.
Competition[65]	Evolutionary development of private sector in delivery and financing, including entry and some privatization; managed competition among insurers for supplementary care and later for integrated packages of basic and supplementary care; etc.
Transparency[66]	Public involvement in process for prioritizing public financing and defining and updating the basic benefit package; formal demand-side cost sharing rather than gratuity payments; etc.
A new government role[67]	A new role in order to finance government basic care for all citizens; develop institutions for prioritizing public financing and delineating basic benefit package; license providers; quality assurance, etc.

Table no. 2 Guiding Principles for Reform

Usually, the shaping of a system is realized in time, being both difficult and expensive. Health, as a determinant element of a democratic society, has to be ensured considering the following important facts:

- the recognition of the predominant role of health within the making of material production and services;
- the control and permanent balance of health costs, in order not to negatively affect the economic prosperity;
- in transition periods, specific indicators confirm an increased damage of health, i.e.:

1. increased lack of medicines and consumable sanitary materials;
2. preventive services are absent or inefficient;
3. the formation and allocation of the sanitary staff is inadequate.

- financing is inconsequentially supplied, on an inflationist ruling fund;
- the development of an uncontrolled private market.

The main objectives of reform for the health care system in Europe are: allocation balance of financial resources and cost control; the reduction in demand inequities and services' accessibility; the reduction of inadequate usage of modern technologies; the correction of inadequate stimulation of medical consuming; introducing the controlled competition, between the public and private suppliers, the insurance organizations, etc; separating the service suppliers (doctors, hospitals) from the service buyers; the payment of doctors and institutions based on performance criteria; introducing modern managerial methods in health services management and decentralization of the health care system through deconcentration and authorities' delegation.

Furthermore, priorities in health care system reforms for Central and East Europe are:

- to decentralize the health care system;
- to modify the administration and planning methods;

---

[64] Help the suffering, the troubled and the disadvantaged.
[65] Competition among various ownership forms and coordination mechanisms.
[66] The link between social services provided by the government and the tax burden that finances them must become apparent to citizens
[67] The main functions of the government in the social services sector must be to supply legal frameworks, supervise private institutions, and provide 'ultimate,' last-resort insurance and aid. The government is responsible for ensuring that every citizen has access to basic education and basic health care.

- to maintain large accessibilities;
- the development of communitarian health services;
- the development of preventive services based on risks factors;
- Improvement of health staff's forming system.

Health System Reform in Romania

The health system reform in Romania depends on the economic system reform, on its transformation through property decentralization, the consolidation and the development of private property, as resource and spinning center.

The health reform strategy in Romania focused on the following domains :

- structural organization and system management;
- system financing;
- assuring the necessary health services for population;
- reasonable usage of human and physical resources.

The strategic objectives regarding the configuration and functionality of health services on a long term are:

- the creation of a hued and performing system (ambulatory integrated caring, day-hospitalization, diagnostics and treatment services improvement;
- the extension of primary assistance services (home care assistance, within ambulatory medicines, creating multifunctional health centers);
- suitable, sustainable and stimulating performance financing ,
- shutting down the low performing medical units;
- perfecting operational management systems;
- realizing a compatible normative frame with institutional and functional reforms;
- facilitating private financed systems of medical services
- setting up and improving the insurance for pensioners within specialized units of daily care.

By achieving the up-mentioned objectives, we foresee the perfecting redefinition of the medical units, the improved local access of the community to primary assistance integrated services, financial support, quality assurance, the development of investments, the decentralization and faster supply of health services.

To conclude, the following aspects have to be approached and solved:

- the set up of databases and the improvement of information flow and distribution within a local, regional and national system;
- the standardization of coding and implementation of the national data register;
- the development of primary and ambulatory care, through the lease of medical cabinets towards doctors;
- the finalization of the extern financing programs;
- the extension of the integrated ambulatory services;
- the operation of multifunctional health centers, the standardization of the finance methods, the hiring and usage of the medical staff;
- the implementation and improvement of regional resource allocation;
- the founding of a national organism for monitoring the health services' quality, by using a minimal set of unitary indicators;
- the implementation of improved information management systems, based on performance parameters;
- the providing of health services through stimulated public-private partnerships.

A COMPARATIVE STUDY ON THE INCOME TAX FOR PHYSICAL PERSONS AND LEGAL ENTITIES

Cucoşel Constantin

Universitatea de Nord Baia Mare, Facultatea de Ştiinţe, Catedra de discipline economice, Str. Victoriei nr. 47/8, Email: costin.contab@xnet.ro, Telefon: 0722896131

Abstract: As per the Fiscal Code, the incomes obtained from independent activities are included in the category of incomes that are subject to the income tax. They include: trading income, income obtained from freelance activities, and income resulting from intellectual property rights, obtained individually and/or in some sort of association, including from related activities.

Key words: the income tax, the corporate tax, the income tax for physical persons, the income tax for micro-companies.

1. The taxation on the incomes obtained from independent activities

The income obtained from freelance activities is the kind of income resulting from professions such as: medical practitioner, lawyer, notary, financial auditor, fiscal advisor, expert accountant, chartered accountant, advisor for security placements, architect, or practitioner of any other profession established by law, carried out in an independent manner.

The practice of these professions is established through distinct laws, specific to each of them, and from a legal point of view these activities can be organized either in individual offices or in trading or civil companies, as is the case.

Thus, for instance, in the case of such professions as expert accountant and chartered accountant, the laws under effect in this field provide that these professions can be practiced either individually, within own offices, or the professionals can form trading companies, as per the applicable law.

When these professions are practiced individually, the income resulting is subject to taxation as per the legal regulations specific to the income obtained by physical persons; when these professions are practiced within civil or trading companies, the income obtained is subject to taxation as per the rules applicable to legal entities (either income tax, or income tax for micro-companies, as is the case).

In Romania, the taxation of these incomes obtained by physical persons in an individual manner was conducted, until the year 2004 inclusively, by applying on the net income, established in a real system, a set of tax quotas established by instalments of taxable income, according to the annual standards set forward in legal regulations; the tax quotas then varied between 18% and 40% for the income that exceeded the maximum limit.

Following the introduction of the flat income tax, beginning with January 1st 2005, this kind of income is taxed by applying a quota of 16% to the net income established in a real system.

The tax payers who obtain incomes by performing an independent activity (except for the incomes for which the tax is withdrawn at the source), must pay a tax, during the year, in the form of advance payments, on the account of the income tax, such tax being established based on the income estimated for the current year or based on the net income obtained from that activity in the previous year, by applying to it the legal tax quota. The advance payments are to be made in 4 equal instalments, until the 15th of each month of each trimester.

In the year subsequent to the year when these incomes were obtained, a final taxation is carried out, based on the data actually achieved, and the tax on the net annual income is calculated by the competent fiscal body, in basis of the income statement, by applying the legal tax quota to the net annual taxable income of that fiscal year.

The net income obtained from independent activities is calculated, in a real system, as a difference between the gross income and the expenses entailed by the process of obtaining the income, deductible, based on the data provided by the single-entry bookkeeping. The tax payers who establish the net income in a real system must keep a record of the operations through the single-entry bookkeeping system, to fill in the Check register, the Inventory-register, and other accounting documents, as provided by the law.

Since, as it was indicated before, these tax payers may choose to pay the income tax either as per the laws specific to physical persons, or as provided by the laws applicable to legal entities (corporate tax or income tax for micro-companies, depending on their option), my paper will conduct a **comparative study** between the three forms of taxation – **the income tax for physical persons – the corporate tax – the income tax for micro-companies**, as they were in 2004, respectively 2005, to emphasise the differences between them and the advantages of each of them. To this purpose, the paper analyzes a private consulting room where income is obtained by performing medical professions; the tax due for this income, in the three versions described above, was calculated based on the data provided by the accounting registers.

2. General presentation of the private consulting room

The general medicine consulting room of "Doctor Andru Dana" is a sanitary unit established as per the Government Order no. 124/1998, on the establishment and registering of private consulting rooms. This consulting room is working according to the provisions of the Government Order no. 153/2003 on the organization and functioning of private consulting rooms. This private consulting room has no legal personality, and it exists only in the form of "Consulting Room".

The scope of this consulting room includes:

- providing primary medical assistance (as treatment or prevention);
- providing emergency medical assistance;
- providing activities related to the medical profession.

A. The income of the consulting room is obtained from the following:

- medical services provided in basis of the contract signed with the District department of health insurance, or other physical persons or legal entities;
- medical services paid directly by the clients;
- donations, sponsorships;
- counselling and advising activities in the field of medicine;
- activities contracted with the units that coordinate the learning and research activities in the network of the Ministry of Health;
- other sources obtained in compliance with the legal provisions, including the ones obtained from selling the owned equipment that is worn out (either physically, or no longer up to date), as well as the exceeding equipment owned.

The income obtained from the activity of the consulting room is to be submitted to taxation according to the legal provisions on the taxation of the incomes resulting from activities carried out in basis of free initiative.

The bookkeeping of the private consulting room uses single entries, as per the Accountancy law, and is performed by qualified personnel, in basis of a service providing contract for performing bookkeeping activities.

B. Categories of deductible expenses for the private consulting room

The character of the activity carried out in the private consulting room entails deductible expenses which are common to other companies too, as well as specific expenses:

- expenses related to the personnel:
  - salary expenses;
  - compulsory contributions;
  - travels, assignments, transfers, related to the medical activity carried out;
- expenses related to materials and services – drugs and sanitary materials;
- expenses related to maintenance and administration;
- materials specific to the sanitary field;
- materials and services that have a functional character;
- taxes for professional organizations;

– taxes for continuous medical training;
– insurances;
– inventory items;
– current and capital repairs;
– books and published materials;
– protocol.

3. Calculation of the net income and due tax

The present study is based on the accounting documents of the private consulting room.

According to the accounting registers, in 2004 the Consulting Room of Doctor Andru recorded incomes amounting to 277.141.299 lei, as follows:

– income obtained from medical services provided in basis of the contract signed with the District department of health insurance 270.525.799 lei
– income obtained from medical services paid directly by the clients 1.320.000 lei
– income obtained from various taxes 5.295.500 lei

TOTAL INCOME 277.141.299 lei

According to the laws under effect concerning the deductible expenses for a private consulting room, as well as to the explanatory accounting documents, in 2004 the total expenses amounted to 261.251.220 lei, as follows:

– expenses related to salaries	69.805.200 lei
– expenses related to sanitary materials	35.138.939 lei
– expenses related to inventory items	23.261.164 lei
– expenses related to pharmaceutical products – drugs	18.187.800 lei
– expenses related to fuel	15.394.075 lei
– expenses related to the insurances	18.915.900 lei
– expenses related to the monthly car instalments	46.381.440 lei
– expenses related to taxes and contributions	9.389.000 lei
– expenses related to heating	7.480.918 lei
– expenses related to the phone bill	3.800.000 lei
– expenses related to services provided through third parties	3.372.081 lei
– expenses related to the power supply	2.425.396 lei
– expenses related to water supply, the sewage system, and cleaning	4.004.455 lei
– expenses related to the rent for the location	1.474.352 lei
– travelling expenses	2.220.000 lei
TOTAL EXPENSES	**261.251.220 lei**

A) The tax on the income obtained from independent activities

The net income obtained from independent activities is established in this case as the difference between the gross income achieved and the expenses entailed by the process of achieving this income – deductible, registered in the single-entry bookkeeping, as follows:

Gross income = 277.141.299 lei
Expenses = 261.251.220 lei
Net income = 15.890.079 lei

For the year 2004 the tax quota applied to this part of the income was of 18%, and for the year 2005 the quota applied was that of 16% (the flat income tax).

The due income tax is shown in **Table 1.:**

Table 1

The income tax due for the period 2004-2005

Year	Net income (lei)	Tax quota	Due Tax (lei)
2004	15.890.079	18 %	2.860.214
2005	15.890.079	16 %	2.542.413

B) The corporate tax

The taxable profit is calculated as the difference between the incomes obtained from any source and the expenses made in order to obtain income, during one fiscal year, out of which non-taxable incomes are subtracted, and to which non-deductible expenses are added.

Incomes = 277.141.299

Expenses = 261.251.220

Profit = 15.890.079

The corporate tax quota applicable to the taxable profit was of 25% until the 1st of January 2005; afterwards, the system changed to apply the flat income tax of 16%.

The due corporate tax is shown in **table 2.:**

Table 2.

The corporate tax due for the period 2004-2005

Year	Taxable profit (lei)	Tax quota	Due Tax (lei)
2004	15.890.079	25 %	3.972.250
2005	15.890.079	16 %	2.542.413

C) The income tax for micro-companies

The Romanian legal entities that meet the legal requirements for being established as micro-companies may choose between paying the tax either as corporate tax or income tax.

Total incomes = 277.141.299 lei

The tax quota for the year 2004 was of 1,5%, and beginning with the 1st of January 2005, it changed to 3%.

The income tax for the micro-company is shown in **table 3.:**

Table 3.

The income tax for the micro-company due for the period 2004-2005

Year	Total income (lei)	Tax quota	Due Tax (lei)
2004	277.141.299	1,5 %	4.157.119
2005	277.141.299	3 %	8.314.239

The comparative status of the three tax categories, for the years 2004 and 2005, applied to the study conducted on the private consulting room, is shown in **table 4.:**

Table 4.

Comparative status of the three tax categories, for the years 2004 and 2005

Year	Independent activities		Corporate tax		Income tax for a micro-company	
	Tax quota	Due tax (lei)	Tax quota	Due tax (lei)	Tax quota	Due tax (lei)
2004	18 %	2.860.214	25 %	3.972.250	1,5 %	4.157.119

2005	16 %	2.542.413	16 %	2.542.413	3 %	8.314.239

4. Conclusions

This comparative study of the situation of the three tax categories for the years 2004 and 2005, applied to the same income, to the Private Consulting Room of "Doctor Andru", leads to the following conclusions:

a) In **2004** the most disadvantageous situation from the point of view of tax obligations was that of the micro-company that paid an income tax, although the tax quota was the smallest of them all. This is due to the fact that the 1,5 % quota was applied to all the incomes. The most advantageous form of organization, taking into account the calculation of the tax for 2004, is that of freelance professional, which was also the form chosen by the Private Consulting Room of "Doctor Andru".

In conclusion, in 2004 the Private Consulting Room had the most advantageous form of organization.

b) For **2005** the comparative study leads to the same conclusion as for 2004, which is, that the micro-company paying an income tax has the most disadvantages. In return, there is an equality of status between the freelance professionals (physical persons) and those who pay the corporate tax, because the same quota of 16 % is applied in both cases.

c) **The comparative situation for the years 2004 and 2005,** in that which concerns the three tax categories, clearly shows that the tax quotas for physical persons and the corporate tax payers were down in 2005 to the flat income tax quota of 16 %, which puts the year 2005 in a more advantageous situation as 2004.

By contrast, for the micro-companies paying the income tax, the tax quota doubled from 1,5 % to 3 %, which is a disadvantage. Still, the new laws provide the micro-companies with the option of choosing to pay the corporate tax instead, which is an option that didn't exist in 2004.

In conclusion, in the case of the income tax for independent activities, and of the corporate tax, the introduction of the flat income tax quota of 16 % led to an obvious decrease of the due tax and, implicitly, is the most advantageous option from this point of view. In that which concerns the micro-companies that pay an income tax, although the tax quota doubled, many economic agents have chosen this form of organization most probably for other reasons related to fiscal control.

THE ECONOMIC AND FINANCIAL ELEMENTS USED IN ASSESSING THE COMPANY ACTIVITY

Cucoşel Constantin

Universitatea de Nord Baia Mare, Facultatea de Ştiinţe, Catedra de discipline economice, Str. Victoriei nr. 47/8, Email: costin.contab@xnet.ro, Telefon: 0722896131

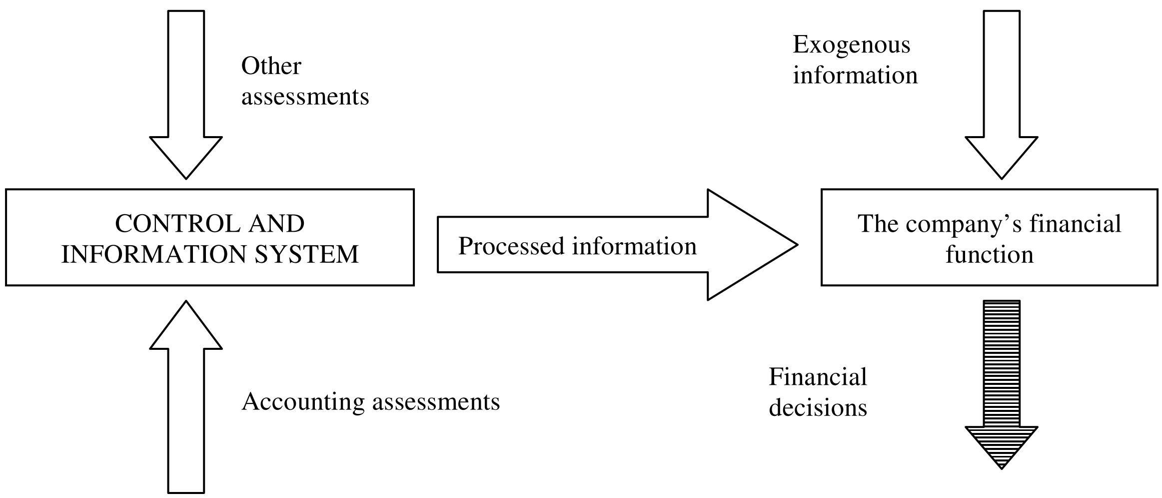
Abstract: The financial administration can be defined as an assembly of decisions and activities for regulating and adjusting financial flows and funds, at administrating the financial resources of the enterprise. The financial administration has as its aim the regular providing of the company with funds necessary to equipment and current exploitation, but also to control the good use of funds and profitability of the targeted operations. The financial administration has multiple aims subordinated to survival, to obtaining profit and economic growth of the company.

Key words: the economic elements, the financial elements, the financial resources, the enterprise

1. Indicators – concentrated expressions of the economic and financial data

According to modern conceptions with regards to the role and attributions of a company's financial function, the most common opinion is that the purpose for performing it is to make decisions concerning the cash flows that characterize the life of the company. The focus is not so much on the resource itself, but on the way it is used, which makes it necessary to emphasize the decisional aspect in performing this function.

The role of the financial function within the informational and decisional process can be illustrated through the figure below:



The data obtained and used with regards to the company performing its financial function takes the form of indicators. These become an essential tool for the financial activity and, through that, for the decision-making process at micro-economic levels.

To make it simpler, indicators may be considered to be concentrated expressions of the economic and financial data, used in the process of administrating the company. It follows from this that the first function attributed to an indicator or system of indicators, within the management process, is the function of reflecting and providing data on the phenomena involved. Because of this, indicators ensure a quantitative illustration of the structure, level, and dynamics of the phenomenon under observance. Indicators may be expressed either as absolute values at a given time or as average values over a given period, or as a secondary indicator in the form of a relative value connecting two absolute values.

Thus, in the practice of financial management these economic and financial indicators are formed as significant relations or, sometimes, as differences between two values or group of values in the income and expenditure budget, in the company's balance sheet and/or profit and loss account.

So why is it required to analyze the company's activity starting from this aspect – of the economic and financial indicators? The balance sheet of any economic agent or company, through its content, provides a static image of the capital existing at the end of the accounting period.

The calculation of these economic and financial indicators is made based on data collected from the balance sheet, the results account, as well as based on certain information that will be collected from the balance and turnover records for the completed accounting period.

I reckon that: to actually conduct this analysis based on economic and financial indicators (rate of return, financial autonomy rate, self-financing capacity, etc.), we must have access to a highly organized database of financial and accounting information, which would allow us to update the data provided by the accounting records, and access to this data must be ensured to applicants that process and draw-up documents with the financial information.

The path completed during the research represents the reverse of the phenomenon's actual evolution. The study or research starts from the results of the completed process and goes back to elements and factors from previous periods.

The content of the analysis may be described in several stages:

- Outlining the object of the analysis, which implies acknowledging certain facts, phenomena of economic and financial nature. Most often results are recorded both through absolute values and through indicators. The object is outlined in time, space, from a quantitative and qualitative point of view, utilizing certain assessment and calculation methods.
- Outlining the elements, factors, and causes of the phenomenon that is being studied. Breaking it into elements implies a structural analysis.
- Establishing the correlations between the factor and the phenomenon that is being analysed. It is required to outline the cause and effect relation.

In fact, the conclusions we will analyze must answer the following questions:

- What means are used to ensure the financial balance of the companies that are being analysed (self-financing, loans, etc.)?
- Does the company prove sufficient efficiency in utilizing its economic and financial resources?
- What are the appreciations on the structure, utility of the resources, assets, working capital?

It is answers to such questions, falling within the scope and limits of this work, that any user of the information will try to get, whether he is an insider of the company (the management of the company) or an outsider (banks, fiscal bodies, business partners).

2. An analysis on company profitability

It must be kept in mind that the financial purpose of any activity is to obtain profit, and the policy of self-financing is only a method for achieving it.

Profitability is defined as a relation between the result that was obtained and the means that were used. Most often the term of profitability refers to the result obtained from utilizing a capital.

The notion of profitability concerns a comparison between two or several values and requires the intervention of the time factor. From this point of view profitability is more than just a technical concept, as the technical concept alone cannot explain the various economic situations that we encounter in the actual life of an economic agent. At the same time profitability isn't only the result of a comparison between the technical, material, and human elements.

The essence of profitability is that it represents a monetary surplus, the balance between the total expenses and the total receipts. These elements will appear in the company's income and expenditure budget.

The income and expenditure budget is the concrete expression of the company's financial strategy, and through that it underlies the possibility to apply the development strategy over a longer period of time. The construction, and most importantly the motivation of the budgetary provisions require an in-depth horizontal analysis with the competitors in that branch, and a vertical – retrospective - analysis of the absolute values of the items included in the budget, which, taken separately, are not particularly relevant for the relation between the planned effort and the prospective results to be achieved.

This analysis involves utilising the appropriate system that would ensure clear but not imperative comparisons both vertically and horizontally. This system is formed of a group of economic and financial indicators. Five categories of indicators are known: liquidity ratios, financial balance indicators, profitability ratios, working capital indicators.

In my work I will place a special emphasis on the group of financial indicators pertaining o profitability and financial yield.

This group of indicators, which are particularly synthetic, is meant to provide the analyst with information concerning the level of economic and financial achievement obtained from the capital. They are built following the model of efficiency indicators, by calculating the relation between the effect and the effort.

I will also stress the role of these indicators starting from the significance assigned to profit in the market economy. Any entrepreneur aims to obtain sufficient profit to ensure the following:

a) convenient remuneration of the capital made available;
b) maintaining the technical and economic potential in compliance with the requirements imposed by technical and scientific progress in the company's field of activity;
c) ensuring a reasonable expansion on the market, taking into account its evolution and the conjectural tendencies it manifests.

This profit results from a group of activities and operations that work together for the achievement of the targets assumed by the enterprise, in compliance with its market strategy. It follows from this that the profit is a method, a signal (information), and a result of the concentrated actions that the company performs in basis of its functions.

As a consequence, the indicators for financial yield and profitability are meant to outline these very aspects and to serve the act of management precisely by providing the most relevant information with regards to profit and profitability.

There are two separate kinds of selective indicators within this group, and they are as follows:

a) financial yield indicators;
b) profitability indicators.

2.1. Financial yield indicators

The following are included in this type of indicators:

a1 – the gross profit coefficient (margin), established through the relation:

$$m_{pb} = \frac{P_b}{C_A}$$

a2 – the net profit coefficient (margin), established through the relation:

$$m_{pn} = \frac{P_n}{C_A}$$

Both values indicate to the analyst the proportion (margin) that it holds in the whole of the company's receipts. At the same time, these indicators reflect the financial yield for the company business, by indicating how many monetary units represent profit, per received monetary unit, following the sale of the products. Obviously, the purpose is to have this coefficient reach a level as high as possible, and to make its evolution an increasing one.

2.2. Profitability indicators

This group contains indicators obtained from the general relation "profit/capital assets".

Based on the calculation values that are taken into account, we may discriminate between several types of profitability ratios, and they are as follows:

b1 – profitability ratio of the share capital, calculated with the following formula:

$$r_{CS} = \frac{P_b}{K_S}$$

Profitability ratios are rather economic than financial in nature, that is why this appears more like a financial yield indicator for the share capital. In this framework, it may be argued that this indicator reflects the capacity of the share capital to produce profit.

b2 – profitability ratio of the share capital, calculated with the following formula:

$$r_{CS} = \frac{P_n}{K_S}$$

It may be argued that this indicator is purely financial in nature, and this is actually the one indicator that expresses the capital's profitability. It is extremely utilized in the practice of companies located in countries with well established market economies, and it is acknowledged as an indicator of the efficiency of the company's administrators in utilizing the plant assets made available to them.

3. Economic and financial aggregates

Financial analysis makes use of two types of aggregates: the first kind is derived from the financial balance sheet and they constitute the fundamental relation of the bank vault, the second kind originates in the profit and loss account and they form the intermediary balances of administration. The fundamental relation of the bank vault provides indications with regards to the company's financial structure, while the intermediary balances of administration provide information on the administration, as suggested by the name itself.

3.1. The fundamental relation of the bank vault

To establish the fundamental relation of the bank vault three aggregates must be taken out of the balance sheet:

a) The net working capital (F.R.N.)
b) Working capital requirement (N.F.R.)
c) Net bank vault (T.N.)

A) *The net working capital* is the essential element for appreciating the financial structure of a company. It is used for measuring the conditions of the financial balance that results from the confrontation between the liquidity of the assets and the payability of the resources.

The net working capital is the permanent capital surplus relative to the net fixed assets, that is the share of the permanent capitals that is used for financing the circulating assets.

F.R.N. = C.P. – A.I.N.

The attention paid to financial security and caution leads us to state a rule according to which sustainable utilization must be financed through sustainable sources, that is through permanent capitals. This implies the fact that the net working capitals must have positive values. A negative net working capital indicates that some of the fixed assets are financed through short-term resources. Such a situation is deemed to be an important factor of vulnerability. Still with the aim of ensuring financial security, a second problem that needs to be addressed is establishing whether the net working capital should finance the operating cycle and if yes, up to what point. As a general rule, the net working capital may be considered as indicating good financial health if it meets the following criteria:

– it is equal to half the stocks;
– it varies between 1 and 3 months of the average turnover, without taxes.

Thus, the net working capital allows us to draw the following conclusions:

– a positive net working capital is a favourable signal in that which concerns solvency;
– a zero-value net working capital indicates tension over the liquidity and is a sign of a certain vulnerability with regards to solvency;

– a negative net working capital indicates difficulties in that which concerns solvency, if no corrections are made to improve the stability of the financing.

B) *The working capital requirement* outlines the financing requirements created by the operating cycle. The difference between the financing requirements of the operating cycle (the circulating assets) and the operating debts is called the working capital requirement.

$$N.F.R. = A.C. - D.E.$$

That is to say:

WORKING CAPITAL REQUIREMENT = CYCLIC ALLOTMENTS – CYCLIC SOURCES

As a rule, companies must deal with a very high working capital requirement. If this difference is positive, it indicates a surplus of temporary (cyclic) requirements in relation to temporary (cyclic) sources that could be mobilized. Such a situation can be deemed as normal if it is the result of an investment policy with regards to the increase of the financing requirements for the operating cycle.

If the working capital requirement is negative it indicates a surplus of temporary requirements in relation to the corresponding requirements for circulating capitals. This can receive a positive appreciation if it results from an acceleration of the rotation of circulating assets and of taking up debts with more relaxed due dates.

The evolutionary character of the working capital requirement lies in the fact that this requirement depends on the activity volume, and its size may be inflected through administration measures (reducing the stocks, reducing the number of clients or increasing the credit of suppliers).

The whole of the resources that the company can self-procure, having as source the self-financing and the divestiture.

The self-financing is based on the forecasts for the gross operating output resulted from the operations. The gross operating output depends on the profitability of both the existing capital and the new added capital. Starting from the gross operating output, the calculation for self-financing requires mainly an establishment of the financial expenditure and income, as well as a calculation of the tax and of the participations to the profit.

Forecasting financial expenditure is a very delicate issue, since the financial expenses related to treasury credits (short-term credits) are treasury requirements themselves. But the very existence of the bank vault depends on the chosen financial policy. The chain procedure is advised. Also, another element that must be taken into account is the policy for distributing benefits, in the case of dividends received from subsidiaries.

Divestitures represent selling of certain asset elements to allow the procurement of significant capitals. One must discriminate though between the divestitures that are consequences of completing new investments, and divestitures caused by a deliberate choice with regards to the company's capital.

Conclusions

When a company chooses a financing source, whether it is short-term, medium-term or long-term, it must have certain criteria based on which it can make a selection. For this decision, as with other decisions made by the financial leader, the final criterion is maximizing the wealth of the shareholders. But this criterion has more than one dimension as several factors need to be taken into account when making a choice between debts, potential actions and common actions. Among these are the following: cost, fund availability, company control, changes in the structure of the capital, opportunity cost, taxes, etc.

From the management's point of view, the impact over the cash flow is one of the most important factors taken into account when making the financing decisions.

The company is left with money supplies that it may use either to complete the distribution of the dividends or to purchase subsidiaries or participations, thus becoming a "parent" company of a group or holding. Still, it is required to examine the nature and size of the balance (surplus). If it shows a tendency of keeping a high level (as a consequence of the unitary strategy), the company may also consider a policy of remunerating shares and external development. But if this balance shows a reverse tendency, there is a risk that the company may get in a negative situation.

This analysis (research) indicates that there is a strong connection between the company's strategic situation and its financial performances.

At the same time, a company's financial performances shouldn't be measured only in terms of profitability but also, using flows, in terms of capacity, generating liquidities, equally conducted at the level of strategic activities.

Without having exhausted all the aspects of business administration in the field of *self-financing,* we have tried to analyse and discuss some aspects that we found useful.

Abstract: The goal of the present paper is a short analysis for the insurers' foreign equity in Romania and the development of a mathematical approach for the chronological evolution of the study regarding the insurers' equity from the point of view of assessing the insolvency probabilities and the risk provision so the estimating insolvency risk will not over overcome an accepted value.

Key words: Insurer, broker, adjusting coefficient, overcharging factor, probability of ruin, compound Poisson repartition.

Introduction

Since 1989, Romania faced a development of private property and a concentration of indigene capital, facts that determined continuous growth of the insurance market. In a first phase, the permissible legal framework (Law no. 47/1991) and the lack of the Romanian capital but also the attractiveness of the Romanian market were the main factors for the market penetration of the foreign capital on the Romanian insurance market. The same phenomenon took place in the insurance mediation sector.

The number of insurers reached a normal evolution, with a spectacular growth at the beginning of the insurance market, followed by a decrease according to the concentration and centralization of the capital, as shown below: (P is the percent of foreign capital to equity of the insurers).

Year	Number of insurers	P %
1997	47	-
1998	64	-
1999	72	62,11
2000	73	75,80
2001	47	61,70
2002	48	50,20
2003	44	59,21
2004	45	48,00
2005	43	50,00
2006	41	53,10

Source: - OSAAR Reports, Bucharest, years 1997-1999;

- ISC Reports, Bucharest, years 2000-2006;

As it can be seen, a significant share of equity is represented by the foreign capital, mainly Austrian or German. Since year 2007, it is evident a foreign capital domination due to the fact that the first 6 insurers have a market share of more than 70%. Since year 2000, there are changes in the sales management for the insurance products, so the insurance agent is replaced by the insurance broker. The law 32/2000 sets a clearer view on mediation sector, especially for brokers. This is supposed to be a legal person, to prove cash equity, to have valid third party liability insurance, and the only subject of activity – the insurance mediation, to have qualified human resources.

The evolution for the number of brokers is shown below:

Year	1999	2000	2001	2002	2003	2004	2005	2006
Number of brokers	749	817	198	150	204	266	317	344

Source: O.S.A.A.R. and ISC Reports, Bucharest, years 1999-2006.

It is important to assess the risk that an insurance company faces bankruptcy. In order to explain this, we shall provide a mathematical model regarding the insurer's capital and we shall determine the ruin probability, this means the probability that the insurer has no more resources to pay the indemnities (obviously this isn't a de facto ruin, but an attention for the financial management).

2. The modeling of risk of ruin

In order to study the variation of insurer's equity, we shall note with $U(t)$ the insurer's equity at moment t, with u the initial capital, with $S(t)$ the total claim demand (more precisely the amount of total claim demand) occurred till the moment t, with m the number of insurance policies, with $N_k(t)$ the number of individual claim demands till the moment t for a given policy type k, with Y_i^k the individual demand number i for the insurance type k and with $S_k(t)$ the claim demand occurred till the moment t for a given policy type k.

We have:

$$S(t)=\sum_{k=1}^{m} S_k(t) \text{ and } S_k(t)=\sum_{i=1}^{N_k(t)} Y_i^k \text{ .}$$

Additionally, we presume the following hypothesis to be fulfilled:

1. there are no other expenses than the paid indemnities and no other incomes than the cashed premiums.
2. the unit income is c.
3. the individual claim demands for every policy type are independent identically distributed random variables. The individual claim demands for every insurance type are independent and identically distributed variables
4. the stochastic processes $\left(N_k(t)\right)_t$, $k=\overline{1,m}$, for the number of demands are Poisson processes of parameter λ_k. It results that process $\{S(t)\}_t$ is a compound Poisson process composed of parameter $\lambda=\sum_{k=1}^{m}\lambda_k$, so we have $S(t)=\sum_{i=1}^{N(t)} X_i$, where random variables X_i are independent and identically distributed, having the moment of order k noted with m_k, $m_k=M\left(X^k\right)$. The variables X_i equalize mathematically the individual real claim demands Y_i^k, but there are not identically distributed. In these hypothesis, we have $M(S(t)) = \lambda \cdot t \cdot m_1$ and $D^2(S(t)) = \lambda \cdot t \cdot m_2$.
5. The insurance premiums are determined with respect to the medium value principle, with an overcharging relative confidence θ:

$$\text{k}\, c=(1+\theta)\cdot m_1 \cdot M(N(1)) \text{ .}$$

We have: $U(t) = u + c \cdot t - S(t)$ (1).

We shall name ruin the situation this capital is negative and we shall consider the moment of ruin at the moment this happen for the first time. So we are dealing with the problem of ruin for a given, undetermined period of time, called finite horizon. So:

$$T = \inf\{t > 0 \mid U(t) < 0\}$$ is the moment of ruin.

In this context, the ruin probability (noted with Ψ) is the probability that the moment of ruin is finite. From the point of view of initial capital u, the overcharging factor θ, the claim files rate λ and the medium individual claim demand m_1, the function is: $\Psi(u,\theta,\lambda,m_1) = P(T < \infty)$.

The equation (in r) strictly positive solution: $\lambda + c \cdot r = \lambda \cdot M\left(e^{r \cdot X}\right)$ is called adjustment coefficient. This coefficient (when does exist) shall be noted as R.

Considering an existing adjustment coefficient R, we have:

$$\psi = \frac{e^{-R \cdot u}}{M\left(e^{-R \cdot U(T)} \mid T < \infty\right)}.$$

If the adjustment coefficient R does exist, then $\Psi(u) \le e^{-R \cdot u}$ (this is known as the Cramer inequality).

This is determined by the fact that for a finite T ($T < \infty$), we have $U(T) < 0$, so $M(e^{-R \cdot U(T)} \mid T < \infty) > 1$.

Generally speaking, because the adjustment coefficient is difficult to compute, we seek for a convenient interval, whose margins are used in the Cramer inequality. Because $M\left(e^{R \cdot X}\right) > 1 + R \cdot m_1 + \frac{R^2}{2} \cdot m_2$ we obtain: $R < \frac{2 \cdot \theta \cdot m_1}{m_2}$. Considering the function $\omega(r) = \lambda \cdot (m_X(r) - 1) - c \cdot r$ which is strictly convex and due to the fact that net profit condition is fulfilled ($\omega'(0) = \lambda \cdot m_1 - c < 0$), the results are $\omega(R) = \omega(0) + \int_0^R \omega'(s) \cdot ds > \lambda \cdot m_1 \cdot R - c \cdot R + \lambda \cdot m_2 \cdot \frac{R^2}{2}$ and $R < \frac{2 \cdot c - 2 \cdot \lambda \cdot m_1}{\lambda \cdot m_2}$.

If the individual demands have an exponential repartition of parameter α (so $m_1 = \frac{1}{\alpha}$), because the medium income per unit time is $c = (1+\theta) \cdot \frac{\lambda}{\alpha}$, we find for the ruin probability the expression:

$$\psi(u,\theta,\lambda,\alpha) = \frac{\lambda}{\alpha \cdot c} \cdot e^{-\left(\alpha - \frac{\lambda}{c}\right) \cdot u} = \frac{1}{1+\theta} \cdot e^{-\frac{\alpha \cdot \theta \cdot u}{1+\theta}} \quad (2).$$

Considering the initial capital as a β number of medium individual claim demands, we obtain:

$$\psi(\beta,\theta) = \frac{1}{1+\theta} \cdot e^{-\frac{\theta \cdot \beta}{1+\theta}} \quad (3).$$

We could improve this model by setting the problem to compute a risk provision (V), in order to define the probability that paid indemnities should not overcome the incomes plus this provision, under an accepted value p. If the medium number of claim demands (in our case $n = \lambda \cdot t$) is big enough, we can use the central limit theorem (TLC) and approximate $S(t)$ with a normal variable of mean $\lambda \cdot t \cdot m_1$ and dispersion $\lambda \cdot t \cdot m_2$. So we want to determine *V* in order that $P(S(t) \geq u + c \cdot t + V) \leq p$. Using TLC we obtain $V \geq z_{1-p} \cdot \sqrt{\lambda \cdot t \cdot m_2} - u - \theta \cdot \lambda \cdot t \cdot m_1$, where z_{1-p} is the quartile of order $1-p$ of the normal repartition. If we choose the minimum risk reserve in order not to block higher financial resources, we have:

$$V = z_{1-p} \cdot \sqrt{\lambda \cdot t \cdot m_2} - u - \theta \cdot \lambda \cdot t \cdot m_1 \qquad (4)$$

In the hypothesis that individual claim demand follows an exponential repartition of parameter α, so $m_1 = \frac{1}{\alpha}$, $m_2 = \frac{1}{\alpha^2}$, we have:

$$V = z_{1-p} \cdot \frac{\sqrt{\lambda \cdot t}}{\alpha} - u - \frac{\theta \cdot \lambda \cdot t}{\alpha} \qquad (5)$$

Choosing an initial equity to represent a number of individual medium claim demands (β), we obtain:

$$V = \frac{z_{1-p} \cdot \sqrt{\lambda \cdot t} - \beta - \theta \cdot \lambda \cdot t}{\alpha} \qquad (6)$$

3. Numerical results

From relation (3) we have determined the values for ruin probabilities for a few values of premiums overcharging factor θ and parameter β, that provide the number of medium individual demands to cover the initial equity.

The results are listed in the table below:

$\theta \backslash \beta$	5	10	20	30	50	60	100
0.1	0.5770	0.3663	0.1476	0.05945	0.00965	0.00428	0.0001
0.2	0.3622	0.1574	0.0297	0.0056	0.0002	$4.5 \cdot 10^{-5}$	$4.8 \cdot 10^{-8}$
0.4	0.1712	0.0410	0.0024	0.00014	$4.5 \cdot 10^{-7}$	$3.6 \cdot 10^{-8}$	$2.8 \cdot 10^{-13}$
0.6	0.0958	0.0147	0.0003	$8.1 \cdot 10^{-6}$	$4.5 \cdot 10^{-9}$	$1.7 \cdot 10^{-10}$	$3.2 \cdot 10^{-17}$

Obviously, the higher the initial equity and the bigger the overcharging premiums are, the smaller the ruin probability is. The diminution of risk of ruin realizes exponentially compared to the growth of those two factors. The increasing overcharging factor is limited by the necessity to maintain an adequate premium level for the competitiveness of the insurance company on market. We also emphasize this model is correlating to strong the incomes and the indemnities, the medium income per unit time being proportional to the medium number of individual claim demands multiplied by the value of medium individual claim demand.

This is due to the principle of medium value for the premiums computation. We consider the use of medium annual claim index instead of claim demand in order to obtain a more realistic model.

Using relation (6) we obtained the following results:

- for $p = 0.005, \alpha = 0.001, \lambda = 1, \beta = 2$, values of *t* and β, the risk reserve *V* (u.m.) is provided in the following tabel:

$t \backslash \theta$	0.1	0.2	0.5

1	480	380	80
5	3269	2769	1269
10	5159	4159	1159

- for $p = 0.001, \alpha = 0.01, \lambda = 5, \ \theta = 0.1$, values of t and β, the risk reserve V (u.m.) is provided in the following tabel:

$t \setminus \beta$	5	10	20
100	1590	1090	90
400	1680	1180	180

We underline that the negative values for the relations (4)-(6) mean a risk reserve equal to zero. We also ascertain the risk reserve to be proportional to the claim medium individual demand, decreasing when the initial equity covers many claim individual demands and decreasing when the requested margin for the insolvency risk decreases.

THE INFLUENCE OF TAXES ON FINANCIAL EQUILIBRIUM

Csegedi Sandor,

"Sapientia" University, Targu Mures, telephone no. 0744809997, email: exkontalex@yahoo.com

Abstract. *In this paper, the authors present the method of evaluating the effect of taxation on the financial equilibrium of the company.*

Key words: working capital, working capital requirement, net treasury, net standing.

1. Financial diagnosis- the evaluation method of the company's equilibrium

The financial diagnosis is a group of instruments and methods which enable the appreciation of the financial standing and the performances of a company.

The purpose of the financial diagnosis is of evaluating the financial standing of the company. Basing on this diagnosis, there takes place the creation of a new strategy of maintaining and developing in the local economic environment. In a general sense, the finality of the financial diagnosis consists of providing financial information both to those inside the company and to the interested ones from outside the company.

When the issue of the diagnosis occurs inside the company (internal financial diagnosis), the users may be the leaders, current shareholders or employees. The objective is, in this case, to detect the possible situations of financial instability and to adopt new decisions concerning the administration of the company. These decisions are based on the identification of the origins and causes of the lack of balance and, on the other hand, on the determination of the curative measures.

When the issue occurs outside the company (external financial diagnosis), the users may be financial analysts, potential shareholders, banking and financial institutions or even the state. The objective pursued is the company's financial capacity of generating profit, the company'c capacity of paying its short term or long term obligations (the liquidity nad solvability of the company), as well as the company's value.

External users usually require a financial diagnosis either for crediting the company (especially banks), or for making the decision of entering the capital of a company (potential shareholders or other companies).

Both the internal and the external analysis have the objective of appreciating the performances of the company and the risks it faces and they refer to: profitability analysis, risk analysis and company's value analysis.

Irrespective of the results obtained by the company or of the unfolding of the events, the making of a financial diagnosis has to take place on a periodical basis. The financial diagnosis identifies the favorable and unfavorable factors that will influence the future activity of the company.

The information resulting from the financial diagnosis often have to be completed with information referring to the external milieu of the company (standing of the economy, of the industry), information referring to the technical and human potential, commerical and juridical potential , the company's management (information depending on companies). All these elements influence the financial performances of the company and determine its competitive nature.

The information required for making the financial diagnosis are taken from the simplified financial statements that include: balance sheet, profit and loss account, annex to the balance sheet.

2. The double meaning of taxes in the case of the economic unit

From the definition there can be extracted the following characteristics of taxes:

1. the compulsory nature of paying taxes and, in relation to this, their legality and legitimacy;
2. tax is a take over without equivalent and, in relation to this, there occurs the issue of the reversibilty of taxes and their redistributive role;
3. taxes' fundament and measure is the contributive capacity of each tax payer;
4. the double quality of taxes: resources for covering public expenses and fiscal leverages used by the state.

Stating that tax has as main purpose the overing of public expenses and to sustain the primary nature of its financial purpose implies the explict determination of al least four things:

- tax has a financial purpose: obtaining the necessary resources for covering public expenses;
- tax also has other purposes, also referring to the fulfillment of certain economic or social objectives;
- its objectives may be contradictory, therefore they must be harmonized;
- among its different objectives, the most important is the financial one.

Taxes have a double quality as far as the financial equilibrium of the companies or tax payers is concerned. Under this hypothesis, taxes represent, on the one hand, an expense for the companies or tax payers and, on the other hand, they represent their debt or obligation.

The development of the company is related to the ensurng of the economic equilibrium expressed as a value. The financial equilibrium expreses the equality and correlations between the required financial resources and the possibility of collecting these resources. The financial equilibrium of the company implies the covering of all the operational expenses out of own or borrowed incomes, of the expenses not shown in costs, of the development and modernization expenses, of the expenses with personnel and shareholders incentives, as well as of the contractual and financial obligations towards banks and state budget.

The activity of a company has to be performed so that there is ensured an equality among financial resources (R) and their use (F), so that R=F.

The financial resources (R) of a company may be made up of incomes resulting from the basic activity and from other activities (V), financial incomes (Vf), extraordinary incomes (VE), liabilities of operation and those from the investment sector (Pe), bank and other financial institutions credits (C) and new cash contributions of shareholders and other resources (Ar), so that:

$$R = V + Vf + VE + Pe + C + A + Ar$$

The uses of resources can be represented by clients inventories and assimilates (S), expenses with personnel and other salarial rights (Ce), expenses with investments and modernization (Ci), research and development expenses (CE), non deductible expenses (Cn), payment of obligations to the state as taxes and the contributions to the social insurance budget (imp), payment of credits and corresponding interest (Rc) and other expenses (Ac), so that:

$$F = S + Cp + Ci + Ce + Cn + Imp + Rc + Ac.$$

Taking into account the financial resources and their use, the financial equilibrium of the company is presented through the following equality:

$$V + Vf + VE + Pe + C + A + Ar = S + Cp + Ci + Ce + Cn + Imp + Rc + Ac$$

Taxes may influence the financial equilibrium of the company. Taxes represent a factor of influence over the financial stability of a company as far as the two aspects analyzed – expense and debt- are concerned.

3. The effect of taxes on the net standing

The net standing calculted as difference among total assets and total debts provides a first (accounting) evaluation of the company at the end of the financial period. This fundametal equation of the balance sheet represents the net wealth of the shareholders, respectively the asset not engaged in debts.

Indicators	Period			
	S_1	S_2	S_3	S_4
Total assets	10.000	10.000	10.000	12.000
Debts	3.000	4.000	2.000	3.000
Out of which taxes	1.000	2.000	500	1.800

Net standing	7.000	6.000	8.000	3.000
Variation of net standing	x	6.000	- 2.000	1.000

NET STANDING = ASSET – DEBTS

The net standing presents an increase or decrease in timpe, a fact that signifies the increase or decrease of shareholders' equity.

Analyzing the due taxes, we may say that the increase, respectivley decrease, of the taxes included in total debts influences with a positive or negative effect the net standing of a company and, consequently, its financial equilibrium.

During the S_2 period with increased debts on the account of taxes, the net standing of the company decreases. Under these circumstances, the debts and expenses of the company increase and we may notice a fiscal pressure.

Net statement S_2 = 10.000 – 4.000 = 6.000

During S_3 period with the decrease of debts on the account of taxes, THE NET STATEMENT of the companies increases. Under these circumstances, the expenses and the debts of the companies decrease and we may notice a fiscal relaxation.

The net statement S_3 = 10.000 – 2.000 = 8.000

During the S_4 period, when the value of the asset is determined by other factors but from total debts we notice a increase of taxes. Under these circumstances, even if the net standing records an increase, we may say that the fiscal pressure is positive as compare to S_1.

Net statement S4 = 12.000 – 3.000 = 9.000

4. Working capital, measure of the financial equilibrium

In order to accomplish the financial equilibrium of the company, it is necessary to respect the principle of maturities parity according to which permanet allocations (intangibles) have to be financed on the account of permanent sources (shareholders' equity and long term credits) due to their slower rotation; cyclical allocation (non current assets) are financed on the account of the temporary sources (short term liabilities).

The higher permanent sources are as compared to permanent requirements of funds allocation, the more the company enjoys a security margin, which protects it from unforeseen events.

This surplus of permanent resources, resulting from the financing cycle of investments, may be rotated for renewing inventories and account receivable. This potential use is responsible for its name, which is working capital. It expresses the long term financial equilibrium and its contribution to the accomlishement of the equilibrium of short term financing.

WORKING CAPITAL = PERMENENT SOURCES – PERMANENT ALLOCATION

Working capital = (Shareholders' equity + Financial debts) – Net amortization non current assets.

INDICATORS	S1	S2	S3	S4
SHAREHOLDERS' EQUITY	790.000	802.000	925.000	1.123.000
FINANCIAL DEBTS	0	0	0	12.000
NET NON CURRENT ASSETS	800.000	839.000	972.000	1.160.000
WORKING CAPITAL	- 10.000	- 37.000	- 47.000	- 25.000
WORKING CAPITAL VARIATION		- 26.000	- 10.000	22.000

FR S1 = (790.000 + 0) – 800.000 = - 10.000

FR S2 = (802.000 + 0) – 839.000 = - 37.000

FR S3 = (925.000 +0) – 972.000 = - 47.000

FR S4 = (1.123.000 + 12.000) – 1.160.000 = - 25.000

FR VARIATION S2/S1 = - 37.000 - (-10.000) = - 26.000

FR VARIATION S3/S2 = - 47.000 - (-37.000) = - 10.000

FR VARIATION S4/S3 = - 25.000 - (-47.000) = 22.0000

The negative value of the working capital reflects the absorbtion of a part of the temporary resources for financing certain permanent needs, contrary to the principle of financial administration: to permenent needs there are allocated permanent sources, so that long term allocations are finances by short term resources. These situations may be less unfavorable if the company leads an investment policy – an orientation towards development. At any rate, a negative working capital has serious effects on treasury and payment capacity.

During the S_4 period, there may be noticed a tendency of improving this long term lack of balance, thw working capital, even if still negative, is half the value of that of the preceding year; the company better administers the resources attracted from shareholders or creditors.

5. The need of working capital – way of reflecting the financial equilibrium.

It is the expression of the short term financial equilibrium, of the equilibrium between the requirement and use of operational capital.

NFR = CYCLIC ALLOCATIONS – CYCLIC SOURCES

NFR = (INVENTORIES + ACCOUNTS RECEIVABLE) – OPERATIONAL DEBTS

INDICATORS	S1	S2	S3	S4
INVENTORIES	75.000	49.000	27.000	54.000
ACCOUNTS RECEIVABLE	88.000	820.000	71.000	61.000
DEBTS	330.000	653.000	1.053.000	963.000
NFR	- 167.000	- 522.000	- 955.000	- 848.000
NFR VARIATION		- 355.000	- 433.000	107.000

NFR S1 = (75.000 + 88.000) – 330.000 = - 167.000

NFR S2 = (49.000 + 82.000) - 653.000 = - 522.000

NFR S3 = (27.000 + 71.000) – 1.053.000 = - 655.000

NFR S4 = (54.000 + 61.000) – 963.000 = - 848.000

NFR VARIATION S2/S1 = - 522.000 - (-167.000) = -355.000

NFR VARIATION S3/S2 = -955.000 - (-522.000) = -433.000

NFR VARIATION S4/S3 = - 848.000 (-955.000) = 107.000

NFR is negative. There is a surplus of temporary resources, this standing is accepted only if it results from the increase of the rotation speed of current assets and the engagement of debts with more relaxed due times. Otherwise, it implies the inadequate administration of inventories.

6. Net treasury – form of reflecting the monetary resources of the company

Net treasury represents the difference between the working capital and the required working capital.

Net treasury is the most conclusive expression of the unfolding of a balanced and efficient activity. It indicates the quality of the general equilibrium of the company both for long and short term.

TN = WORKING CAPITAL – REQUIRED WORKING FUND

INDICATORS	S1	S2	S3	S4
WORKING CAPITAL	- 10.000	- 37.000	- 47.000	- 25.000
WORKING CAPITAL VARIATION		- 26.000	- 10.000	22.000
REQUIRED WORKING CAPITAL	- 167.000	- 522.000	- 955.000	- 848.000
REQUIRED WORKING CAPITAL VARIATION		- 355.000	- 433.000	107.000
NET TREASURY	157.000	458.000	908.000	823.000
NET TREASURY VARIATION		- 328.000	423.000	- 85.000

Net treasury is positive for all the years, showing that the financial periods ended with a monetray surplus, the real expression of net profit from balance account liability anf other monetary accumulations. The increase of net treasury in S_3 as compared to S_2 and, respectively, the decrease in S_4 as compared to S_3 represents the cash flow which goes to the shareholders as dividends to be cashed and/or profit to be reinvested.

7. Intermediary administration balance account – modalities for reflecting the company's efficient activity

TRADE MARGIN = GOODS SALE – COST OF THE SOLD MERCHANDISE

INDICATORS	S1	S2	S3	S4
GOODS SOLD	2.000.000	1.999.000	3.250.000	3.761.000
EX. WITH MERCHANDISE	1.300.000	1.200.000	1.695.000	1.642.000
TRADE MARGIN	700.000	799.000	1.555.000	2.119.000

PRODUCTION OF THE PERIOD = PRODUCTION SOLD +/- PRODUCTION RETAINED + INCOMES FROM PRODUCTION OF NON CURRENT ASSETS

INDICATORS	S1	S2	S3	S4
PRODUCTION SOLD	12.431.000	14.000.000	1.985.000	25.650.000
PRODUCTION RETAINED	0	27.000	116.000	117.000
INCOMES FROM PRODUCTION OF NON CURRENT ASSETS	2.195.000	3.286.000	3.700.000	3.546.000
PRODUCTION OF THE PERIOD	14.538.000	17.313.000	23.401.000	29.313.000

ADDED VALUE = TRADE MARGIN + PRODUCTION OF THE PERIOS – CONSUMPTION FROM THIRD PARTIES

The added value expresses the increase in the value resulted from the use of the production factors, especially work and capital, over the value of the materials, energy, services purchased from third parties.

This added value represents the source of monetary accumulations out of which there is made the remuneration of the direct and indirect participants to the economic activity of the company: personnel, state, creditors, shareholders and company through the capacity of financing itself.

INDICATORS	S1	S2	S3	S4
TRADE MARGIN	700.000	799.000	1.555.000	2.119.000
PRODUCTION FOR THE PERIOD	14.538.000	17.313.000	23.401.000	29.313.000
CONSUMPTION WITH THIRD PARTIES	6.989.000	7.555.000	8.617.000	9.834.000
ADDED VALUE	8.849.000	10.557.000	16.338.000	21.598.000

GROSS SURPLUS

FROM OPERATIONAL ACTIVITIES (EBE) = ADDED VALUE

+ SUBVENTIONS

- EXPENSES WITH THE PERSONNEL

- TAXES

INDICATORS	S1	S2	S3	S4
ADDED VALUE	8.849.000	10.557.000	16.338.000	21.598.000
INCOMES FROM SUBVENTION	0	0	0	0
EXPENSES WITH TAXES	79.000	237.000	992.000	1.342.000
EXPENSES WITH THE PERSONNEL	1.298.000	2.325.000	3.922.000	3.730.000
EBE	7.472.000	7.995.000	11.424.000	16.526.000

EBE expresses the gross accumulation from the operational activity, taking into account the fact that anortization and provisions are only expenses calculated, not paid. EBE expresses the potential capacity of self financing investments (from amortizations, provisions and profit), paying the debts to the state budget and remuneration of capital investors (shareholders and creditors).

The self financing capacity expresses a financial surplus resulting from the profitable activity of the company. It has only a potential character if not sustained by effective financial means. The monetary surplus resulting from the increase of net treasury during the most recent financial periods shows that the largest part of this self financing capacity is sustained by an available treasury.

8. Conclusions of the tax effects on the financial equilibium

The finances of the companies represent the main, basic link of the entire financial and credit system. This statement bases on the fact that most of the monetary funds formed on different levels result from the incomes created in the basic cells of the economy through taxes. The financial phenomenon emerges from the realtions that the company has with all the companies, the state and other institutions.

On a overstructural level, the finances of the company appear as a branch of financial science, which analyzes the mechanisms and processes of procuring and administering financial resources, their sources and destinations, in order to satisfy the different needs and to obtain profit.

In a company there may be created numerous funds, among which: fixed asset fund, working capital, reserve funds, scientific research funds, funds for training, rewarding and including employees in the profit disctribution. These funds that ensure the financial equilibrium of the company are conditioned by the total amount of taxes to be sustained.

The fiscal pressure may cause a state of financial lack of balance, respectively fiscal relaxation may generate financial equilibrium. Companies, through financial mechanisms and their specific methods may proceed to the formation and administration of capital.

The investment process implies, at a certain point, an amount of financial resources in a direction that might produce incomes during several successive periods of time.

Investments represent expenses that are made for obtainingfixed assets. For the financial manager, investment is, first of all, a decision of making capital intangible for the purpose of obtaining a future profitability. If the budgetary constraint of taxes is a strong one, the company cannot get the used funds.

The payment capacity expresses the possibility that a company should cope with due payments towards suppliers, employees, bansk, state budget, social insurances budget and social protection.

Payment capaicty refers to the report between a certain part of liquid assets – main liquidities - and due time payment obligations.

Under the circumstances of an exaggerated fiscal pressure, taxes have a negative influence over the financial stability of the companies, expressed as financial balance. NET STANDING, WORKING CAPITAL, REQUIRED WORKING CAPITAL, NET TREASURY and by intermediary administration balance accounts: TRADE MARGIN, PRODUCTION FOR THE PERIOD, ADDED VALUE, GROSS SURPLUS FROM OPERATIONAL ACTIVITIES, NET RESULT, SELF FINANCING CAPACITY, LIQUIDITY, SOLVABILITY.

Fiscal pressure via taxes negatively influences the administration rates. Under the circumstances of fiscal relaxation, taxes have a positive influence over the indicators of financial balance.

An effect of taxes is also held by the concordance between the measure of taxes and the paying capacity of the companies.

Abstract: In modern economies, the public authority entrusted to manage the public affairs of the community is the state. In fulfilling their objectives the public decision makers assume a number of tasks according to the doctrines embraced by the government. The government results as an outcome of the election process and thus, faithful to its own doctrine is more or less invasive in the economy provides more or less protection and public goods therefore increasing or decreasing its spending according to its needs. The final outcome pursued by the state is the welfare of its citizens. Eventually, the way this goal is achieved as well as the perception the society has regarding the way the state performs is a matter of choice the state makes in order to fulfill its tasks. Traditionally, the main roles assumed by the state are: the distributive role, the regulation role, the stabilising and the assurance role.

Key words: public sector, governance, public spending, performance

JEL classification: H

1. Public sector performance

The intensive financial flows, migration and trade raise the question defining the public goods in the context of globalisation. Under these circumstances several issues must be addressed:

- firstly, the identification of fiscal authority enabled to collect taxes on income and wealth for individuals and firms residing abroad in order to prevent free riding;
- secondly, the provision of public goods to accommodate the new needs of the community.

Such questions become more acute for the European Union which faces new challenges in achieving sustainable development. Under the new economic environment, the global public goods become ever more important. Within the EU individual countries should make efforts to subordinate their local interests to the general welfare of the community. This approach requires a revision of public goods definition. Traditionally they are considered as the goods whose consumption by an individual does not diminish another individual consumption (meaning they are non-exclusive and non-rival). Under the new circumstances this definitions should be extended by considering as public goods *the advantages the society is taken from the provision of utilities meant to satisfy certain particular wants, eradication of poverty, disease, environment protection, and social protection.* Moreover, it should be clearly stated that whether they are referred to as goods or public services they should bring advantages to the society as a whole, as well as individually. Though public goods are traditionally supplied by government bodies, their provision can be delegated to private entities under certain conditions: the quality of goods and services, availability and price.

Moreover, public goods should be cost effective, should enhance productivity and diminish unemployment. All these aspects become more challenging because nowadays public goods become global, range beyond national borders, and once put in place the future generation can benefit of their advantage.

Given the high costs of public goods, either merchandise or services, and the limited funds available to finance them the question of expenditure effectiveness is raised. Therefore the public goods should complement private goods, and the intervention of the state should not trespass the line beyond which private incentives diminish. We consider that the provision of public goods and advantages to the society should support individual development, should sustain economic activity and tax benefits toward contributors should be maximized. Global sustainable development will require an unprecedented level of international co-operation in the field of public sector. And it must be a co-operation in which the developing countries are brought in as true partners and not underdogs. Key challenges for achieving this objective are the eradication of poverty and the protection of our environment from the damaging processes. Existing models of economic globalization are not delivering these results. More specifically, the European Union has to deal with problems it has not encountered before. The economies within its frontier have deep differences of structure, development, and face specific problems. Its peoples belong to different cultures, have different morals, and different points of view on the Union's problems. Therefore it is compulsory for the European Union to support poverty reduction, reduce the gap between the poor and the rich nations, to preserve the quality of the environment and harmonize the European economy as a whole. To achieve these goals, social measures that promote democracy and participation, expand education, improved access to medicine and healthcare and help the transfer of technology are to support economic growth. Countries need transportation and telecommunication infrastructure to sustain commerce and trade, the more so in a global competitive world. Fuel and energy services are necessary for agriculture and modern industrial functions. Water and sanitation services are essential to support population settlements in both urban and rural areas. Whether provided by the public or the private sector, the extent and quality of infrastructure services is critical for growth and development. If public goods fail to provide these services we may assist to a ever divided Europe, wide spreading migration, free riding, waste and exhaustion of financial resources and turmoil that will affect the stability of the economies. Performance may be achieved on many ways, none of them ensuring success: there are approaches relying on administrative procedure, others on political and/or professional techniques. Some approaches follow the traditional public administration while others are founded on the *new public management*. In search of better performance governments use formal and informal remedies but often neglect the principles of good governance. Performance also has both managerial and political dimensions. Therefore there is an interrelated connection between politicians and managers: political encouragement often helps managers focus on what their work and dedicated managers help politicians in implementing their visions. Because politicians and managers often speak different languages and have variant interests, it is hard to get the interface between them right. When breakdowns in performance occur, the culprit often is confusion or misunderstanding over the respective roles and responsibilities of elected leaders and senior managers. Getting the relationship right is a necessary condition for the performing state. The discussion on public sector measurement rests on the processing mechanisms (input, output, income, impact). For instance, in education services *inputs* are the resources assigned for this purpose: teachers, equipment, facilities, etc. and their social value is measured by their costs (i.e. the value the society tags to this task). The budgeting performance criterion corresponding to inputs is *compliance,* i.e., defined as close adherence to budgetary ceilings and *ex ante* allocation, as well as a proper but agile procurement process.

Output is the service itself, number of pupils and students. The social value of output is approximated by the market price for the same or the closest equivalent service (or, in its absence, by total unit cost). The performance criterion corresponding to outputs is *efficiency*, i.e. minimizing total input cost per unit of output (or maximizing the quantity of output in relation to a given total cost of inputs).

Outcome is the purpose that is achieved by producing the service—e.g., literacy vs. illiteracy, number of graduates and employment. The social value of outcomes is subjective and arbitrary, except as revealed by public reaction in the political arena. The performance criterion corresponding to outcomes is *effectiveness,* i.e., maximizing outcomes in relation to the outputs produced.

The i*mpact*, is defined as the *value added* from the activity. It can be explained by the positive externalities induced on the counterpart fields (transfer of productivity by hiring educated labour).

Processing management is the manner in which inputs are procured, outputs produced, or outcomes achieved. For inputs, good process consists of intelligent compliance with input acquisition and utilization rules and, of course, integrity. In some areas of public activity, such as law or politics, "due process" has its own independent validity and is a key element of good governance.

Building performance indicators is not an easy task. Nevertheless, measuring is of an utmost importance because what gets measured will presumably get done In order to have a valid measurement three rules should be considered: a correct and accurate definition of what must be measured; the goods and services must be measured correctly; consequences if tasks are not fulfilled. In the public sector, these rules are quite difficult to apply, because seldom, the least measurable activities may be the most important ones. Moreover, the rules should be adjustable, entailing behavioural changes. It is important to assess the long term outcomes of measurements because the benefits or dysfunctions depend on the ways and fairness of the performance assessment system. Because of the difficulties in measuring the public sector performance, a system of benchmarks is necessary. For this purpose, the best performances of similar countries are to be considered as benchmarks. Benchmarking and performance measurement are closely linked. Performance measurement can be the first step towards improving the performance of a public sector organization and, if backed by an appropriate incentive system, it can help shift organizational focus from inputs to outputs and outcomes and thus improve efficiency and effectiveness. However, the real benefits come from using the performance measures as the basis for internal or external comparisons with the objective of improving the performance of an organization. This is called Benchmarking, which can be defined as the technique of comparing *business practices* and *performance levels* between organizations to identify opportunities for making improvements in *economy, efficiency or effectiveness* of an organization's activities.

There is a long debate going on whether the public sector enhances economic performance. Nevertheless, economists agree that there are circumstances in which lower levels of government spending would enhance economic growth and other circumstances in which higher levels of government spending would be desirable. If government spending is zero, presumably there will be very little economic growth because enforcing contracts, protecting property, and developing an infrastructure would be very difficult if there were no government at all. In other words, some government spending is necessary for the successful operation of the rule of law. Economists generally agree that government spending becomes a burden at some point, either because government becomes too large or because outlays are misallocated. In such cases, the cost of government exceeds the benefit. Generally, the public sector is not (or should not be) profit seeking and public spending requires costly financing choices. Since public spending requires public funds collecting the necessary funds means that the public authorities are confronted with the taxpayers' reluctance to comply with the tax laws, especially if taxes discourage productive behaviour. Government spending displaces private-sector activity. This dampens growth since economic forces guide the allocation of resources in the private sector, whereas political forces dominate when politicians and bureaucrats decide how money is spent.

Some government spending, such as maintaining a well-functioning legal system can have a high "rate-of-return." In general, however, governments do not use resources efficiently, resulting in less economic output. Anyway, the impact of public spending on welfare and growth is not straightforward, and therefore the question that it is raised concerns whether the problem should be addressed in an aggregate manner, considering the public spending as a whole, or by judging each type of spending individually. Obviously, economic spending differs as nature and characteristics from the social and administrative public spending. While the first category is regarded as having a direct, positive impact on growth, the latter (i.e. the administrative spending) is regarded as GDP consuming with a negative influence on growth.

One of the biggest challenges of the extended European Union is to set up a harmonised financial policy in order to accommodate the needs of the older as well as the new member states. The challenges concern the collection of funds, the level of tax compliance, but foremost providing quality public goods under financial constraints. In addressing these issues, the main goal pursued should be the economic growth and the welfare of the citizens.

The framework to discuss these problems contains public sector governance, transparency and credibility as well as defining the public goods and their beneficiaries. In addressing these issues the EU must face cultural differences, customs and habits that define the financial behaviour of its citizens i.e. tax compliance and public funds spending. It further affects the efficiency and effectiveness of public expenditure. Of course, individuals and firms express their options for public goods according to the goods offered by the state. From the state's point of view, the individual preferences should be aggregated thus complying with the mutual interest of the community and stating an objective pursued by the community. The efficiency and effectiveness of public expenditure in the European Union are critical to outcomes, including growth. A country that spends resources in a way that does not complement private sector initiatives or in a cost-effective way will undermine its growth prospects. In the new member states, cost-overruns, poor project management, and poor maintenance of new assets result in inefficient creation and maintenance of infrastructure assets. Leakages and waste may imply that increases in health and education spending do not necessarily translate into better outcomes. Typically these reflect underlying problems of capacity for budget management and, in some cases, of governance. If institutional weaknesses and problems of governance that cause poor outcomes are not addressed, even spending on potentially high return programs will have little impact on growth. The net impact will be to erode the government's solvency and reduce its fiscal space.

Country specific conditions are therefore important in the design of fiscal policy for long-term growth. Creating fiscal space will depend on initial conditions in a country and the strengths of its public sector institutions and the likely trajectory of ongoing reforms to improve their performance. Fiscal policy design that emphasizes the deficit but ignores the composition of spending effectively ignores an important transmission channel for the growth impact of fiscal policy. There is a rich but not uncontroversial literature, for example, on the relationship between public investment and growth. The sustainability of a fiscal deficit itself depends on the productivity of the expenditure. By allowing a fuller consideration of the growth effects of fiscal decisions, an explicit focus on the composition of expenditure would allow both stabilization and growth objectives to be addressed in more sustainable ways.

Comparing public sector in EU countries, it could be easily stated that the dimension of this sector reaches different levels. There are several old member states that have a large public sector. Those countries are mainly Sweden, Netherlands, Denmark, and Austria. In opposition to those countries are situated Eastern European countries with a smaller public sector. This situation is due to several factors. Firstly it is worth mentioning the specific financial behaviour.

Scandinavian countries but also Austria and other western countries seem to assume a higher compliance to taxes and agree a larger public sector. Consequently, the protection offered by the state in those countries to the citizens is much more important. Eastern countries but also Ireland and other western countries tried to encourage private sector for growing their economies by reducing taxes. Anyway, this is also correlated to the lower trust which people show towards public institutions in eastern countries.

Another important issue would be the composition of public expenditure and the comparison of productive and not productive public expenditures. There are countries like Sweden, Denmark, Italy but also Poland that spend important percent of their GDP for social security while others like Romania, Czech and Hungary spend little money for social security. There is also very obvious evidence that eastern European countries have small budgets for sectors like health and education but do spend more money than western countries on economical activities. The authors will present in the final paper through suggestive figures the composition of the expenditure for different countries, the differences and an analysis of the resulting effects.

The issue of the impact of public spending on welfare and growth is even more acute for the emerging economies, since the authorities, in these countries, need as many a tool as possible in order to ensure a sustainable growth. It is well known that beside the taxation tool, public spending may be an important channel to boost the economy. Since these countries are en route to harmonise their economies and living standard with the more developed countries in Europe a well proportioned mixture of private and public spending may be of valuable help. Above all, spending in education and health may be rewarding on medium and long term due to their positive impact induced on productivity.

2. The Romanian state performance beyond rhetoric

The structure of the Romanian state budget for 2008 foresees 10% of expenditures for the state administration, 19% for law and order, 7% for defence, 12% for education, 3% for health, 19% for social security, 20%for economic activities, etc.

At first sight, such a budget, structured by book, resembling a developing country, stresses non productive expenditures and economic ones. Given the decentralisation of education and health services, a smaller percentage is distributed for these activities. A significant percentage of expenditures go to social security. So, theoretically at least, there is nothing wrong with the figures stated in the budget, and its structure is not a problem *per se*. But, when corroborated with the facts in the economy and the wellbeing of the population, the budget becomes an issue.

Firstly, public services – or “services of general interest” – must be recognised not only rhetorically but also through corresponding policies as a central element of a European Social Model based on solidarity and fairness. Public service provisions in the liberalised sectors must be strengthened and implemented and where this becomes increasingly difficult, a tighter direct public control should be envisaged, including new forms of public ownership and administration. The exemption from the internal market and competition rules should apply to all public services – even if they are of an economic character. The European dimension of these services can best be served by the definition of minimum standards with upward convergence, co-operation in border regions and joint research and educational projects.

Discussing the efficiency of public services comes to a contradiction when compared to the performance indicators such as corruption, infant mortality, life expectancy, illiteracy, poverty, emigration, stability. In spite of the high percentage allocated to administration and law and order, these fields are highly inefficient given that 3 individuals out of 10 working people are enrolled in the public sector having low wages. Moreover, according to the corruption perception index (CPI), Romania ranks above the average having a CPI of 3[68], showing a high degree of rent seeking attitude among public servants. Education and health are quasi public expenditures considered as investments in human capital, able to increase productivity and wealth.

The highest percentage of these expenditures is covered by the local authorities considering that they have better knowledge of such needs. Nevertheless, the lack of effective educational programmes and further enrolment of graduated renders these expenditures highly inefficient. For primary education 9,8% of

GDP is allocated for education go to the primary education, 15% to the secondary one whilst for the tertiary education 26,2 % is allocated per student. We think that, this distribution of funds is ineffective given the low level of knowledge provided in primary and tertiary education. Moreover, tertiary education students tend to emigrate, meaning that a percentage of GDP is transferred to host countries. Therefore a higher percentage of funds should be allocated to basic education in the primary and tertiary education, whilst in the tertiary education should prevail the privately obtained funds, including research.

The heath sector is also confronted with a gross inefficiency of expenditures. There are only 20 doctors to 10000 inhabitants and 6,6 hospital beds to 1000 inhabitants. Infant mortality is still high 16,5 to 1000 living births, the mortality rate is 11,9 to 1000 inhabitants, and the life expectancy barely exceeds 71,9 year.

Poverty is another matter of concern. About 40% of the population is affected by moderate poverty, while 11% by extreme poverty (under 1 dollar per day). There are also regions with a high rate of exclusion, about 30% in the NE, for individuals above 15. Under these circumstances, more than half of the population receives a form of assistance, justifying the 20% of expenditures channeled for this purpose. The question that is raised is why isn't there rather financed inclusion, value adding programs than such ineffective forms of assistance that only deepen poverty. Corroborated with the economic expenditures it means that these aren't channeled towards efficient, expending areas, but towards loss making areas.

Conclusion

Under actual requirements, the construction of the expenditure part of the state budget is highly ineffective, a great volume of funds being absorbed by either the black holes in the economy or by nonproductive destinations. Moreover, these ineffective destinations are publicly funded, requiring a greater volume of funds each year. The manner public funds are spent influences tax compliance at great length, given that tax payers are interested in the taxation benefits, i.e. the quantity and quality of public goods and services provided by the state.

Therefore, given the limited funds the budget can make use of it is imperative that the budget be built on effective programs that may add value to the economy and sustain growth.

IMF AND INTERNATIONAL FINANCIAL ARCHITECTURE REFORM PROPOSALS

Duca Ioana

Titu Maiorescu University Bucharest, Faculty of Economic Sciences, ioana.duca@utm.ro,

Gherghina Rodica

Titu Maiorescu University Bucharest, Faculty of Economic Sciences, rodicagherghina@yahoo.com

During the past few decades, the radical changes that have occurred in the global economy – uncontrolled inflation rhythms, the growth in interest rates, the increase in foreign debts and in budget and current account deficits, financial crises – have led to the accumulation of a set of issues whose solution generates heated debates at international level and tensions among the global actors. Therefore, it is necessary to make a concerted effort at world level to rethink the International Financial Architecture, especially that of the International Monetary Fund (IMF), by adopting adequate legislative and institutional regulations.

Key words: International Financial Architecture, gradual reform, radical reform, the International Monetary Fund

1. Introduction

The current configuration of the international financial system was created before globalisation reached the size it has nowadays. In the past few years it has become obvious that the international mechanisms (the IMF, the World Bank, and the World Trade Organisation) need another „philosophy" and architecture in order for them to be valid in the new economic and political world order, their reform being imperative. In time, there were numerous critical opinions of the insufficiency, lack of action and weaknesses. Most of them targeted the International Monetary Fund. Actually, after the Jamaica Agreement, no substantial change has occurred as far as the principles guiding the activity of this organisation are concerned.

2. Criticism of the IMF activity and philosophy

The objections to the IMF and its activity can be classified into *exogenous criticism*, which is related to the technical-bureaucratic interaction of the IMF with the other institutional actors, and *endogenous criticism* which targets the political aspect of the decisions taken by the Fund and the activity performed by this institution (Toderean, O., 2002: 31).

Among the *exogenous criticisms* made in time, we can enumerate the following:

- The surveillance function is implemented asymmetrically. The IMF cannot influence the developed economies of the world, but it puts severe adjustment pressures on emerging countries. The latter are often forced to sign agreements with the IMF because such agreements are a „green light" for their entering international capital markets, which is an indirect guarantee for potential investors.
- The conditionalities included in the IMF programmes block development, diminish the economic potential and deepen social polarisation. In addition, they are imposed to countries that already have poor economic performances and that are faced with serious social problems.
- The IMF provides simplistic and universal „recipes", ignoring the peculiarities of each country's economic and social context, which require a different reform rhythm.
- The IMF often proves it lacks the pragmatic economic knowledge. Although initially the IMF was based on knowing the fact that markets often operate inadequately and concerted action at global level is necessary to ensure economic stability, nowadays, the initial Keynesian orientation was replaced in the 1980s by the *Washington Consensus*. It represents a different approach, with three pillars: fiscal austerity, privatisation and market liberalisation, namely the so-called „market fundamentalism" (Stiglitz, J. E., 2003). It generated *judgements* of the type *free markets operate more efficiently, and higher efficiency leads to the acceleration of*

economic growth. The IMF orthodoxy thus legitimated capital mobility and free trade, ignoring the role of the states in providing the necessary conditions for these to occur. As a result, many of the IMF policies through which early market liberalisation was induced by force generated not a better allocation of the resources, but a global instability, because the respective markets became vulnerable.

- The IMF programmes ignore the so-called „social contract", namely the principle which requires that the benefits and costs of the measures should be fairly allocated to social classes. In many cases, through the structural adjustment programmes – SAPs – the IMF imposed privatisation and liberalisation in a way and at a rhythm which generated very high costs for the countries which were not prepared to bear them, the IMF claiming that these costs were a part of the price that must be paid for progress.
- The lack of global financial supervision and coordination, determined by the lack of instruments necessary in limiting speculative movements (Pauly, L. W., 1994).
- The IMF is an untransparent institution, the decision-making process being opaque. We must mention, though, that after the Asian crisis, the communication process has improved visibly, the Fund's activities, missions, debates and decisions being brought to the attention of those who are interested by means of press releases, periodical reports and the permanent update of the web page.

Regarding the endogenous criticisms, the most frequent are:

- The voting system based on participation quotas is undemocratic.
- The IMF is a facade for American interests (Allais, M., 1993), contributing to the consolidation of the USA position and often serving this country's interests. Instead of being a cooperative-type institution, it changed into a super-state decision-making organism, in which the key position is held by the USA. Moreover, the IMF was not limited to its initial purpose – to strengthen global stability, but it started supporting the elitist financial community interests – many of its employees originating from banks or Wall Street (Stiglitz, J. E., 2003).
- Any form of civil society participation are excluded (the IMF does not work with NGOs).
- The process of selecting the IMF employees, especially the managers, is untrasparent, the criteria not being public.
- There are no mechanisms through which the institution can be held responsible for the negative effects or failures of the policies that were implemented.

3. IMF reform proposals

Regarding the role the International Monetary Fund should play in an international-globalised financial system configuration there is a consensus in terms of the opinions that were expressed: a reform, a new legitimacy are necessary. The IMF should become a support for the new international financial architecture. At this point, though, the advanced solutions are divergent and many of them are questionable. We can group the IMF reform proposals in two large categories:

Gradual or incremental reform proposals

They do not affect the fundamental principles in the IMF Statute. Among them we can mention:

a) The reform of the conditionality principle, in terms of an increased flexibility. Certain authors (Stiglitz, J. E., 2003) claim it must be reconsidered, replaced with the one of *selectivity* (which means that the countries which can support the respective measures will benefit from finances). On the other hand, it is necessary to approach the programmes on the long term, not on the short term as before and to grant more decision-making freedom to the benefiting countries (Leandro, J. E., Schafer, H., Frontini, G., 1999: 285-299).
b) The reform of the voting system, probably according to the UNO system – *one country – one vote*. Yet, these measures would diminish considerably the influence of most OECD countries. A proposal that is more likely to be implemented is that made by R. Gerster, which consists in increasing the minimum number of votes for each country up to 5000, instead o

250 as it has been the case so far, to which the votes assigned according to participation quotas should later be added (Gerster, R., 1993: 121-136). Recently, the IMF has announced that in April 2008, a general increase of 10% in the votes is possible, accompanied by at least a 100% increase in the basic votes. The expansion of the votes using the new formula would benefit emerging countries, allowing them to have an increased power in the organisation.

c) The implementation of an NGO collaboration pilot programme, which will improve the IMF relationship with the civil society (Scholte, J. A., 1998: 42-45).

Radical reform proposals

These deeply alter the principles and procedures underlying the IMF actions. Many of the proposals are, yet, arguable and hardly feasible, involving a change in the essence of the paradigm which supports the activity of this organism. In addition, a radical reform does not necessarily guarantee radical consequences, because there are numerous factors influencing this process. Among the noteworthy proposals, there are:

a) taking into account alternative solutions to the economic problems of the countries which request the Fund's support and assistance, in order to ensure a fair, participative and sustainable development. The selection of the reform package should be made on the basis of an IMF-assisted country partnership, not by unilaterally imposing certain conditions.

b) identifying new sources of financing for the IMF activity. Proposals envisage either levying a Tobin-type tax, or reducing the military expenditures of each state and reallocating the respective amounts or a kind of tax on the balance of trade surplus for the countries that record such a surplus.

c) transforming the IMF into a *lender of last resort*, which will stabilise financial markets, regulate the international liquidity levels, regulate the financial institutions' operation, but also act as crises manager as before, refunding the financial-banking institutions through guaranteed loans, with interest rates above the market level (Fisher, S., 1999: 85-104; Calomiris, C., 1998). The premise is that, because a central bank, regardless of how many reserves it may have, cannot financially support measures to fight crises under the conditions in which the capital account is open, this function can only be performed at a supranational level. The proposal is seen by its supporters in the spirit of the original plan designed by J. M. Keynes in 1944 at Bretton-Woods, regarding the International Clearing Union. But it is highly criticised by other authors, being considered unrealistic in the context in which the IMF is not a bank and should not be one (Coyle, D., 2005: 84), therefore it cannot create liquidities. B. Eichengreen considers that such a direction that the IMF activity would take could encourage financial actors to become involved in risky operations even more, namely they could increase *moral hazard*, despite the surveillance measures and the prudence requirements (Eichengreen, B., 2002: 99). Even under the conditions of introducing systems to guarantee commitments and assess risks, banks will still be tempted to become involved in crediting less secure projects. Certain economists recommend that, when crises occur, the function of international lender of last resort should be performed by the Central banks' Club and by the Bank of International Settlement, not by the IMF (Aglietta M., De Boissieu C., 1999).

d) Another proposal belongs to J. Sachs and it was promoted intensely after the crisis in Argentina by the former deputy managing director of the International Monetary Fund - Anne Kruger. It aims at transforming it into an *International Bankruptcy Court (*Krueger, A. O., 2002; Sachs, J., 1995). The new system would be designed following the model of the mechanisms in the USA (chapters 9 and 11 in the American law on bankruptcy), the International Monetary Fund having a bankruptcy trials supervision and administration role. The solution is not feasible for at least three reasons: firstly, because it is difficult to define what *a country's bankruptcy* would mean, and secondly the country-company parallel is faulty – a country's main objective is not profit, but social welfare, and thirdly the responsibility for the failure of macroeconomic policies in a country is associated with a group of economic actors, one cannot identify only one culprit. In addition, political agreement at international level for such an institution, whether it is about transforming the IMF or about a new one, is difficult to be reached in the near future.

e) The dissolution of the IMF and revision of Keynes's initial plan regarding the International Clearing Union, which will administer international reserves and operate with a unit of account called International Money Clearing Unit (Davidson, P., 2004: 591-605). Post-Keynesians consider that the existence of such an organism would clearly diminish the panic on the international capital markets.

f) The dissolution of the IMF, the World Bank and the Bank of International Settlement and their replacement with a single financial authority - *World Financial Authority.* This radical proposal was also made by post-Keynesan economists – J. Eatwell and L. Taylor (Eatwell J., Taylor L, 1998).

4. Final remarks

Although they can be criticised, the reform proposals previously enumerated provide a support in terms of ideas which can improved in time, leading to solutions with actual chances for implementation, but only with an adequate political support.

The need to reform the international financial architecture is acknowledged at all ideological levels, as being a priority, the initiatives and debates in this respect being numerous. In our opinion, a few measures are necessary and can be implemented gradually, in order to ensure their effectiveness. We should not overlook, though, the fact that all these endeavours aim at moving targets, given the dynamic and versatile international economic and financial environment:

- To improve the quality and relevance of the assistance provided by the IMF and also by the World Bank by means of operating major changes in the visions of these institutions. This means that both the World Bank and especially the IMF must become open, flexible and participative institutions which are not only the mirror of the distribution of power at international level.
- To reposition the IMF in the equation of the responsibilities shared by IMF and the governments of the countries benefiting from financial assistance.
- To increase the transparency of the IMF and World Bank operations, namely to implement *good governance principles* in the activity of these institutions.
- To improve the set of conditionalities (a first step was made in 2000 by adopting a new guide in this respect – *Interim Guide on Streamlining Conditionality*) and to increase the IMF responsibility for the implemented measures. The programmes will have to reach a viable compromise between the adjustment component and the economic growth one. In addition, we consider that it would be advisable to reduce the system of conditionalities to relevant aspects in the case of a financial crisis or to aspects that fall into the IMF expertise.
- To improve the intervention systems in the case of financial crisis, by means of ensuring the necessary mechanisms and resources. After the events in Asia in 1997 the Supplemental Reserve Facility (SRF) was introduced for interventions in case of market confidence crises and the Contingent Credit Lines (CCL) in 1999 aimed at counteracting the contagion effects. The introduction is being debated of a new liquidity instrument and the characteristics it should exhibit, meant for the countries that have access to international capital markets and which implement firm economic policies.
- To use an Independent Assessment Office in the case of the IMF activity.
- To encourage he participation of all countries in establishing the IMF and World Bank Agenda by reforming the voting system. The distribution of votes should be established according to the relative position of that country in the world economy, but the emerging countries' right to an opinion should be strengthened. This reform could be made taking into account, for example, each country's actual GDP per capita, which would increase the participation quota of Asian countries. At the annual meeting in 2006, the IMF members agreed upon an ad-hoc increase in votes for China, South Korea, Mexico and Turkey. In the future, a new formula should be established for the participation quota and a second increase should occur for a wider range of countries.

- To create a new process for the selection of an IMF Board of Directors, according to professional performance, not nationality criteria.
- To develop an *information highway* role for this institution, which would strengthen collective confidence.

STRUCTURAL ADJUSTMENT ON THE ROMANIAN STOCK MARKET PURSUING EUROPEAN INTEGRATION

Duhnea Cristina

Ovidiu University, Constanta, Faculty of Economic Sciences, Address: 33 1 Mai Blvd, building PM2 entrance A, apartment 18, Constanta, zip 900117, Romania, cristinaduhnea@gmail.com, 0040-723519530

Abstract: The paper reviews the stages of the Romanian stock market's establishment and development, and later of structural change in pursuit of a level harmonisation with European legislation and institutions that would allow its integration into a mature market. While not perfect, the structural adjustments were successfuly finalized when Romania entered the EU, providing compatibility between the Romanian and European institutions.

Keywords: financial integration, capital market, structural adjustment, regulation, institutions

1. Stages of structural adjustments on the Romanian stock market

Romania's EU integration involved a complex process of both establishing structures essential to any functioning market economy, and overhauling those left from the comunist era. This would ensure the Romanian laws and institutions' compliance with European regulations and compatibility with EU structures. Financial services hold an important place in this context, and a transparent and liquid stock market, able to connect with the European stock market, is of the absolute essence.

In our country the stock market's foundations were layed after 1989 over certain communist left-overs. On the one hand, there was a stable national currency and an important balance of payments surplus, and on the other a super-centralized financial system, within which the banks and goods and personal insurances were state monopolies.

The events of December 1989 opened the way for the establishment of a free market and functioning economy, a development process that started from scratch, given that Romania had lacked a stock market for the last 50 years, and had no experience in the field.

In the early 90s Romania faced many stock market dillemas, over the techniques, sizing and stages of the funding process, modern portofolio management strategies, the establishing and upholding of general market principles and regulations, and also the trading techniques, crediting, guarantees, clearing and settlement of operations, and financial instruments.

The Romanian stock market's establishment and development took place during the harmonization of Romanian market institutions and legal framework with the European regulations and institutions managing the EU's financial services market. After expressing its desire to join the EU in the 90's, our country initiated a wide and complex process of alignment with European regulations and restructuring of market institutions in accordance with EU rigors.

The principal events in the stock market's evolution, marking both introduced regulations and the founding of the main market institutions, can define the following stages in the establishment and development of the Romanian stock market while pursuing EU integration:

- **1990 – 2002 - laying down a legal framework for the stock market and founding fundamental stock market institutions.** This first stage was a process of forming organizations, drafting and introducing regulations, and forming and surveying specific stock market behavior (educating operators and the general public about concepts long forgotten or never known, still an ongoing process).
- 2002 – 2004 – the first harmonization of Romanian stock market laws with European legislation. The second stage begun while the EU accession negociations were prepared and organized, and the regulatory and institutional stock market reform was launched.
- **2004 – 2006 – institutional consolidation and stock market restructuring** pursuing Romania's EU integration. The third stage opened with the passing of the **Consolidated stock market law** in 2004. It finalized the Romanian stock market structural adjustments for

integration into the European Union, and the NSC declared it finished when the Romanian stock market legislation was considered completely harmonized with current European regulations. This harmonization process defined two distinct sub-stages:

- 2004 – 2005 – the introduction of the consolidated stock market law and the secondary legislation for its implementation; architectural changes.
- 2006 – the alignment of Romanian legislation to the latest European regulations introduced after the Financial Services Action Plan was finalized.

2. The founding of the Romanian stock market and first harmonization with European regulations

The first stage in the Romanian stock market's existence was its actual establishment, in a economy that had no free securities market in the previous 50 years. The lack of market experience available at first-hand to its participants, initialy the law maker's lack of professional training and certification, made for the establishment and development of market institutions and operator categories without continuity and un-coordinated or even non-existent regulations.

We can assert that the lack of a coherent stock market legal framework enabled some participants to enter the market and operate for years at the edge of the law, gravely damaging, through fraud and lack of ethics, a sector of the economy extremely important to funding the real economy, but very sensitive to information.

Nonetheless, we must admit that, even given these defects, politic willpower on the one hand and investor interest on the other enabled within 10 years the esstablishing of all necessary institutions for a functioning stock market.

The implementation of specific stock market mechanisms and the trading of the first financial instruments on the Romanian market – shares and bonds – did not happen effortlessly.

The small number of issuers on the Bucharest Stock Exchange has been to this date an obstacle for increasing capitalization and market turnover, and it has been kept low by Romanian entities' lack of interest for listing on the exchange.

The other stock market segment – the RASDAQ Electronic Exchange – has also been established in a fashion particular for the Romanian economy, which entered an ample privatization process, creating over-night millions of „shareholders" who were unaware of or not interested in the stock market mechanisms. Its introduction on the market – also forced - has made for a tough, years long, struggle to surpass a ridiculously low trade volume and impose a market discipline for investor information and market transparency. Due to these issues, the main tier contained for a long time thousands of inactive companies, whose shares were never traded.

In this climate, there were few financial instruments offered on the Romanian market: not many firms considered an IPO, the first corporate shares issues were failures, municipal bonds didn't enter the market until 2001, and derivatives have only begun being traded in 1997-1998.

The second stage in the Romanian stock market's evolution was directly related to the intention in the '90s to become a full EU member, as soon as possible. This required Romania to enter a pre-accession process that would align its regulations and institutions with the European standards.

This process was more difficult for the stock market, than for the sectors of the economy with an actual history. The difficulties were due partly to having to conform its legislation and institutions to a mature market, with tens of years of trading, and partly to the European financial services market's own ongoing integration process, involving regulatory changes which took place in parallel with Romania's integration. This required successive legislative harmonizations for the Romanian stock market, in order to keep the pace with European regulations.

The legislative harmonization included with the 2002 regulations package brought important changes concerning market participants and operations, and as mentioned above, had no pretention to perfection, but represented a step forward for the stock market in the pre-accession process.

At the end of the secong stage, exchange institutions on the market began putting forward the ideea of consolidating th Romanian stock market. The BSE and RASDAQ set as their main goal for the next period advancing the Romanian stock market to the first positions among the Central and Eastern Europe stock exchanges. One direction toward this was identifying optimal solutions for stock market consolidation, either by a RASDAQ takeover by the BSE, as the BSE proposed, or by a merger, as proposed by the NASD. On 22nd May 2003, the RASDAQ Electronic Exchage and the Bucharest Stock Exchage made an official announcement of their intention to merge into a single, well capitalized and liquid stock exchange, with a trading system, clearing, settlement and modern register, and regulations compatible with the ones of European exchanges.

The institutions on the Romanian stock market had evolved , by the end of the stock market's second stage, to a position superior to that of their inception, with well defined structures, oriented toward qualitative goals targeting transparency and integrity, the elimination of dishonest practices like market manipulation and insider trading, and dedicated to increasing competivity on the market. Among this stage's missed accomplishments we find the failure to implement the universal bank concept, due to credit institutions unability to operate directly on the capital market, and the absence from the market of institutions imposed by the European directives, like the investors' compensation fund, even though they were included in the legislation.

3. The completion of Romania's stock market structural adjustments targeting European integration

The final stage of the capital market's structural adjustment process pursuing compliance with the European standards for the financial services market took place between 2004 and 2006, beginning with the introduction of the consolidated legislation for the capital market in 2004. We must point out that this last, finalizing stage of harmonization with European legislation and building institutional structures compatible with the European ones, happened simultaneously with the definitization, at the EU level, of the legislative framework intended to accelerate the financial integration process initiated after the Maastricht Treaty, and continued by the Financial Services Action Plan.

The review of the stock market evolution between 1990-2003 and the analysis of the stages it went through during this period leads to the conclusion that in 2004 the Romanian capital market hadn't made significant progress toward alignment to European standards, and shows that the interval leading to the integration moment should have marked major changes that would have built a Romanian stock market capable to take up the challenge of integration into the mature European financial services market.

The regulatory process on the Romanian capital market and the new market architecture achieved by restructuring some institurion and introducing new ones in accordance with Law 297/2004 demonstrates that some important progress has been made in this last stage, toward alignment to the European standards, but some unresolved issues remained, leaving the Romanian financial services market's potential only partially exploited.

Firstly, we consider that only at this stage was the concept of a market conforming with European regulation correctly defined and implemented on the Romanian capital market, and thus in January 2007 there were two regulatesd market operators : the Bucharest Stock Exchange and the Sibiu Monetary-Financial and Commodities Exchange. Secondly, the consolidated legislation for the capital market introduced the „unique European passport" concept, by regulating the authorization conditions for financial intermediaries able to provide financial services within the EU, based on the capital market authority's authorization, and the regulation of activity on the Romanian market of intermediaries authorized in other EU member states.

Thirdly, this in stage the concept of universal bank was successfuly implemented, by regulating the access of credit institutions to financial intermediation activities. This was an subject of criticism from the European Commission, as the first attempt at regulation in 2002 was a failure. After 2004, at least 10 Romanian credit institutions solicited NSC's authorization for financial services intermediation. Fourthly, we think that an important was taken toward a capital market thatguarantees investor protection, through the introduction of the Investor Compensation Fund. This institution was regulated since 2002, but it only came to reality in 2005. Although it became operational on the market the maximum compensation per investor is much lower than the 20000 Euros imposed by European regulations, and Romania asked since 2002 for a gradual increase of this ceiling.

Another positive effect of the consolidated legislation for the capital market was its unification effect on post-trading services institutions, through the establishment of a unique such institution – the Central Depository, thus aligning the Romanian market to European standards.

In our oppinion the consolidated legislation for the capital market has the merit, even with all the critiques by market participants, of defining on the Romanian market concepts such as market manipulation, insider trading, and transparency, long since consacrated on the European financial markets, but new or little known to Romanian market participants.

We also consider that the implementation of the latest regulations meant to bring the Romanian legislation up to the European standards had qualitative effects for the structure of capital market institutions, and also on educating market participants on financial instruments and the opportunities of the capital market's segments. We remark the growing preocupation for imposing stronger quality criteria for listing on a regulated market – the BSE, the beginning of diversification of financial instruments offered to the investors by the exchange (preemptive rights trading, international issuers), imposing performance criteria that led to cleansing companies traded on RASDAQ, which finished the technical support phase for trading shares of companies participating in the mass privatization program.

Educating market participants and awareness of the advantages of derivatives trading has determined a remarkable evolution for the only derivatives exchange in Romania, recording 200-300% growth in traded volume for futures and options, from 2004 until EU accession.

Considering all these aspects, we can affirm that this last stage in the Romanian capital market's structural adjustment process towards EU integration was successfuly finalized, and on 1st January 2007 Romania had a market segment able to join the other European capital markets in the complex process of financial integration still taking place in all the EU.

4. Conclusions

Going through these stages was a difficult process, both because the Romanian capital market was rebuilt from the ground up, since in 1989 it didn't exist even in an incipient form, and because of the authorities' lack of experience in creating and implementing a coherent legislation for capital markets. The market participants were thus in the position of participating to trading activities with unknown mechanisms, and using poor undestood financial instruments. These difficulties were amplified by the need to harmonizea fragmented legislation, created after anglo-saxon models, with European regulations undergoing themselves redefinitions and restructuring.

The process of harmonization of Romanian regulations with the European ones had its failures too. We find that the European regulations were transposed in Romanian legislation with excessive verbosity, with ambiguous and vagues provisions, and references to a future secondary regulation which would cover for specific issues. One cause for this was NSC's wish to declare the Romanian legislation completely harmonized with the European one, while not paying sufficient attention to signals from market participants. Thus, the entire EU regulations were transposed, not taking into consideration the Romanian market's different stage of development, shorter history and fewer experience.

The result was not perfect, but it led to a capital market that even still under development, can compete with similar European structures, and benefit from the advantages of integration into a mature market.

Abstract: In planning of this paper we have started from the question whether those 27 states belonging to the European Union are able to promote, due to their fiscal systems, the fiscal co-ordination within the European Union or to accept the fiscal systems, consequently. In this way, the paper provides a breakdown of taxes according to different classifications: by types of taxes (direct taxes, indirect taxes, social contributions) and by levels of government. The breakdown of tax revenue data computed in percentage of GDP provides indicators of the tax burden and of the structure of taxation in the different Member States, as well as developments over time. As the interpretation of the tax-to-GDP ratio as an indicator for the tax burden requires additional information, an economic classification of taxes has been developed and implicit tax rates have been computed for the economic categories identified.

Key words: tax systems, new member states, old member states, differences in tax system

1. Introduction

Taxation, by using three main sources, can make up both developments and wellbeing:

- firstly, the taxation system has to attract income effect in order that public services should be properly financed, as well as social transfer at high standards;
- secondly, taxation persuades ultimately economical judgement and it would have to offer a stimulus for the key personnel to be deeply engaged. Moreover, the natural resources, efficiently used are consequently required;
- thirdly, the taxation system undeniably redistributes gainfulness and this has to be done in such a way that to strengthen the effective request as well as social balance that is the covering of huge misuses from the income distribution.

Regarding European fiscal policy, this one has to contribute towards the accomplishment of the general goal established by the European Union, namely, “by the end of 2010 the European Union economy should become the most competitive and dynamic from the world, capable of a long-lasting economical development, displaying the best places of employment as well as a greater social cohesion” (target established by the European Council, Lisbon, March 2000). This goal demands a drastically diminishing of a fiscality general level from the EU, and, consequently, requires that the taxable basis be extended so that a balance should be achieved among this diminishing financial consolidation supporting through public debts decreasing and proper investments in essential public services.

Starting from this strategic target proposed by the official meeting in Lisbon, it has been concluded that home market should act a sole market. However, a great contradiction is to be noticed: the measures referring to taxation, the ones that develop inequality and halt the demand, are hardly supposed to achieve such an economical area with a dynamic economical growth, mentioned by the Lisbon Strategy.

Undeniably the question, whether the 27 states, members of the EU are able to contribute through their fiscal systems to the fiscal co-ordination within the EU is to be raised; in other words they have to accept the fiscal systems mandatory, systems that proved to be lately more and more distasted because of the inner logic of such fiscal competition.

The question raised is as judicious because the multinational cooperations are able to complete set of strategies of fiscal optimization provided that the capital is a mobile one.

The transfer facilitated for the profits relocation to the areas with a slight level of taxation as well as financial departments creation in so-called tax heavens/tax shelters are being used in order that investments should be financed by credit lines from the group.

2. Tax structures by type of taxes

Bearing in mind the inherent heterogeneity of tax systems, it is perhaps not surprising that there are significant differences between the new and the old Member States tax systems. The structure of tax revenues differs between new and old Member States, as the former raise relatively little revenue from direct taxation (personal and corporate income tax) and proportionately more from indirect taxation (VAT in particular) and social contributions (figure 1).

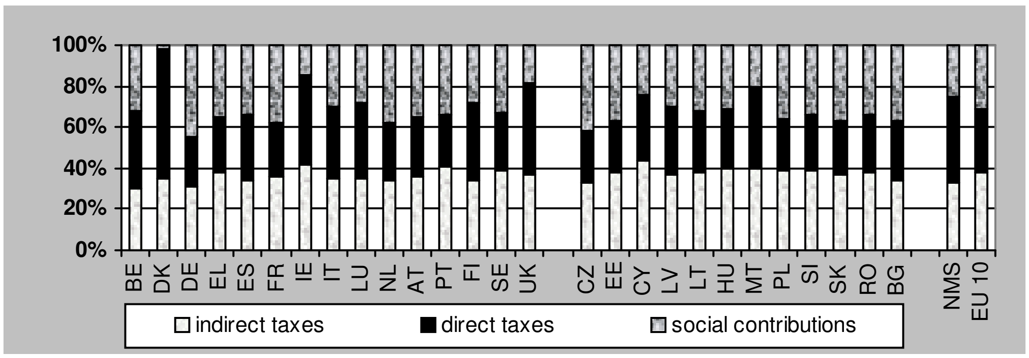

Figure 1. Structure of tax revenues, 2006 (% of total tax burdens)

Source: European Commission (2007)

In 2006, the difference between the EU-15 and the new Member States averages was about 10 percentage points (36.0% vs. 25.7%). With the exception of Malta, all the new Member States are below the EU-15 average. The lowest shares of direct taxes are recorded in Slovenia (19.8%), Poland (24.1%) and Hungary (24.2%). One of the reasons for this difference can be found in the generally lower tax rates applied in the new Member States regarding corporate tax and personal income tax. The following figures 2 and 3 however highlight the limited predictive power of the top rates viewed in isolation as neither Slovenia nor Poland particularly stand out in this respect.

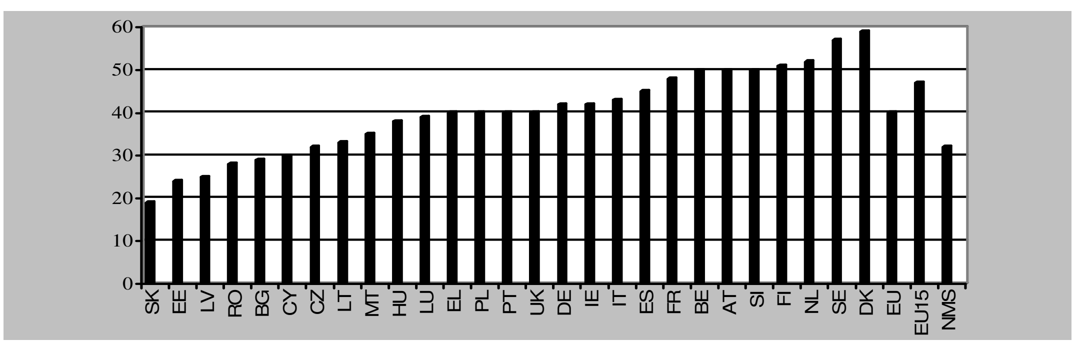

Figure 2. Personal income tax rate ,2006 (% of total tax burdens)

Source: European Commission (2007)

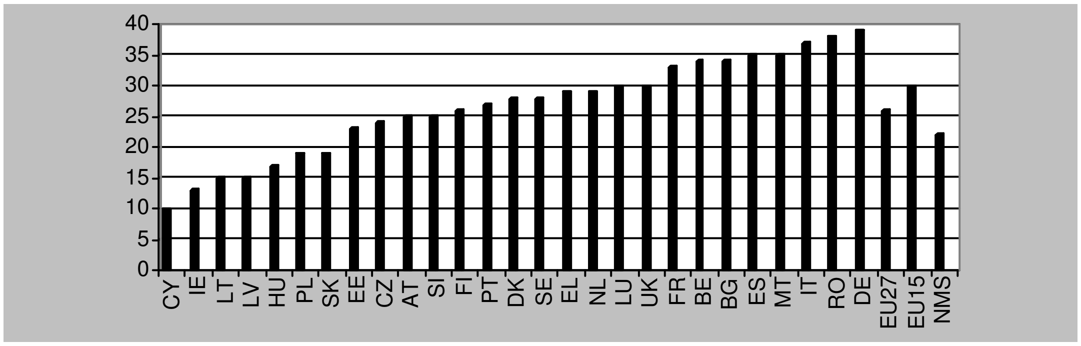

Figure 3. Corporate income tax rate, 2006 (% of total tax burdens)

Source: European Commission (2007)

The low share of direct taxes in the new Member States is counterbalanced by higher shares of social contributions (+4.2% respect to the EU-15) and indirect taxes (+5.7%) on total tax revenues; the gap between the EU-15 and the NMS-12 in the shares of social contributions had been shrinking in the last few years but increased in 2006. The highest shares of social contribution among the NMS-12 are found in the Romania, Czech Republic, Poland and Slovakia. Cyprus and Malta have the highest share of indirect taxes. Also among the EU-15 countries there are some noticeable differences, as illustrated by figure 1. The Nordic countries (Sweden, Denmark and Finland) have relatively high shares of direct taxes in total tax revenues, whereas some southern countries (in particular, Portugal and Greece) have relatively high shares of indirect taxes compared to the EU-15 average. In Denmark and, to a lesser extent, also in the United Kingdom and Ireland the shares of social contributions to total tax revenues are relatively low compared to the EU-15 average. In Denmark, most welfare spending is financed out of general taxation. The share of direct taxation to total tax revenues in Denmark is in fact the highest in the Union. Germany has the highest share of social contributions in the total tax revenues. Germany's share of direct tax revenues, on the other hand, is the lowest in the EU-15. France also has a relatively high share of social contributions and a corresponding relatively low share of direct tax revenues, compared to the EU-15 average.

3. Tax structures by levels of government

In the new ESA95 framework of national accounts, taxes are usually classified according to four different units of government that may operate within a country and to the Institutions of the European Union. The combination of the different government levels operating within a Member State is called the general government, and may include:

- Central (or federal or national) government, including all administrative departments and central agencies of the State whose competence extends normally over the whole economic territory, except for the administration of the social security funds;
- State (or regional) government, when relevant within a Member State, which are separate institutional units exercising some of the functions of government at a level below that of central government and above that at local level, except for the administration of social security funds;
- Local (or municipal) government, whose competence extends to only a local part of the economic territory, apart from local agencies or social security funds;
- Social security funds, including all central, state and local institutional units whose principal activity is to provide social benefits.

Figure 4 displays a classification of aggregate tax revenue (including social contributions) by receiving level of government.

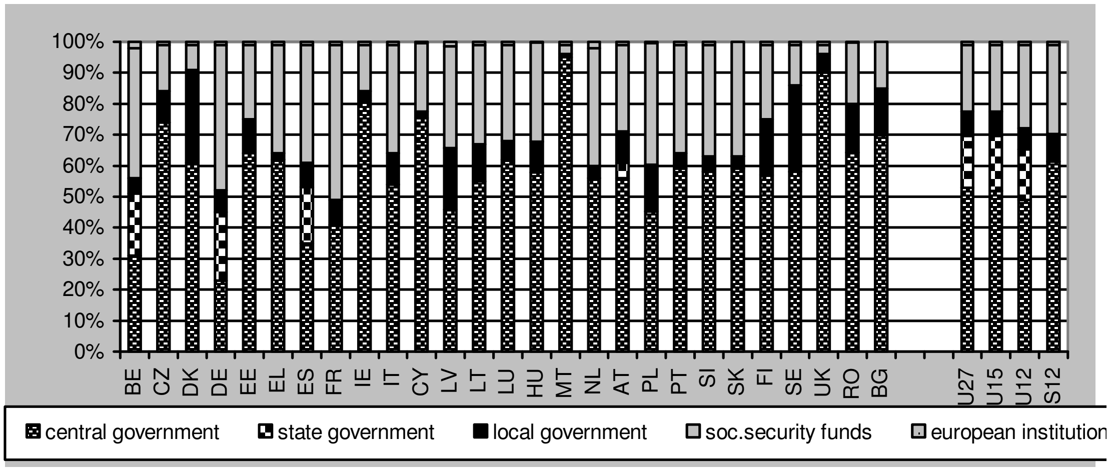

Figure 4. Classification of tax revenues, 2006, (% of total tax burdens)

Source: European Commission (2007)

The figure 4 represent "ultimately received" tax revenues. This means that the shares displayed under State and local governments do not only include 'own' taxes of government sub-sectors, but mostly also the relevant part of the tax revenue that is actually "shared" between the different levels of the general government, even in cases where a government sub-sector has practically no power to vary the rate or the base of those particular taxes.

In 2006, in the EU-15 about 56% of the "ultimately received" aggregate tax revenue (including social contributions) was claimed by the central or federal government, roughly 29% accrued to the social security funds, and around 11% to local government. Around 1% of this tax revenue is paid to the Institutions of the European Union. There are however considerable differences from one Member State to another. For instance, a few Member States have a State government level. The share of regions and municipalities varies from less than 1 % in Greece to 35% in Denmark. Not only Denmark, but also Sweden (33%), Belgium (29%), Spain (29%) and Germany (28%) show relatively high shares of total taxes received by government sub-sectors. The share is around the EU average in Austria (18%) and Italy (16%). The share is noticeably small in Greece (1%), Ireland (2%), the Netherlands (4%) and the United Kingdom (5%). Concerning social security funds, the highest shares in the EU are reported by France and Germany.

In the new Member States the State government level does not exist. Concerning local government taxation the figures vary between Malta, which does not apply local taxes, to Latvia with a share of 18%. Relatively high shares of local taxes can be seen also in Estonia (13%), Hungary (12%), Poland (13%) and Lithuania (10%). Concerning social security funds, high shares appear in Poland (40%)5, Slovakia (39%), Slovenia and Lithuania (37%).

Conclusions

The competition extension among the member states made them exceed themselves in order to attract a large number of economic operations. As it has already been shown "taxation" is one of the implements used. From this point of view, there is a sharp competition among these states, an issue which, inevitably, may cause disturbances in the assurance of the best level. Moreover, according to W. Koko, this type of conduct may lead to "such an extreme race" for taxes or income (W.Kok, 2003).

In the latest years, especially in the states from Eastern Europe, an increasing amplification has been registered regarding preferential fiscal systems promoting various investments, some of them even displaying high efficiency in attracting foreign investments.

This happens according to a well known opinion suggesting that preferential fiscal systems, the reduced taxation being included, may represent premises of an attractive location for foreign investments (G.Nicodeme, 2003).

In present, 27 taxation systems coexist in the EU, afferent to the 15 member states, plus those taxation systems belonging to the 10 new states which joined on May 1st 2004, besides Romania and Bulgaria entered the EU at the beginning of 2007.

There are noticeable differences among all these states according to their fiscal policies regulations because the national fiscal policies signify a consistent of the member states sovereignty.

The tax system inherent heterogenity being taken into account, the significant differences between the former member states do not make anybody feel surprised at such diversity in tax systems.

The structure of tax revenues differs between new and old Member States, as the former raise relatively little revenue from direct taxation (personal and corporate income tax) and proportionately more from indirect taxation and social contributions. While direct tax revenues represent more than one third on average in total revenues in EU-15, these are closer to 20% in the new Member States.

The new Member States collect less tax from the corporate sector than the old and corporate tax revenues are less important both in terms of its share of GDP and relative to other tax sources. *Corporate tax rates* are generally lower in the new Member States. While the average corporate tax rate in EU-15 is around 30%, it averages nearly 10 percentage points lower in the new Member States.

However, corporate tax rates in the new Member States vary widely, and the differences fall comfortably within the range of Ireland’s 12.5% and Germany’s rate just below the 40% mark.

Finally, while EU-15 Member States have reduced rates and have broadened tax bases since the 1980s the new Member States have cut rates more aggressively, especially since the late 1990s.

THE ROLE OF INVESTMENTS IN THE METROPOLITAN DEVELOPMENT OF PITESTI MUNICIPALITY

Sebastian Ene

Constantin Brâncoveanu University – Pitesti Calea Bascov no.2A, George_sene@yahoo.com

Mihaela Ioneci

Constantin Brâncoveanu University – Pitesti Calea Bascov no.2A

The metropolitan development represents a present issue in Romanian local communities. Romania's 1st January 2007 integration imposes a new model of economic and social development at the level of the local community. Sustainable development gets new connotations, the role of investments and community policies become the main pillars in achieving local strategic objectives.

Pitesti, a city that intends to launch a new type of development, initiated a series of activities and investments meant to contribute decisively to the accomplishment of all its goals.

Key words: social development, sustainable development, investments, development, minimax principle.

Sustainable development, a new type of post-industrial development, has been argued worldwide for over 30 years (Stockholm Conference on the Environment in 1972). On the other hand, the reference moment is represented by the United Nations Conference on Development and Environment held in Rio de Janeiro in 1992. At that time, an official document (Agenda 21 and Rio Declaration) mentioned for the first time the name and the concept of sustainable development.

Sustainability gets today new connotations (economic, ecological, social and cultural, moral and spiritual, as well as temporal). Regardless the applicability area, sustainable development cannot be done without investments. The role of an investment is that of intensifying the capacity of an economy, social and cultural sector or field. An investment implies an allocation of resources on economic principles so that the tension between needs and the possibilities of accomplishing them should be diminished at maximum. A fundamental investment on efficiency-based criteria reflects the application of a fundamental economic principle that contemporary economy should take into account: the minimax principle (minimum consumption of resources with maximum results).

National statistics place Pitesti and the neighboring areas among the most attractive economic, social and investment-related places. Located in a transit region, Piteşti was firstly developed as a market town, and then it became on e of the country's largest cities. Its economic, financial and human potential is represented by its area (4,100 hectares), by its population of more than 170,000 inhabitants, by the large number of economic agents, by the regional branches of various banks and insurance companies, etc.

The large development of Pitesti Municipality also implies a local economic development promoted by the local authorities. This attracted and will attract investors by the facilities it offers: urban infrastructure (road, water, and sewerage), social services, secondary and higher education, development of neighboring areas, environment protection etc. Sustainable economic development will have effects upon the entire local community: public authorities, private sector, and community.

A SWOT analysis of the main features of Pitesti emphasizes a series of aspects that support the metropolitan development of the city.

Strong points:

- a diversified industry with large development potential;
- increasing population not due to the birth rate but to the migration towards rural areas or less developed urban ones;
- a modern infrastructure;
- a relatively large number of pre-school educational institutions;
- the existence of some multinationals representative at international level;

- the existence of two universities that provide qualified labor force;
- an active preoccupation of local authorities for a local sustainable development;
- Pitesti – Bucharest motorway;
- the population’s purchasing power exceeds the country average;
- unemployment rate under the country average;
- foreign investment exceeding the country average.

Weak points:

- limited land area for real estate investments;
- various congested crossroads that create long waiting time;
- relatively low capitalization of some small enterprises;
- activity restructuring at S.C. Rolast S.A., S.C. Arpechim S.A.;
- insufficient green spaces;
- an insufficient number of playgrounds;
- poorly developed tourism;
- the non-arrangement of the Arges river for nautical sports;
- the low usage of the city belt road.

Opportunities:

- using various structural funds for a social and economic development;
- using various lands of Dobrogeanu Gherea, Turceşti, Zamfireşti, Baloteşti, Stadionului, Trivale for real estate development;
- building some road passages in the congested areas of the city;
- extending the industrial platform by creating the Development Area of Piteşti which should include its neighbouring villages;
- relatively qualified labor force.

Threats:

- taking over the main economic responsibilities by the neighboring areas of Piteşti due to their unexploited territorial potential;
- the foreign capital migration to more attractive areas;
- the qualified labor force migration to Bucharest or to the European Union;
- the incapacity of the current road infrastructure to face any future development.

There were permanent preoccupations for a smooth development of Piteşti at the level of the local officials, mainly in the last 8 -10 years. The efforts were intensified in 2005-2007, when important amounts from the local public budget were directed towards important investments. The following sectors were taken into consideration:

1. Investments in primary and secondary education;
2. Investments for culture, entertainment and religion;
3. Investments for housing, public services and development;
4. Investments for environment protection;
5. Investments in general economic, commercial and work activities;
6. Investments in transportation;
7. Investments regarding public order and national safety.

From the analysis of the expenses and incomes budget we found out that in 2007 they were directed to cover all investment expenses of over 43 billion lei, an important amount of money for the local level.(anexa 1)

The efforts that aim at the sustainable development of Pitesti Municipality as European Metropolis are meant to reduce the differences between our city and other similar cities in the European Union.

Setting up the investment strategic objectives implies identifying investment needs and also continuing the developing projects, so that they can support the citizens' real needs.(anexa 2)

An important problem is the identification of financing sources that could let put into practice all our proposed objectives. Undoubtedly, local public authorities will finance a part of the projects costs form their own sources (the local budget), but we have to use at maximum the capacity offered by the structural funds. Literally, any investment objective can be financed with European funds.

The main investment objectives proposed in 2007 – 2013 are:

1. ***Investments in road infrastructure*** – Possible sources of financing: the local budget by its contribution to the project and the Regional Operational Program – AXA 2.
2. ***Development and extension of the water network and the sewerage system*** **–** Possible sources of financing: the local budget by its contribution to the project and the Regional Operational Program – AXA 1 and 2; POS MEDIU – AXA 1.
3. ***Projects with impact on the environment and entertainment activities*** **-** Possible sources of financing: the local budget by its contribution to the project – POS MEDIU – AXA 1, 2, 3, 4.
4. ***Modernization of the city public transportation*** **-** Possible sources of financing: the local budget by its contribution to the project - POR AXA 2.
5. ***Investments in the public lighting network and in the electricity network*** **-** Possible sources of financing: the local budget by its contribution to the project- POS – CCE AXA 4.
6. ***Investments in education and human development*** - Possible sources of financing: the local budget by its contribution to the project – POS – DRU.
7. ***Investments in developing the administrative capacity*** - Possible sources of financing: the local budget by its contribution to the project- POS – DCA.

There is no doubt that the accomplishment of investment-based strategic objectives proposed above will lead to a harmonious development of Pitesti Municipality and will turn it into a modern, European city. The finance sources should not represent a big issue since we previously showed that there various possibilities to finance these projects with structural funds. The only thing that we have to do is to put into practice all our initiatives, to prove willingness and capacity to access such funds.

The Romanian capital market seems to continue a positive process of convergence to other European markets in terms of market indicators and market infrastructure as it benefits from harmonized regulation to best standards and practices, which stimulate growth. Mutual funds represent a very strong investment vehicle by offering investors access to the stock-exchange growth and the monetary market with less effort, money and risks than the direct investment. These investment vehicles raise a great number of questions, most of them related to their performance evaluation. The main question is whether actively managed mutual funds managers are able to add value for their investors. We will analyse in this paper Romanian mutual funds performance indicators and their evolution during the last years. Romanian mutual funds industry is poorly developed, mutual funds assets detaining an insignificant percent in the GDP.

Keywords: active management, mutual fund, performance evaluation, performance indicators

Introduction

Comparative to the situation in other member states, Romanian investment funds hold an extremely low market share in the financial intermediation institutions structure. At a global level the net active value of mutual funds has doubled in the last seven years especially due to an impressive increase in Europe and Asia. In Europe a substantial increase of almost 30% has taken place in 2006 (from $ 6 trillions in December 2005 to $ 7.7 trillions in December 2006), Europe controlling 36% of mutual funds global actives comparative to the share of 34% in 2005.

Even if in Romania the growth ratios of mutual funds actives have been very raised in the last years, there value is still extremely low in comparison to other European member states. In our opinion this is not a reason of concern since Romanian mutual funds begin to regain investor's trust and to become an attractive investment vehicle for all categories of investors. More than that Romania's integration in the UE facilitates Romanian investors' access to foreign mutual funds and raises the competition and creates the premises of an adequate functioning framework more rigorous and in the same time more flexible towards the investment policy.

At the end of 2006, UNOPC was reporting a total number of 32 open-ended funds: two monetary funds, seven bond funds, eleven balanced funds and twelve equity funds. Most of them are young funds which have started to function after the year 2000 on a small capital market, characterized by poor transactions, low liquidity, legal instability and investors' lack of trust. We will try to follow the evolution of Romanian mutual funds through performance indicators using data furnished by UNOPC in its annual reports.

Evolution of the main performance indicators

Romanian mutual funds performance indicators registered an accelerated rhythm of growth during the last years due to the positive evolution of the capital market, corroborated with the improvement of the management quality and the increase of investors' interest in these entities.

The development of financial instruments on the capital market and the enlargement of the selection area of investments for mutual funds' managers favored the introduction of strict classification criteria of these investment vehicles. Mutual funds managers operated during the last years severe portfolio' structure adjustments dictated by the increase of investors' toleration of risk and a reorientation towards the capital market after past unfortunately experiences.

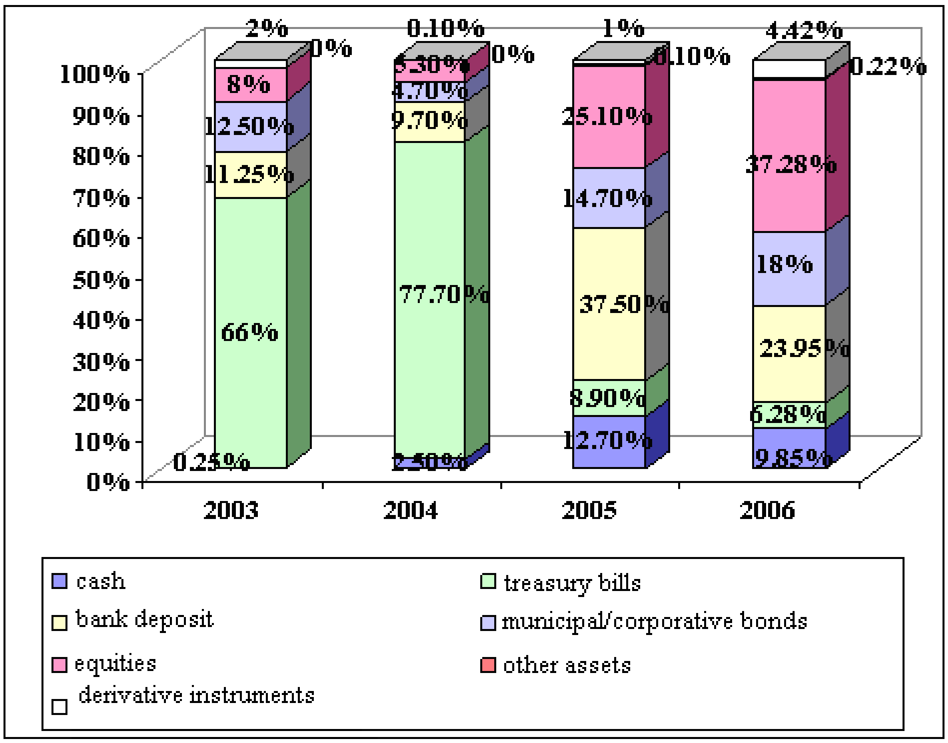
Tab. 1 The dinamic of the global portfolio structure during 2003-2006

Assets' structure	2003	2004	2005	2006
cash	0.25%	2.5%	12.7%	9.85%
treasury bills	66%	77.7%	8.9%	6.28%
bank deposits	11.25%	9.7%	37.5%	23.95%
municipal/corporative bonds	12.5%	4.7%	14.7%	18%
equities	8%	5.3%	25.1%	37.28%
derivative financial instruments	0%	0%	0.1%	0.22%
other assets	2%	0.1%	1%	4.42%

Source: UNOPC Reports at the 31 of Decembre of each year.

In 2005 and 2006 an equilibration of different assets classes weights in the global portfolio took place by the augmentation of quoted financial instruments weights to the prejudice of money markets instruments which dominated the market in the previous years.

Graph. 1 The evolution of the global portfolio structure during 2003-2006



Source:Author's processing.

Investors' preference for traded financial titles is justified both by their superior return and the decrease of interest rate for bank deposits and treasury bills. The increase of mutual funds total assets is the result of launching new funds, attracting new investors and also the result of assets value appreciation.

Tab. 2 Main indicators characterizing mutual funds performance during 2003-2006

Indicatori	2003	2004	2005	2006

Growth of net assets /investor (%)	-1,49%	110,3	41,27%	69,08%

Source: UNOPC Reports and author's calculation.

The tendency of growth of mutual funds performance indicators and especially the performance generated by these investment vehicles will lead in the following years to their confirmation as viable alternative of investing available capital. Managers of actively managed portfolios are expected to consistently outperform the index or the benchmark. In order to prove their ability in generating excess returns, managers have to rely on their past performance. Financial industry spends considerable amount of resources in measuring and ranking the performance of actively managed portfolios.

We present below the evolution of the Romanian mutual funds performance in the last four years compared to inflation rate and the growth rate of BET, which is the Romanian capital market index. The average performance is calculated as the average variation of the unitary value of mutual funds (we include all Romanian mutual funds regardless their investment policy) net assets taking into account the market share of each mutual fund.

Tab. 3 Mutual funds performance evolution during 2003-2006

Indicator	2003	2004	2005	2006
Inflation ratio1)	14,1%	9,30%	8,60%	4,90%
BET Index 2)	30,91%	101,20%	50,90%	22%
Average mutual funds performance3)	15.5%	22,34%	20,29%	12,19%

Source: 1) www.bnro.ro; *2)* www.kmarket.ro*; 3) author's calculation.*

Mutual funds average performance exceeded the inflation rate each year and was exceeded by the BET Index. This high positive variation of the market index is due to under-evaluated stocks on the market. As the capital market matured the evolution of the index stabilizes. Meanwhile mutual funds adopted a more prudent strategy and balanced their portfolios by investing in monetary instruments with low risk and return characteristics. Each mutual fund has a specified investment policy, which is described in the fund's prospectus. Equities, bonds and money market instruments are major assets categories, largely used by long-term portfolio investors. The safety of any mutual fund is determined by the fund's strategy, activities and investments. The risk is the same whether it is sold by a bank, stockbroker, financial adviser or other marketing organization.

Taking into account that BET Index is composed of the 10 most liquid stocks on the market which have also registered the highest performance, that mutual funds diversify their portfolios and that we don't expect managers to have had high selectivity capacity, the discrepancy between BET and average performance is understandable. Anyway, the declared objectives in the prospectus of each Romanian mutual fund are connected to the increase of assets' value and return exceeding the inflation rate without mentioning a target related to the capital market.

According to the funds' stated objectives, the National Union of Collective Investment Schemes, classifies them into four classes:

– Equity funds are mainly orientated to listed stocks. These funds represent a very strong investment vehicle by offering access to the stock-exchange growth. Investing in such a fund implies less effort, money and risks than the direct investment on the stock-exchange. They offer smaller investors the benefit of diversification and professional management. They include different investment styles such as growth, value or growth and value, and concentrate in alternative-sized firms, including small-cap, mid-cap and large capitalization stocks. The investment term is long and very long. The criteria of funds enclosure in this category is a minimum investment of 45% in stocks.

Tab. 4 Main indicators characterizing equity funds during 2003-2006

Indicators	2004	2005	2006
Market share	8,9%	21,3%	32,3%
Number of funds	5	8	12
Net assets (mil. lei)	18,77	72,28	204,283
Growth of net assets (%)	-	285,08%	182,63%
Number of investors	6.945	11.860	15.417
Net assests/investor (lei)	2.703	6.094	13.251
Growth of net assets /investor (%)	-	125,45%	117,44%

Source: Author's processing after UNOPC Reports at the end of each year

– Bond funds or fixed income funds that invest in long-term government, corporate or municipal bonds. The enclosure criteria is an investment of more than 90% in bonds and money market instruments. These are investments on the medium term implying small risks. They address to investors with high risk aversion and also to stock investors who aim an equilibration of the global portfolio and risk diminution.

Tab. 5 Main indicators characterizing bond funds during 2003-2006

Indicators	2004	2005	2006
Market share	12,1%	14,9%	9.7%
Number of funds	6	6	7
Net assets (mil. lei)	25,361	50,608	61,285
Growth of net assets (%)	-	99,55%	21,1%

Source: Author's processing after UNOPC Reports at the end of each year

- Balanced funds invest both in fixed income instruments and in stocks, adopting a balanced strategy in order to obtain high returns but keeping a medium risk level. They invest between 10% and 45% in stocks and the rest in fixed income instruments. They address to investors who aim performances above interest rates without exceeding a medium level of risk.

Tab. 6 Main indicators characterizing balanced funds during 2003-2006

Indicators	2004	2005	2006
Market share	22%	31,9%	37.9%
Number of funds	6	7	11
Net assets (mil. lei)	46,105	108,22	239,72

Conclusions

The Romanian mutual fund industry registered in the last years a constant growth in assets but most important is the consolidation of the market with respect to such investment. After huge frauds in the industry finally we have a law and an authority that supervises these institutions. A solid infrastructure will ensure future development of these investment companies which will have to face in the nest years a strong competition with funds from other European countries.

At European level a new regulating framework is conceived in order to simplify the functioning of investment funds whose objectives pass beyond the origin country. The 85/611/EEC Directive with the subsequent amendments, which as we have shown, created the juridical harmonized framework for facilitating cross border investment fund marketing, is being revised in order to facilitate the construction of a perfectly integrated European market for investment funds. The following aspects are aimed:

- simplifying the procedure of **launching a fund** on another member state market;
- eliminating the discrimination between contractual funds and corporative funds as far as the **company passport** is concerned (it is at present valid only for corporative funds);
- regulating the functioning of investment schemes that allow for the co administration of several member state mutual funds' assets **(entity pooling**);
- **simplifying funds prospectus**;
- a better **cooperation** between member states' supervising authorities as far as the legislative framework is concerned.

Romanian mutual funds represent a young industry with a high potential of growth in a safe profitable investment environment. Such an environment also implies a developing economy. We remark and appreciate CNVM efforts of assuring the compatibility with the highest European standards and directives in order to frame the Romanian capital market in the developing tendencies of the unique market.

THE PROBLEMATIC OF REAL VALUE ESTABLISHMENT FOR PROPERTY INSURANCE

Gavriletea Marius

Universitatea Babes Bolyai Cluj Napoca, Facultatea de Business, Horea 7 Cluj Napoca, mgavriletea@yahoo.com

Baiescu Alin

Universitatea Lucian Blaga Sibiu, Facultatea de Stiinte Economice, alinconsulting@yahoo.com

***Abstract**:"The practice of insurance is permanently confronting with a delicate problem related to the real value of property insurance. In this paper we will analyze thecorrelations between real value, insured sum and market value for motors' insurance, homeowners' insurance and insurance for stock of goods. The sum insured may genereate an adequate value for the insured object, or a subinsurance, and this fact will be put into evidence through compensation principles.also, we will present practical and technical situations in order to maintain the insured sum at the real value level, and this autimatically will generate a full compensation of any loss."*

***Keywords**: Insurance, Real Value, Sum Insured, Compensation Principles*

Introduction

A delicate problem inside the property insurance contracts is referring to the real value of the insured object. The way this value is determined depends of the type of the property: motors (or equivalent fixed assets), buildings, stock of goods. All these aspects must take into account different knowledge related to evaluation process.

All the insurance companies expect the client to insured their assets at the real value. In case there appear differences is very important to have a discussion about how this value is determined.

Literature review

In the insurance literature and also in the claims adjusting process, inside the insurance companies there are two principles of damages' compensation. The debating problem inside these two principles is the correlation between the insured sum and the real value of insured object (Motors, buildings, stock of goods).

The first principle is known as first risk principle (prim risk). No matter the real value of the insured object is the compensation of the insurance company is limited to the insured sum. In that case a partial loss is reimbursed entirely by the insurance company, and the owner of the insurance has no financial prejudice. For example if a building has a real value of 100,000 Euro and the insured sum is of 60,000 Euro we are in a traditional case of underinsurance. Using this principle any loss will be paid by the insurance company up to 60,000 Euro. So if the loss is of 3,000 Euro the compensation will be of 3,000 euro. The situation is negative for the owner of the property if the loss is a total one. In that case the reimbursement of the insurance company is only 60,000 Euro, and the owner will support the difference up to the real value of 100,000 Euro.

The second principle is the proportional compensation one. In this case the compensation from the insurance will be the report from the insured sum and the real value.

$$C = L \times \frac{S.I.}{R.V.}$$

Where C. – Compensation

L – Loss

S.I. – Sum Insured

R.V. – Real Value

Using the same presumption as in the first principle if we have a loss of 3,000 euro the compensation is:

$$C = L \times \frac{S.I.}{R.V.} = 3{,}000 \times \frac{60{,}000}{100{,}000} = 1{,}800 Euro$$

That principle is similar to a mathematical report, in our case the insurance company judge that the insured object was insured at a 60% of its real value.

Problem solution

After analyzing the insurance market we noticed that the first principle – prim risk principle, is more a theoretical one and it was used only in the beginning of the insurance markets in more developed countries. Also this principle is still used by some small insurance companies in the homeowners insurance in their expectation for insurance premiums increasing. Using such a principle is very uncomfortable for the owners just in case of total losses. But also the insurance premium is lower than for a quotation applied to the real value.

So if the quotation for block of flats insurance - whole risks is around 0.25%, if the sum insured is 60,000 Euro the insurance premium is 150 Euro per year, instead of 250 Euro per year in case of insured sum equal to the real value of 100,000 Euro. So the premium for the insurance is at a lower level and cumulated with other losses for the same type of insurance may cause financial problems in loss payment. This is why the most insurance companies used the second principle.

The second principle is very used by the insurance companies, and the fair insurance companies that followed strictly ethic principles, let their insured people know about this principle at the moment of initial payment. These differences between insured sum and real value must be explained very well and understood, because nobody desire to argue in the moment of a loss.

In this research we will focus on the real value for three types of cases: homeowners, motors and stock of goods.

In case of homeowners insurance the potential insured persons may choose the sum insured between the actual value of the building (market value) or the reconstruction value. No matter the option will be made the person will be entirely reimbursed in case of partial or total loss. In case of personal houses the market value is usually higher than the reconstruction value. The difference may be done by the land value. But the land is not insurable, so the client may choose for a lower level of sum insured. If a property has a price of 500,000 Euro and a premium quota is 0.25% – whole risks policy, the insurance premium is 1,250 Euro per year. But if the house is evaluated at 350,000 Euro and the land at 150,000 Euro there is no reason to pay insurance for the land. So the premium is only 875 Euro. The insurance company may put this aspect into evidence also. Each insurance company has theirs own evaluation systems correlated to the existed situation on the market. Moreover the insurance companies use the services of professional evaluators to determine a medium price per square meter, taking into account the location, materials and utilities of the house. In our case if the house has 250 squared meters the insured sum of 500,000 Euro (2,000 Euro/square meter) will be refused by the insurance company because is too high and we are in a case of over insurance. But if we decrease the land value, it remains 350,000 Euro (1,400 Euro/square meter) that may be close to reality of the real estate market.

The other option – the reconstruction value involve more technical issues because the owner of the house must calculate (using the initial house planning and the actual prices of the materials) the value of its components. Usually, this value is lower than the first one.

No matter these option are taken, the person is insured entirely and in case of a partial/entire loss there will be an equality between the sum insured and the real value, and the compensation is equal with loss:

$$C = L \times \frac{S.I.}{R.V.} = L$$

In Eastern European countries the real estate market is now into an ascending trend, both for the price evolution and number of the new buildings. So there appears a very probable situation that the price to increase 10-20% per half of year, and in the moment of a loss the real value of the building is 20% higher than the insured sum. Because this trend is very hard to be exactly predicted, if the insured sum was equal to real value at the beginning of the insurance policy, the insurance companies will not make any proportion in case of any type of losses.

There is in practice another situation that may generate proportional compensation principle. We refer to the case when a person insures its unfinished house. In that case the person chooses for an open insured sum at the beginning of the insurance, adjustable at every three, four or six months. The adjustment of the insured sum will take into account the added value since the last period. In case the owner refuse or forget to adjust the insured sum, in case of a loss the insurance company will reimburse him proportionally (the rapport between the insured sum and undeclared existed value).

But if the owner adjusts the insured sum, he will pay only for added value and for the remaining period.

For example the owner of the house that is building decides to make an insurance policy for an insured sum of 60,000 Euro. The insurance quota is 0.25%, so the insurance premium is 150 Euro per year. The owner agree a special clause for adjusting the insured sum at every 4 months, so after the first four months period the value of the house became 100,000 Euro.

In that case the insurance companies use the formula:

$$P' = (S.I._1 - S.I._0) \times Cp \times \frac{n}{12} = (100.000 - 60.000) \times 0.25\% \times \frac{8}{12} = 67\,Euro$$

S.I. – Insured Sum at moment 0, moment 1

Cp – Premium quota

n – Numbers of months to the end of the insurance contract

In that case, after the payment of this supplementary insurance premium, if any type of loss occurs, the insurance company pays the entire loss. The situation will be the same after the next period mentioned in the insurance contract.

Secondly we will analyze the situation existed in the motors' insurance market.

The situation is referring to the real value of the motors. In case the motor is a new one, the situation is very simple the sum insured is equal to the new value. Also, in case the motor is buy as new from a Romanian dealer in the next year the real value is determined simply by reducing the new value with the depreciation.

$R.V. = S.I. = N.V. - D.$

R.V. – Real Value

S.I. – Sum Insured

N.V. – New Value

D. – Depreciation – determined by actuarial departments of each insurance company

In that case if a loss occurs the compensation will be entirely.

The same formula operates also in case of used motors (imported used motors) but there is a very important aspect related to the establishing of the new value. The insurance agents must identify in the specialized catalogues (APIA, Schwacke, Nuts) the new value taking into account the model of the motor and existing features (cube centimeters, power, model, additional options etc.). After this step the real value is determined very simple:

$R.V. = N.V. - D.$

There appear a difficult moment is insurance negotiation when the potential client find the real value of the motor, that may be 10-15% higher than the price he paid for it. In many cases the market value of a motor on the Romanian second hand market, or the value of a used motor imported from other countries are lover than the real insurance value.

So if the market price of a used car (let assume 3 years old) is 15,000 Euro and the new value determined from the specialized catalogues is 24,000 Euro and the depreciation is 30%, the real value is:

$R.V. = N.V. - D. = 24{,}000 - 30\% \times 24{,}000 = 16{,}800\,Euro$

The percentage quota for full insurance is 7% and in that case the insurance premium is of:

- 1,176 Euro per year if the insured sum is equal to the real value or
- 1,050 Euro per year if the insured sum is equal to the market value

As we notice there is a difference between the insurance premiums of 126 Euro per year.

In case the owner of the motor agrees the insured sum propose by the insurance company in case of any loss the compensation will be entirely.

In case the option will be for an insured sum equal to the market value in the compensation process there will be applied the proportional principle. So if we assume the client has a minor loss of 1,000 Euro the compensation is:

$$C = L \times \frac{S.I.}{R.V.} = 1{,}000 \times \frac{15{,}000}{16{,}800} = 893 Euro$$

The owner of the car will support the difference of the 107 Euro.

This situation will be very delicate in the moment of the loss, so the most famous insurance companies in the Romanian market refuse to insure a car at the market value, in that case they eliminate from the beginning the potential negative situations in case of losses.

The other insurance companies accept the market value as an insured sum and worse; they don't explain what this value implies. So in the moment of the loss appearance they will make a proportional compensation, and definitely the client will be unsatisfied.

It is generally known that after each loss the insured sum is depreciated with the loss value. So the insurance will continue for a reduced insured sum:

$$R.I.S. = S.I. - L.$$

R.I.S. – Reduced Insured Sum

L. – Loss

So if the Insured Sum is of 20,000 Euro and the loss is 1,500 Euro, the Reduced Insured Sum is of 18,000 Euro. In that case we fall in the situation of o potential proportional principle because the new insured sum is lower than the real value,

$R.I.S. \triangleleft R.V.$, and any loss is paid:

$$C = L \times \frac{R.I.S.}{R.V.}$$

This is also an inconvenient for the owner of the motor that may not agree a proportional compensation in case of a future loss. In order to cancel this disadvantage the insurance company offers the possibility to pay a supplementary insurance premium:

$$Ps = L \times Cp \times \frac{n}{12}$$

Ps. – Supplementary insurance premium

L – Loss

Cp – Premium quota

n – Numbers of months to the end of the insurance contract

After the payment of this insurance premium the contract will continue at the real value and if there appears a loss the compensation will be entirely.

The last problem related to the real value and debated in this paper refers to the insured sum of the stock of goods and materials. The value of this insured sum includes the acquisition costs or the cost of the final product, and very important does not include the profit of the company.

The insurance companies offer two possibility of insured sum:

- Sum insured equal to a maximum stock or
- Sum insured periodically adjusted

Sum insured equivalent to maximum stock give the potential insured company to choose for the sum. The company will follow the trend of the stock in the last year, and judging after the existing flux of goods or product, may opt for a maximum value. It is very difficult to predict an exactly maximum stock for the next period and this problem may choose difficulties in claims adjusting.

In case of a loss, the insurance companies verify the accounting papers of the insured company and in case the maximum insured sum is overlapped at least one time, they will apply the proportional principle in the loss compensation.

$C = L \times \frac{I.M.S.}{M.E.S.}$, Where

C – Compensation of the loss

L – Loss occurred

I.M.S. – Insured Maximum Stock

M.E.S. – Maximum Existed Stock

If we assume that I.M.S. is 1,000,000 Euro and one time the M.E.S. were of 1,200,000 Euro and there is a fire that destroys stock in amount of 25,000 Euro, the compensation is:

$$C = L \times \frac{I.M.S.}{M.E.S.} = 25{,}000 \times \frac{1{,}000{,}000}{1{,}200{,}000} = 20{,}834 Euro$$

In case the insured company decides to increase the insured sum in the moment they realize that they exceed the maximum stock, they will pay only for the exceeded value and for the remaining months:

$$Ps = (M.E.S. - I.M.S.) \times Cp \times \frac{n}{12}$$

And if we continue our example, the quota is 0.30% and the moment when the Insured Maximum Stock is exceeded occur after 4 months from the beginning of the insurance, the supplementary premium is of

$$Ps = (M.E.S. - I.M.S.) \times Cp \times \frac{n}{12} = (1{,}200{,}000 - 1{,}000{,}000) \times 0.3\% \times \frac{8}{12} = 400 Euro$$

In case of payment, any loss occurs the compensation will be entirely.

The second option is to adjust the insured sum at a specified term (every three/four/six months). This option is benefic for the insured company because anytime a loss occurs the compensation will be entirely.

So after the mentioned period the insured sum will be increased (only if the insured sum was exceeded) and there will be paid a supplementary premium:

$Ps = (M.E.S. - I.A.S.) \times Cp \times \frac{n}{12}$, Where

I.A.S. is Insured Adjustable Stock.

Conclusions:

After these analyze in the insurance market we conclude that the real value is very important for the insured person or insured company. There is a directly connection between the real value, insured sum and the compensation principles.

For each type of property insurance (motors, homeowners, stock of goods) there are exactly solution to opt for the real value as insured sum, at the initial moment of the insurance or even during the contract, or after a loss is occurred. The insurance agents have a very important role: to explain the advantages and the methods of the real value' determination.

So in conclusion, it is recommendable to agree the real value suggested by the insurance company, because in this case the reimbursement of the loss will be entirely.

LOCAL BUDGETS' OWN REVENUES IN ROMANIA

György Attila

Bucharest University of Economics, Faculty of Finance, Assurance, Banks and Stock Exchanges, 6 Romana Square, gorgi_mc@yahoo.com, 0744114340

Local own revenues represents a very important financial issue for every local community because their dimension assure the prosperity of the municipality. The decentralization process determined a rise of own revenue number, giving the possibility to local authorities to finance more objectives in their community.

The main local own revenues are presented and analyzed in this paper, emphasizing their role in the local budgetary process. The three categories in which local own revenues were divided are: local taxes and fees, rates from income tax and other local own revenues.

Key words: own revenues, local budgets, taxes, fees

The budgetary revenues are collected to different components of the budgetary system. These revenues include taxes, fees, property incomes etc. In many cases, the amounts owed to the budget are established by law and the most frequently these become revenues in state budget or social security budgets. But there are revenues collected to different budgets and their level is established by the beneficiary public entity respecting the limits imposed by law. This are considered own revenues in Romanian budgetary system.

The main own revenues categories, in the Romanian budgetary system, can be found in the following budgets or budgetary components:

- Local budgets – in every year, the State Budget Act presents in a special annex a list with the local revenues and expenditures, some of them being own revenues that can be collected by local budgets;
- Out-local revenues and expenditures - special local fees should be administrated in distinct account, opened apart from the local budget;
- Subsidized public institutions' budgets – subsidized public institutions can collect fees for the services they supply. These fees represent their own revenues;
- Autonomous authorities' budgets – autonomous authorities collect taxes and fees established by the legal acts that settle their activity;
- Wholly auto-financed public institutions' budgets – auto-financed public institutions cover all their expenditures from own revenues obtained performing services;
- Wholly auto-financed public activities' budgets - auto-financed public activities are organized by ministries and other budgetary entities and has a separate financial regime;
- Special healthcare tax.

Local budgets' own revenues represent the main category because all local budgets have such incomes. These can be divided in three main categories:

- Local taxes and fees – taxes established by the Fiscal Code;
- Rates from income tax – the most important local revenues;
- Other local own revenues.

The Romanian local budgeting system consists of 41 county budgets and over 3,000 municipality budgets (including the General Budget of Bucharest Municipality and the six separate district level budgets corresponding to the six administrative parts of Bucharest Municipality).

Every county has tens of municipalities: cities, towns and communes. From budgetary point of view, the tasks are clearly separated by law. Sub-regional interest public expenditures are financed from county budgets and local interest public expenditures are financed from municipality budgets.

The local own revenues include the fiscal revenues (excepting the amounts of VAT transferred from the state budget) and the capital revenues. The main categories of local own revenues are presented bellow:

- Building tax
- Land tax
- Fee on means of transport
- Hotel fee
- Tax on shows
- Fee for the issuance of certificates, permits and authorizations
- Fee for using means of advertising and publicity
- Rates from income tax
- Property revenue
- Revenue from service supplies
- Fine and penalty
- Capital revenue
- Financial operations.

The local own revenues proportion in total local revenues is very variable. In many cases, the excluded amounts of VAT transferred from the state budget and subventions from other public budgets (like unemployment budget or health insurance budget) are less important than the local own revenues.

Although the variation of proportions of local own revenues is quite large, a careful analysis can light the situation. The local own revenues can be grouped into three main categories:

- Local taxes and fees – taxes established by the Fiscal Code;
- Rates from income tax – the most important local revenues;
- Other local own revenues.

1 Local taxes and fees

The Fiscal Code (Law no. 571/2003) has a special part dedicated to the local taxes and fees. This act establishes the main rules that must be respected by local authorities when set the rate of taxation.

Any person that owns a building located in Romania owes an annual tax for building. In physical persons' case, this building tax is determined using the standard rates established by the Fiscal Code. The building tax paid by physical persons varies between 3 and 38 eurocents per square meter per year. In legal persons' case the local council establishes the rate and may be between 0.5% and 1%. This rate is applied to the inventory value of the building. In the case of a building not revalued, the rate of tax will be between 5% and 10%.

Any person that owns land that is located in Romania owes an annual tax for land. The land tax is to be determined by taking into account the number of square meters of land, the rank of the locality where the land is located, and the zone and/or category of use of the land, in accordance with decisions of the local council. The land tax is not higher than 21 eurocents per square meter per year.

Any person that owns a means of transport that is required to be registered in Romania owes an annual fee for the means of transport. The tax is established separately for cars, buses, commodity transport vehicles, trailers, means of water transport, etc. This tax per year is between 2 and a few hundreds of euros.

Local authorities may introduce hotel fees by establishing a rate of the fee between 0.5% and 5% applied to the cost of the accommodation.

The organizers of artistic performances, sporting competitions or other entertainment activities in Romania have to pay tax on shows with a rate of tax between 2% and 5%.

Any person that must obtain a certificate, permit or other authorization from the local authorities must pay a fee for certificates. There are many kind of certificates issued, the most frequent are those related to urbanization certificates, construction permits or permits to carry out economic activities.

Fees for advertising and publicity services are paid by the persons that benefit from advertising and publicity services in Romania on the basis of a contract or another form of agreement. The rate of the fee is to be established by the local council and is to be between 1% and 3%.

Fees for the display of advertising and publicity regards the persons that uses a sign, display or display structure for advertising or publicity in a public place. The amount of the fee for the display of advertising and publicity is to be computed on an annual basis by multiplying the number of square meters, or fraction thereof, of the area of the advertising or publicity display by an amount established by the local council, but not more than 6 euro.

For the functioning of local public services created for the benefit of physical and legal persons, local councils, county councils and the General Council of the Municipality of Bucharest, as the case may be, may adopt special fees. The domains, in which the local authorities may adopt special fees for local public services, as well as the amount of such fees, are established in accordance with the provisions of the Law for local public finance.

2 Rates from income tax

The income tax is cashed in the state budget, but every month 88% of the amounts collected in the previous month are transferred to the local budgets: 47% goes to the budget of cities, towns and communes, 13% is transferred to the county's budget, and 22% is kept in a special account in order to balance the local budgets. To assure a correct share of amounts to every local authority, the employers should have separate fiscal codes for every working places that have more than 5 employees.

The 22% rate is divided in two categories: 27% is transferred to the county's budget and the remaining 73% goes to the local budgets of cities, towns and communes after the following rule: 80% is distributed in two stages by the director of the county's public finance directorate and 20% is distributed by the county council's president.

The director of county's public finance directorate should establish the amounts respecting the legal methodology:

1. in the first stage are eligible only that local authorities that have per capita income taxes under the county's average. The amounts established in this stage can not exceed the average value registered at county level.
2. the remaining amounts are distributed in the second stage to all the local authorities depending on their financial capacity.

Beginning with 1st of January 2009, the balance of local budgets will be made in correlation with the possibility of financing the functional expenditures with own revenues, the minimal cost and quality standards of public services offered to population, and so on.

3 Other local own revenues

Other local own revenues groups property revenues, revenues from service supplies, fines and penalties, capital revenues and revenues from financial operations.

Property revenue refers to the payments made by local authorities owned companies (such as public transport companies, sanitation companies). All the payments are made from the net profit obtained by each local level owned company. All the state owned companies have to pay to the budget at least 50% of their net profit.

Other local property revenues are represented by the concession fees and rents. If local importance public spaces are leased or rented, the fees cashed become property revenues. The most frequent leased or rented items are parking places, markets and commercial areas owned by local authorities, mortuary places in cemeteries.

There are assimilated with property revenues the entire amount that should have been returned to the local budget in previous years. The Romanian budgetary mechanisms are cash based. This is why any amount cashed in a budgetary year becomes the revenue of that year. In the case of taxes, the problems are simple because the accounts are the same. Special problems are related to the operations regarding the year-end operations that can not be completed till the 31st of December. Examples of such operations met at local level are (provided that the later operation to be different to those of former one): differences to pay back by those employees that were sent in mission and had received cash advances in the previous year, recovers of amounts spent in previous years without respecting the legislations.

In case the local public authorities supplies services that are not compulsory, they can collect fees for services in order to cover partly or entirely the cost with this service.

In this category are included also the contributions of parents for children in state owned crèches, contributions of parents for keeping up the children in social protection units, the contributions of the beneficiaries of social restaurants, fees paid for survey services.

Fines are paid to local budgets in every case natural persons are sanctioned for not respecting the law. In legal persons' case, local budgets collect only those fines that are applied by local authorities or refer to running on public roads.

Penalties refer to that amounts that should be paid by those who omitted or delayed to declare at the local authorities some legally stipulated information such us property acquisition or car acquisition.

The revenues obtained from selling the confiscated or abandoned goods represent also a separate revenue type that weight very little in a local budget.

Donations represent an extraordinary budgetary revenue category because this are collected depending of the availability of donors or sponsors to support some actions or activities developed by local authorities. Usually, donations are not included in the budget drafts, but during the execution of budget there are made changes in order to present the exact amounts cashed from donors and sponsors.

Capital revenues represent all the amounts that are cashed from selling immobile goods of local communities or financial assets owned by local authorities.

In only some local budgets we can find financial operations. These operations refer especially at loan reimbursements. Local authorities can land certain amounts to organize self-financed activities by subordinated entities. When amounts are returned, they appear as financial revenues in the local budget.

Local authorities can obtain short term loans by borrowing the necessary amounts from State Treasury or by the territorial-administrative unit's working capital. State Treasury is authorized to land those local authorities which have cash deficit deriving from discrepancies between the income and payment. These loans should be paid back in the same financial year. The second loan type supposes borrowing the amounts necessary to cover the cash deficit from the territorial-administrative unit's working capital. The local working capital is formed by cumulating annually budgetary surpluses of the local budget and is used. The available funds of the working fund shall bear interest, shall be kept in a distinct account, opened for each territorial-administrative unit, with the territorial units of the State Treasury, outside the local budget, and may be utilized, temporarily, for covering the cash deficit deriving from discrepancies between the income and expenditure of the current year, as well as for the definitive covering of the potential budgetary deficit resulting at the end of the budgetary year. The working fund may also be utilized for the financing of certain investments within the competence of the local public administration authorities or for the development of the local public services in the interest of the community.

THE IMPACT OF STATE AID ON PUBLIC DEFICIT

György Attila

Bucharest University of Economics, Faculty of Finance, Assurance, Banks and Stock Exchanges , 6 Romana Square – Bucharest, gorgi_mc@yahoo.com, 0744114340

György Adina Cristina

Competition Council, 1 Presei Libere Square – Bucharest, adinan@yahoo.com, 0744670257

The present paper comprises relevant aspects regarding the state aid and budgetary policy. The aim of the study is to examine to what extent state aid measures that distort competition can affect the budgetary deficit. In order to highlight the relation between the two indicators, we will focus on the following elements that will be developed separately:

1. State aid: concept, types of measures, policy developments;

2. General consolidated budgetary deficit;

3. Correlation between state aid and budgetary deficit in Romania and European Union.

Key words: state aid, public deficit, public budgets

State Aid : Concept

State aid is a member state's financial aid to business which meets all the criteria in Article 87(1) of the European Community Treaty. Article 87(2) of the EC Treaty declares that state aid, in whatever form, which could distort competition and affect trade by favouring certain undertakings or the production of certain goods, is incompatible with the common market, unless the EC Treaty allows otherwise.

The key criteria provided by Article 87(1) are presented below:

1. State aid is granted by state or through state resources. State resources include public funds administered by the member state through central, regional, local or other public or private bodies designated or controlled by the state. It includes indirect benefits such as tax exemptions that affect the public budget.
2. State aid favours certain undertakings or production of certain goods. It aids an undertaking, i.e. an entity engaged in an economic activity. Economic activity is activity for which there is a market in comparable goods or services. It can include voluntary and non profit making public or private bodies such as charities or universities when they engage in activities which have commercial competitors. It includes self employed traders, but generally not employees as long as the aid does not benefit the employers, private individuals or households. The aid is available to certain undertakings but not others in the member state, it selects individual business, sectors, areas, sizes of business or production of certain goods. In other words, a benefit available to all kinds of business is not state aid, but a general measure.
3. State aid constitutes an advantage granted to undertakings. These benefits can be measured using the economic methodology.
4. State aid distorts or threatens to distort competition and may affect trade between member states. Almost all selective aids will have potential to distort competition – regardless of the scale of potential distortion or market share of the aid recipient. Most products and services are traded between member states and therefore aid for selective business is capable of affecting the competitive structure inside the Community by eliminating or threatening to eliminate a competitor operating within the Community that does not benefit from the state aid measure.

The conclusion is that the existence of state aid is based on the sum of these four criteria. For a better understanding, we define the state aid function taking into account the factors presented above, namely x1, x2, x3 and x4 in this order, where:

$$f_1(x) = \begin{cases} 0, \text{if the aid is not granted through state resources} \\ \\ 1, \text{if the aid is granted through state resources} \end{cases}$$

$$f_2(x) = \begin{cases} 0, \text{if the criteria of specificity is not fulfilled} \\ \\ 1, \text{if the criteria of specificity is fulfilled} \end{cases}$$

$$f_3(x) = \begin{cases} 0, \text{if a commercial advantage is not granted} \\ \\ 1, \text{if a commercial advantage is granted} \end{cases}$$

$$f_4(x) = \begin{cases} 0, \text{if the trade between member states is not distorted} \\ \\ 1, \text{if the trade between member states is distorted} \end{cases}$$

We have: $f(x_1, x_2, x_3, x_4) = \prod_{i=1}^{4} f_i(x_i)$

As a consequence, we can have state aid if the four conditions are satisfied, that means: $f(x_1, x_2, x_3, x_4) = 1$, if $f_i(x_i) = 1$, for any value of i belonging to the interval of {1,2,3,4}.

If $f(x_1, x_2, x_3, x_4) = 0$ (for at least one value of i belonging to the interval mentioned before, the function $f_i(x_i) = 0$), there is at least one condition that is not fulfilled and, consequently, there is not state aid.

The four conditions are relevant in the state aid analyze. However, in practice, the degree of competitiveness on the relevant market can influence significantly the state aid assessment.

State aid: Types of measures

The notion of state aid doesn't only comprise contributions in the form of pure capital, but also includes tax relief, certain depreciation rules, parafiscal levies on goods imported from other member states, acquisition and sale on favourable conditions, such as the sale of real property, loans granted on favourable conditions, relief regarding interest rates, tax exemptions, price differentiations, warranties, social contributions, if certain companies or certain forms of production thereby achieve an advantage.

All these measures have a direct impact on the difference between public revenues and expenses that is budgetary deficit.

State aid: Policy developments

In the internal market with an increased competition, the member states are more inclined to grant subsidies, rather than tax exemptions. Moreover, the removal of technical barriers to trade and tax harmonization contribute to an increase in the volume of subsidies. The evaluation and the controlling mechanisms are carried out in a wider geographical perspective.

The trend registered in the last 10 years regarding the volume of state aid granted has shown a progressive decrease of this indicator. The method used to quantify the global state aid allocated by member states is known as Scoreboard Technique.

The strict control of state aid is one of the European Commission responsibility. In considering proposed state aid, the Commission is guided by criteria in published frameworks and guidelines that apply to particular aid categories or purposes and in all member states.

General consolidated budgetary deficit

The Romanian economic policies that will be implemented during the year 2008 aim to ensure the objectives accomplish that was assumed in the process of European integration. The budgetary revenues will continue the increasing trend between 2006-2007, as a result of a favourable cyclical position as well as the improvement in the collection of revenues.

The general consolidated budget comprises federal budgets, local budgets, social security budgets and others that rule financial public flows. The consolidation is required in order to avoid double records of economic operations between the components of the public budget.The items that should be eliminated are:

- the transfers between different levels of public administration,
- capital reimbursements for the account of public debt.

Correlation between state aid and budgetary deficit in European Union

Analysing the budgetary deficits registered in the member states, by means of Eurostat, and comparing the results with those obtained for state aid, we can formulate the following conclusions:

- The state aid had a general constant trend, slowly decreasing, without significant changes. The exceptions were recorded in Poland (2003) and France (1997). The general trend can be explained taking into account the Commission policy in order to control and monitor state aid. 2. State aid represents a percent of at most 5 percent of GDP. A percentage higher than 2% can cause serious macroeconomic imbalance by reducing public revenues or/and increasing public fund allocations.
- The budgetary deficit must be smaller than 3% of GDP, according to the criterion established by the Maastricht Treaty. The limit imposed hasn't determined a constant trend in the value of budgetary deficit. This is due to the differences within the fiscal policy of each member state. As a consequence, there are significant variations recorded in the trend of public deficit for the last 10 years.
- State aids imply a financial effort from state budget, local budget, social security budget, unemployment budget or health assurance budget. It is evident that budgets are affected by state aids because budgetary revenues are smaller or expenditures are higher. In this way, the deficit is higher in absence of other variable factors.

BUCHAREST STOCK EXCHANGE –EVOLUTION AND PERSPECTIVE

Grecu Eugenia

West University of Timisoara, Faculty of Economic Studies and Business Administration, e-mail:eugeniagrecu@yahoo.com

Abstract: Bucharest Stock Exchange(BSE) registers important achievements regarding the organization and regularization, but also a disatisfactory level of the activity indicators (stock indicators, transactioning volume, number and strucure of the issuers).

Keywords:capital, market, stocks, development, perspectives.

Premises of the appearance and development of capital market

The appearance and development of the Romanian capital market has been and still is influenced by decisional and economic factors. The capital market in Romania was market by the late appearance of the legal frame. The institutions tipical to the capital market have registered a series of deficiencies in the supervision and even sincopes in the functioning. The disrespect towards the share holders insuficiently informed and without investitional knowledge regarding the capital market was shown both through legislative measures as well as by the management. The functioning of the capital market was influenced by the slow rythm of privatisation, economic recession, the saving level, the investmental capacity and the investments' rhythm[1].

The saving rate has met an increasing tendency, but still insignificant and limited to a reduced segment of the population. The saving rate in Romania increases to 13% of Gross Domestic Product (GDP), half of the level registered in EU. At the same time, there has been created a hiatus between the tendency to increase the saving and its attraction so as to finance the real economy. BSE has met a permanent process of growing up, made real by increasing the number of quoted companies, the number of shares and transactional bonds, the volume of transactions and of the financial intermediators[2].

2. Contradicting evolutions at BSE

1995 is the year in which started the transactions to the Bucharest Stock Exchange, after the re-opening of this institution in Romania. From the first day of transactioning (November 20) till the end of the year had been transactioned the shares of 9 companies. We are talking about companies with most state capital, of very different sizes and importance. The investors have not benefit of dividends this year (because they are distributed in spring) and neither of increasing in the registered capital. The shares have generally evolved in a decreasing manner: from the nine listed companies five have decreased and only three have increased with insignificant results. Cumulated, the evolution of the stock exchange was of 12.75% up to the end of the year. As a beginning year for the stock exchange transactions, the year 1995 represented more a curiosity from the BSE investments point of view, without real benefit possibilities.

The stock exchange remained an anonymous institution in 1996 too. The number of listed shares increased to 17. The average output of the listed shares that was counted based on the price differences only were of -44.36%. If we add the dividends too, then it is of -43.01%. By adjusting the result with the inflation rate we obtain a total real performance of the BSE of 62.28% in 1996, performance that marks the weakest year in the stock exchange history.

In 1997, the stock exchange got out of the anonymity and registered a major qualitative step. It began a common five days a week transactioning schedule, and the number of the issuers and that of the real estate companies has accelerated the increasing and in the course of the year a number of 75 listed companies were transactioned. The first official index of BSE was launched: Bucharest Exchange Trading (BET), counted as a balanced average of the prices of 10 1st category representative shares. In Romania, the capital market registered a first period of glory in the 1st semester of the year 1997 when the prices of various shares had rapidly increased and brought big benefits to the investors. The foreign investors have invested a lot of money on the market and the prices of the shares increased spectaculously [3]; but not being sustained by economic results by the issuers, the prices dropped in the same spectacularly way.

The enthusiasm on the capital market continued a little bit longer out of inertia. The number of the listed issuers and that of the investment firms continued to increase. Thus, the number of the companies whose shares were transactioned in 1998, reached 125. But the general trend of decreasing the prices was unstoppable while the investors' interest in the stock market decreased.

The general trend of decreasing continued in 1999 too, and on the market the depressing ruled. The number of the investment firms began to decrease. The number of the transactioned issuers (138) in 1999 was higher than in the previous year. In 1999, began the fever of increasing the capital out of personal funds – 13 companies gave free shares to the share holders. Among them, important companies such as Terapia, Arctic, or Electroaparataj. The investors in the shares of the Transilvania Bank and those of Impact started to realize that these companies bring very good profit every year ; 48 shares shared dividends, but they were modest. The general trend of decreasing prices continued in 1999 too, but the balance started to move downwards; although in 1999 had been listed the SIF shares, these elements were not enough to regain the investors' interest.

In 2000, the market decreasing stopped, many shares started to increase and the interest in the stock market revived. For the first time, the number of the transactioned issuers (125) was lower than the one in the previous year. The stock market started to apply more rigorous criterion in listing, so that, in this year only two new issuers reached the stock market quota. From the 125 transactioned companies, a number of 83 ended the year with a positive output for the investors; moreover, 56 of them brought real profit over the inflation rate.29 shares brought nominal profit over 100%; six issuers gave free shares and 51 gave dividends. For the first time, the dividends started to be important for some of the issuers, and the dividends' influence in the total output of the stock market overpasses 10%. Practically, the stock market stopped from decreasing and most of the shares ended the year with a positive output on the market; As a result, it was the first year of real-positive increasing of the stock exchange from its setting up [4].

The increasing trend started in 2000 continued in 2001 too. More important, the stock market registered the second major qualitative step in its history. Among the measures adopted in 2001, there were the down-listing of a high number of unattractive issuers for the investors, the increasing of the transparence level imposed to the issuers, the beginning of the transactions with bonds and the listing of some companies with a major impact over the Romanian economy. These elements, together with the performances obtained by the stock exchange in the previous year, attracted more and more investors and the prices continued to increase [6]. The increasing was generalized out of the 110 transactioned issuers, 94 brought a positive output (out of which 76 over the inflation rate); The increasing was speeded for the 47 issuers who brought nominal profit of over 100%.

The measures taken in the previous year by the new management of the stock exchange and the performances from 2000-2001 brought up results; in 2002, BSE marked the best year in its history. As a result of the hardening of the regulations, the number of the transactioned issuers decreased to 66, while the number of the investment firms to 75. These measures have had a positive influence leading to the increasing of the trust in the investments in listed shares at BSE. The number of the municipal bond emissions listed at the stock exchange also increased, but the transactions remained sporadic. Although the legal frame of the capital market has been modernized, the stock exchange has not announced any significant events this year while the danger of stagnation began to threat the benefits expected by the investors. It seems that the investors did not notice these lacks since they had been busy with calculating their registered benefits [4]. From 75 transactioned issuers, 56 brought positive output in 2002 (out of which 52 over the inflation rate). Helped by the reduced inflation and by the performances in the past years, the BSE marked an extraordinary year; Practically, it was registered the highest real average output in the BSE history: 81%.

In 2003, the evolution of the shares listed at the stock exchange, offered reasons for joy to the investors, but this joy did not equal the one in 2002. The BET index registered an increase of only 30, 91%, much less than the one in 2002 (+119, 79%), and even less than the one 2001 (+38, 58%). Another tendency was that the capital increasing based on the re-evaluation differences, which brought great benefit in the past, disappeared. As a result, the number of own funds capital increasing operations reduced considerably. Besides these, we still have to follow the capital increasing with cash at prices below the market; neither these were many, but some of them were significant. In 2003, the importance of the dividends as income source continued to reduce itself; From the 65 companies, 27 gave dividends in 2003 based on the profits from 2002, but the benefit brought by them were not significant. Another trend was that of consolidating the issuers by fusions. 2003 is also the first year from the modern history of the stock exchange when this did not list any new issuer. For a change, the opposite trend of down-listing continued in force. All in all, in 2003 were down-listed the shares of three issuers. Although many shares increased, the investment firm registered its first year of stagnation after a period of accelerated increasing.

The year 2004 was a year of exception for the stock exchange investors and from various points of view the best year in the BSE history of after 1990. Of course, the major interest for the investors is the output offered by the shares, and from this point of view, the situation was more than satisfying: the official stock index, BET, counted as average of the prices of the most representative 10 shares listed at the stock exchange, increased with over 100% in 2004. In other words, the average profit offered by the shares listed at the stock exchange doubled the investors' money. The increasing registered in 2004 was quite surprising, if we think of the evolution in the past two years. Thus, after a 2002 excellent from all points of view, when there was registered a generalized increase of the shares and an appreciation of the BET index of 119, 8%, followed a 2003 relatively disappointing, with stable evolutions and an index increasing of only 30, 9%. In these conditions, there were fears that stock exchange (or at least the shares listed at the stock exchange at that moment) reached their potential and, lacking some issuers or new instruments, the prices of the shares would stagnate. The year 2004 contradicted this hypothesis: the BET index increased with 101, 2%, the BET-C index (counted on the basis of the prices of all shares listed at the stock exchange) with 103, 8% and the BET-FI index (counted on the basis of the SIF prices) with 115, 5% [5]. The fluctuations on the currency market made the performances of the stock exchange expressed in currency to be even better than those expressed in lei. Thus, the increase of the stock index expressed in EURO was of +111,5%, +114,1% and +127,0% for BET, BET-C, namely BET-FI. The stock exchange made the first (timid) steps towards new instruments by transactioning two preference right emissions; the bond market continued its development through new emissions; BSE registered some new interesting listings and made big steps towards the institutional consolidation through the fusion with the Rasdaq Electronic Stock Exchange. We may say that 2004 was a very good year, but with a series of new tendencies, such as: higher volatility on the market and more selective increasing [6].

2005 may be considered the SIF's year due to the spectacular increasing of the shares of the five financial investment companies. Starting with 2005, the stock exchange evolution became more agitated, due to the stronger and stronger correlation with the stock exchange from other countries.

The year 2006 was a pretty good year from the point of view of the investment on the capital market, but the performances were generally below expectations. The stars of the stock exchange (including the SIF shares) show more and more clear signs of tiredness. The BET index which expresses the average increase of the prices of the listed shares at the stock exchange, registered an increase of 22,2% in 2006 (the smallest output in the last six years), while BET-C+28,5%. The performance remains solid compared to the bank interest level at deposits, being of about three times larger than this. At the chapter positive events we may mention the conclusion of the fusion between BSE and Rasdaq, the introduction of the transactions in the margin for the spot market (shares), the successful run of two public emissions of important bonds (those of the World Bank and those of BCR), the setting up of the Central Depositary, and the successful listing of shares after concluding an initial public offer of the shares. Transelectrica (the first issuer in the field of utilities listed at the stock exchange); the initial interesting public offers are more and more attractive. As lacks in the stock exchange activity we may mention the disapproval for the fusion between BSE and Sibiu Monetary Financial and Commodities Exchange (SMFCE), the ending without success of one of the three Initial Public Offers launched (CCC Blue Telecom), the small number of new listings, not beginning in 2006 the transaction the state titles and not introducing the selling in absence.

From certain points of view, 2007 evolved in similar coordinates with 2006. The official BET index registered a positive performance of 22, 1%, and the composite index, BET-C won 32, 6%. After the fusion of the two stocks exchange (BSE and Rasdaq), the companies in the Rasdaq market became more visible. I noticed an increasing interest for these, materialized in the increasing of the price and of the transactioned volumes. The shares listed at BSE have had a constantly positive evolution in the past years; as a result, the investors searched for new challenge. They set their attention on the companies; thus, they oriented themselves towards the companies with increasing potential. Their option was for those listed on Rasdaq, since many were part of dynamic sectors or had very good actives, namely lands. This way we can explain the fact that the highest increase was hold by the RASDAQ market indexes with appreciations around 100%. The capital market registered a spectacular Initial Public Offer (IPO) – that of SNTGN Transgaz which attracted record sub-subscriptions of EUR 1, billiards and an exceptional sub-subscription order number of over 12.000. The Transgaz offer brought a new premier – the transaction of the allocation rights. The BSE derivates had no success and the spot market is still awaited at Sibiu Monetary Financial and Commodities Exchange. 2007 was also the year when the private pension system was launched in Romania, system that might have in time positive influences over the capital market. I may say that 2007 resembled 2006 from the point of view of the market evolution positive performances, higher at category II than at category I and high volatility. The SIF shares disappointed while IPO Transgaz was the most spectacular Initial Public Offer till now. In 2007, the correlation index of BSE with New York Stock Exchange(NYSE) reached 0, 52 of the maximum 1, which explains the reason for which when the market drops there, we also feel it strongly. The crisis on the sub-bonuses market extended and the negative signals on the external markets affected also BSE. The internal context proved to be a less favorable one in an international crisis.

The bigger and bigger influence that the external markets have over the evolution of the market in Bucharest marked the beginning of the year 2008 at the Stock Exchange; thus, the debuted of 2008 was an unusual one because instead of the usual increasing, in the first semester were registered massive decreasing. The average capitalization companies from the Stock Exchange have been the most hurt by the decreasing from then beginning of this year, losing between 40% and 60%, in the conditions in which the BET decreased with 30%.

Perspectives

The bad news that came from the external markets brought great decreasing at BSE. For now, the trend is negative and on short term (at the date when the work was written at the end of March 2008) new decreasing are expected. The correlation of the stock's internal local indexes with the external ones is more on the decreasing trend [4].

Still, the evolution of the stock exchange can be mainly considered as a cyclic one and it is estimated that the most expected increasing will not be long waited for; it is foreseen that BSE shall have a total stock capitalization of EUR 45 billiards at the end of 2008 (BSE + Rasdaq) and a daily average value of the transactions of EUR 30 million.

Even if the private pension funds shall start this year to invest at the Bucharest Stock Exchange, in 2008 their influence on the market shall be low due to the reduced size they will have in the first year of function. It is estimated that the weight of the foreign investments shall increase in the total of acquisitions, there will be more Initial Public Offers and the volatility shall continue to be high;

Up till now, BSE and Sibiu Monetary Financial and Commodities Exchange (SMFCE) have no success in developing themselves on each other's market. It seems that cash attracts cash; so far BSE has had no success on the market on time, although its launchment had been prepared for a long time and the panders were anxious for it.

One problem of the BSE is the little cash which can also be explained through the more reduced transactioning program compared to the developed stocks in the area that are closed after 16.00. There are wanted much more cash, more sophisticated investors but there is no way to satisfy their needs because of the lack of correlation with the external markets.

In the conditions when BSE wants to become a reference market in the East-European region, the transaction program is helpless. On the one hand, the run of the transactions during four hours daily limits the cash of the Stock. The daily average value of the transfers from BSE is of only EUR 12, 1 million, which raise questions regarding the attainment of the BSE representatives' objects for this year, of EUR 30 million. And more when we take into account that the immediate effect of a short program is the moving of the investors' interest towards long schedule markets.

Conclusions

Presently, the big economies of the world have to deal with certain economic problems and this fact may generate unfavorable effects on the capital markets and, implicitly, on the emergent markets too, which correlated as trend with the mature capital markets.

Although, under the aspect of the institutional construction, of the automatic and flexible electronic transaction technical systems, of the flexible mechanisms for forming the prices and of some regulations adjusted to the BSE and Rasdaq international standards they detached from other stocks, under other aspects they are beyond other stocks in the Central East-European are.

The number of the companies quoted at BSE and of investors is still low; despite the increase of the volume of the transactioned shares and bonds, their contribution to the optimum allocation of the financial resources is low.

THE INTEREST FOR THE MUNICIPAL BONDS

Grecu Eugenia

West University of Timisoara, Faculty of Economic Studies and Business Administration, e-mail:eugeniagrecu@yahoo.com

Abstract: The emissions of municipal bonds are a pretty recent apparition in the evolution of the Romanian capital market. The reduced level of the local administrations available funds and the impossibility to increase the local taxes so as to get higher incomes cashed by the local budgets, impose the finding of some alternative financing sources to sustain the local investment programs.

Keywords: bonds, investments, advantage, lower risk

1.The legal frame of the municipal bonds

The municipal bonds are movable values issued by the local authorities, especially cities and towns, through which are attracted funds form the capital market to finance some investment projects of local interest [1].

In the ex socialist states, the local authorities started to issue municipal bonds in 1995, Poland being the first country in the Eastern Europe in which these titles are largely used to attract financing for investments. In Romania, existed some unsuccessful attempts to launch municipal bonds, including on the international markets (Sinaia, December 1996), but the issuers did not received the necessary certificate from the Ministry of Finance.

The emissions of municipal bonds were not possible till 2001 because there had not been found the pandors to provide the security and the good development of such action, there was no legal basement to allow such operations.

According to Govern's Order(GO) 45/2003 regarding the local public finance, Art.58 (2) The instruments of the local public duty to which the local administrations have access are the value titles and the loans from banks or other credit institutions. According to the same normative act, through local public duty we understand the general debenture that must be reimbursed from the self incomes of the administrative-territorial units, according to the concluded contracts [2]. The regulation allows the municipality to create some budgets of whose execution is responsible; to plan average and long term investments based on the foreseen incomes; to establish local priorities; to finance by loans from the bank or by municipal bonds; Law 525/2002 of the capital markets regulates the emission and transaction conditions.

The emissions of municipal bonds are a pretty recent apparition in the evolution of the Romanian capital market, because they became possible only the entering in rule of Law 189/1998 regarding the local public finance, replaced in the present by Law 273/2006, completed by the Govern's Emergency Order no. 64/2007. The legal frame of the municipal bonds emissions is completed with the Capital Market Law and with Regulation CNVM no.1/2006, regarding the public offer of movable values and other financial instruments regarding the issuers and the movable values operations.

The advantages of the municipal bonds

The reduced level of the local administrations available funds and the impossibility to increase the local taxes so as to get higher incomes cashed by the local budgets, impose the finding of some alternative financing sources to sustain the local investment programs. From the point of view of the costs, of the reimbursement terms, of the easiness to obtain financing, the obligatory loans are more advantageous in comparison with the bank loans. For investors, the bonds offer an intermediary output between the shares holdings directly on the stock exchange and the bank deposits. They are also called "determinate income instruments", which refer to their coupon. Their enormous advantage to the deposits is that they are transactional on the organized markets.

In the mature markets, the volume of the transactions with bonds is bigger than the volume of transactions with shares or other derivate financial instruments. This is because the bonds market is the investment place of many investment banks and the bonds are their favorite instrument, from the corporative ones to

Eurobonds, from those issued by the local administrations to the ones issued by governs or multi-national companies or national banks, etc [4].

The bonds are always an alternative to the stock investment and to the bank deposits that is why they function quite reversely: if the stock or the interests to deposits decrease, the transactional prices of the bonds increase and vice-versa. As to the influence of the currency market, generally it is the same: when the national currency decreases in comparison with other currency, the bond market increases and vice-versa. The advantages of the bond emissions are clear both for the investors and for city halls. They both avoid the financial intermediation of the banks. The investors receive higher interests than at deposits while the city halls get cheaper loans than if they would make a bank credit [5].

3. The interest for the municipal bonds

In 2001, for the first time after the World War II, two resort-towns in Romania, Mangalia and Predeal, proclaimed their independence to the state budget for investments in the sub-structure and launched a municipal bonds emission.

For Romania, this was a premiere and this emission was also a test to see how things evolve. The interest of these bonds was counted with an arithmetic average between the active and passive interests on the interbank market - BUBID/BUBOR – at which we add 2 percentage points for the titles issued by Mangalia and 3 for those issued by Predeal. At the initial value, this represented for their first semester an interest of 36% for Mangalia and 37% for Predeal. In that moment, on the Romanian bank market, for the natural persons the interests fluctuated in the interval 26-36% for the bank deposits on three months, 27-37% at six months, and 26-38% for one year. At the state titles for the population, the interest was of 36% for six months. For the state titles for the population, the interest was of 36% for six months.

These emissions of municipal bonds were later followed by other municipalities: Zalau, Alba Iulia, Cluj-Napoca, Breaza, Bacau, Sebes, Targu Mures, and Slobozia. Presently, the interest for the municipal bonds is much below the values registered 7 years ago. Thus, for the bonds launched by Bacău at the end of the past year, the interest is variable, counted according to the interbank rate average [(BUBID$_{6M}$ + BUBOR$_{6M}$)/2] + 0,85%; at the beginning of April 2008, the average rate of interest at deposits on the interbank market at 6 months is around 10,37 %, while for Romanian Interbank Offer Rate (ROBOR), the average rate of interest for the loans given on the interbank market is of 11,12%, which means that for the Bacău municipal bonds the interest is around 11,595 %, while the deposit interest is between 7,25-8,5%.

2007 was the year of the credit titles at the Bucharest Stock Exchange. From the 16 transactioned emissions, seven started at the stock exchange in 2007. Nevertheless, the credit titles market at the Bucharest Stock Exchange is still modest even if lately, the number of bond emissions almost doubled. The values of the emissions are relatively small, in a total of LEI 182 million. Presently at BSE there are present a series of 16 municipal bonds issued by 12 city halls that decided to finance their projects with the help of the capital market. Some of them were attracted by the bonds reaching the second or even the third emission. We talk here about Alba Iulia, Bacău, Deva, and Timişoara, which all have at transaction two bonds emissions(Table1).

Table 1. Municipal Bonds(Bucharest Stock Exchange)

Although from the number point of view, the credit titles emissions listed at the Stock quota should have insured a minimum cash amount, in reality, the number of transactions with such movable values was up to the present extremely low due to the reduced value of the emissions.

Municipal bonds perspectives

Even if at first sight the total value pf the bonds emissions and of the bank credits accessed by various municipalities was low, in the past years it increased significantly. For 2006, the credit market accessed by the local municipalities reached and important amount (EUR 1,5 million), which increased in 2007 at about EUR 2 million. The market is reduced in value due to the few listings and to the small values; In the following years, the number of the municipalities to choose this solution of financing shall increase, being stimulated by the example given by those in Timisoara, Deva, or Alba Iulia, who each have at transaction two bond emissions and the money was efficiently invested in local development programs. This year, various city halls in the country announced that they want to launch bond emissions on the local capital market. If initially neither the city halls, nor the state made loans on longer terms than seven years on the capital market, in the last years, the municipalities have tried the internal market with three times bigger maturities. Together with the EU adhering, the municipalities shall have more and more work to do. The rehabilitation of the sub-structure shall benefit of the biggest structural funds, but to access them they will need their own money too [3]. The money may be obtained through bank credits or bonds. More advantageous are the municipal bonds that can be run on longer periods and which are immediately "absorbed" by the market (insurers and private pension funds) considering that the non-payment risk is almost zero. Together with the apparition of the private pension funds, it is estimated a bigger and bigger volume of bonds and long term loans. Almost 30 municipal bonds offers issued by at least 10 city halls, could be run in 2001, through the agency of the Bucharest Stock Exchange (BSE), doubled to the ones run in 2007. The municipal bonds are among the most successful titles transactioned at the Stock due to the interest over the market's average and to the investment guarantee assured by municipalities. 2008 could bring a real revivement on the bond market, in concordance with the expected increase of activity on the whole local capital market. If in the present there are run 16 bond emissions, this year we could assist at a double number, 10 new offers having already been confirmed. Till not long ago, the seven years loans made the rule with the titles issued by city halls and by the Ministry of Finance, now, the mayors or the district boards launch bonds emissions on 18-20 de years. They need to attract money on longer terms in order to co-finance the projects for which they want to attract structural funds from the European Union. Especially the sub-structure works but other big local projects too, brought on the financial market with such titles the authorities in Iaşi, Alba, Hunedoara, Timişoara, Bistriţa, Bacău, Focşani, or Târgu Mureş. The Iaşi city hall shall even launch an emission with a record value – LEI 200 million having the term in 2028. It is one of the few municipal bonds who used the bridge credit (a pre-finance of the future bond emission that allows the payment of the interest for the amounts used on the investment period only). In its turn, the Ministry of Finance shall launch in April the first state titles on ten years. These instruments shall be a reference point for other actors of the financial market too, interested in issuing bonds with higher and higher maturity. The offer for such titles becomes more and more consistent when the request shall also greatly increase in the following years. The most interested shall be the insurance companies, but mainly the administrators of the private pension funds. About to function from 2008, they will need to put the contributors' money into low risk instruments and on longer terms possible. The municipal bonds and state titles fulfill all these conditions. That is why they could attract the interest of the foreign investors who would wish to build more diversified portfolios. A benefic effect over the future outputs of the municipal bonds shall also have the cash on the market and the presence of the non-residential interested in more various investment instruments.

Moreover, the municipal bonds have the advantage of a very long running period with output over the market average, both for legal and natural persons [6]. The outputs shall be influenced by the evolution of inflation that acts for decreasing, but also by a cash price for the mobilization of the amounts on longer terms, that act for the increasing of the output.

Conclusions:

The signals were positive and we may expect that in some years all important cities in the country develop local investments based on the funds obtained from the bond emissions.

The positive evolutions both of the emission values and of maturities mark a positive and correct direction of development of the municipal debt market in which the bonds are basically used for the long term financing of the municipality needs.

The interest shown to the municipal bonds prove that the issuers consider these instruments as an efficient way of financing their investment projects, while the investors find them an instrument which offers interests superior to those existent on the bank market and with a lower risk degree in comparison to the shares on the stock exchange.

FISCAL EQUALIZATION SYSTEM IN ROMANIA

Grigore Gheorghe

Universitatea „Constantin Brancoveanu", Facultatea de Finante si Contabilitate, Calea Bascovului nr 2A, Grigore_gh@yahoo.com, Tel. +40(0)721 27 65 93

After 1990s, the countries in transition have been in a process of finding their own path for public sector democratization and construction of a sound public finance management system. This paper aims to provide an overview of the system of fiscal equalization transfers in Romania starting from the first major step of decentralization taken after the fall of the communist period and the subsequent modifications for adapting to the new environmental conditions imposed especially by the European Union perspective. Therefore, in the first section of the paper I will provide a conceptual framework addressing fiscal equalization, in the second part I will approach the intergovernmental transfers and the design of the equalization transfer process while in the third section, I will present an overview of the system and its evolution in the post-communist period and the last section will provide the concluding remarks on fiscal equalization.

Cuvinte cheie : decentralisation, fiscal equalization, intergovernmental transfers

Conceptual framework

After 1990s, the countries in transition have been in a process of finding their own path for public sector democratization and construction of a sound public finance management system and fiscal decentralization is one of major importance in the current context of public policies.

Fiscal equalization is a transfer of fiscal resources across jurisdictions with the aim of offsetting differences in revenue raising capacity or public service cost. Its principal objective is to allow sub-central governments to provide their citizens with similar sets of public services at a similar tax burden. Fiscal equalization can be seen as the natural companion to fiscal decentralization as it aims at correcting potential imbalances resulting from sub-central autonomy. (OECD 2007)

Fiscal equalization is shaped by the wider institutional framework such as size, number and geographical distribution of sub-central governments, the responsibilities and fiscal resources allocated to each jurisdiction, or the mechanics of power sharing between the central and the sub-central level. Those arrangements often form the constitutional backbone of a country and will, if ever, be difficult to change.

The main rationale for fiscal equalization is the presence of unequal economic circumstances, which produce disparities in the capacity of different regions to generate wealth and thus fiscal resources. Policies to reduce these disparities are justified by equity concerns. Specifically, it is assumed that citizens of the same country should have approximately the same access to public services independent of the place where they live.

The central government generally keeps for itself most of the revenue-raising authority and at the same time, it is typical of decentralized systems that sub-national governments are responsible for more expenditures responsibilities than they can finance. The result is that the local governments rarely have, on average, the means to finance a standard basket of local public goods and services by themselves. Equivalently, central government typically has relatively more resources than those needed to provide the public goods and services for which they are responsible.

In this context, it is clear that local governments normally depend, at least to some extent, on centrally raised revenues to balance their budgets; and additionally, it is also clear that different local governments will end up with unequal abilities to cover their expenditure responsibilities. The concept of fiscal disparities provides a useful framework to define and analyze the budget imbalances generated in a decentralized system of government. Fiscal disparity can be defined, for every level of government, as the excess of expenditure needs over fiscal capacity. Moreover, expenditure needs consist in the funding necessary to cover all expenditure responsibilities assigned to the government at a standard level of service provision; and fiscal capacity can be broadly defined as the ability of a government to rise revenues from its own sources, exerting a standard level of fiscal effort, in order to finance a standardized basket of public goods and services. In general, whenever the fiscal disparity of a unit of government is positive, then it might be said that it has no enough per capita revenues to cover its per capita needs.

The differences in per capita fiscal disparities among units of governments are called fiscal imbalances, and represent the asymmetric conditions under which the government units are financing their respective expenditure responsibilities. There are two types of fiscal imbalances. First, vertical fiscal imbalances refer to the difference in fiscal disparities between the central government and all sub-national governments. Second, horizontal fiscal imbalances refer to the differences in fiscal disparities among governments at the same level. As it can be easily seen, the existence of fiscal imbalances so defined do not arise as a result of the behavior of government units, but rather depend on the mismatch between the assigned expenditure responsibilities and revenue-raising ability of the government units. Moreover, such a mismatch will likely exist even under optimal conditions, and thus a proper measure to reduce it becomes essential to virtually all decentralized system of government.

Of course, it will always be possible to reduce fiscal disparities at the sub-national level by increasing the revenue-raising power of local governments or by decreasing their expenditure responsibilities, but these options could potentially be either inefficient or contrary to the spirit of a decentralized organization of the public sector. In order to address the problem of fiscal imbalances, it is important to recognize that their solution does not require a correction of local government incentives by changing the relative price of public goods and services, nor the imposition of any condition beyond the simple presence of a positive fiscal disparity.

Intergovernmental transfers

Intergovernmental transfers represent the basis for sub-national government financing in most developing and countries in transition. In the process of design and implementation of equalization transfers one has to consider several issues and one has to make sure that the proper equalization is used for a country depending on its specific objectives. All the elements (sub-national expenditures, revenues, transfers) are part of a whole system that should not be disregarded. Even if our main concern refers to equalization grants, it is important to notice that all types of transfers are just a part of the fiscally decentralized system, together with expenditure assignment, revenue assignment and borrowing. Intergovernmental fiscal transfers finance about 60% of sub-national expenditures in developing and transition economies and about a third of such expenditures in OECD countries (Shah : 2006, page 3).

The central government has several types of transfers available, from which a proper combination can be chosen in order to design the transfer program that better suit the objectives of policymakers. For example, intergovernmental transfers can be *conditional* or *unconditional*, depending on whether the purpose of the grant is defined/controlled by the grantor or not. Unconditional or "general purpose" grants are openly defined, and thus the recipient government can use its own discretion to decide how to use the funds. In contrast, when grants are conditional the grantor specifies the destination for which the funds must be used, and so the recipient government has less discretion over the final use of the funds(Grigore:2006, p 147).

Intergovernmental transfers can also be categorized as *lump-sum* versus *matching* grants. Lump-sum transfers are fixed in amount, and can be either conditional or for general purposes. In contrast, the amount of funds received in the form of matching grants varies proportionally with the recipient's expenditures in certain project or function: for any given funds provided by the grantor, the recipient must contribute with certain sum of money to finance the same project or function. Therefore, due to their basic structure, matching grants are essentially conditional. Additionally, matching grants can be *closed-ended* or *open-ended*, depending whether they are limited to a maximum amount or not. Clearly, lump-sum transfers are closed-ended by definition (Velasquez: 2007, pg 14).

The design of a system of equalization grants is a complex and demanding task which requires having clear objectives, transparent procedures and good data. The design of equalization transfers needs to be framed with the rest of the components of the fiscal decentralization.

The design of fiscal transfers is critical to ensuring the efficiency and equity of the local service provision and the fiscal health of sub-national governments. Shah suggests the following guidelines in designing fiscal transfers (Shah: 2006, pg 15):

- *Autonomy*–sub-national governments should have independence, flexibility in setting priorities

- *Revenue adequacy* – sub-national governments should have adequate revenues to discharge designated responsibilities.
- *Responsiveness* - the grant program should be flexible enough to accommodate unforeseen changes in the fiscal situation of the recipients
- *Equity/fairness* - allocated funds should vary directly with fiscal need factors and inversely with the tax capacity of each jurisdiction
- *Predictability* - the grant mechanism should ensure predictability of sub-national governments' shares and the grant formula to have ceilings and floors for yearly fluctuations
- *Transparency* - both the formula and the allocations should be disseminated widely, in order to achieve as broad a consensus as possible on the objectives and operation of the program
- *Efficiency* -the grant design should be neutral with respect to sub-national governments' choices of resource allocation to different sectors or types of activity
- *Simplicity* -grant allocation should be based on objective factors over which individual units have little control. The formula should be easy to understand *Incentive* - the design should provide incentives for sound fiscal management and discourage inefficient practices. Sub-national government deficits should not be covered by transfers
- *Reach* - all grant-financed programs create winners and losers. Consideration must be given to identifying beneficiaries and those who will be adversely affected to determine the overall usefulness and sustainability of the program

Equalization transfers in Romania – an overview

In order to understand the developments in fiscal equalization one has to consider the different political and economic factors which represent the backdrop of ongoing changes in fiscal relations and affect the intensity of reform performance (Slukhai: 2003, pg 14). There have been many negative developments and steps backward and the reforms are far from being completed. The mechanism of equalization are rather unstable – sudden changes take place due to shifting balance of political power between the center and sub-national entities. All post socialist countries use equalization schemes and this is due to the inherited unequal territorial allocation of industries and weak fiscal basis for local government (Slukhai 2003, pg 17)

Briefly looking into the structure of the local governments (LGs) in Romania one can notice that the local administration is organized on two tiers: counties and localities. However, there is no hierarchical relation between localities, counties and central government, each of them being politically legitimate. When decentralization was adopted immediately after 1989, being regarded as a mandatory stage on the "road towards Europe," the historical experience of local self-government was neither rich, nor very useful in the new context. Creating a functional network of local governments turned out to be both a challenge, because of the difficulties since a new system could be built up from scratch in a coherent manner (Slukhai: 2003, pg 18). Therefore, many decisions regarding the process of decentralization were taken by default rather than consciously and the results were below the expectations. However, a change is still in progress. In terms of intergovernmental fiscal relations there are a few streams of legislation that I am going to briefly mention:

- *The Law on Local Public Administration (LLPA)* adopted in 1991 and amended several times until its replacement with the new LLPA in 2001. It defines mainly the structure and attributions of the local governments at the two levels.
- *The Law on Local Public Finance (LLPF)* adopted in 1998 which is the cornerstone of the system of transfers among tiers of government, the shared taxes, the equalization grants and the municipal borrowing issues. In the same time, local governments control over their own revenues increased and the local councils were allowed to administer their own taxes. Moreover, a formula of sharing the PIT among the three tiers of government was introduced which improved the predictability of the intergovernmental finance. A system of grants equalization was introduced reducing in this way the central government's discretion in assigning sums for LGs.

- *The Emergency Ordinance 45/2003* approved by Law 108/2004 on Public Finance provided the basis for the system of intergovernmental transfers, improving the LLPF of 1998, the law that has incorporated for the first time provisions on intergovernmental transfers.
- *The Law 273/2006 on Local Public Finance*, defined the "principles, broad framework and procedures for local public finance generation, administration, commitment and use, as well as the responsibilities of local government authorities and public institutions involved in local public financing" (Article 1). The new law came into effect in 2007 and with it, a substantially revised system of inter-governmental equalization transfers (Articles 32-33 of the new law).

Until the reform from 1997-98, Romania faced a slow process of decentralization. Nations in transition engage in decentralization activities in order to increase the efficiency of the public sector being in line with Oates' theorem of decentralization (Oates 1972), to diminish the costs of public administration, to reduce horizontal disparities. Potential motivations behind this low performance could be: governments faced external pressure for reform implementation from international organizations or EU agencies providing aid – and here comes the proof for the argument made earlier that decisions were made by default, being pushed by external factors; the central government sought to dispose of some spending and therefore transferred responsibilities to lower levels; one should also consider the possible constraints that made the process go slowly: lack of managerial capabilities, fraud opportunities.

The system of fiscal equalization in 1999-2003

However, the major starting point was represented by the law adopted in 1997-98. The Law 189/14.10.1998 brought major changes in the process of decentralization. It established the transfer of responsibilities from the central government to lower tiers and defined the tasks and responsibilities of the local governments: drafting and approving the local budgets in due time, setting, and cashing in and watching the flow of the local taxes, administer efficiently the public goods, efficiently manage the financial resources, setting priorities in public expenditures (Art. 5 of the Law 189). The main revenues come from the local taxes and quotas and sums allocated from the state budget or local budgets having a specific destination. The salary tax remains the main source of revenue – the paying firm has to pay 50% towards the state budget, 40% to the local budget-local territorial administrative institution to which it belongs, and 10% goes to the county's budget. Article 10 of the law refers to fiscal equalization transfers. Different sums are allocated from the state budget towards the lower tiers. Out of the amounts allocated, 25% go to the county's budget and the rest is allocated by the county council to the municipalities, towns and communes according to some criteria pre-established in consultation with the councils from lower levels.

The system of equalization in 2003-2007

The system of intergovernmental transfers in Romania comprises a system of equalization grants (within and across counties) and a system of conditional grants. The main sources of equalization comprise a lump sum amount determined annually at the central level subject to the discretion of the central authorities and a percentage share of the revenues collected from PIT (personal income tax). The pool of funds is determined according to a rule based on pre-established (in the law) revenue sharing rates in the central government personal income tax. For instance, in 2005, the share of PIT revenues retained at the county level for equalization purposes was 22 percent.

The equalization funds determined under the discretion of central authorities are distributed to counties according to a formula with two factors:

- c*ounty fiscal capacity*, which is measured by the inverse of per capita personal income tax collections in the jurisdiction, and given a relative weight of 0.7 in the distribution formula
- *county land area* of the local jurisdiction, has a relative weight of 0.3 in the formula

Of the total amount of funds received for equalization at the county level 25 percent is retained by the county council. The law required the county councils to distribute the other 75 percent of these funds applying a formula with the following components:

- *local fiscal capacity*, which is measured by the inverse of per capita personal income tax collections in the jurisdiction, given a relative weight of 0.3

- *land area* of the local jurisdiction, given a relative weight of 0.3
- *population* of the jurisdiction, given a relative weight of 0.25
- "*other factors*" as determined by the county council, given a weight of 0.15

The current system of equalization transfers

The last Law on Local Public Finance (L 273 / 06), came into force in January 2007, and involved substantial modifications not only to the institutional arrangements in place for the disbursements of equalization transfers, but also to the formula employed in order to distribute the funds across counties and communes.

Article 32 of the Law states that 22 percent of all revenues collected from the income tax will be deposited in "a distinct account opened on behalf of the county general directorates for public finance…for equalization of local budgets." The county general directorates for public finance, the de-concentrated arm of the Ministry of Finance, thus replaces the county councils in the task of implementing the equalization amounts corresponding to every level of government (Velasquez: 2007).

The law's definition in Article 32 of a 22 percent share of PIT revenues for equalization purposes effectively sanctions the increase in transfers conducted in 2005 (from 17 to 22 percent) to offset the expected lower tax revenues from the introduction of a flat rate income tax schedule. The previous distribution formula is maintained at the county level. The funds determined annually in the national budget, are distributed by county on the basis of financial capacity (70 percent) and county surface area (30 percent).

Concluding remarks

The systems of fiscal equalization starting from 1999 onwards are characterized by an increasing complexity, instead of simplifying it more elements and steps are added which undermines the transparency and objectivity of the process. A major concern remains the formula which seems to be far from its ideal shape now being even more complex, a four variable formula. An important issue encountered refers to the interaction between county and locality officials in the process of drafting and allocating the transfer funds. Counties have to wait for the annual state budget law to be passed in order to find out the funds allocated to them and the localities in turn will have to wait for the county councils to conclude the equalization process.

Despite all the shortcomings, the reforms had also some achievements that are worth mentioning. For instance, the formula has improved in the sense that it avoids negative incentives in terms of collecting revenues. Moreover, a cap was imposed in terms of the funds withheld by the county as own budget out of the funds received for equalization purposes. However, the process is far from being complete but the important thing is that a change has emerged. In order to improve the process, I would suggest some considerable changes in terms of formula, allocation of resources, management and control of the financial statements and reporting:

- The formula needs to be simplified – the fiscal capacity should be avoided to be double used
- The flow of funds should be easier in the sense that passing through so many tiers it takes time; probably, a good option would be a direct allocation from the center to the lower tiers
- The lump sums are still established by the central government; probably, a better option would be to increase the share of PIT and make less the lump sums
- In terms of data availability, a software should be acquired in order to gather data from all levels of local governments; this would make easier the process of forecasting and would increase predictability and improve the system on the overall

However, all the changes have to consider the whole environment, including the social, economic and political conditions.

ON DETERMINING THE FINANCIAL STRUCTURE OF A TRADING COMPANY BASED ON ITS YEARLY FINANCIAL STATEMENTS

Hada Teodor

University "1 Decembrie 1918" Alba Iulia, Faculty of Science

Abstract: The present article addresses the following concepts: financial structure, financing structure, capital structure and the connection between all the three. Methodological aspects are addressed regarding advance expenditure, advance incomes, provisions included in the accounts balance as capital resources, long-term and short-term debts.

Based on a case study, a number of twenty-eight ratios are determined which will support the evaluation of the enterprise structure.

Key words: Structure, ratio, provisions, equities, permanent capitals, assets, liabilities

In Romania, yearly financial statements are regulated by O.M.F.P. 1752/2005 and its subsequent changes approved by Order no. 2374/2007.

The capital structure is defined as "the capital of a trading company which can contain ordinary shares and other types of preferred shares, bonds, capital as long-term loan. Capital structure shows the weight of each capital category in the overall used capital."[69]

Nicolae Hoanță, in the book *Finanțele firmei* (Company Finance), Economică Publishing House, 2003, defines the financial structure of a company as follows: "it refers to the size of short-term and long-term loans, to preferred shares and common stock used for company financing. Thus, capital structure is part of financial structure and thus represents the permanent funding sources of a company."

Other authors use the term of funding structure:[70] "the funding structure encompasses all elements (irrespective of their nature and deadline which determined the company to draw funding); funding structure is only defined based on medium- and long-term funding sources."

We believe these additional descriptors of the funding structure and of the financial structure to be adequate, as short-term debts are also included in the funding of a trading company. The following assets and liabilities balance published by a trading company is used for calculating structure ratios:

TOTAL ASSETS	
Permanent assets	7.774.952 lei
Circulating assets	27.336.582 lei
Expenditure in advance	961.545 lei
	36.073.079 lei
TOTAL LIABILITIES	
debts < 1 year	17.974.868 lei
debts> 1 year	569.256 lei
provisions	-
Incomes in advance	1.673.140 lei
Owners' equities	15.855.815 lei

[69] Gheorghe D. Bistriceanu, 2001, Lexicon de finanțe, bănci, asigurări, vol. III, Economică Publishing House, Bucharest, 2001,p.332.

[70] Mihaela Brânduşa Tudose, Gestiunea capitalului întreprinderii, Economică Publishing House, 2006, p.101

36.073.079 lei

Before proceeding to the calculus of the structure ratios, we consider the following:

- Expenditure in advance are considered to be elements of circulating assets;
- Provisions are "a category of intermediate resources between equities and debts; they can be considered when determining the equity size"[71];
- "incomes registered in advance are assimilated to the obligations that the trading society has toward third parties and they refer to future exercises, as they do not affect the incomes of the accounting period."[72] This point of view is considered also when determining net circulating assets, the balance position according to O.M.F.P. 1752/2005.

Based on the data in the accounts balance at 31.12.2007 and based on the profit and loss account, the structure ratios are calculated in the table below:

Financial structure ratios[73]

Name of the financial structure ratio and calculation	Current year	Normal limits
Financial stability ratios		
$R_1 = \frac{\text{permanent } capitals}{Total \text{ liabilities}}$	$\frac{16425071}{36073079} = 0{,}455$	-
$R_2 = \frac{Debts \text{ on a short term}}{\text{Total liabilities}}$	$\frac{19648008}{36073079} = 0{,}5445$	-
Financial autonomy ratios $R_3 = \frac{\text{Owners' } equities}{Total \text{ liabilities}} \times 100$	$\frac{15855815}{36073079} \times 100 = 44\%$	30%-35%
Financial autonomy ratios		-
$R_4 = \frac{Debts \text{ on a medium and long term}}{\text{Total liabilities}} \times 100$	$\frac{569256}{36073079} \times 100 = 1{,}58\%$	-
$R_5 = \frac{\text{Owners' } equities}{\text{Permanent capitals}} \times 100$	$\frac{15855815}{16425071} \times 100 = 96{,}53\%$	-
$R_6 = \frac{Debts \text{ on a medium and long term}}{\text{Permanent capitals}} \times 100$	$\frac{569256}{16425071} \times 100 = 3{,}47\%$	<50%
$R_7 \frac{Debts \text{ on a medium and long term}}{\text{owners' equities}}$	$\frac{569256}{15855815} = 0{,}0359$	>1 debt capacity is saturated
Debt structure ratios for a company

B_1. Permanent capitals composition ratios $R_8 = \frac{\text{Owners'}\textit{equities}}{\text{debts on a medium and long term}}$	$\frac{15855815}{569256} = 27{,}85$	Values close to 1
$R_9 = \frac{\text{Permanent}\textit{capitals}}{\text{debts on a medium and long term}}$	$\frac{16425071}{569256} = 28{,}85$	>2
$R_{10} = \frac{\text{Own } \textit{funds}}{\text{total financial debts}}$	$\frac{15855815}{569256} = 27{,}85$	The higher R_{10} and R_{11} are, the better the company is structured financially
B_2 Financial security ratios		
$R_{11} = \frac{\text{Permanent } \textit{capital}}{\text{Total liabilities}}$	$\frac{16425071}{36073079} = 0{,}455$	
$R_{12} = \frac{\text{Permanent } \textit{capitals}}{\text{debts on a medium and short term}}$	$\frac{16425071}{17974868+1673140} = 0{,}0836$	-
$R_{13} = \frac{\text{Permanent } \textit{capital}}{\text{immobilised } \textit{assets}}$	$\frac{16425071}{7774952} = 2{,}112$	>1
$R_{14} = \frac{\textit{debts} \text{ on a medium and long term}}{\text{owners'equities}} =$	$\frac{569256}{15855815} = 0{,}0359$	≤ 1
$R_{15} = \frac{\textit{debts} \text{ on a medium and long term}}{\text{permanent capital}}$	$\frac{569256}{16425071} = 0{,}0347$	$\leq 1/2$
B_4 Medium and long term financial balance ratios		
$R_{16} = \frac{\text{stable}\textit{resources}}{\text{invested capital}} = \frac{\text{Owners'}\textit{equities} + \text{DTL} + \text{DTM}}{\text{Ai}}$	$\frac{16425071}{7774952} = 2{,}1126$	$\xrightarrow{\textit{tends}} 1$
B_5 Medium and long term debt reimbursement capacity ratios		
$R_{17} = \frac{\textit{debts} \text{ on a medium and long term}}{\text{internal financing capacity}}$	$\frac{569256}{495805 + 686575} = 0{,}4814$	-
$R_{18} = \frac{\textit{annuities} \text{ for medium and long term debt reimbursement}}{\text{internal financing capacity}} \times 100$	$\frac{-}{1184380} \times 100 = -$	<50%
$R_{19} = \frac{\text{financial exp}\textit{enditure}}{\text{turnover}} \times 100$	$\frac{2514334}{61136536} \times 100 = 4{,}1$	-
Or $\frac{\text{financial exp}\textit{enditure}}{\text{gross profit}} \times 100$	$\frac{2514334}{495805} \times 100 = 507{,}12\%$	-

Or $\frac{\text{financial expenditure}}{\text{net profit}} \times 100$	$\frac{2514334}{101149} \times 100 = 2485{,}77$	-
C Ratios of short term assets and liabilities		
Current liquidity $R_{20} = \frac{\text{Circulating } assets}{\text{short term debts}}$	$\frac{27336582 + 96.545}{17974868 + 1673140} = \frac{28298127}{19648008} = 1{,}44$	>1
Quick liquidity $R_{21} = \frac{\text{Circulating } assets \text{ - stocks}}{\text{short term debts}}$	$\frac{28298127 - 7744059}{19648008} = 1{,}0461$	>0,5
$R_{22} = \frac{available\ assets}{\text{short term } debts}$	$\frac{552363}{19648008} = 0{,}02811$	0,35-0,65
D. Activity turnover ratios		
Ratio of economic capital profitability: $R_{23} = \frac{\text{gross } profit}{\text{economic capital}}$ [74]	$\frac{495805}{360736079} = 0{,}014$	>25%
Ratio of permanent capital profitability: $R_{24} = \frac{\text{gross } profit}{\text{permanent capital}}$	$\frac{495805}{16425071} = 0{,}0302$	-
Ratio of owners' equities profitability: (ratio of financial profitability)		
$R_{25} = \frac{\text{net } profit}{\text{owners' equities}}$	$\frac{101149}{15855815} = 0{,}0064$	-
Ratio of social capital profitability: $R_{26} = \frac{\text{net } profit}{social\ capital}$	$\frac{101149}{4945203} = 0{,}0205$	-
Ratio of share profitability: $R_{27} = \frac{\text{distributed } dividends}{\text{social capital}}$	$\frac{-}{4945203} = 0$	-
Ratio of gross operation immobilised assets $R_{28} = \frac{\text{depreciation fund}}{\text{gross operation immobilised assets}}$	$\frac{10681446}{18451235} = 0{,}5789$	-

The data presented above lead to the conclusion that the company under analysis does not fall within the normal limits for the ratios: R22, R23.

[74] Total assets were used.

The calculus of structure ratios produce information which can lead to decisions concerning the level of the company's structure and in the case in which the ratios do not fall within the normal limits, the deviations show if the companies can continue or if they have to adapt their structure to normal limits.

Jean-Piere Labille, in his book Analyse financière, Dunod Publishing, Paris, 2007, p.130 also calculates the ratio: $\frac{\text{Immobilise d } assets}{\text{Total balance}}$; thus, a "value of 50% would be ideal and it would bring harmony because ½ of the capital i mobilised in stable elements (machines, equipments, patents) and the other ½ in elements that are easily immobilised in case of need (stocks, debts, clients)".

In the example shown, this ratio has the value $\frac{7774952}{36073079} \times 100 = 21{,}55\% < 50\%$

According to the same author, the ideal balance will look like:

Immobilized assets 50%	Owners' equities 33% 1/3
Short-term assets 50%	Financial debts 33% 1/3
	Operation-based debts 33% 1/3

In the presented case study, the balance is as follows:

Immobilized assets 21.55%	Owners' equities 43.95%
	Financial **debts** 1.58%
Short-term assets 78.45%	Operation-based debts 54.47%

The structure in the presented balance is not the same with that of the ideal balance.

FINANCIAL ANALYSIS OF POLLUTION PREVENTION ACTIVITY

Horhotă Luminița

Universitatea Româno-Americană, Facultatea de Relații comerciale şi financiar bancare interne şi internaționale, Bdul Expoziției nr 1, sector 1, Bucureşti, luminita.horhota@gmail.com, Tel: 0743.55.44.51

Abstract: The concept of pollution prevention, or "P2," is emblematic of a new, proactive environmental mindset that promises more sustainable industrial management. By targeting the causes, rather than the consequences, of polluting activity, P2 seeks to eliminate pollutants at their source and thereby avoid the need to treat or dispose of those pollutants later. The P2 concept has given rise to talk of win-win opportunities in which innovation and new ways of thinking will lead to waste reduction and, at the same time, make firms money by reducing costs or stimulating new products. Unfortunately, the vision of pollution prevention as a set of win-win opportunities is somewhat at odds with actual corporate experience. While anecdotal evidence from a number of studies suggests that such opportunities exist and that many firms have pursued them, proponents say the pace of P2 is too slow and that the private sector is somehow failing to see opportunities in front of it.

Key words: pollution prevention, reducing costs, profit, ecoprofit

Pollution prevention is a challenge for the private sector because it requires diverse forms of innovation. Pollution prevention can require the redesign of products, the reconfiguration of manufacturing processes, and the realignment of supplier and customer relationships. Because innovation is difficult, often costly, and inherently uncertain, firms must also find new ways of integrating environmental concerns into the corporate planning process.

Pollution prevention, cast as both a corporate and an environmental benefit, has ignited hope in less adversarial environmental regulation. It has also created optimism in the private sector's ability to come up with low-cost solutions to their environmental problems. Unfortunately, the vision of pollution prevention as a set of win-win opportunities is somewhat at odds with perceptions of actual corporate behavior. While anecdotal evidence suggests that win-win opportunities exist, and have been pursued by many firms, there is some frustration that the pace of change is inadequate.

The idea that pollution prevention can save firms money, but that they nevertheless neglect these opportunities, colors debate over regulatory reforms geared toward pollution prevention. For some, it calls into question the desirability of regulatory reforms often associated with pollution prevention, such as regulatory flexibility. If firms cannot be counted on to make environmental improvements that save them money, the argument goes, then only the blunt instrument of command and control regulation can be counted on to get the job done. Others undoubtedly consider failures to invest in profit-making pollution prevention a further example of corporate environmental intransigence.

Another line of thinking holds that "organizational barriers" account for firms' failure to be aware of and pursue win-win investments. Organizational barriers may arise, for example, due to information barriers, accounting-based distortions, or inappropriate. For their part, corporate environmental managers tend to be more skeptical of pollution prevention's profitability. They point to regulatory barriers that reduce the financial incentive to change production processes or introduce new products with uncertain regulatory mandates. Much of this debate hinges on whether pollution prevention can actually be counted on to save firms money.

Consider the implications of evidence that companies fail to pursue pollution prevention opportunities that would profit them. First, this evidence would lend credence to the argument that regulations should mandate pollution prevention. Second, it would point toward the need to reform private sector capital budgeting, accounting, and environmental management techniques to overcome organizational barriers to P2. If, on the other hand, pollution prevention's economic benefits are overstated, a different set of issues arises for regulators and firms. If firms do not pursue pollution prevention because it is simply not profitable to do so, attention should be focused on factors that contribute to the difficulty, cost, and benefit of implementing P2 innovations. Perhaps environmental costs are not being adequately imposed on the firms creating them. Perhaps technical assistance and government R&D could be used to lower technical barriers. Or perhaps regulatory reforms should be used to lower regulatory barriers to P2 product and process changes. These issues are of central importance to the future of environmental regulation. Unfortunately, very little is known about why - in the real world - firms pursue or do not pursue pollution prevention opportunities.

First, the investment or product marketing effort had to involve a pollution prevention opportunity. Pollution prevention was defined as a new product or process that allowed for pollutant source reductions or that involved in-process recycling. Environmental benefits had to come from these types of innovations, not from new disposal or treatment methods.

Second, the investment or marketing opportunity had to be promising enough to be evaluated by the firms themselves. More specifically, the opportunity had to involve not only technical, but also financial, analysis. The financial analysis is critical. Even if a pollution prevention technology passes muster in engineering labs or environmental health and safety meetings, it will not succeed in a practical sense unless it survives a firm's strategic analysis and capital budgeting process. Strategic and financial analysis is the key corporate decision making nexus. It is the decision-making activity during which the widest variety of internal corporate expertise is brought to bear to evaluate costs, rewards, and risks. What types of information are collected? How is the information used? Since investment analysis is the principal information-processing function of a corporation, firms' investment analysis are the best place to look for answers.

Third, the investments or product had to be in some way "unsuccessful." That is, the firms chose to not invest in the product or process changes, or investment was significantly delayed, pending the resolution of market, technical, or regulatory uncertainties.

Finally, the analysis required the participating firms to provide detailed, often proprietary, data on the investments considered. Only with this level of detail was a full portrayal of the decisions possible.

One of the primary challenges to pollution prevention is the need to define and quantify the benefits of such investments. An emerging literature emphasizes the desirability of methods such as environmental cost accounting as a means to improve corporate decision making. With the identification and quantification of environment-related financial benefits, firms can be expected to make better private, and environmental, decisions. For instance, environmental accounting can highlight the way in which changes in a production process reduce future environmental compliance costs. This reveals a benefit to investment from a process change, a benefit that may not otherwise have been captured in a capital budgeting decision. The quality of environmental accounting is of clear importance, and not least to firms themselves. Are financial benefits being captured adequately?

As we evaluate firms' accounting of environment-related financial benefits and costs, it is important to distinguish between two types of questions. First, to what extent are financial benefits and costs *quantified*? Second, are environment-related financial benefits and costs, even if not quantified, being given sufficient *weight* relative to non-environmental benefits and costs? Note that the first question deals with the detail and numerical sophistication of quantitative estimation techniques - the way in which the firm determines the bottom-line impact of activities that affect the environment. The second question deals with the impact of accounting techniques on the firm's decisions. Failure to accurately quantify benefits and costs could bias investment decisions against pollution prevention.

The analysis of financial evaluation procedures has highlighted significant information barriers faced by firms. This underscores the continued importance of improved environmental cost accounting methods to better estimate environment-related financial benefits. Improved data collection, estimation, and evaluation techniques can only improve corporate decision-making. The important, and open, question for future research is: what forms of environment-related information are likely to be most valuable to the private sector?

The firms can be expected to do a relatively good job of evaluating the environmental and financial characteristics of P2 opportunities, once those opportunities are identified. Perhaps the greatest challenge for firms, however, is the initial identification of those opportunities. The technical identification of P2 opportunities may be well served by greater efforts at basic R&D and firm-specific "materials accounting." Mandated accounting requirements are of questionable value, given the idiosyncratic needs of specific firms and facilities. And confidential business information issues undermine the practicality of mandatory and publicly-disclosed P2 planning.

However, government promotion of state of the art accounting practices, including materials accounting, is likely to concretely benefit firms that are increasingly concerned with environment-related costs and opportunities.

A CLUSTER ANALYSIS OF FINANCIAL PERFORMANCE IN CENTRAL AND EASTERN EUROPE

Horobet Alexandra

The paper studies the pattern of financial performance for listed companies originating from different industries - financial intermediation, beverage and food industry, energy, pharmaceuticals and chemicals - in four Central and Eastern European countries - Czech Republic, Hungary, Poland and Romania over a four year period (2003-2006). The financial performance is addressed by taking into account companies' return on assets (ROA) and return on equity (ROE). The research methodology consists of hierarchical and k-means clustering amalgamation techniques, in order to distinguish between naturally occurring similar groups that are statistically significant in terms of industry and/or national influences. Our analysis encompasses a dynamic approach, as it refers to changes in clusters' structure in time and searches for possible explanations of corporate financial performance in this region.

Key words: financial performance, cluster, profitability, Central and Eastern Europe

1. Introduction

The research undertaken in the case of financial markets from Central and Eastern Europe is relatively recent, and it is trying, in general, to adapt the analysis already made in the case of developed markets to the region's particularities. The relative degree of novelty and the reduced number of research in this field can be explained by the recent opening of these markets towards the market economy and, consequently, by the lack of information and data necessary for the carrying of consistent and robust analysis. The use of multivariate statistical techniques such as cluster analysis, principal components analysis, discriminant analysis and factor analysis, is present in the international literature that addresses companies' financial performance. Pandit, Cook, Swann (2001) examine the cluster building mode in the financial services industry in Great Britain and study the effect of the cluster power in explaining companies' growth and their survivorship rates on the market. Fifield et al. (2002) investigate the measure in which the global and local factors can explain the returns on the emerging markets, the factors being identified through the principal component analysis. Bensmail and DeGennaro (2004) apply cluster modelling to financial data, their purpose being that of analyzing the missing data and identifying homogenous groups in the interior of the available data. Having a flexible approach and working with complex data structures in the case of missing quantitative and qualitative observations, the authors include the data in a new structure that does not depend on the hypothesis connected to the traditionally necessary distributions for choosing homogenous groups of observation. Dhankar and Singh (2005) use principal components analysis to estimate the factors that influence the returns on the Indian capital market, while Sueyoshi (2005) compares the financial performances of a number of 147 companies without financial difficulties with those of 24 companies in the American energy industry, using non-parametric discriminant analysis, which assigns a set of weights to a linear discriminating function that consequently generates a score regarding its belonging to a group. Ganesalingam and Kumar (2001) use a set of financial indicators for 71 companies from the Australian capital market to determine the chances of success of an investment made in these companies. The authors identify a discrimination rule between the companies and a series of factors that explain the profitability of the companies, which is afterwards used to predict the companies's stability and to build diversified portfolios.

The purpose of our research is to identify sector groups that are natural, and at the same time significant, of companies from Romania, Bulgaria, Hungary, Poland and the Czech Republic, depending on their financial performance, by considering two integrative measures of performance: return on assets (ROA) and return on equity (ROE). Section II presents the data used in the analysis and the research methodology, Section III outlines the main results and Section IV concludes.

2. Data and research methodology

Our paper uses data collected on a number of 115 companies from Romania, Czech Republic, Hungary and Poland and from five industries: financial intermediation, food and beverages, chemicals, energy (oil and gas production and distribution), and pharmaceuticals. The industry sample was constructed in such a way as to allow the observation of financial performance from one industry to another. The data on companies' ROA and ROE was gathered from REUTERS and covers the 2003-2006 financial years. The selection of companies in our sample was based on the following criteria: (1) the company had to be listed on the country's stock exchange at the end of 2006; (2) the company had to be listed on the stock exchange at least during the financial years 2003, 2004, 2005 and 2006: (3) the financial data on the company had to be available during the 2003-2006 period.

Two clustering algorithms were used in our research: a joining tree algorithm and a partitioning algorithm, specifically the k-means. From our research point of view, we used the hierarchical algorithm to identify the number of clusters to be included in the k-means algorithm, by the use of the City-block (Manhattan) distance and following the Ward's amalgamation rule. From the plot of linkage distances across steps we selected the distance that we subsequently used in the vertical icicle plots to determine how many clusters to retain and interpret. In the k-means algorithm we introduced the number of clusters previously identified and have studied the analysis of variance (ANOVA) in order to evaluate the appropriateness of the classification. We afterwards identified the members of each cluster and studied their characteristics. Before the application of the clustering amalgamation techniques, all data has been standardized.

3. Results

Before the application of clustering amalgamation techniques to financial performance data, we consider necessary a brief depiction of financial performance in terms of ROA and ROE, at an industry and country level, both static and dynamic. The maximum and minimum ROA are quite fluctuating from a year to another, regardless of the industry, which suggests that companies are struggling to stabilise their financial position and do not operate in mature markets yet. In all years, the lowest ROA are negative, while the maximum ROA are more or less similar across industries, with the only exception of the financial intermediation industry in 2004 that displays a maximum ROA of 81.03, which belongs to a Polish company. Also, for the financial intermediation industry, 2006 seemed to be the best of the years, since the lowest ROE is slightly positive – 0.07. In dynamics, all industries included at least one company with increasing ROA from 2003 to 2006, the highest number (7) being recorded in the financial intermediation industry and the energy industry. Two companies with increasing ROA were found in the food and beverage industry, and one company each in chemicals and pharmaceuticals. For what concerns the companies with decreasing ROA, the highest number (3) is recorded in the financial intermediation industry, followed by two companies in the chemicals, energy and pharmaceuticals industries. The only industry with no declining ROA was the food and beverages industry. Nevertheless, the majority of companies have seen their ROA oscillating from one year to another, no easily discernible pattern of evolution being identified.

In terms of ROE we can notice a higher diversity for the maximum and minimum values, as well as high differences in the values between industries, particularly for some years. A couple of returns on equity are quite surprising: an astonishing 1004.23 recorded in 2003 in the energy industry, followed by 745.01 found in the same year for the chemicals industry, and at some distance by a ROE of 167.41 also in the chemicals industry, but in 2004, and by a ROE of 121.21 in the financial intermediation industry in 2003. As known, the difference between ROA and ROE is given by the financial leverage multiplier (the well-known Du Pont system decomposes decomposes ROE in three parts, as follows: ROE = profit margin × Total assets turnover × Financial leverage multiplier = ROA × Financial leverage multiplier), therefore we may interpret these considerable differences between ROA and ROE as a high degree of indebtedness of the companies included in the analysis, particularly in 2003 and 2004. From 2003 to 2006, a number of 16 companies see their ROE increasing: 7 from the financial intermediation industry, 3 from the food and beverages, 5 from the energy sector and only one from the pharmaceuticals. Decreasing ROE from 2003 to 2006 are identified for two companies in the financial intermediation industry, one for the food and beverages, 3 from the chemicals, one from the energy sector and 2 from the pharmaceuticals. All other companies show oscillating ROE during 2003-2006.

The cluster methodology was used to analyse companies' financial performance on two grounds: the first one took into account the main profitability ratios – ROA and ROE – for each of the four years, and the second one tried to identify groups of companies depending on the evolution of each of these two indicators in time. In terms of ROA and ROE considered for each year, we used a number of 8 clusters in the k-means clustering algorithm, as indicated by the observation of clusters previously formed by the use of the joining tree algorithm. For all years, the analysis of variance (ANOVA) indicated that the within-cluster variability was statistically significantly lower than the between-cluster variability, as shown by the F-statistic. As a general observation, the clusters' structure in terms of countries and industries of origin changes from a year to another, as one would normally expect given the fluctuating performance in during the period. Figure 1 shows the plot of clusters means for 2006, the similar plots being available for all years.

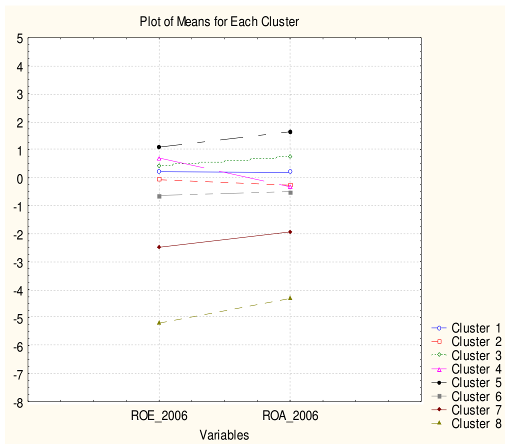

Figure 1. Plot of means for ROA-ROE clusters, 2006

For 2003 we identified three big clusters – one formed of 41 companies, another one of 35, and another one of 20 -, each of them including companies from all countries and industries. One company is excluded from all clusters – a chemical Czech company, due to its very low ROA and ROE. The highest average ROE is displayed by cluster 8 that includes two Romanian companies, one from the chemicals industry and then other one from the energy sector. At the same time, cluster 8 shows the second worst performance in terms of ROA, while also being the least homogeneous from the perspective of both indicators. For what concerns ROA, then highest average ROA belongs to cluster 7, that includes companies from all industries and from all countries except for the Czech Rep. The highest homogeneity in ROA terms is demonstrated by cluster 3, which includes the highest number of companies of all, but it is also an "average" cluster in terms of both ROA and ROE. From the point of view of companies' distribution among clusters depending on their country and industry of origin, the big clusters collect the largest part of companies, maybe the most interesting being cluster 4 that includes more than half of the companies in the financial intermediation industry, and clusters 3 and 4, that gather 40% each of the Czech companies. Both are "average" type of clusters. 2004 is a different year in terms of clustering results. A big cluster is formed, including 73 companies (cluster 3), the vast majority of firms from all countries and industries entering this cluster. As expected, this is a cluster with an average performance in both ROA and ROE. At the other extreme, three companies belong to their own cluster: a Polish company from the energy sector, displaying the highest ROA and ROE (cluster 5), a Czech company from the pharmaceutical industry with the lowest ROA and the second lowest ROA (cluster 6), and another Polish company, but from the financial intermediation industry, enjoying an average ROE accompanied by the highest ROA (cluster 8). Also interesting are clusters 1 and 4. Cluster 1 includes 10 companies, of which 9 are from the financial intermediation industry and is characterised by the highest homogeneity in terms of ROA and a ROE above average. Cluster 4 consists of 14 companies, from all industries and countries – this cluster shows the highest homogeneity in terms of ROE, but the lowest in terms of ROA, the mean for this indicator being above average.

The clusters formed by taking into account the performance for 2005 and 2006 are different from the ones in 2003 and 2004. The first important observation is that no company forms its own cluster, which generally indicates a higher homogeneity of performances among companies. The second observation is that the eight clusters formed for each of the two years manage to spread the companies between them, as we do not find anymore a cluster that collects more than 50% of the total number of companies, either on a geographical or industry basis. In 2005, only two clusters have an average performance – cluster 5 and cluster 1, with 28 and 36 companies from all countries and industries -, while the others are easily identified either by their high or low performance. The worst performers are grouped in cluster 3: the two companies are both from Poland and come from the food and beverages and energy industries, respectively. The best performers from both ROA and ROE perspective – two Romanian companies and two Polish companies, from the financial intermediation, food and beverages and energy industries - are grouped in cluster 8. Cluster 2, with 8 companies mostly from Romania and Hungary, is the second lowest in both ROA and ROE, while cluster 6, including mostly companies from Romania, Hungary and Poland, and from all industries except for financial intermediation, shows the second performance in ROA terms. The best performing cluster in 2006 – cluster 5, includes 12 companies, of which none is originating from the Czech Republic and also none from the pharmaceutical industry. The lowest performing companies are included in cluster 8 – a Hungarian and a Czech company, one from the food and beverages industry and one from the energy sector, while the second lowest performance is displayed by cluster 7, with 4 companies from Romania, Hungary and Poland, and from the chemicals, energy and pharmaceutical industries. Cluster 6 is also interesting, as it is the cluster with the highest homogeneity in ROA, with 20 companies, mostly from Romania (8) and Poland (9), spread equally among four industries (financial services, food and beverages, chemicals and energy). Also, cluster 3 shows the highest homogeneity on a ROE basis, and it includes companies from all countries and industries, except for the food and beverages industry.

Another manner of observing the overall financial performances of these companies that we used involved the application of hierarchical and partitioning clustering methods to the same financial indicator, but using as variables in the clustering algorithm its values in all years, 2003 to 2006. Under this approach, the joining tree clustering indicated also the configuration of eight clusters, and the ANOVA methodology showed us that this number of clusters in statistically significant both for ROA and ROE. Figures 2 and 3 show the plot of means for these clusters.

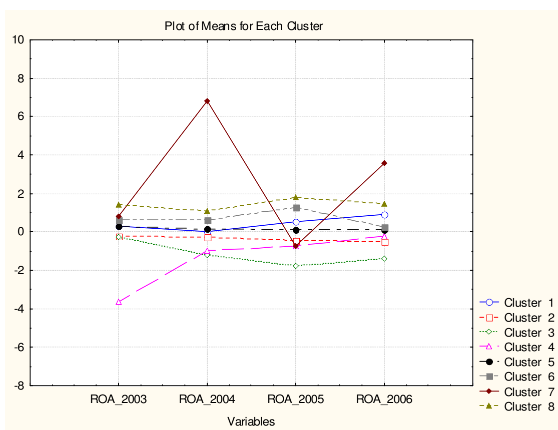

Figure 2. Plot of means for ROA clusters, 2003-2006

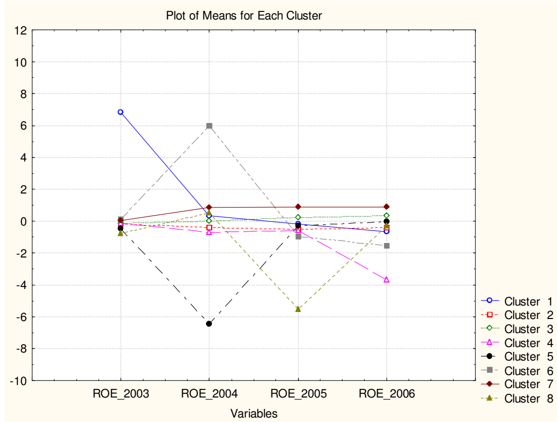

Figure 3. Plot of means for ROE clusters, 2003-2006

A number of characteristics of ROA clusters are interesting to notice. There are two companies that form a cluster on an individual basis – cluster 5 includes a Czech company from the pharmaceutical industry and cluster 6 includes a Polish company from the energy sector. While cluster 5 is an average cluster, cluster 6 has an oscillating performance from one year to another, albeit in all years its performance is above the average. The cluster showing the highest fluctuation is number 7 that groups 16 companies from all industries and countries. Another interesting cluster is number 3, but its fluctuation during 2003-2006 is lower as compared to cluster 8. The only cluster showing an increasing performance between 2003 and 2006 is number 4, which includes companies from two industries only – chemicals and pharmaceuticals -, but from three of the countries: Hungary, Czech Republic and Poland.

Taking into account ROE, the number of companies in the eight identified clusters varies from 1 (cluster 7) to 46 (cluster 2). The company in cluster 7 – a Polish company from the financial services industry – shows the highest oscillating performance of all companies included in our sample: ROE was 121.21 in 2003, then it declined to 58.66 in 2004, then it reached a negative value of -1.44 in 2005, to return to a positive ROE of 33.34 in 2006. Another interesting cluster is number 4, with 5 companies split between countries and industries, showing improved performance from 2003 to 2006, since their average ROE moves from the lowest in 2003 progressively towards the average of all clusters, although somehow below the average, in 2006. The best performing cluster is number 8, demonstrating an above average performance in all years. Cluster 3, with 9 companies, includes companies with declining ROE in 2003, 2004 and 2005, but somehow improving in 2006, although it remains below the average in all years.

4. Conclusions

Our research analyzed the financial performances of companies from four Central and Eastern European countries and from five industries: financial services, food and beverages, chemicals, energy and pharmaceuticals. The main objective of the research was to identify natural groups of companies depending on corporate performance. When observing the changes in financial performances over four years (2003 to 2006), and forming clusters of companies taking into account these financial performance, no clear-cut evidence on their grouping according to industries and/or countries can be identified. Moreover, since their performance is sometimes widely oscillating during the four years, we might reasonably say that corporate performance in the area is more or less similar, with just a couple of companies showing deviating performance in a particular year, but in most cases followed by a correction towards the average in the subsequent years.

TENDENCIES OF DIRECT TAXING OF EUROPEAN UNION CORPORATION

Ispas Roxana

Summary: The hypothesis of fiscal competition that generates an alignment "lower" than the imposed level only partially verified empirically, that is for nominal rates, and almost none for effective rates. Also, the impact upon the budgetary incomes can't be made visible. That being said, there are opinions considering that the stout of budgetary money from the companies tax income can't continue on undetermined term. That is because the "space" left for continuous reduction of the imposing rates is still vast while the continuing extending reserves of the legal imposing base have almost exhausted and the companies' rewards can't improve for ever.

Key words: taxing, taxing rates, imposing bases, budgetary incomes, corporation, European Union.

The evolution of the taxing rates among the corporations' incomes offers a good possibility to verify the manifestation of some of the up mentioned effects of the fiscal competition. In this field operate several notions:

a)nominal rate(legal)

This does not offer in formations upon the effective fiscal problem suffered by the company because it doesn't take into consideration different ways through which the imposing base can be determined. Still, the nominal rates seem to have an important psychological function because they are being seen as signals of the general fiscal climate of a country, by the international investors[75].

b)the effective rate

The economical effects of the taxes not only depend of the nominal rates, but also of all the elements that determine the fiscal burden supported by the company-the nominal imposing rate and also the precautions referring to the determination of the imposing base(the foresight of expenses, fiscal credits, fiscal treatment of the reinvested profit, etc).It is very possible that high nominal rate would transform into an effective modest rate if the value of the incomes, consume and wealth is bigger than that of the taxing.

The most important effects of taxes upon investing decisions are determined by the marginal effective rate, which represents the imposing rate of a marginal investment, which obtains an equal efficiency to the economy interests rate, taking into consideration the fiscal liquidation, the inflation rate and the imposing systems.

In exchange, the tax effects upon the public incomes and their function are determined by the medium effective rate, defined as a rapport between the total tax considered on an activity and the total level of the income (economically real) produced by the activity or, in the indirect taxes, of the consume.

Both up mentioned effective rates affect investing decisions, but differently. While the medium effective rates orientate the decision upon the placement chosen for an investment, the level of that investment is more powerful influenced by the marginal effective rate.[76]

Because the fiscal regulations can vary in the activity sector, their effects differ in the active types used and the finance sources of the investments, and the existence of non-linear taxing systems imply the vary of imposing rates according to the theoretically obtained profit rates and there can be an infinity of effective imposing rates.[77]

c) the implicit rate(apparent)

This indicator is calculated at macro economical level(through the tax rapport taken by the PIB) or micro economic(through the tax rapport taken from the gross income).

He has a big relevance problem for the characterisation of the importance of the fiscal factor. On one side, if it is determined at macro economic level, it is strongly influenced by the level and the dynamics of the PIB and also the companies' sector structure(the importance of companies in it) which affects its capacity to facilitate both international and inter-temporal comparisons.

At a micro economical level, on the other hand, its dimension depends on that of the gross income, which is difficult to compare between fiscal jurisdictions, because of the differences in the accountant standards (especially at the reserves, the extra-balance elements).[78]

On the other side, this is also the only indicator that can globalise the effect of a parameter of the fiscal system, other than the rate and imposing base, that the up-mentioned indicators can't have: the administration tax method. Indeed, aspects such as the honesty of the taxpayers, the intensity of the fiscal controls or the effective payment of the taxes can differ a lot in time or through different jurisdictions.

According to the complexity of the tax operation, the effective rate is more or less tightly associated to the nominal rate. As a general rule, the difference between the two rates is bigger in the cases of the direct investments that in those of portfolio.

This fact explains why some countries come up with low nominal rates(to introduce the profit rapports into their own jurisdiction) and high effective rates(to have a larger imposing base).Still, the differences recorded between European Union state members from the point of view of the effective rates explain principally through existing differences at the level of the nominal rates and only through differences at the level of the elements that determine the taxing base.

In the last 25 years there have been some major reductions of the nominal tax rates for the companies' income in EU, and the tendency seems to have accelerated in the last years. That is how, in 2007 less that 5 member states operated reductions of the imposing rates: Greece, Holland, Spain, Bulgaria and Slovakia[79]. Between 1982-2001 the nominal medium rate went low from 48% to only 33%. Generally the reductions operated by the small countries were more important than those applied in the big countries of the Union. The nominal taxes for corporations' income started to go low strongly in the last years also in the new members of the EU. The medium level of the imposing rate in the new 12 member states was of 21.5% in 2003 and it has reduced to 17.8% in 2006. In the old member states, the reduction was from 30.1% in 2003 to 27.7% in 2006, this representing less that two thirds of the 45% level recorded at the beginning of the 80s'.

Although there is the temptation to attribute this reduction to imposing rates, commune to other extra-European advanced countries, fiscal competition, mustn't neglect the fact that other determinants might have played a same important role. We are talking about, firstly, of the ideological preferences evolution, factor of whose importance can be evidenced by the almost systematically major reductions coincidence of the imposing rates of the capital with presence of the governing persons that come from the right position of the political sceptre. In the same way there can also be explained some very important reductions of the imposing rates of the corporation income that is registered in east-European countries who had the same economical transaction process characterised by the major restrain of the state's interference and the public economical sector.[80]

Secondly, we must take into consideration the fact that a state's reaction to reductions of taxes that were operated into another state can introduce not a competition, but a different behaviour determined by the preferences of the citizens, who compare imposing rates from their own jurisdiction with those existing in other countries[81]. Finally, evolutions correlated into the concern of the rates and the imposing rules applied into different countries can reflect the existence of common intellectual tendencies, usually released by

the discovery of certain solutions to difficult fiscal problems (introduction of VAT or the proliferation of certain types of fiscal incentives initially used only by a certain country can be such examples.)[82]

In the last two decades of the past century there has been a o reduction of the disperse of the nominal rates applied by the member countries of UE-15 : standard deviation decreased from 3,4 to 2,0 in the range 1990-97. It rose again, but, in the years 2000. In the conditions where the New Member States of the EU tend to have levels of profit imposed rates noticeably smaller then the old members, the disperse in the UE-27 is even bigger. More , the recorded tendency over the last decade is the deepen of the discrepancy of the imposed rates practiced by the old member states and the new members , even when the rates are decreasing in both country groups. It has to be mentioned that if you take into consideration and local taxes imposed to companies (important in countries like Germany, Italy, Luxembourg and Portugal), the disperse of nominal rates rises even more.

Reversibly, *medium effective rate* in different member countries of the EU has been less mobile :it recorded a certain decrease during the 80's , but has been stabilised since the second half of the 90's . The disperse of the recorded effective rates has been very important at the beginning of the range, sensitive narrowing later. In 2001, it was just less marked then the recorded one due to legal (nominal) imposed rates, suggesting a high degree of correlation between the two types of rates, which the Pearson coefficient of 0,92 confirms it empirically.[83] Otherwise, according to the European Commission, approximately three quarters of the recorder differences between Member States under the aspect of effective medium imposed rates due to the existing differences between the nominal rates.

The joining of new member states doesn't change the situation as significantly as it happens in the nominal rates case, because these countries don't have such low medium effective rates. It is true that the estimations made for the new members don't take into consideration the different schemes of fiscal stimulants applied selectively to those countries.

We are talking about measures such as: the un paying of tax for 10 years for companies new born in Czech Republic and Slovakia, the fiscal credit is of 35-50% of the investments value, given in Hungary in the first 5 years, the reductions of tax on the companies income that are established in "special economical areas" from Leetonia and Lithuania; the accelerated amortization given in Poland for certain new acquired categories of actives.[84]

If it would have been taken into consideration also the effects of these stimulants, the medium marginal imposing rate would decrease, in some cases (Lithuania, Leetonia, Poland, Slovakia) at almost half! But how most of these schemes are incompatible with the community *acquis* concerning the helps the state is giving, they have been destroyed once with the entrance of those countries in the European Union.[85]

The medium effective imposing rate (%)

Source: **-** *Margit Schratzenschaller: Company Tax Co-ordination in an Enlarged EU, Austrian Institute of Economic Research (WIFO), May 2005; p.17-18;*

– Wolfgang Eggert, Andreas Haufler: *Company tax coordination cum tax rate competition in the European Union,* University of Munich, Discussion Paper 2006-11, March 2006; p.4;

According to some studies, the effective marginal rates of taxing have been much more stable through time than the medium ones, which explains through the extending process o imposing bases parallel to the reduction of imposing rates. If this tendency hasn't repeated in the case of the medium effective rates, who, as it is seen in the charter above , have reduced considerably, the explanation must be seek in the increase of investments profitability. Since the more deep capital tends to be also the mobile one, the evolution up-mentioned can be interpreted as a growing competition for the mobile capital, especially for the multinational companies.[86]

Effective marginal rates of taxing on corporations' income, 2000

Source : Dirk Gopffarth: The Effect of Tax Harmonisation on Effective Tax Rates in the European Union, June 2001; p.5

The most used implicit tax rate is that resulting from the incomes upon the corporations' profit rapports at PIB. This indicator of "fiscal burden" remained remarkably constant in period characterised still by major reductions of the imposing rates. It is true that in time, we can remark some fluctuations, but they reflect conjectural evolutions, imposed by the phases of the economical cycle. Another finding is that generally, countries with smaller economies have come to increase, including in relative terms, more the budget cashing from the income tax of the corporations comparing to big countries. Furthermore, there is no clue of any tendency to convert this "fiscal burdens" in the EU. The most important changes at the analysed level were in the countries with the smallest "fiscal burdens"(and these variations were in both directions) which means that the preferences of the countries who wanted a better redistribution through the budgetary lever haven't been let down.

There are two important reasons from which the reduction of the imposing rates haven't transformed into decreases in the budgetary incomes. In a way, what worked was the enlarging effect of the imposing base, effect described graphically by the well known "Laffer curve".

The relative constancy of the tax cashing, despite the very important reductions of the imposing rates is because of the fact that parallel, more countries have adopted measures to enlarge the imposing bases. In the EU's case, this seems to be also an effect of the initiatives adopted at community level to destroy the damaging fiscal competition.[87]

This suggest a special interest to attract investments that have a high degree of profitability, as tend those effected by trans-national corporations. To reach this, it has come to the reduction of the imposing rate, and several fiscal deductions have been eliminated. Because the importance of the fiscal deductions decreases with the increase of profits, this measure combination is favourable especially to trans-national companies.[88]

The enlargement of the imposing bases through the reduction of fiscal deduction possibilities can also have unknown consequences in the conditions of the internationalisation of the production and the unstopped circulation of the capital. Firms with essentially aboriginal activity, especially the small and medium one have to support a higher fiscal burden, while the multinationals have access to a wider range of instruments that allow them to restructure the national imposing bases("on paper", not with physical movements of the actives) so they could maximise dimensions of the bases in jurisdictions with the smallest imposing rates.[89]

On the other hand, the incomes from the tax on profit not only depend of the fiscal legal parameters(rate and imposing base) but also on the inside evolution of the variable submersed to taxes.

The companies' profitability evolves in the same way as the economical cycle and may explain the variation of the analysed indicator. Still, a study that was taken recently said that the effect of economical conjecture factors upon the budgetary cashing from the tax on corporation income in EU was very less important in 1990-2003. [90]

There are also more "technical" explanations to the variation of the analysed indicator, like evolutions in the "economy corporation" rates. The cashing increases can reflect a higher weight of the companies'

economical sector, while the tax on corporation income reductions have encouraged the organisation as companies of previous economical activities.

In the analyse of known data it must be considered also the fact that the indicator is an “ex post” one and its level can be affected by previous events who still have effects now. It is the case of the previous clauses(who allow an investment to benefit a while from the fiscal regime from the moment it was effectuated, even if that who is now has been modified) or of the possibility to rapport fiscal loses in the future.

The product of taxes on the corporations’ incomes (% din PIB)

Source: - Alfred Boss: Tax Competition and Tax Revenues, Intereconomics, January/February 2006; p.45

- Frank Zipfel: *One Europe, one tax? Plans for a Common Consolidated Corporate Tax Base,* Deutsche Bank Research, EU Monitor 49, 25 September 2007; p.4

Another important factor for the characterisation of the known evolvements by the tax on corporations’ income is the *percent cashed of this type of tax from the total budget cashing*. The general tendency known by this indicator was decreasing starting with 1965, but lesser at the end of the 80’s. This suggests that, although the member states have managed to keep their incomes constant comparing to PIB, they couldn’t grow that much as other taxes. In the 90’s, the tendency was of a small increase, followed by a new trend easily descending on this decade. At the EU level 15, this indicator’s level was 2.7% in 1995, growing until 3.7% in 2000, so that it would decrease to 3.1% in 2003.[91]

[91] Michael P. Devereux: *Taxes in the EU New Member States and the Location of Capital and Profit*, Oxford University Centre for Business Taxation, WP 07/03, January 2006; p.11

At the new member states level, the modifications in the last decade have been less marked, and the tendencies were opposite: decrease in the second half of the 90's followed by increase in our decade. Generally, the new member states are more addicted to this types of tax cashing for their budget increase than EU-15.

There are big differences between the EU member states according to the tax contribution at the corporations' income and at the realization of the budgetary cashing. In 2002, these taxes contributed with only 1.5% to the federal budget of Germany, but with 20.5% at the budgetary Irish incomes. It is normal that these differences reflect in the priorities that the member states take connected to the harmonization of this type of tax at community scale. As a paradox, at least in the extreme up-mentioned cases, the preference for harmonization isn't what it would be expected: Germany is in the front line of the member states who support harmonisation initiatives for the imposing rates, while Ireland remains into the most reticent members for such proposals.

FOREIGN DIRECT INVESTMENTS AND THE KNOWLEDGE SOCIETY IN THE CEE COUNTRIES

Ivan Mihail Vincentiu

The foreign direct investments play an active role in transforming the Central and East European economies aiming at the construction of the knowledge-based society, by the development of some research-development activities with innovating character.

Generally, it has been noticed a more powerful impact either in the countries that have received massive foreign direct investments, namely the Czech Republic, Hungary and Estonia, or in countries in which the quality of the attracted foreign capital has completed, at a certain moment, their quantity (as for example Slovenia).

In this paper we are going to approach the relation between foreign direct investment (FDI) inflows and knowledge society building in an explicit manner, analysing the empirical data for the Central and Estearn European (CEE) countries, new members of European Union.

Key words: foreign direct investments, knowledge-based society, innovation activities, research, development

Introduction

Most of the studies tackle this subject in an indirect manner, through the positive effects of foreign direct investments upon host economies, in terms of productivity and competitivity.

In this paper we are going to approach the relation between foreign direct investment (FDI) inflows and knowledge society building in an explicit manner, analysing the empirical data for the Central and Estearn European (CEE) countries, new members of European Union.

Our main goal is to demonstrate that, supporting the development of innovative research-development (R&D) activities foreign direct investments attracted by Central and Estearn European countries had been playing an active role in transformation of these economies, in their way towards a society based on knowledge.

1. FDI and innovative R&D activities

Specialists agree that technological innovation is essential for the economic development and growth. Even more, practice proved that any sustainable economic development requires more than a "receptive" economy to technological inflows inputs.

During the technological innovation process, transnational corporations (TNC) hold a significant role as the globalization and production internationalization processes of the economic inflows deepen. In the extent that these forecasts shall become true, positive effects of the technological progress upon the involved sectors competitiveness and productivity may take place in Romania too, by means of the R&D investments made by the foreign companies that relocate these activities.

In essence, the transnational corporations that develop R&D activities abroad, place it in one of the following categories:

Assets exploiting: these generally originate from the developed countries and internationalize the production in order to get access to national resources or cheap labor force, thus placing the R&D activities in the middle ground;

Augmenting exploiting: these generally originate from the developing economies and by means of FDI they intend to gain access to local research-development capabilities (for increasing competitiveness by means of technological innovation), reason for which R&D activities are placed in the foreground.

Practice showed that transnational companies from the first category (assets exploiting) hold the main share within TNC that internationalize the research-development activities. The developing states generally benefit from the process of the R&D activities abroad localization.

As per the host country, the internationalization of the R&D activities represents an opportunity not only for the technology transfer created somewhere else, but also for the development of technological innovation own capabilities, as long as the particular economy has managed to connect to the innovating and technological global research network. Taking into account the specific of this activity, that assumes not only the existence of some capabilities and knowledge, but also their easy and sometimes unspoken transfer between the producers and the users, the cluster development becomes imperative.

The importance of the clusters in R&D promoting and intensifying has been often underlined by the Romanian specialists, pointing out that given the deep disparities regarding the other EU member countries, Romania must tackle "the complex and difficult aspects associated to the knowledge-based economy construction in a totally changed manner, if it is felt the need to remove the disparities…and reach performance." Thus, among the strategic options, concerning the main directions for the construction of the knowledge-based economy, one must find as compulsory those options regarding "the use of the clusters, the company networks and business centers for the research-development promotion and intensification "(Roşca, 2006, p. 71,74).

Of course, easier said than done as the setting up and development of the own capabilities of technological innovation are not only low, but very expensive processes that require a constant technical effort, the existence of a developed infrastructure (mainly an informational and communicational one) and some powerful and lasting institutions (universities, research centers).

We need to emphasize that the effects of localizing the R&D activities of the transnational corporations within the host economies are multiple and sometimes conflicting. Thus, beside the positive effects, there are other unwanted effects that can develop, namely: attracting the qualified personnel from the domestic companies; disloyal competition in TNC case, that behave totally unethical; on a long term, one can even register a job diminution.

Both the economical theory and practice showed that there is a set of determining factors that encourage the positive impact, namely:

The R&D activity type (adaptive or innovative);

The absorption capacity of the implanting economies;

The innovating system of the host economy.

As a consequence, we appreciate that the foreign direct investments attracted by the CEE countries can impel the R&D activities with innovating character, thus supporting the Central and Eastern European economies on the way of the construction of the new society, based on knowledge.

2. FDI and the knowledge society

Regarding the construction of the new society, the Society of Knowledge, Alvin Toffler specified in his book-the Third Wave (1981) that "the persons, groups, communities, societies or nations that shall have access to information and the potential to process them, shall then gain access to the new society."

Therefore, the construction of the knowledge economy implies the transition from "the industrial approach" of the economy to "the informational approach" whose main characteristic is represented by the speed of change. Consequently, the economic success is no longer guaranteed only by the existence of the technology that changes rapidly due to the high rhythm of the technological progress, because it also depends on adopting a new flexible production system, which may be quickly adjusted in order to comply with the market needs and the distribution system radical change (Roşca, 2006, p.341).

Thus, within the globalization context, the transnational corporations deal with a more and more severe pressure due to the massive and rapid changes that register within the global economy, at the production and distribution level. Taking into consideration the intensive informational character of the globalization, in order to keep their competitive advantages, TNC must achieve significant investments in research-development activities, along with the IT and communication high tech integration within the production process.

As a consequence, the bitter global competition changed the knowledge into the vital force of the economy. Therefore, in order to survive, the transnational corporations have to allocate important resources in view of obtaining knowledge.

The importance of knowledge in the new world economy has been officially acknowledged across the EU once with the adopting of the Lisbon Agenda, that established as a priority for the member countries to build up the knowledge-based society in view of providing the competitiveness increase and a sustained economical development.

Following the adoption of the Lisbon Strategy (2000), The European Commission monitors the progresses recorded by the member countries regarding the capabilities and the innovative performance. In this respect, a survey drafted based on the data supplied by EUROSTAT (The CE Office for Statistics) showed that, during 2002-2004, over 42% of the enterprises that work in the production and services sector within the 27 EU current member countries reported the development of some innovating activities (Eurostat news release, Feb. 2007).

Within the 27 analyzed countries one can notice severe disparities regarding the percentage of the enterprises that achieved innovative activities from the total of the enterprises. Thus, the highest values register in Germany (65% of the overall enterprises), Austria (53%), followed by Denmark, Ireland, Luxembourg (52%), Belgium (51%) and Sweden (50%). At the opposite pole, are ranked the countries with the lowest rates, namely Bulgaria (16% of the overall enterprises), Latvia (18%), Romania (20%), Hungary and Malta (21%).

In what concerns the accomplishment of some partnerships between the public and the private sector, in view of developing the innovative activities it has been ascertained that they occur more frequent in countries like Finland, Slovenia, Slovakia, Latvia, and Lithuania and less frequent in Italy, Malta, Romania and Cyprus.

Moreover, at the EU level, the partnership between the companies involved in the innovation process (suppliers or users) and the public research institutes, as well as the higher education institutions is relatively low (6%, respectively 9%). Though, there are some countries inside which the cooperation level is very high, namely Lithuania (56%) and Slovenia (47%).

Similar to the EU recorded situation, the Central and Eastern European countries present severe disparities in what concerns the enterprise involvement in innovating activities (table 1).

Table 1. Innovation activity and co-operation during 2002-2004 for CEE countries

Countries	Enterprises with innovation activity (% of all enterprises)	Co-operation partners (%of all enterprises with innovation activity)			
		Suppliers	Clients or customers	Universities or other higher education institutes	Government or public research institutes
EU-27	42	17	14	9	6
Bulgaria	16	16	13	6	4
Czech Republic*	38	31	26	13	7
Estonia	49	23	23	9	6
Hungary	21	26	20	14	5
Poland	25	28	16	6	9
Romania	20	14	10	4	4
Slovenia	27	38	33	19	13
Slovakia	23	32	30	15	11

Source: Eurostat News Release, 27 feb.2007, p.2, FCIS 4 (Fourth Community Innovation Survey)

*Data for Czech Republic correspond to the reference period 2003-2005

Estonia and the Czech Republic, states that received massive foreign capital inflows, are ranked the first (with 49%, respectively 38% of the overall enterprises), while the disadvantaged countries, under the FDI inflows, namely Bulgaria and Romania, are among the last places with rates of 16%, respectively 20%.

Starting from the assertion regarding "the 3I of knowledge", according to which "the processes considered as defining for the phenomenology of a knowledge-based society are: innovation, partnership learning and interactivity" (Dragomirescu, 2001), we shall compare the data concerning the innovative activity and the human capital, previously presented and analyzed, to those related to the FDI inflows (inward FDI stock per capita) within the CEE countries in order to emphasize in a more explicit manner the relation between the attracted foreign direct investments and the knowledge based economy.

In this respect, we shall allocate a number from one to eight to each of the eight countries submitted to analysis, according to the ranking in top (1 for the first place, up to eight for the last place), according to the level of the following indicators: inward FDI stock per capita, the innovation index (ICI), the human capital index (HCI) and the percentage of the enterprise with innovative activities (table 2).

Table 2. Relation between FDI and knowledge-based society for CEE countries

Countries	ICI 2001	HCI 2001	Enterprises with innovation activity 2002-2004	Inward FDI stock per capita 2001	
-	(rank)	(rank)	(rank)	(rank)	USD/capita
Bulgaria	5	5	8	7	432
Czech Republic	4	6	2	1	2638
Estonia	2	3	1	3	2307
Hungary	3	4	6	2	2310
Poland	6	1	4	6	1073
Romania	8	8	7	8	351
Slovenia	1	2	3	4	1613
Slovakia	7	7	5	5	1155

Source: UNCTAD, World Investment Report 2003 and 2005, Eurostat and own calculations

From the above-mentioned data, it comes out that the CEE countries placed on the first positions in what concerns the foreign direct investment inflows, namely the Czech Republic, Hungary, Estonia and Slovenia, still occupy top places regarding the innovative activities and the human capital.

Also, Romania and Bulgaria, ranking last within the CEE analysed countries in what concerns the FDI inflows are occupying the same low positions regarding the innovation capabilities and the quality of the labour force.

Consequently, there is a correlation between foreign direct investments inflows and the positive evolutions recorded by some Central and East European countries (as for example Slovenia, Estonia, the Czech Republic and Hungary) on the way of the construction of the knowledge–based economy.

In our opinion, the presented data suggest that in these countries foreign direct investments contributed to the development of the enterprise innovative activities and the improvement of the human capital.

We shall henceforth end by emphasizing the cases of Slovenia and Poland. As per Slovenia, the positive difference between the rank according to FDI inflows and the ones regarding the knowledge society (ICI, HCI and innovation activity) underlines the importance of the FDI inflows structure and of the domestic resources (human and capital) within the social and economic development of this country.

In what concerns Poland, in our opinion, the positive impact is mostly due to the fact that transnational companies, following the internal market potential have diversified the production, achieving new products to respond the local consumer requirements.

3. Conclusions

In our opinion, given the above-mentioned facts, the foreign direct investments play an active role in transforming the Central and East European economies aiming at the construction of the knowledge-based society, by the development of some research-development activities with innovating character.

Despite all, given the foreign capital input reduced level in most of the analyzed countries, as well as the structure of the FDI inflows (aiming at the market and the reduced cost of the production factors) the foreign capital impact is relatively low in most of the CEE countries. Generally, it has been noticed a more powerful impact either in the countries that have received massive foreign direct investments, namely the Czech Republic, Hungary and Estonia, or in countries in which the quality of the attracted FDI has completed, at a certain moment, their quantity (as for example Slovenia).

Therefore, learning from these countries' experience, Romania that register big discrepancies compared to the other Central and East-European economies that have joined the European Union, can maximize the FDI positive contributions attracting more foreign direct investment inflows especially in those branches intensive in technology and knowledge. In this respect, it is imperative to improve the training level of the labor force and to develop the innovative capabilities.

Abstract: Globalisation is not a new phenomenon but it had opened up the national economies and created the global marke, where capital and labour can move freely. Combine with the fiscal competition phenomenon it influences the evolution of the national and international businesses environment.

The authors are trying to underline, in this paper, the connections between globalisation, fiscal competition and the small and medium businesses sector because these businesses are the most affected busineses by the fiscal policies decisions, that are subjet to the globalisation phenomenon and the fight against the negative effects of the fiscal competition phenomenon.

Key words: globalisation, fiscal competition, small and medium businesses sector,economic growth, tax hevean

Globalisation, the creation of the goods and services common market in the European Union, the complete liberalisation of international financial transanctions, capital and labour, the monetary unification, all these, have led to the rethinking the national fiscal policies especially in the direct taxation area. Every national jurisdiction has to answer to questions like: “What tax rate should be used to impose the revenues?”, “How to uphold the small and medium businesses sector?”, “What facilities should be granted to this sector?”, “How to attract new investors or how to make the national territory more attractive?”.

Globalisation will lead to the creation of a economy atfer the operating and organisational model of the existing states (Depoutot, 2003) and this will have as effect a higher capital mobility then labour mobility.

Fiscal competition is differently seen by the economic agent (the small and medium business) and by the state. While the state (the public actor) is seeing the fiscal competition like an obstacle to achieve it’s sovereignty forcing it to drop certain fiscal revenues so some tax payers categories will not emigrate and invest in some other places, the small and medium businesses are seeing the fiscal competition like an opportunity. This opportunity regards the favorable fiscal regulations that will permit an increasing activity and capital mobility and so the result after tax will have the higher possible value.

From the economic theory point of view the fiscal competition can be seen both as a negative and positive externality. The state how is losing capital through it’s run away will assimilate the fiscal competition to an negative externality, but the receiving state, the state where the capital has relocated, will assimilate the fiscal competition to a positive externality.

At the European Union level the fiscal competition is underlining the conflicts that are emerging from the base model of the European Union it’s self (Pisany & Ferry, 2005): the competition space between the system the state, for some, and the cooperation and reconstruction space for a colective sovereignty, for others. And nevertheless, the different policies regarding the social standards, the public investments and the macroeconomic policies are influencing the fisal competition not only at the European Union level but also at international level. In Europe the fiscal competition is shown clearly by the low profit rates applied to companies and we can add the facilities promoted by Holland, Denmark, Belgium and Sweden and many other european contries where the holding revenues are tax free. You can also obtain fiscal advantages in the form of decreasing taxes by applying the stipulations of some Conventions regarding the double taxation avoidance or through the European Union Directives in reference to dividends and interests.

Fiscal competition can be defined as the non cooperanting competition between different fiscal administrations that are wishing for the increase of their national territories through an advantageous fiscality (Le Cacheux, 2000).

Starting from the free circulation of the capital, labour, services, goods and under the globalisation effect the states are still maintaining differnt fiscal systems when it comes to direct taxation.

The indirect taxes, like the value added tax, are harmonised in the European Union through a series of directives and regulations this way thier negative impact upon the european market is reduced at minimum. But when it comes to direct taxation and especially to the profit tax there are no common regulations and only proposals. The European Commission has proposed the establishment of an common unique consolidate bases, but until now no political agreement has been signed. In the European Union the national fiscal systems are divers (27 systems) some beeing characterized by tax free (Greece, Portugal, Denmark) when it comes to tax the mobile bases or by lower taxes applied to the mobile bases in comparison whit the taxes applied to the less mobile bases. The most talk about subjects are the profit tax and the tax on the revenu obtain by placing capital, case these two are very mobile and can easly influence the fiscal pressure.

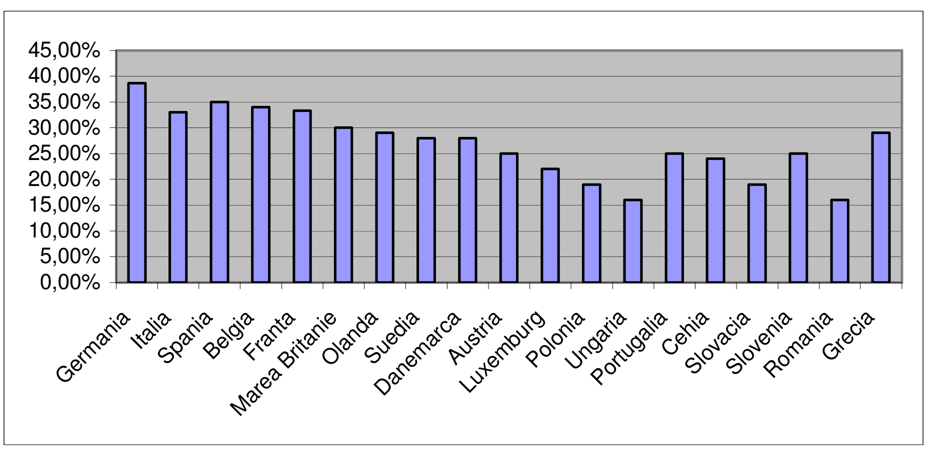
Starting from these aspects the European Commission is underlining the counter productive character of the fiscal competition and of the risks that can manifest at the level of the national public finances (OECD,1999). After 1999 again the European Commission took the first steps to align the national systems into a better coordination, excluding the discrimination and the double taxation of the profit and of the dividends this way reducing the fiscal evasion (COM, 2006, 823). These regulations are underlining the fact that in the absence of an coordination between the fiscal systems regarding the direct taxation we can get involuntary taxation or abuses, that will reduce the fiscal revenues of the state.

At the European Union level because of the adhesion of new state members with a lower fiscality, the ancients states have been forced to rethink their fiscal policy regarding the direct taxation because is clear that the activities are locating in these new areas. This way the Lisbone starategy is evidentiating a series of fiscal regulation that will help the small and medium business activity like: tax free, subventions for reserach and development or fiscal credits. Each country will have the capacity to use different mechanisms to support the small and medium businesses activities, for example, France is the first country to introduce a special fiscal system to sustain the innovating businesses. The stimulents are regarding:

- tax free for the first three years when the businesses are obtainting profits;
- decreasing the profit tax up to 50% in the next two years;
- tax free for a 8 year period for the social contributions afferent to the highly qualified labour.

We have to mention that the profit tax has been reduced in the majority of the european countries furthermore there are a large number of countries that are using the flat taxation: Republic of Estonia, Russian, the Republic of Serbia, Ukraine, Poland, Romania, the Czech Republic – see figure 1.

Figure 1. The nominal adjusted quota of the profit tax in the European Union in 2005



(Source: Eurostat)

Because of the fiscal competition some countries wishing to draw the mobile fiscal bases have modified the tax rate for the profit tax or are using different tax quotas for the small and medium businesses activities, because these are the main tax payers contribuing with 70%-90% from the gross domestic product and are possessing the main part of the active labour. Furthermore some countries are practicing a different fiscality when it comes to this sector – see table 3.

Table 3. Tax quotas fro the small and medium bunisesses in 2006

Country	Quotas
Spain	30% if the profit is ≤ 90.152 euro 35% for the rest
Estonia	0% for the reinvested profit 28,27% for the net distributed amount
France	15% if the profit is ≤ 38.120 euro
Portugal	20% for a three years period or less if the annual turnover is ≤ 149.639 euro
Romania	3% from the anuual turnover

(Source: Direction de la legislation fiscale – The National Statistical Institute-Romania)

We consider that Austria had fiscal competition in view when decided to change the tax quota for the small and medium businesses from 34% in 2003 to 25% in 2006, furtehrmore the state beeing neighbor with Poland and the Czech Republic where the quotas were lower. This measure has been partialy compensated by the inlargement of the tax base.

Starting from the fiscal competition concept the studies that have been realized at the European Union level (OEFE, 2007) have shown that the Europea Union countries can be pun, according to the medium global fiscal pressure determined at the Europea Union level (this value beenin 2005 13,1%) into three categories:

1. countries where the fiscal pressure upon enterprises is low –United Kingdom 9,7%, Holland 9,7%, Denmark 4,6%;
2. contries where the fiscal pressure is around the medium – Germany 13,3%, Belgium 13,3%, Spain 14,1%, Austria 12,2%;

countries where the fiscal pressure is high – Sweden 17,8%, France 17,8%, Italy 15,2%.

We have to take into consideration the fact that the country where the foreign investment will be done has to provide a high quantity and quality of public goods and services. But usually the quality of the public goods and services is higher where the fiscal pressure is higher, in contries like France, Germany or Denmark. This way the small and medium businesses will locate their activity according to the after tax outturn that, meaning, according to the redistribution public finance function, that the tax is seen as a payment for an received service, in this case a public one, and this is way the delocalisation of the capital will take place according to the optimal relantionship between the taxes payed and the received public goods or services.

Small and medium businesses are very important in Romania because:

- they are contribuing with almost 70% to the formation of the gross domestic product;
- assuring almost 2.600.000 working places that beeing 60% of the total active population in economy;
- contribuing with 60% to the formation of the state revenues;
- contribuing directly to the romanian exports – almost 50% of those are done by the small and medium businesses sector.

In order to make more attractive the romanian territory from a fiscal point of view and in order to reduce the brain-drain phenomenon the fiscal system makes the following amendments:

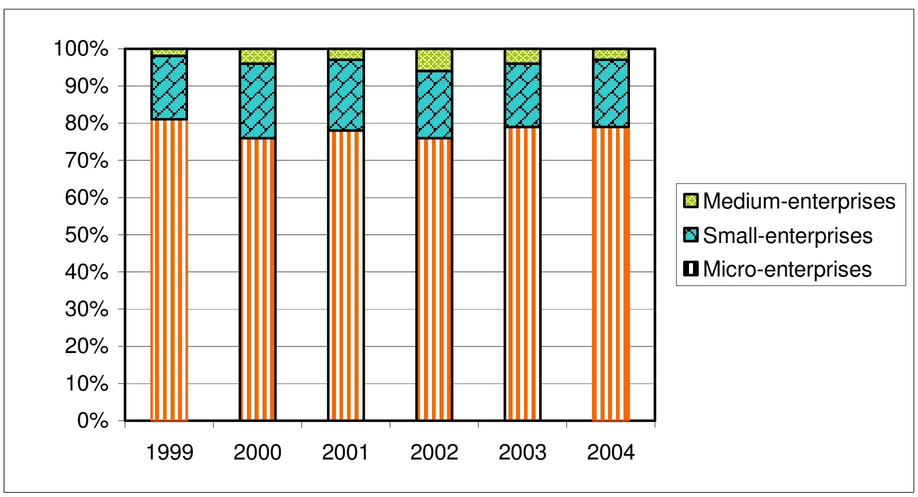
– the possibility to choose an absorption system fitted with the development strategy of the entreprise;
– deductibility of the credits interest;
– fiscal regime to integrate the revenues;
– the possibility to choose between beeing a profit tax payer (16% applied to profit) or beeing a revenue tax payer (2,5% applied to the annual turnover). We mention that this quota has been increase from 1,5% in 2004 to it's actual level 2,5% and in 2009 it will be 3%.

In Romania the legal aspects regarding the taxation of the labour are paying an important role in the emigration phenomenon of the highly educatated "brains", even if here since 2005 the taxation of the revenues is done according to a flat tax by 16% and the quotas of the contribution have been reduced, but at the same time the bases have been increased! When Romania adhered to the European Union in 2007 contrary to all that was aspected – that between 40% to 60% of the existing small and medium businesses will fail, because of the lack of experience and working capital, lower competitiveness – in 2007 the number of wiping off decreased with 74,14% in comparison with 2006, at the same time the number of small and medium businesses that registered a higher profit in 2007 in comparison with 2006 has been in increasing with 4-5% and the numer of small and medium businesses that registered losses in the same period of time has been decreasing with 3-4%.

Fiscal competition (through the use of the same flat tax to impose both the revenues and the profits) had had a positive effect in Romania increasing the number of new created small and medium businesses with international and mixt capital, in 2007 in comparison with 2006 by 9,15%. Another positive aspect is that the cost of labour in Romania in comparison with other european countries is lower. An example in this sense is the new location of the Nokia Factory in Romania from Germany.

From the economic growth point of view the year 2006 has been a better year for the small and medium businesses in the European Union then 2005 registrating an increase of the annual turnover by 10% and in some countires even a higher level – Romania and Estonia 24% and at the opposite position Cyprus and Portugal with an increase by only 4%. In Romania the small and medium businesses structure has registered an evolution similar to the one presented in the following figure.

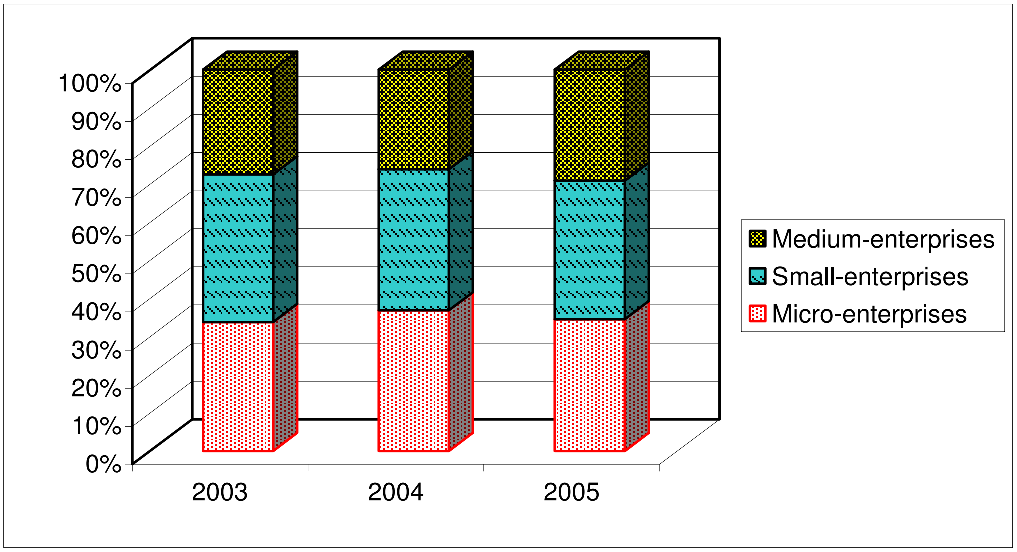
Figure 3. The evolution of the structure of the small and medium businesses



(Source: The National Statistical Commission, Romania)

We can see that the net profit had evolve in the three years analyzed and the most important change was in 2005, when the small and medium enterprises had been put to advantage by the decrease of the profit tax rate but drawback by the increase of theturnover tax rate. The turnover of the small and medium businesses is concentrated at the small businesses level although the micro enterprises are achieving one third of the small and medium businesses turnover their profit range is larger reaching almost 50% of the total.

Figure 5. The turnover structure according to the small and medium businesses types



(Source: The Public Finance Ministery)

For Romania the small and medium businesses are representing the engine of the economic growth and a vector for disseminating the research and development results. The increase of the small and medium businesses sector had a positive influence upon the businesses environment reducing the unemployment rate and increasing the productivity. It is necessary for the romanian state to rethink the fiscal system in order to better sustain the growth of the small and medium businesses sector taking into consideration that eventhough it's major role in the development of the country is known and admited the support is not likewise. We think of this considering that eventhough the number of the small and medium businesses in Romania has grown, the number of small and medium businesses to 1000 inhabitants is under the number from the European Union (in Romania the number of small and medium businesses to 1000 inhabitants is 25 and in the European Union is 64). We should take into account the fiscal changes of our neighbour countries because in comparison Romania is not so attractive to foreign investments.

CONCLUSIONS

Fiscal competition in the context of globalisation is seen as the efforts done by the state to reduce the tax quotas (most times this is done in correlation with the inlargement of the tax base) because it is trying to attract as many activities as possible.

In the last years the majority of the European Union countries, especially in the context of the inlargement of the union – the last 12 countries adhered, have changed or have in view of changing their tax quotas: Austria has diminish the tax rate from 34% in 2004 to 25% in 2005, Irland has moved from a maximum tax rate by 40% in 1994 to one by 12,5%in 2003, Romania has decrease the tax quota from 25% in 2004 to 16% in 2005,Germany has as scope the decrease of the total fiscal expenditures levied on the firms (29,83% in 2010 in comparison with 38,6% in present), the Czech Republic has diminish the profit tax from 24% to 21% in 2008 and in 2009 it will be 19%, as for the dividend tax Poland is using a tax of 19%, Romania 16%, Bulgaria 5% and there are countries where this revenue is tax free like Croatia, Hungary, Slovakia.

This phenomenon has not only positive effects (increase of the gross domestic product, of the added value, decrease of the unemployment rate and the development of the small and medium businesses sector, the increase of the national and international competitiveness) it has also negative effects like: imposing the revenues of the plusvalue obtain atfer selling goods, public deficits and others.

This phenomenon is directly connected with the brain-drain phenomenon, the emigration of the high educated "brains" who are choosing to leave the origin country and to develop an activity in another one who is more suitable to their fiscal and public choices. The brain-drain phenomenon has both negative and positive effects – negative or positive externalities – in the origin country where the individual has been educated and in the receiving country where the individual is developing his activity. Most times these externalities are monetary based.

We can assert that in the European Union the aim is not to harmonize the national fiscal systems because a loyal competition will contribute to the development of the countries, to the stimulation of the small and medium businesses sector who will take into account not only the characteristics of the fiscal system when it comes to locate their activity but also the geographical position, the labour cost and the infrastructure quality.

VEHICLES TAXATION IN ROMANIA: A COMPARATIVE APPROACH

Lazăr Sebastian

"Al. I. Cuza" University Iaşi, Faculty of Economics and Business Administration, E-mail: slazar@uaic.ro, Phone: 0744 567 695

Abstract: The taxes on vehicles are a very controversial issue nowadays, especially in Romania. The actual registration tax was much contested and, as a result, new projects were proposed by government authorities. The present paper makes a comparative analysis of the three versions, trying to see if the new versions are within the European Union requirements and to make some recommendations in order to improve the actual assessment of the tax.

Key words: vehicles taxation, comparative analyses, progressivity of taxation, solutions for improvement

JEL Classification: H20, H 21, H 23

The recent tax on passenger vehicles raised a lot of controversies, which have culminated with a recent petition addressed to the European Parliament signed by approximately 120.000 Romanian citizens, which was the biggest (in terms of number of people who had signed) in the entire history of the European Union. In spite of some issues that must be considered in order to judge the opportunity of such an initiative, it is a fact that the so-called "tax on first registration" represents a major issue of fiscal and environmental policy in Romania. Enacted at the 1st of January 2007 when Romania had became a full member of European Union, the tax had two major objectives: to provide revenues to the Romania state budget to offset the abolition of customs duties and partially of VAT in commercial relations with the other member states and to prevent the massive imports of used passenger vehicles in order to improve the age structure of the vehicles in circulation.

The criticism of measure was very intense. The amount of tax can range from 0 EUR/cm3 (for hybrid cars) to 2 EUR/CM3 (for non-euro vehicles). There are also, correlation coefficients that vary in accordance with the years of service and the depreciation of the vehicle. The formula used for calculating this tax is:

$Tax = A * B * C * ((100-D)/100$ (1),

A = cylindrical capacity (cm3)

B = unit of taxation (EUR/cm3) varying on pollution level;

C = correlation coefficient depending on the years of service of the vehicle;

D= depreciation coefficient depending on the years of service of the vehicle

The main critics of the assessment of this tax consist in its discriminatory characteristics, because it affects only imported second-hand cars, leaving indigenous second-hand cars untaxed and also in restricting the possibility of replacement of the old car, which is a non-desirable situation when the old car is more polluting than the "new" car. The European Commission had also criticized this measure, claiming its inconsistency with the European requirements. The registration taxes on vehicles put some problems like: double taxation, administrative procedures and extra costs, which creates obstacles to the free movement within the Community. In a recent paper[92], I have made some recommendations in order to improve the design of such a tax:

- the introduction of the CO2 based element in the assessment of tax;
- the implementation of a refund system in order to avoid double taxation;
- the gradual abolition of registration tax until 1st of January 2016 (Directive of the Council of European Union (2005/0130));

[92] Lazăr S. - „Registration Taxes on Vehicles: Evolutions and Trends in The European Union and Romania", Annals of Oradea University, Economics Series. Oradea, 2007;

On the other side, the partisans of such a tax considered that it has a positive impact on environment protection, and contributes to the development of indigenous automotive industry due to the prevalence of small cylindrical capacity vehicles in our domestic production.

Due to the numerous critics of the registration enacted on 1st January 2007, the authorities have came up with a new project of the tax[93], called now "vehicles pollution tax", meant to eliminate the inconsistencies with the EU requirements. The proposed formula used for the tax is:

Tax = A * B * (100-C)/100 (2),

A = cylindrical capacity (cm3)

B = unit of taxation (EUR/cm3) varying on pollution level;

C = diminution coefficient depending on the years of service of the vehicle, medium annual mileage, technical condition and optional equipments;

A starting point of analyses of the complying degree with the European normative is to reveal what European rules stipulate. In the field of registration taxes, there are few common rules that may be taken into account when it comes to tax the cars put in circulation. Nevertheless, a recent Directive of the Council of European Union (2005/0130) stipulates that every member state shall abandon any registration tax by the 1st January 2016. Nevertheless, in order to respond to environmental targets, the design of the registration tax must take into account the CO2 emissions as the main pillar of assessment. The reform of registration tax means that by 1 December 2008 (the start of the Kyoto period) at least 25% of the total tax revenue from registration taxes (but also from annual circulation taxes) should originate in the CO2 based element of each of these taxes. By 31 December 2010, at least 50% of the total tax revenue from both the annual circulation tax and the registration tax (pending its abolition) should originate in the CO2 based element of each of these taxes[94]. The proposed formula of the tax takes into consideration the CO2 emissions, but only indirectly, through the emission standards of vehicles and cylindrical capacity. But, too often such indicators do not reflect the real level of CO2 emission, due to the alteration of the nominal car specifications. Also, the new formula eliminates the depreciation coefficient (D) that was depending on the years of service of the vehicle and proposes new intervals of years of service for used cars. One major critics of the proposed project is the excessive taxation of new cars compared to the taxation of the same cars in the previous situation. For new cars that posses Euro 4 engines, the tax will rise by 2.614379 for capacities below 1600cm3 and by 1.24183 for capacities above 3000cm3. This will influence the selling of new vehicles in Romania, especially of those with lower power, but more environmentally friendly, greatly affecting the domestic producers which have the majority of the their cars below 1600 cm3.

Recently, Romanian authorities have come with the third version of the tax, which was under public debate, until April, the 10th. The major change consists in the introduction for Euro 4 and Euro 3 vehicles of a CO2 based element in the assessment of tax, in order to comply with the EU recommendations. For the rest, the tax is assessed in the same way, the only difference being the introduction of a supplementary interval of taxation for the vehicles with cylindrical capacity between 1401 and 1600 cm3. For Euro 4 and Euro 3 vehicles, the tax is determined as follows:

Tax = A * B *30/100 + C * D *70/100 * (100 – E)/100 (3),

A = CO2 emission (g/km) as mentioned in vehicle identification document;

B = unit of taxation (EUR/g CO2) varying on quantity of CO2 emitted;

C = cylindrical capacity (cm3)

D = unit of taxation (EUR/cm3) varying on emission standard;

E = depreciation coefficient depending on the years of service of the vehicle

The first term of the tax is taking into consideration the quantity of CO2 emitted by the vehicle, counting for 30% of the amount of the tax, while the second is taking into consideration the emission standard and the years of service of the vehicle, counting for the rest of 70%. The unit of taxation D was also changed, being now more progressive for Euro 2, Euro 1 and Non-euro vehicles (see figure no. 1). The 30 percents allocated to the CO2 emission may be questionable, but nevertheless it must be taken into consideration

[93] Available at http://www.mmediu.ro/proiecte_acte.htm;

[94] COMMISSION OF THE EUROPEAN COMMUNITIES - Proposal for a COUNCIL DIRECTIVE on passenger car related taxes, Brussels, 5.7.2005, COM(2005) 261 final, p. 8, available at: http://eur-lex.europa.eu/LexUriServ/site/en/com/2005/com2005_0261en01.pdf;

that the CO2 emission is just one of the pollutants generated by cars, along with nitrogen oxide, hydrocarbon and particulate matters which are more polluting, but do not generate global warming. The CO2 is the major source of the global warming, but the global warming is not the only concern when it comes to fight against pollution. The specific tax related to the CO2 emission (B from equation 3) is presented in table no. 1

CO2 emission (g CO2/km)	Specific tax (euro/g CO2
<=120	0
121 - 150	0,5
151 - 180	1
181 – 210	2
211 – 240	4
241 – 270	6
>=271	8

Table No. 1 The specific tax related to the CO2 emission

Source: http://www.taxapoluare.audieripublice.ro/view_page.php?hash=9d828cc97915a651d29106b8e49bb60e

It is clear that the specific tax is progressive, the amount paid for every gram of CO2 increasing dramatically along with the amount of CO2 emitted. Thus, for a vehicle that emits less than 120 g CO2 per km there is no tax to pay, for a vehicle that emits 280 g CO2 per km the tax will be 2240 EUR and will generate 672 EUR in the general formula of tax (30% as specified in equation 3). The amount of tax generated by the CO2 emission is presented in figure no. 1

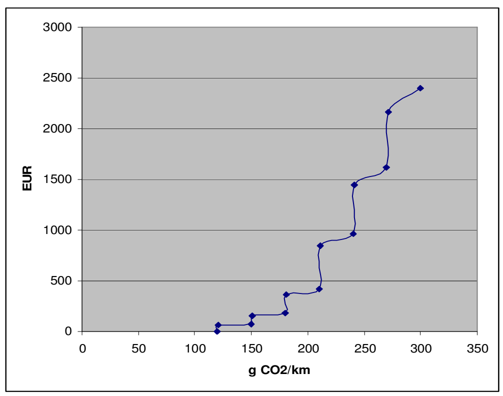

Figure no. 1. The amount of tax generated by the CO2 emission

The progressivity of taxation is obvious and one could appreciate it as being exaggerate. The simple progressive rates have the major inconvenient that they tax excessively the lower limit of an interval comparative to the higher limit of the previous interval. Thus, for 150 g CO2 emitted per km the tax will be 22.5 EUR (75 EUR * 0.3), but for 151 g CO2 emitted per km the tax will be 45.3 EUR (151 EUR * 0.3), more than twice as much. So, for just 1 g of CO2 emitted, the owner of the car will pay 22.8 EUR in extra taxes. Even though the partisans of this draft proposal must claim that such a solution of taxing the CO2 emission may discourage the acquisition of high polluting vehicles, the marginal taxation of an extra gram of CO2 emitted is, in our opinion, ***extremely progressive***. A solution may consist in imposing of a system based on ***compound progressive tax rates***, designed as follows:

CO2 emission (g CO2/km)	Specific tax (euro/g CO2)
<=120	0
121 - 150	0,5
151 - 180	75 EUR + 1 EUR for every g of CO2 emitted above 150 g
181 – 210	105 EUR + 2 EUR for every g of CO2 emitted above 180 g
211 – 240	165 EUR + 4 EUR for every g of CO2 emitted above 210 g
241 – 270	285 EUR + 6 EUR for every g of CO2 emitted above 240 g
>=271	465 EUR + 8 EUR for every g of CO2 emitted above 270 g

Table No. 2 The alternative specific tax related to the CO2 emission

Source: http://www.taxapoluare.audieripublice.ro/view_page.php?hash=9d828cc97915a651d29106b8e49bb60e

Graphically, the alternative specific tax may be represented as follows:

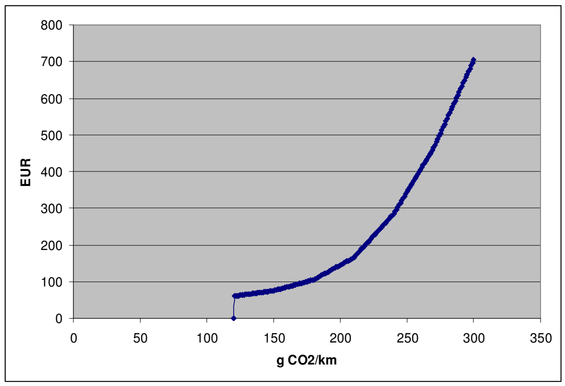

Figure no. 2. The amount of alternative tax generated by the CO2 emission

Such a taxation eliminates the situation in which for an extra gram of CO2 emitted, the owner has to pay much more in taxes. Also, we must take into consideration the fact that ***the quantity of CO2 emission is not a precise amount, being subject to numerous variations***, such as driving conduit or outside temperature. Nevertheless, almost everyone knows that consecutive tests on CO2 emissions may result in different results, an error of 1 g of CO2 being almost negligible. These are the reasons for which we plead for compound progressive tax rates and not for simple progressive tax rates as the authorities have proposed. The other part of the tax, the one that counts for the rest of 70 percents for Euro 3 and Euro 4 vehicles is related to cylindrical capacity, emission standards and depreciation of the vehicle. For Euro 2, Euro 1 and Non-Euro vehicles, this formula counts for the entire amount of tax (100%). The specific tax is denominated in EUR per cm3 of cylindrical capacity and it is presented in figure no. 3 by comparison with the actual variant (equation 1) and the precedent proposal (equation 2).

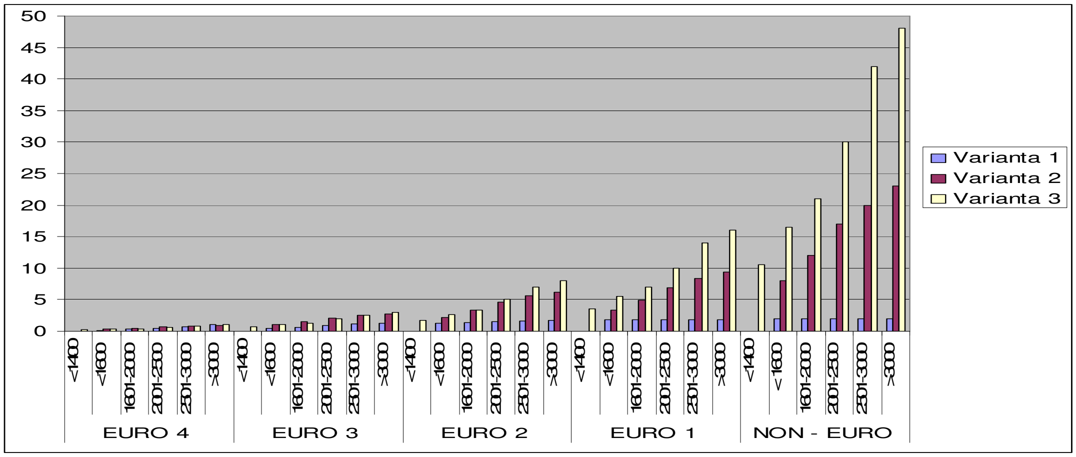

Fig. No. 3 The unit of taxation (EUR/cm3) for the three versions of the tax

The level of taxation is the highest for the last proposal (variant 3), especially for the Euro 2, Euro 1 and Non-Euro vehicles, when this form of taxation counts for the entire amount of tax (not just 70% as for Euro 3 and Euro 4 vehicles). Also, in the last proposal it has been introduced a new interval for cylindrical capacity, the one for engines below 1400 cm3. The tax rate has increased dramatically especially for Euro 1 and Non-Euro vehicles which are the most polluting in accordance with the "polluter pays" principle.

Another major critics that was tackled consists in the depreciation factor that has to be in accordance with the years of service of the vehicle, the average annually mileage, the technical status and the level of equipment. So, the actual proposal takes into consideration these factors, proposing new coefficients of depreciation better corresponding to the period of service of the vehicle, as seen in table no. 3.

Period of service	Depreciation coefficient (actual variant) (%)	Depreciation coefficient (proposal) (%)	Period of service	Depreciation coefficient (actual variant) (%)	Depreciation coefficient (proposal) (%)
new	15	0	6 - 7 years	47	49
< 1 month	15	3	7 - 8 years	47	55
1 - 3 months	15	5	8 - 9 years	47	61
3 - 6 months	15	8	9 - 10 years	47	66
6 - 9 months	15	10	10 - 11 years	47	73
9 months - 1 year	15	13	11 - 12 years	47	79
1 - 2 years	25	21	12 - 13 years	47	84
2 - 3 years	32	28	13 - 14 years	47	89
3 - 4 years	32	33	14 - 15 years	47	93
4 - 5 years	43	38	>15 years	47	95
5 - 6 years	43	43			

Table no. 3 The depreciation coefficient in actual variant and proposal

Source: http://www.taxapoluare.audieripublice.ro/view_page.php?hash=9d828cc97915a651d29106b8e49bb60e

By comparison to the existent scheme, the proposal takes into consideration much more intervals for the years of service of the vehicles, and the coefficient is rising up to 95% for cars of more than 15 years of service. Also, for new cars the proposed depreciation coefficient is zero, as it should be. The comparative evolution of the depreciation coefficient in the actual scheme and the proposal can be seen in the figure no. 3.

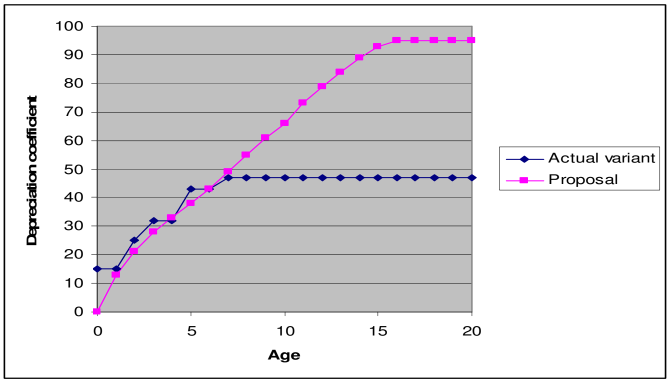

Figure no. 4. The comparative evolution of the depreciation coefficient

In the case of the proposal, the depreciation coefficient rise constantly with every year of service of the vehicle, reaching the maximum level of 95% for vehicles of more than 15 years of service. The increasing of the coefficient is more accelerated in the first years of service, as it can be seen in the figure no. 3. Another major critic of the registration tax, respectively the double taxation was tackled by instituting a ***procedure of reimbursement*** of the tax when the car is taken out from the domestic park of vehicles. The value to be refund is set to the residual value of the tax which represents the tax that would have been paid if the vehicle has been registered at the moment of the taking out. So, if a Romanian resident registers a car of two years of service, he pays the tax accordingly, and if he sells the car abroad (in the other member state) after four yeas, he is entitled to a refund calculated for the same car but with 6 years of service. This mechanism requires the tax to decrease along with the years of service, in order to avoid situations when the owner of the car receives more than he had been paid when he first registered the car. The new tax that will replace the actual one will not be a revenue for the state budget, but it will represent a revenue for the special fund for environment, thus, ***being dedicated to the financing of the specific environment preservation actions***, emphasizing the ecological characteristics of such a tax. The public debates did not change in any way the draft proposal of the authorities, but it is still to be seen the final form of the tax after the European Commission consultation, which could improve the assessment of the tax, by applying the ***progressive taxation using compound tax rates.***

Abstract: Having in view the importance of creativity, innovation, financing and knowledge management in the entrepreneurial activities, this paper is focused on underlining some aspects regarding the structure of the creative and innovative approach and the business incubators which are the best background to activate creativity and innovation. Because many business incubators stopped their activity, we try to find solutions for them.

We present knowledge management as a new type of management for incubators, innovation indicators and the modern innovative structures which are the optimum background to apply knowledge-based strategies.

Keywords: Innovation, SME (small and medium enterprises), Business incubators, Knowledge management, Financing, Indicators

1. The structure of the creative and innovative approach

Creativity is very important in the entrepreneurial activities. A creative process involves four stages [1] :

1st stage – The storing of knowledge

Successful entrepreneurial activities are generally preceded by explorations and documentations in order to provide the storing of knowledge. Among these we can count: reading informative materials from different domains, professional groups' reunions and research on internal and external published works concerning the subject of interest, the development of a specialized bibliography.

2nd stage – The incubation process

The incubation process takes place while people that have already covered the first stage detach from the question in study to let the subconscious work. The incubation process can take place while: thinking of the problem during the moments of relaxation and meditation; embarking upon routine and entertaining activities.

3rd stage – Experiencing the idea

The evolution from the second to the third stage often takes place unconsciously because, after the incubation process, the idea can suddenly emerge, but reflecting on it will define more clearly the idea.

4th stage – The evaluation and the implementation of the idea

Thinking on the idea will determine a re-processing and refinement that would lead to the creation of an original final idea.

Building a successful entrepreneurial activity supposes making a connection between creativity and innovation.

But innovation supposes a systematic approach, it also implies science, technology, economical – financial principles, spirit of initiative, management and it transforms creative ideas in realities with noticeable modifications.

Innovation is materialized in the transfer of a brand new idea or of a new concept until the final stage of a new product, process or service activity accepted by the market. [2]

Any form it could take, innovation must offer an increased value and a technological development to the new product to such an extent that could also ensure commercial success.

The innovations generated by inventions are also known as product innovations and those generated by the implementation of new techniques and technologies, in order to get a highest quality, are known as process innovations.

2. Business incubators – the best background to activate creativity and innovation

In Romania, the small and medium sized enterprises (SME) sector emerged on an immature market and that situation was the source of great difficulties in finding the resources but also of lot of opportunities as a result of the clients' unsatisfied demand.

The main problem that the private entrepreneur faced was determined by the great number of public institutions that had to work together but also the insufficient entrepreneurial and management training.

The vulnerability and the social and economical costs induced by the failure of such enterprises led to the clear conclusion that they must by supported by the government. That is why the contemporary time is appreciated as being the time of creativity and of the powerful implication of the government to develop the small and medium sized enterprises. Therefore, by the implementation of START program, the government offered the opportunity of developing the entrepreneurial abilities among young people. For the period 2006 – 2009, the procedures of implementation of the national multi-annual program for supporting the SME access to training and consulting services and for exportation development were also approved (Disposition 55/2006 and Disposition 52/2006).

An important help offered to the companies immediately after their establishment is represented by the business incubators for which The SME (the small and medium sized enterprises) and cooperatives National Agency set up a "multi-annual establishment and development program (between 2002 – 2009) for technological and business incubators".

Nowadays, in Romania, there are few incubators, with weak impact that can not satisfy the special needs of the new or already functioning SME. With a low outliving rate, number of incubators stopped their activity because they didn't have enough financial support that could offer them the required viability until self-support. Their creation wasn't based on partnerships that could support the financing after financial discontinuation.

The activity and the success of an incubator depend on the choice of goals and distinct strategies but also on a initial financing supported later by an adequate financial discipline.

Consequently, nowadays, the creation of a business incubator must comply with new requirements regarding:

- The creation and development of innovative SME that use efficiently the resources existing in the research system and technology and that create new jobs;
- The creation of an efficient relation between the technological and entrepreneurial potential;
- The improvement of access for incubated SME to information, consulting and also to services and specific research equipments;
- The use of facilities, of human resources and materials existing in that area.

At this time, the only business segment where the innovation degree is higher in Romania than in the European Union is the one in which these SMEs feel the competition pressure to enter the international market, i.e. the textile, leather and shoes industry.

In Romania, small enterprises come with few innovations, in comparison with big enterprises. Even if small enterprises, theoretically, should be the main promoters for innovation due to their internal flexibility and adaptability, they don't have the financial power to innovate, they are not open to risk and the most of them are found in non-innovative domains as retail trade.

Placing the SME under the protection and monitoring of an incubator would generate the background capable to establish politics that could determine the development of their innovative potentialities and that could help them penetrate domains with high added value.

3. A new type of management for incubators – knowledge management

Efficient managerial systems to manage the new ideas and knowledge are also necessary in order to develop the activity of the SME included in a business incubator.

The old saying “knowledge means power” proved ineffective because life proved that the real power comes not from the existence of knowledge but from the ability to implement this knowledge by means of an efficient management.

It has been proved that excellence ensuring the competitive advantage depends, mainly, on the knowledge management. The totals of knowledge existing in a company represent the intellectual capital and the aim of the entrepreneurs and managers is to develop this capital.

The intellectual capital includes four categories of intangible assets [3]:

- Market assets: trade marks, market shares, order reserves (as far as the production process could cover them), chains of distribution, license of franchising agreements, etc. These assets generate the competitive advantage.
- Infrastructure assets: technologies, work systems, specific technical procedures that make a company run efficiently. These assets represent the culture of the organization indicating the ways the employees work and communicate what management systems are used in the company.
- Intellectual property assets: patents, software, brand-marks, product-marks, service-marks, copyrights, etc.
- Human values: the employees’ talents and professional abilities, the experiences, leadership, the capacity to state and to solve problems. These values have synergic effect because their sum can be larger than the sum of the parts if the companies managed to set up communities where the creative capacity is stimulated.

In a business incubator, knowledge management means adopting a new attitude towards intellectual capital development within the framework of companies.

Knowledge management will become a reality when the incubator or the structures including an incubator moves from the spirit of competition to the one of co-participation and partnership.

4. The modern innovative structures – the optimum background to apply knowledge-based strategies

The transition to the knowledge-based economy implies stronger relations between companies and relations between companies and the education and research-development institutions, etc.

The creation of connections between the business incubator and such institutions will generate the creation of complete innovational networks. In the framework of such structure, knowledge management has two distinctive tasks: to facilitate the creation of new knowledge and to organize the way the employees of the companies helped by the incubator and those of the education and research-development institutions communicate their knowledge to be applied in concert.

There is a strong relation between the innovation associate and the knowledge production. In such a context, the companies stimulate the production of new knowledge by means of accepting audacious visions on economic strategies, meanwhile promoting the values and knowledge already existing in the company.

The application and the use of knowledge suppose that they circulate among the component structures of the innovational network.

Innovation and knowledge management imply the application of some distinctive strategies. “Knowledge-based strategies rely on two new elements that generally can not be found in classic strategies: knowledge becomes the most important strategic resource of the organization, and learning represents the most important capacity of any system” [4]. In these conditions, one can speak about new strategies as it follows:

- qualification
- standardization
- personalization
- vision-based strategies and strategies based on emergent studies which are able to generate competitive advantages on national and international level.

5. Innovation indicators

The performance indicators considered in present as relevant for the SMEs activity evaluation it is proved more useful in the performance evaluation from the past and less useful in the performance evaluation from the future.

A list of innovation indicators proposed by different institutions (such as the Ministry of Small and Medium Sized Enterprises, Commerce, Tourism and Liberal professions and others) was analyzed using the innovation criteria.

The indicators analysis permit the selection of the most suitable indicators for the SMEs, thus became a system of indicators that evaluates the SMEs performance in innovation. This system of indicators has:

a) Input indicators

(Indicators which are under direct control of the SME management)

b) Output indicators

(Indicators which make the results evaluation on medium or short term, the consequence of the taken measures regarding the innovation)

c) Indicators for measuring the efficiency of the activity

(Indicators which are due only partial to innovation, but they make references to the general objectives of the business):

1. General results
- Survival (for example years)
- Increasing of profitableness
- Number of new work places
2. Products and processes
- Market quota at regional level
- Market quota at national level
- Market quota at european level
3. Focus on client and extern image
- Clients satisfaction determined by mail, phone or direct contacts
- Sales for the new customers
- Benefits from sales to the new customers
- Extension of brand or name promotion of the SME
- Number of references in mass media regarding the SME in cause, such as example for good practice in the field of innovation.

Because the performance indicators list seems always to be extended, it is necessary for each SME to select a set of adequate indicators to the specific situation, indicators which constitute “the board table” of the SME performance in cause.

6. Conclusion

Like a set of conclusive considerations, it is noteworthy that in the case of Romania, there are few incubators, with weak impact that can not satisfy the special needs of the new or already functioning SME. The activity and the success of an incubator depend on the choice of goals and distinct strategies but also on an adequate financial discipline.

Efficient managerial systems to manage the new ideas and knowledge are also necessary in order to develop the activity of the SME included in a business incubator. Life proved that the real power comes not from the existence of knowledge but from the ability to implement this knowledge by means of an efficient management.

Knowledge management will become a reality when the incubator or the structures including an incubator moves from the spirit of competition to the one of co-participation and partnership.

STRUCTURAL MUTATIONS INTERVENED IN THE SOCIAL INSURANCE SYSTEMS

Major Dan

Universitatea Babeş-Bolyai Cluj Napoca, Facultatea de Ştiinţe Economice şi Gestiunea Afacerilor, Miercurea Ciuc, Bd. Frăţiei nr. 17, sc. B, Ap.7, Harghita, danmaior@yahoo.com, 0722-262738

Social insurance doesn't stand much chance of survival to the wave of globalization. Principles, such as inter- and intragenerational solidarity or the redistribution of the national wealth are gradually replaced by completely different or even opposite ones, such as individualism and capitalism, which are closer to the mercantile spirit of the globalization movement. The principle of solidarity is dangerous to the promotors of globalization because it creates a sense of unity and empathy between people and this diminishes the effect of the "divide et impera" policy which needs to be applied even on the individual level. Actually we are witnessing a process of atomization of the society by the autization of the individuals. We can say that one of the tendencies of today's world manifesting itself in a striking manner in the social domain is represented by the convergence of social systems towards the North-Western social model which, in the absence of a credible alternative, expands rapidly to a planetary level.

social insurance, globalization, pensions

Introduction

The social domain doesn't stand a chance to the wave of globalization, its economic component having probably the greatest influence on the changes in the social policies of the states in the recent years. Social principles, such as generational solidarity and the redistribution of the national wealth were replaced in the last two decades by others which are totally different, for example individualism and saving, and these are closer to the mercantile spirit of the globalization movement. The main financial institutions leading this process, The World Band and the IMF (International Monetary Fund), realized that the social sector, which handles an important part of the wealth of a country, can become a suitable domain to the involvement of the private capital in the purpose of gaining significant profit. On the other hand we also have to take into consideration the fact that imposing the laws of private economic competition in a sector which may represent the largest function of the nation-state at this moment, namely the protection of the citizens against some social risks, led to the considerable reduction of the role of the state.

We can say that one of the tendencies of today's world manifesting itself in a striking manner in the social domain is represented by the convergence of the social systems to the Norh-Western social model which, in the absence of a credible alternative, expands rapidly to a planetary level. It hasn't been implanted in all the regions of the planet yet because the local societies of some geographical regions are not "modern" enough to implant it. But when we talk about the modernization of regions like this, about rising their level of civilization, their living standards and the quality of the lives of their population, we take into consideration their advancement within the framework of the coordinates of the neo-liberal model[95]. From this point of view the globalization consists of the "export" of this model from the "central" states to the ones on the outskirts, as well as the "import" of the model and eventually its adoption, implantation and adaptation to the local requirements[96].

1. The controversies of the involvement of the private sector in social insurance

The debates connected to the degree of involvement of the private sector in financing and handling the social services began when the first forms of social insurance appeared because this is, in fact, the main difference between the models of insurance: the degree of involvement from the state in protecting its own citizens and the social risks that the private firms should cover. This balance changed in time depending on several economic, social and especially political factors because the social insurance systems are organized in most states by central public institutions. If at the beginning of the operation of the systems the targeted

[95] Roth, A., *Modernity and social modernization*, Polirom Publishing House, Iaşi, 2002, p. 64.
[96] Maliţa, M., *Ten thousand cultures, a single civilization. Towards the geomodernity of the 21st century*, Nemira Publishing House, Bucureşti, 1998, p. 20.

risks were few and the degree of the population coverage was not important, involving only certain social categories, with the development of the society the complexity of social needs increased considerably because the state tried to protect the citizen during his whole life and the services were extended practically to the level of all social categories. This development of the social insurance systems led to the increase of financial resources handled by these systems and also to a growth in the interest of private investors in taking over the handling of some of their components.

The involvement of the private capital in the social sector is not based on social reasons, its purpose is, like in any investment, the profit. This is an almost certain profit because the targeted problems (health, old age) affect every inhabitant of the planet, no matter their living standards or geographical region, so they become certain customers of the offered services. The private capital undoubtedly produces an evolution in the quality of "the social products" because the competition between the supplying firms is beneficial and they have to innovate and develop continuously the offer they promote. In this way innovations appear in medicine, new treatment methods and medicine for diseases which were previously untreatable are discovered, the private hospitals provide better conditions for treatment and recovery, in the domain of pensions a better income is promised at an old age and the concept so dear to the western society of individual property over the contributions to the private system is promoted (unlike the public one where the funds were distributed on the level of the whole society). All these aspects may seem as a positive evolution of the human civilization and up to a point they are. But the problem that such an evolution implies is that it eliminates exactly the notion "social" from the system, the beneficiaries of all these innovations are only those who can afford to pay the asked price and those with a difficult financial situation and in the biggest need of this type of services are left out of the system.

The more and more significant intrusion of the private capital in the domain of social insurance in the recent years is due to the phenomenon of economic globalization, to the increase of the role of transnational firms to manage financial flood on the world market and their need to identify new directions of investing the enormous capital they hold. The clear intention of acquiring the social domain is illustrated by Bill Gates' statements at the beginning of 2007 in which he says that "the private money is going to make the policy of the industrialized states more effective in the direction of assistance for development" and there is a need for "the planning of charitable actions according to strict managerial criteria". It is to be seen how the economic efficiency can be applied in the social domain in which we do not deal with merchandise or production units any more but with people and their needs which have to be met because some of them are elementary and not artificially created.

One of the effects of the increased involvement of the private capital is the diminished importance of the public institutions in managing some social aspects, the role of the state becoming a residual one, of solving the problems of the lower stratum of the population which doesn't have enough income to be able to contribute to the privately managed funds and to be attractive to the private firms. The exclusion of this population category (which in some cases adds up to a considerable percentage) is realized by imposing some minimal limits to the contribution to the private pension funds or determining prices for the medical services which are inaccessible to this category. So the efficiency of the private system is not so much due to the efficient methods used but more to the fact that the system doesn't take over the population percentage with difficult financial situation and it doesn't make transfers between population categories, from those with higher income and financial capability to those with very low income or without any income because this would reduce a part of the benefits enjoyed by the former and also the efficiency of the system.

The privatization of social services also has an important political consequence: it reduces the dependence of the population on national governments. One of the most attractive features of public social systems, as far as full coverage within the pension systems is concerned, is the dependence of the majority of the population on the system. Thus those who politically control the system can manipulate the electorate to reelect them by promising the elderly a stable annual income which could increase the value of the pensions. But as in the case of economic monopoly, the phrase according to which "competition destroys power" is valid also in the public sector.[97]

The descentralization of the system by privatization leads to the existence of more systems which are in competition, to different products and policies which determine the redistribution of the power centres

[97] Biedenkopf, K., *The Privatization of Social Security*, in *The Geneva Papers on Risk and Insurance*, vol. 24 nr. 3 (July 1999).

within the social security systems. The effect is the substantial reduction of the state monopoly and its power and the appearance of new players on the market of social services (the transnational firms), some of them even more powerful than the state. The positive results should be felt at the moment of the payment of the social benefits where the efficiency of the private capital constitutes a premise for the superior results than with the public methods. But this efficiency comes from the elimination of the unpredictable and unquantifiable factors which can affect the operation of financial transactions so that the mecanism can work without obstructions. And one of these factors is the social, human factor. The results achieved by the private pension systems (if they prove to be viable) will be beneficial only to those with high income during their active life, while the taxpayers who paid less, because of different objective or subjective reasons, will have a less quiet old age. The private capital will try to take over everything that can become a source of income, that can be exploited from the social sector leaving the latter the residual role of managing the difficult, unlucrative situations which consume financial and human resources.

2. The multipillar model of pensions proposed by the World Bank

The most important changement in the social insurance systems in the last decades occurred in the domain of pensions and it was the implementation in the whole world, in a relatively short period of time (approximately 20 years), of the multipillar model of pensions proposed by the World Bank.

Starting from a series of punctual data referring to the evolution of some pension systems in certain countries of the planet and from some estimates referring to the aging of the world's population in the period between 1990 and 2030, in 1994 the experts of the World Bank made up and published a report entitled "The prevention of the crisis of the third age" by which they wanted to draw attention to the potential danger represented by maintaining the existing systems and the necessity of the introduction of the privately administrated component within these. Thus the World Bank proposed a system in which the function of the redistribution of the pension systems would be separated from the function of saving and more than that, the latter would pass over from the public administration to the private one. In other words this work was going to become the textbook with the promotion, the acquisition, the implementation and the usage instructions of a product which was presented as an aid to the social services but which had nothing to do with this domain.

The main causes[98] which (in the opinion of the WB experts) determined the reorientation in the conception of the social security system models in the case of the elderly were the following:

- the ageing of the population;
- the resources saved by the publicly administrated funds are often wasted because of the bad management;
- governmental pensions are rarely increased in the rhythm of the inflation so the workers are poorly protected at an old age;
- due to the wide diffusion of medical knowledge and the decline of fertilily, the developing countries age much faster than the industrialized countries did, so they will have old demographical profiles reported to the levels of individual income which is much lower than those in the developed countries;
- the demand for health services grows as the countries (nations) get older because the health problems and the expensive medical technologies appear within the ranks of the elderly. As the expenses on the health and the pensions grow together, they both burden the resources of a country and the governments' budgets can exponentially grow with the ageing of the population;
- the high taxes distort the labour markets and reduce the economic growth;
- the governmental expenses which are raised with the social security of the elderly reduce the resources given to other public goods and services;

[98] *Averting the Old Age Crisis*, A World Bank Policy Research Report, Oxford University Press, 1994

- in developed countries the workers who retired in the first 30 years of the existence of the public system were given important transfers, while those who will retire in the future will get less than they would get from other investments and they will get back less than they gave;

The key recommendation of the report is that a national social security programme of the elderly should focus on all the three functions of the system, namely the functions of saving, redistribution and insurance, but with a very different role of the government for each of them:

- *the saving* implies the uniformity of the income during a person's life: people postpone a part of their consumption when they are young and their income is higher to be able to consume more than they could afford with their reduced income when they are old;
- *the redistribution* implies the movement of a lifelong income from one person to the other, maybe because if the workers with low income saved enough money to afford to live normally when they are old, it would mean for them to live as poor people when they are young;
- *the insurance* implies protection against the possibility that recession or badly made investments could cancel the savings, that the inflation could erode the real value, that people could live more than they saved for or that the public programme could fail;

The report recommends the separation of the function of saving from the function of redistribution within a system and their placement in different financial and administrative arrangements, in two different obligatory components-a publicly administrated and tax financed one and another which is entirely financed and administrated by the private sector-supplemented with an optional component for those who want more. Thus the new model based on three pillars was built, with the following features:

A) the public component -compulsory- would have the limited task of diminishing the poverty of the elderly and of coinsuring against a multitude of risks. Supported by the power of taxation of the government, this has the only ability to grant services to those who get old a short time after the introduction of the plan, to redistribute the income to the poor and to coinsure against long periods of obtaining small profits from the investments made, the recession, the inflation and the fall of private markets.

The public component could assume three alternative forms in the opinion of the WB experts: a) a part of a functional income programme for the poor of all ages with criteria of eligibility which should take into consideration the diminished working ability of the elderly and with levels of services which should take into consideration the tipical needs of this age; b) it could grant a minimal pension which is guaranteed by a compulsory component of saving; c) it could supply a uniform universal service or one connected to the employment of the labour force which could affect a larger group of people.

Whichever the chosen variant would be, the WB states that it should be of a modest size to leave place to the other components (the private ones) and to avoid the problems usually associated with the public administration of national supplying funds. A clear and limited objective for the public component would substancially reduce the rate of contribution to the system and the fraud, as well as the pressures to overspend and intra- and intergenerational transfers.

B) the second component, also compulsory, should be *managed on private bases* and there are two alternative forms for this: *personal savings* or *occupational plans.* The explanation for the necessity of the presence of the private management in this component lies in the fact that the majority of the publicly supplied and managed schemes would produce poor results as public funds usually have to invest in governmental guarantees or the bonds of the quasi-governmental entities which frequently have levels of interest under the markets'. Because of this, public funds would produce less than on the open market and they would have to collect higher rates of contribution or grant lower services than they could do in other cases. On the opposite side would be the private schemes managed on principles of competition which are rarely in the situation of accepting reduced profit, under the level of the market. These are stimulated to invest in shares and bonds which offer less risky combinations and they can take advantage of the possibilities offered by international diversification and the competence in administration. Beside the higher profit brought to the taxpayers, the privately managed compulsory pension schemes can offer a series of advantages to the whole economy. They can constitute a part of a national policy of creating new financial institutions and intesifying the capital markets by the mobilization of economies on a long run and their distribution to more productive ways of usage. For these reasons the WB report firmly recommends the private management of the compulsorily supplied component.

C) the third component could be represented by *the optional occupational plans* or *the personal savings* which could supply an additional protection to those who want higher income for when they are old.

3. Critical thoughts about the WB model

Although it was mentioned that a good combination of the components is not identical in every moment and every place, the WB recommendation is that "all the countries should start planning the reforms now" (the call was made in 1994). This planning must take into consideration the objectives of the country, its history and current conditions and most of all the importance given to the redistribution opposed to the economy, the financial markets and the regulatory and taxation capacity. When giving all these pieces of advice and recommendations *the WB takes no account of the possibility that some countries may not need such a model of pensions* and it states that this model has to be imposed on a world level, the necessary type of reform and the rhythm of introduction will vary from fast in the countries with high and medium income whose systems have serious problems to slow in countries with low income which should avoid making the same mistakes.

The social insurance systems are disintegrated and threatened with privatization, the pensions, the health and education are on their way to be transformed into merchandise. We consider that the model of pensions based on three pillars proposed and spread by the WB and which is seen as a product of the neo-liberal economic model is the best example to support this statement.

Firstly it is a "custom-made" luxury product for the world market in limited number (for the countries that implemented it or they are going to implement it in the following years). Like any luxury product, it has a high price, both on the financial and socio-economic level. In order to be able to purchase it, a government needs to bear a considerable sum which cannot be paid in one instalment so it needs to identify supplementary sources of income. The handiest and fastest of these is the international loan which is generously offered by the producer of the good, namely the World Bank.

Whether the countries need this product or not is not important because usually the luxury products are not strictly necessary, the need for their demand and consumption is artificially created, not pre-existing. The same phenomenon occurred in our case. *Starting from the 90s the bigger or smaller national governments were "convinced" that they needed this kind of model.* The reports of international financial institutions, the IMF experts and the WB "demonstrated" that the world was going through a severe demographical crisis and even if it wasn't, this crisis would occur in the following 50 years and the governments were not ready to solve the socio-economic problems that would arise from it. The saving solution is "the acquisition" of the WB model which can be applied, with some modifications, to any social structure. The problem is that, once purchased, the product will start to show the first results only in 20-30 years without a guarantee that the expected results will be achieved and the economic, social and demographic situation predicted in the present will show the expected trend. But this aspect is less important because in case of a malfunction, there is a clause in "the selling contract" which states that the one who will bear the expenses of repair is the buyer (the national government).

Another problem raised by the promotion and spreading of this product is that, although it appeared as a "necessity" of the present difficult situation, it doesn't solve in any way the present problems of the redistributive pension systems. Actually by promising welfare to those who will retire in 20-30 years, the implementation of the model financially burdens even more the systems which already face difficulties in balancing the financial resources of the budgets of the public social insurance. The persons who are pensioners today and those who will fall in this social category in the next 20-30 years will entirely stay in the state's care, which, beside the huge costs of implementing the new model, will be forced to identify supplementary resources to grant at least satisfactory social services.

An aspect that we consider important to approach is that of *the marketing and advertisement that this product had.* Tested in the South-American laboratories, its successes were not as resounding as they were presented. The well-known and promoted Chilean model represented a relatively singular success in that part of the world as the other South-American countries which accepted the model obtained results much below the expectations or even disastrous ones and they had to reconsider a new system of social security. In these cases the responsible were identified within the given state and the national institutions and the persons who implemented the model were accused of lack of professionalism and corruption. Although these factors may have caused the failure, *the reality proved that the WB model cannot work unless elementary conditions of the existence of a viable market economy are met, with a powerful and transparently controlled capital market.* Without local experts in the given domain and with consultants of international financial institutions who were not familiar with the economic, social and political facts in the given countries, the model was implemented with the same proportions even when the existing conditions were different. This situation may be compared with the acquisition of a TGV (a train of great speed) by a country with a railway infrastructure which is technologically exceeded (for example Romania). Nobody can deny how useful that means of transport would be and how many benefits it would offer to the passengers. But the TGV cannot run yet because the infrastructure existing at the moment of its acquisition doesn't allow it to do that. This aspect is not an inconvenience: the important thing is that it has to be purchased and there is plenty of time to build the necessary infrastructure until the fairly high price for this technological innovation is paid. Yet there are three problems: firstly the TGV doesn't have 3rd class seats and the people belonging to this category can travel by it only if someone (maybe the state) provides them, by different means, the necessary resources to purchase the travel fares for the superior classes; secondly if the infrastructure is not well built there is a chance that the train derails when it starts to gain speed and thirdly there is a chance that after 20-30 years from the acquisition, due to the evolution of the technology, the buying government will realize that the newly built infrastructure doesn't meet the demands of the society at the moment when it is put to use. In the case of the WB the risk doesn't come from the development of the economy but from its involution, because the possibility that a major crisis appears on the financial markets of the world in the next years is growing.

The model was accepted in Europe probably because of the pressures of the financial institutions and due to the need of making homogenous the multitude of social security systems which were extremely heterogenous within the European Union. Its successes were not resounding and the model underwent some significant changes, a series of concessions were made especially as far as the importance and the proportions of the public pillar was concerned. Unlike the developing countries which had a less evolved social security system, the European countries had more powerful and traditional social models and the experts in this domain did not accept the implantation of the WB model without a fight. This explains that, with a few exceptions, the introduction of the new model was realized but the importance of the public pillar was maintained and the role of the state remained much more significant than the WB would have expected. But this is just a temporary compromise, the direction of evolution has already been indicated: *we are heading toward a privatization of the social services and especially of the pension systems.*

Conclusions

It is to be seen how beneficial the replacement of the public systems with private ones will be in the next 20-30 years but we can already ask a question: what will happen if the private management of the social domain will fail in the countries which are implementing this component now? The guarantees offered by the state do not cover even the nominal value of the sums transferred by the population and there are no sanctions or payment obligations for the managing firms in these situations. This private construction is built on a less safe ground which is periodically shattered by powerful earhtquakes (financial crises) and these can considerably affect the value of social services and the very existence of the system. There are not very many solutions to prevent such situations but we think that the internal legislations should force the private firms to guarantee for the managed sums (at least in the case of those obligatorily collected) at the value of the deposits, actualized with the percentages of the inflation, because these are not speculative investements that a person risks in order to obtain a large profit but the resources which will assure his living standards in the last period of his life.

The principle of solidarity which is at the base of social insurance is dangerous for the promotors of globalization because it creates a sense of unity and empathy between the people and that can lead at a given time to a sense of aversion, of rejection in a nation or a significant geographical region (for example Europe) towards some necessary elements of the process of globalization. *This aspect may lead to the diminution of the effect of the "divide et impera" policy which is promoted under the mask of global unity and this division needs to be applied even on the individual level via state-nation-society.* **Practically we witness a process of atomization of the society by the social autization of the individuals,** in other words their detachement from the problems of society and the inoculation of the concept of inequity of the solidarity and redistribution as modalities of solving these problems.

THE MAIN COORDINATES OF THE FISCAL AND BUDGETARY ROMANIAN POLICIES: PRESENT CHALLENGES

Marcu Nicu

University of Craiova, Faculty of Economics and Business Administration, 13 A.I. Cuza Street, 200585, Craiova, marcu.nicu@yahoo.com, 0752 166361

The fiscal and budgetary construction developped at national level is focused on the maintenance of the macroeconomic stability process in order to achieve the nominal and real convergence criteria concerning the membership of the Romanian economy to the European Union integrated monetary space. The orientation of the fiscal and budgetary national policies is subdue to some major constraints regarding their capacity of ensuring the external sustenance, of developping the non-inflation process, of forming and consolidating the financing resources necessary to the accomplishment of the post-adhesion engagements assumed by Romania as a member state of the European Union.

Fiscal policy, fiscal administration, budgetary policy, nominal and real convergence

Economic policies and actions that will be realized by authorities in the year 2008 are sub amount to the context of fulfilling the objectives assumed as part of the process of European integration, ensuring the nominal and real convergence with member state of the European Union. The projection of the main macroeconomic indicators will reflect, as follows, a performing and stable evolution that will allow the consolidation of the macroeconomic equilibrium already existing, maintenance under control of the budget deficit and continuation of the disinflation process.

The following coordinates characterize the internal and external macroeconomic frame, in which the Romanian economy will evolve during 2008:

- maintenance of favorable evolutions regarding economic increase, which proved to be robust, sustainable and of long period, sustained by structural reforms and of initialization of a sector convergence of European type;
- evolution of the international frame is favorable to financial stability in Romania, the following evolution being forecast:
- economic increase is estimated for the entire Union at 2.7% and for the Euro zone at 2.5%, Japan and China will continue to have favorable results, meanwhile emergent economies will maintain their robust trend;
- public finances in European Union, which beneficiated from 2006 of a significant economic bending, as well as an upturn regarding fiscal elasticity, reflected especially in fiscal vivacity of the companies will register in the future an improvement of their sustainability, forecasting for the year 2008 a deficit of Euro zone of 0.8% and for the entire Union of 1% from the Gross Internal Product;
- attentive supervising of some macroeconomic variables to avoid some eventual side-slip like:
- the level of the deficit of current account (estimated at 13.3% in 2008), which represents a major challenge, even if sustainability will be endured, as follows, by direct investments and capital transfers;
- the level of inflation and wage increase over the growth in productivity.

1. The main coordinates of the fiscal and budgetary policies

The configuration of the fiscal and budgetary policy in 2008 integrated in a context consistent with the economic tendencies and based on the Government determination to warrant the rapid convergence to the European Union standards, is defined by some major features:

- maintenance of a performing approach and oriented on the priority sector policies to ensure the continuity and consolidation of the macroeconomic equilibrium and continuation of the disinflation process;

- ensuring and consolidatin of necessary financial sourcing to support commitment which derives from integration in the great European familiy;
- formulation of a budget of development, positioned in a vision on long term, which will encourage investments and absorption of European funds.

The key elements of the fiscal and budgetary construction in 2008 are centered on:

- the maintenance of a stimulating fiscal policy, fiscal stability without precedent, characterized by maintenance of main taxes, no introduction of new taxes and without increasing the existing ones;
- the reduction of contributions of social insurances during 2008 with 6 percentage points, gathered (employee and employer);
- the observance of the conditionalities of the Maastricht Treaty, especially the one regarding the consolidated deficit of the general budget situated under 3% from the Gross Internal Product, given the conditions that the budgetary revenues have 39.3% and budgetary expenses represents appreciatively 42% in the Gross Internal Product, in order to maintain the forecast inflation target in 2008 under the controllable limits;
- attentive orientation of the budget funds to those sector policies that are considered priority and that observe the increase of the efficiency of public funds: education, health, social insurances, infrastructure, regional development, agriculture, research and innovation, defense;
- consolidation of conditions for the absorption and functionning of structural instruments, resource of which Romania will take advantage as part of the European Union in order to reach the objective of long-lasting increase. In this sense, it must be mentioned the approval of the National Strategic frame of reference that facilitates the projection of budgetary policies on multi annual basis, formed of seven operational programes financed by the European structural instruments and national funds.

The consolidated general budget, formed by a unitary system of budgets, the main instrument of orientation of the economy, generally and of diverse governmantal politics is formulated for year 2008 at a level of revenues of 39.3% from Gross Internal Product, increasing with 2.4 percentage points in comparison with 2007, the highest level from the past years and a level of expenses of 42% from the Gross Internal Product, increasing with 2.4 percentage points in comparison with 2007, with a budget deficit estimated at 2.7 % from the Gross Internal Product, under the limit of 3% forcast by the Maastricht Treaty - the same as one registered in 2007, reflecting thus a continuous process of fiscal consolidation.

2. The objectives of the fiscal and budgetary policies

The vision of the actual Government in the field of fiscal polices is centered on ensuring a stimulating role of taxes and charges, with the purpose of consolidation of economic increase and development, of fiscal consolidation, and of their stability. The reform process of the fiscal policy started at the end of 2004, aimed at the stimulation of productive activity by introducing the unique percent of taxation of work incomes. Romania is thus one of the countries with the highest level of attractivity for investments that will allow a sustained modernization and increase, which will get us near the medium level of European development, as soon as possible.

The main coordinates of the fiscal policy in 2008 are the following:

- maintaining the unique quota that had multiple advantages such as re-launching the economy, reducing the underground economy, generating higher revenues for enterprising, generating higher revenues for employees;
- reducing contributions of social insurances with 6 cumulated percentage points (employer and employee);
- continuous perfection of the legislative frame to respond to criteria of harmonization of communitarian legislation;
- improvement of fiscal administration characterized by the following values: increased transparency, equal treatment of taxpayers, relation of superior quality with citizens, services

adapted to their needs, responsibility and adhesion of employers at the objectives of the National Agency of Fiscal Administration.

The great line of evolution ruling the activity of the fiscal administration in the following five years, are the following:

- Improvement of the collecting process of budgetary revenues;
- Improvement and extension of services offer to the taxpayers;
- Modernization of the fiscal control. Application of techniques of informatics control. Modernization of selection techniques of taxpayers (based on the risk analysis) and the inspection procedures;
- Consolidation of custom control, simplification of procedures and their modernization;
- Professional development of employees;
- Impelling the strategic planing and control of results. Improvement of the instrument of strategic and operational planning (management on objectives). Delimitation of the risk areas;
- Extended international presence.

The budgetary policy in 2008, formulated in the context of the implementation of the policies assuring the macroeconomic stability, takes into account a budgetary deficit under 3% from the Gross Internal Product, target that will be respected on the 2009-2011 reference horizon, in order to contribute to:

- reducing the excessive aggregate demand and continuing the disinflation process;
- intensifying the stability and long term economic increase according to the particularities of the Romanian economy.

The national authorities formulated the budgetary policy for 2008 in the context of:

- continuation of the reform process that will be realized through horizontal consolidation of economic policies, improvements of the budgetary programming on medium term and increasing transparency of this process, observing the perfection of the budget based on objectives, results, performance;
- reformation of the budgetary philosophy, in the sense of supporting economic sectors with high added value, as well as those based on knowledge. The intervention of state, in conformity with the communitarian rules, will avoid the support of these non-viable economic sectors or social measures of protection that endanger the insurance of durability of development and prove to be vulnerable in front of competition and challenges of globalization. Development of competitive advantages will take into account the advantages and opportunities offered by the Internal Market;
- financing the priority public policies, as a correct approach of Romania in front of the challenges of European integration and globalization, under the conditions ensuring coherence and complementarities with already existing strategic-programmed instruments (National Plan of Development 2007-2013, National Program of Reforms 2007-2013, National Strategic Frame of Reference 2007-2013.

The main objectives of the budgetary policy in 2008 could be synthesized as follows:

- Direction of the budgetary resources to those sector policies considered priority: education, health, support of social insurance, transports, environment, regional development, research-innovation and development – essential objectives of the Strategic of Lisboan, agriculture and defense. This objective must be situated in the context in which:
- Since the 1st January 2007, Romania, as a member state of the European Union applies the provisions of the Social European Charter, which anticipates the right of the old persons to social protection. During 2008, pensions point will represent only 37.5% from the gross medium wage. Support for realization of this objective is given by the economic increase forecast for 2008 to 6.5% estimated to reach 5.8% in 2011, the improvement of the collecting of the budgetary revenues, the legislative modification from fiscal field and the one of social insurances.

- The new approach of the elaboration of European Union budget forecasts for 2008 the allocation of about 44% of the funds to the economic increase and occupation of force labor, indicating a major change that demonstrates the Union volition to concentrate funds on general economic welfare. Important is the fact that common agricultural policy and administration of natural resources passed on second place, in the sense that funds allocated to programs of continuous rural development to increase, while the direct payments for farmers are decreasing.
- Development of the concept of strategic planning which will allow the consolidation of the connection between planning of public policies and elaboration of budget and increasing efficiency of coherence of public funds.

Starting with 2007, the stage of strategic planning was introduced as part of the process of elaboration of budget for 2008, as first stage of the process of elaboration of the annual budget project. As part of this project, public policies that are financed through budget must be found in the priorities of the Governing program, the National Plan of development and programmatic documents issued in Romania's position as member state of the European Union.

A major advantage of the phase of strategic planning is given by the fact that even from the beginning of the budgetary process, the connection between priority public policies, their objectives and medium term budgetary resources will be realized.

The expected result of the strategic planning phase consists in the development and consolidation of the budgetary approach, based on programs. Thus, the public budget for 2008 includes a number of 236 programs, in comparison with 194 programs registered in 2007, representing about 76.2% from the total expenses of the public budget. From the 50 main credit officers, a number of 25 presented budgets entirely based on programs.

- Ensuring the amounts for co-financing of the projects financed from the European funds and the contribution of Romania to communitarian budget, in the condition of a deficit situated under 3% from the Gross Internal Product. The European structural financing instruments have the role of stimulating the economic increase of the member states, of reducing the disparities between regions, and require, according with the additional principle, the participation of public sources of the member states, in certain fields being also necessary the private financial contribution.
- Increasing the economic and financial discipline in ministries and governmental agencies, as well as in units under their subordination, being observed the efficient and attentive addressed allocation of the budgetary funds, the reinforcement of mechanism of control of public expenses, the increase of responsibility and managerial performances, the elimination of registered dysfunctions, the risk identification and monitoring.

This paper uses the structural models methodology to estimate the credit risk for the Romanian companies that are listed at the Bucharest Stock Exchange. Under the new Basel Capital Accord that is also spreading to the capital markets, financial institutions are allowed to report using internal ratings. We present a methodology for computing the probabilities of default on the Romanian capital, which constitutes the first part of the development of a rating system based on market values.

Cuvinte cheie: Expected Default Frequencies, Structured Credit Risk Model, Romanian Capital Market,Credit Rating

Introduction and Objective

This paper uses the structural models methodology to estimate the credit risk for the Romanian companies that are listed at the Bucharest Stock Exchange. Under the new Basel Capital Accord that is also spreading to the capital markets, financial institutions are allowed to report using internal ratings. We present a methodology for computing the probabilities of default on the Romanian capital, which constitutes the first part of the development of a rating system based on market values.

Generally the defaults occur when the firm is unable to meet its financial obligations. Here, the models are based on the timing of the event that causes the default. Most of the time, these models depend on the balance sheet interpretations. In other words the default occurs when the assets are too small compared to the liabilities.

The first developers of models in this area were Black and Scholes (1973) and Merton (1974). In these models default occurs at the maturity date of the debt, and when the condition of assets of the issuer is less than the face value of the debt is satisfied. In practice KMV corporation has developed estimated default frequency, which is based on this model and used for empirical estimator of default probabilities. Moody's also developed an estimator which depends on the balance sheet information for the same purpose.

The main idea of the structural models originating from Black-Scholes(1973) and Merton(1974) is to consider corporate liabilities as contingent claims on the assets of the firm. In other words the market value of the firm is the fundamental state variable (Giesecke 2002). Here, there is also the paper by Longstaff and Schwartz (1995) that we need to mention which is considered to be the second general methodology to price debt instruments subject to credit risk and also correlated interest rates and the credit risk.

In the classic papers Black-Scholes(1973) and Merton (1974), the contingent claims-based approach to valuing the corporate debt assumes that the interest rates constant and the default risk was modeled by means of option pricing theory.

The unrealistic part of the approach was that the default only occurs when the firm exhausts its assets. This point was taken into account by Black and Cox (1976) and they allowed default to happen when the assets of the firm reaches a specified level of threshold. This new addition of default condition enabled Black and Cox to construct a model where credit spreads would be consistent with the ones existed in the corporate debt markets. However, they carried the same assumption as before and, took the interest rates constant. This would make the calculation of the risky fixed income securities very difficult.

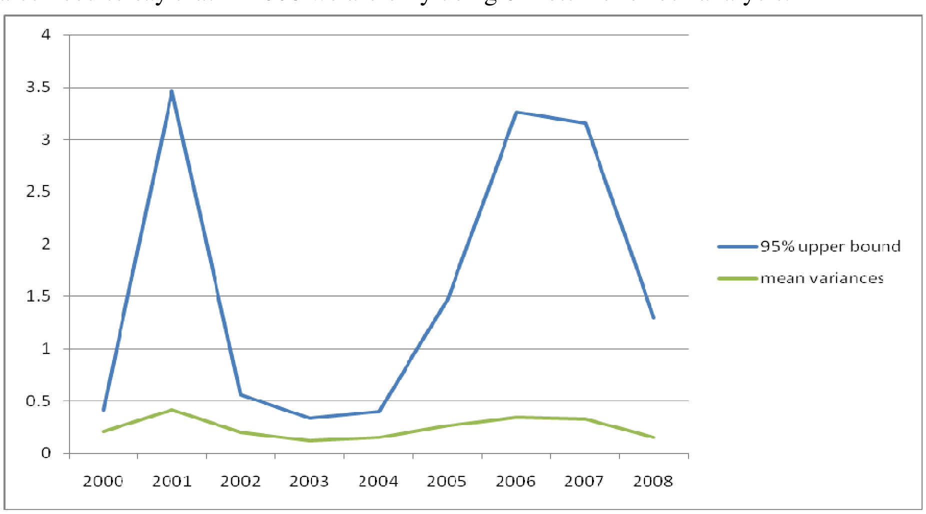
The importance of the Longstaff and Schwartz (1995) is to extend the Black and Cox (1976) Model in order to generate a new basic model for valuing risky debt where they combined default risk and interest rate risk and added the possibility of deviation from strict absolute priority. One of the most important results of the study was that; if there is different correlation between the assets of the firm and changes in the interest rates, there can be significant variations in the credit spreads of the firms whose default risks are similar. By the same token, they answered the existence of the different credit spreads of the bonds with similar credit ratings in different sectors.

Data and Methodology

We used data from the Bucharest Stock Exchange website and the first task was to organize it so that we can compute daily variances for each year. The variances were multiplied with square root of the number of observations that we had for each year for each stock in order to have annual variances. The Matlab software was used for all the computations. We obtained 77269 data for closing prices of all the stocks listed at the exchange from the 5th of January 2000 until the 29th of April 2008. For the days in which we lacked prices (due to holidays or days when the respective stock was not traded) we considered returns to be equal to zero. In this case we are aware that we reduce the variance for the respective days, by using introducing higher constancy into the data, but, on the other hand, the possible jumps, which would eventually happen at the next trading day, will sometimes compensate this fact. On the other hand, the usual interpolation techniques do not seem reasonable for the movement of the returns, as they showed to have low autocorrelation in previous studies. One way to extend the analysis would consist in fitting a GARCH process to the movement of the returns for each stock, but, we also had in mind the fact that we are only concerned with finding one statistic that proxies the volatility of the logarithmic returns for the entire year, so in the end we would have also had to average the volatilities out.

The variances that we obtained for each stock were computed as the variance of the daily logarithmic returns multiplied by the number of observations in each year. One part of the work we developed was to build a vector with all the working days in the respective time interval and fill in returns for each day, so the number of observations was considered to be the same for all the stocks in our sample.

The variances were computed for 62 stocks for each year from 2000 until 2008. As we can see in the following graph, the variances at the beginning of our period were relatively high, with respect to the rest of the period. The blue line shows that the average returns were not so important but their dispersion among the stocks taken into account was quite impressive. The same thing can be observed in 2006 and 2007 and we can observe that the dispersion of the stocks around the mean variance is reducing towards 2007. We also need to say that in 2008 we are only using 84 returns for our analysis.



Average variances and the 95% upper bound for all the stocks in each year

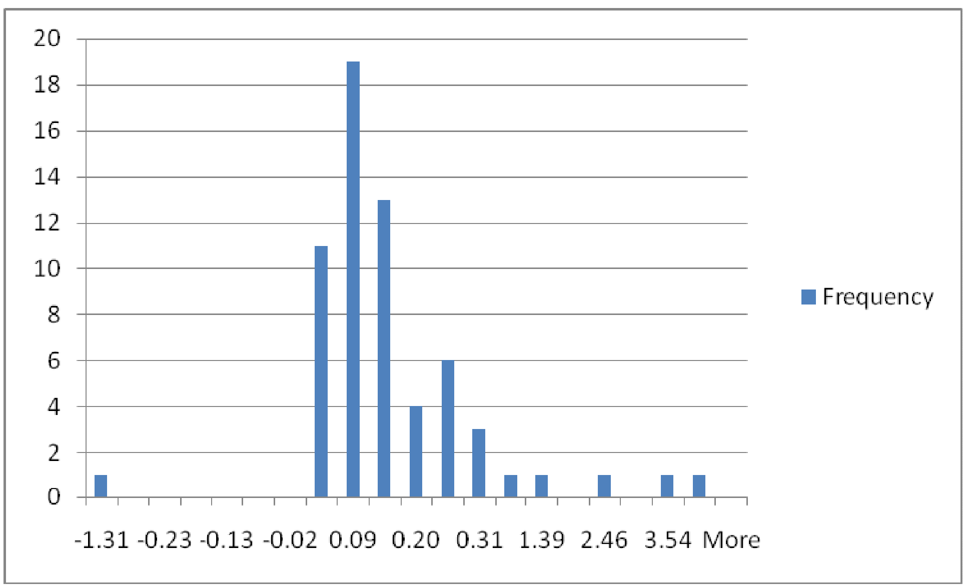
As shown in the following table, the number of companies is increasing from 2000 until 2008, mainly due to the fact that we focused on characterizing the credit risk for the companies that are now listed at the Bucharest Stock Exchange, many of which were not traded such a long time ago.

Year	**2000**	**2001**	**2002**	**2003**	**2004**	**2005**	**2006**	**2007**	**2008**
Mean variance	0.209	0.418	0.205	0.121	0.154	0.263	0.348	0.328	0.155
Standard deviation of variances	0.105	1.519	0.180	0.110	0.123	0.609	1.453	1.413	0.570
95% upper bound	0.420	3.456	0.566	0.341	0.401	1.481	3.254	3.154	1.296
Number of stocks	42	45	46	46	49	54	56	59	62

Dynamics of the yearly variances from 2000 until 2008 for the Romanian listed securities

The reduction of the variances, followed by the reduction of the dispersion of the variances among the Romanian stocks, might be interpreted as a period of reduced risk. An interesting analysis might consist in checking for the relation between the dispersion of the variances among stocks and the market efficiency or the application of the standardized models of analysis. We can observe that the change in the mean variance is not linearly connected to the dispersion of the variances – in 2002 until 2004 the mean variance was the smallest from our analysis, and a very small movement in this mean created an impressive dispersion in 2005 until 2007 as well as in 2000 until 2002. We can conclude that a small change of the mean variance determines an important change in the dispersion of the variances among stocks. Also, one might look at the similar movements of the mean variance and its upper bound in the other countries in the region.

We also computed the values for linear trends for all the stocks taking as input the movement in variances in all the 9 years.



Histogram of the linear trends in the variances for all the listed stocks

As can be seen in the histogram, the trends of the variances are dispersed very much around 0, so we could not say much about the average trend in the variance – the largest part of the trends are focused in the interval from 0.04 to 0.2, which means a very slight increase in the variance in the year to come.

All this information about the variance will provide important perspective as far as risk of the companies is concerned. As previously mentioned, our focus here is not to analyze the variance but to compute the risk-neutral default probabilities for our listed stocks. Consequently, the next step was to collect information about the market capitalization of our stocks as well as the book value of assets and total debt. We obtained information about these financial indicators by consulting the website www.ktd.ro, which contains electronic versions of financial reports for the stocks under analysis. We obtained annual reports for years 2000 until 2003 and quarterly reports for the years 2004 until 2007. Despite the information provided in the public sources we were not able to compute reliable figures for total assets, which made us, in the end, to reduce our analysis to the years 2005 until 2007 (we did not include any reports for 2008 being mainly preliminary computations of the indicators).

Our main focus was to match the variances computed in the first part of the study with the information provided by these reports. We needed the total assets and the market capitalization at the moment of the reports as well as the variances and the risk free rates for each year. As proxy for the risk free rates we computed the average of the ROBID and ROBOR for the annual rates from 2000 until 2008 using the quotes supplied by the Romanian National Bank. The average rates are to be used in the Black Scholes Merton equation in order to find the market value of assets and the variance of these values.

In order the find the two factors we had to solve the system of two nonlinear equations containing two unknowns[99]. As in Delianedis and Geske (1999) the equations are the following:

$$S = VN(k + \sigma_v\sqrt{T-t} - Me^{-r_f(T-t)}N(k) \qquad (1)$$

where

$$k = \frac{\ln\left(\frac{V}{M}\right) + \left(r_f - \frac{1}{2\sigma_v^2}\right)(T-t)}{\sigma_v\sqrt{T-t}}$$

and

S = current market value of the stock (in our case the market capitalization of the company);

V = current market value of the firm (the market value of the assets – variable we need to find);

M = face value of debt (total debt considered to mature in one year);

rf = the theoretical risk-free rate of interest (average of the ROBID and ROBOR rates in each year);

σv = the instantaneous variance of the return on the firm's assets (the variance of the market value of assets, the other variable we need to find);

t = current time;

T = maturity date of the debt (one year into to future);

N(.) = univariate cumulative normal distribution function

The second equation relies on the relation between the variance of the market value of assets and the variance of the stock returns, as follows:

$$\sigma_s = \frac{\partial S}{\partial V}\frac{V}{S}\,\sigma_v \qquad (2)$$

From equation (1) and (2) we need to find the values for σ_v and V, considering that we know all the other data (σ_v is computed as the mean variance of the daily log-returns multiplied by the number of observations in each year). We computed the first part of equation (2) as the changes in the values of the market capitalization divided by the changes in the values of the market values of assets from one year to another. Sometimes, in cases where we did not have information about one of the variables, we had to consider these changes to spread over many years. As previously said, equation (1) provides a setting in which the shareholders have the option to pay the debt (assumed to mature in one year[100]).

The two variables will help us to find the risk-neutral probability of default, expressed as the probability that the company will not have enough resources to cover for the debt they have to pay until the end of the year, in a world where all the investors are risk-neutral. As shown by standard theoretical developments, initiated by Black, Scholes and Merton, the risk-neutral world is a theoretical setting under which all

[99] The Matlab setting consisted in building a function that contains the two equations and then use the "fsolve" function to find the solution in an optimization manner – the values for our unknowns were found at the level where the value of the function was closed to 0

[100] The assumption is not so strong as we know that Romanian companies usually use short term debt.

investors are satisfied with the risk-free rate as a compensation for their investments (no risk-premiums), which means that the utility functions are linear (not concave, as in the case of risk-aversion, neither convex as in the case of risk-lovers). If we decide to assume risk-aversion, which is usually the case in most of the markets (risk premiums are positive) it can be shown that the risk-neutral probabilities of default are larger than the real probabilities of default, which means that, in all the cases, this methodology provides a rather conservative and not at all flawed measure of the credit risk. We estimated this as the probability that the market value of assets to be lower than the face value of debt in the following year.

Results

Our estimates of the risk neutral default probabilities were computed for the available information concerning the value of assets and the face value of debts for years 2005, 2006 and 2007. Due to the lack of space, the data for each stock in each year is not going to be shown here but it can be presented upon request.

As shown in the following table, the probabilities of default seem to be relatively low, but we need to notice that about half of the companies in our sample have default probabilities in the extremes – around 20% very close to 0% probability of default and about 20% close to 50% probability of default. In between these extremes the values for the risk of default seems to be relatively constantly dispersed.

Intervals	2005	2006	2007
0.00	9.52%	21.43%	19.05%
0.05	14.29%	16.67%	11.90%
0.10	7.14%	4.76%	4.76%
0.15	9.52%	0.00%	4.76%
0.20	0.00%	0.00%	7.14%
0.25	4.76%	4.76%	0.00%
0.30	7.14%	16.67%	0.00%
0.35	11.90%	4.76%	7.14%
0.40	7.14%	9.52%	2.38%
0.45	9.52%	7.14%	19.05%
0.50	19.05%	14.29%	23.81%

The frequency of the risk-neutral probabilities of default

We can also notice that the trend shows n increase in the risk of default as the percentage of companies with low values for the default probabilities is decreasing close to the 0 probability tail while on the other tail the probabilities are increasing – a higher percentage of companies with higher risk neutral probabilities on the 50% extreme.

Concluding remarks

Our paper aims at providing a framework for a methodology to use market date of the listed companies to find estimates of the probabilities of default. The setting is interesting if we have to take into account the fact that it could provide a methodology to establish a rating system for the Romanian companies listed at the Bucharest Stock Exchange.

Using the methodology of Merton and Delianedis and Geske (1999) we estimated risk-neutral probabilities of default considering a one year horizon for the total payment of the actual debt. We found that the market estimates for the probabilities of default are very much concentrated on the extremes of very close to 0% and close to 50%, for 42 Romanian companies.

The next step that we can envisage consists in finding proper thresholds for possible ratings. We aim at developing a matrix for the probabilities of transition of the companies from one rating to another, in a setting similar to Moody's KMV methodology. The challenge resides in finding the proper method to obtain steady ratings using the structural models.

Abstract: Since this capital gains tax liability is associated with the appraised value of the corporate assets, it is typically called the built-in gains (or BIG) tax liability. The asset-based approach analysis is often performed using the asset appraisal premise of value of: value in continued use, as part of a going concern. This premise of value assumes that the subject corporate assets would be sold as a going-concern business. The Company frequently furnished operators for the equipment that it rented to its customers, charging for both equipment and operators on an hourly basis. For example, a significant portion of the Company's revenues resulted from the renting of large cranes, both with and without operators.

Key words: decision, stock,market.

Introduction

The valuation of the stock of a closely held business is an integral component of the formation, financing, contribution, and redemption phases of an employee stock ownership plan (ESOP). In the case of an ESOP formation, the closely held business may be a family-owned or other privately owned corporation that is sold (in total or in part) to the trust. Or, the closely held business may be a division or subsidiary of a publicly traded corporation that is being divested through an employee buy-out.

In any event, due to the ERISA adequate consideration requirements, employer corporation stock that is sold to or purchased from the ESOP must be independently valued. In addition, the employer corporation stock owned by the ESOP must be independently valued at least annually.

In compliance with both Internal Revenue Service and U.S. Department of Labor guidelines, analysts use three generally accepted approaches to value the securities involved in ESOP transactions. These three approaches are called the income approach, the market approach, and the asset-based approach. Analysts typically synthesize the quantitative value indications of two or more of these analytical approaches in reaching a final ESOP stock value conclusion.

The income approach values a corporation as the present value of the future income expected to be earned by the owners of the business. The most common income approach business/stock valuation methods are (1) the direct capitalization method and (2) the yield capitalization (or discounted cash flow) method.

The market approach values a corporation by reference to market-derived pricing multiples extracted from actual sales of comparative companies or securities. The most common market approach business/stock valuation methods are (1) the guideline merged and acquired company method and (2) the guideline publicly traded company method.

The asset-based approach values a corporation by reference to (1) the current value of all its assets (both tangible and intangible) less (2) the current value of all of its liabilities (both contingent and recorded). The most common asset-based approach business/stock valuation methods are (1) the net asset value method (where total corporate asset appreciation is estimated collectively) and (2) the asset accumulation method (where the company's individual tangible and intangible assets are separately identified and valued).

The big tax liability issue

In the asset-based approach, the analyst estimates the value of the corporation's assets either in aggregate (the net asset value method) or individually (the asset accumulation method). In any event, this appraised value (either aggregate or individual) is typically in excess of the income tax basis of the subject corporate assets. This is almost always the case with regard to the corporation's intangible assets. This is because these intangible assets typically have little or no income tax basis.

If the company's assets were sold in a fair market value transaction (i.e., the conceptual premise of the asset-based approach), the corporation would have to pay capital gains tax. The amount of the capital gains would be based on the appreciation of the company's assets that is, the assumed fair market value sales price of the assets less the income tax basis of the assets. The capital gains tax liability would be based on (1) the amount of the capital gains (i.e., the asset appreciation over income tax basis) and (2) the corporate capital gains tax rate.

Since this capital gains tax liability is associated with the appraised value of the corporate assets, it is typically called the built-in gains (or BIG) tax liability. The asset-based approach analysis is often performed using the asset appraisal premise of value of: value in continued use, as part of a going concern. This premise of value assumes that the subject corporate assets would be sold as a going-concern business.

However, such a hypothetical sale would, in fact, trigger the BIG tax. This conceptual issue ultimately relates to a basic procedural question: how should the analyst account for the BIG tax liability in an asset-based business/stock valuation?

There are three possible answers to this procedural question. First, the analyst can ignore the BIG tax liability. Historically, this is the procedure that many courts (and many analysts) have adopted.

Second, the analyst can estimate the amount of the BIG tax liability that corresponds to the appraised corporate asset values. Then, the analyst can adjust this gross BIG tax liability by an estimated probability reflecting (1) whether the subject company actually will sell its assets and (2) when that asset sale will take place. Because of perceived conceptual inconsistencies in this alternative, most analysts have not adopted this procedure. However, in recent years, many courts (implicitly or explicitly) have applied this probability-adjustment procedure.

Third, the analyst can estimate the amount of the BIG tax liability that corresponds to the appraised corporate asset values. Then, the analyst can adjust (i.e., reduce or "discount") the total net asset value by the full amount of the tax liability. Based on the facts of each individual analysis, this last procedure appears to represent the developing consensus of the business valuation community.

This valuation issue has not been specifically addressed in an ESOP-related addressed over the years in several federal gift and estate tax court cases. Recently, the Fifth Circuit weighed in on this valuation issue (based on an appeal of a U.S. Tax Court estate tax case). While this recent Fifth Circuit decision does not relate specifically to ESOP matters, it does provide important professional guidance to valuation analysts who practice in the ESOP arena.

Case Summary

In the *Estate of Beatrice Ellen Jones Dunn, rev'g and rem'g*, the U.S. Court of Appeals for the Fifth Circuit accepted the taxpayer argument that C corporation stock valuations should be adjusted for the potential BIG tax on appreciated corporate assets. Prior gift and estate tax cases have held that a C corporation holding company valuation may be adjusted (i.e., discounted) for the potential BIG tax liability. However, the valuation discounts allowed by the courts in these previous holding company valuation cases typically did not reflect the full 34 percent corporate capital gain tax rate.

The *Estate of Dunn* provides practical guidance on two issues related to the application of the BIG tax discount. First, the Appeals Court upheld the taxpayer position of a BIG tax valuation discount on appreciated assets based on the full 34 percent corporate capital gains tax rate .

Second, in addition to allowing a valuation adjustment for the full BIG tax liability, the *Estate of Dunn* is significant because of the type of business enterprise involved. The subject corporation in the *Estate of Dunn* is an operating company, not a property holding company. The previous judicial precedent related valuation discount all involved property holding companies. Such companies included real estate development companies or companies that just owned a portfolio of marketable securities.

The facts of the case

On the date of her death, Beatrice Ellen Jones Dunn (the decedent) owned a block of stock in Dunn Equipment, Inc. (the Company). Dunn Equipment, Inc., was incorporated in Texas in 1949. It was a family-owned business throughout its existence. The Company operated from four locations throughout Texas. In 1991, the Company had 134 employees, including three executives and eight salesmen.

Dunn Equipment, Inc. owned and rented out heavy equipment and provided related services, primarily in the petroleum refinery and petrochemical industries. The personal property rented from the Company by its customers consisted principally of large cranes, air compressors, backhoes, manlifts, and sanders and grinders.

The Company frequently furnished operators for the equipment that it rented to its customers, charging for both equipment and operators on an hourly basis. For example, a significant portion of the Company's revenues resulted from the renting of large cranes, both with and without operators.

The Company was consistently profitable. Historically, however, the Company's stock return on equity was lower than contemporaneous rates of return on various risk-free investment instruments.

The Tax Court further concluded that, in addition to lacking a super-majority herself, Ms. Dunn would not have been likely to garner the votes of additional shareholders sufficient to constitute the super-majority required to instigate liquidation or sale of all assets. This was because the other Company shareholders were determined to continue the independent existence and operations of Dunn Equipment, Inc., indefinitely.

The Service's Position

In the Tax Court proceeding, the Service valued the decedent's stock ownership using an asset-based valuation approach and, specifically, the NAV method. The Service, however, did not apply a valuation discount related to the potential BIG tax liability on the Company’s appreciated assets.

At the Tax Court trial, the Service argued that a BIG tax valuation discount was not an appropriate methodological procedure in an asset-based business/stock valuation analysis. In addition, the Service argued that there was no plan to liquidate the profitable company or to actually sell the appreciated corporate assets. Therefore, the Company would not actually have to pay the BIG tax liability in the foreseeable future.

However, the Service did not present an independent valuation expert at the Tax Court trial. Instead, the Service presented its position through legal argument and rebuttal testimony. The Appeals Court did not find this strategy convincing. In its decision, the Appeals Court stated the following regarding the Service's presentation of evidence:

Indeed, at trial, the Commissioner did not favor the TaxGourt with testimony of an expert appraiser, even though the Commissioner had affirmatively proposed his own, geometrically higher value for the decedent's block of stock—values that started out higher than the ones reported on the estate tax return and that were then multiplied, by virtue of the Commissioner's amended answer, to almost four times the Estate's figures. Yet instead of supporting his own higher values (for which he had the burden of proof) by proffering professional expert valuation testimony during the trial, the Commissioner merely engaged in guerrilla warfare, presenting only an accounting expert to snipe at the methodology of the Estate's valuation expert. The use of such trial tactics might be legitimate when merely contesting values proposed by the party opposite, but they can never suffice as support for a higher value affirmatively asserted by the party employing such a trial strategy. This is particularly true when, as here, that party is the Commissioner, who has the burden of proving the expanded value asserted in his amended answer.

Using such tactics remains the prerogative of the Commissioner and his trial counsel, at least up to a point. But when his choice of tactics is viewed in the framework of the substantive valuation methodology urged by the Commissioner in the Tax Court, his posture at trial is seen to be so extreme and so far removed from reality as to be totally lacking in probative value.

The taxpayer's position

At the Tax Court trial, the taxpayer's valuation expert estimated the value of the decedent's stock ownership using two business valuation approaches. First, the taxpayer's expert used the income approach and, specifically, the direct capitalization of income method. In this expert's application of the direct capitalization method, the income was measured as net income, not as net cash flow.

Second, like the methodology proposed by the

The appeals court's decision

The Appeals Court started its review of the subject valuation issues by quoting the authoritative literature regarding business/stock valuation, as follows:

The Appeals Court ultimately assigned (1) an 85 percent weight to the income approach value indication and (2) a 15 percent weight to asset-based approach value indication. Within the asset-based approach value indication, the Appeals Court rejected the Tax Court's 5 percent BIG tax valuation discount. Rather, the Appeals Court applied a BIG tax valuation discount based on the full 34 percent corporate capital gains tax rate.

Commenting on this valuation issue, the Appeals Court decision states:

No one can dispute that if Dunn Equipment had sold all of its heavy equipment, industrial real estate, and townhouse on the valuation date, the Corporation would have incurred a 34% federal tax on the gain realized, regardless of whether that gain were labeled as capital gain or ordinary income. The question, then, is not the rate of the built-in tax liability of the assets or the dollar amount of the inherent gain, but the method to employ in accounting for that inherent tax liability when valuing the Corporation's assets (not to be confused with the ultimate task of valuing its stock).

The Appeals Court reasoned that the asset-based business/stock valuation approach should not consider the likelihood of a corporate liquidation in determining the corporation's NAV. Rather, the Appeals Court concluded that the estimation of the BIG tax liability is an integral component of a corporation's value as derived by an asset-based approach valuation. Regarding this fundamental valuation issue, the Appeals Court decision stated the following:

Bottom Line: The likelihood of liquidation has no place in either of the two disparate approaches to valuing this particular operating company.

Reiterating the position that it took in the *Estate of Jameson,* the Appeals Court stated:

In our recent response to a similarly misguided application of the built-in gains tax factor by the Tax Court, we rejected its treatment as based on "internally inconsistent assumptions."

The Appeals Court reached this overall conclusion regarding the Tax Court's decision in *Dunn* v. *Commissioner.*

We conclude that the Tax Court erred as a matter of law in the valuation methodology that it selected and applied to facts that are now largely uncontested by virtue of stipulations, concessions, and non-erroneous findings of that court. This legal error produced an incorrect valuation and thus an erroneous final Tax Court judgment as to the Estate's tax deficiency, requiring remand to that court.

The Appeals Court specifically describes the perceived errors in the Tax Court decision as follows:

The Tax Court's fundamental error in this regard is reflected in its statement that for purposes of an asset-based analysis of corporate value a fully-informed willing buyer of corporate shares (as distinguished from the Corporation's assemblage of assets) constituting an operational-control majority would not seek a substantial price reduction for built-in tax liability, absent that buyer's intention to liquidate. This is simply wrong: It is inconceivable that, since the abolition of the General Utilities doctrine and the attendant repeal of relevant I.R.C. sections, such as 333 and 337, any reasonably informed, fully taxable buyer (1) of an operational-control majority block of stock in a corporation (2) for the purpose of acquiring its assets, has not instituted that all (or essentially all) of the latent tax liability of assets held in corporate solution be reflected in the purchased price of such stock.

We are satisfied that the hypothetical willing buyer of the Decedent's block of Dunn Equipment stock would demand a reduction in price for the built-in gains tax liability of the Corporation's assets at essentially 100 cents on the dollar, regardless of his subjective desires or intentions regarding use or disposition of the assets. Here, that reduction would be 34%. This is true "in spades" when, for purposes of computing the asset-based value of the Corporation, we assume (as we must) that the willing buyer is purchasing the stock to get the assets, whether in or out of corporate solution. We hold as a matter of law that the built-in gains tax liability of this particular business's assets must be considered as a dollar-for-dollar reduction when calculating the asset-based value of the Corporation, just as, conversely, built-in gains tax liability would have no place in the calculation of the Corporation's earnings-based value. [Pratt et al., *Valuing a Business, at 47* ("Tax consequences of ownership and/or transfer of stock . . . usually are quite different from those of ownership and/or transfer of direct investment in underlying assets. These tax implications often have a significant bearing on value.").]

The Appeals Court also presented a strong opinion of the conceptual position—and the trial tactics of the Service in the *Dunn* v. *Commissioner* case:

Consequently, the Commissioner's insistence at trial that the value of the subject stock in Dunn Equipment be determined exclusively on the basis of the market value of its assets, undiminished by their inherent tax liability—coupled with his failure to adduce affirmative testimony of a valuation expert—was so incongruous as to call his motivation into question.

Regarding the Service's position in the *Estate of Dunn* appellate case, the Fifth Circuit stated the following: The Commissioner's abrupt change of position on appeal is so inconsistent and irreconcilable with his pretrial and trial positions that all of his urgings to us are rendered highly suspect. We keep this duplicity in mind as we proceed to examine the Tax Court's valuation methodology.

Summary and conclusion

Valuation analysts typically use income and market approach methods (more commonly than asset-based approach methods) in business/stock valuations for ESOP purposes. However, the asset-based approach is a generally accepted approach for ESOP valuations. And, the asset-based approach is applied often enough so that the BIG tax discount conceptual issue should be resolved. There appears to be a growing consensus in the valuation community regarding this issue. The asset-based approach assumes that the subject company sells the business in an asset (versus a stock) transaction. The corporate assets sell, as a going concern, at the total of their appraised fair market values. All business/stock valuations are based on hypothetical sales transactions. In the market approach, there is a hypothetical saie of the corporate stock (in either a public market or in a private transaction). The fact that the company does not actually sell its stock does not invalidate the use of the market approach. Likewise, the fact that the company does not actually sell its assets does not invalidate the use of the asset-based approach. In a hypothetical sale of the corporate assets, a hypothetical BIG tax liability would be paid.

The *Estate of Dunn* concluded that a company's NAV should be adjusted (discounted) for the amount of this hypothetical BIG tax liability. The Appeals Court concluded that this adjustment should be made regardless of (1) whether or not the company plans to actually sell its corporate assets and (2) whether or not the company is an operating company or a property holding company. The *Estate of Dunn* provides important professional guidance to valuation analysts on two issues. First, when the asset-based approach-and specifically the NAV method is used to estimate business/stock value, the *Estate of Dunn* supports the calculation of the BIG tax valuation discount at the full capital gains corporate tax rate. According to the *Dunn* decision, the estimated BIG tax liability should not be reduced by an estimate of the probability of a near-term corporate liquidation.

Second, the *Dunn* decision indicates that the BIG tax adjustment I should be considered in the asset-j based valuation of any going-concern j business and not just in the valuation of property holding companies. The estimation of the potential BIG tax liability on appreciated assets is an integral methodological step in any asset-based approach business valuation. The consideration of the capital gains tax on revalued assets is a function of the selected valuation approach (i.e., the use of an asset-based approach valuation method). The consideration of the capital gains tax is not a function of the type of subject business enterprise (i.e., operating company versus holding company).

Although the *Estate of Dunn* does not have legal precedent value in an ESOP controversy, it does provide practical professional guidance to valuation practitioners. This is because the BIG tax valuation adjustment is as relevant an issue to ESOP business/stock valuations as it is to gift and estate tax business/stock valuations.

Abstract: In its review of the Tax Court decision in Jameson, the Fifth Circuit noted that the stock value for estate tax purposes depends on the timberland's fair market value on the taxpayer's date of death. Any sale of the subject company shares would cause a transfer of the timberland which would trigger the built-in capital gains tax liability. The estate's valuation experts noted that the only sound economic strategy for a hypothetical willing buyer of the holding company would be an immediate liquidation of the timberland. This discussion will summarize the various issues related to the valuation of a C corporation with appreciated underlying assets. This discussion will also present a practical framework for quantifying the appropriate valuation adjustment (if any) related to the capital gains tax contingent liability related to such corporations.

Key words: decision, stock,market.

Introduction

The valuation of a C corporation is a common valuation assignment. Experienced analysts routinely value 100 percent of the stock of a C corporation for such purposes as: merger and acquisition pricing; estate and gift tax planning and compliance; shareholder buy-sell agreements; ESOP formation and ERISA compliance; transaction fairness analysis; and shareholder disputes and other litigation matters.

The valuation of a C corporation with appreciated underlying assets is also a common valuation assignment. A C corporation will have appreciated underlying assets when the market value of its owned assets exceeds the income tax basis of its owned assets. This is a common phenomenon for C corporations whether the company is (1) an operating company or (2) an investment or holding company.

When the C corporation owns appreciated assets, a question arises as to how the analyst should consider the built-in capital gains tax liability. This is the tax liability that would be paid if (and only if) the C corporation liquidated (i.e., sold) its underlying assets at their current market values. The built-in capital gains tax is determined by (1) the amount of the gain on the sale of the assets multiplied by (2) the corporation's capital gains income tax rate. Particularly with regard to the estate and gift tax arena, there is conflicting judicial precedent regarding the valuation effects (if any) of the built-in capital gains tax liability of a C corporation with appreciated assets. Some courts have allowed a valuation adjustment (i.e., a valuation discount) of 100 percent of the estimated built-in capital gains tax liability in arriving at a business value. Other courts have allowed some valuation discount—but less than 100 percent of the subject company's estimated built-in capital gains tax liability.

This discussion will summarize the various issues related to the valuation of a C corporation with appreciated underlying assets. This discussion will also present a practical framework for quantifying the appropriate valuation adjustment (if any) related to the capital gains tax contingent liability related to such corporations.

Recent judicial precedent

The *Estate of Helen Bolton Jameson,* is the most recent federal taxation precedent with regard to this valuation discount issue. In *Jameson,* the taxpayer died owning the shares of a personal holding company. The main asset of that company was timberland. The Service and the taxpayer's estate disagreed on how the built-in capital gains taxes (which would be incurred on the sale of the timber or on the sale of the land) would affect the value of decedent's interest in the corporation.

At the trial level, the Tax Court allowed a valuation discount for the capital gains tax liability that the holding company would incur but only the capital gains taxes from its ongoing timber sales. The Tax Court disallowed a valuation discount based on the immediate sale of the timberland. Instead, the Tax Court concluded that a willing buyer of the timberland would operate it on an ongoing business. The taxpayer appealed the Tax Court decision to the U.S. Court of Appeals.

In its review of the Tax Court decision in *Jameson,* the Fifth Circuit noted that the stock value for estate tax purposes depends on the timberland's fair market value on the taxpayer's date of death. Any sale of the subject company shares would cause a transfer of the timberland which would trigger the built-in capital gains tax liability. The estate's valuation experts noted that the only sound economic strategy for a hypothetical willing buyer of the holding company would be an immediate liquidation of the timberland, thereby triggering the 34 percent capital gains tax.

According to the Appeals Court, the Tax Court should not have assumed that there was a strategic buyer for the timberland that could have continued to operate and produce timber. Instead, the Fifth Circuit stressed that a fair market value analysis depends on a hypothetical (instead of a specific) willing buyer. Therefore, according to the Fifth Circuit, the Tax Court erred in disallowing a 100 percent valuation discount for the built-in capital gains tax liability.

Lesson from judicial precedent

A review of the relevant judicial precedent indicates that, recently, federal courts are consistently allowing a valuation discount for the built-in capital gains tax contingent liability. The critical issue in most recent court cases is not: *if a* valuation discount should be allowed. The critical issue is: *how much* of a valuation discount for built-in capital gains tax should be allowed.

Acquiring the stock of a c corporation with appreciated assets

Certainly, buyers are willing to make stock acquisitions of C corporations with appreciated assets. Of course, these buyers recognize that the target C corporations come with an associated built-in capital gains tax liability. Such acquisitions are consummated if the transaction purchase price is sufficiently discounted to reflect the economic impact of the built-in capital gains tax liability.

In fact, if the transaction purchase price (i.e., the C corporation value) is appropriately discounted for the effect of the capital gains tax on the target company appreciated assets, the acquirer will realize the following economic benefits from the acquisition:

1. The acquirer (a) buys control of the target company appreciated underlying assets at a price discount and (b) earns investment returns based on the discounted purchase price; this has the same economic effect as an interest-free loan.
2. The "effective interest-free loan" is contingent—that is, it does not have to be "repaid" (the acquirer does not actually pay the corporate capital gains tax to the Internal Revenue Service) to the extent that the acquired appreciated assets decline in value (to their income tax basis) over time.

Therefore, some valuation analysts have argued (and some court decisions have held) that the value of a C corporation should be greater than the subject company's net asset value adjusted (i.e., discounted) for a full 100 percent of the built-in capital gains tax liability.

Stock Purchase versus Direct Asset Investment

The economic differences (1) between acquiring 100 percent of the stock of a C corporation and (2) making a direct investment in the underlying asset (through the use of borrowing) are:

1. The direct investment in the underlying asset requires the payment of cash interest expense during the investment holding period, a factor in favor of the acquisition of the C corporation stock.
2. The debt associated with the direct investment in the underlying asset is (a) fixed and (b) not contingent on earning any particular rate of return on the underlying asset, a factor in favor of the acquisition of the C corporation.
3. The direct investment in the underlying asset has a greater tax basis (i.e., $1,000) than the investment in the C corporation stock, a factor in favor of the direct investment in the underlying asset.

4. The acquisition of the C corporation stock means that all of the investment returns will be subject to double taxation (i.e., once at the corporate level and once at the distributee/shareholder level), a factor in favor of the direct investment in the underlying asset.

There is a potential economic disadvantage of acquiring the C corporation stock (with the built-in capital gain liability) relative to a direct investment in the underlying appreciated assets. This relative economic disadvantage depends on whether (1) the amount of the built-in capital gains tax liability of the C corporation is less than (2) the avoided cost of debt service from the direct investment in the underlying asset.

Valuation adjustment illustrative example

In the following discussion, we will present the comparative after-tax results of these two investment alternatives: (1) the acquisition of C corporation stock versus (2) underlying appreciated assets. We will analyze these two investment alternatives over a 10-year investment holding period.

It is noteworthy that our illustrative example assumptions present the most favorable case for measuring the economic advantage of the acquisition of the C corporation stock (relative to the direct purchase of the underlying asset). For example, all of the analyses assume that (1) the inside tax basis of the C corporation assets is zero and (2) the avoided cost of borrowing (i.e., the debt interest rate) is equal to the expected rate of return on the asset investment.

Adjusted base case scenario

Considering the put options, the asset purchase debt is arguably risk-free to the lender. This assumption supports an 8 percent interest rate spread. In the analysis presented in Table III, the direct asset investment alternative clearly generates a greater after-tax benefit than does the purchase of the C corporation (Target Company) stock.

In the direct asset purchase alternative, Buyer can cover this contingency by purchasing a put option. The put option will have a strike price equal to the market value of the security in an amount equal to the value of the security times the corporate tax rate. The intrinsic value of the put option would exactly offset the amount by which (1) the return on the investment in the C corporation exceeds (2) the return of the direct investment under any combination of tax assumptions and basis assumptions.

Where Target Company has any positive tax basis in the purchased assets, we assume that the sale at a loss will generate an income tax benefit equal to (1) the income tax rate times (2) the amount of the loss. To the extent that there is no "inside" income tax benefit available from the loss, the put strategy should be correspondingly adjusted.

Put option strategy

Whether or not the direct asset purchase alternative is more attractive than the purchase of Target Company stock depends on (1) the price of the put relative to (2) the financial advantage of the direct asset purchase.

We should, therefore, adjust the amount of the year 10 value to a present value. The discount rate for this calculation is adjusted to reflect the fact that the excess of the year 10 benefit of the direct asset investment alternative is after individual income taxes.

The rate of return assumption is, therefore, adjusted to reflect the fact that the year 10 benefit is after tax. This adjustment is based on individual income tax rates. The present value of the after-tax amount of excess return is the maximum amount the direct asset investor would pay for the put option.

The maximum price of the put option using "real world" assumptions amounts to approximately 53 percent of the value of the underlying asset. Based on "real world" assumptions, Buyer would pay no more than 53 percent of the asset value of the direct asset investment alternative for the put option.

Subchapter Selection

Accordingly, let's expand the analytical model to allow for the avoidance of the capital gains tax entirely. This assumption regarding the deferral/avoidance of capital gains tax makes the acquisition of the C corporation stock more attractive than the direct purchase of the underlying assets.

However, the price that Buyer will pay for the C corporation stock is affected by the illiquidity of the S election. That price reflects the fact that the asset cannot be sold—and therefore lacks marketability—for the statutory 10-year holding period. A sale of the appreciated asset within the 10-year holding will generate a lower rate of return than a direct purchase of the underlying asset.

The lack of marketability impact is measured by setting (1) the after-tax terminal value of the C corporation alternative equal to (2) the after-tax (post-debt) terminal value of the direct asset purchase alternative. By solving for the beginning dollar amount of the stock required to be inside the C corporation, we can estimate the amount of stock necessary to provide an equivalent rate of return to the direct asset purchase alternative.

It would be a lesser amount because both (1) the cost of borrowing and (2) the built-in capital gains tax are avoided. The amount, however, has a bearing on whether or not Buyer is willing to "lock up" the asset ownership position—that is, to forgo marketability, for 10 years.

Simplifying assumptions

For purposes of the analysis , we made the following simplifying assumptions:

- Transaction costs are ignored. 88 Dividends are assumed to be zero.
- The price of a 10-year put option is estimated using market volatility, current risk-free rates of return, an assumption of zero dividends, and a 10-year duration in the Black-Scholes option pricing model.

The Black-Scholes option pricing model may not be the best analytical procedure for estimating the price of a long-term option. Moreover, the price of a series of put options covering the interest component of the direct asset investment alternative is ig no red.

If we assume the cost of these options was the same as the put on the principal (which is probably overstating the case), then the basic conclusion remains the same.

- The price of put options is not considered in the estimate of the discount for lack of marketability. This discount is used in measuring the rate of return on the direct asset investment in order to set it equal to the C corporation asset. This assumption does not change the basic conclusion.
- Income taxes are estimated as follows:

1. The income tax benefit of the interest deduction is simply considered an addition to tax basis in year 10, and the individual capital gains tax rate is used. To the extent that a current interest expense deduction is available at ordinary income tax rates, it is an economic benefit to the direct asset investment alternative.
2. The income tax basis in the put option is ignored in all calculations
3. The proceeds from the exercise of the put option is assumed to offset the loss on the underlying asset. The income tax benefit of the loss is calculated at the assumed individual income tax rate.
4. Losses at the individual taxpayer level are assumed to generate an economic benefit equal to the income tax rate times the amount of the loss.
5. Losses inside the Target Company C corporation are assumed to generate income tax benefits equal to (a) the corporate income tax rate times (b) the amount of the loss.
6. State and local income taxes are ignored.

Summary and Conclusion

Each S corporation valuation depends on its unique set of facts and circumstances. However, there appears to be no financial advantage to (1) the stock acquisition of a C corporation with built-in capital gains relative to (2) the direct purchase of the underlying assets and a put option. Accordingly, no willing buyer would pay a price premium for the acquisition of the C corporation stock over the tax adjusted net asset value of the target. company. No willing buyer would pay a price premium over the target company tax-adjusted net asset value, and no willing seller would accept less than the target company tax-adjusted net asset value.

The principal reason for this outcome is the fact that 100 percent of the gains inside the target corporation are subject to double taxation. This double taxation offsets the apparent financial benefits described in the introduction. No rational tax adviser will advise a client to structure his or her transactions in a way that will subject investment returns to double taxation if it can be avoided.

The apparent economic advantage of (1) buying the C corporation stock and (2) electing S corporation status is more than offset by the fact that the underlying assets become non-marketable for a 10-year holding period.

Any asset holding period of less than 10 years will cause the direct asset purchase alternative to generate a greater after-tax rate of return than the acquisition of C corporation stock alternative.

L'EQUILIBRE FINANCIER ET DES DEVISES ET LA DETTE EXTERNE

Mitea Neluța

Université Andrei Saguna, Faculté des sciences économiques – Constanta, E-mail : miteala@yahoo.com, Tél ; 0727 – 223190, Section : Finances, Comptabilité et Banques, Sous-section : Finances

This paper focuses on the synthetic analysis of the financial-currency equilibrium and the external debt. The major problems of humanity such as poverty, diminishing of the natural resources, the external debt crises, etc., showing global dimensions, cannot be solved but with common efforts, while others having specific features can be solved only within the national framework, which has to get to a specific decisional autonomy.

The main function of the global financial market is to direct the capital fluxes from the producing resources to the most efficient locations, confirming the adequate rentability, and the less risky placement. The world development of the financial market is not uniform, as a result of the various economic evolutions. Forming the capital within the developed areas, and the placement of the necessity for financing within the developing areas leads the financial fluxes towards an opposite direction than that of the beginnings of the economic increase, when the countries 'natural resources, very poor now, sustained the development of the rich countries.

Key words: financial fluxes, currency equilibrium, external debt, deficit, and current account

L'apparition des flux financiers est déterminée par les activités de commerce extérieure et des transfères de capital. Dans le cas des importations et des exportations se crée un mouvement des devises en contrepartie qui peut être immédiate ou décalée dans le temps. Les flux de capital apparaissent sous forme de crédits financiers et d'investissements qui entraînent de futurs engagements monétaires. Les entrées et les sorties monétaires d'un pays s'imposent à être gérer d'une manière satisfaisante afin d'assurer l'équilibre financier et des devises. La différence de volume et de temps où se manifestent les flux de sens contraire conduit, selon le cas, à un état de déficit ou excédent externe. L'apparition de ces décalages est déterminée dans des conditions normales par la stratégie de développement adoptée par chaque pays. La croissance économique impose dans une première étape, l'attraction d'un volume élevé de capitaux externes, après quoi se produit une inversion des flux qui, au final, conduisent à l'équilibre avec l'extérieur. L'équilibre des devises représente une composante de l'équilibre général d'un pays qui, synthétiquement, peut être exprimé de la sorte:

$$\boxed{PIB + M = E + I + Ci}$$

Où : M – valeur des importations; E – valeur des exportations;

I – volume des investissements; Ci – consommation interne

L'accélération des mouvements des devises et financiers dans les conditions de la croissance du degré d'intégration des économies nationales dans l'économie globale a imposé l'élaboration d'une méthodologie unitaire pour l'expression de l'équilibre externe par chaque pays sous la forme de la balance d'encaissements et de payements en devises. Celle-ci est couramment connue sous le nom de la balance de payements externes qui comprend tous les flux induits par des opérations commerciales, non-commerciales et financières d'un pays avec l'extérieur pendant une certaine période, d'habitude un an. A son tour, la balance de payements externes est formée par plusieurs balances qui exprime l'état de chaque domaine : balance commerciale, balance des services, balance du capital et balance des mouvements internationaux des ressources de devises. La réalisation de l'équilibre des devises se suivit au niveau général, le déficit d'une sous-balance étant compensé par l'excédent d'une autre. En fonction des termes échéants des flux financiers ceux-ci sont groupés en deux chapitres : le compte courant et le compte de capital et financier.

Le compte courant comprend les encaissements et les payements résultés à la suite du commerce de marchandises et de services , des revenus du mouvement international des facteurs de production, ainsi que des transfères courants sans équivalent. Conformément à la méthodologie F.M.I., le prix utilisé pour l'inscription dans la balance des marchandises est FOB, c'est-à-dire celui qui existe à la frontière de l'exportateur. Les frais effectués dans le parcours externe pour le transport, les assurances, les manipulations etc., sont inclus dans les services. Le moment de l'inscription de la valeur d'un bien ou d'un service est celui où se fait le transfère de propriété. L'importance majeure de ce chapitre est détenue par le commerce de marchandises.

Le compte de capital et financier a comme fonction principale l'équilibre du compte courant. Le déficit courant est compensé par le compte de capital par l'attraction des ressources financières externes, et l'excédent courant suppose des placements externes par le même compte. La position active du compte courant crée une situation favorable pour le pays possesseur qui peut choisir indépendamment les variantes de placements, parmi lesquelles les plus importantes sont:

La réalisation des investissements directs à l'étranger, qui valorise les avantages offerts par le pays hôte. Le chiffre d'affaire des firmes remplacées à l'étranger contribue au croissement du Produit National Brut, et par le rapatriement du profit au maintient de la situation excédentaire du solde courant.

- L'acquisition de titres de valeur émis par autres états par lesquels on assure un rendement supérieur aux placements monétaires. L'avantage obtenu par l'investissement dans des titres négociables est donné par la mise en valeur supérieure et le maintient d'une liquidité élevée, ceux-ci pouvant être vendus à tout moment.
- L'approbation des crédits à l'étranger, publiques et privés. Ceux-ci sont porteurs de d'intérêt et, en plus, créent une position favorable pour le pays créditeur par rapport au pays débiteur.
- L'achat de devises pour l'augmentation des réserves propres et pour la réalisation d'une structure adéquate au portefeuille de devises.

Les pays ayant un déficit de compte courant essaient de trouver les modalités les plus avantageuses pour le recouvrir. Les principales sources de recouverte sont:

- L'attraction des investissements étrangers directs par l'approbation de facilités pour les investisseurs étrangers. L'avantage de l'attraction de capital sous cette forme consiste dans le fait que les investissements ne génèrent pas de dette externe, et leur implantation crée de nouveaux circuits économiques par lesquels se met en valeur les facteurs de production internes. La réalisation de biens et de services de l'exportation contribue à l'équilibre du compte courant du pays ôte, tout comme la rapatriement du profit a un effet inverse.
- L'engagement contractuel d'emprunts par l'émission de titres de valeur (obligations, chèques de trésorerie) porteurs d'intérêt, mais qui gérés dans une certaine manière désirée par le débiteur peuvent distribuer les obligations de celui-ci dans un intervalle de temps correspondant pour pouvoir les acquitter.
- L'engagement contractuel des crédits bancaires externes. Outre le fait que ceux-ci comportent des coûts , ils présentent le désavantage qu'ils génèrent des dettes externes. Outre certaines limites, la dette externe est difficilement à gérer.
- Crédits non remboursables. Cette modalité de financement du déficit est la plus avantageuse, mais leur poids est très réduit dans le total des ressources attirées.

La recouvertes des déficits de certains pays par les excédents des autres représente la modalité de circulation internationale des capitaux qui manifeste la tendance d'uniformisation mondiale. L'emploi des ressources externes d'une manière rationnelle pour l'assurance d'une augmentation économique équilibrée et dans de hauts rythmes, permet aux pays débiteurs de réduire les décalages qui les séparent des pays développés et résister aux obligations de payement externes. La Roumanie, en tant que pays en transition vers l'économie du marché, a enregistré, après 1989, de grands difficultés réfléchies synthétiquement dans l'évolution de la balance des devises. Dans les dernières années, s'est réalisée une stabilisation au niveau macroéconomique qui a permis un équilibre de même en ce qui concerne les rapports avec l'étranger.

L'analyse comparée du compte courant présente la situation suivante:

Indicateurs	2004	2005	2006	Variation (%)		
				2005/2004	2006/2005	2006/2004
a) Solde balance commerciale (biens)	-5.323	-5.908	-7.748	-10,99	-31,14	-64
- exportation (FOB)	18.935	21.754	26.133	14,89	20,12	38
- importation (FOB)	24.258	27.662	34.495	14	24,70	42,20
b) Services. net	-213	-184	370	13,61	300	371
c)Revenus. net	-2.535	-2.101	-2.519	17,12	19,89	0
d) Transfères courants	2.972	2.786	3.133	-6,25	24,55	5,41
Solde compte courant	-5.099	-5.223	-7.748	-2,43	-48,34	-51,95

Tableau nr.1. Evolution du compte courant

Source: www.bnr.ro

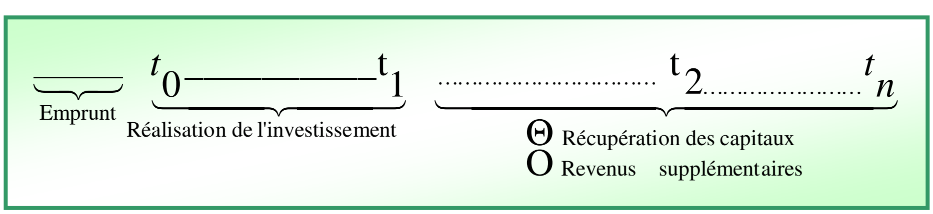
Le solde du compte enregistre une augmentation du déficit annuel avec un ralentissement en 2006. Le plus important facteur d'influence est la détérioration de la balance commerciale. L'accentuation du déficit commercial est due à la croissance du décalage en faveur des importations commencée pendant la seconde partie de l'an 2004. Les causes principales se retrouvent dans le manque de compétitivité des exportations et en faveur des importations par la tendance d'appréciation de la monnaie nationale. L'exportation de biens a augmenté dans la plus grande partie (trois quarts) grâce à l'augmentation des prix externes. Des modifications favorables se sont également produites en ce qui concerne le volume et la structure des exportations.

Le problème de fond est que l'économie n'est pas encore en mesure de produire des biens à valeur ajoutée élevée et les importations en complètement qui se retrouvent dans les marchandises exportées occupent un poids élevé d'environ 70% . Les importations ont augmenté grâce à la croissance des prix externes pour les ressources et les biens à longue utilisation mais aussi sur le compte de l'extension du crédit non gouvernemental . Le degré de couverture des importations par des exportations s'est réduit du 78,6% en 2005 à 75,8% en 2006. Les services enregistrent en 2006 pour la première fois en trois ans un excédent sur le compte du tourisme et d'autres services notamment d'informatique.

L'accentuation du déficit de la balance des revenus est due au rapatriement des non résidents des profits, à la retraite des capitaux spéculatives sur le fond de l'appréciation du leu , à la diminution des intérêts et à la création de conditions favorables de placement aux Etats-Unis. De même, l'augmentation du volume des intérêts payés dans le compte de la dette externe a accentué le déficit des revenus. La seule position ayant un solde positif dans le cadre du compte courant est celle des transfères. La valeur des excédents est due aux flux monétaires venus de l'extérieur notamment des ouvriers roumains en Ouest. Le financement du déficit de compte courant a été fait, en 2006, intégralement par des investissements étrangers directs en comparaison avec 81% dan l'année antérieure.

La prise en considération d'un horizon de temps d'un an dans le cas de la balance de payement externe, ne permet pas l'évaluation correcte des relations financières et des devises internationales.

La prise en considération d'une période moyenne de temps est imposée tant par les termes de remboursement que par la distribution temporelle des revenus à l'intermédiaire desquels les dettes s'éteignent. Le comportement rationnel du débiteur suppose qu'il fasse des emprunts au moment actuel pour réaliser un projet d'investissement qui constitue à l'avenir la source pour l'augmentation économique propre ainsi que pour la restitution de l'emprunt.



Le problème le plus astringent dans la gestion de l'équilibre financier pour les pays en voie de développement et sous-développés est celui de la dette externe. La dette externe d'un pays inclut les ressources financières attirées de l'extérieur sous forme de crédits et investissements de portefeuille. Une distinction doit être faite par le prisme des couts et des conditions de mise en accord entre les sources de financement externe. Les emprunts sur le marché de capital sont faits conformément aux exigences de celui-ci concernant le niveau des intérêts, des garanties, des termes etc. . Les coûts sur le marché de capital sont sous l'influence décisive de la classe de risque où est inclus le pays. Autre source d'emprunt international est représentée par le soit-disant financement officiel qui se déroule entre le gouvernement ou un pays et les organismes financiers internationaux. Ces emprunts nommés concessionnels peuvent avoir une composante non remboursable de petite valeur et qui n'est pas incluse dans la dette externe et une composante majeure qui revet la forme classique d'un crédit. La différence consiste dans le fait que pour le crédit officiel le taux de l'intérêt est plus réduit que celui sur le marché financier et les termes de remboursement sont plus grands ce qui conduit ç un degré plus réduit de charge du service des dettes externes pour le pays débiteur. Actuellement, pour les pays en voie de développement et sous-développés on parle d'une vraie crise de le dette externe qui doit être abordée sous deux angles:

- l'efficacité de l'utilisation des crédits externes par les pays endettés,
- les pratiques des pays créditeurs en ce qui concerne les conditions d'approbation des prêts.

Dans le premier cas, la comparaison entre les pays de l'Asie de Sud-est et ceux de l'Afrique peut être éloquente.

Après la seconde guerre mondiale, le volume des financements orientés vers les deux zones a été égal. Tandis qu'en Asie, pays comme Indinésie, Taiwan, Hong Konf, Corée de Sud ont investi la grande partie des crédits obtenus en économie, en Afrique ceux-ci ont été détournés de leur destination naturelle. Toujours dans le sens de l'utilisation non efficiente des crédits a actionné l'instabilité politique militaire dans beaucoup de pays en voie de développement. En même temps, les conditions dans lesquelles ont été accordés les prêts ont été pesantes en ce qui concerne le niveau des intérêts et des termes de remboursement.

Pendant la dernière décennie, le volume échéant de la dette externe a augmenté vertigineusement, en diminuant durement les entrées nettes de capitaux dans les pays en voie de développement approximativement de 70 %. La conséquence est qu'une série des pays ayant de grosses dettes et une situation économique précaire ont été obligés à interrompre les payements dans le compte des dettes externes, ce qui a conduit à l'augmentation du volume des arriérées externes par incapacité de payement. Pratiquement, ces pays sont sortis du circuit financier international et les effets négatifs se sont reflétés sur l'économie par la restriction de la production et de l'activité de commerce extérieure.

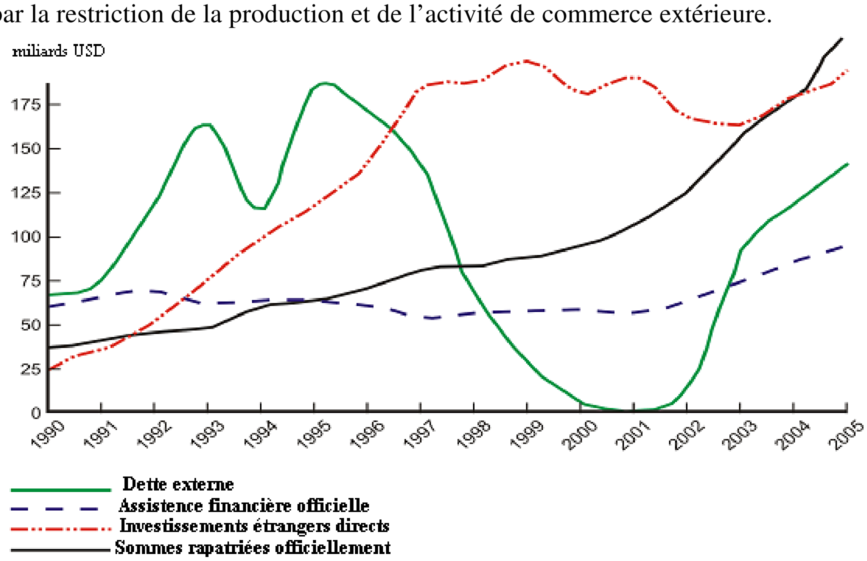


Diagramme nr.1. Les flux financières internationaux vers les pays en voie de développement

Source: Banque Mondiale

Une gestion rationnelle des créances et des dettes internationales suppose des conditions acceptables pour l'assurance d'un rendement convenable du placement de capital ainsi que pour l'obtention d'un minimum d'efficience des investissements internes. Il semble que, après la déclaration de l'insolvabilité d'une série d'états aux grosses dettes, cette chose a été comprise par la communauté financière internationale. Dans ce sens, on a créé in programme international d'assistance financière externe pour développement – A.F.E.D. - qui prévoit des opérations de rééchelonnement des dettes, des donations, des crédits non remboursables etc. Une autre mutation, beaucoup plus importante est celle du remplacement du crédit classique par des investissements directes étrangers qui, au présent, représente plus de la moitié des placements externes de capital. Les avantages pour les pays qui enregistrent des déficits est que ceux-ci ne sont pas partie de la dette externe et conduisent à l'augmentation de l'économie nationale. En même temps, est éliminée la suspicion concernant la non utilisation efficiente des crédits par l'emprunteur, les unités économiques réalisées par ces investissements étant dans l'administration directe des propriétaires de capitaux.

A l'équilibre de la balance externe de ces pays, une contribution de plus en plus importante est, pendant les dernières années, celle représentée par le rapatriement des revenus réalisés à l'étranger par les résidents. La tendance de ce flux financier est de dépasser toute autre forme d'entrée de capital : investissements, crédits aides etc. Il y a des pays comme la Moldavie où ces sommes représentent 27 % du PIB. La crise des dettes externes se manifeste par l'arrêt des payements, par le transfert inverse de ressources financières , par la décapitalisation des économies endettées par la vente des actives réels dans le compte de la dette externe etc. donc par une accentuation de la pauvreté et des difficultés avec lesquelles se confrontent les pays affectés. Le dépassement de la crise de la dette externe suppose la prise des mesures coordonnées à l'échelle planétaire.

La situation de débiteur net est caractéristique aux pays au niveau économique bien réduit, pays qui ont contribué, pendant les deux derniers siècles, à l'augmentation économique des pays du groupe des pays développés. Moralement, ces derniers sont obligés à manifester plus de compréhension dans les relations avec le reste du monde. Et sous l'aspect économique, un changement de l'attitude s'impose bien.

L'entrée dans le circuit mondial basé sur les principes de l'économie du marché des pays ex-communistes et des pays de l'Asie, avec plus de deux milliards d(habitants, a créé un immense marché de vente et d'opportunités particulières pour le placement du capital. L'ajustement économique et l'application des mesures de réduction des décalages économiques sous la coordination des institutions internationales constitue la prémisse essentielle pour l'élimination des crises et des contradictions mondiales.

MARKET NICHE IN AGRICULTURAL INSURANCES

Mitu Narcis Eduard

University of Craiova, Faculty of Economy and Business Administration, A. I. Cuza Street, No. 13, phone. 0251-411593, e-mail: narcised@yahoo.com

As the negative effects of climatic warming are more and more obvious, the demand for insurance solutions to cover the costs resulting from weather whims shall increase in direct ration with risk exposure. Although the situation might be interpreted as a business opportunity, in order to be able to offer the proper cover it is necessary to comply with fundamental demands regarding the weather risk insurance. Thus, when conceiving viable insurance solutions of the consequences intervened in case of a catastrophic event generated by harsh weather conditions we must take into consideration factors such as measurement possibility of the respective risk, in order to decide if this can or can not be accepted. Thus, in this item we tried to illustrate some elemental aspects connected to agricultural insurances perspectives.

Keywords: agricultural insurance, weather insurance, weather derivative.

1. The existing background of agricultural insurances

The experience of economically developed countries revealed the fact that without a stable development of *agricultural insurances,* there is no chance for high performance agriculture. The investment necessary for working the field by means of an intensive technology is too important to disconsider the climatic risks whose manifestation may ruine the entrepreneurs. The agricultural field of activity confronts with climatic risks which acquired lately a frequence and an intensity of manifestation unknown for us. In our country, calamities produced in agriculture, such as the drought, the hail, very low temperatures (under the limit of biological stand for crops and large farms), rainstorms causing indirect effects: overflowing, flooding, landslides etc., are very known due to their wide broadcasting.

A world classification of the flooding risk was undertaken, taking into account the quantification of 26 variables, within it Romania occupied the 49th position[101]. According to the statistics, during the years 1960-2003, 1.923.000 hectares of agricultural surface were damaged by flood.

Concern for risks that stifle investment and contribute to vulnerability of the rural poor is a driving force behind various types of agricultural insurance. Insuring small-scale farmers against crop losses to adverse weather or other hazards has attracted public sector involvement in the provision of agricultural insurance in many countries among which Romania. With few exceptions, such interventions have encountered severe problems owing to high administrative costs, moral hazard, adverse selection etc. Government interventions should be aimed at improving the accessibility and quality of private sector insurance. This will require the establishment of a framework for responding to severe systemic events affecting agricultural production, and establishing an appropriate regulatory environment to foster private sector innovation and investment in services for less catastrophic events.

2. Limits of the classical agricultural insurance

“The collaboration between public authorities and the insurance industry is necessary for the implementation and the operation of a protection strategy for insuring against disasters”, represents one of the conclusions formulated by ICAR Forum 2006[102]. The implementation of strategies of managing natural disasters leads to the diminution of the total cost allocated to damages. But, most of the time, it is impossible to implement similar strategies in different countries.[103] In this situation, the political will is determined within each country, different targets being followed.

In Romania, especially during the development process existing at present in agriculture, the public-private relationship is still absolutely necessary due to the failure proved by small farmers in dealing with multiple

[102] The International Catastrophic Risks Forum, 3rd edition, held at Bucharest on 2nd -3rd of October 2006.

[103] As Alberto MONTI, Principal Administrator (Insurance), Financial Affairs Division, EOCD (European Organisation for Cooperation and Development) mentioned in his presentation held within ICAR Forum 2006.

issues (the partitioning of fields, the lack of equipments and of a suitable infrastructure, new European rules, climatic changes generating effects which become more and more disastrous etc.). A long term and serious involvement of the government may cause negative consequences.

The governmental involvement on any market presents the possibility to exclude the particular sector. For this reason, the agricultural insurance market does not constitute an exception. The governmental aid in managing the risk in agriculture is materialized in the support allocated to the insurance premiums for certain categories of policies and risks and in the financial and material aid previous to the manifestation of risks considered disasters.

The damages alloted by the government are received only by those who have already concluded an insurance, even the utmost simple one, such as the insurance against the hail – it is the cheapest one. Then, the authorities are forced to declare by Government Decree, (according to the existing pseudopolitical interest) as a "calamity-stricken area" any surface affected by nature caprices, because of the large sums of money paid in this purpose. Such a conduct leads to an uneven environment, where the private insurers' interest decreases gradually, in a proportional manner to the lack of interest proved by possible customers of private insurances.

Private insurance companies may be no longer interested in making an offer of agricultural insurance if the rules of the game are not known from the beginning. It is necessary to be informed upon the previous establishment of the intervention level (of the sum) to which the government interferes in order to offer assistance. If the governmental acts and decisions are clear and transparent, the insurance providers will prove much trust working on the agricultural market.

One may conclude that the governmental involvement in managing the risk within the agricultural sector explains the possibility of dealing with an increased risk affecting the producers' activity.[104] Generally, farmers should not count on the aid offered when dealing with a disaster, as long as they are not applying all the measures meant to control the risk. An important way in the evolution of the agricultural insurance system, as it is shown by the experience of economic developed countries, is to combine the classical type of insurance with the deriving products.

The traditional agricultural insurance which may be multi-risk (it considers a variety of risks) or uni-risk (it refers to the manifestation of one single risk), presents a series of limitations, that is why it is more and more avoided by the possible customers. The main limits of the classical agricultural insurance may be:

- informational asymmetry;
- denatured stimulation;
- unfavorable (adverse) selection;
- administrative costs;
- moral hazard.

3. New types of agricultural insurance

During the last few years, at the international level, a variety of new financial mechanisms present the capacity of solving many issues related to the traditional projection of agricultural insurances. New instruments operate based on the configuration of the insurance indemnity payment, thus it will be paid when it reaches a certain level determined by statistic calculations and designed as the "index".

The international practice registers two types of agricultural insurances based on the index: weather insurance depending on the index and surface insurance depending on the index. The use of the two types of policies for the insurance against natural disasters intensified the access to insurance services for the poor persons living to the country. The "release mechanism" (the index) may be verified in an independent manner, thus the vulnerability to political interaction and the manipulation of the loss registered by farms reduce. Reduced administrative and transactional costs together with other profits force the private sector of agricultural insurances to offer to possible customers' unsignificant subsidies or no subsidies.

I. Weather insurance based index – the insurance indemnity will be paid by the insurer under the circumstances of reaching a release mechanism previously established, called the "index".

[104] Mahul, Olivier - "Optimal Insurance against Climatic Experience." *American Journal of Agricultural Economics* 83(3), 2001, pp. 593–604.

The index may consist of a variety of weather indicators, such as: rainstorms volume, temperature, humidity, wind intensity or the number of sunny days, each indicator is confirmed by a independent third person and mutually related to individual damages registered as a result of the event manifestation.

II. Surface insurance depending on the index – the payment of the indemnity is completed when the cropped surface is reduced (the output too) under a certain percentage determined according to climatic characteristics of the area, as a result of the manifestation of a disaster (drought, flood etc.).

The insurance is sold using standard devices (for example, currency units or "units") corresponding to a policy or to a certificate for each bought unit. The insurance premium is the same for each buyer, providing an equal indemnity if the insured event takes place. Buyers are free to purchase as many insurance units as they want.

III. A weather derivative represent a contract between two parties which stipulates the value of the payment taking into account meteorological conditions manifested during the period of the contract.

Weather derivative is a financial instrument used by companies to reduce the risk associated to unfavorable or unpredictable weather events evolutions[105]. The derivative seller accepts the risk by cashing a bonus (derivative price). If the event doesn't take place, the seller makes a profit, but if the event takes place, the buying company cashes a preliminarily agreed amount. In USA, Europe and Australia, temperature, snowfall quantity, freeze expansion and rainfall quantity are key conditions for which corporations buy weather derivatives. The cost of a weather derivative depends on the probability of weather negative impact upon the business and duration of the contract concluded between the bank and corporative entity.

A weather derivative is defined by many elements, as it follows:

Reference weather station. All contracts of weather derivative type are based upon weather observations accomplished at one or more specified weather stations, accomplished by an entity certified by national weather authority of the state on which territory there are the respective stations. Most part of the dealings are based upon only one station, but some contracts are based upon a combination of reports from many stations, and others upon differences between the values noticed at two stations.

Index of a weather derivative defines the weather parameter which establishes when and how the payments agreed by contract shall be accomplished. The indexes most frequently used are Heating Degree Days (HDD) and Cooling Degree Days (CDD) – which measure the cumulated variation of daily average temperature comparing to the level of 18°C (65 Fahrenheit degrees) along a season. We must mention that other basic temperature levels may be adopted, for instance in Great Britain these are of 15,5° C.

The arithmetic expression used in order to determine the HDD and CDD is the following[106]:

$$HDD = \sum_{i=1}^{N} \max\left(0, 18^o C - T_i\right)$$

$$CDD = \sum_{i=1}^{N} \max\left(0, T_i - 18^o C\right)$$

were,

N represents the number of days for which a contract is developing;

T_i - arithmetic average of maximum (T_{max}) and minimum (T_{min}) thermic temperatures of day *i.*

For instance, the daily accumulated CDD number is equal to the difference between the average temperature of the day and the value of 18°C (65 Fahrenheit degrees), if the temperature is over 18°C and to zero if the temperature doesn't exceed 18 Celsius degrees. If the average temperature of the day is under 18°C (T_{base}), then the difference between 18°C and average temperature of the day leads to HDD number, CDD and HDD values are never negative, being at least equal to zero.

As a consequence, if T_i shall be of 10 °C when the HDD value for that day is of 8 (18 °C - 10 °C = 8 HDD), instead, if T_i shall be of 20 °C, then the HDD value is 0. In the same way there can also be determined the CDD value. If T_i shall be of 20 °C, then the CDD value is 2 (20 °C - 18 °C = 2 CDD), and if T_i shall be of 10 °C then the CDD value is 0.

---

[105] http://en.wikipedia.org/wiki/Weather_derivatives

[106] Lixin Zeng, *Weather Derivatives and Weather Insurance: Concept, Application, and Analysis*, Bulletin of the American Meteorological Society, Vol. 81, No. 9, September 2000, pp. 2075 -2082.

During a month there can be accumulated both CDD (during the days with average temperature over 18 degrees – days with high temperature) and HDD also (during the days with average temperatures under 18 degrees – days with low temperatures). The weather (options) derivatives are defined on HDD or CDD accumulation over a specific period.

A wide range of indexes is used for the dealings restructuring which offer the most adequate hedging mechanisms for the users from different economic fields. Many dealings are based on the so-called event indexes, which count the number of days when the temperature exceeds or drops under a defined limit, during the contract. Similar indexes are used for other variables; for instance the rainfall accumulation or the number of days when the rainfall accumulation as snowfall exceeds a defined level.

Term. All contracts have a defined day of beginning and termination, which define the period for which the specific index is calculated. The most frequent market terms are 1st of November - 31st of March for the winter contracts and 1st of May - 30th of September for the summer contracts. However, there has been noticed an increasing level of contracts for a month or a week, along with the market development. Certain contracts also specify various calculation proceedings of the index in the agreed term - such as weekends exclusion or the double share for the specified days – in order to meet some individualized exposures.

Structure. Weather derivatives are based on standard structures of the derivative financial instruments, such as put, call, swap, collar, straddle, strangle. The key attributes of these structures are:

- Strike – meaning the specific index value when the contract begins the payment;
- Tick – meaning the paid amount per growing unit of the index over strike;
- Theoretical limit or value – meaning the maximum payment stipulated by contract.

Premium. The buyer of a weather option pays a premium to the seller that is typically between 10% and 20% of the theoretical amount of the contract. Still, the bonus may significantly vary depending on the risk profile of the contract. In order to exemplify, we may take into account a common shape of weather derivative, meaning the put option which offers protection to the effects of a warm winter.

There are two commonly used forms of weather derivatives: call and put.

A. "Call" contracts imply the existence of a buyer and of a seller who agree over the period of the contract and over a weather index (W) considered the main element of the contract. For example, the W may be the total amount of rain-fall during the entire period of the contract.

From the beginning, the seller receives a premium from the buyer. At the end of the contract, if the W is more important than the planned step sensitivity (S), the seller is obliged to pay to the buyer a sum $P = k(W - S)$, where k is the predetermined constant factor which sets the value of the payment according the weather index unit. The step sensitivity (S) and the k factor are known as the "stike" (the approved price previously determined or the exercise price) and the "tick" (the minimum fluctuation of price) of the contract. The payment planification of the sum (P) may be dual or linear (the fixed sum, established in the contract - P_0 – will be paid if the W is more important than the S, if this condition is not fulfilled then the payment does no longer take place) .

B. "Put" derivatives are similar to "call" products except the fact when the seller pays to the buyers the sum P if the W is lower than the S. This sum is determined considering the following formula $P = k(S - W)$. "Call" or "put" products represent the equivalent of an insurance policy: the buyer pays a premium and receives the indemnity pledge in exchange, if a previous defined condition is accomplished.

A generic weather derivative contract can be formulated by specifying the following seven parameters:

- contract type (call or put);
- contract period (e.g., from 1 Nov 2006 to 31 May 2007);
- an official weather station from which the meteorological record is obtained;
- definition of weather index (*W*) underlying the contract;
- strike (*S*);
- tick (*k*) or constant payment (*PO*) for a linear or binary payment scheme;
- premium.

The parameters mentioned above determine the payment sum (P) for a linear payment planification:

$P_{put} = k\max(S - W)$ where $(S - W)$ is at least 0

P_{call}= kmax(W – S) where (W – S) is at least 0

The function max(*x, y*) returns the greater of values *x (S)* or *y (W).*

For a binary payment scheme:

$P_{put} = P_0$ if $W – S < 0$; $P_{put} = 0$ if $W – S \geq 0$

$P_{call} = P_0$ if $W – S > 0$; $P_{call} = 0$ if $W – S \leq 0$

The payment diagrams for a linear “call” and “put” contracts are presented as it follows:

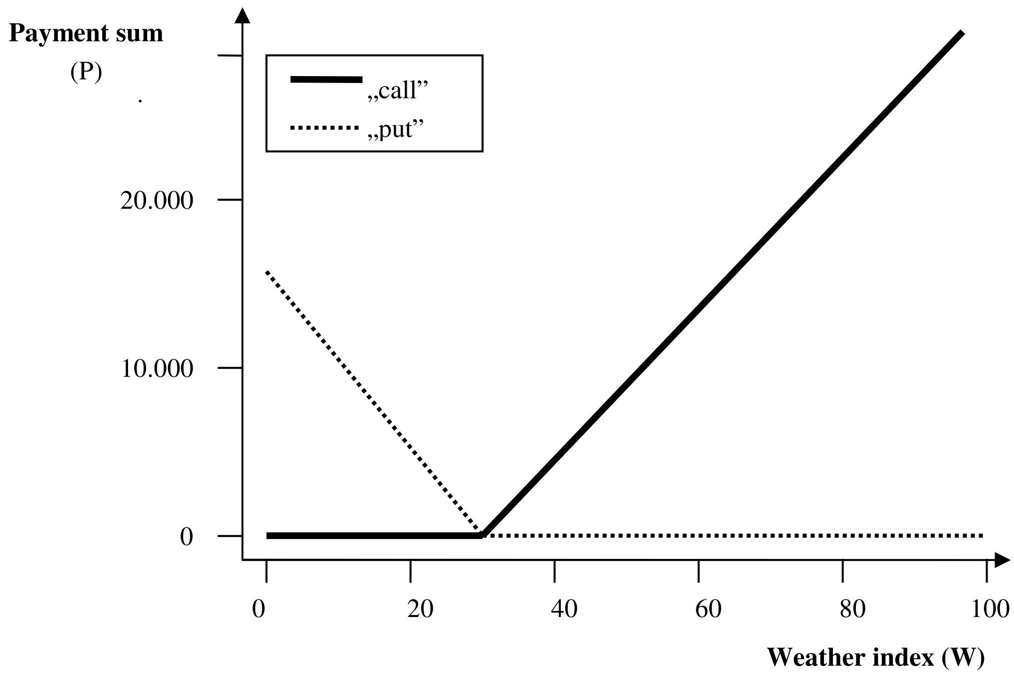

Figure no.1 – The payment diagrams for a linear “call” and “put” contracts

CORPORATE INCOME TAXES. EVOLUTIONS

Abstract: taxing the income of the companies has been an important issue for the last two decades, from the point of view of the budget and of the influence of the tax on the economic environment and on the society in general.

Key words: tax, evolution, conciliation of the result

With the Law of the commercial companies - nr.31/1990, the state enterprises turned into commercial companies and autonomous public corporations, and the small enterprises partially became commercial companies.

The corporate income tax was conceived to be a progressive one, composed by a rising fix amount and an amount calculated by applying increasing tax rates. Tax rates were between 5% and 77%. One may say this law affected the enterprises by an excessive taxation. This taxing method was lively criticized, and the HG[1)] 804/1991 introduces a new way of calculating income tax as a proportional tax, calculated with a 30% rate for the taxable incomes of less than 1 million ROL and a proportional tax of 45% for more than 1 million, the tax base being thus split in two.

This taxing method brought a fiscal pressure of about 40% for an income of 3 million ROL whereas the first method brought this average fiscal pressure only when the taxable income reaches 100 million ROL. Although it seems that the method of the two-rate tax aimed to increase the neutrality of the tax, this principle was distorted by the fiscal facilities granted. In this period, the number of private commercial companies increased vertiginously, not as a consequence of the raise in the economic potential, but mainly because of the fiscal facilities granted. Granting fiscal facilities meant to create a healthy private sector and to attract foreign capital. Temporary tax exemptions were granted, differentiated on objects of activity, to encourage creation of new private commercial companies; but many of the newborn companies were really taking on the activity interrupted in the companies that no longer benefited from the temporary exemptions.

Also, deductions of the tax base were granted, for the incomes used to improve quality of products and to advertise and promote, a deduction of 50% was granted for the tax on the profit that is reinvested to get supplementary profits; this deduction expired in two years time if the goal wasn't reached.

A 25% deduction was granted to foreign capital companies that imported energy and fuel for their activity, used Romanian equipments for investments, created at least 50 new jobs through investments or through modernization of their activity, made exports, and performed research.

Although many of these facilities had a contradictory nature, such as the acquisitions of Romanian equipments that on one hand generated a new investment, and on another limited performance in some fields, yet the goal was to increase the productive potential. As any advantage, these facilities generated discrimination – the domestic capital companies had not the same advantages. A deduction was granted to the income tax for the companies that employed physically disabled people, depending on their percentage in the total number of employees.

All these facilities created difficulties in the calculation and registration of the fiscal obligations. They proved to be encouraging for the commercial companies, but only partially. Too many advantages and feeble results, maybe also due to too many exceptions from the basic rule, which caused discriminations more important than the advantages received.

Beginning with January 1st 1995, through the OG[2)], the income tax was rearranged as a proportional tax with a rate of 38%, some exception being made – 25% for taxpayers whose income came more than 80% from agricultural activity, 80% for the BN.

Two additional rates were created, one of 22% applicable to the taxpayers whose income came for more than a half from gambling, the other of 6.2% for the foreign legal entities that developed commercial activities in our country.

For the small taxpayers, the taxable income is calculated by adding to the result of the exercise the non-deductible expenses and subtracting the legal deductions.

OG[2)]/1994 does not revoke the tax facilities of HG[1)]804/1991, thus: the exemption periods remained the same for the companies established before January 1st, 1995, that had been granted these rights. We find these facilities under the name of tax credit, a denomination that includes the deductions for the employers of disabled persons, for the reinvested profit, as well as the external tax credit.

The external tax credit represents the tax paid abroad, it will work in a way to avoid the double international taxation – the common credit procedure.

For the big taxpayers, the taxable profit is calculated as the difference between the net assets at the end of the year and the net assets at the beginning of the year updated for inflation, plus the non-deductible expenses and the distributions paid to the owners during the fiscal year, less the tax deductions, all these also updated for inflation.

Thus, the income tax for the big taxpayers affects the variation of the increase of the assets in a fiscal year.

Tax payments are made monthly by the small taxpayers, and the big taxpayers have to make monthly for payments of their due annual tax.

It is also important to notice the different fiscal treatment of the tax deductible amortization for the big taxpayers and the small ones.

For the small taxpayers, fiscal amortization was the economic amortization included in costs, depending on the degree of utilization, without being updated for inflation.

Fiscally deductible amortization for the big taxpayers was calculated considering the six fiscal categories of the fixed assets, the settling of some rates of fiscal amortization, the updating for inflation of the existing fixed means and the ones acquisitioned within the year, these being influenced by their utilization rate during the fiscal year.

There is another discrimination between the two categories of taxpayers: for the small taxpayers, a 50% deduction on the profit tax is granted for the sums used in updating processing technology, enlarging the field of activity, and in environmental protection.

After 1997, the distinction between small and big taxpayers disappeared, as the technique of updating for inflation, the system of fiscally deductible and economic amortization as well as the differentiated periods of loss reporting became uniform, and the payment terms of fiscal obligations were modified. In fact, the technique of profit tax became almost identical to the one applied before with small taxpayers.

The deduction remained, and the additional rate of 22% for profit obtained from gambling, clubs and pubs would be applied only to the profit obtained from these activities, thus lowering the marginal tax rate for such activities of small importance in real economy.

In order to attain social finalities, the deduction on imports for the companies with over 250 employees and at least 3% disabled persons hired was maintained, proportionally with their share in the total number of employees.

The deduction of 50% on the income tax on exports aims to encouraging the companies to sell abroad; the same level of deduction is maintained for reinvestment of the profit in technology improving or modernization, in order to stimulate investments. The Budget Law of 1997 ended the deduction on exports for budgetary reasons.

Cumulated deduction cannot exceed 50% on profit tax calculated before the deductions, and this is a meant to ensure a certain level of the budgetary incomes.

Starting with 1998, expenses for advertising and promotion became deductible on the whole, and the losses reported were to be recovered in five years time.

These alterations of the Tax Law after 1997 regarding the amortization system, the treatment of the non-resident tax payers, the deduction system, marked a step ahead in profit taxation, but the issue of letting go of the "big taxpayer" attribute has other connotations too, beside the positive fact of simplifying the technique of tax calculation.

The object of the tax for the big taxpayers was the variation of their assets and this really showed the true evolution of the capital of the company and the quality of its activity, in inflation conditions; for the small taxpayers there was no more the matter of updating for inflation, and thus the evolution of their assets had no true representation. In inflation conditions, some elements of the costs are under-evaluated compared to the results that will be expressed in prices more or less of the day, overestimating the profit of the company, which represent the most important part of the tax base. Material consumptions will be evaluated at the historic price, moreover the labor expenses and expenses assimilated to salaries don't watch the prices evolution. On the other hand, prices are continuously rising and their evolution shift the evolution of the prices of production factors which are insured sometime in advance. Linear amortizations create the same phenomenon of over dimensioning the result and taxation of a false rising, and this means an arbitrary sanction of a part of the turnover which does not represent the true growth of the total assets.

If the elements of the tax base were updated in current prices supported by an inflation accounting system, a positive result would show the real net capital increase based on its fructification. Thus, we witness a hidden decapitalization on behalf of the taxation, very damaging both for the economic agent, for the state, and for the need for the capital and for investments is important in real economy.

Small tax payers are in such a situation nowadays although they get a positive accounting result, this is not a rise, a phenomenon which is best illustrated by the lack of liquidities (it has, however, other causes too). To lessen this negative influence, the net result should be at least at the level of such extra-accounting losses (capital evaporation), and the rate of the net profitability should be at least equal to the price index of the respective products. Thus the tax on profit turns into a punitive tax for the economic agents with positive results.

Beginning with the year 2000 this tax was recalculated to diminish the fiscal pressure. Thus, the base rate was reduced to 25% and a series of facilities have been granted to the investors for the investments made that year, part of which were deductions for the taxation base.

Through OG 70/1999, the tax on profit will again be recalculated and again through OG 414/2002, with major changes in the taxation base, regarding the number and the kind of the expenses fiscally non-deductible. Most interesting were the reglementations regarding the difference between the non-deductibility of the prices lower than production costs or than market prices for the goods, services and works implied.

The issuing of the Law 571/2003 – The Fiscal Code, fiscal legislation concentrated in a larger and unique source of information. This law has been modified more than once since it was issued.

That is, the use of OG (governmental ordinances) generated more adjustments of the Fiscal Code. In 2004, this document was modified by OG 83/2004, OUG (urgent governmental ordinance) 123/2004, OUG 138/2004. For theses changes and for others, Law 163/2005 was promulgated. In 2006m OUG nr. 21/2006 and Law 343/2006 were issued and, in 2007, OUG nr. 155/2007.

These legal adjustments brought about a lot of problems to be solved from the fiscal point of view, and from the point of view of the accounting result, the problems of the reconciliation of accounting and taxation rising several specific topics.

The relation between taxation and accounting is based on a tight connection and aims to their disconnection on one hand; accounting is a source of information; on the other hand, the two are based on different principles and rules.

Each tax payer as a legal person or as a authorized natural person, makes financial statements and fiscal declarations, as they are, moreover, obliged by the law in power in this field. Thus, item 12 from "Methodology for application of Law 571/2003 regarding the Fiscal Code", approved by HGM 44/2004, stipulates: "the incomes and expenses taken into account in establishing the taxing income are those registered in the accounting books, according to the accounting regulations in the Law of accounting nr. 82/1991 as any other elements similar to the incomes and expenses, diminished by the non-taxing incomes and increased by non-deductible expenses, as in art. 21 Fiscal Code".

The base of this relation is directly connected to the calculation of the taxing income as a taxing base for the tax on profit. As it is known, the legislation regarding the tax on profit changes at short time intervals, while accounting reglementations have a slower dynamic.

As the fiscal law differs even by the simple adjustments from the accounting one, the instrument of adjustment – reconcilement is the fiscal statement, through which the accounting result is adjusted at the level of fiscal requests.

Accounting, in its turn, offers a solution of reconcilement between the two results, by applying the IAS 12 – tax on profit. This standard presents the modality of reconcilement between the fiscal profit and the accounting one, and the instrument used in tax on delayed profit; also for intermediary reports, IAS 34, intermediary financial report is applied.

The accounting result is known to be determined by the closing of the income and expenses accounts, following recognition in the result of the exercise, according to the accounting regulations.

Yet, as a rule, fiscal results differ from account in results and in these cases to determine the tax on profit, the information from accounting registrations must be processed; this is made by a fiscal book which must contain all the adjustments of the accounting result in order to determine the taxing profit and, implicitly, of the due tax on profit.

In order to determine the delayed tax on profit, the economic agent must admit a debit or a credit, when it is possible that the recovery or repayment of the accounting value of an asset or of a debt may determine bigger or smaller future payments for the tax on current profit, that their would-be value if such a recovery or a repayment would not have fiscal consequences.

The accounting-fiscality reconciliation, in the context of this standard imply a certain treatment regarding the financial immobilizations, stocks, depreciations and provisions, own capitals, expenses with interests, incomes from differences in currency rate, accounting recordings of the tax on current profit and those of the postponed one and other linked to the assets and liabilities of the company.

The main goal of the scientific approach in this field is that of discovering and defining the connections that generate organizing potential and efficiency between the taxes of the present fiscal system and the connections between the parts of the fiscal authority and between the fiscal authority and the tax payers.

Universitatea Pitesti

Summary. Fiscal mechanism is part of the financial one , mechanism that refers to a large and difficult domain, namely the financial one. Fiscal mechanism' functionality is defined by two components, namely by the level of conception that outlines the structure of the mechanism and on the other side, by the influences of the environment in which it exists. Technical procedures , the instruments and the modalities of taxes administration, fiscal charge itself and the human action marked by ideologies, customs and subjective compulsions are fluctuations that determine the functionality of fiscal mechanism.

Key- words: mechanism, functionality of mechanism, fiscal charge.

Fiscal mechanism, as any other functional entity, is defined through its content and its working capacity. Modalities, procedures, rules, the legislative, technical , political, civic compulsions, instruments of the mechanism' endowing , fiscal politics, even ideologies are component parts of fiscal mechanism. Methods, technical instruments are outlined by the fiscal politics which reflects more or less the objective regularities, and also reflects the subjective wish of the executive power of those who propose the conception of mechanism. The influences from real economy , from society are important quantitatively but also important in content and even wasting sometimes.

Fiscal methods, modalities of taxes' administration, practices established along the time, social morality , ideologies are fluctuations of the fiscal mechanism and in the same time they are instruments or levers handled by those who direct and control the functionality of mechanism.

Fiscal technology is a special part of the budgetary process, a subject outlined as part of budgetary science or, fully, of public finances. Taxes and fiscal process improved in time, but not enough for this important source of incomes for public budget not to generate administration problems of those, namely: not cashing the taxes in time, defalcation from paying the taxes, syncopes in the relation between fiscal organ and the payer, problems of evidence and of following the payer , the absence of a beautiful and efficient relation between fiscal organ and payers and also concrete issues of informative evidence of taxes on their elements.

This subject has a scientific importance that is justified by the affiliation of this theme to financial science and especially to public finances, and by the need of the domain's improvement.

Administration of taxes is a well outlined issue , conceptually speaking , but also practically. Fiscal science and technique were outlined and delimitated in time by specialists' effort and experience in domain. Nowadays, fiscal technique improves itself continuously under the influence of informatic applications and of the literature of speciality at which we have access in present.

However, fiscal efficiency is generally low and we think that there are two reasons on the basis of this phenomenon, namely: gaps in general fiscal legislation and gaps of procedure and secondly, the management of taxes' administration. This last cause proposed to be examined by us, considering that this issue still hides more reserves and being analized , corrected it may praise the real capacities of fiscal mechanism and of taxes of our fiscal system.

The relations between taxes are of conceptual, technical and practical nature. All the taxes that function at a given moment in an economy and the relations between them make up the fiscal system.

Taxes established on settlements specific to fiscal domain generate, beside the relations between them, other influences on social environment.

Taxes, working of fiscal system , its relations with payers and the influences on economy are settled by juridic, subjective, specific laws.

Working of fiscal mechanism is influenced by the working of each submechanism for each tax partly.

Modern methods of calculation the taxes suppose a permanent relation with payer directly, at pay-office, on the phone, electronically, relations that are cultivated by fiscal organ who collaborates with the payers , giving up at his position of oppressing organ to an efficient relation's advantage.

If nowadays the decrease of fiscal pressure was realized both by deduction of taxes' level and by promotion of fiscal advantages , it seems that the last method is more performant from the viewpoint of effects on payer. Grouping together the fiscal advantages in deductions from subject of taxation and deductions from calculated taxes , these seem to be the main methods of deduction of the fiscal charge.

The main aim of scientific process in this domain is to discover and to delimitate the connections which generate organizational potential and efficiency from taxes that make up the actual fiscal system and connections between the components of fiscal organ and between this and the payers.

Choosing the most efficient relations and realization of a functional table would justify its forming in order for the specialists to chose easier the alternatives that generate organizational potential and fiscal efficiency.

Such a model could be capitalized twice , namely: practically for modernization of organizing the informational tide within fiscal organ and in his relation with payers , and theoretically, by putting at students and specialists ' disposal the models and the proposed structures.

Fiscal charge aims the efforts of all the persons and releases unexpected reactions even from some so-called non-payers of taxes, but who stands the effort under the effect of fiscal charge' impact.

It is known that taxes are a necessary evil , being indispensable a state form of social organization and that's why fiscal charge is accepted by payers till a certain level without too big oppositions.

From the moment when fiscal charge grows from different reasons, such as covering the budgetary deficit , this fact releases unexpected social interactions and still undiscovered totally.

If persons and collectivities have reasons of joy when it is contracted a public credit with destinations that bring social benefits, on the other hand, when it is time to reimburse these credits, when big taxes are asked, their reaction is reverse to the initial one, such budgetary measures suppose many changes within financial politics and implicitly on some indicators such as: rate of interest , of inflation, of consumption, etc.

If we are interested by the growing effects of budgetary incomes from taxes and implicitly from public expenses , growths which , if they are accompanied by growths in rates of interest , then they will generate a smaller growth in relative and absolute numbers in gross intern product, then we have to follow at least the following judgments.

It seems that this growth is influenced by the way of using the public resources, which are partly directed to unproductive sections and are generally fructified with a smaller rate than the medium interest rate . It results from these judgments that state will always spend worse its sources, in comparison with private sectors and that public sector should be divided such as to generate more rarely or at all such situation, such needs of financing by taxes' growth.

The benefic effects of incitations by taxes will have to be combined with suitable currency measures , which to generate an economic re-launching in conditions of maintaining the rate of interest under control or till a certain level.

The main aim of fiscal politics is to cover the budgetary needs and to assure the intervention of state through taxes in economy and society .As any other social environment , the fiscal one is negatively or positively influenced , both inside and outside, generating some secondary wanted or unwanted effects.

If we don't take in consideration some restrictions of fiscal politics such as: its correlation with financial potential of the society, correlation with monetary politics, social politics in general, assuring the standing degree of fiscal pressure , subordination of fiscal politics ' aims to economical politics in general , assuring the working of fiscal system, integration of national fiscality into the international fiscal trends, assuring an efficient informational system and many others of the same kind, then the secondary consequences are multiple and most of them will be negative.

The unwanted effects will be: reduction of the productive effort, amplification of swindle and fiscal evasion , stressing of inflationist process, deterioration of international competition and generally, a dereglation of economical and social values of the system.

If the fiscality rate exceeds a certain limit , this fact will dishearten the efficient work, will dishearten saving and investing. Possibilities of evasion and fiscal frauds will be looked , underground economy will take proportion , both regarding the mastership who wants a reduction of subject of taxation mass for its own incomes and fortune , and regarding the physical persons who will stand raised taxes in conditions of small net incomes in comparison with the level of gross income.

Taxes' increase implicitly generates prices 'increase with effects on inflationist process and on trade union politics who immediately looks salaries' increases and in this way the inflationist spiral goes on.

Such correlative conditions regarding taxes' increase can be identified in time, on longer periods, content in which a morality problem can be put, namely supplementary fiscal charge generated by reimbursing of public credits puts its stamp in time on future generations which , we don't know if they are disposed to such an effort. On the other side, we don't know if we have the right to mortgage a part of our children's incomes for aims considered to be necessary but unaccepted by all persons of the collectivity.

In social reality there are no recipes able to solve such frustrations , all these adding in time and sometimes, as history shows, they reveal as social reactions , even revolutions from time to time. The humanity' s history has such moments.

Many other social resorts can be identified in the relation of payer with the fisc , also in the credit domain, the assurances' domain , on financial market and in all the domains of social life.

Economy is practiced between people with the purpose of obtaining an extra- income which to assure a certain level of living and proceeding the lucrative activities. Such social relations generate ideas, theories, about economical science along the time. Most sciences generate applications, but the economical one has a special practical importance.

Its practical importance puts particular methodological problems , some of them being able to be solved objectively on the account of objectives and economical regularities , others are solved on the account of some ideologies more or less objective. In this context, economists have to chose between objective and subjective. We want to know if objective truths can be expected from the economists. Obviously, personal interests, values and ideology influence all the people , including the economists. We also want to know in what way economical science stands at the basis of political elaboration.

Swedish economist Gunnar Myrdal points in an article about the values of economical science that " politics is an art circumscripted from reality and possibility, and that's why it can appeal to economical science" .

The politicians can expect from the economists to explain real situations and to reveal the effects of different possible ways of action to initial situation.

Beyond this approach , the scientists don't have to venture. To give up the objective and abstract approach in the favour of some definite aims- reasons but that cannot be realized on the account of politics and some ideologies which rely more or less on economical regularities, this means not to recognize the importance of scientific approach and of objective truth.

The objective truths must be looked in people, all the more in economists. The philosopher D. D. Rosca in his work " Philosophical studies and essays " (Scientific Publishing House, Bucharest, 1970, p.160) points the role of the objective in this way: " the function that real intelligence has to accomplish in general economy of the spirit's life of civilized man is searching the objective truths, that are confirmed truths by practice and truths that impose themselves by interior compulsions of all good-faith spirits … at many of civilized men , exactly as to primitive men, intelligence can substitute muscles and teeth , with the difference that it learns them to hide, to dissemble" .

To dissemble in politics means to create ideologies which are not checked in reality , to dissemble in economy means to make an attempt on people's well-being.

The scientific approach, objective-abstract in economy doesn't let place to dissemble. To accept general ideas sometimes for fear of unconsideration ,sometimes lucidly, other times unconsciously, represents the degradation sign , sometimes even irreparable for person and devastating for economy.

Not to respect the economic regularities , recognized and checked in life means to create social paradoxes.

Economic science puts at the base of scientific approach the economic regularities depending on which were elaborated in time different economic theories; the best equilibrium, the best demographic, the accurate and just repartition of taxes, etc. But economic practice was sometimes dispossessed by checked theories in economic life , sometimes in time, other times in different parts of the world, depending on the ideologies practiced by politic powers.

If economic science doesn't go away from abstract approach and from objective values, it doesn't have to go away from society too, neither from its rules. To practice objectivity means a normal behaviour.

Objectivity and morality are implicit values in economic sciences.

Social morality can be found analytically in economic life , in relation between economic agents, in relation between generations , between state and payers , morality represents a behaviour modality, an aim, a politic objective, a cause.

The system of social and economic values generally keeps up by practicing the morality and conversely, lack of morality dispossess recognized social values.

Is it moral to transfer fiscal charge from one social level to another, from one person to another, from one generation to another? Is it moral to use instruments of objective economic science in order to promote subjective politics, ideological interests? Morality is practiced in this way too and it is understood also.

If objectivity and morality are implicit values of economic science , by their non-respecting appear paradoxes , blockings of economic mechanisms, implicit calculations with contradictory influences on real economy.

Actually, we practice economy through unfurling relations with our neighbours with only one purpose, namely to obtain a plus-value which to use to preserve our existence and eventually to raise our living level.

THE LOCAL DECENTRALISATION AND THE ISSUES OF MUNICIPAL BONDS IN ROMANIA

Abstract: This paper work analyses the connection between local financial decentralization and the potential of local public administration to sustain the local economic and social development by its own forces by taking part to the capital market. Next to the ordinary financial sources, which are the local taxes, the local collectivities resorted last years more and more to the loans, by issuing municipal bonds. As an effect of the local autonomy and financial independence, these kinds of financial instruments gave the chance to the local public administrations to answer all community needs in efficiency and efficacy terms. Very attractive for investors because of the rate of return offered, up to the level of the reference rate of interest fixed by the Romanian National Bank, the municipal bonds are used to reduce the risk of their portfolio.

Key words: local autonomy, financial decentralization, local public revenues, municipal bonds, local public administration, Hunter's index

1. The Financial Decentralization in Romania

The Romanian Constitution from 1991 recognizes the distinct existence of local collectivities as a part of the sovereign state, with particular interests and needs. These ones are organized as cities, municipalities and villages and are leaded by local public administrations[107] which principal task is to answer the citizens' demands (both social and politic ones) by specific public services, in accordance to the principles stipulated in law[108]. Each of their actions is supervised by the central public administration authorities[109].

Local financial resources[110] have a special role in local development, because they represent the base for a prompt replay, in optimal conditions, to the community needs. Banking on these kind of resources, it may be initiated every kind of plan in the community' interest, but with the condition to consult first the citizens, who have the right to debate the public problems and to suggest solutions[111].

Local administrative autonomy is conditioned by the financial autonomy, which assures the material support of first one's service[112] and offers the possibility to submit the local and national public services to the local specific demands and needs, in terms of efficiency and efficacy. This way, the specific problems which the members of the communities confront with may be better identified, especially the economic and social ones, and the appropriate solutions may be adopted.

Starting the financial decentralization expansion, the responsibilities of the local public administrations increased proportionally with the taxes/benefits ratio, the level of external effects and the scale economies

---

[107] The Romanian Constitution from 1991, the article no.120;

[108] The law no. 273/2006 of local public finance, stipulates principles as fallows: the local autonomy, the decentralization of public services, the eligibility of local public authorities, the legality and the citizens consultancy in solving local problems, all of that above the power of the national, unitary and indivisible state of Romania;

[109] The Romanian Constitution from 1991, the article no.122;

[110] The Local Autonomy Book stipulates that the local public authorities, in the national economy politics context, have the right to possess proper financial sources, sufficiently and proportionally with their competences established by the law, which to dispose free to exert their attributions;

[111] The law no. 215/2001 of local public administration;

[112] Iulian Vacarel (coordinator), Finante publice, Didactica si Pedagogica Publishing House, Bucharest, 2003;

for the public assets[113]. To increase efficiency for local public expenses, these should be orientated to those programs with a few external effects and low scale economies, that meaning to consider only particular communities' objectives. This way, the social welfare reaches maximum, only if the public services are managed at the closer administration level to the citizen[114] and it's evident that "financial decentralization begins to work beyond the limit that suppose the area of using national public services and goods start to stint and the comparative cost of making decisions at the central level becomes very high" [115].

Financial decentralization refers to the right of the local public administration to collect its own revenues, in proportion to its needs, both from local taxes and complementary sources, like loans, only if the first category of incomes is not sufficient. In the same time, the financial decentralization supposes the freedom to select to which objectives to allocate the local finance (the ordinary ones, the borrowed ones and also the ones obtained by the public sources balancing process). The local autonomy gives the right to the authorities to decide the appropriate level of the local revenues but also the opportunity and necessity of the public expenditure from these sources.

2. Analyzing the Financial Decentralization Level in Romania

The public revenues of the local administrations registered an exponential growth between 1991 and 2005[116]. After the oscillation of the proper revenues in the years of 1991-2001, these ones established at 20% from all finance. Seeing the continuous and sustained growth of total incomes, we may conclude that even the percent of proper revenues is almost the same every year, it augment period by period, as a sign of local autonomy and financial decentralization development. We had the same conclusion by reporting the local budget revenue to GPD, from 3% in 1991, to 6.8% in 2005, on the background of an exponential growth of GPD[117]. Also, public revenues per capita enhanced continuously[118], even more starting the year 1998, when the local tax law improved. This moment marks the apparition of financial decentralization in Romania, being also cause and effect of the economic development of some regions.

Between the years 1999-2004, the biggest local revenues were registered by villages and municipalities[119]. For the villages, most of the finance (over 70% in the period we focused on) is transfers from other public budgets. That suggests a high level of financial dependence and also the concern of the public authorities to sustain rural development because of the inferior financial capacity of the population (given by the smallest medium income per capita as against the municipalities and cities) and the low tax collection level. For the municipalities, the situation is explained by the better economical and financial situation of the tax payers (because of the bigger tax basis) but also superior tax pursue and collection. This fact becomes relevant when we are comparing the big percentage (over 50%) of proper public local revenues in total local ones, that meaning a high financial decentralization level which offers independence in allocating the founds and flexibility seeing the financial sources for the local investment projects.

Globally, there is used a specifically index to measure the level of local financial decentralization, the Hunter's index.

$$H = 1 - \frac{Rnc}{Rt}$$

where:

H- Hunter's index;

Rnc- revenues not controlled by local public administration;

Rt- total revenues of the local public administration.

---

113 Mosteanu Tatiana, Iacob Mihaela, Teorii, politici si mecanisme ale descentralizarii fiscale in Europa si in alte state, work paper presented and published in the volume of the International Conference from Sankt Petersburg, november, 2007;

114 Dascalu Elena-Doina, Sistemul bugetar in Romania, Didactica si Pedagogica Publishing House, Bucharest, 2006;

115 Iulian Vacarel (coordinator), Finante publice, Didactica si Pedagogica Publishing House, Bucharest, 2003;

116 The data we used have been obtained by processing the local budgets execution accounts, from the public informations offerd by the Romanian Ministry of Economy and Finance on its official website, www.mfinante.ro;

117 Idem 10;

118 Idem 10;

119 Idem10;

As the index result is higher, to 1, as the financial autonomy level is higher[120].

Practically, this index shows how much from the local public expenditure is based on revenues with absolute freedom for the destination[121].

After we analyzed the revenues and expenditures for all the districts of our country[122], we computed some values for Hunter's index as follows:

Table no.1 Hunter's index[123]

Year	Hunter–minimum level	District	Hunter–maximum level	District	Hunter-average
2001	0,34	Vaslui	0,79	Bucharest	0,48
2002	0,25	Vaslui	0,71	Bucharest	0,39
2003	0,25	Botosani	0,71	Bucharest	0,41
2004	0,19	Harghita	0,70	Bucharest	0,35

Source: calculations made by the authors, relayed on information from the official website of the Romanian Ministry of Economy and Finance

We may observe from the given table that the local public budgets are dependent of the state public budget, because the average indexes are very small. We may notice also the big dependence of the poorest districts which confirms our expectance (the poor districts have a population with small incomes, so taxation basis is as inexistent).

3. Municipal Bonds Issue-an Alternative Source for Financial Local Investment Projects

The local public administrations authorities have a legal right to complete their financial sources with other kind of incomes because the ordinary ones, from taxes, may be some times insufficient. One of these extraordinary revenues is the internal or external loans, used to sustain local public investments or to refinance the local public debt[124]. The law of public debt[125] imposes some restrictions (for example, the maximum level of the amount borrowed along with the interest and the commissions has to limit to 20% of current revenues of the local public administration) to prevent the insolvency. These loans may take forms as bank credits or bonds issues.

If until 1995 the local collectivities did not borrow money, after this year, the amount of loans registered a high percentage from entire local financial sources, with a top period in 1996, 1999 and 2004[126]. Staring the year of 2001, on the development of the capital market context, the local authorities identified a new source of financing in bonds. First issue was realized from Predeal city, having like objective the arrangement of a ski track[127]. Till nowadays there were listed 42 municipal bonds at Bucharest Stock Exchange. From all these, 16 did not reached their maturity yet. Many municipalities appealed to more than one bond issue (as Bacau, Alba Iulia, Lugoj, Timisoara, Oradea, Deva, Predeal, Sebes), as a sign of their success and opportunity. The objectives of the municipal bonds issues are looking to modernize some

[122] Idem 11;
[123] We used only the data from the period 2001-2004 because of the next reasons: the informations registered before the year of 2001 are not comparable with the ones registered after; for 2005 the public informations for local budgets executions are incomplete; for 2006 and 2007 there are only informations seeing the budget projects, not execution accounts, which we need;

[125] The law of public debt no. 313, Monitorul Oficial no. 577/2004;
[126] Idem 10;
[127] Informations from www.kmarket ro ;

principal roads in towns, cleaning water systems, way of access to turistic areas, extensions of water nets, sewerage, natural gas nets, modernizing districts etc. [128].

The revenues and expenditures of the municipalities who issued municipal bonds reveal a decentralization level superior to the average level. We have to notice Predeal, Bacau, Alba Iulia, Timisoara, Oradea, Cluj Napoca, and Navodari, which decentralisation level passes over 60% for all the period of research. From these ones, the municipality of Predeal got the top level, with a 90% decentralisation.

The bonds of Predeal municipality got the best rating BB+ from Bucharest Equity Research Group (BERG), a financial consultancy firm which initiated first rating service in Romanian financial market. The good marks which Predeal obtained bank on the fact that the proper revenues are highest than the ones received from the state budget and the city tries to get the financial independence[129]. On the other side we find Zalau bonds that got a 2C rating which shows the vulnerability in managing revenues and puts question mark on its capacity of assuming financial independence.

The marks are based on the information published by local authorities. The relevant indexes of the financial component of the rating were obtained by analyzing the local budgets' execution accounts, the financial data of local employers registered from the Romanian Ministry of Economy and Finance and the debts of the tax payer to the local budget. The economical component of the rating includes social–demographic data (like salaries, the population's aging, education and unemployment), their evolution and the structure of the economic activities and of the unpropitious or monoindustrial area risk. Also, the economic component gives importance to the stability and the political structure of local public administration and its capacity to increase the proper income percentage in entire revenues.

For the other municipalities we remarked in our study that the rating was as follows: Bacau B+, Cluj Napoca B+, Targu Mures B+, Alba Iulia B. This rating completes our conclusions seeing the level of local decentralization. Many from these cities issue more than one time bonds and they assume a higher maturity of the loan (until the year 2025 or even 2026). This fact suppose a risk increasing, both for investors (who will have to wait more to receive back the loan and maybe will register opportunity costs) and for municipalities, because the market medium rate of interest keeps growing up as a result of the Romanian National Bank's actions to stop the increment of inflation rate. The growth of the market rate of interest's level generates a supplementary financial effort to pay the variable coupon, lied to the rate of interest evolution[130]. To be able to take this risk, it supposes to be solvent and that is reach information about the local capacity and potential in finance area.

After we analysed step by step every municipal bond issue from Romania, our conclusion was that as the maturity is longer, as the extra remuneration up to the medium rate of interest decreases. That is a sign that local administrations try to prevent assuming debts bigger than their potential, because in the future may happen everything.

We computed the level of decentralisation for the cities which issued municipal bonds using Hunter's index. Generally, we discovered values up to the average level [131](excepting Camp lung, Zalau, Medgidia, Bistrita). That ones which registered a high level for this index (closer to one), so they are more independent financially, realized by now more than one issue on market. We have examples as Predeal (90%), Bacau (over 60%), Alba Iulia (between 50% and 60%), Timisoara (60%), Targu Mures (60%), Lugoj (about 50%), Sebes (over 55%). Their financial independence sustains and explains them as actors on the Romanian capital market.

4.Conclusions

Starting with the increasing transparence of the allocation and the use of budgetary state sources at the local level, set by the public finance law from 2006, but the changes in tax law brought by the Tax Code, the level of the public local administrations sensitively increased. These means bigger possibilities to collect proper revenues and to use it both with equilibration revenues received from other budgets the way they want to, according the real and particular needs. The increment of decentralization sustained the local development. Proper revenues, the equilibration revenues and the possibility to earn new sources from the

[128] Informations from www.kmarket ro ;

[130] The formula used for computation, the generally one, is: (ROBID+ROBOR)/2 + X%;
[131] Idem 10;

capital market which to be managed by them selves gives endorsement to the local investments, which may be seen as a platform of a sustainable economical and financial growth. As the decentralization level increased, as the local investments initiatives took place. So, because of the finance needs, the local authorities asked for it using the capital market. Their demand is guaranteed by their solvency. The rate of interest is attractive and variable, fallowing the same tendency as the rate of interest of banks but in lower risk conditions (the municipalities' loans have only bankruptcy risk, and that in cases there are not guarantees from the state, and the market risk, much of it being annulated because of the sensitivity of the coupons at the market level of the rate of interest).

So we may conclude about the tendency of financial decentralization of the local public administration, fact sustained by their frequent appeal to the capital market, which comes to consolidate the local autonomy. The growth of decentralization level made possible the maturity of the loan to increase in terms of financial security. The investors are encouraged by the extra rate of interest given over the average rate of interest on market. The apparition of the municipal bonds on Romanian capital market offered a new instrument which may be used to diminish the portfolio risk, a viable alternative to the bank deposits, in lower risk conditions and much attractive as remuneration rate. So, the municipal bonds do play a double role, as well in Romanian capital market development as in the financial local autonomy increscent.

THE NEED OF USING INDICATORS IN SIZING THE EFFICIENCY OF EXPENDITURE FOR EDUCATION

Moşteanu Tatiana

Academy of Economic Studies Bucharest, Finances, Insurances, Banks and Stock Exchanges

Gherghina Rodica

Titu Maiorescu University Bucharest, Faculty of Economic Sciences, e-mail: rodicagherghina@yahoo.com

Abstract: In order to be used in sizing the efficiency of expenditure for education, the indicators must reflect its specific aspects and their calculation must be needed and in accordance with the requests of the educational activity.

The need of using a system of indicators is imposed by the complex character of the efficiency of expenses for education, due to the fact that each of these indices takes a certain efficiency criterion, contributing to the development, implementation and evaluation of the educational policies.

Key words: indicators/indices, efficiency, expenditure for education.

Within an economy where the public needs claim public goods of high values, continuously augmenting and diversifying, on one hand, and on the other hand, the financial state resources not going up in a sustained rhythm, a gap is created leading mainly to the failure of resources needed for all the economic activities and implicitly, of education activities.

Based on these conditions, the decision makers proceed to sorting and ranking the social needs, respectively to sizing the public expenses, taking into account many criteria: priority, opportunity, efficiency and effectiveness, public services quality.

If we take into account the efficiency of the expenditure for education, its quantification can be elaborated either as a ratio between the obtained results by the education operation and the money spent for this action during a certain period of time, or as a ratio between the size of the efforts spent into the education activity and the size of the effects (results) obtained into the development of the respective activity.

The efficiency of the education must be expressed by indicators to reflect the quality of the education activity, comparing thus the effects and the effort spent.

In order to be used in sizing the efficiency of expenditure for education, the indicators must reflect its specific aspects and their calculation must be needed and in accordance with the requests of the educational activity.

The indices of the efficiency of the expenditure for education are used for underlining the effects obtained further to the education expenditure and for their size determination. On the basis of their analysis, there can be identified new actions in line with the improvement of the use of funds within education field.

The necessity of using a system of indices is entailed by the complex character of the efficiency of expenditure for education because each of these indicators takes a certain efficiency criterion.

Each indicator must answer to the calculation level: for example, indicators calculated at national, county or local level, indicators calculated on educational levels or on total education. But some indices are calculated only at national level, such as: public expenditure for education as a percentage from the Gross Internal Product, proportion of public current expenses on educational levels.

Other indicators are calculated at county level or on educational levels, such as: gross/net rate of schooling, rate of school years repetition, etc.

The calculation of indices must be based on real data in order to answer the scope of indicators use; these data refer to:

- measurement of progress registered at the education system level;
- assessment of policies impact within the field;
- setting out new priorities.

In order to assess the efficiency of expenditure for education there are used characteristic indicators for this field, which can be calculated both at macro-economic level and at micro-economic level. These indices have the role to underline the specific elements of the educational activity in evaluating the efficiency and expenses for education.

In order to better understand the usefulness of calculation of efficiency indicators of education expenditure, there can also be calculated social indicators, in physical or material form, some of them being requested for the understanding and analysis of the others while offering different judgment elements.

At the same time, in order to ensure the comparison of these indices and allow the analysis according to the time factor, they have to be calculated using updating methods. Thus, it can be established the moment when the ratio effort/effect is unitary and it is achieved the compensation of expenses from revenues.

Although the economic efficiency indicators of the education process lead to a comparison of the obtained results and consumed resources, they also have to take into account other defining elements, such as: the structure of resources and results, their quality, the abundance degree, the time factor insufficiency.

It is very important the detailed presentation of the calculation method with emphasize on formula, as there are indicators that can be calculated in different ways. Moreover, in each indicator presentation must be included the way of interpreting it in order to avoid confusions and to unify the methods of usage. In this paper, we present two indicators relevant for the efficiency of public expenses allotted to the educational process.

An indicator calculated both at national level and on education levels is the one for public expenditure for education as a percentage from the Gross Internal Product.

The goal of this indicator is to emphasize the proportion of the resources allotted to education by government from taxes and duties collected at budgetary level during one year.

The growth of public expenditure for education is mainly explained by the constant growth of the gross internal product during the last years. During 2000 – 2007 this indicator had the evolution presented in table 1.

Table 1

Public expenditure for education as a percentage from the Gross Internal Product

2000	2001	2002	2003	2004	2005	2006	2007
3,4	3,6	3,5	3,7	3,9	3,9	4,7	5,2

Source: Ministry of Public Finances, Ministry of Education and Research 2000-2007

We notice an increase of the expenses for education from 3,4 % in 2000 to 5,2 % in 2007. To this percentage (5,2%) there have been added 0,50 % from the gross internal product for research and 0,23% from gross internal product for insurance and social welfare. This indicator emphasizes both the education importance as compared to the other public services provided by state calculated on education levels and the priority of public funds allocation for a certain level of education. We have also studied the evolution of public expenditure for education indicator as a percentage from the total public expenditure during 2000 – 2006, when this indicator undergone little modification, as shown in table number 2.

Table 2

Public expenditure for education as a percentage from the public expenditure during 2000-2006

2000	2001	2002	2003	2004	2005	2006
8,1	8,3	8,3	8,2	8,2	8,3	8,4

Source: Ministry of Public Finances, Ministry of Education and Research 2000-2006

This indicator is calculated as a ratio between the total public expenses for education and the total public expenses from a financial year on the basis of data provided by Ministry of Public Finances, Ministry of Education and Research, National Institute for Statistics.

It is an indicator calculated both at national level and on education levels. This indicator emphasizes the proportion of expenses allotted by government for the educational sector development from the annual public expenditure.

It is important that the indices system for education should get together several conditions

- it has to be a multidimensional system so that it can be used in different circumstances, it can comprise not only data related to education but also the reports to the given context;
- it has to ensure comparison with the most well-known indicator systems used by international organizations and mostly by European bodies to which we report to;
- it has to cover the main domains of the educational policy;
- it has to allow multiple uses regarding the annual assessment of the education system (by basic indices), and the analyses both at central level and at regional level;
- it has to hold a certain information power to allow communication sizing and great caution in analyzing statistic data.

This insertion of indicators is justified by the need of monitoring and evaluating the degree of carrying out one of Lisbon priority objectives concerning the education quality development:

- education efficiency can be expressed by indices which must reflect the specific aspects of this activity and their calculation is requested and in accordance with the respective activity requests;
- the requested data for the calculation of indices have to be updated in order to answer the scope of their use;
- the use of indices for the education system assessment and the evaluation of achieving the educational policy objectives at national and local level;
- in calculating the efficiency indices of expenditure for education, the gap between the effort period for sustaining education and the result (effect) period for this action should be noticed (as a characteristic);
- the efficiency index system calculated for the educational activity has a certain information power, these indices can be transferred in certain situations and can be applied to different objectives of education policies.

It is necessary to identify new directions to act in line with the improvement of funds within education field, taking into account the fact that the indicators are not significant as information; they are important only reported to certain criteria related to the education objectives and to the end products of the system.

CONSIDERATIONS REGARDING GROWING FINANCING CAPACITY OF SME`S

Nanu Roxana Maria

Small and Medium Enterprises are very important part of both developed and less developed national economies. The European Union experience shows that it has a significant contribution to the GDP and to the reduction of the unemployment rate. In Romania, as in many countries in the area, there is still a long way ahead for reaching an adequate support for SME development potential. Romania has a sector which, although has recently followed a positive trend, it possess performances which are still low in comparison with the countries from European Union, including the countries which entered the European Union in May 2004. The paper highlights financing methods used by SME, the reasons for the present situation as well as the measures thought to be the best for its improvement. In order to amend the situation the Romanian SME are in, Romania must take multiply sided actions, the main role being assigned to government, banks and guaranteeing institutions, that must develop a series of transparent, efficient and correct instruments.

Cuvinte cheie: SME's, financing, credit, leasing, guaranteeing funds, structural funds

The challenges caused by regionalization and globalization of markets demand the compliance of SME to the competitive environment, by consolidating their market position and benefit from the economical opportunities. If traditionally, small and medium enterprises were considered economical operators belonging to the internal market, today a growing number of SME are managing to conquer the global markets. Approximately one fifth of the SME involved in the productive activity in the OCDE countries realize a proportion of 10 to 40% of the their turnover from international activities. SME contribute in a high proportion to the global industrial exports and increase the volume of foreign direct investments worldwide.

In the European Union, SME play an important role, their number being predominant: nearly 99% of the companies are SME, while 90% of them are micro enterprises. At the same time, European SME work force accounts for nearly 70% of the total confirming the social role of SME. In fact, all EU Member States have taken steps in stimulating entrepreneurial spirit. These measures widely vary and consist of loans and grants offering, on one hand, and, on the other hand, in offering support services, such as technical, juridical, managerial consultancy and information centers for setting up companies, training possibilities for potential candidates and new entrepreneurs and market studies.

In Romania, the role of SME is lower from the point of view of the turnover percentage or the added value created in economy, but, on the other hand, at their level, there exist 57% workers of the total number of employees. As for SME structure, there is a slight tendency of micro enterprises predominance and most of the employees may be found in the services sector.

Comparative definition between Romanian SME and European Union SME

Necessary conditions for situating within SME	Micro	Small	Medium
Romania			
Employees number	<10	<50	<250
Turnover (in millions EUR)	<8		
Other conditions (other companies 'shares/social capital)		25%	25%
European Union			
Employees number	<10	<50	<250
Maximum turnover (in millions EUR)	n/a	7	40
Maximum own capitals (in millions EUR)	n/a	5	27
Other conditions (other companies 'shares/social capital)	n/a	25%	25%

As we may see, the notion of SME is the same in the Romanian legislation and in the European Union; nevertheless, there are slight differences regarding turnover and their own capitals that insure equality conditions for Romanian SME on EU integration.

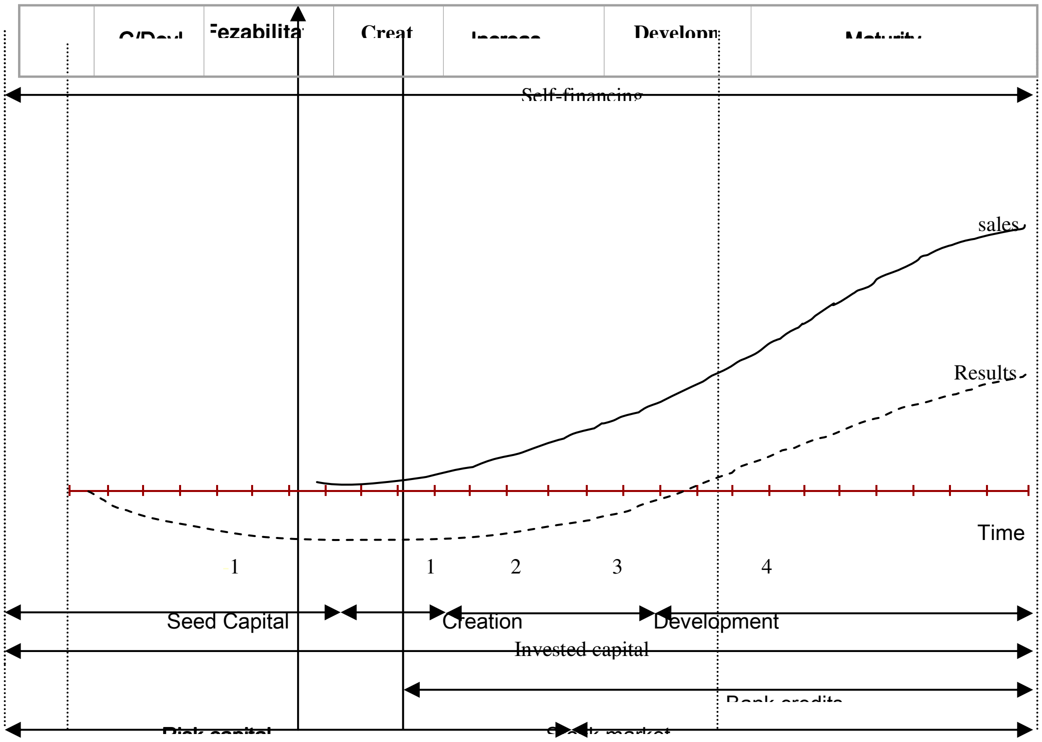
In spite of a positive dynamics, registered during recent years in the tendency towards productive sector as well as in the resources of the local entrepreneurial spirit, SME contribution at GDP still remains low; this fact proves the necessity of stimulating quantitative and qualitative increase of the SME sector. SME access to capital, technology and infrastructure is much beyond the extent that would allow using SME significant role in strengthening economic competitiveness, in particular adaptability to market demands and introduction of new processes.

In the context of competitiveness, most of the small and medium enterprises in Romania need financial support if we were to take into account that their productivity is lower than the big enterprises'. SME financing has gone a long way in the last 17 years in Romania. However, we still have to wait a little longer until we reach an adequate support for SME development potential.

We must bear in mind that, on their evolution, SME have to pass different business development stages, and that in each of these stages, there are needed other types of financing having different terms and conditions.

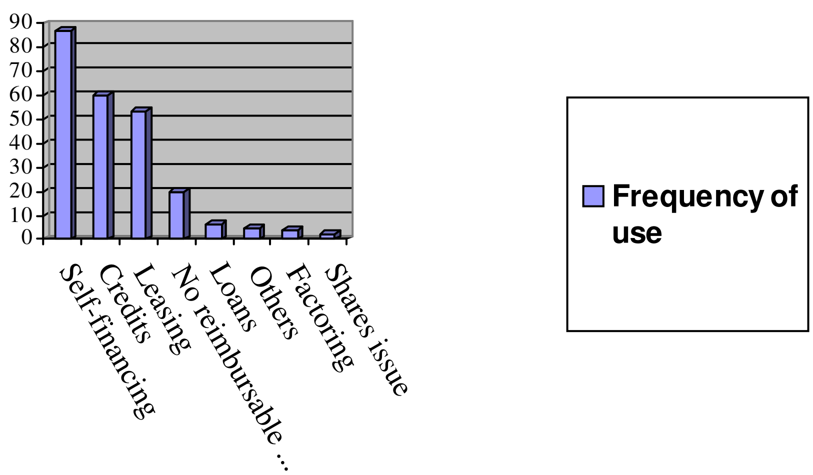
As we may see in the chart, the main financing method that SME dispose of, consists of self-financing, irrespective of the development stage, while banking credits as well as the resources originating from stock market, are relevant only in SME raise, development or maturity stages. Likewise, in the first SME development stages, we may also use risk capital financing.

SME access to financing represents an important side of the entrepreneur's stimulation; we may improve this aspect by financial system and public sector support. The role of the financial system tends to be offered a particular size, all its sectors (banking, leasing, and credit guaranteeing funds) having a significant potential in SME development.



Financing types in different business development stages

The results of some surveys on financing methods used by SME prove that 57.66% of SME carry on their activity only through their own sources. Thus, the most frequently seen financing methods used by SME consist of self-financing (used by 86.7% of companies in the survey), banking credits (60.1%) and leasing (53.2%). This is due primarily to difficult crediting conditions in Romania (high interest rates, high bonds, numerous and difficult grant formalities etc) but also to the possibility for some companies to finance their own activities, especially in the trade sector. We may see the SME method used in financing in chart no.2.



Used financing methods

Covering the financing necessities, primarily from own sources, generates a decrease in liquidities total of companies that may prevent, first of all, taking advantage of some business opportunities and secondly, financing investments having an impact on technological modernization. The lack of liquidities is emphasized by the delayed deduction of delivery as well as the increased tax system. These shortcuts in financing small and medium enterprises generate and develop the vicious cycle of illegal payments that are not included in bookkeeping, thus triggering tax avoidance and corruption.

Although in 2005, SME bank debts represented only 10.5% of total debts, in the first half of 2006, the increase in banking financing was considerable (33%), but if we compare to the European Union where SME financing is around 79% by means of banks, we may easily conclude that there is still a long way ahead of us.

In the last three-year period, according to the ENSR-Survey, 76 % of UE SMEs which asked for a bank loan, received it. The reasons for not obtaining bank financing differ between size classes: lack of collateral mostly affects micro and small enterprises, while poor business performance and insufficient information are the main reasons for medium-sized firms. In fact, in the last period, taking into account the remarkable potential of SME sector, the banks from Romania have begun to offer products and services aimed at these companies, in line with their needs and capital. However, at the same time, starting with January 1, 2007, there are important changes in the banking system also together with the appliance of new requirements of Basel II. Thus, trade companies must have a very good rating in order to receive credits according to new requirements of capital equalizing; in this respect, they must have capital accumulation and select the activities that may offer them good financial results. According to new capital requirements, SME credits will be balanced by 100% if they fall under the category of corporate or by 75% if they fall under the retail category, which means maintenance of the existing situation or even an improvement regarding credit risk appreciation of SME.

Thoroughly analyzing the causes preventing SME banking credit system from developing, we may discover the difficulties that entrepreneurs claim in their relation to banks. Decreasingly, difficulties with negative impact on banking credit system are the following: bank officer relationship, thorough documentation required by the bank in view of granting a credit; the length period of approving the credit by the bank; guarantees level and interest rate.

The ENSR Survey 2002 reports that European SMEs are satisfied with bank services. About two thirds of the SMEs are satisfied, approximately 12 % dissatisfied. The major reasons for dissatisfaction are: poor service, bank charges and frequent changes of contact persons. Especially in the case of medium-sized enterprises, banks do not seem to offer the best solutions to their clients. Medium-sized enterprises are also more often concerned by the refusal of additional loans or the withdrawal of existing credit facilities. There is a certitude that entrepreneurs are not reluctant in soliciting credits primarily because of the interest rate (that they include in products price anyway), but mainly because of reasons regarding client-bank relationship. There is a serious alert for banks that, in the context of market economy, would have to choose between adapting its policies to clients that is, always satisfying the clients' increasing needs and cut in turnover and profitability.

From the UE SMEs' point of view, the cost of borrowing (interest rates as well as charges) is still an important issue. External finance tends to be more expensive for smaller enterprises than for large ones as the fixed costs of lending (e.g. administrative costs and the costs of collecting information about the borrower) are not proportional to the size of the loan and make small loans more expensive than large ones[132]. This price difference is also caused by different risk positions taken by banks and some other size-related factors such as the greater financial acumen existing in LSEs and the greater leverage often available to LSEs.

These difficulties on obtaining a credit are doubled by the ones specific to reimbursement: fluctuating exchange rate, further costs generated by payment reallocation of unsuccessful credits, interest adjustment during the credits reimbursement period.

In order to have an easier access to banking credits, SME should benefit from a series of measures, such as:

- Thinking the business over in perspective;
- Presenting a well-structured and conceived business plan;

---

[132] Wagenvoort, R., Are finance constraints hindering the growth of SMEs in Europe?, EIB Papers, Vol. 7, No. 2, 2003.

- Apply to specialty consultancy unless they dispose of their own expertise to start with;
- Developing their own expertise in carrying out their relationships with the financing bank;
- Building up a mutually confident relationship with the bank: carrying on the operations through accounts opened at the bank from which the loan is asked for, credible and solid information, information supply in due time;
- Operatively informing the bank on further difficulties encountered during the credit period; and talking the solutions over.

A solution would come up if banks and guaranteeing funds had a common strategy for SME financing because one of the most important issue that entrepreneurs deal with when accessing a financing line is the lack of guarantees. Guarantees work on the principle of shared risk between the bank and the guarantee association, thereby significantly reducing the degree of risk for the bank. In the context of regional policy, guarantee schemes can play an important role in improving access to finance, creating private sector funding leverage and encouraging the development of SMEs. Guarantee schemes are especially suitable for very small loans to micro enterprises unable to provide the lender with the required collateral. In table the advantages and disadvantages for the participating parties are listed[133].

Advantages and disadvantages of guarantee schemes

Advantages	Disadvantages
SMEs, which cannot easily get finance, benefit from facilitated access to loan financing on better terms.	Only a part of the risk is covered by the guarantee society or fund.
Risk sharing between the guarantee society or fund and the bank reduces the capital requirement of the Basel rules.	By reducing the risks to banks, guarantee schemes may also reduce the extent to which banks scrutinize new loan applications.
Through guarantee societies and funds, private sector financing for SMEs is leveraged promoting regional development.	The extent to which guarantee associations and guarantee funds receive support from public authorities varies across the European Union and is mainly dependent on the prevailing banking culture.
Guarantee societies and funds provide local input and tailored business support and advice.	

In most of the European countries loan guarantee funds and mutual guarantee schemes offer guarantees to SMEs with insufficient collateral, especially micro enterprises. Loan guarantee schemes are often used by 'young' enterprises (12 % of SMEs with less than 5 years compared to 8 % of SMEs with more than 10 years in business). In this respect, in Romania was founded the SME Credit Guaranteeing Fund, a ventured capital institution aiming at facilitating the access to financing through credits guarantees or letters of bank guarantee for SME not having enough financial resources and material guarantees, but with viable business projects.

Another method of financing for SME is leasing. In the European Union, one of two SME has already used a leasing operation for business financing. The average penetration of leasing is estimated to be about 12 % in the European Union.

In Germany, over 70% of small and medium enterprises prefer leasing or loan in order to buy machines and equipments. A study made by the Directorate for Enterprises and Industry of the European Commission indicates that nearly half of small and medium enterprises in the old EU countries have already used the leasing system, loan and account overdraft for investments financing. After Germany, the SME of Austria (65%) and Sweden (63%) take the second place in their preference for leasing or loan. In Romania, the leasing market experienced a significant growth; the specialists think that this sector attraction is closely related to leasing development for the means of transport as a more approachable and easier way of financing for small entrepreneurs.

---

[133] European Commission, Guide to Risk Capital Financing in Regional Policy, Brussels, 2002.

Within the EU economic and social cohesion policy, Romania will benefit from structural funds of nearly 30 billion EUR during 2007-2013. These EU structural funds are treated by the European Commission and aim at financing structural aid measures at the Union level in order to promote low developed areas, reconversion of areas experiencing industrial decline, abolishing long-term unemployment, professional insertion of the youth or promoting rural development. One of the main fields of intervention for operational programmes (Sectorial operational sector – Economic competitiveness increase) aims at accomplishing productive investments and preparing for competitiveness on the European market of small and medium enterprises, the allocations in this field being managed by the National Agency for Small and Medium Enterprises. The Programme of Competitiveness Improvement for SME consists of 6 priority axes, the main ways through which small and medium enterprises will be able to access funds within the sectorial programme, that is:

Axis 1 – Production modern system;

Axis 2 – Research, technological development and innovativeness for competitiveness;

Axis 3 – Information and Communication technologies for private and public sector;

Axis 4 – Energetic productivity increase and durable development of the energetic system;

Axis 5 – Romania, attractive destination for tourism and business;

Axis 6 – Technical assistance

In order to improve the current situation of the Romanian SME, we must take various steps, the main role being played by the government, banks and guaranteeing institutions that must develop a series of efficient, correct and transparent instruments. We strongly recommend priority actions concerning:

- Setting up a system of guaranteeing and co-guaranteeing funds at a national and regional level for enterprises financing;
- Significantly diminishing guarantees values and commissions required by banks on granting credits in line with the European Union procedures;
- Simplifying credit granting procedures;
- Subsidizing interests for SME credits, in particular for the ones in certain fields and categories;
- Drawing up a national training programme for enterprisers in order to access structural funds based on the principle of public-private partnership;
- Granting adequate grace periods for investments credits and periods increase;
- Promotion of the use of non-traditional financial instruments such as risk capital funds etc.

Abstract: Volatility represents the most common used method for risk estimation. The aim of this paper is to estimate volatility based on historical models and heteroskedastic models, GARCH (!,!), in order to identify the crisis moment within American capital market. The database used consists in daily observations about Dow Jones index, spanned within 1928 – 2002.

Keywords: volatility, heteroskedasticity, GARCH, capital market

Introduction

Following the seemingly work of Bachelier (1900) and Markowitz (1952), volatility represents the most common used method for risk estimation among a long list of other methods (see in that sense, Pedersen and Satchell, 1998). The main reasons which support the previous affirmation are: (i) the fact that each rational investor is characterized by a squared utility function, and (ii) financial assets' returns normal distribution hypothesis. But, both assumptions were not entirely demonstrated by empirical studies and tests.

Using a second order polynomial utility function proves to be inconsistent with the fact that averse risk investors could seldom decide to invest in risky financial assets (Kahneman and Tversky, 1979), or with a cautious investors' behavior (Kimball, 1993).

The hypothesis of normal distribution probability of financial assets is not confirmed by empirical studies (see in that sense, Fama, 1965 and Mandelbroot, 1997). In fact, returns distribution is asymmetric and leptokurtic (Christie and Andrew, 1982). Using the leverage effect, active and passive portfolio management strategies and derivatives go to convex profit functions (Bookstaber and Clarke, 1981), while credit and liquidity risk are the main source of potential large losses on financial markets. Long run investment strategies and returns heteroskedasticity are the causes of financial assets asymmetric and leptokurtic probability distribution (Fama, 1996; Bollerslev, 1986).

Consequently, using volatility as good estimator for risk is inconsistent with investors' informational asymmetry or the statistics of returns distribution. Even if volatility represents a friendly method, it has some drawbacks. For instance, volatility is an unobservable element, which makes its estimation very difficult. Based on stochastic models, there were explained dynamic characteristics of volatility, so it could be measured using regular observations on financial assets' prices. It is a stochastic volatility, which is not constant over time and depends on the average conditioned by past shocks. The estimation of such process

[134] This paper is a preliminary study elaborated within research project PN II, type IDEI „Measuring the amplitude of financial market crisis and turbulences using an index following the Richter scale from seismology. An application of the econophysics principles", project contract no. 169/2007, financed by Romanian Government through UEFISCU.

is difficult, and the estimators could be distorted (Barndorff-Nielsen and Shephard, 2002; Bollerslev and Zhou, 2002).

The aim of this study is to estimate volatility using historical methods and heteroskedastic methods, GARCH (1,1).

Database

The database used is represented by closing quotations of Dow Jones index within October 1928 – December 2002.

Empirical results

Historical volatility was estimated as standard deviation at the end of each quarter based on daily rates of returns, calculated as natural logarithm of closing quotations of Dow Jones index.

The estimated quarterly volatility based on historical methods is presented in Figure 1.

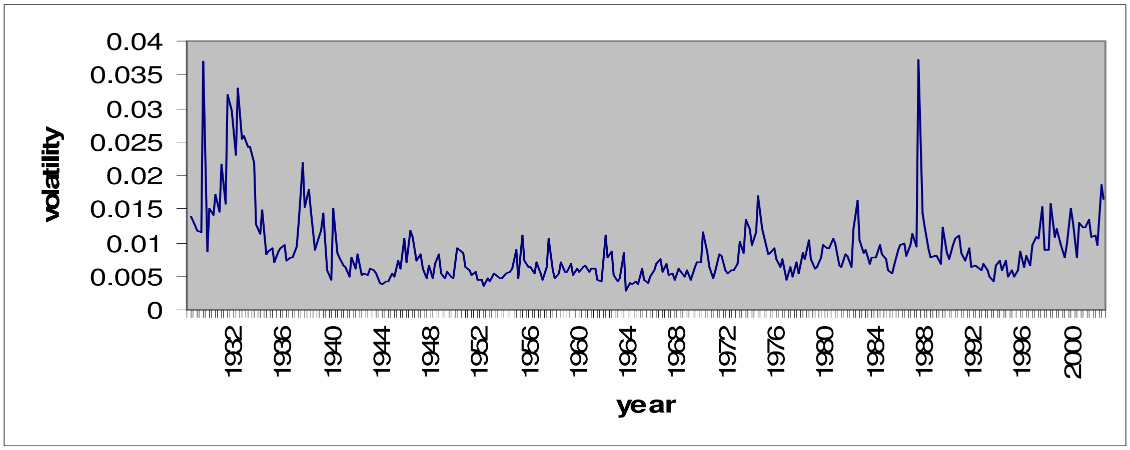

Figure 1 Historical estimated quarterly volatility

In order to estimate volatility based on heteroskedastic methods, it was used a GARCH (1,1) model, similar to one proposed by Bollerslev for obtaining a maximum likelihood. Model's equations are the following:

$$r_t = \mu + \rho \cdot r_{t-1} + \varepsilon_t \quad (1)$$

$$\sigma_t = a_0 + a_1 \cdot \sigma_{t-1} + b_1 + \varepsilon_{t-1}^2 \quad (2)$$

where:

r_t : rate of return calculated related to return at t-1;

σ_t : estimated volatility depending on volatility at t-1 and residuals at t-1;

μ, ρ, a_0, a_1 and b_1 : coefficients.

In order to obtain relevant results, residual term, $\varepsilon = N(0,\sigma_t)$, has to follow normal distribution of zero average and variance equal to volatility.

GARCH (1,1) estimations go to a maximum likelihood of 65691.3270, and estimated parameters are presented in the table below:

	μ	ρ	a_0	a_1	b_1
Estimated value	0.0004	-7.7400	-0.0009	12.0740	3.5962
σ^2 parameters	0.0001	0.0076	0.0000	0.0041	0.0038
T-statistic	6.8156	14.9179	8.7173	221.3062	21.1474

Table 1. Estimated GARCH

The estimated results show the coefficients significance.

The estimated volatility and variance is presented in Figure 2 and 3.

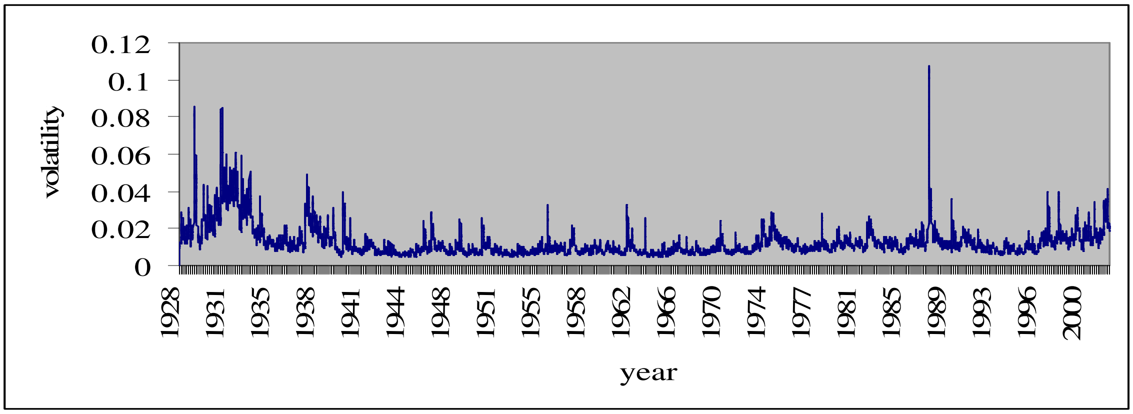

Figure 2. Estimated daily volatility based on heteroskedastic models

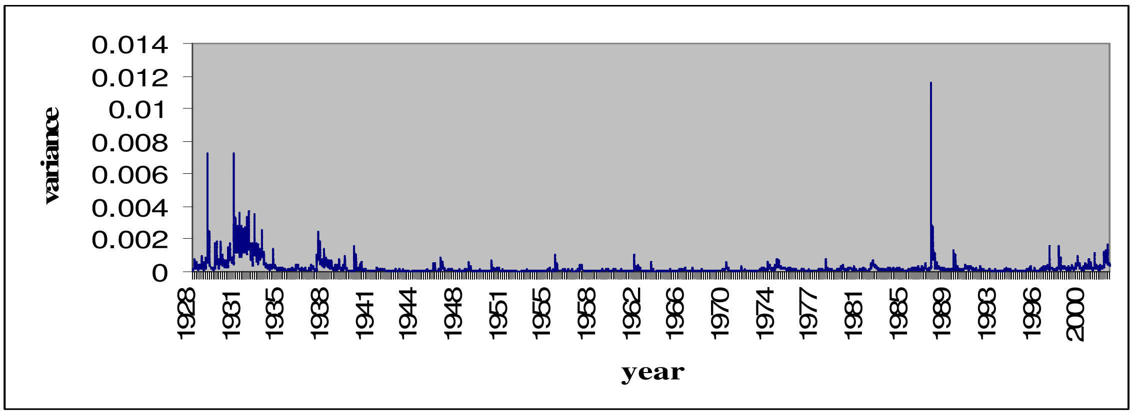

Figure 3. Estimated daily variance based on heteroskedastic models

The estimated residuals are presented in Figure 4 and 5.

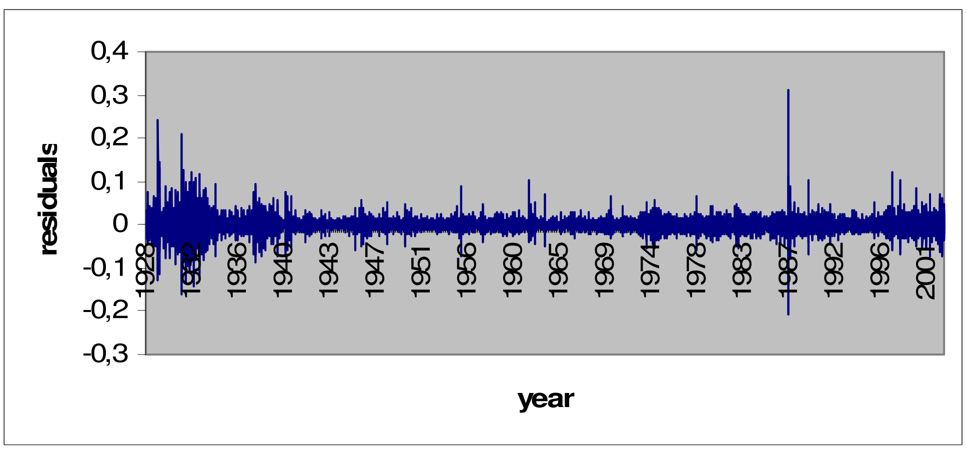

Figure 4. Return estimated residuals

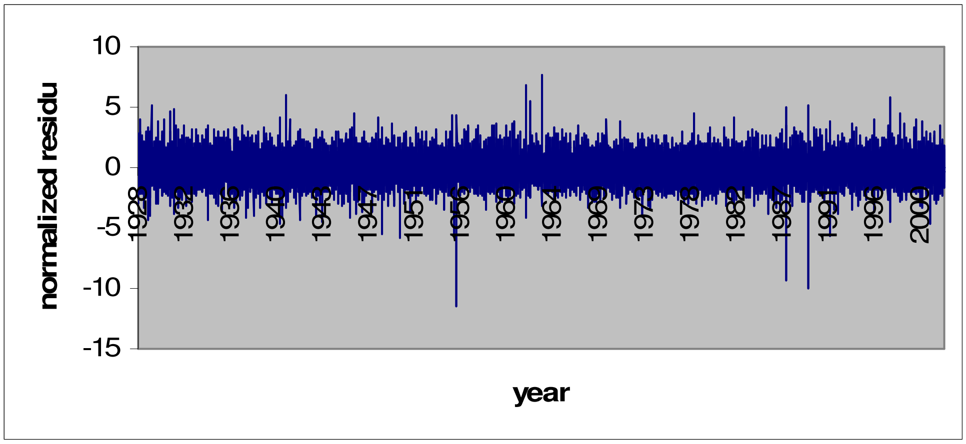

Figure 5. Normalized residuals

Normal distribution of residuals is presented in Figure 6 and 7.

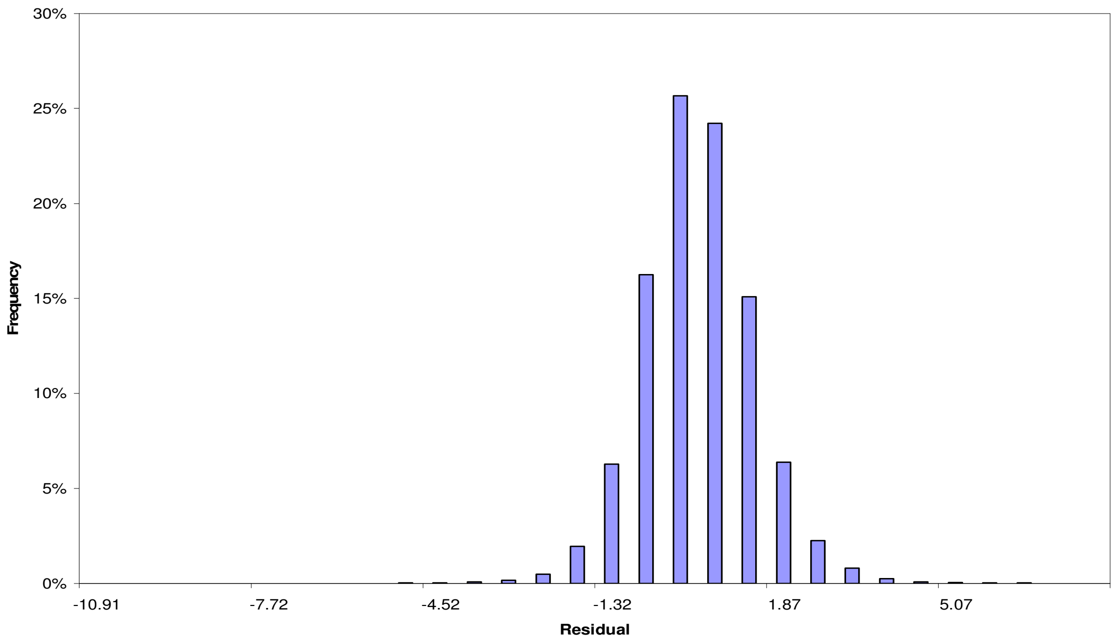

Figure 6.Residuals empirical distribution

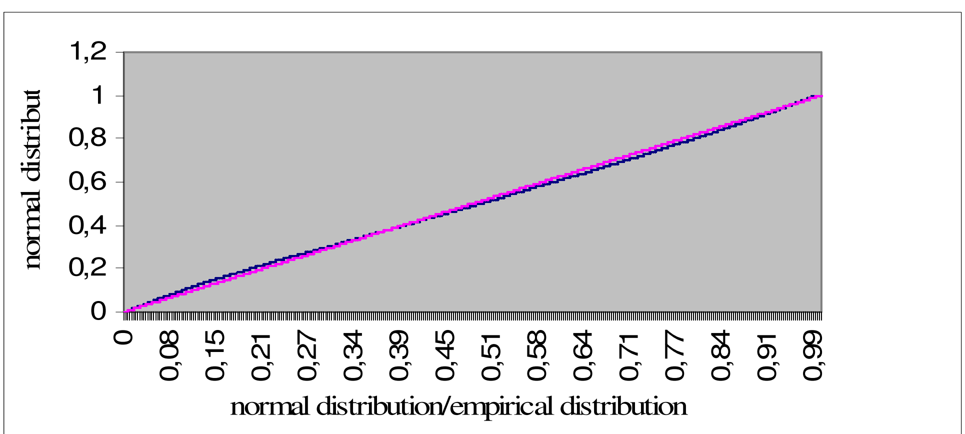

Figure 7. Residuals Henry line

Concluding remarks

The estimated volatility based on historical methods and on GARCH (1,1) model reveal the crisis from American capital market. It could be noticed some crisis moments, such as the peak within 1928 – 1933 (characterized by large volatility and duration), and within 1986 - 1988 (characterized by large volatility and small duration, only one month, at the end of 1987). Both moments are revealed by the historical estimated volatility and by GARCH estimated volatility, but the difference appears related to their size. There were, also, identified some other distortions on US capital market at 1938, 1941, 1946, 1950, 1957, 1960, 1962, 1966, 1970, 1973-1975, 1978 – 1981, 1982 – 1984, 1990. After 1997, it is noticed an increasing volatility for 1997, 1998, 2000, 2001 and 2002.

Corporate finance is mainly oriented towards the management of money resources and financial relationships that rise between economic agents in the process of pecuniary circulation. Moreover, financial management represents the process of settling the purposes for influencing finances with the help of the methods and the levers of the financial mechanism. The structure of the financial mechanism is further analyzed as well as the constitution of the financial management's object and subject.

Key words: corporate finance, financial management, financial mechanism

Corporate finance is an area of finance dealing with the financial decisions corporations make and the tools and analysis used to make these decisions. The supreme purpose of all corporations is to increase their value, i.e. to increase the price (the market value) of their shares, to pay dividends to the shareholders and to remunerate the work of their employees. This is why *the financial aspects* of corporative management are central problems of it.

Corporate finance is oriented towards the management of money resources and financial relationships that rise between economic agents in the process of pecuniary circulation.

The corporate finance as a discipline can be divided into long-term and short-term decisions and techniques. Capital investment decisions are long-term choices about which projects receive investment, whether to finance that investment with equity or debt, and when or whether to pay dividends to shareholders. On the other hand, the short term decisions can be grouped under the heading "Working capital management"[135]. This subject deals with the short-term balance of current assets and current liabilities; the focus here is on managing cash, inventories, and short-term borrowing and lending (such as the terms on credit extended to customers).

Financial management contains a system of principles, methods, forms and procedures for regulating the finance market mechanism in order to increase the competitivity of economic agents.

Financial management represents the process of settling the purposes for influencing finances with the help of the methods and the levers of the financial mechanism.

The fulfillment of financial functions is based on the evidence and financial analysis system for the financial means, resources, goods and capitals of the corporation. The functions of corporate finance are further presented in table no. 1:

Type	Finance function
Object management function	Organizing monetary circulation; Providing the financial means and investment instruments; Supplying the main fixed and current funds (equipments, raw material, technical-material means); Organizing the financial activity; *Financial Planning*: a complex of measures regarding the evolving of tasks and their fulfillment.

[135] The goal of working capital management is to ensure that a firm is able to continue its operations and that it has sufficient ability to satisfy both maturing short-term debt and upcoming operational expenses.

	Financial Forecasting: long term evolving of modifiers in the financial status of the company (of the corporation) on the whole and of its subsidiaries.
Subject management function	*Organizing:* organizing and drawing up the financial programs. *Settlement:* acting upon the object of management, through which the financial stability status of the company's system is reached, in case of deviation from the fixed parameters. *Coordination:* coordination of the activities of all shackles of the management system, administrative system and of the specialists. Financial analysis: analysis of the financial status of the company (corporation), the execution of financial programs, etc The Control: verifying the organization of the financial activity, the execution of financial programs, etc. In the controlling process, the information about the financial means usage and financial status of the object is selected, supplementary reserves and possibilities are found, modifications of the financial programs are introduced and financial management is organized.

Table no. 1 Corporate finance functions

For corporate administration, the finance management function also implies providing financial means (the leading of capital: to attract, set and use it) and the distributive functions – assuring balanced movement of material and financial resources in the production process.

The existence and efficient functioning of corporative management in the market economy conditions, are not real without a strict financial management and its capital leading is not possible, i.e. assuring the main types of financial resources (investment resources) like material and monetary means, diverse types of financial instruments.

The corporation's capital is on one hand, *the source*, and on the other hand, *the result* of the corporative management activity.

The structure of corporate finance is presented in the following table:

Corporate finance				
Financial relationships				**Financial means and funds**
With other companies	Inside the corporation	With the resort organization within the association	With the creditor-financial system	
The providers	The corporation's workers		With budgets of different levels	Registered capital (share)
The buyers	The shareholders		With the banks	Supplementary capital
The building and transport companies	Between subsidiaries and branches		With the insurance organizations	Reserve capital
External economic relationship			With the extra-budgetary funds	Fixed assets
			With the commercial-papers market	Current assets

			With the investment funds	Investment funds
				Reserve fund
				Depreciation fund
				Exchange fund
				Other funds

Table no. 2 The structure of corporate finance[136]

The finance notion is wider than that of capital because it includes not only the financial means, but the financial relationships, too. Capital management is analyzed from the point of view of financial management – the management of finance (the own and borrowed means) and that of financial relationships set between economic agents involved in entrepreneurial activities.

The object of financial management is constituted by the totality of fixed and circulating means of the company (its assets), and their forming sources (the passives) the conditions for money circulation and value rotation, financial resources movement and financial relationship.

The subject of financial management is constituted by a specialized group of persons (direction of financial subsidiary), which takes care of evolving and applying all sorts of administrative actions upon the objects of management. The structure of the financial management system of the company (corporation) is presented as follows:

The financial management system of the corporation			
The administrative subsystem (the subject of management)			
The financial department		The financial manager	
The management system (the object of leading)			
Monetary circulation	Value rotation (capital)	Financial resources and their sources	Financial relationships

Table no. 3 The structure of the financial management system of the corporation

The corporation capital management actually is the main task of financial management.

The main directions for capital management include:

- **working with the financing sources** (equity and borrowed capital, short term and long term borrowing, profit distribution, the issuing of securities, etc);
- **the investments of the company (corporation) and evaluating their efficiency** (the capital return, the current and future value of the company, evaluating financial risks, etc);
- **the management of fixed and circulating capital**;
- **financial planning** (the financial plan, the budget, the business plan, management accounting, etc);
- **the analysis and control of the financial activity**.

In order to realize the tasks of company's financial management, the financial mechanism is applied (table no. 4), which represents a system designated for organizing the interactions between financial relationships and the monetary means for their efficient action upon the final results of the corporative management activity. The leading of the company's finance includes the strategy and tactics of management.

[136] joint-stock company

The tactics in the finance management domain is oriented towards reaching the set purpose in definite conditions. For the current activity, the expense reduction problems are solved, as well as stimulating the entrepreneurial initiative, the increase in labor productivity and the rationalizing of production and circulating expenses.

The strategic management of finance pursuits to find ways of accumulating capital and redistribution of financial resources towards the most efficient spheres of economic activity. From the point of view of finance management, the company has to maximize its profit and to increase the finite production volume.

Financial methods	*Financial levers*	*Juridical insurance*	*Informational insurance*	*Normative insurance*
Planning	The profit	Laws	Diverse types of information	The instructions
Prognostication	The incomes	The President's decrees		Normatives
Crediting, auto financing	Depreciation deductions	The Government's Resolutions		Norms
Taxation	Financial sanctions	The orders and dispositions of ministries' and departments'		Methodical indications and recommendations
Material stimulation and responsibility	Dividends			
Insurance	Interests			
Leasing	Investments			
Factoring	Special funds			
Forming the funds	Deposits			

Table no. 4 The structure of the financial mechanism within corporate management

To conclude with, the signs of a successful financial management of a company are:

- the survival of the company (corporation) in competition;
- avoiding bankruptcy and great financial failures;
- leadership in competition;
- maximizing the value of the company;
- acceptable development rhythms of the company's economic potential;
- the increase of the production volume and its accomplishment;
- maximizing the profit;
- minimizing the expenses and the losses;
- assuring a profitable activity.

The accomplishment of the financial functions is based on the evidence and financial analysis system of the financial means, the resources, the goods and the capital of the corporation.

ARE ALL FINANCIAL CRISES THE SAME ? PREMISE FOR FURTHER RESEARCH.

Nistor Ioan Alin

"Babes-Bolyai" University, Faculty of Business, Str. Horea nr. 7, 400174 Cluj-Napoca, Romania, Tel: 0040-264-599170, Fax: 0040-264-590110, e-mail: inistor@tbs.ubbcluj.ro

Abstract: The entry of Romania in the EU has brought advantages and disadvantages. This fact made Romania prone to the influence of other economies especially from developed countries. The paper examines the possible correlation of Romanian economy with other economies and like this the effects that a financial crisis would influence Romania. In case of a financial crisis many emerging markets will suffer because the investment flows will move away, as an adjustment of risk aversion.

Keywords: Financial crisis, banking distress, emerging market, risk aversion

Introduction.

From the economic point of view, a change that is adopted, whether is within a company, financial institution or government, comes with advantages and disadvantages. As long as the sum of advantages is bigger then the sum of disadvantages the adopted change will be for the benefit of the firm or society and should be considered a positive change.

Like this, the entry of Romania in the EU came with advantages and disadvantages. The free movement of goods, persons and capital within the boundaries of EU, has brought advantages and disadvantages. These facts made Romania prone to the influence of other economies especially from other developed countries.

Recent events of the USA financial sector draw the attention of both specialists and nonspecialists to many of the problems related to the financial distress, how quickly and unexpected crises arise and spread over different sectors of the economy. Living in a globalize world the crisis will not remain within the boundaries of one country but will, in a very short period of time expend all over the world affecting more countries with different degrees of influence.

Banking crises have become common place during the past two decades, but the range of experience in terms of the nature of the crises, causes and effects, vary across countries and time periods. George Soros, a well known financier, said to be very acid in his predictions, states in his recent book (The New Paradigm for Financial Markets, 2008) that: "We are in the midst of the worst financial crisis since the 1930s."… "The United States is facing both a recession and a flight from the dollar. The decline in housing prices, the weight of accumulated household debt, and the losses and uncertainties in the banking system threaten to push the economy into a self-reinforcing decline. Measures to combat this threat increase the supply of dollars. At the same time, the flight from the dollar has set up inflationary pressures through higher energy, commodity, and food prices. The European Central Bank, whose mission is to maintain price stability, is reluctant to lower interest rates. This has created a discord between U.S. and E.U. monetary policy and put upward pressure on the euro."

The full impact of the banking crises on the American economy is unclear at this point, but even the most optimistic researcher would say that it is clearly substantial. Several papers have attempted to identify the key factors preceding or coincident with episodes of banking sector distress. The author of this article has developed a past research (銀行｛ぎんこう｝の 破たんや 金融危機｛きんゆうきき｝に対処｛たいしょ｝する "Handle bank failure and financial crises") conducted on the Japanese past banking crisis. At that point (2004) we investigated the causes and consequences of Japanese banking sector distress from 1992-1994 and if this can fit or not with the experiences of other countries. In addition to the macroeconomic developments we considered specific institutional characteristic that may increase the probability of a banking problem. And like the case of Japan, the new American crisis has emerged also from the drop of asset prices, but the cause of the drop in prices being a little bit different. Like Japan, USA has seen a steep rise in housing prices during the four years preceding the crisis, a steep rise in equity prices, a large increase in its current account deficit, and increase in public debt.

Institutional characteristics. Data analysis.

An IMF (International Monetary Found) report summarizes and identifies several general categories of problems frequently associated with financial crises, for example: unsustainable macroeconomic policies, weakness in financial structure, global financial conditions or political instability. But we can stress that macroeconomic instability and particularly fiscal policies within the asset prices bubbles had been a factor in many episodes of banking sector distress, including the Japanese crisis of the 1992's and the nowadays financial problems from America. External conditions, such as large changes in terms of trade and world interest rates, have played a more important role in financial crises in emerging markets economies by affecting the profitability of domestic firms and thus have an impact on bank's balance sheets. These risks often appear in times of rapid financial liberalization and greater market competition when banks are taking new and unfamiliar risks on both assets and liabilities. An important role in assessing and controlling the risk should stay in the hands of supervisory and regulatory financial institutions which under weak policies create the circumstances for banks with low capital ratios to increase their risk position in newly competitive environments and allowing them to avoid full responsibilities for mistakes in monitoring and evaluating risk. Central banks have frequently failed to quickly identify institutions with problems or to take corrective action when problem arises, thus resulting in larger and more difficult crisis situations.

The above mentioned aspects suggest that several mutual characteristics of economies can be associated with financial crises. But do these aspects apply also to the emerging markets?

No need to mention that an emerging market can not stay away and not be affected by a financial crisis that arises in a developed economy. Several aspects can be good variables in order to analyze financial crises. Here we can mention Real GDP growth, Exchange rate depreciation, Real interest rate, Inflation, Real credit growth, Stock price change.

In the following, let us have a look at the movement of stock price index before and after beginning of the US financial distress, within the period of April 2007 and April 2008. In the following charts we can see the movement of the following index: Nikkei, for Japan, Dow Jones Industry Average for USA and FTSE 100 Index for the UK.

NIKKEI 225

Source: Bloomberg

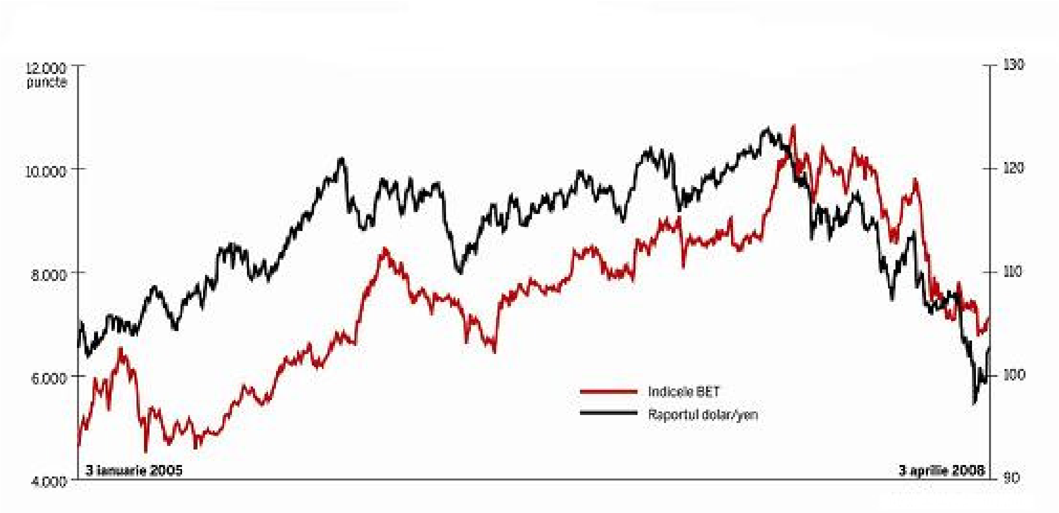
The FTSE 100 Index is a capitalization-weighted index of the 100 most highly capitalized companies traded on the London Stock Exchange.

As can be seen, striking similarities can be observed for the 3 presented models. Even the "bubble" pattern prior to the beginning of the distress as well as the reaction of the market during the period of the crisis has, in a certain degree of deviation acceptance, striking similarities.

It would be interesting to see if the recovery from the distress will follow a similar pattern. An important aspect to this will stay in the economic situation of the country prior to the beginning of the distress period.

One thing is sure, and that is that a financial crisis that appear in a developed country will, eventually, affect the other countries in a certain level of degree. And that includes also the emerging markets, and the case of Romania. Since the beginning to the US financial distress we were able to see sharp decline in stock prices in Romania, an increase in inflation and changes in the exchange rates. Although, some similarities between the movement of foreign stock exchange indexes and the Romanian indexes can be observed, the Romanian stock exchange market was affected in a higher degree due to the exit of external funds from this market, considered a more risky market. But a more risky market, an emerging market will bring higher returns, higher yields. Therefore we tend to predict that the recovery of an emerging market will be done in a shorter period of time compared to a developed one.

In a recent discussion on the website of "Bursa Noastra", (www.bursanoastra.ro), a website dedicated for the investors on the Romanian market, Emil Pop, a freelancer in IT, posted a chart that presented a striking similarity between the evolution of the Romanian index BET and USD/JPY exchange rate.



What conclusion can we draw from here? Investors borrow “cheap” money from countries where the cost of capital is low (in Japan the official basic loan rate in 0.75%) and invest in countries where a higher yield can be obtained.

As the time goes by, more and more similarities between the movement of the Romanian market and the movement of foreign markets will be observed, as they will be more connected. The entry of Romania in the EU and the free movement of capital that came along with it, made Romania more opened to the influence of other economies from other developed countries.

The US problems of the sub-prime market turn into a deeper problem that has affected the mortgage markets from UK, Spain and other countries and made the investors to be increasingly concerned about other forms of credit.

Conclusion.

If massive capital will move away, following a brutal adjustment of risk aversion, many emerging markets will suffer because investment flows will decrease and credit conditions will worsen. Here we have in mind Central and Eastern European countries where high economic growth rates might be badly disrupted. And like this many countries might see their prospects for continuing economic recovery substantially affected.

Therefore, excess liquidity, over-borrowing, massive bets made by hedge funds, lack of transparency and poor regulations, improper valuation of investments, high risk acceptance, and the appearance of new financial trading instruments have created the premises for new financial problems. But there are also grounds to believe that a global crisis can be avoided. Many emerging economies have plenty of reserves and their exchange rates are more flexible. Risk diversification and better risk management techniques would help some institutions to avoid serious financial problems.

To sum up, if major crises should knock on the door at the economies of more and more countries, a perfect coordination among the main central banks, governments, and financial institutions should be created in order to avoid bigger loses and make a better damage control of the situations.

Abstract: All transition countries inherited pension systems based on the principles of pay-as-you-go and definedbenefit (PAYG-DB). In the early years of operation, such systems had advantages over a fully-funded, defined-contribution (FF-DC) system. For, under a PAYG-DB arrangement, those who retire receive pension benefits immediately and contributions initially tend to exceed the payments. These advantages, however, disappear later on, when population (and employment) growth rates decline and when people live longer after retirement. Under such circumstances, an FF-DC programme has the advantages of greater flexibility and transparency, hence greater financial viability. The changeover from PAYG-DB systems to FF-DC systems is therefore a worldwide trend.

Although Romania has undertaken many necessary and difficult reforms to public pensions to contain the fiscal cost of ageing, much more remains to be done. Replacement rates are low and falling to a degree that undermines workers' willingness to participate in the state pension plan, particularly at contribution rates that are among the highest in the region.

Key words:pensions system, pay-as-you-go, reform, public pension.

After 16 years of economic and social transition, Romania is still struggling

*to develop a financially sustainable and reliable social protection system***.** In the years following 1989, the Romanian Government pursued a comprehensive structural reform that - combined with the difficulties inherent in any fundamental economic transformation - placed the country's social protection system under extreme financial stress. This emphasized the system's shortcomings, particularly in the area of pensions and other forms of contributory social insurance, and resulted in calls for change that successive governments have heeded to differing degrees.

Romania inherited a generous but fragmented and unsustainable mandatory, pay-as-you-go (PAYGO) pension regime from the socialist period. Replacement ratios were high and benefits were paid to a wide range of pensioners (including early and normal length of service, survivor and invalidity/disability benefits). The regime also financed several generous non-contributory benefits (such as sick leave, maternity/child upbringing leave, and farmers' pensions). The first years of the transition were marked by ad-hoc and hesitant reforms. As the transition advanced, the pension regime suffered from several fundamental shocks, including a rapid increase in beneficiaries as a result of population ageing and generous early retirement plans, a decline in economic growth, and a sharp fall in the number of contributors from the growth in unemployment and informal employment. These problems were aggravated by weak administrative capacity and policies that encouraged early retirement as well as the use of invalidity pensions to compensate increasing unemployment among older workers. Consequently, the pension plan's dependency ratio increased dramatically and remains one of the highest dependency ratios in the region today. With its population old-age dependency ratio expected to grow further (from 30.9 in 2003 to 59.5 in 2050), Romania's demographic profile creates another source of concern for sustainability. This aging process will create an additional burden on the working age population, as each worker will have to support an increasing number of retirees.

The Government has attempted to cope with these strains by raising contribution rates to levels that are high even by OECD standards. To make up the shortfall in revenues and the increase in system expenditures during the 1990s, the social security contribution rate was increased from 14 percent to 35 percent in 2001. Although the rate was then decreased to 29.75 percent in January 2006, it remains high by international standards. Moreover, aggregate social insurance charges (pensions, health, unemployment, work injury and disability) count for almost 50 percent of gross wages, making the Romanian workforce one of the most heavily taxed in Central and Eastern Europe. Romania with a pay-roll tax of 46.25 percent, ranks the sixth (out 26 countries) in Europe on social security contributions in the neighborhood of Albania (49 percent) Poland (46.64 percent) and Hungary (45.50 percent), some of the highest in the Central and Eastern European Region. Even the Italian payroll tax rate, considered burdensome by OECD standards, is significantly below Romanian levels. High payroll taxes increase non-wage labor costs and can have adverse consequences for the generation of formal employment and, by extension, for coverage of the public pension plan.

Table 1. Pension Contribution Rates and Total Social Security Contribution Rates in Europe

	Old Age, Disability, Survivors			All Social Security Programs		
	Insured Person	Employer	Total	Insured Person	Employer	Total
Netherlands	19.15	8.90	28.05	39.45	17.20	56.65

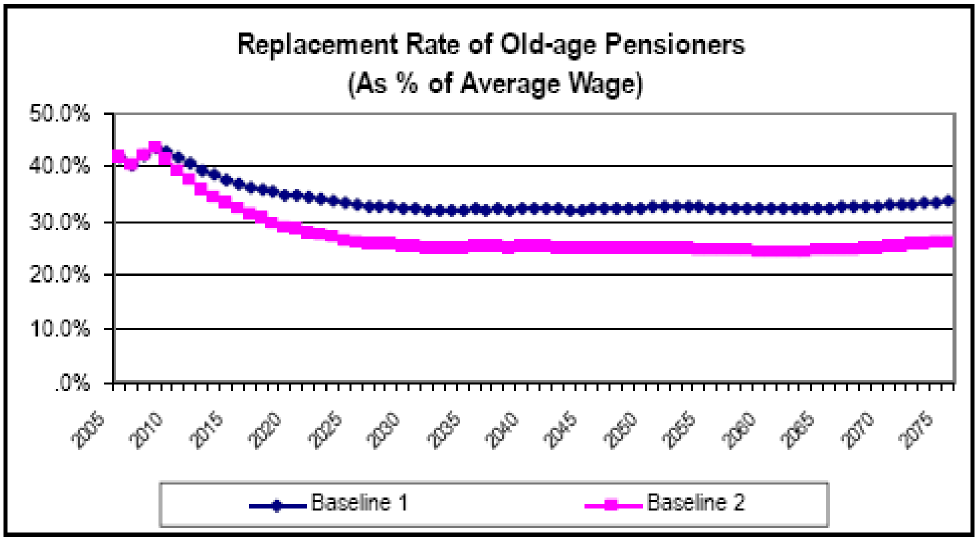
Replacement rates from the public pension plan which were already low have begun to fall, and without further adjustment, they will continue to decline for another 10 years**.** Figure 1 compares replacement rates of old-age pensioners under two sets of assumptions about indexing: Baseline 1 and Baseline 2. The initial replacement rates are in the order of 42 percent rising to 44 percent in 2008 with the impact of 12 percent planned real increase in benefits in 2007 and 2008. Replacement rates in both Baseline 1 and Baseline 2 decrease gradually over the long term. The estimated long term replacement rates under Baseline 1, where the benefit is 150 percent inflation indexed, is 33.6 percent. The long term replacement rate under Baseline 2, where the benefit is inflation indexed, playing only the poverty alleviation role of pensions, is 26 percent.

Figure 1. Average Replacement Rate of Old-Age Pensioners-Baseline Scenarios



Source: World Bank PROST simulations 2006
Note: ***Baseline 1,*** the more realistic scenario, which assumes a long-term indexation of benefits of 150% of the inflation rate starting 2009 in line with the recent experience where indexation has been above the level of inflation. ***Baseline 2*** and assumes a long-term indexation of benefits to inflation only starting in 2009.

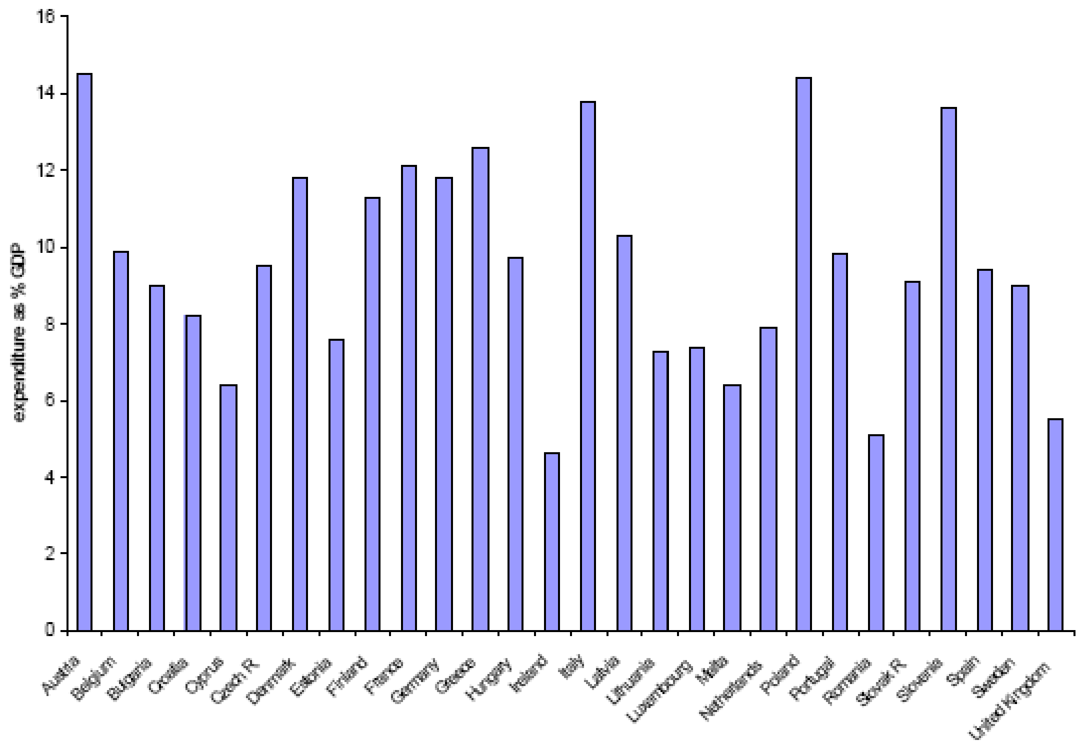
The authorities are very conscious of the problem of low and falling replacement rates and have indicated publicly that they intend to increase pensions by 30 percent in real terms over the period 2005-2008. In spite of the increases granted in 2005 and 2006 (almost half of the envisaged increase) and the recalculation of pensions, completed in 2005, replacement rates continue to remain at very low levels (36.1 percent in August 2006, compared with 51.1 percent in 1990). Encouraged by the current fragile financial surplus of the public pension fund, the Government will continue its policy of increasing public pensions. However, any other future increases of pensions will have to be accompanied by additional reforms in order to make the process sustainable on medium and long term.

As noted earlier - so far, during transition, pension expenditures in Romania have been kept low in relation to GDP. However, simulations indicate that the contribution rate must increase from 25.5% in 1996 (and 32.5% in 1999) to 41.5% in 2040 in order to maintain the 1998 ratio of pensions to wages (De Menil *et al*, 1999). In 1998, this ratio, at 36.2%, was much lower than in Hungary and Poland. Romania is therefore expected to experience social pressure to increase that ratio in the future. This pressure and the expected increase of the coverage of the population by pension insurance are two major factors which prompted the Romanian government, in 1999, to propose a reform of the state pension system along the Hungarian-Polish model (G. De Menil, *et al*, 1999).

After the first step of the pension reform – the introduction old Law no.19/ 2000 for the public pension schemes - Romania postponed for too long the next steps. Compared with Hungary and Poland Romania is well behind. Even Bulgarian authorities were more decided in implementing funding pension schemes. Finally – in 2004, forced by the Romania's perspective to become an European Union member state, the politicians gave up their fears that the launch of funded pension scheme would be an unpopular decision. The laws concerning private and occupational pension schemes were issued and only the specialists and those interested to become pension fund managers reacted. The major part of Romanian working population still ignores this continuation of pension reform and how it would affect them. Funded pension schemes are at the beginning of their long road on Romanian pension reform. And the road could become even longer and more difficult without a proper campaign for public information. The potential contributors would not understand their rights and their options, wrong decision could be made and – as we shown previously – potential crisis could arise. After the last elections, the new Romanian government made no declaration regarding the laws concerning the second and third pillar of pension reform. We hope that no radical decisions would be taken.

`As the contribution base of the PAYGO plan erodes and claims increase the financial sustainability of the plan is put at risk and a persistent systemic deficit has emerged. The state social insurance budget suffered a continuous decrease - from a surplus of 1.1 percent of GDP in 1991 to a deficit of 0.85 percent of GDP in 2003. Given that public spending on social security programs has historically been high, reaching 6.7 percent in 2003, this further increased the fiscal burden the pension plan placed on the general budget. Since 2003, spending on pensions has fallen to 5.3 percent of GDP in 2005, mainly as a result of shifting the financing of the non-contributory farmers' pension plan to general revenues. Long term projections prepared by the World Bank in 2006 show spending rising and stabilizing at around 6 percent of GDP. Furthermore, by conventional measures of implicit pension debt (IPD), the contingent liabilities of Romania's public pension regime outstrip those of most of its neighbors and even of several OECD countries. Although recent comparative data are scarce, and estimates of IPD will vary greatly (with the methodology and discount rates applied), Romania's international relative ranking by contingent pension liabilities is a cause of concern.

Figure 2. Spending on Public Pensions as a Percentage of GDP, Selected European Countries



Source: World Bank

Although the financial viability of the PAYGO plan improved following recent reforms the system still falls short of achieving fiscal sustainability. Too much room is left for discretionary interventions by politicians that make medium- and longterm actuarial forecasting uncertain. In addition to low average retirement ages, a recurring threat to the sustainability of the pension system is the practice of recorrelation. Having experienced erosion in the real value of pensions, pensioners demand a readjustment of pensions to a similar level to what new retirees receive, essentially an ad-hoc wage indexation of benefits. Although re-correlation should have applied only to those who retired with a full length of service prior to 1999 and to their survivors, it was expanded to new categories of retirees. This occurred as a series of discretionary measures resulting from political lobbying, rather than any formal policy or predictable benefit adjustment rule.

ROMANIAN FISCAL SYSTEM PROGRESSIVE QUOTATION VS. UNIQUE QUOTATION

Abstract : In simple terms, fixe tax means that every person is taxed with the same percentage. In such a system, in place of a complex set of taxing, the state declares a limit over which every person pays a fix tax for personal incomes. This limit is generally very low, in order to stimulate the people to pay their taxes, instead of trying to avoid them. This kind of system bases on the single taxing of incomes. In what concerns the corporatistic taxes, the idea is similar: only one rule for everybody. The analysts are disposed to take into evidence that, if the unique tax was a rule in every industrialized states in the first half of XIXth century, the first demandings that were pronounced plainly for a "strong progressive or tax gradual" system, appeared in the communist manifestation of Karl Marx in 1848. But, at least, the capitalist states adopted this system.

Key words: fiscal system, unique quotation, fiscal incomes, fiscal evasion.

At the begging of the year 2005, the new government was introducing the unique quotation of taxing of 16%, over the incomes of the natural persons and over the firms profit, reforming completely the Romanian fiscal system.

- Which are landing differences of fiscal system until 2005 and after 2005?
- Which of the two systems is sustenabil on mid and long-term, being a reduced probability that be generated macroeconomics dezequilibriums?
- In what way can raise the weight of collected incomes from the budget in PIB from 29% (in 2006, Romania situating, at this indicator, on the last place in EU27) at 40-45% , which means the average of EU27 countries?

At all these questions we will try to answer. First of all, we will analyse comparatively the two fiscal systems: the one until 2004 and the actual system, initiated at January 1st 2005. Following, we will comparate the actual fiscal system from Romania with other fiscal systems from EU27 countries.

The fiscal system until 2004: progressive, redistributive, social

In 2004, the fiscal system was a progressive one, with differenciated quotations in what concerns the tax applied on the incomes of natural persons. Thus, the ones that had incomes of maximum 28 millions ROL, payd 18% as income tax, the persons that had incomes between 28 millions ROL and 69,6 millions ROL, payd 23% and the tax could reach 40% in conditions of an over 156 miilions ROL income. The tax applied over the taxing profit of companies was of 25%. The interests were taxed with 1%, and the dividendswith a percentage of 5%. The microcompanies were paying an income tax of 1,5%.

In 2004, the fiscal system from Romania was considered by the International Monetary Content[1] as being a sustenabil one, which does not create macroeconomics dezequilibriums on mid and long-term. The improved economies-investements balance, in a rapidly diminution, the salaries maintaining in the approved limit of budgets and high collecting rates of 95-98% at the main utilities were substanciating the positive analyse of FMI specialists: "The budgetary politic in 2004 will sustain the objectives of disinflation and the limitation of the extern current count deficit, creating in the same time conditions for the raising of private sectory."

What was going to happen with the fiscal system in 2005, if that government continued? The government was already decided with FMI, from July 2004, a fiscal reform program, which would entranced in vigour at January 1st 2005. The main pillars of this program foresaw a reduce of profit tax from 25% to 19%; a reduce of income tax for the smallest imposing portion , partially compensated through the stopping of personal decutions to the level of 2004, and a reduce of contribution rate through the social insurances with 1,25%. In order to compensate a part of incomes loss, the authorities wanted to introduce simultaneously a spot tax, to grow the dividend tax, begging to July 1st 2005. The net income loss associated to the reform would be raised at 0,25% from Intern Gross Product to the base reference, thanks to the effect on the entire year elimination of imposing reduced rate at profit tax for exports activities, the reported effect of the growth of the ACCIZA from July 2004 and of some reducing of fiscal evasion.

The objectives proposed by the government from 2004 were in coherension to the equitable distribution supporting of the gains from the raised economic growth, the improval of business climate and the strenghthening of competitive position of Romania. Besides, the fiscal reform wanted to answer to the expectations of business men about the predictability growth in fiscal domain, the reducing of administrative costs about the taxes, and the reducing of the pressures about the work taxing.

Fiscal system from 2005-2007: stimulatively for big businesses and consume

Although the analyses effectuated by the business men in the last 5 years shows that the level of fiscality is one of the secondary preoccupations of companies' management (much less important than, for example, the fiscal predictability), the fiscal reform from 2005 aimed at the encouraging of big businesses, of raised financiary force companies, basing on the training effectsof massive investitions realised by these investors.

From January 1st 2007, entranced into vigour the amendaments, very disputed, brought to the Fiscal Code. The amendaments did not have into account the modification of some essential elements of Romanian fiscal system, built, in special, based on the unique quotation of 16% applied to the incomes and added value tax of 19%.

The dividend tax, payd by the juristic person, is of 10% in some conditions: they not have participations of minimum 15% until January 1st 2009, respectively 10%, after this date for a period of minimum two years before the scandent date. The exception from taxing rule of the commercial societies is, gave by the taxing of micro-enterprises, with the condition that these realise minimum 50% from incomes from another activities than the consultance for businesses and management. The foresee wants to be a solution in sense of elimination of using the micro-enterprises for the collecting of the salaries by some employed persons. The taxing quotation of incomes is, in micro-enterprises case, of 2% in 2007, 2,5% in 2008 and 3% in 2009.

For the obtained gains from the redemption of opened investements funds titles, is applied a taxing rate differenciated depending on the length of time of holding these titles, thus: if are holded for a period smallest than 356 days, is applied a general taxing rate of 16%; if are holded for a period of time bigger than 356 days, is applied a rate of taxing of 1% on net gain obtained.

For the value titles, personal values, bought and redempted, is applied a tax of 16% on net gain obtained from sales and purchases operations from the fiscal exercise. The dividends, inclusively the sums received because of the holding of closed funds titles of investements, obtained by natural persons, are taxing with a quotation of 16% from the value of gross adequate dividends.

The fiscal system entered into vigour in 2005, and adjusted in 2007, has established as objective the insurance of some bigger available incomes, the potential expansion of businesses, the growth of direct investements, the diminution of economic subterranean weight, an economic sustenable raise, more places of work, the raise of the saving and investements. From all these aims, the analysts consider that has been touched the raise of foreign investements, (a record in post-decembrist, 9,1 billions EUR in 2006), a high raised economy, (7,7% in 2006, even if in a big part is based on consume) and the expansion of businesses made by big enterprises, and financiary strong. What did nou succeed to obtain the reform of fiscal system promoted by the government after year 2005 were the raise of budgetary weight funds in PIB, the raise of saving, and what did the worst situation was the accentuation of current count deficit. The bigger available incomes meant a bigger consume (especially of import goods) and the accentuation of the commercial balance deficit.

The adoption of unique quotation in numerous countries

All the countries that have introduced the unique quotation registered positive evolutions:

ESTONIA: which in 1994 introduced a taxing unique quotation of 26%, conducing to an economic growth of 5,2% annual average. Ulterior, the unique quotation haas reduced at 20%.

LETONIA: in 1997 adopted an unique quotation of 25%.

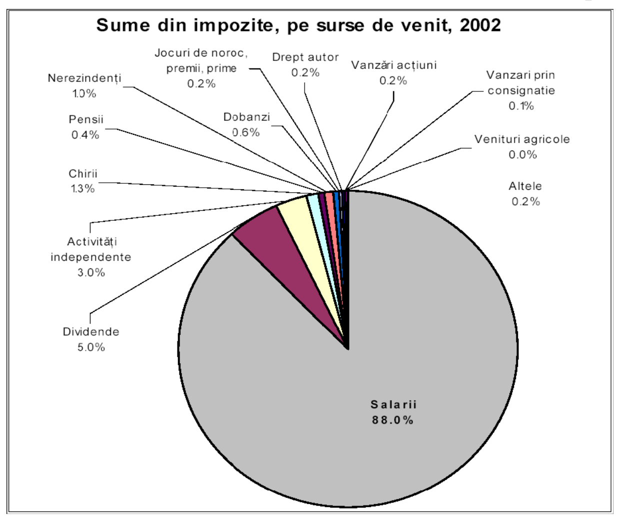
RUSSIA: in 2001, has adopted a 13% unique quotation. Has remarked through an economic spectaculous evolution; thus, the entrances obtained at the budget through the taxing of natural persons incomes has registered a real raising in roubles of 28%, and in 2002, the incomes taxes has summed 357,1 billions roubles, which means a raise of of 20,7% in real terms. The adjustements had realised taking into consideration the taxing rate of 18% in 2001, and 15,8% in 2002).

SLOVACIA: in 2004, Slovacia has adopted a 19% unique quotation.

UCRAINA: has adopted a 13% unique quotation.

The advantages brought by the unique quotation in Romania

1. The unique quotation answers to the equity criteriums in fiscal domain. The option for the taxing in unique quotation constitutes one of the modalities through which can be acted over the rising tide from economy, and assures the reglementation of the fiscal system. This has a bigger efficience in the reglementation of inequalities between different categories of persons which obtain the same income from different sources.
2. The unique quotation eliminates the double imposing of savings and investements. Taking into consideration that the income forms are taxed equally and only one time, people are free to choose any investement that they consider profitable, that, through the intermedium of fiscal instruments, the economy can function at maximum potential.
3. The unique quotation will increase the incomes collected from the state budget. Through the application of taxing progressive system in Romania, in the period anterior the date 1.01.2005, it has taken place a pushing over a very small number of medium and big salaries, the system subexploiting itself from another sources. It appeared from another reason an evident target of fiscal discrepancy, defying the horizontal equity principle: to the same sum must be paid the same tax, no matter the income source. We exemplificate:



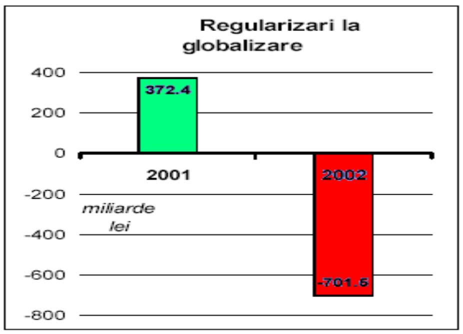
Source: Romanian Academic Society

Thus, it can be observed how big is this difference of pushing the taxes on the salarieds, on the enterprisings and free-profesionists, even admitting that in their case, the tax should have been something smaller in order to produce a bonus that reflected the business risk.

4. The unique quotation comes to support the persons with reduced incomes through a system of deductions very efficient.
5. The unique quotation reduces the fiscal evasion, through the diminution of opportunity cost of the avoiding of the payment of taxes at the state budget. In conditions that the fiscal system is a simple and efficient one, the pshycological effect that has the diminution of taxing

quotation makes that people proceed to the payment of the debts to the state very rapidly and correctly. These are not tempted anymore of searching some complicated methods to facilitate the reducing of taxing base, because the cost of these activities can raise in some cases over the taxing quotation that must be paid. The progressive taxing system of the salaries created strong premises for the movement of the incomes on less taxed ways. In these conditions, the proportion of small salaries raised, and the mid and small salaries reduced,in a period of economic growth, fact that conduces to the conclusion that is very probable that a part of incomes to be transferred on some other ways with a more reduced imposing. People learn and adapt rapidly to the system, that, in the old system, state had less and less to collect from the liables to pay the duties as a following of globalisation procedure and more to give back.

6. The unique quotation reduces the fiscal administration expenditures. The public administration will spend less money with the monitoring and the auditing of the system, because the tax is unique and is calculated much clearer. In the system of progressive taxing, the state had less to collect from the liables to pay the duty as a following of globalisation procedure and more to return.



In the year 2002, the state had to return to the liables for pay the duties from Romania 700 billions ROL in net value, and after the aplication of progressive taxing, system the administrative costs of function were about 800 billions ROL.

7. The unique quotation offers to the liables to pay the duties more control over the money and reduces the involvement of the authorities in the administration of the surplus of every person. Through the aplication of the unique quotation, people is stimulated to work harder, because only a small part from the their gain enters in the possesion of the state. Thus, the difference that remains can be administrated as anybody wants, this freedom accentuating the development of private property and private sectory from economy, more than on the public sectory, where the state initiates programs and politics that come in the help of citizens. The unique quotation reduces the time and number of the formulares that must be completed for the obligation discharging confronted by the state. Thus, the unique quotation brings two benefits:

– on a side, it offers a more transparency to the fiscal system, because assures easily the possibility of every liable to pay the duties to calculate his own fiscal obligation, and to understand the whole imposing mechanism without having any types of vagueness concerning the calculation mode and the debted sums.
– on the other side, the productivity of the taxes raises as a following of the reduce of expenditures with the establishing and the collecting of these because of the simplity of the system. In the same time, the persons that pay taxes reduce their expenditures concerning the financiary consiliation and the guideness necessaries in the progressive quotations system, and the specialists in fiscality can orientate their activity area to some more productive zones.

8. The unique quotation develope a very attractive environment for the investors. The competition concerning the level of taxes represents a benefit of globalisation. In a global economy in which the work force and capital move free besides the national limits of every state, the fiscal political sets adopted by every country represents an important instrument used in the attraction of limited international resources.

Conclusions:

In simple terms, *fix tax* means that every person is taxed with the same percentage. In such a system, instead of a complex set of taxing rules, the state declares a limit over whose all people pay a fix tax for personal incomes. This limit is, in general, enough low, in order to stimulate the citizens to pay their taxes, instead of trying to avoid them. Such type of system bases on the fact that all the incomes are taxed only one time.

In what concerns the corporatistics taxes, the idea is similar: only one rule for everybody.

The analists incline to take into evidence that, if unique tax was a rule for every industrialized states in the first half of the XXth century, than the firsts demandings that were made very clear especially for a "strong progressive or taxes gradual" system appeared in the communist manifest of **Karl Marx** in 1848. But, at last, the capitalist states were the ones that adopted such kind of system.

Since then, the idea of unique tax was brought into life a few times, an appreciable number of countries adopting one or another variant of unique tax regim. And however, till today, non of occidental "major" economy has not passed back to the unique tax regim.

It is believed that, in the entire world, the persons liables to pay the duties loose 8 billions annual for complete their income declarations.

The modern revival of unique tax on the income was initiated by Estonia in 1991, than Letonia in 1994, Lituania in 1994, Rusia in 2001, Serbia in 2003, Ucraina in 2003, Slovacia in 2003, Georgia in 2004 and *Romania* in 2005. Hungary seems to take into consideration the introducing of a unique tax version in the near time future.

Even if the "unique tax" is not considerated a medicine for all the economic problems, more and more countries - the new member states also – had introduced or are in the elaboration process of some universal taxing regimes. The majority of these countries confront with appreciable budgetary deficits and some others confront with the necessity of ranging the economic statut to the Euro Zone demandings:

The unique tax should:

- help to the reducing of the birocratism;
- reduce the inequities;
- counterbalance the avoiding of taxes and evasion;
- generate bigger budgetary incomes;
- produce an economic "mini-boom".

In the same time, a fix tax regim is understood as:

- eliminating the all forms of taxing sparings and facilities;
- being non-progressive (at least in what concerns the "marginal" rates);
- preferring the rich ones for the poor ones;
- preffering the posessors of shares and dividends, when the profits are taxed only one time, at the source (unique tax is a consum based tax).

If this measure, apparently popular of the passing to a taxing fix system is motivated by healthy fiscal strategies or only by the desire of determinating the citizens to contribute more to the state budget, it is a debating point.

An essential conclusion quotated by few researchers is that the efficience and success of unique tax regim are dependent by the level of this unique tax: the lowest it is the unique tax, the most efficient tend to be.

The experts point that, besides tax system or type of support gave to the new enterprisers, the competitivity of a country is determinated of some other factors. If it is true that, in general, than the lower taxes leave more money to circulate and to be invested in an economy, and the fix taxes raise the desire of citizens to pay them, big budgetary deficits and the uncovernement of budgetary deficits.

More than that, a few leaders of the strongest economies of Europe, for example *Gerhard Schroder* and *Goran Persson* showed that the transition economies from East can permit reduce their taxes, not in the last time because every lost income is compensated by the subventions of the European Union. This argument was rejected in many times in the noticed transition states.

Meanwhile, Germany, as Italy, Austria, Finland, Denmark and Greece decided also to introduce taxes reduces under many forms in order to stimulate the investements and the expenditures (the consum) and to determinate the economic growth.

The unique quotation improved the competitivity of the enterprises:

1. The introducing of unique quotation conduced to an improval of effective rates of taxing.
2. A second major effect has been constituted by the improval of profitability, seen through the profit side and also, on the other side, through the profitability rate.
3. The loosings of economic agents are still a problem of Romanian economy.
4. A positive aspect, because of the fiscal modifications that had placed at the beggining of the year 2005, besides the maintaining of profitability rate was registered a diminution of the backwards, that at the end of the year 2005 the backwards had approached at 18,8% as a weight in PIB, than 20% that was estimated by CNP, finding a high level of estimations predictability.
5. The improval of the Romanian enterprises longevity is illustrated also by the improval of the debting level of economic agents, even if this continue to situate still at a high level.

As a general conclusion, it can be affirmed that the introducing of unique quotation had improved the business medium and conduced to the raise of concurential capacity of the enterprises.

SUPERVISION ON THE SINGLE EUROPEAN INSURANCE MARKET – INTERACTION BETWEEN REGULATION AND COMPETITION

Novac Laura Elly

Academia de Studii Economice Bucuresti, Facultatea de Finante, Asigurari, Banci si Burse de Valori, Str. Mihail Moxa, nr.5-7, cam.3101, lauranovac@gmail.com,0724261318

Even though the financial markets have developed in the last decade, new requirements became strictly needed in order to create a common ground for the national markets and in the same time to enhance the development of the global market. If the authorities in fields began their activities as simple regulators, their role included also a new scope – the one of monitoring the relationship between the suppliers of products and services and the customers. Such a development can be noticed in insurance industry, all over the world, especially in the European territory, starting with the Solvency II project that intends to offer sounder financial stability for the insurance companies and higher transparency towards the clients and the supervisors.

Key words: prudential, solvency, supervision

Competition and supervision share one of their ultimate objectives: the interest of the consumer and client. Historically there had been a quite different legislative approaches to secure consumer protection in the financial sector, more over on insurance industry.

Before the European deregulation come into force in the early 90s, the main idea in many countries had been to highly regulate companies, products and pricing of the sake of policyholders. This approach had been working for many decades without producing major insolvencies and losses for consumers. Form a today's perspective this can be considered the centralized system of state regulated industry, with subordinated options for competitors.

In those days, supervisory authorities were assigned the job as competition authorities within the financial services as well ass the job of financial regulation and supervision. However and under tension or even a conflict of interest between the objective of competition and supervision the two functions have been separetated.

Supervision and competition on the insurance markets

For more than 10 years now insurance regulation and supervision developed quite new objectives and innovative instruments. It had always been an developing process including some transitional steps with term "supervision" not any longer described to cover the design or pricing of products but in a wider sense as the permanent process of monitoring that financial institution comply with the regulation, and the process of taking remedial action to secure the objectives of regulation. Parallel to the supervisory process these 10 years have seen increasing competition processes between insures in national markets as well as in cross-border business.

Two aspects of supervision might be noticed: prudential supervision and conduct of business supervision. Prudential supervision is monitoring the soundness of individual financial institutions, as whether they have the ability under all reasonably foreseeable circumstance, to fulfill their obligations as they fall due. To put it simply, supervisors assess individual financial institutions – the specific risk circumstances of each bank or insurer. The supervisor needs to tailor supervision and any action taken to the risk profile and specificities of each financial institution. When it comes to insurance industry, this risk profile refers to the solvency, the sufficiency of the technical reserves, reinsurance coverage and the security of reinsurers, asset portfolio and corporate governance. In other words, the prudential supervision does not primarily takes into account the actual process of designing or pricing the insurance products offered on the market, but on the financial resources needed by the insurance company in order to honor its obligations.

There are some tensions between the prudential supervision and the competition. Consider the case in which there is applied a risk-based and capital approach of the supervision process and the horizontal cooperation between insurers. Even if not obvious, the sharing of certain risks or certain functions might be significantly responsible and prudent risk mitigation for the insurance companies.

The risk pooling is in fact the essence of insurance and in a healthy market, the sharing is the only way of covering risks, that otherwise would be uninsurable. The sharing of databases is also an important factor for the success of the conduct of the business. The data must be representative for the population they apply to – reliable and extensive -. The lack of information would be disastrous for pricing, financial control, profit and other decisions of the insurance company.

Besides the data to be used by an insurance company, the supervisors are much interested also on the reinsurance companies, as their undercapitalization would be harmful for the world financial system (the year 2005 – the hurricanes season brought about losses of more than 25.76% at the level of international reinsurances, after which in 2001 and 2002, the Word Trade Center brought about bankruptcies and the promise that a renewal of those events would bring the entire industry to its knees).

New risks are producing effects on the insurance industry lately – such as long term liabilities, changes in legislations or risks of new technology. The effects are visible both on the insurers and reinsurers but also on the supervision and competition processes.

The competition process has developed also – the insurers will evaluate their loss potential on different levels and thus create a very differently risk profile of the products. The competition is no longer a common, normal competition but a risk-prone competition, which can bring about even pure speculation on the market.

High risk products will generate high volatile losses which at a certain point can lead to a non-insurable risk or highly-priced product. An example might be the terrorist attacks risk that became non-insurable after September 11 2001, the main insurance and reinsurance policies excluding this clause from the standard form.

What might be the counteracting measures in this case – exclusions on the policies, pricing, limits, right of termination and covering named perils only, transfer on other markets (securization) or even closing down of the operations. As the economic value will be damaged, the competition process can come in and based on prudent risk-sharing and agreed risk-transfer, as a cooperation way, can limit the effects of the highly volatile products. Moreover, a partnership between the insurance industry and the governments might be useful – as the state will be considered the last resort reinsurer. The states can act in the situations where the market finds itself unable to offer coverage or it can work as a mediator in designing the best solutions, for example the natural disasters' risks for the households or the aviation industry.

Competition and supervision on the Romanian insurance market

In 2007 alone, the insurance market recorded a volume of gross written premiums of 7.165 billion lei[137], showing a nominal increase of 25.07% compared with the provisions year. 79.9% of the total gross premiums was generated by non-life insurance, while the personal insurance had recorded again a lower level than the European average of 25.65%[138]. The insurance penetration ratio was 1.84% in 2007, as compared to 1.68% in 2006.[139]

As the confidence of the insured increased during the last 10 years, also the insureds' expectations regarding the quality of the insurance products became higher. The Romanian insurance market must prove that it is capable to comply with these expectations, otherwise it puts to danger the existing portfolio and also the potential one, as the customers can mitigate to European competitors.

The rush of the insurance companies after the market share, at any risk, in the detriment of the quality of service and financial stability, will definitely generate severe errors and discontent of the customers. The legal norms implemented last year concerning the establishment of technical reserves and also the ones concerning the risk management committee were destined to reduce the number and the severity of the deviations from the expected levels, as the arbitration is growing stricter.

[137] Figures based on Insurance Supervisory Commission estimations
[138] CEIOPS Market Release – March 2008
[139] Insurance Supervisory Commission Annual bulletin no.1, March 2008

New acquisitions took place on the Romanian market, such that one of Viena Insurance Group of ASIROM after acquiring the majority of shares from Omniasig, Omniasig Life and ASIRAG, putting to danger the competitiveness of the market. The Austrian company asked for the agreement of the Competition Committee in order to be allowed to buy also the majority package, without endangering the oligopoly market. The first 10 companies on the market (out of 44 in 2007) concentrate over 92.3% of the market – a concentrated market brings about better pricing, better quality in the products offered for the customers.

Since its occurrence, the Insurance Supervisory Commission has developed its goal of regulator of the Romanian insurance market to the status of supervisor of the market. That is, the transfer from imposing the legal requirements on financial institutions to the one concerning the monitoring of compliance of the insurance companies with the legal provisions and also the process of taking remedial actions to secure the objectives of the regulation. The ISC became a consultant for the players and the consumers of insurance, especially concerning the new wave of capital requirements for the industry – the Solvency II directive. In this regard, the ISC organized several meetings in Romania together with CEIOPS for enhancing the cooperation and the supervision for the Romanian customers.

Solvency II – method of enhancing the competition and supervision

In order to develop the competition on the European market by 2010, the financial services action plan has been introduced (part of Lisbon goals) and part of it represent the Solvency II project. This structure is also known from Basle II in the banking sector.

Solvency II is based on a three pillar structure:

- Pillar I covering Minimum capital requirements;
- Pillar II covering qualitative requirements, i.e. risk management and supervisory processes and
- Pillar III covering disclosure requirements.

The first pillar establishes certain limits concerning the investments (covering the technical provisions, the minimum capital requirements and the solvency capital requirements) and concentration. Moreover, the model for computing the MCR and the SCR can be either a standard one, a partial internal one or a full internal one. In addition to the pillar I investment diversification rules, a further capital requirement could be included to address diversification – level of diversification in the portfolios of undertakings and the feasibility of portfolio.

Pillar 2 complements pillar 1 requirements. As part of the supervisory process, the authorities must evaluate the adequacy of the diversification process. The insurers are expected to do more than just satisfy the limits imposed by pillar 1. The authorities must also consider the need of additional capital. The SCR addresses those types of risks where material correlation effects can be expected between the asset and liability sides of the balance sheet, such as an asset-liability management policy (plans or procedures) to deal separately with the short-term and long-term risks.

This new system will assess the overall solvency and build on a more risk-sensitive approach, with incentives for proper risk management. Furthermore the system will support the harmonization of quantitative and qualitative supervisory methods and ensure consistency between financial sectors. Solvency II as the new prudential regime for insurance which CEIOPS[140] is helping the European Commission to develop has as one basic objective the improvement of the European internal market and the enhancement of the efficiency and competitiveness of the European insurance industry. It is aimed to include more efficient and cheaper capital for the industry and its allocation, which will definitely influence the pricing of the insurance products.

There is naturally some interaction when it comes to conduct of business and the competition. The purpose of conduct of business supervision is to evaluate the relationship between financial institutions and their customers. It is here that we might find concerns over market issues, pricing, timely and relevant information to policyholders, distribution and conflicts of interest. Requirements of the conduct of insurance business help to protect consumers, and eventually build consumer confidence in the insurance industry.

[140] CEIOPS – Committee of European Insurance and Occupational Pensions Supervisors

Solvency II gives an important contribution by enhancing public disclosure and better consumer information. The benefits may encourage customers to become policyholders, and to say so it will certainly be up to the market to decide if Solvency II should also provide standardized consumer information on the risk profile of the product, a guarantee fund in place or the supervisory authority in charge with the handling the complaints just to mention some important issues. Reliable and understandable information is a key parameter for future European wide competition process. Information to policyholders has to improve, as to the amount, the relevance, the clarity and its timing.

Although solvency II is promoting competitiveness of the insurance industry it cannot deny the need for some closer cooperation between insurers. Let us take as an example the field of data sharing. Imagine that we are introducing brand new, European wide harmonized market values approaches for technical provisions, the future obligations toward customers. Those technical provisions had never been harmonized throughout Europe before. Future values have to be based on entity specific collected data over a period of 10 to 20 years. Not all insurers have these data available – such as the Eastern European countries that known a development of the industry after 1989 and a clear collection of data only a decade later. The question of excluding these companies from Solvency II, just because they do not meet the requirements of this regulation or because they have poor databases is out. Moreover an encouragement is more proper, by offering them the possibility of relying on data and models of several insurers with comparable businesses from specialized countries that have reliable databases.

Conclusions

Supervision and competition are two sides of the same medal. However they are two different sides. The more that major insurers and reinsurers are seen to perform a social role in society, the higher the expectation that they will be able to provide coverage. This includes usual and unusual circumstances. They are expected to be able to manage their exposure and their capital strength. They have to be well understood. A good dialogue between the supervisors and competition authorities might help. Both have to be strong over their interests and enlightened to each other.

Solvency II will imply a major shift towards a risk sensitive framework, providing incentives to move towards more sophisticated methods for measuring and controlling risks. It will imply massive resources but it will generate better understanding of the balance between regulatory need and business efficiency.

Abstract: Since the fall of the communist regime, Romania had experienced a long period of structural reforms aimed to readjust the society and the economy to the requirements of democracy and market values. Public finances had played a major role in this assignment, but their tasks were impeded by the necessity of reforming the public finances itself. The transition from the central economy to the market economy had to be made simultaneously with the reform of the public finances. This had generated great difficulties in designing the new framework of the local finances which further, generated major difficulties for local governments. The paper tries to make a brief description of the decentralization of public finance in Romania, identifying the major evolutions and criticizing the actual system which is not yet compatible with the requirements of the EU.

JEL Classification: H72, H74

Key Words: decentralisation, local revenues, local expenditures, intergovernmental transfers

An efficient providing of public goods imposes that the responsibility of their management should fall in the hands of the public authority that it is the closest to the level where the public needs appear. As a practical matter, the central authorities cannot deal effectively with all public necessities. The existence of local communities determines various but common needs, for which the citizens have different preferences. An appropriate response to these preferences depends on the level of decentralization. As a process, decentralization is necessary and it is taking place more obvious in ex-communist countries, Romania included. These same countries have switched to democratic systems, meaning that they have to rethink and redesign public authorities' competences. The Romanian Constitution adopted in 1991 stated the following principles for organizing local public administration: local autonomy and decentralization of public services. Its revue in 2003 has added also the deconcentrate administration principle. These principles were extended by secondary legislation, such as Local Public Administration Law, no. 69/1991. However, even though the legal frame was existing, in reality the decentralization was non-existent. The competences transfer process has really began starting with 1993-1994.

Administrative decentralization has to be accompanied by financial decentralization. First steps in this regard were the adoption of local taxes law in 1994. Unfortunately, the act did not respond to the need of local financial resources according to the figures of local public expenditures. Only starting with 1998, these financial needs started to be met in practice. Another important step has been added in 2004 when the legal framework of decentralization has been adopted and thus, all previous incoherent measured have been repressed. The lack of a well-established financial decentralization strategy has generated the following problems for local administrations:

- legislative instability;
- the absence of a transparent system in establishing intergovernmental financial transfers;
- the impossibility of local administrative revenues prediction;
- the lack of precision in defining competences fro local administrative authorities;
- the augmentation of local administrative responsibilities without the transfer of needed/appropriate/covering resources.

The present study is going to focus on the following issues regarding financial decentralization in Romania:

- the correlation between local revenues and local responsibilities;

- the measurement of local finance dependence on the central one (Hunter coefficient);
- the objectivity, efficiency and the simulative features of intergovernmental transfers system;
- the predictability of local budgets revenues;
- the degree of local autonomy ensured for local authorities.

A good comprehensive outcome of the first two issues can be reached analysing the competences transferred to local municipalities and the data regarding the general consolidated budget, gross domestic product, state budget, local budgets and equalization transfers. The main stages of administrative decentralization in Romania are reflected in the following figure:

Figure No. 1 The transfers of responsibilities to the local governments during 1991 – 2005

Source: adaptation after www. ipp.ro

Starting from 1994, the prerogatives of local authorities have extended continuously, thus confirming the trend towards decentralization, which had to be supported by the revenues side of local governments' budgets. As we can see from the table below, many of the actions were financed by special destination transfers, being in contradiction with the local autonomy requirements, defined by Strasbourg European Chart.

The local government's expenditures have continuously increased during the 1991 – 2005 period, both in absolute and relative terms. The evolution is presented in table no.1.

Year	1991	1992	1993	1994	1995	1996	1997	1998	1999	2000	2001	2002	2003	2004	2005

Table No. 1 The amount and the share of local budgets expenditures (LBE) in GDP

mil RON

Source: **http://www.insse.ro/cms/rw/pages/index.ro.do;**

http://discutii.mfinante.ro/static/10/Mfp/buget/executii/rom09_2007/rom01_septembrie.pdf

We can easily see the increasing share local budget expenditures in GDP along the whole period, in spite of some short inconsistencies. The share of local expenditures in GDP has doubled from 1994 (3.49%) to 2004 (6.75%). The pattern is quite interesting: it increased during 1994 – 1996 as a result of the new prerogatives transferred to local governments, followed by a slight decrease during 1997 – 1999 as a result of structural adjustments of the public sector. The raising had started again in 2000, with a big leap forward in 2001 (from 4.13% to 6.05% due to the financing of personnel expenses in education sector. Another leap was in 2003 as a result of social assistance programs that were passed to the local governments. The same evolution is encountered when we considered indicators such: share of local budgets expenditures (LBE) in general consolidated budget expenditures (GCBE) and state budget expenditures (SBE).

http://discutii.mfinante.ro/static/10/Mfp/buget/executii/rom09_2007/rom01_septembrie.pdf

The previous explanations are valid also in this case. At the beginning of the period (1991), the local budgets expenditures were 10.87%, but at the end (2005), they were almost half of the state budget expenditures (48.42%), thus reflecting the vast dimension of the decentralization process. The financing of these continuously increasing expenditures need local financial resources, which, in Romania, consist in two major sources: own revenues from local taxes and samplings and transfers from the state budget. The evolution of these indicators is reflected in the following tables.

Year	1991	1992	1993	1994	1995	1996	1997	1998	1999	2000	2001	2002	2003	2004	2005

SSB	0.00	0.00	23.18	66.81	120.30	197.26	464.46	499.80	1039.89	1842.99	5092.45	7095.97	9374.30	11909.80	14667.10
GDP	220.39	602.92	2003.57	4977.32	7213.55	10891.96	25292.57	37379.82	54573.00	80377.30	116768.70	151475.10	197564.80	246468.80	288047.80

http://discutii.mfinante.ro/static/10/Mfp/buget/executii/rom09_2007/rom01_septembrie.pdf

The continuously increasing of the share of samplings from the state budget (SSB) in GDP used for balancing the local budgets, from 1.16% in 1993 to 5.09% in 2005 is quite remarkable. The financial decentralization was supported mainly by the samplings from the state budget which had represented the largest share in total local expenditures which in 2005 had reached 6.52% of GDP (see table no. 1). The evolution is quite spectacular in 2001 with a huge increase from 2.29% in previous year to 4.36% due to the special education expenditures and minimum reinsertion revenue which became financial tasks for the local governments.

The transfers from the state budget had a contradictory evolution marked by increases, but also decreases, due to the many changes in the regulatory framework concerning the local finances. Their evolution is reflected in table no. 4.

Year	1991	1992	1993	1994	1995	1996	1997	1998	1999	2000	2001	2002	2003	2004	2005
GDP	220.39	602.92	2003.57	4977.32	7213.55	10891.96	25292.57	37379.82	54573	80377.3	116768.7	151475.1	197564.8	246468.8	288047.8

http://discutii.mfinante.ro/static/10/Mfp/buget/executii/rom09_2007/rom01_septembrie.pdf

From the table above is easily distinguishable the year 1999, when the transfers dropped to 0.72% of GDP due not only to the general contraction of public expenditures, but also due to a new regulatory framework which increased spectacularly the own revenues of local governments. The Hunter coefficient also reflects this, reaching its peak in 1999.

Year	1991	1992	1993	1994	1995	1996	1997	1998	1999	2000	2001	2002	2003	2004	2005
Local budget own revenues	1,74	3,20	16,24	36,70	96,92	117,70	209,08	339,05	766,87	882,94	1191,55	1682,12	2855,60	3660,70	4114,80
Total local budget revenues	5,86	19,97	71,25	176,72	333,65	499,85	1046,85	1345,42	2224,37	3344,50	7119,57	9322,77	13078,10	15955,80	19480,90
Hunter coefficient	0,30	0,16	0,23	0,21	0,29	0,24	0,20	0,25	0,34	0,26	0,17	0,18	0,22	0,23	0,21

Table No. 5 The amount and the share of own revenues in total local budget revenues (Hunter coefficient) mil. RON

Source: http://www.insse.ro/cms/rw/pages/index.ro.do; http://discutii.mfinante.ro/static/10/Mfp/buget/executii/rom09_2007/rom01_septembrie.pdf

The Hunter coefficient reflects the dependency of local governments from the state budget transfers and samplings. During 1994 – 1998 there has been a little variation from 0.21 to 0.25. In 1999, it has been reported a huge increase up to 0.34 as a result of the decentralization process enacted by the new Local Finance Bill of 1998. In 2001, when there has been a massive transfer of responsibilities to the local governments, which were financed from the state budget, the Hunter coefficient reached its minimum level (except the year 1992). In 2004, the coefficient reached the level of 0.23 due to the increasing of own revenues which had to cover larger amounts of expenditures.

The efficiency and the predictability of the intergovernmental transfers must be analyzed taking into account their mechanism of implementation. The actual system of intergovernmental transfers may be represented as in figure no. 2:

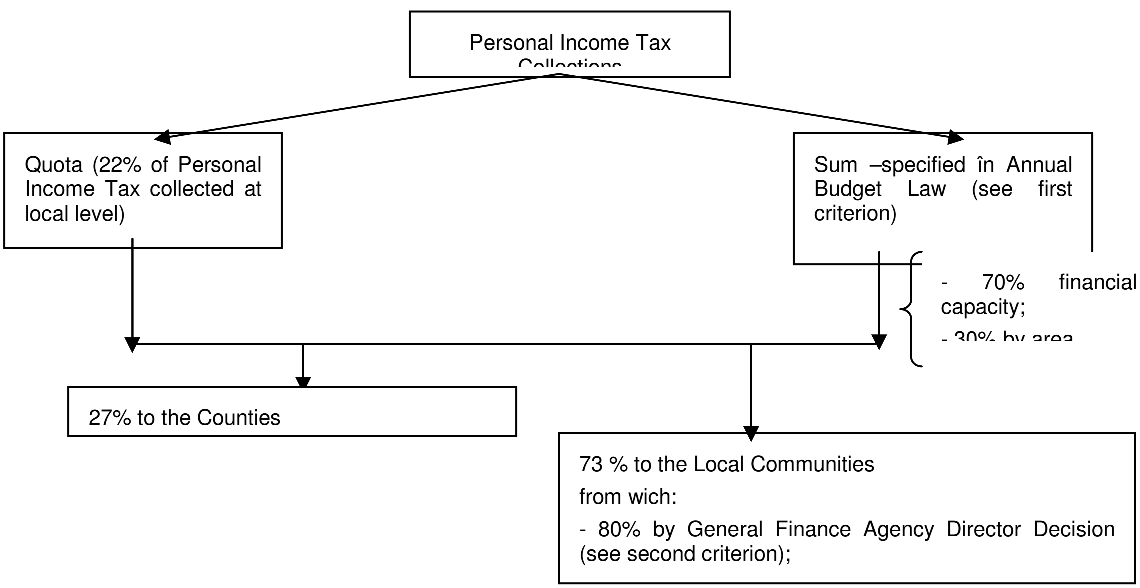

Figure no. 2. The present structure of the intergovernmental transfers in Romania

The annual sum is determined as follows:

a) financial capacity based on personal income tax collected per person, 70% in amount, using the following formula (first criterion):

$$Sr.j = \frac{\dfrac{Ivm.tj}{Ivm.j} \times \dfrac{Nr.\ loc.j}{Nr.\ loc.tj}}{\displaystyle\sum_{j=1}^{n} \left[\dfrac{Ivm.tj}{Ivm.j} \times \dfrac{Nr.\ loc.\ j}{Nr.\ loc.\ tj}\right]} \times Sr.tj,$$

where:

Sr.j - recouped amounts assigned to the counties ;

Sr.tj - recouped amounts to be assigned to all counties;

Ivm.j – average personal income tax collected in previous year in each county;

Ivm.tj – average personal income tax collected in previous year in all counties;

Nr.loc.j – number of residents of each county;

Nr.loc.tj. - number of residents of all counties;

b) county area, 30% in amount.

Twenty seven percents of the annual legal approved sum and twenty two percents of personal income tax to be collected at central budget are allocated to county budget. The remaining percents are allocated to municipalities budgets as follows:

- 80% of the sum are going to be allocated in two stages by the head of General Public Finance Department (at county level), according to the following criterion: number of residences, inside city area, financial capacity of the municipality;

- 20% of the sum are going to be allocated by county council regulations only to co-financed infrastructure projects.

At the General Public Finance Department level, the legal procedure is the following:

a) calculation of two indicators: „*average municipality revenue based on personal income tax per resident*” and „*average county revenue based on personal income tax per resident”*, using the following formula (second criterion):

$$I_{vm.l} = Iv.l / Nr.loc.l$$

$$I_{vm.j} = Iv.j / Nr.loc.j$$

where:

Ivm.l – average personal income tax per resident, collected during the previous year,

Iv.l – personal income tax collected at municipality level during the previous year;

Nr.loc.l – number of municipality residents;

Ivm.j – average personal income tax per resident, collected at county level during the previous year;

Iv.j – personal income tax collected at county level during the previous year;

Nr.loc.j – number of residents in each county.

During the first stage of the process, the sums are allocated only to the municipalities that are registering a smaller average of personal income tax than the county average one, based on residents number (75%) and inside city area (25%). These sums are limited in such a way that their average should be smaller or equal to average county personal income tax for the previous year. The average itself is calculated using the following formula:

$$M_{loc.e1} = [Iv.l + Sr.e1]/Nr.loc.l$$

where:

Mloc.e1 – first stage allocation average per resident;

Iv.l – personal income tax collected at municipality level during the previous year;

Sr.e1 – first stage allocation sums per municipalities;

Nr.loc.l – number of residents.

During the second stage, the unallocated amount is going to be recouped to all municipalities according to their financial capacity using the following formula:

$$Sr.e2 = \frac{\frac{Ivm.j}{Ivm.l} \times \frac{Nr.\ loc.l}{Nr.\ loc.j}}{\sum_{l=1}^{n} \left[\frac{Ivm.j}{Ivm.l} \times \frac{Nr.\ loc.\ l}{Nr.\ loc.\ j} \right]} \times Sr.j.e2,$$

where:

Sr.e2 – second stage allocated sums to each municipality;

Sr.j.e2 - second stage allocated sums to all municipality;

Ivm.l – average personal income tax per resident, collected during the previous year;

Ivm.j – average personal income tax per resident, collected at county level during the previous year;

Nr.loc.l –number of residents in each municipality;

Nr.loc.j –number of residents in each county.

The amounts will be corrected using the revenue collection degree for previous year, excluding litigious revenues.

As a conclusion, we consider that the actual transfer system has improved in comparison with the previous one but it is not flawless considering that:

- the sum to be recouped to local municipalities is annually established and thus it can be modified affecting the predictability of local revenue;
- the allocation at the county level is subject to a discretionary administrative decision;
- there is no municipalities' exclusion criterion at the second stage of allocation;
- the residents criterion is a global one, without taking into account the structure of public goods consumers (pupils, retired population, students etc.);
- there is no criterion to considering the institutions that offer public goods to residents from other municipalities (retirement homes, institutions for mentally challenged persons).

When the revenues from local taxes and those from transfers from the state budget are not sufficient in order to cover the local expenditures, local governments may contract loans. The local authorities may warrant these loans with their own revenues, except the case when the total amount of the local public debt (present and future) exceeds 30 % of total own revenues. In order to cover the risks generated by the loans contracted, local governments may constitute a risk fund, outside of the local budget. The revenues of this fund came from commissions and interests from the beneficiaries of the loans warranted by the local authorities, interests paid by the state treasury and penalties for the overdue payments made by the beneficiaries of the loans to the local budgets representing capital, interests and commissions. In the case of consuming the risk fund, the amounts used to cover the loans granted by the local governments are to be recovered from the debtors.

Source: **http://www.insse.ro/cms/rw/pages/index.ro.do;**
http://discutii.mfinante.ro/static/10/Mfp/buget/executii/rom09_2007/rom01_septembrie.pdf

The loans contracted by local governments were insignificant during the whole interval. The biggest share was in 1999 as a result of a new Local Finance Bill which had extended the local authorities prerogatives in contracting loans. Thus, many big projects of urban development were unable to be fulfilled, generating much discontent among citizens. This solution of local budgets balancing implies greater responsibility from the local authorities and generates more focus in getting more future revenues to the local budgets, in order to repay the loans.

In conclusion, in spite of the fact that Romania had made important steps towards decentralization, the actual local budgetary system needs continuous improving, mainly in the field of providing the predictability of the local governments revenues, that will allow the initiation and the implementation of long and medium terms programs and projects. The high dependency from the state budget, the discretionary decisions in allocating the transfers and the increase of the prerogatives only when it comes to local expenditures are the major factors that impede a real decentralization process in our country.

Abstract: The positive effects of Romania joining the European Union are business opportunities for Small and Medium Size Companies, entities that should provide products and services of best quality, in order to meet customers' expectations and to increase competitiveness.Within this context, we consider the capital market one of the solutions that can be used without high costs, while, the Romanian capital market, in spite of its instable activity, can provide accessible financing possibilities to different companies.

Keywords: capital market, competitiveness, financing possibilities, financing sources

Any organization is compelled to adjust to the environment it works in, which makes business financing a need. Any aquisition of new assets requires the raising of additional capital and long-term assets are generally financed by long-term capital. Requiring additional capital, a company has several options to raise it, respectively the use of own resources or the help given by external sources. Within the category of internal sources there are owners' or organization members' contributions along with the surplus ensuing from the organization's activity.

As far as external resources are concerned, companies may: use the financial instruments provided by capital market, that is issuing stocks and bonds, contract loans from banks, use special financing techniques (leasing, factoring, lumping, discounting).

Choosing any of the financing sources supposes several advantages and disadvantages. Thus, if entities choose to finance themselves from internal sources, they can have advantages such as keeping their financial independence and autonomy as there are no additional requests (interests, guarantees); keeping organizations' ability to make loans is a secure means to cover financial needs with the main disadvantage that they have fewer chances to invest the money in other sectors. Financing from external sources has the main advantage in getting a variable level of financial resources whose reimbursement terms can sometimes be negotiated.

In a survey regarding the financing sources used by the SME's in Romania before the EU accession it is shown that Romanian managers use as financing sources: own sources belonging to the stockholders – 44,6%, self-financing – 26,22% and bank loans – 22,22%, and hardly between 0 and 2,22% they use capital market or other special financing techniques.

1. Bank credit

The access to the funds provided by banking units requires that applying entities have a certain preparation, namely:

- getting the necessary information about the financing possibilities provided by financial organizations;
- choosing the financing organization in compliance with its credit offers;
- drafting the documents demanded by the financial organization that facilitates the access to financing;

– properly assessing the available guarantees.

The main problems that can occur when accessing and using some financing options are related to the interests and commissions charged, the need to provide the financial organization with real guarantees for credit reimbursement, the long time taken to analyze the credit papers which can cause the company to miss favourable market opportunities, the lack of previous economic and financial activities. When it comes to newly-born companies, banks are reticent to give loans since the former cannot ensure security of credit reimbursement from various reasons: they have no history, no experience, scarce elements to allow a pertinent economic and financial analysis.

On the other hand, commercial banks do not always have enough courage, know-how or financial power and decline credits because they cannot determine reimbursement. Over the last years, the financial structure of Romanian companies either corporations or SME's has significantly changed in terms of interest reduction, private property's share increase and economic restructuralization.

2. Financing by means of the capital market

Accessing the capital market can be considered a rapid and efficient way to find the necessary resources.

The main financial instruments that can be used on the capital market either as a financing source or to adopt investment decisions are: real estate, participation in collective placement, instruments of the monetary market including public securities with less than one- year due date, financial futures contracts, options, swaps on interest rate etc.

Financing by means of the capital market supposes a typical device meaning a public sale offer. An original public offer on the Romanian capital market took place in 2007, as compared to three such offers in 2006, three in 2005 and one in 2004. Therefore, 2007 features the accomplishment of SNTGN Transgaz public offer, Romania's national carrier of natural gas, between 26 November and 7 December. The Transgaz offer beat all the records Romania had previously had, attracting total submissions of 1.8 billion Euros which meant the twenty-eightfold oversubmission of the 1,177,384 offers provided. The offer price was 191,92 Lei/share and the number of submission orders was 12,089, another record. The offer's success relied on the issuer's profile, monopoly position, way to set up the revenues by regulations, and prospects related to the Nabucco project; a good offer price; the sale ability of the distribution group. As to the exchanges in the region, Romania ranks behind the Czech Republic and Hungary from the perspective of original public offers, countries that have had two original public offers and the one that ranks first is Poland's exchange where 81 public offers have taken place as compared with 28 recorded at all the other exchanges in the region.

The Romanian exchange market therefore needs new companies, either small or medium, but having potential, acting in growing sectors that are weakly or not at all represented at the exchange. They might be the fields of IT, logistics and retail.

The advantages of common stock financing of a company are that it does not force the company to pay its stockholders fixed amounts or to redeem them. As common stocks ensure a buffer against lenders' losses, the stock sale increases the credit granted to a company. In its turn, it improves the rating of bonds (of the same issuer), cuts down the debt cost and ensures the flexibility of future long-term financing actions. Thus, the company will have the basis to gather more debts or issue more shares if that is the most recommended way to raise funds.

Among the disadvantages of common bond issuing in a company there are the extension of voting rights and the increase in the submission and distribution costs of new common shares. Empirical observations show that when announcing a share issuing there is a 3% reduction of the price of industrial companies' shares. Financing by means of the capital market supposes a specific device, that is a public sale offer. Yet, it is true that SME's' access to the capital market by stock issuing depends on certain conditions regarding the entrance admission to BVB quota.

When the structure of stockholding is not desired or they want to avoid the risks of capital watering, an alternative is issuing bonds.

From the perspective of costs, statistics over the years have shown that the dividends paid when issuing new shares are more costly than the interests paid to bondholders.

As compared with loans, the bond market involves:

– lower operational and maintenance costs;
– recycling by issuing new bonds at due date;
– lower financial cost.

Bonds are a good investment to the stock investors on Romania's capital market as completing a share portfolio by bonds will generate lower risks of the portfolio by diversification as well as improve the performance by ensuring a stable revenue such as interest. bonds are also recommended to institutional investors as they can ensure higher profitability of the instruments currently used by the same institutions.

In order to attract investors, bonds should be issued at good prices and their efficiency should be higher than a bank deposit's or a treasury note's. Bonds should also be sold all throughout the country by a large network of specialized and professionally qualified people.

The first corporate bonds in Romania were issued in 1997 by Siderca S.A. Călăraşi. The company issued then 350,000 bonds being worth 6,300,000,000 Lei. The main features of the issued bonds were:

– three-year due date;
– the ability to turn bonds into shares, respectively four shares into one bond;
– the binding loan was guaranteed by the company's assets;
– the interest was 57%/year, paid every term.

The issuer's financial status deteriorated during bonds' duration which made the company find it impossible to pay interests or redeem bonds in 2000.

As it also pursued bonds' exchange listing, the shares were unlisted at the RASDAQ which made investors' facility of turning bonds into shares never come true. Although accepted at the BVB listing, the Siderca bonds have never been traded.

The amount of corporate bonds issuing actually increased to 6 in late 2007 (compared to 7 in early 2006 and 6 in late 2005): The Romanian Commercial Bank (BCR09) and International Leasing (YTLS10) in the second bond category, Carpatica Commercial Bank (BCC09) and ProCredit Bank (PRCR09) in the third bond category, and the European Investment Bank (EIB14) and World Bank (IBRD09) in the international bond category. Accomplishing bond issuing imposes, as general rules and irrespective of the category aimed for subscription, a public bond sale offer performed according to an offer prospect approved by CNVM and getting a minimum compulsory Lei loan even to 200,000Euro

3. Advantages of financing by means of the capital market

The main advantages of financing by means of the capital market actually aim to:

– improve the access to capital and financing conditions, as share issuing provides long-term capital for a company that does not need to be reimbursed, there is no interest paid as a financial obligation. On the other hand, if after share issuing the company is listed at the exchange, new share and/or bond issuing is likely to take place in more favourable conditions than the former ones;
– list companies at the exchange which also gives them the opportunity to become famous and have more prestige thus increasing the competitiveness of the goods and services they supply their customers;.
– set a real value of a company. Share issuing in a listed company is going to generate a device involving the setting up of listed shares' market value which can be extremely important in mergers or aquisitions and the value provided by the capital market (exchange capitalization) could be considered as one closer to economic reality;
– increase the listed company's prestige due to the duty of periodically informing the shareholders and all those concerned about the company's economic and financial activities;
– improve the company's market image which will lead to the reduction of future financing costs and the easier access to potential partners and customers.

Abstract: The performances of a society depend both on operational management (of production, of human resources) and on the financial management. In the economic specialists' opinion the objectives of the financial management are both profits maximization and maximization of shareholders' wealth.

The management process in a company means the assembly of stages, processes through which its objectives and those of the incorporated systems are determined, work resources and processes necessary to their achievement and their executors, through which they register and control the staff's work using a complex of methods and techniques in order to achieve most efficiently the reasons that determined the setting up of the company .

Key words: the financial management, the result account, the operational management

Introduction

To conduct this analysis we chose the „SALAMANDRA" S.R.L. Trading Company of Baia Mare, and we performed the analysis based on the data provided by the balance sheet and by the profit and loss account for the period 2003 – 2006, with the data expressed in lei – ROL to ensure their compatibility.

In the field of services the company provides its services through catering in the restaurant S.C. SALAMANDRA S.R.L. of Baia Mare, 6 Unirii boulevard. In the field of production the company manufactures a very wide range of meat products and by-products, processed meat, salami and sausages.

This study aims to uncover the potential of the economic agent S.C. SALAMANDRA S.R.L. for producing profit both through its current activity and through its perspective one, and to watch the behaviour of the economic agent in the case of changes in the structure of the capital, entailed by an increase of the fixed assets and of the company's indebtedness.

1. LIQUIDITY INDICATORS

These indicators allow an assessment of the financial status of the trading company and provide potential creditors with a minimum of data with regards to the way the company disposed and disposes over the period that is analyzed.

The capacity of the S.C. SALAMANDRA S.R.L. trading company to pay its obligations is illustrated through several indicators that are established based on various elements of the patrimony. The liquidity indicators and their evolution are presented in table no. 1.

Table no. 1.

Liquidity indicators

No.	INDICATORS	2003	2004	2005	2006
1	CAPITAL LIQUIDITY %	318.71	83.38	445.82	388.76
2	IMMEDIATE LIQUIDITY %	261.79	48.98	348.36	253.85
3	CAPITAL SOLVENCY %	0.00	81.38	93.85	84.30
4	NET ACCOUNTING CAPITAL (thousands lei)	1645450	7434280	21166590	388206813

Capital liquidity and immediate liquidity: the dramatic increase in the value of these indicators (except for the year 2004), well above 100%, reflects the high degree of both overall company liquidity and short term liquidity.

The evolution of the capital liquidity is presented in figure no. 1, and that of the immediate liquidity, in figure no.

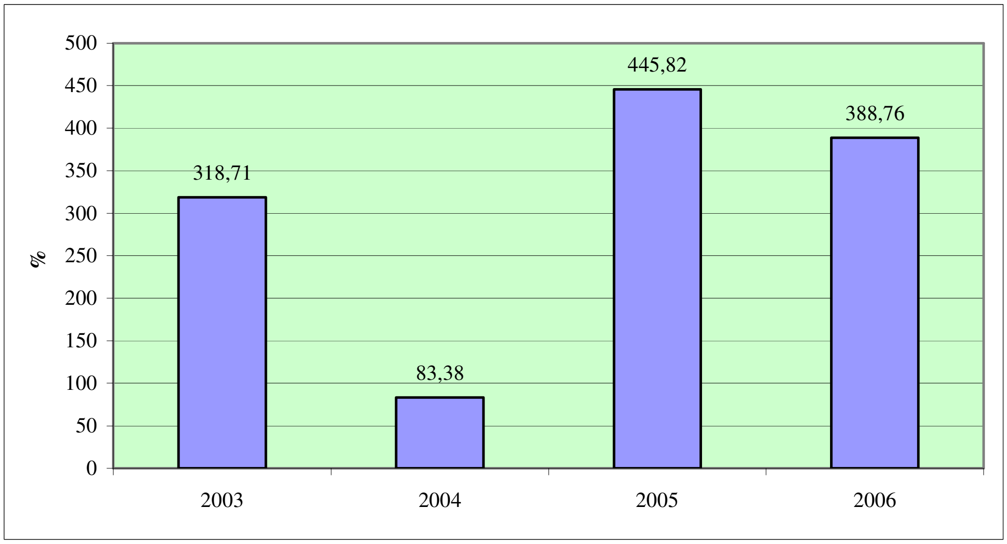

Figure no. 1. Evolution of the capital liquidity over the period 2003-2006

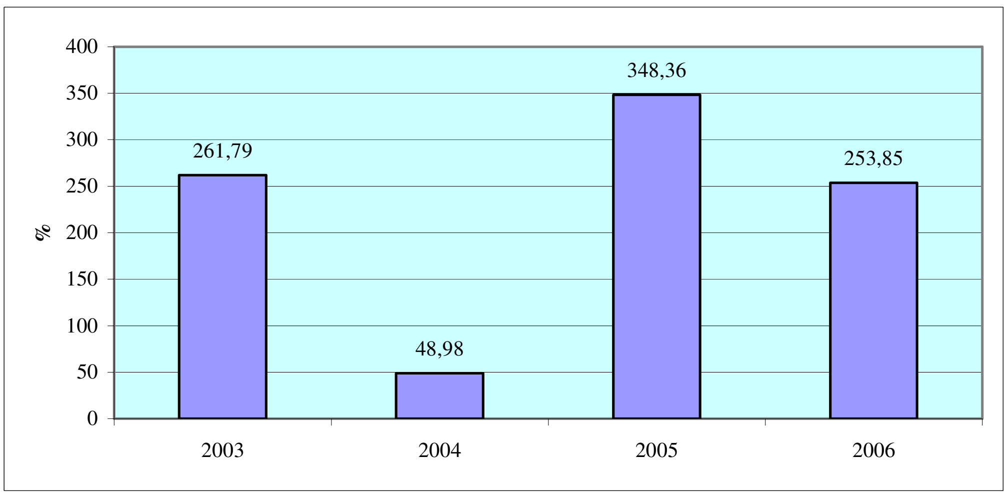

Figure no. 2. Evolution of the immediate liquidity over the period 2003-2006

Capital solvency: based on specialist opinions, the minimum acceptable value for this indicator is of 30%; at over 50% the status of the company is considered as normal from the point of view of capital solvency, and at over 70% it is deemed to have a high degree of solvency. The evolution of the capital solvency is presented in figure no. 3.

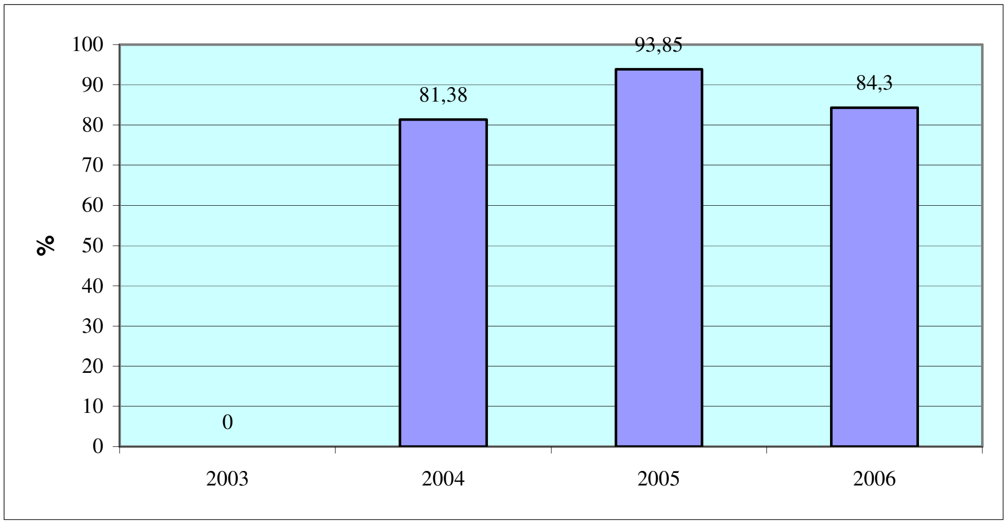

Figure no. 3. Evolution of the capital solvency over the period 2003-2006

Net accounting capital: the clearly positive and improving situation at the end of each accounting period indicates the existence of a net capital, therefore of an active framework that is free of debt, which is in fact the wealth of the two owners of S.C. SALAMANDRA S.R.L.

The increase by 17.7 times of the net statement is a consequence of having reinvested almost the entire profit obtained in the production process, and it is a proof of interest from the company's managers to develop and consolidate their own business. The evolution of the net accounting capital is presented in figure no. 4.

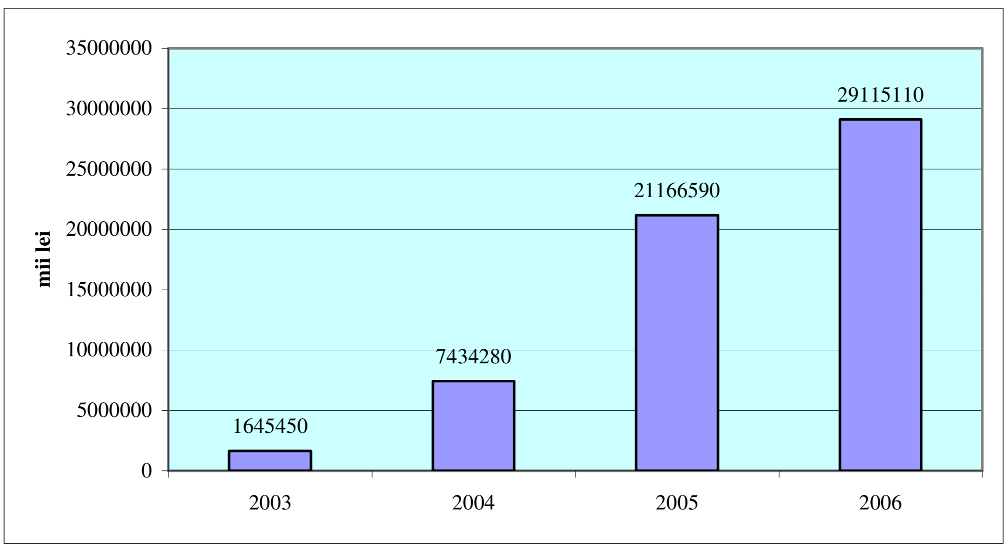

Figure no. 4. Evolution of the net accounting capital over the period 2003-2006

2. FINANCIAL DIAGNOSIS BASED ON THE RESULT ACCOUNT

The financial performances of the S.C. SALAMANDRA S.R.L. company are expressed through the income, expenses and profits obtained over the periods that were analyzed.

The purpose of the analysis is to draw a general picture of the evolution of the main indicators that characterize the economic and financial activity, and that are used as a base for future projections.

The structure of the operating expenses is presented in table no. 2.

Table no. 2.

Structure of the operating expenses

INDICATORS	SHARE
Merchandise related expenses	28.41%
Raw material related expenses	55.69%
Consumable materials related expenses	7.83%
Power related expenses	0.75%
Other material expenses	0.05%
TOTAL MATERIAL EXPENSES	94.32%
Third parties related expenses	1.96%
Tax and fee related expenses	0.27%
Staff related expenses	3.35%
Amortization expenses	1.69%
TOTAL	100.00%

The share of material expenses and merchandise related expenses out of the total operating expenses is very high, exceeding 90%. Under these circumstances the difference between the company's incomes and expenses is a decisive element for the newly created value.

Value added: this is a very important indicator in the factor analysis of expenses, as it actually expresses the added value that is obtained from utilizing the production factors (labour and capital) above the value of goods and services provided by third parties within the company's daily activity

The evolution of the value added over the period 2004-2006 is presented in table no. 3.

Table no. 3.

Evolution of the value added

No.	SPECIFICATION	2004 thousand lei	2005 thousand lei	2006 thousand lei
1	Mark-up	1271490	3208270	4001213
2	Production of the period	20183440	36650060	55552800
3	Daily consumptions	16662620	34357100	53498307
4	VALUE ADDED	4792310	5401230	6055707

In fact, the *value added* is the source of financial accumulations used for remunerating the factors participating in he company's economic activity.

The structure of the value added is presented in table no. 4.

Table no. 4.

Structure of the value added

No.	SPECIFICATION	2004 (%)	2005 (%)	2006 (%)
1	STAFF REMUNERATION	15.67	29.11	44.70
2	STATE REMUNERATION THROUGH TAXES	16.31	1.88	3.72
3	CREDIT REMUNERATION THROUGH INTEREST RATE	8.75	13.41	21.47

4	INVESTMENT REMUNERATION THROUGH LIQUIDATION	0.73	6.73	22.64
5	OWN CAPITAL REMUNERATION THROUGH DIVIDENDS	0.50	0.59	-
6	COMPANY REMUNERATION THROUGH CAF	58.04	48.28	7.47

The greatest share of this value is taken by the sources permanently available to the company, which constitute its self-financing capacity. The expenses related to the staff and those of financial nature are, along with liquidation expenses, the true cost of utilizing the production factors mentioned before.

Self-financing: this is the main element in financing companies, and for many of them (especially private companies) it is the only source for financing the production activity, the operating costs, but also for supporting the decisive or risky stages of the development.

The size of the self-financing in the case of S.C. SALAMANDRA S.R.L. plays an important role in indicating the company's performances. For potential creditors and investors this is a sign that the company is capable of efficiently using the capitals entrusted to it and to ensure an interesting remuneration for them.

The absolute size and the relative size of the self-financing certify the level of the reimbursement capacity and the level of the company's non-payment risk.

The structure of the operating income: for the year 2006, S.C. SALAMANDRA S.R.L. has earned the income presented in table no. 5.

Table no. 5.

Structure of the operating income

SPECIFICATION	**VALUE (thousand lei)**
Income from sale of end-products	55550787
Income from sale of merchandise - retail trade - public catering	26941547 25199640 1741907
Income from sale of packing materials	2013
Operating income	10044320
Income from interest rates	61547
Income from discounts obtained	41107
TOTAL INCOME	92641318

The income obtained from the actual production activity cover 60% of the total achievements.

The selling of over 25% of the manufactured products through the company's own network, respectively the two retail stores “Vlăduț” and “Turist”, as well as through the company's public catering unit, have favourably contributed to the achievement of a mark-up of over 175 of the trading activity.

Net result of the activity*:* this expresses the absolute size of the profitability through which the owners are remunerated for their own subscribed.

The structure of the profit and loss account for the three types of activity (operational, financial, exceptional) allow the establishment of intermediary balances of administration (SIG), meant to remunerate production factors and to finance the company's future activity.

These balances are in fact consecutive levels in the forming of the final result. The net result fof the activity is presented in table no. 6.

Table no. 6.

Net result of the activity

No.	SPECIFICATION	2004 thousand lei	2005 thousand lei	2006 thousand lei
1	VALUE ADDED	4792310	5401230	6055707
	+ Subventions from operations - Taxes, fees, deposits - Staff related expenses	195410 781650 751070	7435020 101860 1572830	1004432 225627 2707413
2	GROSS OPERATING OUTPUT	3455000	11161560	13166989
	+ Income from commissions + Other operating income - Amortizations - Other operating expenses	- - 35360 -	- - 363860 -	- - 1371440 -
3	RESULT OF THE OPERATIONS	3419640	10797700	11795549
	+ Financial income - Financial expenses	500790 419340	408130 724380	102653 1300173
4	CURRENT RESULT	3501090	10481450	10598029
	+ Extraordinary income - Extraordinary expenses - Profit tax	- 8970 -	1000 86240 -	- - -
5	NET RESULT	3492120	10396210	10598029
6	FINANCIAL PROFITABILITY	13.54	18.15	12.91

The **gross operating output** expresses the gross accumulations obtained from the operating activity, and it is the main resource of the company with decisive influence over its final profitability.

The size of the output and the increasing evolution in the case of the S.C. SALAMANDRA S.R.L. company allows the enterprise to renew its fixed assets through amortizations and ensures the conditions for the external financing that entails financial expenses.

The **result of the operations** reflects the absolute size of the operations, obtained by deducting the payable and calculated expenses (liquidation).

The **current result** is obtained from all the daily operations of the enterprise. The influence of losses in the financial activity varied between 2.38% in 2004 and 10.15% in 2006, relative to the result of the operations.

The **net result of the activity** expresses the absolute size of the company's financial profitability that, along with commissions, amortizations, and any existing differences between divestitures, represent the company's self-financing capacity.

The **financial profitability** is a relative value that reflects the results of the activity in all the stages of the circular flow both in the study of production and in the one of sales.

The variable value of this indicator, that is the increase from 13.54% in 2004 to 18.15% in 2005 and then the decrease recorded in the year 2006 reflect both the managers' interest and their ability in reaching their final aim, which is to increase the turnover and, by that, increasing the absolute value of the turnover, and by that, increasing the absolute value of the net earnings.

Table no. 7 presents the basic synthetic indicators.

Table no. 7.

CONCLUSIONS

Financial administration may be defined as a system of decisions and activities that all contribute to adjusting and regulating financial flows and funds, to administrating the company's financial resources. Financial administration aims to regularly provide the company with the funds required for current equipment and operations, but also to verify the correct utilization of the funds and the profitability of the operations to which these funds are assigned. Financial administration serves several purposes, all within the scope of the company's survival, achievement of profit, and economic development.

The financial function of the company has an operational role, a functional role, and a political role. The main financial activities are as follows:

- Drawing up and applying the income and expenditure budget;
- Conducting studied and analyses on the formation;
- Appropriating and utilizing capitals;
- Establishing prices and fees;
- Taking measures to ensure liquidity and solvency;
- Maintaining financial balance and avoiding risks.

A TRUE AND FAIR VIEW OF IMPLEMENTATION OF THE IAS REGULATION IN THE EUROPEAN UNION

Pietraru Alina

Universitatea „Constantin Brâncoveanu"Piteşti, FMMAE Rm Vâlcea, N. Bălcescu, nr. 39, pietrarualina@ k.ro , 0744.523479

Abstract: The Regulation of the European Parliament and the Council of the European Union on the application of international accounting standards, was a key instrument to enhance comparability and transparency of financial statements prepared by publicy traded companies, in order to ensure the completion of a single financial services market. Never the less, Member States were allowed to extend the application of IAS to unlisted companies and to individual accounts.

Key words: European Directives, IAS Regulation, IAS endorsement process

European Union accounting requirements contains primarily four Accounting Directives: the Fourth and Seventh Directives on the annual and consolidated accounts of companies, the Directive on the annual and consolidated accounts of banks and other financial institutions, the Directive on the annual and consolidated accounts of insurance undertakings. With the accelerating pressure towards the convergence of accounting standards, the existing directives do not meet the needs to facilitate the access of European global players that wish to raise capital on international securities markets.

In this context, the Accounting Directives proved to be (Linder, 2006):

- - difficult to integrate into national law and even more complicate to make work in practice;
- - sensitive to some political compromises as is the tendency to avoid reopening issues;
- - reflecting the accounting thinking at the time they were writen.

With the European Legislation silent on many aspects of accounting, in 1998, according to IASC statistics, some 210 European Union companies reported in accordance with IAS while 235 reported under US GAAP while, in 1999, 275 European Union companies used IAS. Both financial reporting frameworks were investor-oriented financial reporting systems that provide a high levels of investor protection

Globalization of capital markets, the consolidation of stock exchanges and the International Organization of Securities Commissions (IOSCO) work on harmonised requirements for stock exchanges as the IASC focused more on the standard-setting have created a unique momentum to to accelerate completion of the internal market for financial services in order to increase market efficiency and reduce the cost of raising capital for European Union companies.

Consequently, the Lisbon European Council of 23 and 24 March 2000 underlined the key importance of a single financial market and set the deadline of 2005 for all publicly traded companies to prepare their consolidated financial statements in accordance with one single set of accounting standards, namely International Accounting Standards (IAS).

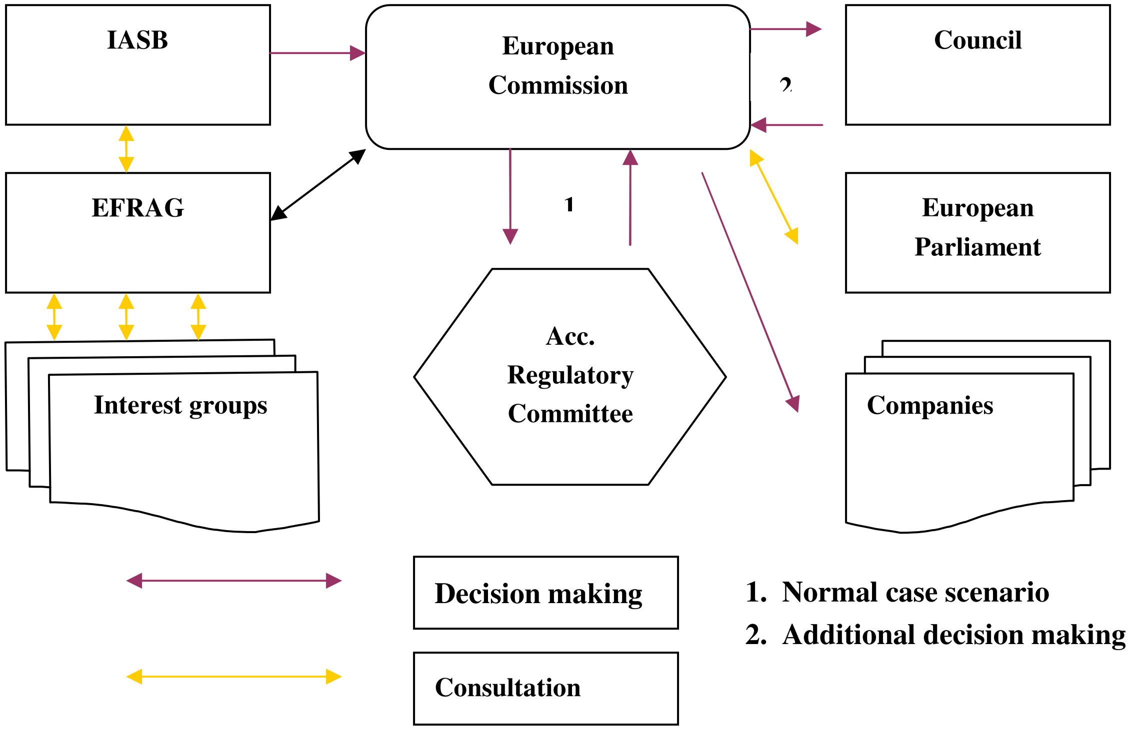
The Commission also, proposed that Member States to permit either to require or to allow unlisted companies as well as unlisted financial institutions and insurance companies**,** to publish financial statements in accordance with the same set of standards as those for listed companies.

Further more, the European Union Accounting Regulation gave European Union member states the option to:

- - Permit companies whose only listed securities are debt securities to delay IFRS adoption until 2007
- - Permit companies that are listed on exchanges outside of the EU and that currently prepare their primary financial statements using a non-EU GAAP (in most cases this would be US GAAP) to delay IFRS adoption until 2007.

In order to adopt an international accounting standard for application within the European Union, it is necessary to meet the basic requirements:

– they are not contrary to the "true and fair view" principle of the 4th and 7th Accounting Directives;
– they are conducive to the European public good (competitiveness and convergence);
– they meet the criteria of understandability, relevance, reliability and comparability.



IAS Endorsement process

Source: Linder, Financial Reporting Legislation in the EU, p.23

As the process for adoption of IFRS proceeded, proponents and opponents lined up for public hearing. The supporters believe that the European Union's strategy to adopt an international standard, rather than a particularly European one, has been validated (Zalm,2008). Overall, proponents highlighted that IFRS adoption is a project worth pursuing for three primary reasons:

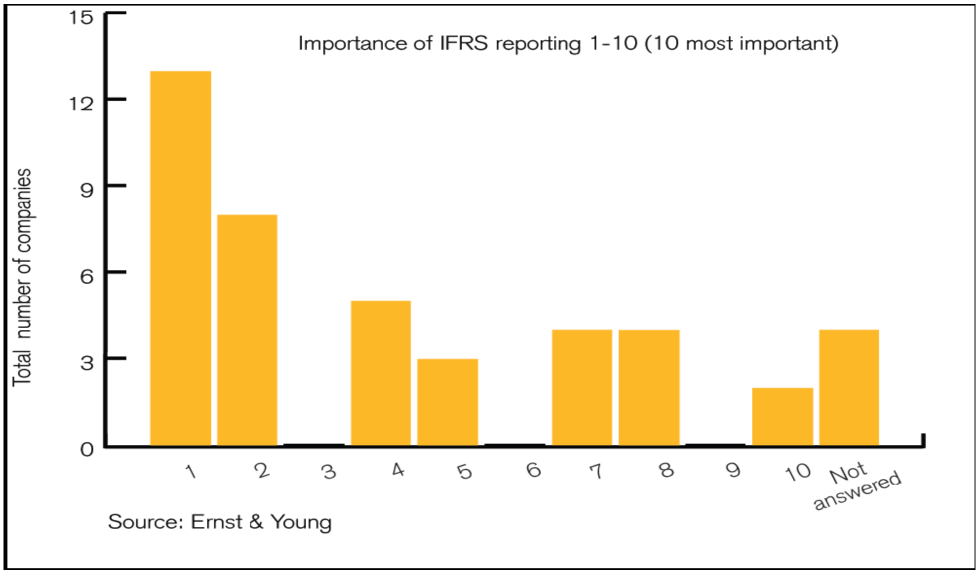
– IFRS can play a powerful role in providing transparency and comparability for investors rather than the application of domestic European standards;
– a single set of standards would lower the costs of of comparing performance of firms from different countries;
– European capital market would become more globally competitive as the result of massive capital flows from outside of Europe.

Nevertheless the European investors responded negatively to movement toward IFRS as the controversy focused on the suspicions that (Armostrong, 2007):

– the IFRS would not adequately reflect regional differences in economies;
– the IFRS would not accommodate differing political and economic member state features that led to existing differences across domestic accounting standards.
– the variation in the implementation and enforcement of IFRS would diminish any potential benefit

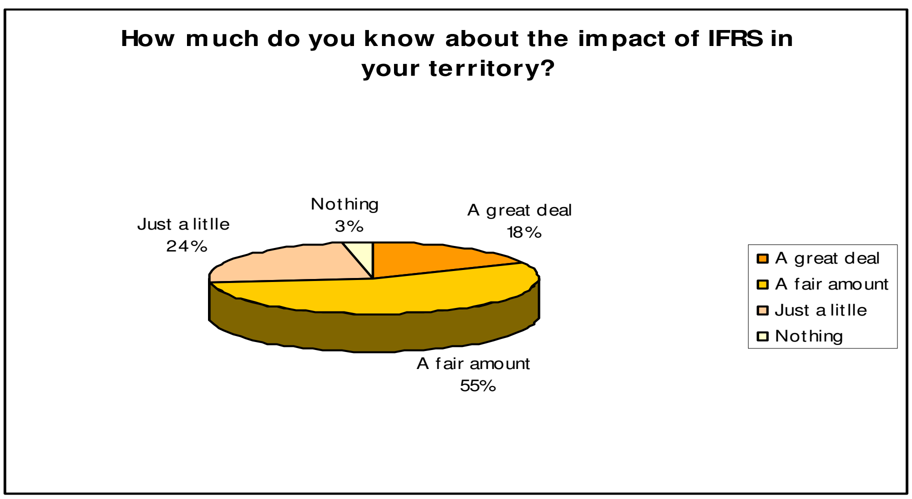
To assess the overall investor sentiment regarding IFRS adoption, we focused on the surveys on the effect of the transition to IFRS, conducted by major major polling organizations. Valuable lessons can be drawn from this researches.

Ernst & Young decided to carry out, in 2004, a pan- European survey of IFRS and the implications for the investment fund industry. The respondents were asked to rank the importance of IFRS reporting within their organisation on a scale from one (not important at all) to 10 (extremely important). The results were mixed, with 49% indicating low importance (ranks one to three) and 23% indicating high importance (ranks eight to 10).



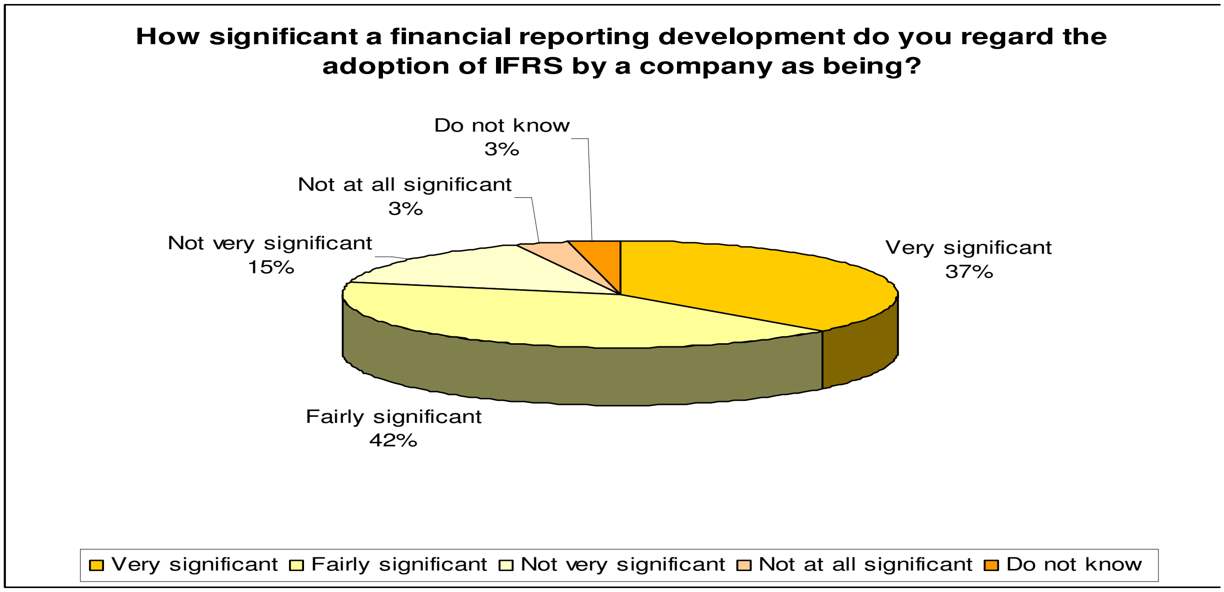
This survey demonstrated that there was a clear need for harmonisation and transparency with regard to the investment fund industry in Europe.

Another research was the PricewaterhouseCoopers /Ipsos MORI survey of 187 fund managers across Europe conducted in 2006. Most of the fund managers interviewed for the survey said they are fairly well-informed and understand the impact of IFRS. Nearly threequarters said they know either a lot or a fair amount about the impact of IFRS on companies in their country



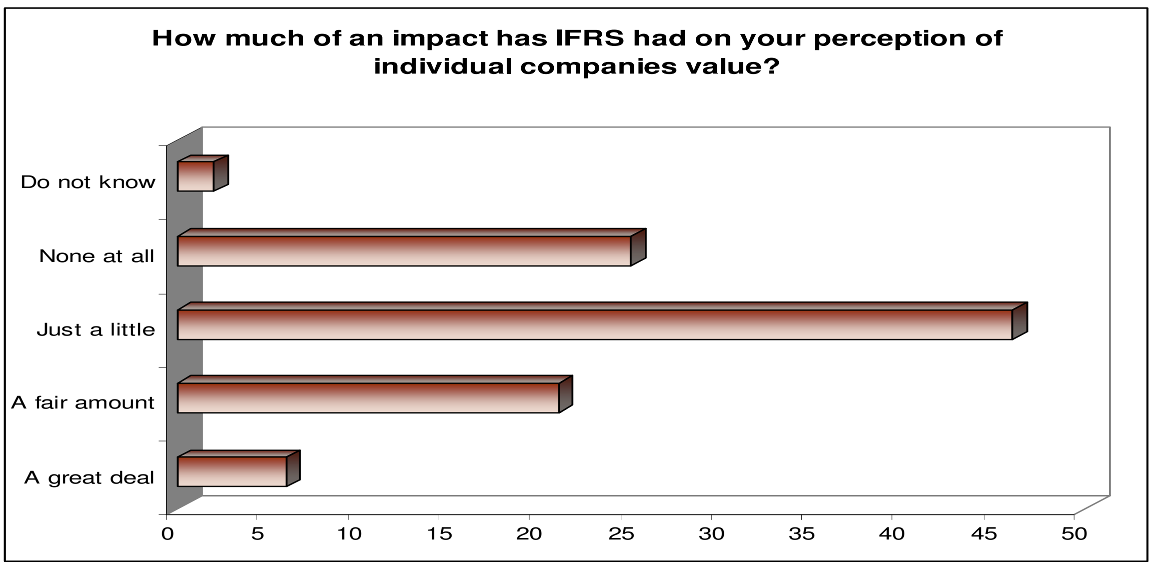
Source: PricewaterhouseCoopers /Ipsos MORI, 2006

Investment fund managers see the change to IFRS as significant. Four in every five believe that the adoption of IFRS is either a very or fairly significant development for financial reporting. The majority (66%) have already noticed its impact on the operational results of the companies they invest in.



Source: PricewaterhouseCoopers /Ipsos MORI, 2006

In spite of this encouraging results, IFRS had already affected fund managers' perceptions of value. Almost three-quarters said that the change to IFRS has had at least some impact on their view of the value of the individual companies they invest in, mainly because financial information is now easier to compare and offers greater transparency.

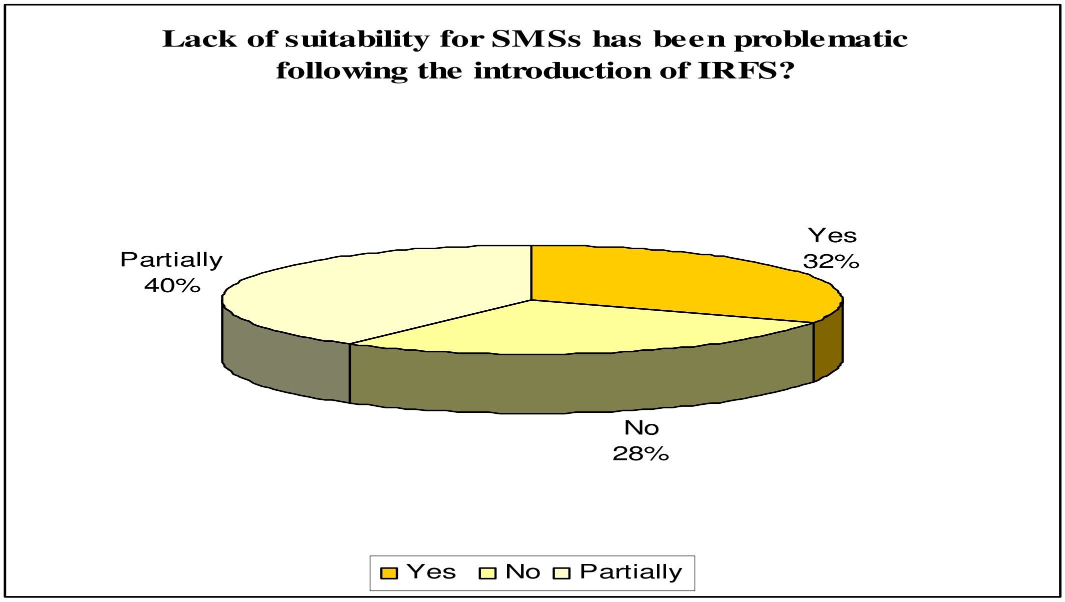


Source: PricewaterhouseCoopers /Ipsos MORI, 2006

Moves towards greater consistency of application, convergence, standardisation of requirements, and improved transparency, were high on the list of investors' hopes for the future development of IFRS, back in 2006.

The Association of Chartered Certified Accountants (ACCA) undertook a quantitative and qualitative survey of its members, in late 2007. This comprised in-depth focus groups with leading members in Poland, Hungary, the Czech and Slovak republics and Romania. The results were not encouraging for small and medium sized enterprises.

In the area of accounting regulation, ACCA focus groups members were largely supportive of the advent of International Financial Reporting Standards (IFRS) in Europe, believing it to have brought more meaning to accounts, which were previously taxdriven and of limited use for investors. Nevertheless the survey identifies the biggest problem which is the lack of suitability for SMEs.



Source: ACCA Central & Eastern Europe members' survey on SME issues, 2007

The results of this article reveal that the introduction of IFRS in Europe can be characterized as "a romantic project" which in time could prove to be a successful marriage or a painful divorce.

OPPORTUNITIES OFFERED BY THE CAPITAL MARKET FOR FINANCING PUBLIC ADMINISTRATION

Pirtea Marilen

West University of Timişoara, Faculty of Economy and Business Administration, Str. J.H.Pestalozzi nr. 16, 300115, Timisoara, marilen.pirtea@yahoo.com, Tel: +40-256-592506

Abstract: Nowadays, covering the financial deficit of public administration in Romania is a difficult task, taking into consideration the fact that in a continous way, this institutional sector must implement and manage investment projects, that suit the local needs of Romanian colectivity and dynamize their adaption to the social,economical and political requirements of the integration in the European Union. Therefore, the alternative of financing through the capital market is well received by the public authorities, especially because there is a lack of flexibility and variety of financing possibilities for the public administration. The interest for this type of financing has increased over the time, once with becoming familiar with the mechanisms and advantages of such a type of financing by all entities that operate on the market (issuers, investors, intermediaries).

Key words: capital market, T-bonds, public debt management

1. The financing need of the "Public Administration" institutional sector

The "Public Administration" area is comprised of the **central public administration** (central bodies whose competence expands all around the country, except for the administration of the social insurance systems), **local public administration** (local administrations whose competence expands only on one local administrative unit – commune, town / city, county, district, Bucharest City-, except for the territorial institutions of the social insurance systems) and **the administrations of social insurance systems** (comprise the authorities managing the social insurance systems – public pensions system and other social insurance rights, unemployment insurance system, health social insurances, insurance system for labor connected accidents and occupational conditions and other such – as well as territorial institutions subordinated to them, no matter their financing manner.)

These entities can have their necessary financing resulting from financing or co-financing the public, local or private concern projects, of the temporary treasury needs due to gaps occurring between the cashing in and payment flows, as well as to the budgetary deficit. Other reasons due to which the public administration can be in a resource deficit might be reimbursing in full or in part the loans already contracted and that reached their due date or paying the interests corresponding to the existing public debt.

During the analyzed period of time the net financing need of the public administration has encountered a dynamics showed in the figure below:

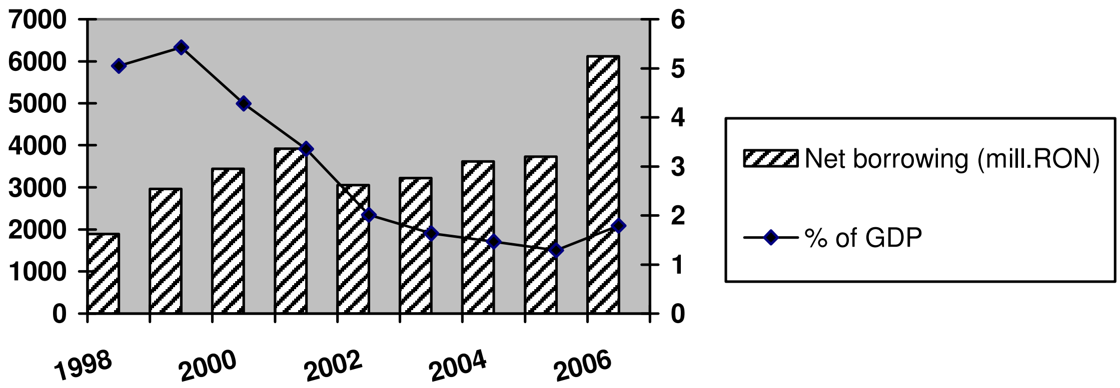

Figure 1 – Evolution of net borrowing of public administration and its weight in GDP in the period 1998-2006

Source: Dates supplied by NBR, and author calculations

In the figure it is pointed out that although the net financing need of the public administration has encountered an increase during the analyzed period of time, until 2005 this represented a percentage smaller and smaller of the GDP due to the fact GDP's increase rate was grater than that of the net financing need. Although, during 2006 the percentage of the net financing need has slightly increased up to 1.79 % of the GDP due to increasing the public debt and the amounts to be paid by the public institutions to the economic entities and to the employees.

2. Financing sources and their effects

During the analyzed period of time, 1998-2006, it is noticed that the greatest part of the financing need for the public administration is provided through loans that from RON 3687 million in 1998 reached RON 26,787 million in 2006, a significant increase. During this period of time, the long term loans have had the greatest percentage, reaching in 2006 over 99 % of the total loans. As important financing alternative there can be noticed the T-bonds, most of them being on a long term. They have also encountered an increase along the time, from RON 3358 million in 1998 to RON 13,829 million. Another financing form that mustn't be neglected, was the deposits of the economic entities in the treasury and the treasury notes, held by the population, that on their due dates have been transformed in deposits. They have increased along the time, from RON 230 million in 1998 to RON 17,428 million in 2006.

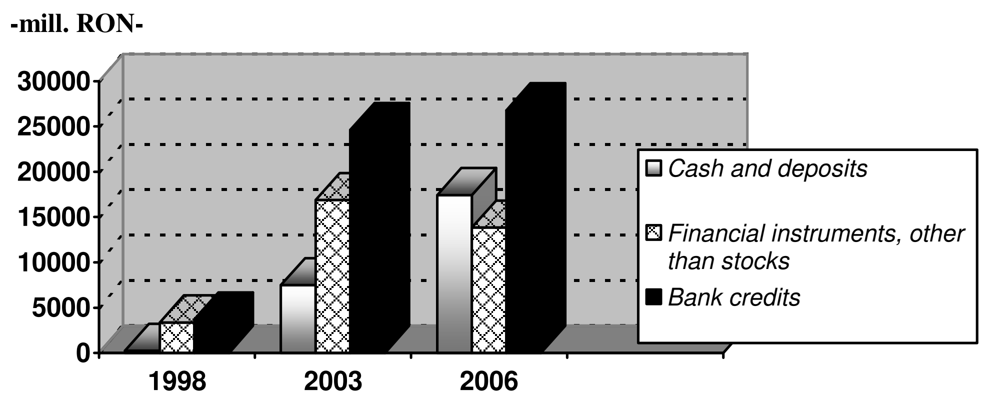

Figure 2 – Structure of financing of public administration taking in consideration the source of financing

The public administration calling to **financing through the capital market** can be made through listing the bonds or treasury notes issued on the capital market. Although the traditional manner for financing the public administrations remains using the bank type of loans, they started to perceive the capital market as a viable alternative for supporting different investment projects or for covering the budgetary deficits. **From our standpoint**, financing the necessary capital of the public administration in Romania seems today even more difficult given that this institutional sector must be able at all times to supply grounds for and to manage the investment projects that would respond to the Romanian communities' local needs and also, that would make dynamic their adaptation to the social, economic and political requirements of the European accession. **Thus, the alternative of financing through the capital market is welcomed** in the circumstances that the public administration's financing possibilities are pretty limited and little flexible. The interest for developing this type of financing grew along the time at the same time with gaining the awareness on the mechanisms and advantages of such a financing by all market actors (issuers, investors, intermediaries).

The municipalities have actively contributed to developing the capital market through issuing bonds developed in view of financing some projects at the local administration level. The low funds level the local public administration have and the impossibility to increase local taxes in order to obtain greater incomes cashed by the local budgets **imposed financing some alternative financing sources** for supporting the local investment projects. Next to the municipal bonds, **the government bonds might have a vital part on the local capital market.** The state loans are guaranteed, thus representing a standard for the remaining of bond issuing. These can be inscribed for listing and thus, they can be transacted either on a regulated market, either within an alternative transacting system. For the time being they are missing from the Romanian capital market, but there are positive perspectives that this will change soon. If in Romania these things are just in their beginning, in Poland, the country having the greatest capital market in the Central and Eastern Europe, the total value of the bonds issued inscribed in the stock market is close to EUR 100 billion and among them the greatest part is represented by bonds issued by the Polish government. This led to the existence of some bond transactions of over EUR 1.4 billion during 2006. Given that Romania has an increasing budgetary deficit and that the public debt is pretty low, approximately 12% of the gross domestic product, there are expectations for the things to change and for the state to issue more and more bonds[141].

3. Arguments for developing a government bond market

The need to develop the bond market is felt not only in Romania, but, after the recent international crises, it has also drawn the attention of numerous decision makers at the national and international level. An intrinsic connection to this subject is provided by the governmental debt theme that has been debated on so many occasions at the IMF and World Bank level[142]. Of course that developing a government bond market represents a complex approach that depends on the developing level of the financial system existing in each country. In some countries, financing the government can depend only on some local banks which inhibits the competition and raises even more the transaction's costs. As well, the lack of an adequate market infrastructure can create difficulties for developing a bond market. The lack of institutional investors, the low saving rates at national level or the lack of interest from the institutional investors can lead to the occurrence of a small and homogenous group willing to invest in such financial bonds, as a contradiction to the heterogeneity requirements imposed by an efficient market. More, an economic instability, usually supported by high budgetary deficits or a rapid increase of the currency supply, correlated with a lower and lower exchange rate can lead to a mistrust from the investors and to increasing the risks connected to developing a government bond market. The bond markets have as role creating a connection between the issuers needing long term financing resources and the investors willing to place their available exceeding capital in interest bearing financial bonds. A mature bond market supplies a range of possibilities for timely financing the government and the private sector, thus that through developing the bond market there are usually also created enhanced possibilities for other non-governmental issuers.

The government bonds are the "back bone", a reference item for most financial bonds with fixed income in the developed countries, but also in the countries in progress of developing, as we will point out in the next paragraph. Through these benchmark type of bonds it is supplied a reference yield curve for the other loan financial instruments having similar traits. As well, the mortgage financing can depend in full or in part of

[141] Ionuț Dumitru, Chief of the Research Treasury Department, Raiffeisen Bank.
[142] Concerning this, please make reference to *Draft Guidelines for Public Debt Management*, IBRD SEC M2000-376 and *Sound Practices in Sovereign Debt Management*, drafted by the World Bank in collaboration with IMF.

the mortgage bonds. The development of a government bond market provides a number of important benefits, if the prerequisites to a sound development are in place. At a macroeconomic policy level, a government bond market provides an avenue for domestic funding of a budget deficit other than the central bank, and thereby can reduce the need for direct and potentially damaging monetary financing of deficits and avoid a buildup of foreign-currency denominated debt. A bond market can also strengthen the transmission and implementation of monetary policy, including the achievement of monetary targets or inflation objectives; and can enable the use of market-based indirect monetary policy instruments. The existence of such a market not only can enable authorities to smooth consumption and investment in response to shocks, but can, if coupled with sound debt management, also help governments reduce their exposure to interest rate, currency, and other risks. Finally, a shift toward market-oriented domestic funding will reduce debt service costs over the medium to long term through development of a deep and liquid market.

4. Bonds issued on the Romanian capital market and comparisons at regional and European Union levels

At the level of the Romanian capital market there has been registered a growth pace from one year to another as regards the bond transactions, but they are still far from the potential the market gives to such instruments. This was due, mainly, **from our point of view,** to the fact that the first bond operations took place only in the autumn of 2001, in other words these fixed income instruments are relatively new on the market. The law that decentralized the local authorities' finance and that allowed the issuing of municipal bonds was applied beginning on January 1, 1999. After this date the structure of local budgets has been significantly changed, the following two years being transition characterized. For analyzing the local finance status, absolutely mandatory for issuing bonds, there was needed similar financial reporting for a 2 or 3 year period of time. 2001 was the year when there were produced reporting starting on the same basis, the one stipulated by the local public finance law applied since 1999. But, the issuers have been from the beginning very open to approaching the financing through bonds due to the fact the in those years the bank loans for local authorities were difficult to obtain, for most of them being requested real estate guarantees, difficult or impossible to be granted by the town or city halls. The bonds took their logical path of guaranteeing the loan with the budgetary execution and they had the major advantage of low interests than the bank ones and of being transparently calculated.

The first municipal bonds issued having an 18 month due date was launched on October 8, 2001 by the Predeal Town Hall. It was followed by Mangalia Town Hall and by other towns and cities: Zalău, Alba-Iulia, Cluj-Napoca, Breaza, Bacău, Sebeş, Târgu-Mureş and Slobozia. There was expected for the European Union accession to truly bring a reanimation on the bond market, thing which actually happened. The actual number of bonds transacted doubled in 2007. Thus, BVB (Bucharest Stock Exchange) strengthened its position of main local stock market and came closer to the goal of becoming a regional reference market through the novelties promoted. Thus, from 2001 and until 2007 the number of bonds newly listed in each year grew from 2 to 11, the number of issuers increasing also from 2 to 22 and the volume of transacted bonds doubled from 2006 and until 2007, reaching 6,652,467[143]. If we take into account just the **municipal operations,** until 2007 have been performed over 40 issuing for such bonds. In 2007 were being transacted on the market 16 municipal bond issuing having a value of RON 182 million of which seven were new to the stock market in that year as against 6 in 2006. The year for accessing the European Union also represented a record as regards bond issuing (Bacău City Hall), having a value of RON 35 million. This proves that these instruments are believed by the issuers as being more and more an efficient manner for financing the investment projects, and by the investors as an instrument supplying higher interests as against the ones existing on the banking market and having a low risk degree as against the shares on the capital market.

From our standpoint, 2008 is forecasted to be a year with even more bond issuing given that BVB went through tremendous efforts in order to make the city and town halls aware of the advantages of such a financing and of the positive examples supplied by the other successfully made bond issuing. It is expected for in the near future the number of municipal bond issuers to increase but at a lower rate than the ones of increasing issuing taking into account that some city and town halls came back to this financing manner, developing now two or three bond issuing. As the local authorities will be developed from a financing

[143] Calculations made by the authors on dates supplied by BSE, kmarket.ro

standpoint and the economic conditions will allow it, the municipal bonds will increase as maturity and value.

The most important elements provided by the evolution of the municipal bonds in the period of time taken into account for the analysis and that represent also the future trends are **increasing the maturity period (over 10 years) and increasing the issuing value.** Although it is expected that the number of issuing to increase, we can notice that during the analyzed period it was diminished which did not lead to also diminishing the value of issuing made because that town and city halls started to issue bonds to a higher value and having a higher maturity period. If we analyze the value of bonds issued we can notice that if in 2001 there was a value of RON 1.5 million of the bond issuing and a number of 2 such issuing, at the end of 2007 the bond issuing amounted to 3 and they accounted for RON 63.7 million, a significant increase showing the increased interest for such financing type[144]. Another important element that encouraged the municipalities for issuing bonds is the so-called "bridge loan". Due to the fact that the town and city halls have encountered difficulties in spending all moneys, as they come following the bond offer, there appeared this type of credit contracted on 1 to 3 years after which they are reimbursed with the money obtained for issuing bonds. Most times, it is created a consortium between one bank and the intermediary of the bond offer. Today most issuing are preceded by a **bridge loan**. A significant element for developing the bond market and the capital market in general is the existence of powerful and long term investors, such as the **private pensions funds**. According to the regulations in the area that have in view diminishing the risks incurred by the savings of the persons making deposits in these funds, these funds must place an important percentage of their contributions in **T-bonds.** But, right now the newly issued T-bond transactions, but also the ones on the secondary market, take place only on the interbank market managed by the National Bank of Romania. Due to the fact that in Romania the first contributions to the privately managed funds will begin in April 2008, these funds' managers are putting additional pressure on the Romanian capital market in order to make possible listing these financial instruments within the stock market. On the contrary, they will have to make short term investments in T-bonds belonging to the European Union member states and to accept lower yields.

If we take into account the structure of the domestic bond markets, and thus the importance held by issuing different bonds, there can be seen that at the level of well developed states (Japan, Great Britain, Germany, France), but also as regards the less developed countries (Argentina, Brazil, Turkey, Poland, Czech Republic) the registered level of the public sector's issuing is very high with values from 50% and above, reaching even 99% in the case of Turkey[145]. As a comparison, at the end of 2006 Romania had a transacted value of the bonds of USD 55.06 million, of which 83% belonged to the private area and just 17% to the public sector[146].

5. Final conclusions

The public administration can perceive the capital market as a **viable alternative** for financing the financial resources needed. The year 2008 is forecasted to be one with many bond issuing given that BVB went through tremendous efforts in order to make the city and town halls aware of the advantages of such a financing and of the positive examples supplied by the other successfully made bond issuing. It is expected for in the near future the number of municipal bond issuers to increase but at a lower rate than the ones of increasing issuing taking into account that some city and town halls came back to this financing manner, developing now tow or three bond issuing. Next to the municipal bonds, **the government bonds might have a vital part on the local capital market.** The state loans are guaranteed, thus representing a standard for the remaining of bond issuing. These can be inscribed for listing and thus, they can be transacted either on a regulated market, either within an alternative transaction system. For the time being they are missing from the Romanian capital market, but there are positive perspectives that this will change soon and that capitalizing the bond sector will significantly increase.

BUDGET DEFICIT PERSPECTIVES IN ROMANIA

Pîrvu Daniela

Abstract: Although Romania engaged itself through the Convergence Program to reduce its budget deficit to less than 1% of GDP by the year 2011, the recent evolution of the public revenues and expenditures contradict this hypothesis. Compared to our country, the public finance in the European Union member states will improve significantly, as the result of fiscal revenue increase.

Key words: budget deficit, the Pact of Stability and Growth, durable convergence

Introduction

Achieving the public financial balance according to the modern directions allows budget deficit and other state debts. They are assumed by the public authorities through special norms and financed from the loans contracted by the public administration authorities, the external non-repayable funds, and other funds the state may obtain (for example amounts from privatization, state assets valuation, financial placements of public deposits).

The idea of constant budget balance achievement has both supporters and opponents. A low budget deficit may produce unfavourable effects on reducing the gaps between the emergent and developed countries, because developing some sectors as infrastructure, health or education requires high budget expenditures. Therefore the expenditures are the major element the finance procedures should adapt to. Due to the permanent increase of the public needs, the financial effort to satisfy them is increasingly higher. Therefore the public expenditures are increasing on long-term, and the public revenues adapt to this. The budget deficit maintained within certain limits represents the rule of budget planning, a rule enforced by the low financial resources compared to the fund needs, and by the governmental policy view that may consider the public unbalance as an instrument of conjectural economic policy.

Budget deficit theories

The classic theories of budget deficit demonstrates its negative impact on economy (by reducing the national revenue) and living standard of the next generations that have to stand a higher fiscal pressure to pay the public debt. Engaging to budget expenditures higher than the current revenues is an imprudent policy with multiple effects. The increase of internal public debt as the effect of budget deficit financing from public loans may cause the bank interest increase with negative effects on investment credit demands and inflation.

Traditionalists argue that a reduction in the budget deficit will significantly help the economy in the long run. This theory is based on the following logic. When the government runs a budget deficit, it is spending more than it is taking in. In this way, national savings decreases. When national savings decreases, investment-the primary store of national savings-also decreases. Lower investment leads to lower long-term economic growth. Similarly, lower investment is accompanied by higher domestic interest rates, which decreases net exports. Based on this logic, a budget deficit is a drain on the long-term economy.

Traditionalists argue that a reduction in the budget deficit will significantly help the economy in the long run. This theory is based on the following logic. When the government runs a budget deficit, it is spending more than it is taking in. In this way, national savings decreases. When national savings decreases, investment-the primary store of national savings-also decreases. Lower investment leads to lower long-term economic growth. Similarly, lower investment is accompanied by higher domestic interest rates, which decreases net exports. Based on this logic, a budget deficit is a drain on the long-term economy.

The present economic theory suggests that the reasonable public loans in a developing country do not alter the economic growth. If the lent resources are used in productive purposes, the repayment of the accumulated debts should be painless. In case of some high public debts there is risk regarding the country's repayment incapacity that might discourage investments and trouble the economic growth. The theory of excessive indebt was defined by Jeffrey Sachs who suggested that the payment owned to the creditors acts like a discouraging tax for production and that there is an indebt threshold beyond which any debt marginal increase generates a significant reduction of investments, a fact that reduces the future repayment capacity.

The mere existence of a budget deficit, meaning a higher amount of monetary resources in economy, generates inflation. If the budget deficit is covered by monetary issue, the impact on inflation will be even stronger. As the main objective of any central bank is to limit inflation, the monetary authorities will take measures to increase the reference interest that may attract speculative capitals, contributing to the national currency strengthen and consequently discouraging exports. Therefore another consequence of the budget deficit is the occurrence of current account deficit.

The modern theories of budget deficit consider that this unbalance does not have only inevitable negative effects. According to the "Ponzi gamble" theory, a less prosperous future is only a possible consequence of a period with high budget deficits. If the economic growth rate is higher that the debt rate, the budget deficits will be covered by the future economic growth from the general resources. This approach of the budget deficit means to study the average interest rate for the public debt and to compare it with the average economic growth rate. The rational game Ponzi in which repayments and debts are always replaced by a new debt was presented in the studies of Minsky (1982) and Kindleberger (1978). Applying the Ponzi game, the government may increase the living standard because each generation benefits by transfers and no generation pays additional taxes for them. But this point of view cannot be accepted because the budget deficit, even if it does not always lead to fiscal pressure increase, will determine lower investments as the savings will be mainly placed in governmental titles.

The Pact of Stability and Growth

The Pact of Stability and Growth is an agreement between the EU member states through which they adhere to a special fiscal and budgetary discipline, as part of their medium-term economic objectives. The member states in the Euro zone engage to achieve balanced or even surplus national budgets on medium-term. Adopted by the European Council in Amsterdam, June 1997, the Pact has two key aspects:

- a preventive alarm system to identify and correct the budget skid before it exceeds the 3% threshold of GNP was settled in the Treaty for the budget deficits;
- a set of rules to discourage the pressures on the member states, so that they avoid the excessive deficits and take rapid measures to correct them if they occur. The sanctions are applicable only to the states in the Euro zone and value between 0.2% and 0.5% of GNP, according to the degree the reference value of 3% is exceeded. These sanctions carry no interest at first, but if the situation is not corrected in 2 year time, they will turn into penalties.

If the above mentioned budgetary objectives are achieved, the quality of public finance will improve and the member states may release the budgetary resources to encourage innovation, investment, education and new jobs. The evolution of the main financial indicators in the EU countries shows their continuous progress in correcting the excessive deficits.

Financial indicators (as a percentage of GDP)

Year	2002	2003	2004	2005	2006	2007
Euro area

Source: Eurostat, Euro-indicators, 142/22 october 2007, 139/23 october 2006

European Commission, Economic forecast Autumn 2007

*from 2003

In 2006 the largest government deficits in percentage of GDP were recorded by Hungary (-9.2%), Italy (-4.4%), Portugal (-3.9%), Poland (-3.8%), and Slovakia (-3.7%). Ten Member States registered a government surplus in 2006: Denmark (+4.6%), Finland (+3.8%), Estonia (+3.6%), Bulgaria (+3.2%), Ireland (+2.9%), Sweden (+2.5%), Spain (+1.8%), Luxembourg (+0.7%), Netherlands (+0.6%) and Belgium (+0.4%).

Compared to the situation before the Pact conclusion, the number of countries with excessive budget deficits is decreasing. In 2006, the budgetary situation improved significantly: the average deficit in the EU reduced from 2.4% in 2005 to 1.7% (and from 2.5% to 1.6% in the Euro zone), and the debt decreased in both the EU and the Euro zone for the first time after 2002. The EU member states' medium-term objective is to achieve a balanced budget ("zero deficit"), a deficit less than 1% or a budget surplus. In some countries, the surplus revenues from taxation are partially used to finance the expenditure increase, so that the European Committee is concerned with the fact that the member states do not consolidate their public finances rapidly enough, in spite of the favourable economic settings. Therefore the European Committee presented at 13th June 2007 a series of proposals to improve efficiency of the preventive component of the Pact of Stability and Growth:

- extending the field of application for the fiscal supervision in the EU. The advantages of a solid fiscal policy may be better understood if the fiscal supervision falls into a larger economic perspective, for example paying more attention to the internal and external unbalances that might jeopardize the economic and fiscal stability.
- strengthening the responsibility for the budgetary objectives established by the stability and convergence programs. There is high possibility to strengthen the connections between the national objectives and the objectives presented by the EU; for example, the national parliaments and other administrative sectors should involve more in program planning and monitoring.
- strengthening the reliability and credibility of the budgetary objectives on medium-term. The recurrent deviations from the plans risk, if repeating, to injure their credibility. Providing more information on how the budgetary objectives will be achieved according to the expenditure tendencies would facilitate the evaluation of the national fiscal policies.
- achieving a viable budgetary situation on medium-term. This means a better monitoring of the budgetary plan application, as well as a deeper understanding of the budgetary situations that may provide a higher absorption of the population ageing impact.

A slight deterioration is expected in 2008, as the draft budgets for 2008 do not envisage any further fiscal consolidation. Based on the usual no-policy-change assumption, the deficit is expected to broadly stabilise in 2009.

Expectations concerning total expenditure and revenue, general government, in EU Members

Country	Total expenditure, general government (as a percentage of GDP) 2008	Total revenue, general government (as a percentage of GDP) 2008	Net lending (+) or net borrowing (-), general government (as a percentage of GDP) 2008	Total expenditure, general government (as a percentage of GDP) 2009	Total revenue, general government (as a percentage of GDP) 2009	Net lending (+) or net borrowing (-), general government (as a percentage of GDP) 2009

Source: European Commission, Economic forecast Autumn 2007

In the Euro area is expected the further improvement in most countries about continuous deficit reduction. Outside the euro area, the budgetary outlook improves substantially in the Czech Republic (with the deficit now expected to fall below the 3% of GDP reference value in 2008, after the strong deterioration in 2007), Hungary (forecast to reach a deficit of 3.8% of GDP in 2009, compared to 6.4% in 2007) and Slovakia (expected to reduce the deficit in the two subsequent years). For several other countries outside the euro area the outlook also improves, for instance in Bulgaria, Latvia and Sweden. The deficit is projected to widen significantly in Romania (with a deficit above 3% in 2008 and forecast to reach almost 4% of GDP in 2009), while the surplus in Denmark and Estonia declines rapidly over the forecast horizon.

Budget Deficit Perspectives in Romania

Since 2005, the governors have been concerned with the following actions regarding the change of the budget main characteristics:

- promoting a challenging fiscal policy;
- reducing the budget duties by reducing the social insurance contributions;
- directing the funds carefully to the priority policies: education, health, social insurance, transport, infrastructure, regional development, agriculture, research-innovation, national defence.

Through the Convergence Program 2006-2009, the public authorities in Romania made a commitment to support the budget deficit reduction by improving revenue administration and increasing the efficiency of budget expenditures. In consequence, the revenues will show an increasing tendency as a result of the implementation of some measures regarding collecting and administration improvement, taxation extend to field such as real estate market, agriculture, environment and enterprises with state capital's majority. According to the budget projection for 2007, it was meant to reach 1.9% of GDP in 2009 and 0.9% of GDP in 2011.

Given the increase of budget expenditures at a rate higher than the revenue increase and in spite of a significant economic growth, Romania has faced the budget deficit increase lately.

The budget deficit evolution in Romania

Year	2004	2005	2006	2007	2008
General consolidated budget deficit (% of GDP)	-1.22	-0.81	-2.3	-2.4	-2.8

Source: The Ministry of Public Finance

The Government's and the European Committee's standpoints toward this evolution are different. According to the Romanian officials' opinions, a responsible budget deficit reported by the European Committee would mean to fall within the Maastricht criteria, in other words we should not exceed the 3 percents. Maintaining a low budget deficit is a good macroeconomic policy, but it does not support development and gap reduction. For the developed countries, members of the European Union, the restriction 3% of GDP is normal, because it means rigour and sustainable development. But for the lagging countries, the effort of limiting the budget deficit may lower the economic growth. The standpoint of the National Bank of Romania regarding the budgetary policy is more prudent. The recommendations of the National Bank of Romania refer to the quality improvements of the budget expenditure structure and avoidance of their increase in certain periods, in order to limit the budget deficit.

Referring to the objective assumed by the Romanian government through the Convergence Program 2006-2009 (a deficit lower than 1% by 2011) the European Committee estimates that there are small chances to attain it. According to the European Committee's forecast, Romania's budget deficit will reach 3.2% in 2008 and 3.9% in 2009, and our country risks the European funds freeze if it keeps breaking the EU regulations. The estimates of the Committee are based on the pension expenditure rise and the revenue decrease from the social pension contributions, once they reduce with 2% in 2008 and 2.5% in 2009 (to finance the second pillar of the private pensions). The costs of the pension reform, once their private administration is introduced, are estimated at 0.25 of GDP in 2008 and 0.3% of GDP in 2009; they were included in the EC forecasted deficits. The forecast also reflects the Government intention to reduce the insurance contributions with 6% in three stages during the next year, a lowering that will have total impact starting with 2009.

Considering the European Committee's evaluation and the need to provide a sustainable convergence, the following recommendations were made:

- reducing the risk of an excessive deficit by establishing more ambitious budget targets in the future;
- improving public expenditure planning and performing;
- limiting the public expenditure increase;
- strengthening the fiscal discipline;
- continuing the structural reforms;
- adopting policies to eliminate inflationist pressures.

Under the European Committee's pressures, the Romanian government performed the first budget correction, reducing the public expenditures with 1.1 billion Euro. This measure is estimated to reduce the budget deficit estimated for 2008 with about 0.5%.

THE INFLUENCE OF THE LIBERAL CONCEPT "BY OURSELVES" ON THE PUBLIC FINANCE IN ROMANIA

Pîrvu Daniela

Abstract: Since the end of the 19th century, the Liberal National Party engaged to rectify the economic situation by itself without resorting to external loans, but running the policy "by ourselves", a policy of budgetary austerity and public expenditure limitations from fiscal revenues, encouraging the state's economic function. The liberal budgetary policy mainly relied on revenue increase from public wealth increase. This budgetary component of the liberal economic policy kept running until the first interwar decade, contributing to the normalization of public finance during the national economic crises. Similar measures were recommended after 1989 to adapt the Romanian public finance to the market economy requirements. But often their application was delayed by the respective political climate.

Key words: provision, initiative, normalization

Introduction

The consolidated domestic capital accumulated by the Romanian bourgeoisie at the end of the 19th century and the beginning of the 20th century generated many disputes regarding the optimal relation that had to be established between the external and internal capitals, so that the national economic development should not be troubled by the foreign interference. At first, the concept "by ourselves" meant a policy to develop the country's productive powers by themselves, without refusing entirely the foreign capital. After the World War I, according to the principle "by ourselves", the liberal leaders proposed a policy of prevention and national initiative in all fields of activity, including the public finance.

Romanian financial policy directions during the interwar period

The end of the World War I generated new challenges for the Romanian public finance which faced since the beginning of the military conflict major problems determined by:

- the large number of public officers that worked 4-5 hours a day to reduce expenses;
- the low taxation base;
- the high financial efforts to equip the army.

Therefore the financial period 1916/ 1917 ended with a 467,506 thousand lei deficit (363,556 thousand lei budget revenues and 831,063 thousand lei budget expenditures) [Axenciuc, V., 2000: 620]. Considering the other external and internal loans contracted by the Romanian state since the beginning of the war, there was a significant pressure on the state budget: 564,477 thousand lei consolidated internal loans, 250,000 thousand lei floating internal loans, 1,571,820 thousand lei consolidated external loans and 312,652 thousand lei floating external loans [Romania's Encyclopaedia, 1944: 773].

The financial situation in Romania could generate, according to the Minister for Finance Vintilă I.C. Brătianu, dangerous and damaging consequences for the country's economy that "settles only available foreign elements" [Brătianu, I.C. Vintilă., 1916: 6]. Therefore the success of the policy of prevention and national initiative planned by the Liberal National Party according to the principle "by ourselves" depended mostly on the rapid settling of the severe budgetary and financial problems mentioned by the liberal economist. Vintilă I.C. Brătianu stated that Romania's economic policy should have relied mostly on the internal financial resources and not on the foreign loans [Brătianu, I.C. Vintilă., 1916: 6].

Even since 1913, Vintilă I.C. Brătianu declared in favour of a prudent financial policy and the need to change the budget planning procedure. He thought that the budget revenue evaluation should take into account "not only the average of the last 3 years, but also the country's economic situation when planning the budget" [Brătianu, I.C. Vintilă., 1916: 11]. Also he expressed concern regarding the tendency of excessive centralization of public funds and the increasing number of officers that exceeded the real administration needs.

Following the concept "by ourselves" to introduce the principle of economy in public money use and to size properly the budget expenditures, the liberal economists proposed the following recommendations even since 1916:

- establishing an institution to coordinate the different budgetary projects in order to keep constant the state expenditures;
- reducing the sizable differences between the central and local expenditures;
- organizing commercially the operations of state-owned domains and goods;
- introducing the obligation to publish the local administration budgets.

During the first years of interwar liberal government, the budgets were conceived according to a severe saving form of government; the priorities were the reduction of public officers and the reorganization of public services. The budget revenue evaluation according to the previous year takings and the expenditures kept within the severe limits of ordinary revenues were meant to attain the budget balance and to cover the expenses of national economy endowment and recover from the budget surpluses. The liberal financial plan proposed for the year 1922 intended to:

- adopt some measures to satisfy the country's urgent needs (coordinating general and local administration, increasing productivity in state-administrated sectors, introducing the principle of order and economy in commercial services and their reorganization to increase their profitability and adaptability to state's requirements, reducing the budget expenditures by increasing the role of private initiative in certain fields of activity, and organizing a more efficient control on public expenditure engagement and completion);
- amend the fiscal legislation made by Nicolae Titulescu in 1921, in view of reducing taxes, so that the fiscal reform in Romania showed two essential characteristics: to be simple because "the Romanian taxpayer is not educated yet to record his income to the last centime" [Brătianu, I.C. Vintilă., 1922: 11] and not to hinder the country's economic development through too high fiscal duties.

The new fiscal and modern system started in 1923 that could satisfy the public financial needs and did not discourage the economic activities was not spared by the critics. For example, Virgil Madgearu, an economist representing the Peasant Party, considered that the fiscal system established by the law in 1923 encouraged the industry to the detriment of the other economic branches and favoured the bourgeoisie through the low taxes for the high incomes. To the problems reported by Virgil Madgearu, Vintilă I.C. Brătianu answered that there is not an income concentration in a small social class in Romania to justify a progressive taxation for the high incomes. On the other hand, the liberal economic policy aimed at stimulating the domestic capital concentration, so that the Romanian enterprises could face the competition on the internal and international market. Thanks to the reform of public services and financial legislation, the financial period 1922/ 1923 showed a significant progress in consolidating the Romanian public finance.

Consolidating Romania's external debt

To settle the financial problems of our country after the World War I, Romania's foreign debts had to be arranged and the amounts for war recovering owned by the Central Powers had to be collected. On the other hand, some urgent measures had to be adopted to achieve the budgetary union and the fiscal reform.

As Minister for Finance, Vintilă I.C. Brătianu involved directly in resolving those problems that he considered to be the priorities of protecting the national interests. He gave well-informed notice to the governments of the allied states about the structures and sizes of the Romania's loss during the war and protested against the small recover share of damage claimed from Germany. Together with other Romanian officials, Vintilă I.C. Brătianu made many approaches during the international conferences for war damage assignments to postpone Romania's terms of payment established in different treaties and to collect the debts from the former enemies. The Romanian authorities' requests to postpone these terms were rejected and at the time the national economy needed important financial resources to recover and endow. This was another reason for the liberal governors to redirect the economic and financial policy during the post-war period. The attitude of the great European powers toward the problems of our country strengthened Vintilă I.C. Brătianu's belief that the liberal formula "by ourselves" had to be applicable in the financial field, too. The Minister for Finance was convinced that Romania's chances to attract resources such as external loans were very small after the war, and declared in favour of joining together all national elements so that "what has to be done can be achieved only with our competence and work" [Brătianu, I.C. Vintilă., 1927: 40].

Considering the sizable implications of the internal debt on the budget balance and the balance of external payments, the consolidation of Romania's floating external debt was essential to normalize the public finance and to improve the general economic situation.

The problem of consolidating Romania's floating external debt was wide press covered at the time and the public opinion could learn the Minister's for Finance point of view and the critical position that doubted the opportunity of that operation. The objections against the floating external debt were expressed and synthesized by I. Dobrovici in the press of the time. They referred to the following aspects regarding the terms of the loan to consolidate that debt [Dobrovici, I., 1934: 416]:

- the high amount supported by the Romanian state to pay the interests, since the consolidating loan amortization would begin after 6 years;
- the customs export taxes were most affected, as they would be cashed only in gold or foreign hard currency, in order to guarantee the annuity payment;
- the National Bank made a commitment with the foreign banks, at the request of the Romanian state, to pay the annuities of the contracted loan if the public authorities had not have the necessary financial resources.

Without reducing the importance of the critics against the liberal government, Vintilă I.C. Brătianu's measure was the first step to reset Romania's credit abroad after the World War I. Moreover, Vintilă I.C. Brătianu himself stated that "you cannot ask for money from those you have not yet paid the debt to or at least made it steady" [Brătianu, I.C. Vintilă, 1925: 39]. Therefore the possibility to attract future financial external resources depended on how the problem of our country's external debts was solved.

Romania's external debt to the governments of the USA, France, England and Italy was consolidated during the period 1925-1928, by budget registration and regular annuity payment of the external debt determined by the war and its consequence liquidation [Văcărel, I., 1998: 17].

During the liberal government, the idea of financing the Romanian economy with foreign resources was disputed when the economic legislation was changed in 1924. In order to make the liberals give up their economic policy based on the principle "by ourselves", the great European powers tried to change the regime of foreign capitals, considered to be discriminating, in exchange of the external loans necessary to recover our economy. The officials of the states Romania was financially indebted to offered to facilitate the conclusion of some concession contracts for the oil fields of the Romanian state, in favour of some foreign companies, so that the liberal government could pay the external debts from those dues. This treatment made the liberal Minister for Finance to state many times that: "to say to the foreign creditors that we can recover only with their help means to beg and not to strengthen our country's financial situation" [Brătianu, I.C. Vintilă, 1923: 11].

Respecting Charles Rist' financial policy recommendations, Vintilă I.C. Brătianu applied, during his six years of governance, the principle of compressing the state's needs, according to which the amount of public expenditure had to be reduced to the level of revenues. Meantime, this component of the financial and budget policy promoted by the liberal economist lowered the possibility to assign resources for some productive investments that could contribute to a more rapid recover of the Romanian economy. On the other hand, the principle of budget balance disciplined the expenditure assignment and along with the fiscal policy measures provided the continuous increase of takings. This was an important step in consolidating our country's financial situation.

Liberal economic doctrine influence on contemporary evolution of public finance

The motto "development by ourselves" launched by the Romanian liberals even since the 19th century did not mean to separate from the rest of the world, but to trust in our own strengths, so that the Romanian economy could produce more and better, to be active in the European and trans-European economy, and not to wait for foreign help, but to see what could be done "by ourselves' to improve life quality. After

1989, these principles of economic policy have been forgotten. Waiting for the welfare generated by Romania's opening outward, the Romanian politicians could not set a precise direction of economic evolution, so that the measures of financial policies were sometimes contradictory. The major macroeconomic unbalances amplified by the lack of some consistent reforms generated budget deficit increase. The budget deficit was caused by the budget expenditure increase given the economic decline, the poor capacity of revenue collection, and the insufficient transparency of the budget period that generated an inefficient use of the financial resources. The attempts to increase the budget revenues were mainly counteracted by the increase of fiscal evasion and/ or arrear accumulation.

Only by the end of the 90's a substantial fiscal adjustment was made by reducing the primary expenditures and increasing the taxes. In consequence, the consolidated general budget deficit and the current account deficit improved. These results were achieved mainly to the recommendations of the international financial community, especially the International Monetary Fund. Otherwise the relation with IMF was defining for the Romanian governments' economic policies. The doctrinaire turnaround of liberalism characterized by minimal state agenda, the liberty to choose and the responsibility of the 19th century second half influenced the financial policy measures promoted by the international financial organizations to recover the economy in certain countries. Some measures similar to those promoted by the Romanian liberals during the interwar period were recommended to restructure and increase the competitiveness of the Romanian economy after 1989: permanent revenue increase, strengthening the fiscal administration, widening the taxation base, and reducing expenditures. The evolution of some financial indicators in the period 2000-2007 show the budget process improvement by developing a credible environment, but also the hesitations in adopting some expenditure limits lately.

Financial indicators (percent of GDP)

Year	2000	2001	2002	2003	2004	2005	2006	2007*
Revenues	31.2	30.1	29.6	28.7	30.1	30.2	31.2	33.5
Expenditures	35.3	33.3	32.3	30.9	31.1	31.0	32.9	36.3
General balance	-4.0	-3.2	-2.6	-2.2	-1.0	-0.8	-1.7	-2.8

In IMF's and European Committee's opinions, Romania's growth deficit and its volatility after adhering to the EU represent a risk for the macroeconomic and financial stability. The recommendations are as follows:

- reduce the excessive deficit to limit the risks regarding the long-term viability of public finance;
- control the public expenditure increase and re-examine their structure to improve the economic growth potential;
- a proper salary policy in public administration.

Conclusions

The financial policy according to the liberal doctrine during the interwar period had an indisputable positive impact on the budget revenue size and structure, and Romania's economic and social development after the World War I was mainly based on budget balance.

The main directions of the financial policy provided by the actual Liberal National Party's programs demonstrate that, at least theoretically, there is still a connection with the past. The policy to reduce progressively the general fiscal level has been promoted since 2005. There was an attempt to reform the public expenditure: reducing them by eliminating the subventions for price differences, eliminating the budget subventions for the enterprises that showed loss, reducing the public investments for unproductive activities or activities of low social profitability. In fact, after Romania's adherence to the EU, the liberal

* IMF estimates and projections

government stated that it would use to the full the budget deficit of 3% of GDP (agreed through the Maastricht Treaty) to finance the development projects of infrastructure, environment and agriculture and to reduce the gap between Romania and the other EU member states.

SOME ASPECTS REGARDING MULTINATIONAL ENTERPRISE

Popa Daniela

Universitatea Româno Germană Sibiu, Facultatea de Ştiinţe Economice şi Calculatoare, 550324 - Sibiu, Calea Dumbrăvii nr. 28-32, dana.popa@xnet.ro, 0723-240520

Abstract: Firms engaged in international trade, but they produced their output only at home. In this paper, we turn attention to the phenomenon of the international company, which Romania had not enough. Traditional trade theory offers few reasons why companies should become international and conduct foreign direct investment. We seek to understand these issues here. Economics has much to say on the subject. In the beginning we provide some brief background, the we define the multinational enterprise and discuss general principles governing location, production, and sales decisions by multiplant firms. We then explore the main characteristics of the multinational enterprise.

Key words: Multinational enterprise, foreign markets, market imperfection

The growth of international companies has been a marked feature of the twentieth century. The world's largest 200 private sector companies, defined by sales, today enjoy a combined turnover approaching one third of the world's gross domestic product [1]. Most of these firms operate on an international scale. In the 1920s, 1950s and 1960s, foreign direct investment was dominated by US firms. In the 1980s, Japanese firms have made much of the running, most often in the forms of new plats in foreign countries rather than foreign acquisitions. Large parts of US business are now owned by Japanese, British, Canadians, Germans and Arab countries concerns. Foreign ownership is still more marked in Australia, Canada, and Latin America, but much less so in Japan.

Most large Europeans countries have tended to confine production to their home base or to other continents, but since 2000s we have seen a big step forward to the East European countries. Cross-border mergers and acquisitions were comparatively rare in Europe a decade ago. The Anglo-Dutch giants, Shell and Unilever, the Volkwagen-Seat link, and the strong Swiss presence in food products and pharmaceuticals are not typical. It seems likely that this may change with the European countries. But at present most large foreign subsidiaries operating in Europe are American owned. France, the UK and Germany are countries where foreign direct investment by domestic companies roughly balances inward investment by foreign firms. The USA and Japan, and now Arab countries, have been major net exporters of capital in this sense, with Japan increasingly overhauling the USA. Many developing countries have hosted inward direct investment by foreign firms, but several have recently started to spawn international companies of their own. This phenomenon is explored by Lal (1983) [2].

Yet international companies are not new. By the end of the nineteenth century, many of Britain's leading firms had spread tentacles over large parts of her overseas empire, particularly in the fields of banking, confectionary, engineering, insurance, mining, shipping and tobacco. The sixteenth and seventeenth centuries saw the emergence of great Portuguese, Dutch and English trading companies, with vast networks of offices, trading posts, and factories spread around the globe. They were preceded on a smaller scale by Genoa, Venice and the Baltic Hansestaedte, and long before that, the Carthaginians, the Phoenicians and the Greeks. The phenomenon usually begins with trade. But the trading companies moves swiftly to establish a strong physical presence in the host country to preempt supplies from competitors. The host country's residents have always had varied reactions to foreign companies. Some welcome them as a channel to technological know-how and wealth. Others see them as latter-day Vikings bent on pillage. These complex attitudes persist. The hope of lucre is tinged with fear of sovereignty. Opinions in the capital exporting country, whose companies internationalize their operations, are simply mixed. The prospects of higher and steadier profits, and considerations of national prestige are qualified by apprehension for exports, wages, jobs and dissemination of advanced domestic technology. Governments everywhere are as excited by the thought of attracting foreign capital as they are fearful that tax revenues will be lost if the prices of intra-firm international transactions are warped with the aim of minimizing global tax payments. In the USA, the traditional home base for most of the world's largest multinational enterprises, there have been growing worries about the scale of recent inward direct investment and acquisitions by foreign firms. Some are concerned at the thought that foreign companies are buying up US businesses to drain off superior US technology. Researchers suggests, however that such fears may be unjustified.

Multinationals tend to fall into one of three categories. Horizontally integrated multinationals are firms with national branches of an enterprise producing largely the same product. American car companies and fast food chains are examples.

In vertically integrated multinationals, the output from one national plant provides an intermediate input to another national plant, all under common ownership and control. Until recently, multinationals in the oil industry were an instance of this: crude oil is extracted in one country, refined in another and marketed in a third. In Romania, in recent years we saw a big number of vertically integrated multinationals, especially in automotive and car producing industry.

Diversified multinationals are firms with national plants the outputs of which are neither vertically nor horizontally integrated. The Nestle Corporation in Swiss owned but 95% of its production is outside the country: it is involved in foods, restaurants, wine and cosmetics. The number of diversified multinationals is growing rapidly.

A company can be multinational in at least three senses. It can sell in more than one country; it ca run plants or own subsidiaries in two or more countries; and it can be owned internationally, with quotations on more than one national stock exchange, for example. Many large companies are multinational by all these definitions. But for our purposes the most important test of multi-nationality is production. Let us define an enterprise as multinational if it owns or runs production facilities in two or more countries. Multinational enterprises on this definition are responsible for much of the foreign direct investment undertaken throughout the world. We know why countries should trade with each other. Still, these explanations take a very limited local view of companies' production behaviour. But just because a theory does not explain every real world phenomenon does not mean that it should be discarded. The principle of comparative advantages is extremely important, whether or not there are multinational enterprises. If the theories are found to be deficient because they do not explain an important phenomenon, the assumptions made in the model must be examined: this is usually the source of the deficiency. When discussing the notion of comparative advantage we could assume that all firms are perfectly competitive and had equal access to the international markets, independent of their country of origin. We have to relax these assumptions if we wish to identify and explain the economic attributes of the multinational enterprise. In fact, we shall see that multinationals do not undermine the concept of comparative advantage. They underline it. For comparative advantage plays a vital role in the multinational's location and trading decisions. A multinational enterprise exists precisely because these assumptions (perfect competition and equal access) may not hold. One can explain the existence of the multinational by acknowledging the existence of certain types of market imperfection in the international economy.

We can note two points that increase the reason for establishment of overseas plants. First, multinationals are typically oligopolists, that is, the output and pricing decisions of firms in a particular industry are interdependent. We can observe that multinationals enjoy market power. The market form in which they operate is usually one of international oligopoly, with elements of monopolistic competition. One possible reason for this is the sizeable setup costs that are involved in establishing an overseas plant. Only larger firms will be willing to incur these costs. Firm size obviously correlates with market power. The establishment of overseas subsidiaries is hardly comparable with the strict conditions of perfect competition. In a perfect competitive industry there are many independent small firms enjoying common access to knowledge. The element of oligopoly power provides some insight as to why certain firms choose to establish cross-border plants. Entry barriers are crucial in maintaining a high profit. If these come to be eroded in the domestic market, then the firm may find it best to set up plants overseas. This argument is false in a world of full information: firms will go overseas anyway, regardless of domestic developments, if there are profits to be had by doing so. But it becomes appealing when information and decision-making costs are taken into account. The expected adverse trends in home profits, due perhaps to increased competition from rivals, will shake a firm into scrutinizing its options carefully, something it would be less likely to do had conditions been tranquil. The outcome could be the discovery that costs are low enough abroad. Foreign direct investments will follow. We can discuss now the case of Nokia, who had relocated a production plant form Bochum, Germany to Jucu, Romania. The movement of the factory became more cost effective in Romania, because of the low work costs here. Nokia announced the cut back of number of jobs (form around 6000 in Germany to around 3000 in Romania) and then calculates that the work related costs here were smaller. Since the ultimate goal of a company is profit, the movement is truly correct. Of course, the social impact on German work force is strong, but we could predict (on a long scale term) that the same thing could happen in Romania. If Nokia will find a lower cost of labour somewhere else, the company will probably relocated there its plant, regardless of social distress produced in Jucu region.

It is assumed that in the decision to set up a plant overseas, locational efficiency conditions have been met. Considerations of locational efficiency, that is comparative production and distribution cost considerations, obviously help to explain where production occurs. But it cannot be only factor at work. If it were, one would have to ask why a host country firm is not producing and exporting the goods. The multinational firm has to have some specific advantage that gives it an edge over potential indigenous producers. There are some reasons for setting up overseas plants. Prominent among them are the importance of gaining access to a particular market, the desire to spread risks, and adverse trends in home-market. There is obviously no single factor at work.

There are many explanations for why firms may choose to establish an overseas plant, all of them essentially related to some form of market imperfection. Such imperfections in turn cause the firm to internalize the market, a concept that we try to explain below. The market imperfections include the following:

- Barriers to international trade due to the tariffs and other barriers to trade mean that not all firms have equal access to the same market. Provided locational efficiency conditions are met, the establishment of the plant in the protected country is one way of overcoming these barriers.
- Market imperfections in the supply market arise from imperfect competition or imperfect information. Suppose that the supplier of a crucial factor input in a firm's production process has some monopoly power. Then the purchasing firm may confront problems such as price discrimination and it will certainly pay a higher price for the input than it would have done under condition of perfect competition. In these conditions it may pay the firm to internalize the supply network by buying up the supply source: making the supplier the part of the buying firm's production process. If the supply firm happens to be located in another country, then the purchasing firm becomes a multinational.
- Product differentiation may also lead to internalization. Suppose that some crucial factor input is supplied by a number of firms, but the products of each of these firms are slightly differentiated. Then the buyer of the product will face a large fixed cost in switching from one supplier to another because of the costs of testing or adapting to new varieties and/ or differences in the organizational structure of the selling firms. In the presence of switching costs, it is in the interest of buyer and seller to enter into a long term "arm's length" contract, which is a contract formed between separately owned firms. With terms specified in advance to take account of every possible contingency. But negotiating such a contract will prove very costly. The alternative is internalization of the intermediate product market.
- Less than perfect information regarding supply is a problem if the supplier of the factor input is external to the production process. Suppose that buyer had less than perfect information on the price and future availability of the input and the supplying firm does not provide all the information (for example, on future price development). If such behaviour is potentially very costly for the buyer, then internalization will ensure that the firm has the most information available. It may be especially important for firms relying on raw materials in the production process, where prices are highly volatile and accurate information on price is very important.
- Presence of increasing returns for the multinational, which transcend any scale economies at the level of individual plants. There could be monopsony power in the market for raw materials and cost savings for coordinating inventories and research and development activity, or economy in the transportation network when the shipment of goods extends beyond the output needs for a single plant. Finally, there may be scale economies from the pooling of the capacities of the different national plants to meet local demand fluctuations. All these are examples of positive externalities between plants, which only an integrated firm, as multinational is in position to exploit.

- Difficulties in trading a firm's intangible assets may explain the establishment of plants across national boundaries. Knowledge is one example of an intangible asset. The firm may possess knowledge of how to produce a cheaper or better product at given input prices which permits production at lower costs. It may take the form of a patented process or design or it may be less formal, involving the know-how shared among the employees of the firm. Marketing skills permit a firm to differentiate its product from those offered by competitors. Managerial skills lead to more cost-effective production. Why is a firm unable to trade some of its intangible assets? The answer is that the traditional market concept may break down in this case. The market fails because there is an important characteristic of intangible assets, which prevents them from being traded in the usual way: the one-sided or asymmetric information aspect of intangible assets prevents there being an efficient market in them. Intangible assets have some attributes of a public good because knowledge or informational advantages are important features. If a piece of information can be used to the firm's advantage at one location, it can be deployed profitably at another without a reduction in knowledge at the original location. The marginal cost of using the knowledge in the production process is zero. Attempts to trade the intangible asset on the open market are likely to fail. For example, suppose a firm tries to sell its intangible asset to another firm. The intangible nature of the asset will mean that the potential buyer is unable to assess the true value of the proposed purchase. If the selling firm reveals the details of why the asset is valuable, the buyer obtains knowledge that has not been paid for. A further problem is the fact that the commercial value of the information, even if it could be established, depends on how many firms are to purchase it, and when. So a firm may be endowed with an intangible asset it might like to sell some off, but cannot. It may have, for example, an excess capacity in managerial skills. It may be profitable to "internalize" the market for intangible assets by selling up other plants, if they meet the test of location efficiency. If conditions point to an overseas location, then the firm becomes a multinational.

The firm has three choices: it can serve a foreign market by exports from its domestic production base; it can license other firms to produce abroad; or it can set-up production facilities of its own overseas. Asset intangibility does not always give rise to the third option of foreign direct investment. If the intangible asset can be embodied in the product without adaptation and if plant level returns are strongly increasing and international trade barriers weak, then exporting is the best method for penetrating the international market. It is worth stressing that multinational production is not necessarily a substitute for exports from the home base. If the intangible asset takes the form of knowledge of a specific process or product technologies that can be written down and transmitted, then foreign expansion is likely to take the form of a licensing: a local firm is licensed to manufacture the company's product in return for royalties and other form of payment. But the firm may find that such a strategy eventually leads to the growing of competitors.

If the intangible asset is inseparable form the firm itself because of the strong public good element in it, then the market fails and the firm finds it is unable to unbundled these skills: the answer is foreign direct investment. The choice between the licensing and foreign direct investment also depends on other considerations, above all the "market solution" bedeviled, as we have seen by the difficulties in drawing up appropriate contracts. The non-market solution for foreign direct investment can suffer from other disadvantages. How is the foreign subsidiary to be monitored and controlled? How much latitude should its managers be given? Should their rewards be related to results, or should the parent company offer them some form of implicit income insurance against risks?

One advantage of foreign direct investment is the reduction of risk through international diversification. Popular saying " do not put all your eggs in one basket" applies at its best here. Much of the systematic or general market risk affecting the corporation is related to the business cycles in a firm's national economy. By diversifying across countries the economic cycles of which are not perfectly phased with the home country, the variance I the firm's overall earnings and cash flows can be reduced. However, many of the political and economic risks specific to the multinational enterprise are unsystematic. Diversification cannot help here. More important, various market imperfections may deny individual investors full access to the international capital markets. Information barriers and legal economic considerations (tax regulations, currency controls) may prevent individuals from fully diversifying their portfolios. Investment in the stock of a multinational is a means by which these imperfections can be overcome. By setting up foreign subsidiaries, the multinational gives investors a geographical spread of risks on their assets more cheaply than they could obtain on their own. Asymmetric information is also relevant here: the multinational can be thought of as an institution rather like a bank, which specializes in exporting private unmarketable information about the particular set of products and markets with which it is involved.

To summarize, the multinational enterprise, or the predominant form of foreign direct investment, is the response of the oligopolistic firm to:

- Market or international capital markets, or imperfections which can arise in the intermediate products market; because of market failure associated with intangible assets.
- The need to achieve economies of scale that extend beyond national plants;
- Government barriers to international trade that deny equal access to markets.

Companies have become multinational for many reasons. Transport costs favour international dispersion of production facilities. Although increasing returns at the plant level make for geographical concentration, there are numerous reasons why they may relate to the firm and not just to its individual plants. If they do, the international company will be admirably placed to exploit them. Tariffs set by individual governments pay a key role too. Also, individual investors will often find that stocks in multinational enterprises give a better risk-return trade-off in their portfolios that an assortment of shares in the different national firms in different countries. Asymmetric information issues are one aspect of this. They also explain why companies often choose to set up overseas subsidiaries rather than license production by foreign firms, and at the same time, why such firms structure their worldwide operations in the different ways that they do. Asymmetric information considerations, and associated game-theoretic concepts, lie at the heart of every facet of the multinational enterprise: its internal operations and transactions; its external dealings with customers, suppliers, rival firms, and national governments; even the reason for its existence. It is also to be regretted that the existing literature on multinational companies by and large ignores them.

Like the great international trading monopolies of earlier centuries, today's multinational enterprises are almost states in themselves. Some generate turnover far in excess for the GDP of smaller countries. This is an appropriate point, therefore, to turn from the microeconomic analysis of international activity to the macroeconomic.

ABSTRACT: The time-honoured financing system of the European Union favours a certain looseness of budgetary responsibilities; while the increase of expenditures seems to be a purpose for itself for the European Commission and the European Parliament, the member states make their net balance the reason for their distinct positions on common policies.

By and large, the current own resources of the European Union formed by agricultural taxation, customs duties, VAT resource and the complementary resource on GDP correspond in fact to simple financial transfers of the member states into the communitarian budget.

The advantages of a reform of the own resource system are numerous despite the difficulties of implementation.

Key words: own resources, reform, unique communitarian taxation, net balance

The resources proper to the Community are the rights in the custom and the agricultural sampling (recently qualified as „traditional" proper resources) as well as the additional resource consisting of the equable contribution of VAT of the state members and the resource based on the GBI of the state members.

The agricultural sampling, the additional or compensatory taxes and other rights established or those to be established by the communitarian institutions regarding the sugar sector were perceived on the import of different agroalimentary products from other countries in order to raise the price to the level of the communitarian one as well as on the products with superoffer. They represented during the period 1962 – 1971 the only financial resource for the communitarian budget destined mainly to the European orientation and agricultural warranty fund.

The common custom taxes and other rights established or those to be established by the communitarian institutions on the trades with other countries were carried into effect starting with the 1st of January 1968 in order to harmonise the import or export rights adequate to the exterior frontieres of the European Communities. The custom taxes and the agricultural sampling are gathered through the national administration of each state member after the sampling of the 25% part according to the perception expenses. The contribution to the communitarian budget of the ammounts accomplished by this resource had an interesting evolution: in the beginning (in the year 1971) they represented 25% from the total incomes of the communitarian budget, a few years later they grew amaizingly reaching 48% (in 1977) and then they went continuously down so that in 2006 they represented only 15,87%.

The resorces resulting from the VAT owed by each state member are obtained by applying a fixed share of 0,5% on the calculation base for the VAT, determined eqaualy for every state members. This calculation base cannot overtake 50% from the NGP of the state member[147].

The fourth category of the proper resources based on GBI of the state members destined to take into account the contribution capacity of the state members was introduced in June 1988 through the packet Delors I. This proper resource is the resource budget balance.

In essence, the present proper resources correspond in fact to some simple financial transfers of the state members on the communitarian budget, when the resouce VAT and NGP represent 81% from the total incomes of the communitarian budget. In a nutshell, opposite to the ambitions of the author of the Rome

treaty, the financing of the communitarian budget is nowadays ensured through masked national contributions[148].

The reform of the communitarian budget always strikes an intrinsic conservatorism, despite the fact that it represents a challenge on political plan.

Although the present financing system accomplished to provide sufficient resouces for financing the communitarian budget, the debate although goes on regarding the possibility to improve it in order to respect in a great part the relevant financial principles (the conomic efficiency, fairness, stability, vizibility and simplicity, the efficiency of the administrative costs, the financial autonomy). The extension of the Union through the continuation of the integration however announces hardly bearable budgetary efforts for the European Union. The introduction of an integrated administration of the frontiers, the development of the cooperation as regards the defense, the promotion of certain common politics at the level of the Union (of research, of transports), increasing the operations of adminstrating the crises, all of them confer new dimensions to the communitarian budget.

The two main sources of income: the proper resources based on VAT and on the GBI contain many characteristics of the national contributions, they are provided by national treasury and are sometimes presented as expenses places in the national budgets. In sequence, the state members have often the tendency to judge the politics and the communitarian initiatives in terms of profit in report to the national contributions, in stead of evaluating firstly the global value of accomplishment of certain politics at European level.

The proposal of the Commission reffering a new decision regarding the proper resources, in spite of the fact that it has been meanwhile approved by the Parliament, is still blocked in the Council by the state members that had initially been in favour to this decision, but they oppose in the present to its application on their territory.

In May 2006, it has reached to an agreement between the European Parliament, the Council and the Commission according to which the Commission must accomplish a fundamental recesion of the EU budget. The European Commission will examine the way in which the budget functions and in which the best balance can be obtained between continuity and response to all the new challenges as well as the best method to provide the necessary resources to finance the EU politics and if these work the way in which it should function in a Union with 27 state memebers.

The report of the French deputy Alain Lamassoure regarding the future of the proper resources of the European Union which was approved by the members of the European Parliament in the 12nd of March 2007 proposes a reform in two stages:

- ***The first stage***: the new system will be based on the internal gross income: each state member will contribute with approximately 1% of it. The abolition „of every budgetary advantage for each state member" will be a key element of this period and will include the abolition of „the British cheque" until 2013.
- ***The second stage*** *anticipates the gradual introduction* of an authentic system of proper resources that should replace from 2014 the national contributions. This system will be able to includ already existent taxes in the state members, for instance the share part of the participation to the VAT payments or the share part on the energy consumption. Other options would be the taxes on financial transactions, on transport or telecommunication services, the "eco" tax. The fiscal sovereignty will further belong to the State Members.

Every reform of the proper resouces system will be a delicate and difficult exercise which will be put into application with the help of the Parliaments of the state members. The first stage, temporary and of transition, would have as an end the improvement of the present system of national contributions for which it should be put into application the following political principles:

- Equalty between state members: the absence of every budgetary advantage for evryone of the state members;
- Simple presentation for the elected representatives and for the citizens: the importance of presenting the improved financing system in the most simple way so that it should be intelligible and transparent for the european citizens;

[148] www.taurillon.org *Apres la monnaie unique, l' impôt européen?* Pierre- Marie Giard

- Equal solidarity and dignity between the state members: these principles are destroyed by garding some advantages in favour of some, meanwhile others are compensated by humiliating negotiations behind closed doors at the reunions of the European Council;
- Establishing a political connection between the reform of incomes and the recension of the expenses, as it is included correctly in the Interinstitutional Agreement.

But according to the opinion of the European Court of Accounts it is very difficult to accomplish a thoroughly studied reform of the proper resources system of the Community, if the discusions in this sense are associated directly with negotiations regarding financial limits and the amounts that are to be allocated to communitarian politics according to multiannual financial perspectives (as it repeatedly happened).

The goal of the Community's income reform must be the creation of an authentic proper resource in order that the European Union should replace the existent mechanisms. A general accord has been created regarding the fact that the moment hasn't come yet, in the context of a short term vision, for the assessment of a new communitarian tax; yet, it is underlined that this doesn't exclude the possibility of, even if the state members decide to perceive new taxes, they can in the same time or later decide the authorisation of the Union to benefit directly of the new taxes.

The creation of a system of proper resouces based on an already perceived tax in the state members, so that this tax should be partly or entirely swerwed directly to the communitarian budget, would establish a direct connection between the European Union and the European citizens and would contribute to the harmonization of the national legislations in the fiscal field.

The financing of the European Union by a communitarian tax put in charge of the tax payers and not of the public treasuries of the state members is an older problem, but the debates in this field go on even nowadays.

If the EU budget shouldn't been satisfied with the marginal contribution to the financing of the public politics, but it would become a real significant instrument of budgetary and economical politics, then, some say, only a financing by a communitarian tax would allow the European Union to assume itself these missions in a satisfactory way alongside with the states and the local managements. Such a tax is presented as a reinforcement factor of the democratic sense in the European Union and in the European citizenship, by the reassertion of a fundamental principle of the fisc, that is that of the consent to the tax, by clarifing the competences and the responsabilities of the involved institutions and by the relegitimacy of the budgetary authority of the European Parliament. The expected advantages are as well of budgetary order. The present system of proper resouces of the European Union seams really very complex, impenetrable and of nature to advantage an approach only bookeeping based on the level of net credit of ecah state member. A communitarian tax shouldn't lend itself to such an individualistic logic and would diminish the perception that the European budget has the quality of a redistribution instrument.

On an institutional level, the continuity of the assertion of the European Parliament as well as of the co-law giver wouldn't allow to be deprived of any power on the EU's incomes. Voting the dimension of the procentual shares and the object of imposing for a communitarian tax, it would benefit of similar prerogatives to those of the national Parliaments and EU could assume the responsability of its action in front of the European citizens. The European Commission and the Parliament would have a more important responsability to determine the procentual dimension and the taxable object of a sampling from the families and the enterprises' incomes.

The first justification of economical nature for the development of the European fisc is linked to the desire of correcting „negative externals" that occur from the existence of some heterogeneous fiscal politics. The fiscal competition with damaging effects could also be diminished through the sampling of a European tax on the aimed taxable bases, especially the most mobile ones as the very well qualified work ant the capital. Among others, according to the economic theory, a communitarian tax would also constitute an instrument adapted for financing the common goods offer which all the European citizens should take advantage of (the European defense, transeuropean networks or the control of the exterior frontiers). The financial support of creating a unique communitarian tax is less important because, opposite to a wide spread idea, Europe doesn't need new budgetary resources. The GBI resource is calculated in such a manner that the budget should be always balanced, this being an advantage almost unique in the world that makes diminish regularly the importance of these resources. This resource is warranted and it adjusts automatically to expenses in a fixed limit of 1,24% of the communitarian GBI[149]. By introducing a unique communitarian tax, EU by its institutions would have total competence in order to sample its resources without depending on a certain approved procedure. The European Parliament would have the initial competences of a parliament and will have to establish the level of expenses through common politics. It would also be about resources sampled directly from the European tax payers, evaluated according to adequate measurement criteria established by European members of the Parliament.

Choosing the adequate tax remains a delicate problem. It confronts with an old dilemma of the fiscal politics, that of harmonizating principles and requests often contradictory. None of the taxes that could be refrained on the basis of economical arguments don't achieve all the desired conditions, of financial efficaciousness or of short term fez ability. The communitarian tax would have as a goal the financing of the communitarian budget, completing or replacing the present proper resorces formed of custom taxes, the VAT resource and the resource set on the GBI. In reality, the mechanisms of calculation for these resouces are of such a nature that they should warranty the finacial autonomy of the Union. Only the taxes for these resources are a real communitarian tax but they do not represent but 14% from the total financing. The others aren't but subscriptions paid by the state members, sampled from their fiscal resources.

The objective is not that of creating a new resource that shloud add itself to the prevoius ones but to replace a contributive system based on the state members by another that should base directly on the tax payers. However, this does not exclude keeping the present proper resources constituted as custom taxes and agricultural samplings[150].

The tax should be mainly as neutral as it can regarding the assessment of the contributions between the state members in the financing of the Union, taking into consideration a principle of equalty. The objective should be that of an equal system in order that everyone should be taxed according to his real contributive capacity, from the point of view of the refrained common criteria. It is important that these criteria of determination of the taxable base should be equal in all of the state members.

Two solutions have been outlined in this sense:

- Creating a new tax with a common satiety: numerous political inconvenients follow this solution and a new tax would be undoubtedly unpopular;
- Founding an existent tax: this should exist in all the state members and the calculation base should be harmonised at the Union's level.

The options in this case are different. It could be about the taxes thrown upon some products like fuel, alcohol and baccy that are all over as harmonized nuisance taxes. A tax on the CO2 emission, although unanimously accepted and of urgent actuality, wouldn't be sufficient for financing the present communitarian budget.

The sampling of a fraction of the volume of the nuisance taxes on fuel, alcohol and baccy is a solution easy to be applied because the calculation base for nuisance taxes is already harmonised in the European Union and the corresponding physical fuxes are easily identified. The nuisance taxes touch „sensitive" products for tax payers who could become interested of communitarian business. The opponents of this solution pretend that the nuisance taxes are not agreable for the consumers and their transfer to the Union's budget risks to destroy the image of Europe[151].

Another solution should be linked to the VAT. In this case also the calculation base is harmonised at a European level, even if the national shares are different. The efficiency of a communitarian VAT would be without any doubt high. This solution thus presents the inconvenient that the volume of the encashment is strongly influenced by the economic conjuncture, fact that could compromise the stability of the communitarian resources. The track of the VAT is considered to be the most promising one because here there have been made the most progresses in the harmonisation field, and its level of transparency for citizens is high.

It has been pretty much disscussed on the choosing of the tax upon the societies and on the incomes of the physical persons. A communitarian tax on the societies due to its high volume would overtake the needs and its legibility for the citizens would be limited.

[149] L'impôt européen – Nicolas –Jean Brehon sursa: Le Monde 26.02.2002

150 Institutul Montaigne „Vers un impôt européen?", 2003, Paris, p 27

[151] La creation de nouvelles ressources propres (www.senat.fr)

Beside the indirect taxes mentioned before, the calculation base of the tax on societies isn't harmonised at European level, although there are serious preoccupations in this sense in the present. The efficiency of such a tax on societies would be, also, high, but maybe too dependent on the rythm of economic growth. This solution present however the advantage of the coherency because societies are the first that benefit of the European economic integration. Among others, the affectation of the communitarian budget of the tax on societies would have the effect to neutralize the impact of the delocalization of the societies inside the European Union and to reduce the fiscal competition between the state members. At the same time, this tax doesn't interest at all the individual tax payer and this solution wouldn't sensitize the citizens to European businesses.

At the same time, the European Parliament, as well as the Commission plead more inconvenients regarding this tax on societies. To the technical difficulties related to the absence of a harmonised base between the state members, two more difficulties are:

- The lack of visibility of such a tax in the measure in which it wouldn't been endured by the citizens in their quality of enterprise owners, but in fact it would push, at least partialy, upon the citizens in their quality of consumers and salaried;
- The extreme dependency of this tax to the ecomonic conjuncture which would determine important variations of the encashments of the European[152].

A communitarian tax on the income of the physical persons would suppose a very high level of fiscal and social harmonization so it cannot be taken into consideration only in a short term perspective.

Except a better perception of the European Union's role by the tax payer citizen, the communitarian tax on the income of physical persons has a theoretical justification in the fact that, applied to a regional level, the tax on the income can induce effects of undesired migration. In the same time, it can object that this statement supposes a mobility of the work force bigger than it is in reality. The Commission underlines among others that there is no direct connection between such a tax and the politics of the European Union and the overlapping of the same tax of the national authorities and of the EU's institutions would complicate the administration of the economical and national budgetary priorities.

Finally, taking into account the real risk of growth of the fiscal pression and of the effect of eviction of the fiscal incomes of the state which would result from these, the attribution of the power to collect the tax by the Union should be followed by a sufficiently rigid framing of the European Union's finances, pemitting to assure, as possible, the neutrality of this transfer to the global fiscal pression.

Not even a „candidate" tax can have the claim to be a miracle solution. The instauration of a European tax wouldn't accomplish without certain inconvenient and will not be without any doubt a popular measure.

The institutional obstacles (especially the unanimity rule of the state members resumed by the European Commission), technical (keeping the five criteria established by the Commission) and political (the fear of federalism and of the budgetary branch) however remain as such the introduction of such resources appear little realistic on average term. The affectation of a communitarian tax to a function or a communitarian public good, like the defense and the security or the transport network would allow the elimination of certain political reticences and the excitement of the citizens'adhesion[153].

The idea of a European tax that should replace the present national contributions for financing the communitarian budget remain for the moment unsolved. Its followed objective would be less financial and more political, becoming again present in the terms of constituting and extending the euro area. The present system is confused but acceptable because the states in the Council remain in control on the competences. Maybe the European tax wouldn't become an acceptable necessity but on the day when some of the states'competences (like defense) will be transferred to a unique authority of the Union.

Taking account of the lack in revenues' popularity that is permanent and general within the entire economy, it is legitimate and extremely important to identify the best way to set up revenues in order to reach maximum acceptance of payers.

Starting from the theory of "fiscal optimization", the article aims at analyzing the degree to which European Union member states' fiscal systems comply with the "optimization" from two perspectives: those of payers – by means of specific indices: fiscality rate, fiscal pressure, fiscality relative degree – and those of the authorities that have duties in the fiscality field – emphasizing the amount of fiscal charges in this respect.

Key words: fiscal optimization, fiscal revenues, fiscal pressure

1. The theory of fiscal optimization

The theory of fiscal optimization as a coherent scientific approach is new, but some of its elements have been analyzed for a long time. Even in the 18th century, Adam Smith asserted the idea that a tax may be rated as good if it obeys four rules[154]:

- Economy- assuming that taxes do not require a costly cashing procedure and they do not discourage business either;
- Facility – all taxes must be collected by a procedure convenient to tax payers;
- Certainty – meaning that the payment time, payment ways and the amounts owed by tax payers as taxes must be certain, not random;
- Equity – all taxes must be perceived as "correct".

Starting from the essence of Adam Smith's explanations, the English professor Stephen C. R. Munday, (Headmaster Of Sixth Form, Saffron Walden County High School) said that "all the discussions about ideal fiscality admit the fact that there are three requirements that must always be taken into account":

1. The need for certainty, irrespective of how it is defined;
2. The need to minimize the administrative costs that fiscality involves;
3. The need to minimize the demobilizing effects of taxes[155].

The issue of fiscal optimization is not easy as its requirements contradict one another, which makes it difficult to compose them and to set up a single "objective function" of theirs.

[154] Florescu Dumitru, Coman, Bălaşa – "Fiscality in Romania – Regulation, Doctrine, Jurisprudence", Publ. All Beck, 2005, page 77

[155] Stephen C.R. Munday- "Avantgarde Ideas in Economy", Publ. Codecs, Bucarest, 1999, page 183

Taking account of the lack in revenues' popularity that is permanent and general within the entire economy, it is legitimate and extremely important to identify the best way to set up revenues in order to reach maximum acceptance of tax payers. Legitimacy can be emphasized both from the perspective of fiscal authority that wants best taxes at least to prove the fiscal system's administration capacity and from the perspective of tax payers that are mostly pleased by "average" rather than extremes.

2. The evolution of fiscal revenues in Romania

The argument of the economic calculations used by the fiscal policy is given by the arbitrary feature. What are the reasons for which the government suggested the shift from progressive quotas on income installments to the unique quota of 16%? Why 16%? The natural question refers to the way income quotas are set up; to the way of emphasizing the best tax that helps the economy flourish and go for the better. Yet, in practice, the reason of any fiscal system is not and cannot be objective. It is neither ensuring the "good running" of the economy, nor reducing the taxes' collection costs, as fiscal authorities often show. The fiscal regime is more often subject to discretionary budget needs and political interests, in a world where most specialists keep talking about "fiscal optimization" like an illusion.

During the debates upon the nature of fiscal regime, specialists have precisely left aside the essential element: the general fiscal burden. The real issue does not relate to the progressive or proportional taxing method, but to the general level of taxing. This is an issue that primarily relates to ethics and secondly to efficiency.

The efficiency of tax cashing depends on several factors among which, especially in our country, the most important are : legislation stability, issuing regulatory acts and their clear implementation norms that should not produce misunderstandings; the reduction of government expenses that are unproductive and non-economic; discouraging tax evasion and removing underground economy; a quicker compliance of the fiscal legislation within the European Union.

Analyzing the effects of the 16% quota in Romania in order to identify the relationship between that fiscal step and the government's practical ability to set up the level of the 'best' taxing rate, one can notice that the goal has been accomplished at least from the perspective of fiscal authority.

Evolution of fiscal revenues in Romania during 2000-2008*

Table 1:

Years	Fiscal revenues (million Lei, current prices)
2000	**23504,8**
2001	**32669,9**
2002	**41816,6**
2003	**53248,2**
2004	**66678,3**
2005	**78281,4**
2006	**96773,9**
2007	**115208,8**
2008	**23274,4**

Source: Made by the author with data from www.mefromania.ro

* - The data for the year 2008 include the fiscal revenues achieved during January-February.

It can be noticed that even if on 1st January the single quota –16%- started being applied for most incomes of individuals and businesses, a quota that replaced the progressive taxing (the quotas between 18% and 40% applied in income installments), of individuals' incomes and the 25% quota of businesses' incomes, the fiscal cashing went up from 66,678,3 mil. Lei in 2004 to 78,281.4 mil. Lei in 2005.

In an interview about the single tax in Romania in the "Capital" newspaper, Arthur Laffer, the author of the famous curve that bears his name, the advocate of the theory saying that small taxes stimulate productivity and economy, stated: "The single quota is going to solve many corruption matters because, if it is applied on a large basis, it can lead to the existence of few incentives to break the law. Yet, at the same time, a fiscal amnesty is necessary, which is very difficult. How can you solve all the crimes of the previous fiscal regime when you replace a corrupted system by a mere one? You must start from nothing, but it is very hard". And he also asserted about the fiscal optimization: "The idea is to collect taxes in the least harmful way and spend them in the most profitable way (…); the most important lesson is not to pay people who do not work and not to tax those who do"[156].

3. The evolution of fiscal pressure in Romania

As far as tax payers are concerned, fiscality level/or the rate of fiscal pressure emphasizes the ratio between the total of all fees, taxes, social dues and other fiscal duties charged centrally or locally and an aggregated economic index (G.D.P., G.N.P., national revenue). Both at economic level and at social, economic and financial levels, the issue to size the share of G.D.P. taken by the state is highly important.

Fiscality rate set up as the ratio between the set of fiscal revenues (taxes and social duties) and the gross domestic product[157]:

$$R_f = \frac{V_f}{PIB} * 100$$

provides a picture of the fiscal pressure exerted by the system of fees, taxes and duties upon tax payers, as well as the picture of the political conception regarding the set up of public expenses' financing sources.

The analysis of the fiscal pressure evolution in Romania should start from the emphasis of fiscal revenues as well as from the level of G.D.P. accomplished in our country.

Source: Made by the author with data taken from the 2005 Statistical Yearbook of Romania, www.fmi.ro, www.mfinante.ro

- Data missing

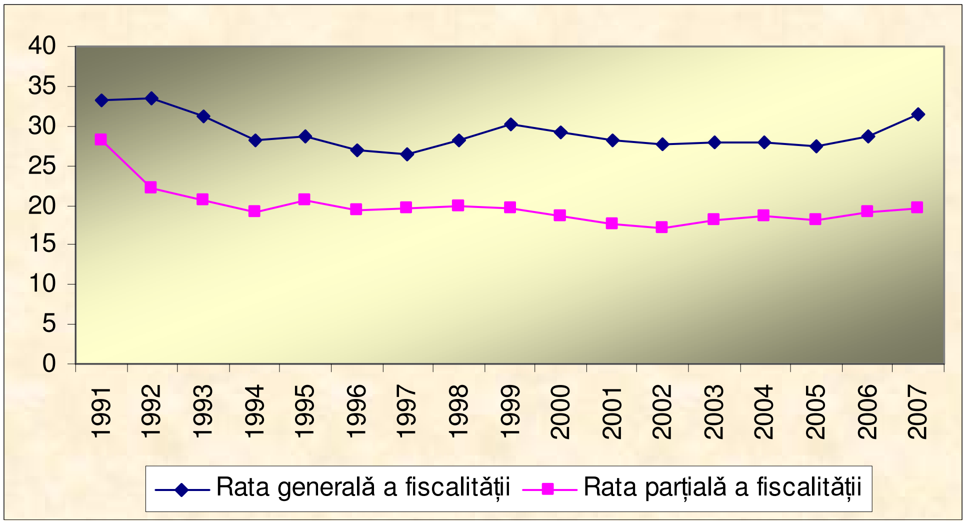
* - The national accounts of Romania have been made up ever since 1989, based on the methodology of the European System of Integrated Economic Accounts 1979 (SEC 1979). In 1998, they started using the new European Account System 1995 (SEC 1995) and in 1998 there was the connection between the two versions of the European Account System.

** - The data shown in the table for the year 2008 emphasize the total of general, public, enhanced revenues cashed between 1 January and 29 February this year.

The overall analysis of the fiscality rate evolution in our country since 1991 up to the present provides an overlook of the fiscal pressure exerted by the tax and income system upon tax payers as well as a picture of the political conception regarding the setting up of public expenses' financing sources. I have highlighted the values of fiscality rate with its two aspects: the general rate set up from the perspective of fiscal revenues' share, including insurance dues in total G.D.P., respectively the partial fiscality rate set up only from fiscal revenues.

Evolution of fiscal pressure in Romania during 1991- 2007

Graph 1



Sorce: Made by the author with data from table 1.

One can notice that general fiscality rate during the analyzed period changed within slight limits and recorded extreme values in 1996 – 26.5%, respectively in 1992 – 33.5%. The overall index trend is about 2% decreasing during the analyzed period.

The partial fiscality degree had a more pronounced evolution, almost 9% decreasing during the analyzed period.

The relative fiscality degree essentially rendered by the sum of main fees and taxes charged on companies and individuals is shown below:

Relative fiscality degree in Romania during 2004-2008

Table 3:

Main taxes	2004	2005	2006	2007	2008

TOTAL	133%	100%	98,5%	96,5%	90,5%*

Source: Made by the author with data from www.cdep.ro, The Bill of Social State Insurance Budget for 2004- 2008,

-* - They foresee a change in 2008 according to the provisions of the Law of Social State Insurance Budget no.387/2007 (M. Of. no. 901 of 31 December 2007) and the Law of State Budget for 2008 no.388/2007 (M. Of. no. 902 and 902 bis of 31 December 2007) aiming at the reduction of 6% as compared to the level of quotas in 2007; the total reductions for employers is 4.5%, and for employees, the social insurance duties are going to decrease by 1.5% in July 2008, so that: 0.5% for unemployment insurances and 1% for health insurances.

As well as fiscality degree, the relative degree of Romanian fiscality has never been and is not among the highest, and its reduction during only one year (2005, the year that witnessed the shift from progressive percentage taxing to proportional quotas) by over 30% is something that rarely occurs in an economy.

4. Conclusion

In a comparative analysis of the public revenue share of GDP in all the European Union member states, one can get a confirmation of the moderate level of fiscality in Romania:

Public financial resources of EU countries (share of GDP and per capita) during 2000-2006

Source: Eurostat, Economie et finance, Statistique des administrations publiques

The above table shows the size of the public administration sector in each European Union member state.

Our country has the lowest income tax in all the European Union. Almost the same can be said about profit taxes that are among the lowest in the European community. It is for these reasons that the tax revenues' share of GDP is small. Practically, in 2005, Romania recorded the lowest level of revenues from taxes and fees as compared with the countries in the European Union.

According to a survey made up by Eurostat[158], the European Statistics Department, Romania had in 2007 the lowest income tax of all the 27 European Union member states, which is 16%. At the opposite side there are Denmark and Sweden that have an income tax of 59%, respectively, 56.60%. As far as the European average income tax is concerned, it is 38.68%, whereas the average in the Eurozone is 45%.

Romania relatively has the same level of profit taxes, too, that is still 16%, but it is not the lowest. The lowest profit taxes are in Bulgaria, Cyprus, each having 10%, Ireland (12.5%) and Latvia (15%). Romania ranks fifth, after those countries. In the other part of the chart, having the highest profit taxes, there are Denmark (38.7%), Italy (37,3%) and Malta (35%).

Yet, a relative fiscality approach does not have a practical relevance without the connection with its real approach. The 33% rate in 2006 in Romania and 56% in Denmark or Sweden (within the same periods) are not comparable because their basis is different: Romania's GDP in 2006 at purchase parity was 192.96 billion Euros that is equal to 8,900 Euros/inhabitant. The figures rank Romania the 26th (last but one) among the European Union member states that had an average GDP/capita at purchase parity of 23,600 Euros. Hence, the conclusion that both the fiscality supporting power and the real effects of promoting a certain fiscality rate are higher in those countries than in Romania[159].

As a conclusion, fiscality, although never to be popular, is objectively necessary ; the issue is to design a fiscal system to diminish social losses and achieve equity goals that are socially accepted at a given time.

Abstract: The policy of regional development is one of the most important and complex policies of the European Union, a statute that derives from the fact, that through it's objective of reducing the economic and social disparities existing between different regions of Europe, act on significant domains for developing like economical growth, small and medium business (SMB), transport, agriculture, urban development, environmental protection, education, gender equality and so on.

Keywords: Structural funds, economic and social cohesion, community initiative, innovative actions, solidarity fond.

Defined as a policy of European solidarity, the regional policy is based primarily on financial solidarity, mainly by redistributing a part of the communitarian budget established by the contribution of state members towards regions and social groups less prosperous. (for the period 2000 – 2006, the sum has represented almost a third of the EU budget[160]).

The principles of the regional policy have been discussed since 1957, with the signing of the Roma Treaty when the six signing states (Belgium, France, Germany, Italy, Luxembourg and Holland) have agreed on reducing the differences between regions and supporting the less prosper, with the aim of achieving a communitarian economy, solid and unitary.

This need was reiterated in 1958, with the birth of FSE, Social European Fund as a primary instrument of this policy, having as an objective the improvement of labor market in different European countries and reintegration the unemployed. In 1962 the European Fund for Orientation and Agricultural Guaranty (FEOGA) was setup in order to support the common agricultural policy and the rural regions. In 1975 a third fund was establish – the European Fund for Regional Development (FEDR), with the purpose of redistributing part of the contribution of the member states towards the poorest regions of the EU, in order to support their economic development. Thus FEDR redistributes the community budget in productive investments and infrastructure.

An important moment in the development of the regional policy was the adoption of the European Single Act in 1986[161] which introduces the concept of economic cohesion, eliminating the existent economic differences between regions and creates the premises of a an economic and social cohesion policy self sustained and which aimed at facilitating the inclusion to the single European market of the states from the southern European.

In 1994 takes shape a new structural fund, the fourth – the Financial Instrument for Fishing Orientation (IFOP), created by all communitarian structures that were involved in fishing decision makings. IFOP was created due to the enlargement to the north of the EU with the joining of Sweden and Finland in 1995. In the same year becomes active the Regional Committee, a consultative organism established by the Maastricht Treaty having a supportive and consultative role for the European Council in their regional activities.

---

[160] It is ablut 35% of the EU budget (http://europa.eu.int/comm/regional_policy)

[161] Single European Act, voted in 1987

Communitarian initiatives

Communitarian initiatives are represented by four programs especially created for ensuring a success of the projects and financing from the structural funds. Each program is financed through a single fund, and together the account for 5.35% of the entire budget allocated to the Structural funds. Initially for the period 1994 – 1999 there were 13 communitarian initiatives, which were reduced through the reform from 1999, to only 4, in order to increase the efficiency of the Structural Funds:

- **Interred III** – financed by FEDR, promotes cross border and interregional cooperation;
- **Equal** – financed by ESF and sustains the development of new ways to fight against discrimination and inequalities regarding access to the labor:
- **Leader+** - financed by FEOGA – the orientation section that also promotes rural development by supporting the initiatives of local action groups (sustained development):
- **Urban II** – financed by FEDR, encourages innovative strategies for regenerating economies and social factor of cities and urban areas in decline.

Financing the Communitarian Initiative implicates a co-financing from the Member States, between 25% in the objectiv1 domain and 50% in the others.

Innovative actions

Innovative actions are a set of measures financed from the budget of structural funds and which have as an objective experimenting the newest ideas that might contribute to the diversification and improvement of the regional development strategies. The structural funds that finance or plan to finance innovative actions are: FEDR, FSE and IFOP. In what regards the budget allocated for Structural Funds, in March 1999, at the Berlin Summit, the European Council has agreed that the resources available for Structural Funds, including assistance for transition, Communitarian initiatives and Innovative actions totalize 195 billion Euros, by objective the spilt this looks like this:

- for objective 1: 69.7% or 135.9 billions Euros for the poorest regions of the EU, including 4.3% for supporting transition in regions that are not eligible for the objective 1 according to the new reglementations;
- for objective 2: 11,5% or 22,5 billions Euros will be allocated for economic and social recon version (including 1,4% for supporting transition);
- for objective 3: 12,3% or 24,05 billions Euros for supporting and modernizing policies linked with education, training and employment outside the regions of objective:
- 0.5% or 1.1 billion Euros of the total Structural Funds is allocated to the Financial Instrument for Fishing Orientation (IFOP) for supporting the fishing policies that are not covered by objective 1;
- 5.35% of the Structural Funds are allocated for Communitarian Initiative (Interreg III, Urban II, Leader + şi Equal);
- 0.65% of the Structural Funds are allocated for innovative actions and technical assistance.

In addition, 18 billions Euros are allocated to the Cohesion Fund and approximately 7 billions Euros are dedicated to the enlargement process for the candidate states. For each of the Objectives, the Commission has created a split of the funds for Member States. The total amount received by each member state as assistance given by structural funds must not higher then 4% of its national GDP.

Economic and social cohesion is one of the must important objectives of the EU. As defined in the article 158 of the European Communities Treaty, cohesion is needed for promoting “general harmonious development” of the community and ask for “a reduction of the disparities between different regions, especially rural ones”. According to article 159, the community acts through structural changes, the cohesion fund and other financial instruments for supporting the achievement of general objectives, defined by the Parliament, or the Commission.

The European Union Solidarity Fund (EUSF)[162] was created in response to the extraordinary flooding disaster that hit central Europe during the summer of 2002. In the aftermath of this disaster it became

[162] Also known as *European Solidarity Fund;*

apparent that a solidarity-based response of the European Union going beyond the maximum use of existing Community instruments was required.

On proposal of the European Commission, the Council adopted on 11 November 2002 the Regulation 2012/2002 establishing the European Union Solidarity Fund (hereinafter "the Regulation). It entered into force on 15 November. According to the Regulation the Fund may be mainly mobilised when a major natural disaster with serious repercussions on living conditions, the natural environment or the economy occurs. A major disaster is deemed to have occurred if the estimated cost of total direct damage exceeds € 3 billion in 2002 prices (i.e. € 3.118381 billion in 2005) or 0.6% of the gross national income of the State in question, whichever is the lower.

In exceptional cases, the Fund can be mobilised for regional disasters that do not reach this threshold, if very specific criteria are met: an extraordinary disaster affecting the majority of the population of a region and having serious and lasting effects on its economic stability and living conditions. The EUSF aims to supplement public expenditure by the individual Member States for essential emergency operations.

The instruments of solidarity for regional development are done according to the NUTS[163] System (the nomenclature for territorial units for statistics) which represents an ierarhic classification on 5 levels (three regional and two local) of the administrative structures that exist in the member states. The nomenclature was created by EUROSTAT in order to place the diverse administrative structures that exist in the member states in one coherent structure. NUTS have no legal power, it is formed on an agreement between the member states and it is not the process of uniformization started at European level in 1988. In 2003, the nomenclature was reformed though a set of rules in order to respond to the changes brought by the enlargement. Thus the NUTS for EU 25 contain:

- 89 NUTS level 1 (while there were 78 in UE 15) – with a population between 3000000 - 7000000 inhabitants; example: German regions (lands) , Belgian regions, Wales, Scotland, autonomous communities in Spain like Catalunia, regions in France and Italy are also classified in this category;
- 1.254 NUTS level 2 (while there were 210 in UE 15) – with a population between 800000 - 3000000 inhabitants; examples: French departments, subdivision of German regions, Austrian regions;
- 1.214 NUTS level 3 (while there were 1093 in UE 15) – with a population between 150000 – 800000 inhabitants; example: germane circles, Spanish and Italian provinces;
- NUTS level 4 and 5 are called Local Administrative Units and represent in fact districts and cities.

At functional level, not like the Solidarity Fund or the Cohesion Fund which function on a project base, the Structural Funds due to their magnitude function on a program based, this being structured according to domains, objectives and regional policies objectives.The principles that stay at the core of the operations regarding structural funds, in the new variant presented in Agenda 2000 are:

a) the principle of programming: in the first stage, the member states will send the European Commission national plans for development and conversion based on their national and regional interest that will contain:

- A detailed description of the current situation in the region/ state taken into account,
- A description of the strategy most suitable to accomplish this objectives;
- Indicating the form and the usage of the structural funds.

In the next stage the member state must petition the Commission with the so called programming documents, documents that can be of two types: DCSC or DUP, the difference being given by their magnitude not be their nature.

b) the principle of partnership means a tight collaboration between the Commission and national/ regional/ local authorities, economic and social partners and other competent organizations, especially by involving them in each stage of the structural funds, from elaborating and approving the development plans and monitoring. This principle highlights the degree of decentralization that characterizes the entire regional policy and the applicability of the subsidiary principle.

---

163 www.ifcro.ro/finantare/finantari_postaderare.

c) the principle of addition has in light the component of adding to any structural funds national or local funds, thus this structural funds come in addition to the national ones

d) the principle of monitoring, the control and evaluating is the new element brought by the reform in 1999 in the structural fund domain. Thus according to the new reglementations the state members have administrative attribution and have he obligation to deputies a national authority according to the specifications of each program in which structural funds are used.

The objectives that indicate the actions in which the structural fund will be used are special to each project and are chosen regarding to the objective and priorities.. For the period 2000 – 2006 there the following priorities:

- Regional competivity,
- Social and economic cohesion,
- The development of urban and rural regions (including those dependent by fishing).

Thus, the objectives of 2000-2006 are:

- **Objective 1** (territorial): developing regions less developed(with a GDP per capita under 75% of the EU average, with high unemployment rate, lack of services, poor infrastructure);
- **Objective 2** (territorial): economic and social recon version of regions with structural difficulties (industrial or services regions that are subject to restructuring; the disappearance of traditional activities in rural areas, urban areas in decline or with fishing problems);
- **Objective 3** (thematic)[164]: de developing human resources through professional training programs and promoting them outside objective (Regions in which the GDP per capita is under 90% of the average GDP per capita of the EU).

Structural Instruments in Romania

The construction of the institutional framework regarding the cohesion policy and structural instruments in Romania is based on the *Government Decision no. 497/2004* **regarding establishing the institutional framework for coordinating, implementing and managing the structural instruments, which decrees**:

- Institutional framework at the level of Management Authorities, Payment Authorities and Intermarry Organizations;
- Main attributes of the Management Authorities for the Communitarian Support Framework for Operational Programs, Management Authorities for the Cohesion Fund and Payment Authorities, on communitarian basis;
- An obligation for all Management Authorities, Payment Authorities and Intermarry Organizations to establish audit teams and units;
- The obligation to respect the principle of adequate segregation of functions;
- Flexibility of the institutional framework regarding the cohesion policy and the future programming exercise.

The Government Decision n0. 497/2004 was modified and suffered completion through Government Decision *no. 1179/2004.*

Communitarian support framework Management Authority – The Public Finance Ministry

FUNDING THE STATE BUDGET WITH TAXES AND PUBLIC DEBT FROM THE PERSPECTIVE OF ECONOMIC GROWTH MODELING –THE DIAMOND MODEL CASE[165]

Predescu Antoniu

Universitatea „Spiru Haret", Facultatea de Contabilitate şi Finanţe Râmnicu Vâlcea, Râmnicu Vâlcea, str. Ostroveni nr. 35, gen3pavo@yahoo.com***, 0721143258***

Abstract: The fiscal lever is of such complexity and range, that is, even in theory, linked to the phenomenon of economic growth – at least, to the phenomenon of the production of goods and services; one link is that taxation is a very effective tool for filling up the coffers of the public budget, but one point is questionable, that is whether, being as effective as it can be, it should be used exclusively, or not. Through this, the object of this paper is, consequently, built: solving the question whether, for the purpose of funding the state budget, public debt is also to be used – or, even, must be used, in conjunction with taxation.

Key words: Cobb-Douglas, effective labor, debt.

Using the demographical perspective of the Diamond model, we will analyze, in this paper, the influence of the public expenses, financed through taxes and public debt, to the balanced growth – and we will accomplish this analysis using the tools the logarithmic utility and the Cobb-Douglas shape of the Solow production function provide us with.

This analysis is very useful, in the case of the production function of Cobb-Douglas type, for practical grounds: the production function, in this shape, is very easily usable – and this especially in an dynamic analysis –, being, furthermore, a very precise (first) approximation of what shapes the production functions applicable to the actual economies should have.

The Solow production function, in its Cobb-Douglas shape, has the following structure:

$$F(K, A \cdot L) = K^{\alpha} \cdot (A \cdot L)^{1-\alpha}, \alpha \in (0,1).$$

The Solow production function, in its *intensive* Cobb-Douglas shape, has the following structure:

$$F(K, A \cdot L) = F(K / A \cdot L, 1) = f(k) = (K / A \cdot L)^{\alpha} \Leftrightarrow f(k) = k^{\alpha}.$$

We must also add this production function satisfies, with no exception, all the assumptions the intensive form Solow production function bounds to.

The amount of capital stock per unit of effective labor, from the demographical perspective of the Diamond model – and, because the Solow economic growth model *is* the mathematical base of Diamond model's economical simulations, of the Solow model too –, is calculable is the following manner:

$$k_{t+1} = [1/(1+n) \cdot (1+g)] \cdot (1/2+\rho) \cdot w_t.$$

The real wage per unit of effective labor, w_t, is calculable, using the Cobb-Douglas shape of the Solow production function, through the use of the following algorithm:

$$w_t = f(k_t) - k_t \cdot f'(k_t) = k_t^{\alpha} - k_t \cdot (k_t^{\alpha})' \Leftrightarrow w_t = k_t^{\alpha} - k_t \cdot \alpha \cdot k_t^{\alpha-1} \Rightarrow w_t = k_t^{\alpha} - \alpha \cdot k_t^{\alpha} \Leftrightarrow$$
$$\Leftrightarrow w_t = k_t^{\alpha} \cdot (1-\alpha).$$

$$\Rightarrow k_{t+1} = [1/(1+n) \cdot (1+g)] \cdot (1/2+\rho) \cdot k_t^{\alpha} \cdot (1-\alpha).$$

[165] This paper is not a tool built for summing up the principal outlines of the Diamond and Solow models, but, instead, is (chiefly) addressed to those who are acquainted with economic growth modeling, in general, and with the bases of the Diamond and Solow models, in particular.

The above stated k_{t+1} equation – with which the effect on the economic growth of the public expenses can be circumscribable, and in dynamics too – is being built according to the above expressed premises, that is taking into account the fact in order to finance the public expenses both incomes generated by taxes and the public debt[166] are used.

But to begin with, we must analyze the basic idea we are, here and in the following lines, minutely analyzing: why do we mention, ant this only, the public expenses? The answer, even if it were not be the final answer, can be thus expressed: the public expenses are, before any others, linked to the *mechanism* of the economic growth – and vice versa.

The public expenses are expenses of a *public nature*, financed by the use of the resources contained by the public (state) budget; in these circumstances, the public expenses *growth* takes place, in principle, and in any economy, given the fact the government acts on the following three levers:

- Goods and services purchases;
- Income transfers (e.g. welfare funds);
- Paying off the interests on the public debt.

In this point of our demonstration, some explaining is required; firstly, and maybe the first, from the point of view of importance, it must be underlined that, because part of the money savings of the young individuals will transform, consequently, not into capital (stock), but into government securities, to the left side of the equation another term will be added – in fact, this term is $b_{t+1} - b$ being the amount of government securities per unit of effective labor.

We say – and use $-b_{t+1}$, and not b_t, because, using a similar expression for – in this realm, where economic growth is interwoven with population dynamics – that of the capital per unit of effective labor, b_{t+1} is a function of the government securities bought in period t.

For the object of our study, it suffices only to sketch the structure of this variable (b_{t+1}) – using a sufficient degree of accuracy, though, in order for the utility of its use, in the domain of taxing and economic growth, not to be meddled with; from this we, therefore, start – from the government securities stock.

Be B_{t+1} the size of the government securities stock, in the period t+1 – these securities are bought in the period t, and, similarly to the mechanism of generating the capital stock, K_{t+1}, the amplitude of this acquisition depends on the interest rate attached to those securities; be r'_{t+1} this interest rate.

This amplitude, also, is determined by the proportion of personal incomes every individual – and, in the end, all individuals – save, in the form of government securities; this proportion is determined, primarily, by the interest rate r'_{t+1} – be it $s(r'_{t+1})$.

In the end, this dynamics can be mathematically modeled like this:

$$B_{t+1} = L_t \cdot [(w_t \cdot A_t) \cdot s(r'_{t+1})] \Leftrightarrow B_{t+1} / (L_{t+1} \cdot A_{t+1}) = w_t \cdot s(r'_{t+1}) \cdot (L_t \cdot A_t) / (L_{t+1} \cdot A_{t+1}) \Leftrightarrow$$

$$\Leftrightarrow b_{t+1} = (L_t / L_{t+1}) \cdot (A_t / A_{t+1}) \cdot w_t \cdot s(r'_{t+1}) \Leftrightarrow b_{t+1} = (L_t / L_t + n \cdot L_t) \cdot (A_t / A_t + g \cdot A_t) \cdot w_t \cdot s(r'_{t+1})$$

$$\Leftrightarrow b_{t+1} = [L_t / L_t \cdot (1+n)] \cdot [A_t / A_t \cdot (1+g)] \cdot w_t \cdot s(r'_{t+1}) \Leftrightarrow b_{t+1} = (1/1+n) \cdot (1/1+g) \cdot w_t \cdot s(r'_{t+1}) \Leftrightarrow$$

$$\Leftrightarrow b_{t+1} = [1/(1+n) \cdot (1+g)] \cdot w_t \cdot s(r'_{t+1}).$$

It must also be added that, because taxes and public debt globally contribute to the financing of the state budget, the total amount of the public expenses will be equal not to the total value of the sum the taxpayers

[166] This debt is materialized, for instance, by the government securities issue – if it were to use only this classic example.

acquitted for their tax taxes they were levied to; so, in the right side of our equation, the term I_t appears – I_t is the amount of tax revenue the state received per unit of effective labor.

Therefore:

$$k_{t+1} + b_{t+1} = [1/(1+n)\cdot(1+g)]\cdot[1/(2+\rho)]\cdot[k_t^{\alpha}\cdot(1-\alpha)-I_t] \Leftrightarrow$$
$$\Leftrightarrow\ k_{t+1} = [1/(1+n)\cdot(1+g)]\cdot[1/(2+\rho)]\cdot[k_t^{\alpha}\cdot(1-\alpha)-I_t]-b_{t+1}$$

As one can notice, starting the analysis from a (given) value of k_t, and, respectively, of b_t, it may seem as if it can be stated for a large(r) value of I_t, the value of k_{t+1} will diminish. It would be like this, but, in this frame, of the existence of the public debt, the most common *status quo* is, in the economy, not that of "a large(r) value of I_t".

In fact, and at least for political reasons, if not, and in the first instance, for economic grounds, the issue of, especially, a large amount of government securities – that is to resort to a deep public debt – is, really, to cut, simultaneously, and not necessarily by the same proportion, the taxes levied on the taxpayers.

Though, the only reachable effect anyone can obtain, by the use of such methods, is anything but a cut – even less a large cut – of public expenses; these will have, and anyway must have, the dimensions needed in order to, among others, pay the interest of the public debt. The k_{t+1} may, therefore, drastically reduce[167].

Through this dynamics, the bottom line has this appearance: the needs of the present are financed, so to speak, with the toil of the next generations, but the story doesn't end here; with a lowering fiscal pressure, the taxpayers tend to consume more (rather than to save more, in one form or another), in every part of their lives. This fact, especially – in these conditions – will make the capital stock to decrease.

[167] In our study we use the simplification through which public debt is nothing but **internal** public debt. In the real world, however, there are, also, external loans, loans not without interests – which interests must be, naturally, paid.

THE INFLUENCE OF THE FINANCIAL FACTORS ON CASH FLOW, AS DETERMINING FACTOR OF FIRM'S INVESTMENT DECISIONS

Predescu Iuliana

Romanian American University, Faculty of Domestic and International Commercial and Financial Banking Relations, Bucharest, no.3,Chilia Veche street ,Bl.TD16, A, 24,sector 6, e-mail:preiul, phone:0723587757

Abstract: Because investment decisions are one of three categories of decision that can be adopted by firms' management (beside the financing decision and the net profit allocation decision), this paper intends to present the influence of the financial factors on firm's cash flow, as determining factor of firm's investment decisions, among the factors which are analyzed, namely dividend payment, information asymmetry, leverage, monetary policy, internal liquidity, and firms' size.

Key words: investment, decision, cash flow

The investment decision is one of three categories of decision that can be adopted by firms' management, beside the financing decision and the net profit allocation decision.The investment decisions have direct influence on the structure of firm's asset structure, moreover, on their degree of liquidity, and consist of spending the financial funds for the purchase of real and financial assets for the firm, in order to gain cash and the growth of the wealth of firm's owners.

The investment decisions and the financing decisions are interdependent, that is the investment decision is adopted in relation to the level of the financing sources, but the option to invest is also crucial, in order to calculate the level of financing capitals and the need for finding their sources. Furthermore, the net profit allocation decisions consist of estimating the amount of money taken from the net profits in order to return it to the shareholders as **dividends**, on one hand, and to determine the amount of money taken from the profits for the purpose of financing the investments.

The share of the net profit distributed as dividends has a direct influence in the size of amount of money taken from the cash flows to be used for financing the investments. The reinvesting of a share of the net profit generates the growth of the self financing capacity of the firm, the financial autonomy's growth and, implicitly, of the firm's value. The dilemma between the use of a share of the cash in order to pay the dividends or to implement some investment projects can grow into a very serious issue when cash flows are not enough to satisfy, fully, both the two categories of decisions (investment and dividends).

In what the cash flow of the investment activity is concerned, its size is estimated in the building stage of the investment project, in the period of investment's exploitation, and at the end if the exploitation period. In the initial stage of the investment project, the firm is confronted with cash outflows in the form of expenses generated by the building up of the project (personnel expenses, research expenses), the price of the purchased assets, and the additional need of circulating capital, who's cause relies in the growth of output capacity, as a result of the project's realization (growth in the size of the stocks and the claims), the opportunity cost[168].

The exploitation carried out by the firm generates cash inflows, materialized in the shape of depreciation and the profit gained as a result of the main activity of the firm. The cash flows from the end of the period of investment's exploitation are cash flows, nonetheless, and are made of the residual value of the investment – the very selling price, or the price of the materials acquired as a result of the liquidation – and the need of circulating capital, recovered through the disappearing of the output capacity, generated by the investment. As a result, the investment projects' adoption must be undertaken by taken into consideration the cash flows required by the various investment projects, at different periods of time, cash flows which, in their turn, are affected by a series of financial factors.

The link between investment and cash flow was studied, on a large scale, between 1950 and 1965[169], and then it disappeared for a while from the investment literature, reappearing only in the 1980, following the

[168] The incomes the firm might have obtained if it would have invested, in some other manner, the funds required by the project.

[169] Meyer, J.; Kuh, E.; (1957); *The Investment Decision*. Cambridge, MA: Harvard University Press

development of information asymmetry models. In 1957 Meyer and Kuh pointed out the importance of finance variables for investments, and the preferences firms have for own funds. The neoclassical investment models were developed, which consider the main factors are materialized, in what investments are concerned, in the real interest rate and taxes. The Q investment theory (Tobin, 1969) can be viewed as a new version of the neoclassic theory, which says the investment demand is determined by the ratio between the market value of a firm's share and its replacement cost[170].

In 1988, Fazzari, Hubbard şi Peterson[171] (FHP) estimated the investment equations as a function of Tobin's Q and the cash flow and considered the cash flow tends to have a far larger effect on investments firms which are confronted with financial constraints make. Kaplan and Zingales[172], in 1997, reinterpreted the results from FHP studies, suggesting that an automatically higher sensibility cannot be foreseen in the case of investments cash flow, in the case of the firms which confront with bigger financial constraints.

The use of Q is based on the principle the desired investment opportunities can be undermined by the participants of the capital market, because of the existing **information asymmetry** of the capital market. In the presence of information asymmetry, on the capital market, the introduction of Q will generate immediate tensions. There are some situations in which the suppliers of the exogenous financial funds cannot precisely evaluate the investment opportunities, given the gaps between the information possessed by the insiders, compared to the outsiders. Q will, thereby, stop the evaluation of investment opportunities by the outsiders only; as such, a possibility appears, for cash flow to affect firm's investments, because this cash flow is correlated to the investment opportunities' evaluation of the insiders.

In order to clarify the role of cash flow in the investment equation, and to improve the evaluation degree of investment opportunities, some authors[173] considered it is high time to take into consideration, for evaluating the investment opportunities by the insiders, a new variable, namely the contractual obligations of the firm, for any new future investment projects.

In the presence of asymmetrical information, which determines gaps between information possessed by the insiders, compared to the outsiders, Q is proven to be an imperfect measure of the investment opportunities of the firm, and for that a hindrance for evaluating the investment opportunities, by the capital market's actors. In this way the need of this supplement variable being taken into consideration can be explained, variable that will take into consideration information about the opportunities available from the insiders only.

It is confirmed that, although cash flow will affect both the investments of the large firms, and the investments of small firms, through the introduction of the second variable the power of the cash flow is diminished in the case of the large firms, remaining constant for the small ones. The reason would be, at least for the second variable, the meaning of the cash flow in the investment equation is possible to be generated by the capital market' information asymmetry.

The information asymmetry, characterized by managers possessing a larger amount of information about the firm than the would-be creditors or shareholders, makes more difficult the prospecting carried out by the latter. The effect of these information problems is the growing of the external financing costs, comparatively to the internal costs. These cost differences is at the base of a certain point of view about how a certain level of investment is built: the cash flow is preferred to the debt, which, instead, will be preferred to the new share issues.

As far as the hierarchy of financing sources, as it exists in the economic literature[174], is concerned, cash flow is the cheapest financing source, followed by debts and, in the end, by the issuing of new shares. Debts can be cheaper than the issuing of new shares, because the loan contract can be created as to minimize the consequences of information problems. Giving the fact the degree of information asymmetry and the agent costs depend on the peculiarities of every firm, some firms are more sensitive to financial factors than others. Thus, a possibility exists, for the small firms, that the investors may not be very well

---

[170] Q = the market value of a firm/the replacement value of its assets; adopting factor of the investment decision: if $0<Q<1$, the firm's shares are undervalued; if $Q>1$, the firm's shares are overvalued.

informed; this might lead to their reticence in increasing the financing funds, and, also, the costs of external financing.

Also, another financial factor, which has an influence on investment decisions adopted by the firm, is the **leverage;** more clearly, the higher leverage firms' investments can be more sensitive to the cash flow than lower leverage firms' investments. The cash flow is the only source of financing for the firms which are characterized by low cash, and for those which don't have access to capital markets, being a relatively cheap source of financing; we can, therefore, state that, among the factors which have an influence on investment behavior, capital structure is one of them.

A higher leverage assumes a higher share of firm's cash flow being used to pay the interests and the debts; for some firms, this might be translated as a high debt capacity, combined with low financial constraints. If the cash flow of the firms is diminishing, it will be not easy for them to deal with these obligations, and they will be forced to diminish the investments, which prove to be far more sensitive to the financial background when the leverage is at a higher level.

The establishment of a link between cash flow, leverage and investments offers a profound image; there is, given the fact the monetary policy and the cyclic factors have a (rather) general influence on the companies. If the cash flow is a powerful determinant of investments, the changes happened in the monetary policy (such as the interest rate) will influence investments and the debt capacity of the firm through cash flow effect.

In this case, it is noted in the present days, **monetary policy** has a larger impact on investments, than had done so in the past. The cash flow of highly geared firms will be far more sensitive to the changes in the interest rate than the cash flows complemented by a minimum sized leverage. The impact of the monetary policy will be felt unevenly through companies: small size firms, highly leveraged firms and firms which rely on the cash flow as source of financing are more sensitive to changes in monetary policy than others.

It was noted, also, the **internal liquidity** is an important dimension of cash flow's sensitivity to investments, because it reflects the capability of a firm to finance its projects without tuning to the capital market. Firms that possess cash reserves can use them for the accomplishment of their desired investment projects, but, if these firms are not facing a difficult access on the capital market, and they predict their internal cash needs, they don't have the need to experience a high level of cash flows.

Firm's size is one of the determining factors of cash flow sensibility to investments, for a number of reasons. Small firms expect to face bigger obstacles when capital increases, the borrowed costs are expected to rise; they obtain smaller evaluations from the part of the analysts and they may have difficult access to the external capital sources. The transaction costs related to share issue decrease in correlation to the size of that issue, which is larger for larger firms, and so the small firms face high costs, whilst large firms face smaller costs. From similar reasons, newer firms face bigger differences between internal financing costs and external financing costs. As a result, smaller and newer firms expect to record an increased sensibility of the investment cash flow.

Smaller firms are, in general, considered to be more sensible to the changes in financial factors than larger firms. The external funds have the tendency to become relatively expensive for them, since the fund lenders possess slightly less information about their creditworthiness. Also, economic shocks which affect the cash flows or the dynamics of intermediaries' loan behavior is probable to have a larger influence on investment decisions of the small firms.

Cash flow can affect investments due to the imperfections of the capital markets, and due to the fact external financing is cheaper than external financing, this playing an important part in investments carried out by the firms which face a series of financial constraints. A high level of the cash flow will lead to the growth of investments, through the use of cheaper internal financing funds and the rise in the collateral backing of the company. We can, therefore, state that, if we wish to see which of the above mentioned determining factors influence investments to a greater extend, firms differ. The results show internal financing sources are far more important for small and highly leveraged firms.

FHP classified firms according to the dividend policy, showing the cash flow tends to affect investments of low dividends' firms to a larger extend than investments of high dividends' firms, by this boosting the hypothesis according to which cash flows affect firms' investments because of the imperfections found in capital markets.

Brav[175] (2005) considers maintaining a certain level of dividends is consistent with the investment decisions. If cash flow is not sufficient enough for both activities to be fulfilled, those who adopt the policies face a dilemma that can be solved in one of the following manners:

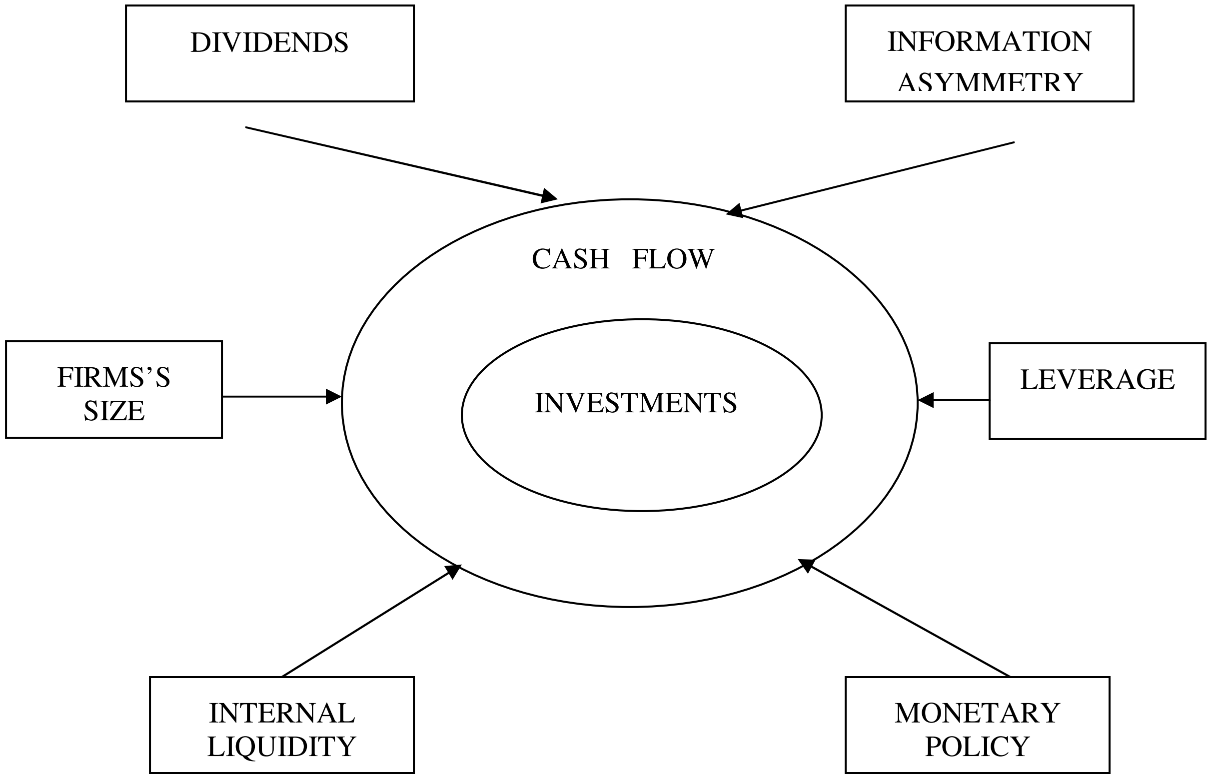
- an increase in external funds, for the completion of cash deficit;
- normal payment of dividends and the abandonment of other investment projects, regardless of their attractiveness;
- partial or total disregarding of dividend payment.

If the first solution is not the optimal one, for a number of reasons, there are another two solutions. On one side, disregarding normal payment of dividends will disturb the investors and will be able to modify their expectations about maintaining the gains of the previous period, and will determine, also, the drop of the share's value of the company. From this perspective, the dividends will be preferable to investments. On the other side, adopting some investment projects will have a long term effect on firm's value, and even more so if certain investment opportunities will not reappear in the near future. Accordingly, investments will be preferable to dividends.

For solving this dilemma, managers must take into consideration the manner in which information about the opportunity of profitable investments will indeed reach the investors, in a way that will allow them the understanding of the reasons behind the decreasing of dividends, or, in other words, the information flow factor.

The graphical illustration of the financial factors which have a sensitive impact on the cash flow, as determining factor which stays at the base of the investment decisions the company adopts, is to be constructed, in my opinion, as follows:

[175] Brav, A.; Graham, J.R.; Harvey, C.R.; Michaely, R.; (2005) Payout policy in the 21th



The influence of the financial factors on cash flow, as determining factor of firm's investment decisions

Member States have continued to make progress, at differing rates. In most cases, steps have been taken towards meeting the commitments contained in the country specific recommendations agreed collectively by the Member States in 2007. Having examined the updated convergence program of most CEE analyzed countries, the European Commission finds that their planned budgetary consolidation is consistent with a correction of the excessive deficits.

Key words:real convergence, nominal convergence, Central and Eastern European countries.

1. RECENT DEVELOPMENTS IN AN ENLARGED EU

The Lisbon Strategy is working. It is creating growth and jobs. It is helping position Europe and European citizens to succeed in the age of globalization. It has given Europe a common, pragmatic economic agenda, fully respecting national differences. But complacency would be fatal to Europe's prospects of shaping globalization. Much more remains to do. Progress is uneven between policy areas and some Member States are moving much faster than others.

Economic growth was 3.0% in EU-27 in 2006 and it remained at 2.9% in 2007. Structural reforms have helped increase the potential estimated growth rate of GDP in the euro zone by 0.2 percentage points since 2005 to 2.25% in 2007. Almost 6.5 million new jobs have been created in the last two years. Another 5 million jobs are expected to be created up to 2009. Unemployment is expected to fall to under 7%, the lowest since the mid 1980s. For the first time in a decade, strong increases in employment have gone hand in hand with robust productivity growth.

EU 27 budget deficits have been significantly reduced, from 2.5% of GDP in 2005 to almost 1.1% in 2007. EU 27 public debt has declined from 62.7% in 2005 to just below 60% in 2007.

It is now possible in all but a few Member States to start up a business within one week by means of a "one-stop shop" and there have been important steps in implementing the EU better regulation agenda.

About half of the Member States have developed - or are developing - policies based on a flexicurity approach. Agreement has been reached on a common set of flexicurity principles which Member States should now implement, tailoring them to their own specific situations. All Member States have now set a national R&D investment target. If all of these targets are met, the EU will reach an R&D level of 2.6% of GDP in 2010 (up from 1.9% in 2005). This would be a significant improvement even if the key EU target of 3%.

However, the proportion of GDP spent on R&D in the EU has recently failed to keep up with stronger economic growth rates and decreased to 1.85 % in 2006, with large differences between Member States. This trend moves the EU further away from 3% target. Despite the deficit and debt improvements, the opportunity to use the relatively strong growth conditions to reduce structural deficits has not been fully seized, especially in the euro area.

Many labor markets remain segmented, with well-protected insiders and more precarious outsiders on contracts with uncertain prospects. Education systems are not doing enough to give young people the skills they and employers need. Worker mobility remains still relatively low. Only 2% of working age citizens live and work in another Member State. In some Member States workers still face significant barriers when changing jobs. The Commission has therefore proposed a Job Mobility Action Plan.

Europe is still lagging behind other leading economies in investment in information and communication technologies and in their use to enhance productivity. Many Member States are not on course to fulfill their

Kyoto targets and will need to make a major effort to reach the ambitious targets agreed by EU leaders at the 2007 Spring European Council and to be implemented through the energy and climate change package the Commission will bring forward at the beginning of 2008. Member States have continued to make progress, at differing rates. In most cases, steps have been taken towards meeting the commitments contained in the country specific recommendations agreed collectively by the Member States in 2007.

2. SOME CEE COUNTRIES' CONVERGENCE PROGRAMS

Romania submitted a new update of its convergence program on 5 December 2007, covering the period 2007-2010. The budgetary strategy outlined in the program is not in line with the prudent fiscal policy necessary to contain the growing external deficit and inflationary pressures which put the convergence process at risk. The program envisages a continuation of high deficits, entailing the risk of an excessive deficit. (See table no. 1 for CEE countries) Progress towards Romania's medium-term objective (MTO) of a deficit just below 1% by 2011 is clearly insufficient and is left until the last year of the program period despite strong growth prospects. In view of the risks to the budgetary targets and the significant adjustment that would be necessary after the program period, the MTO is unlikely to be achieved by 2011 as planned.

		2006	*2007*	*2008*	*2009*	*2010*

Table no. 1 Convergence Programs of the CEE Countries

The long-term sustainability of Romania's public finances has not yet been assessed as calculations on age-related cost projections are still under way. The national debt was 12.4% in 2006, well below the 60% reference value set in the EU Treaty, but it is increasing. In view of the Commission assessment and the need to ensure sustainable convergence, Romania is invited to: (i) significantly strengthen the pace of adjustment by aiming for substantially more demanding budgetary targets in 2008 and subsequent years; (ii) restrain the envisaged high increase in public spending, review its expenditure composition so as to enhance the economy's growth potential and improve the planning and execution of expenditure within a binding medium-term framework; (iii) adopt policies to contain inflationary pressures, complementing the recommended tighter fiscal stance, with appropriate public wage policy and further structural reforms.

Slovakia submitted a new update of its convergence program on 29 November 2007, covering the period 2007-2010. The program is consistent with a correction of the excessive deficit by 2007. Progress towards Slovakia's medium-term objective of a deficit just below 1% slows down, however, in 2008, and the MTO is planned to be reached only at the end of the program period despite strong growth outcomes and prospects (see Table no. 1).

Slovakia is advised to stand ready to adopt a tighter fiscal stance, in particular in view of possible inflationary pressures after the disinflation effect of past exchange rate appreciation fades out. As regards the long-term sustainability of public finances, Slovakia appears to be at medium risk. In view of the Commission assessment and the recommendation under Article 104(7) of 5 July 2004 and also given the need to ensure sustainable convergence and smooth participation in ERM II, Slovakia is invited to: (i) exploit the strong growth conditions to strengthen the pace of structural adjustment in 2008 and strictly implement the envisaged structural consolidation thereafter, (ii) introduce further structural reforms to improve the labor market performance and stand ready to adopt a tighter fiscal stance, in particular in order to contain possible inflationary pressures, especially after the disinflation effect of past substantial exchange rate appreciation fades out.

Having assessed the budgetary developments in Poland since the adoption of a new Council recommendation, last February, the European Commission concludes that the deficit is likely to be below 3% this year. But, at the same time, it is expected to rebound above 3% in 2008, according to the Commission's autumn economic forecasts based, inter alia, on the draft budget adopted by the outgoing government. This calls for additional measures to put the Polish budget firmly on a sustainable path, especially in view of the positive economic outlook enjoyed by the country. In February 2007, European Union finance ministers (ECOFIN Council), on a recommendation by the Commission, found that the budgetary situation had improved in Poland, but not sufficiently to correct the excessive deficit situation by 2007. This deadline was agreed back in 2004, when Poland joined the EU, according to a first ECOFIN Council recommendation under Article 104(7) of the EU Treaty.

Poland informed, in September this year, that it expected a deficit of 3.0% of GDP in 2007 after an outcome of -3.8% in 2006. According to the autumn forecast of the Commission services, the 2007 deficit outturn will be even better, reaching 2.7% of GDP, mainly thanks to an incomplete execution of planned expenditure (see Table no. 1). Also the structural improvement will reach 0.9 percentage point of GDP, which more than satisfies the Council recommendation. Against this background, the planned budgetary adjustment fulfils the Council recommendation concerning 2007.

But the autumn forecast published by the Commission on 9 November points to the risk that the deficit may rebound and breach the 3% reference value in 2008 and 2009, if no additional policy actions are taken. This is because a number of deficit increasing measures were adopted without counteracting measures by the Parliament before the October 2007 elections. The Polish authorities are, therefore, invited to submit, as soon as possible after the new government has taken office, an updated convergence program describing additional consolidation measures for 2008 and the following years. The updated fiscal strategy should be geared towards making permanent the correction of the excessive deficit in 2007 and making progress towards the medium-term objective of a structural deficit of 1% of GDP.

Hungary submitted a new update of its convergence program on 30 November 2007, covering the period 2007-2011. Hungary must take adequate action to ensure the correction of the excessive deficit as planned, where necessary through additional measures. Reinforcing fiscal governance and completing the structural reforms which are essential to improve the long-term sustainability of public finances are crucial in moving towards lasting convergence. The program plans to continue the correction of the high deficits of the past years through a frontloaded adjustment effort (see Table no. 1).

Thanks to the consolidation measures and structural reforms, Hungary is set to considerably outperform its 6.8% of GDP deficit target for 2007. It also improves the target for 2008 to 4% of GDP compared to the previous program which, in view of the better-than-expected outcome in 2007, is both feasible and desirable. However, the lower deficit targets are combined with higher-than-previously planned expenditures on the back of better-than-expected revenues, which cannot be counted on after 2008. Moreover, from 2009 the achievement of the budgetary targets is subject to increasing risks, linked mainly to possible expenditure overruns if the wide-ranging reform agenda is not fully carried out. Ensuring the adjustment is durable requires a strengthening of fiscal governance and the completion of structural reforms. This is also crucial in order to improve the long-term sustainability of public finances, for which Hungary remains at high risk, and to move towards lasting convergence.

In view of the Commission assessment and of the recommendation under Article 104(7) of 10 October 20063 and given the need to ensure sustainable convergence, the Council should invite Hungary to: (i) rigorously implement the 2008 budget, take adequate action to ensure the correction of the excessive deficit by 2009 as planned; and allocate the better-than-expected revenues to further deficit reduction, also given the insufficient margin in 2009 in view of the risks, thereby also contributing to accelerating the pace of debt reduction towards the 60% of GDP threshold; (ii) ensure permanent expenditure moderation by continuing to enhance fiscal rules and institutions and by adopting and swiftly implementing measures announced in the fields of public administration, healthcare, and the education system; (iii) in view of the level of debt and the increase in age related expenditure, improve the long-term sustainability of public finances and continue to reform the pension system as announced after the initial steps taken in 2006-2007.

Bulgaria submitted a new update of its convergence program on 7 December 2007, covering the period 2007-2010. Bulgaria, which has enjoyed high growth since 2003, has carefully refrained from a pro-cyclical fiscal stance and is aiming for ambitious but necessary budgetary surpluses. To ensure sustainable convergence with the rest of the EU, it is vital that it continues on this path with a view to containing inflation and external imbalances, in particular by saving all unexpected revenues (see Table no. 1).

The program proposes an upward revision of the MTO2 from a balanced budget to a surplus of 1½% of GDP, which will be comfortably met throughout the program period. Safeguarding macroeconomic stability and sustaining catching-up in a context of rising external imbalances and high inflation will require the continuation of tight fiscal policies and further improvements in the quality of public spending, including in health care. Fiscal institutions and public sector wage policy need to contribute to overall wage moderation in line with productivity gains. The long-term sustainability of Bulgaria's public finances has not been assessed as calculations on age-related cost projections are still under way. But the current and planned structural surpluses are helping and will help reduce the already low level of public debt.

In view of the Commission assessment and also given the need to ensure sustainable convergence, Bulgaria is invited to: (i) continue avoiding a pro-cyclical fiscal stance with a view to helping contain existing external imbalances, notably by saving all proceeds from any budgetary over-performance and respecting expenditure ceilings; (ii) adopt policies to contain inflationary pressures, including by contributing to wage moderation through a prudent public sector wage policy and preserving competitiveness; (iii) further strengthen the efficiency of public spending, in particular through full implementation of program budgeting, reinforced administrative capacity, and a reform of the health care system.

The Czech Republic submitted a new update of its convergence program on 30 November 2007, covering the period 2007-2010. In view of an expected general government deficit below 2% in 2007 – much less than estimated by the program itself – the budgetary developments and strategy are consistent with a correction of the excessive deficit in 2008 – by a wider margin than initially planned. However, this is conditional on continuing expenditure restraint and a close monitoring of the possible fall in revenues following the introduction of a flat tax in 2008 (see Table no. 1).

Owing to the positive macroeconomic outlook and a better-than-expected 2007 budgetary outturn, the Czech Republic also ought to achieve stronger-than targeted fiscal consolidation afterwards. The main risks are in its reliance on reductions in public sector employment and the lack of information on the consolidation measures after 2008. The Czech Republic remains at high risk with respect to the sustainability of public finances. Initial steps have been taken to reform the health care system, but further measures are still awaited regarding reforms in this field and in the field of pensions. The debt remains at around 30%.

In view of the Commission assessment and also in the light of the recommendation under Article 104(7) of 10 October 2007, and given the need to achieve sustainable convergence, the Czech Republic is invited to: (i) exploit the likely better-than-expected 2007 budgetary outcome to bring the 2008 deficit below the 3% of GDP reference value by a larger margin; (ii) exploit the high rate of growth in the economy by strengthening the pace of adjustment; (iii) in view of the projected increase in age-related expenditure, improve the long-term sustainability of public finances through the necessary pension and health care reforms.

Estonia submitted a new update of its convergence program on 29 November 2007, covering the period 2007-2011. Estonia's program plausibly aims to maintain a sound budgetary position throughout the period with continued surpluses above the MTO. However, macroeconomic imbalances that have accumulated in the economy are expected to moderate only gradually. The budgetary targets seem plausible. But the macroeconomic imbalances that have accumulated during the years of very high growth of close to 10% or more – notably wage growth exceeding that of productivity, price pressures and high net borrowing vis-à-vis the rest of the world – are expected to moderate only gradually and the deceleration path of the economy is surrounded by downward risks (see Table no. 1).

The long-term sustainability of the Estonian finances is good with almost no public debt, and age-related expenditure costs having already been dealt with. In view of the Commission assessment and also given the need to ensure sustainable convergence and a smooth participation in ERM II, Estonia is invited to contribute to reducing risks to macroeconomic stability by: (i) aiming for a broadly neutral fiscal stance in 2008 and beyond so as to contribute to an orderly adjustment towards a balanced convergence path, (ii) complementing the recommended fiscal stance with appropriate public wage policy and further labor market reforms so as to contain inflationary pressures and sustain rapid productivity growth.

Latvia submitted a new update of its convergence program on 29 November 2007, covering the period 2007-2010. For Latvia, the risks to the budgetary targets are high owing to large macroeconomic uncertainty and past slippages from expenditure plans. A considerably tighter fiscal stance is urgently needed to meet the programs aims in a context of large economic imbalances and excessive demand pressure. Latvia urgently needs to adopt a tighter fiscal stance to meet the programs aims in a context of strong inflationary pressures (Latvia had the highest inflation rate in the EU at about 10% in 2007 and increasing), deteriorating cost competitiveness and sharply increasing net foreign liabilities. While medium-term expenditure ceilings have been introduced, they remain to be tested (see Table no. 1).

By contrast the long-term sustainability of the Latvian public finances is good, with a public debt of around 10% and low exposure to the future age-related expenditure costs on account of past pension reforms. In view of the Commission assessment and given the need to ensure sustainable convergence and a smooth participation in ERM II, Latvia is invited to reduce overheating pressures and risks to macroeconomic stability by: (i) aiming for significantly more ambitious budgetary targets in 2008 and beyond; (ii) carefully prioritizing public expenditure within the overall public sector expenditure limits set within the medium-term budget planning framework, and re-examining taxation instruments to avoid demand stimulus in sectors which do not significantly strengthen the economy's medium- and long term supply potential; (iii) adopt further policies to contain inflationary pressures, including through responsible public sector wage-setting, thus contributing to the sharp reduction in whole-economy wage growth needed to break the current cost-price dynamics and put a stop to the rapid deterioration in Latvia's competitiveness.

3. CONCLUSIONS

Having examined the updated convergence program of CEE countries, the European Commission finds that its planned budgetary consolidation is consistent with a correction of the excessive deficit in 2007. But it should speed up consolidation thereafter so as to create a safe budgetary margin more quickly and to counter any possible inflationary pressures. Romanian convergence program projects a continuation of high deficits despite strong growth. This creates the risk of an excessive deficit and is not in line with prudent fiscal policy. All CEE countries have been experiencing a period of strong economic growth. The increasing deficit of Romania since it joined the EU and its volatility are a matter of serious concern. Romania needs to aim for more healthy budgetary targets to avoid breaching the rules of the Stability and Growth Pact and to contain the growing external deficit and inflationary pressures which pose a risk to macroeconomic and financial stability. Some CEE countries' planned budgetary consolidation is consistent with a correction of the excessive deficit in 2007. But looking beyond the correction of the excessive deficit, faster progress towards the medium-term objective is advised, in particular to contain possible inflationary pressures.

Trying to explain economic growth is one of the fundamental questions in economics and has generated a large body of research. The importance of technology for economic growth provides an important link between FDI inflows and host country economic growth. It is theoretically straightforward to argue that FDI inflows have a potential for increasing the rate of economic growth in the host country. Inflows of physical capital resulting from FDI could also increase the rate of economic growth but it is argued in this paper that the most important effect comes from spillovers of technology. MNE operations in the host country can result in technology spillovers from FDI whereby domestic firms adopt superior MNE technology which enables them to improve their productivity. Technology spillovers thereby generate a positive externality that should allow the host country to enhance its long-run growth rate.

Key words: foreign direct investments, technology spillovers, competitiveness, economic growth.

1. Introduction

The economic development of emerging markets and developing countries depends to a large extent on the possibility to make profitable investments and accumulate capital. Having access to foreign capital and investments allows a country to exploit opportunities that otherwise could not be used. Recent experiences with opening capital accounts in emerging and developing economies, however, have proved to be a mixed blessing, as it is becoming increasingly clear that not all types of capital imports are equally desirable. Direct investments are much more resilient to crises, therefore the question is what countries can do to attract more of such capital flows.

While the economic determinants of FDI flows to developing countries have been analyzed to a considerable degree, it is rather astonishing that the importance of changes in political institutions and of other relevant policies in host countries have received relatively little attention. In the 1990s, most existing studies on the influence of policy-related variables on FDI flows consisted of international cross-country studies. Within this framework, it has been found, for example, that there is a negative link between institutional uncertainty and private investment (Brunetti and Weder, 1998), a positive relationship between FDI and intellectual property protection (Lee and Mansfield, 1996), and a negative impact of corruption on FDI flows (Wei, 2000).

The first attempt was made by Jun and Singh (1996), who regressed an aggregated indicator for political risk, based on a number of sub-components, and several control variables on the value of foreign direct investment inflows. For their data sample of 31 developing countries, the political risk index is statistically significant and the coefficient implies that countries with higher political risk attract less FDI. Likewise, Gastanaga et al. (1998) examined the link between various political variables and foreign investment inflows. They found that lower corruption and nationalization risk levels, and better contract enforcement are associated with higher FDI inflows. Yet they state that their findings do not always hold up, which may be due to the relatively small country sample of 22 developing countries.

More recently, several studies have analyzed the relationship between fundamental democratic rights and FDI: Harms and Ursprung (2002), Jensen (2003), and Busse (2004) found that multinational corporations are more likely to be attracted by countries in which democracy is respected. Li and Resnick (2003), on the other hand, argue that competing causal linkages are at work. They found that democratic rights lead, above all, to improved property rights protection, which in turn boosts foreign investment. Apart from this indirect impact on FDI, increases in democracy may reduce FDI.

In previous studies it was also shown that only few indicators for political risk and institutions are closely associated with FDI. These are government stability, law and order, and quality of the bureaucracy. In addition to the three mentioned indicators, we find that investment profile, internal and external conflict, ethnic tensions and democratic accountability are important determinants of FDI flows.

Until now, empirical evidence on a positive relationship between FDI inflows and host country economic growth has been elusive. When a relationship between FDI and economic growth is established empirically it tends to be conditional on host country characteristics such as the level of human capital, see for example de Mello (1999) and Borensztein et al (1998). The difficulty in proving a positive effect from FDI on economic growth provides a strong incentive for further empirical studies. Neoclassical models of economic growth only allow FDI to have a level effect on growth due to diminishing returns to capital. However, the endogenous growth theory provides a framework for studying the link between FDI and economic growth that makes it possible to take the characteristics of FDI into account and should improve the chances of confirming the theoretical relationship by empirical evidence.

The paper argues that it is technology spillovers from MNEs to domestic firms that provide the most important link for a positive effect from FDI on economic growth. But are there differences in the growth-enhancing effect of FDI between different types of host countries such as developed, developing and transition economies? Furthermore, is there a threshold level of technology that host countries need to achieve in order for FDI to have a positive effect on economic growth? Are there other host country characteristics that affect the ability of FDI to enhance the rate of economic growth?

The aim of the paper is to analyze whether FDI inflows have a positive effect on host country economic growth. The paper contributes to the mixed results of earlier research by the finding that FDI inflows have a positive effect on host country economic growth in developing but not in developed economies.

2. FDI inflows and economic growth

FDI inflows can affect host country economic growth in several ways. The purpose of this section is to provide a description of the potential growth enhancing effect of FDI.

2.1. Firm-specific advantages, knowledge capital and externalities

What implications does the importance of knowledge-capital and technology for MNE operations have for the growth enhancing potential of FDI inflows? As argued above, advanced technology is an important component of knowledge capital and technology in many cases forms the basis for an MNE’s firm-specific advantage. Not only is technology very important as a firm specific advantage for many MNEs, it also provides a link between FDI and economic growth.

The non-rival characteristic of technology implies that MNEs try to protect their technology by using brand names and patents. Since the MNE is dependent on its firm-specific advantage (often in the form of technology) for profitable business operations as argued by Hymer (1960), the MNE has an incentive to try to prevent spillovers of technology to other firms.

Spillovers of technology are an externality that can occur through several different channels including imitation, reverse-engineering and supplier linkages. When spillovers do occur it implies that the MNE is unable to internalize all of the returns to its technology resulting in a positive externality since the social return on investment is higher than the private return. It is argued in this paper that it primarily is the positive externalities from technology spillovers that allow FDI to enhance the rate of economic growth1. The emergence of theories of endogenous growth provides a framework that shows how positive externalities can improve long run economic growth. Positive externalities provide non-diminishing returns to capital and therefore enhance growth also in the long run. Endogenous growth theories therefore support the idea that FDI could enhance economic growth. Balasubramanyam et al (1996, p. 95) argues that the ‘new growth theory … provides powerful support for the thesis that FDI could be a potent factor in promoting growth’.

2.2 Physical capital and labor

We argued above that technology spillovers provide externalities that should have a positive effect on economic growth in the host country. Besides of knowledge-capital, FDI can also generate an inflow of physical and human capital to the host country. As the size of the host country physical capital stock increases the productive capacity of the host country also increases. Unfortunately the growth enhancing effect of an ever growing stock of physical capital is not endless. Even though additional capital can have important effects on economies with a low capital-labor ratio, diminishing returns imply that accumulation of physical capital cannot function as a permanent source of long-run growth. Since Solow type models rules out capital as a source of long-run per capita growth, in such a framework FDI can only affect growth through an inflow of capital in the short run while the economy is in transition toward steady state.

Empirical research on the role of capital accumulation for economic growth has not been conclusive. Easterly and Levine (2001) used a growth accounting framework and reached the conclusion that investment in physical capital is relatively unimportant in explaining long run economic growth since technological progress accounts for most of the cross-country variation in growth. However, Bond et al (2004) argues that this conclusion is premature since the modeling framework in Easterly and Levine is too restrictive.

An inflow of FDI is not likely to generate a large inflow of labor to the host country. Except for management, most of the MNE employees are expected to be recruited from the host country labor force. Furthermore, when investment takes the form of brown-field FDI it is not uncommon that MNEs lay off a substantial share of the incumbent labor force as usually done during privatizations. Therefore, a small effects from FDI on economic growth through effects on the host country stock of labor is expected.

Based on the discussion in this section the conclusion is reached that the primary effect from FDI inflows on host country economic growth should arise as a result of technology spillovers rather than through an increase in the stocks of capital and labor. This view is shared by other studies such as de Mello (1997).

2.3 Greenfield and brownfield FDI

The growth enhancing ability of FDI is affected by the chosen mode of FDI. It is argued in this paper that the effects of FDI inflows on variables such as technology spillovers and physical capital is expected to differ between greenfield and brownfield FDI. Greenfield FDI implies that the MNE constructs new facilities of production, distribution or research in the host country. The result is an increase in the host country stock of physical capital that can be substantial, especially for developing economies that tend to be capital scarce. Under brownfield investment, on the other hand, the MNE acquires already existing facilities in the host country. Brownfield FDI should therefore only result in a limited increase in the stock of physical capital since there is a change in ownership rather than an inflow of new capital.

Greenfield and brownfield FDI should affect host country growth differently since Greenfield FDI results in a larger inflow of physical capital. While brownfield FDI results in a small inflow of physical capital, Javorcik (2004) argues that brownfield FDI in the form of a merger or joint venture could maximise the potential for technology spillovers. Unfortunately, lack of appropriate data precludes an empirical analysis of this interesting research problem.

Effect on growth of:	Developed economies	Developing economies
Technology spillovers from FDI	+ High absorptive capacity implies a high potential to adopt technology leakages and realise spillovers - An already high host country level of technology reduces the potential for further improvements from spillovers	+ Low host country level of technology indicates a high potential for improvement even if spillovers are small - Low absorptive capacity implies that only a limited share of an MNE technology leakage can be turned into spillover through adoption
Physical capital inflow from FDI	+ Market structure implies existence of increasing returns to investment - Large per capita stocks of physical capital suggests decreasing returns to investment	+ Small per capita stocks of physical capital implies increasing returns to investment - Market structure studies indicate that constant returns to scale dominate in developing economies

Table no. 1 Host country ability to enhance economic growth through FDI inflows

The developed economies have larger per capita stocks of real capital than developing economies. Consequently these economies should be closer to experience diminishing returns to capital than developing economies when there is an inflow of physical capital. Table 1 summarises the discussion and presents an overview of the differences in the ability of developed and developing economies to realise the growth enhancing potential of FDI inflows.

What conclusions can be drawn based on the summary in Table 1? It does not seem to exist a clear indication whether developed or developing economies should experience the strongest growth effects from FDI inflows.

The discussion in this section suggests two objectives for the analysis of the paper. Firstly, can it be verified that FDI inflows indeed enhance economic growth in the host country? Secondly, how does the growth enhancing potential of FDI differ between developed and developing host countries?

The paper has argued that the two main channels through which FDI can affect host country economic growth are technology spillovers and inflows of physical capital. The paper discusses and models the effects of FDI inflows on host country economic growth. Based on this discussion the paper argues that technology spillovers provide the strongest potential for FDI to enhance economic growth. Foreign MNEs have a technology advantage over domestic firms and MNE entry in the form of FDI results in a positive externality in the form of technology spillover from the MNE to domestic firms. The domestic firms are thereby able to improve their level of technology and become more productive.

The paper investigates whether there are differences in the growth enhancing effect of FDI between developed and developing economies. The paper contributes to the mixed results of earlier empirical studies by the finding that FDI inflows have a positive effect on host country economic growth for developing but not for developed economies.

Foreign direct investments (FDI) are a factor movement which affects the international location of production, patterns of trade, and the way national firms internationalize.

In this paper we utilize firm data on manufacturing plants in four Central and Eastern European Countries (CEECs), namely Bulgaria, Hungary, Poland and Romania, between 1995 and 2004 in order to trace the location of multinational enterprises (MNEs) and estimate the determinants of their location choice.

Since the beginning of the transition process, CEECs have received a constantly increasing amount of foreign direct investments, which being made not only by financial capitals but also by fixed assets, knowledge (both codified and tacit) and technology played an active and dynamic role in enhancing the industrial restructuring process and driving the (re)integration of CEECs into the world economy. Several studies provide in-depth analyses on the contribution of MNEs to the different phases of transition processes. Despite all this interest, very little is known about the factors influencing multinational location choice.

Several reasons explain the need for mapping FDI and understanding their behaviour in location choice processes. First of all, this would help to identify which location advantages make more profitable for firms to produce abroad, provided that they possess organisational and internalisation advantages (Markusen, 1995; Dunning, 1977); secondly, it would directly show the spatial distribution of the benefits generated by FDI, though the mechanism is far from being automatic.

Central and Eastern Europe has been only marginally considered in the empirical literature on firm location choice. A number of difficulties have impeded empirical analysis on this issue in transition countries. In particular, data on foreign firm location and economic and social characteristics of narrowly defined locations have not been readily available since recent times. This explains why among the works quoted above, only two of them focus on multinational firm location choice in CEECs, though from a very limited perspective. In particular, Disdier and Mayer (2003) test how French firms choose the location (at country level) for their production plants abroad within a set of 14 Western European countries and six CEECs. They found that the East-West structure effectively influence French firms location choice in Europe, suggesting that competition for FDI attraction is stronger among CEECs than between Eastern and Western European countries. This difference, however, decreases over time, indicating that CEECs are perceived by French firms as more and more similar to EU countries.

We consider, in fact, multinational firms' location choice belonging to four CEECs. Two of them, i.e. Hungary and Poland, advanced faster on the way to EU membership than the other two, namely Bulgaria and Romania, which still are candidate countries. Moreover, we compare two small with two large countries, thus implicitly considering potential biases deriving from country size. The composition of the set of location alternatives is particularly important, since it allows a better comprehension of multinational firms' location patterns in transition countries, a world whose extremely diversified economic realities have been able to accommodate a large number of multinational firms pursuing different strategies of internationalization.

3. Conclusions

The paper has argued that the two main channels through which FDI can affect host country economic growth are technology spillovers and inflows of physical capital. The paper discusses the effects of FDI inflows on host country economic growth. Based on this discussion the paper argues that technology spillovers provide the strongest potential for FDI to enhance economic growth. Foreign MNEs have a technology advantage over domestic firms and MNE entry in the form of FDI results in a positive externality in the form of technology spillover from the MNE to domestic firms. The domestic firms are thereby able to improve their level of technology and become more productive. The paper attempts to verify whether FDI inflows enhance economic growth. The paper finds that FDI inflows have a positive effect on host country economic growth for developing economies.

The discussion on host-country impact has focused on host developing economies both because they are the principal recipients of FDI from developing countries and because it is the development impact of such FDI that matters the most. The impact of FDI from developing countries on host developed economies is likely to be much less significant than that on host developing economies, because of its much smaller size relative to total FDI in host developed countries.

Although modest in size relative to global FDI flows, FDI from developing countries assumes considerable importance for host developing countries. The direct and indirect effects of the FDI package on financial resource flows and investment, transfer and diffusion of technology, export activity and employment can usefully supplement domestic efforts of host developing countries in those areas. The industrial distribution of developing-country FDI and the technological attributes of developing-country TNCs suggest that developing-country foreign affiliates may be able to interact more effectively with domestic firms in host developing countries than affiliates of TNCs from developed countries.

However, apart from the potential economic benefits of FDI from developing countries – as also in the case of FDI from developed countries – there may also be a number of risks, economic as well as non-economic, for host developing economies. The challenge for host developing economies is to minimize the risks, and benefit to the maximum extent possible from these new sources of FDI. In that context, national and international policies matter.

This paper provides a background discussion of the arm's length principle, which is the international transfer pricing standard that OECD Member countries have agreed and should be used for tax purposes by MNE groups and tax administrations. The paper discusses the arm's length principle, reaffirms its status as the international standard, and sets forth guidelines for its application in a few European countries.

Key words: arm’s length principle, transfer pricing, OECD guidelines

1. General Considerations

The role of multinational enterprises (MNEs) in world trade has dramatically increased over the last 20 years. On one hand this role reflects the increased of integration in case of national economies and technological progress, particularly in the area of communications. On the other hand the growth of MNEs generated increasingly complex taxation issues for both tax administrations and the MNEs themselves since separate country rules for the taxation of MNEs cannot be viewed in isolation but must be addressed in a broad international context.

In order to apply the separate entity approach to intra-group transactions, individual group members must be taxed on the basis of ***arm's length principle*** in their dealings with each other. However, the relationship among members of an MNE group may permit the group members to establish special conditions in their intra-group relations that differ from those that would have been established by the group members that have been acting as independent enterprises operating in open markets. To ensure the correct application of the separate entity approach, OECD Member countries have adopted the ***arm's length principle***, under which the effect of special conditions on the levels of profits should be eliminated.

Arm's length principle is the international standard that OECD Member countries have agreed in terms of determining transfer prices for tax purposes. It is set forth in Article 9 of the OECD Model Tax Convention as follows: where "conditions are made or imposed between the two enterprises in their commercial or financial relations which differ from those which would be made between independent enterprises, then any profits which would, but for those conditions, have accrued to one of the enterprises, but, by reason of those conditions, have not so accrued, may be included in the profits of that enterprise and taxed accordingly".

These international taxation principles have been chosen by OECD Member countries as serving the dual objectives of securing the appropriate tax base in each jurisdiction and avoiding double taxation, thereby minimizing conflict between tax administrations and promoting international trade and investment.

Transfer prices are significant for both taxpayers and tax administrations because they determine in large part the income and expenses, and therefore taxable profits, of associated enterprises in different tax jurisdictions. Transfer pricing issues originally arose in dealings between associated enterprises operating within the same tax jurisdiction. The domestic issues are not considered in this Report, which focuses on the international aspects of transfer pricing. These international aspects are more difficult to deal with because they involve more than one tax jurisdiction and therefore any adjustment to the transfer price in one jurisdiction implies that a corresponding change in another jurisdiction is appropriate.

The authoritative statement of the arm's length principle is described in paragraph 1 of Article 9 of the OECD Model Tax Convention, which forms the basis of bilateral tax treaties involving OECD Member countries and an increasing number of non-Member countries. Article 9 stated that: "[When] conditions are made or imposed between ... two [associated] enterprises in their commercial or financial relations which differ from those which would be made between independent enterprises, then any profits which would, but for those conditions, have accrued to one of the enterprises, but, by reason of those conditions, have not so accrued, may be included in the profits of that enterprise and taxed accordingly."

In respect of arm's length principle, the contractual terms of a transaction generally define explicitly or implicitly how the responsibilities, risks and benefits are to be divided between the parties. As such, an analysis of contractual terms should be a part of the functional analysis discussed above. The terms of a transaction may also be described in correspondence/communications between the parties other than a written contract. Where no written terms exist, the contractual relationships of the parties should take into consideration the economic principles that generally govern relationships between independent enterprises.

2. Transfer Pricing in Europe

This Chapter is presenting some general consideration in terms of transfer pricing in some European countries, like taxing authority and law, regulations, pricing methods, transfer pricing penalties, documentation requirements, categories of documentation required, deadline to prepare documentation, deadline to submit documentation, statute of limitations on transfer pricing, assessments, return disclosure – related party transactions, transfer pricing scrutiny, advance pricing agreements.

2.1. Austria

Taxing Authority is the Federal Ministry of Finance.

The current Regulations in transfer pricing in Austria are the OECD Transfer Pricing Guidelines. In this country are no statutory provisions dealing specifically with transfer pricing.

In respect with the **priorities and pricing methods allowed** in Austria are no binding rules.

There are no special **transfer pricing penalties**. If inter-company transactions are not carried out at an arm’s length price, the tax authorities may consider that the difference should be treated as a hidden distribution of profits. The effect of this is that certain expenses become non-deductible expenses and withholding tax is payable on the deemed distribution, subject to treaty relief.

Is no special provisions in which that consider the **reduction in transfer pricing documentation penalty** that could be gained if the tax payer satisfies certain conditions.

Documentation Requirements should follow OECD guidelines. Taxpayers are advised to maintain adequate supporting documentation justifying their transfer prices, as this can shift the burden of proof to the tax authorities.

In terms of **types of information required** as part of taxpayers documentation there is no specific categories of documents required, but a written transfer pricing contract or other documentation is highly recommended.

The deadline to prepare and to submit transfer pricing documentation is just on time. There are no specific limitations on assessment for transfer pricing adjustments.

The risk that transfer prices are scrutinized during a tax audit are high.

2.2. Belgium

Taxing Authority is Ministry of Finance, Federal Finance department.

Tax law is the Belgian domestic tax law and numerous interpretation circulars issued by the Ministry of Finance.

In respect with **regulations and rulings** in transfer pricing, in Belgium exist the follow provisions:

I. Circulars issued by the Belgian tax authorities mainly make reference to the OECD guidelines.

II. a. Belgian Income Tax Code:

- as from 19 July 2004 the arm’s length criteria as determined in article 9 of the OECD guidelines has been implemented in Belgian domestic tax law under article 185 § 2 and with cross-reference in article 235, 2° for non-residents:
- Article 185 § 2 applicable as from 19 July 2004: if conditions are made between two related companies belonging to a multinational group in their commercial or financial relation which differ from those which would be made between independent enterprises, then any profits

which would, but for those conditions, have accrued to one of the enterprises, but, by reason of those conditions, have not so accrued, may be included in the profits of that enterprise and taxed accordingly.

Where profits on which an enterprise of a Contracting State have been charged to tax in that State are also included, according to the previous paragraph, in the profits of the enterprise of the other Contracting State and taxed accordingly, and the profits so included are profits which might have been expected to have accrued to the enterprise of the other State if the conditions operative between the enterprise had been those which might have been expected to have operated between independent enterprises dealing wholly independently with one another, then the first-mentioned State shall make such adjustment as it considers appropriate to the amount of tax charged on those profits in the first-mentioned State.

These newly implemented stipulations can, however, only be invoked in case an international procedure for avoiding double taxation has been introduced (for instance a bilateral tax treaty or a EU Arbitration treaty) or a (national) ruling has been filed.

b. Other transfer pricing regulations in Belgian domestic tax law

- Article 26: If a Belgian company grants abnormal or gratuitous benefits to a related entity, the so-granted benefit can be added back to its taxable result, unless the receiving entity has been taxed (in Belgium) on such received benefits.
- Article 79 and 207: The company that receives an abnormal or gratuitous benefit may not deduct tax losses carried forward, investment deductions and dividend received income from the received benefit. As from the financial year 2003 (for companies closing per 31 December 2003) the losses of the year may not be deducted either.

There are no specific **transfer pricing methods** allowed in Belgian domestic tax law. Circulars issued by the Belgian tax authorities mainly make reference to the OECD guidelines.

Also, are no specific penalties **for transfer pricing transactions**. General penalties apply upon assessment of the Tax Inspectors' audit. The Tax Inspectors can reject all or part of the expenses and amend the taxable profits of that year imposing income tax for the extra profits assessed plus penalties (interest) for late payment of tax which can reach 200% of the main extra tax assessed.

In respect with the **reduction in transfer pricing documentation penalty** that could be gained if the tax payer satisfies certain conditions, is no specific regulations.

There are specific **requirements** in Belgian domestic tax law.

Based on the circulars issued by the Belgian tax authorities, general requirements for documents supporting any transaction apply, with reference also to OECD guidelines.

In practice, tax authorities are paying more and more attention to the transfer pricing applied within groups of companies. In this respect, upfront documentation is becoming a necessity in order to substantiate intra-group transactions. The Belgian tax authorities have announced that the absence of documentation may trigger an in-depth transfer pricing investigation.

Types of information required as part of taxpayers documentation requirement. No specific for related parties' transactions or for transfer pricing issues. General rules apply, i.e. written contract (especially for royalties or services with analytical description of services, basis for fees calculation, terms and conditions for transactions, etc), invoices, supporting documentation for payments.

Deadline to Prepare Documentation. Upfront documentation is becoming a necessity in order to substantiate intra-group transactions. **Deadline to Submit Documentation** is upon request of the Tax Authorities.

In respect with **statute of limitations on assessment** for transfer pricing adjustments is not specific for inter-company transactions or for transfer pricing issues, thus general rules apply: According to the Belgian general statutes of limitation, the tax authorities can carry out a tax audit for a financial year up to three years as from the closing date of that financial year (in cases of fraud this period is extended to five years). However, in certain specific circumstances other assessment periods may apply.

Assessments. The assessment year starts 1 January and ends on the following 31 December. The corporate income tax can be assessed until 30 June of the year following the assessment year.

For corporations with an accounting year ended on 31 December, the assessment year is the following calendar year. When the accounting year ends at another date, the tax year is the calendar year in which the accounting year ends.

In the absence of documentation substantiating the intra-group transactions, **the risk** is high that the tax authorities trigger an in-depth transfer pricing investigation.

In accordance with ability that Belgium territory could enter into Tax Authority approved multi lateral or unilateral advance pricing agreements between group companies, the Belgium authorities says that: a preliminary tax ruling can be applied for in order to ascertain the tax regime of the transaction. The timeframe for the tax authorities to deal with the ruling request is set in principle at 3 months, this timeframe can however be changed in mutual consent between taxpayer and tax administration.

During this period the transaction cannot take place if upfront certainty is required. A positive decision will be valid for maximum 5 years.

2.3. Denmark

Taxing Authority is Ministry of Taxation.

Transaction-based preferred over profit based. The **transfer pricing methods** allowed are CUP[176], Resale Price, Cost Plus, Profit Split, TNMM[177].

In Denmark the **documentation requirements** are contemporaneous.

Types of information required as part of taxpayer's documentation requirement are the follow:

- Description of the involved entities
- Description of the type of intra group transactions
- Analysis of the functions and risks undertaken and assets employed by the involved enterprises
- Information about the transfer pricing method applied
- Comparability analysis

Deadline to prepare documentation is by the date for filing the tax return. **Deadline to submit documentation** is on request from the Danish Tax Authorities.

The limitation on a transfer pricing assessment is 1st May in the sixth year after the end of the calendar year replacing the income year.

Is no **advance pricing agreements** regime in place, but Danish tax authorities have entered into a limited number of bilateral APAs

2.4. Germany

The Taxing Authority is Ministry of Finance.

The Tax Law is Gewinnabgrenzungsaufzeichungsverordnung (Tax Ordinance on Transfer Pricing (10/17/2003)).

The current transfer pricing and regulatory provisions. In addition to the main statutory provisions mentioned above, there are draft statements of the Ministry of Finance (10/18/2004) which explain certain details of the transfer pricing. The most important is so called "Gewinnabgrenzungsaufzeichnungsverordnung" (10/17/2003) Principles for the Examination of Income Allocation in the Case of Internationally Associated Enterprises and Other Related Parties

The priorities follow OECD Transfer Pricing Guidelines.

Traditional transactional **pricing methods** are preferable to the transactional profit methods. Profit based methods are not accepted since they are not following the dealing-at arm's length principle.

---

[176] Comparable uncontrolled price method compares the price charged for property or services transferred in a controlled transaction to the price charged for property or services transferred in a comparable uncontrolled transaction in comparable circumstances.

[177] Transactional net margin method examines the net profit margin relative to an appropriate base (e.g. costs, sales, assets) that a taxpayer realizes from a controlled transaction. Thus, a transactional net margin method operates in a manner similar to the cost plus and resale price methods.

The **penalty** is applied if taxpayer fails to submit TP documentation. Regular penalty is calculatea at a percentage of 5 to 10 % of estimated income correction and the minimum penalty is in amount of 5.000 euros. This penalty is also due in a loss situation. The late filing penalty of up to 1 million euros is 100 euros per day of delay..

Penalties may not be imposed if the taxpayer is not responsible for lack of appropriate documentation. A loss situation could lead to a lower rate within the 5 to 10 % margin.

Documentation Requirements: General fiscal code - Gewinnabgrenzungsaufzeichnungsverordnung

Types of information required as part of taxpayer's documentation requirement are the follow:

1. General information on shareholder relationships, organizational and operative group structure, area of operations
2. Description of intercompany transactions (incl. related parties)
3. Functions and Risks analysis
4. Transfer pricing methods analysis
5. Separate documentation of extraordinary transactions

Deadline to prepare documentation is contemporaneous (just on time). For extraordinary transactions the deadline is 6 months after the year end. **Deadline to Submit Documentation** is within 60 days upon tax authority's request.

There is no specific **statute of limitations**. It is accepted that there is no exact transfer price. Thus, a certain range of prices is possible. If the taxpayer can prove that his price is within that range an adjustment is not possible

Assessments are possible according to general adjustment principles normally within four years after filing the tax return, starting with the beginning of tax year after the filing year.

Advance Pricing Agreements are generally available but restricted to 'big' cases, due to German reluctant attitude toward APAs.

The role of multinationals in Romania has increased since 1 January 2007, due to the increased integration of national economies and technological progress, particularly in the area of communications. This type of growth presents complex taxation issues for both tax administrations and multinationas, themselves, since separate country rules for taxation cannot be viewed in isolation, but must be addressed in a broad international context. In order to apply the separate entity approach to intra-group transactions, individual group members must be taxed on the basis that they act at arm's length in their dealing with each other. In this context, transfer prices are significant for both taxpayers and tax administrations because ther determine in large part the income and expenses, and therefore taxable profit of associated enterprises in different tax jurisdictions.

Multinational enterprise, associated company, transfer prices, arm's length transaction, tax jurisdiction

What is tranfer price?

Transfer prices are the prices at which an enterprise transfers physical goods and intangible property or provides services to associated enterprises. By associated enterprises, we understand, that one of the enterprises participates directly or indirectly in the management, control or capital of the other or if the same persons participate directly or indirectly in the management, control or capital of both enterprises.

Transfer pricing issues originally arose in dealings between associated enterprises operating within the same jurisdiction, but with time and the growth of world economy and increased integration of national economies, this issue should be dealt at international level. And these international aspects are more difficult to deal with because they involve more than one jurisdiction and therefore any adjustment to the transfer price in one jurisdiction implies that a corresponding change in another jurisdiction is appropriate.

Transfer pricing in Romania vs. North America

In order to achieve the balance between the interest of taxpayers and tax administrators in a way that is fair to all parties, it is necessary to consider all aspects of system that are relevant in a transfer pricing case. One such aspect is the allocation of the burden of proof. In most jurisdictions, the tax administration bears the burden of proof, which may require the tax administration to make a prima facie showing that the taxpayer's pricing is inconsistent with the arm's length principle. It should be noted, however, that even in such a case a tax administration might still reasonably oblige the taxpayer to produce its records to enable the tax administration to undertake its examination of the controlled transactions. In other jurisdictions the taxpayer may bear the burden of proof in some respects. Some OECD Member countries, in respect of Article 9 of the OECD Model Tax Convention, have been established burden of proof rules in transfer pricing cases which override any contrary domestic provisions. Other countries, however, consider that Article 9 does not establish burden of proof rules (paragraph 4 of the Commentary on Article 9 of the OECD Model Tax Convention). Regardless of which arty bears the burden of proof, an assessment of the fairness of the allocation of the burden of proof would have to be made in view of the other features of the jurisdiction's tax system that have a bearing on the overall administration of transfer pricing rules, including the resolution of disputes. These features include penalties, examination practices, administrative appeals processes, rules regarding payment of interest with respect to tax assessments and refunds, whether proposed tax deficiencies must be paid before protesting an adjustment, the statute of limitations, and the extent to which rules are made known in advance.

This Article focuses on the main issues of principle that arise in the transfer pricing area in North America region and Romania.

From the analysis of the legal requirements in United States, Canada and Romania, we conclude that there are a few common issues to be discussed and harmonized, as follows:

a) the name of local taxing authority and what are the main statutory provisions in effect in each country;
b) the current transfer pricing and regulatory provisions in effect in each country;
c) details of the various transfer pricing methods allowed, and the priority with which each method is regarded;
d) the specific penalties that the governing Tax Authority will impose on a transfer pricing transaction if the tax payer is found not to be in compliance with the transfer pricing rules imposed by that country;
e) certain conditions that the tax payer has to satisfy in order to obtain the reduction in transfer pricing documentation penalty;
f) governing tax authority requirements that ask the taxpayers to prepare and maintain written documentation to confirm that the amounts charged in relating party transactions are consistent with the arms length standard;
g) types of information required as part of taxpayers documentation requirement;
h) the deadline to prepare transfer pricing documentation;
i) the deadline for submitting transfer pricing documentation;
j) statute of limitations on assessment for transfer pricing adjustments;
k) when do any assessments based on transactions begin;
l) disclosures required with respect to relating party transactions;
m) the level of risk of transfer pricing issues being scrutinized during the audit by the governing tax authorities;
n) if the state have the ability to enter into Tax Authority approved multilateral or unilateral advance pricing agreements between group companies;
o) the length of such agreements.

Analysis of Transfer Pricing Legal Requirements in United States, Canada and Romania

As it could be seen, the Romanian legislation offers place for improvement, the transfer pricing being a challenging domain both for taxation and economic matters within the Romanian economy. Up to now, it has been identify only a few adjustments made by Fiscal Authorities. For example, the rent charged by a company having a shareholder relation of 5% with a Romanian company has been increased up to the amortization cost plus 30%.

Conclusion

In conclusion, countries need to reconcile their legitimate right to tax the profits of a taxpayer based upon income and expenses that can reasonably be considered to arise within their territory with the need to avoid the taxation of the same item of income by more than one tax jurisdiction. Such double or multiple taxation can create an impediment to cross-border transactions in goods and services and the movement of capital.

Abstract: This paper intends to put into light the particularities of economic policies coordination in general and, more specifically, in the Economic and Monetary Union. The coordination of economic policies and especially of the common monetary policy with the national budgetary policies is determined by growing interdependences between member states and by the existence of some public goods within the Union and it aims at a quicker adjustment of shocks and at stabilizating the economy in the Eurozone. Realizing an efficient coordination of economic policies reprezents a necessary condition for achieving a stable and durable economic growth within the Union and it implies increasing the credibility of the authorities, transparency of the economic policies and, least but not last, increasing cooperation (dialogue) between authorities.

Key words: coordination, national budgetary policies, common monetary policy, external effects, economic interdependence, public goods

1. Introduction

The Economic and Monetary Union is an original construction that individualizes itself through the distribution of the economic policy competences between a common monetary power represented by the European Central Bank, according to the federal principle and a budgetary power represented by the national governments, according to the subsidiarity principle. Consequently, the Economic and Monetary Union disposes of a single currency and 15 national budgets (presently). On this background, the coordination of the economic policies in the Economic and Monetary Union focuses on two fundamental aspects, namely: on the one hand, the coordination of the common monetary policy with the national budgetary policies, and on the other hand, the coordination of the national budgetary policies.

The issue of the coordination of the economic policies in the EU constitutes the topic of numerous studies and debates, but at the same time, it is explicitly provided by the Maastricht Treaty as well. Thus, in compliance with art. 2, the common objectives of the European Community are to "promote a harmonious and balanced development of the economic activities, a durable and non-inflationist growth, a high degree of convergence of the economic performance, a high level of employment and social protection, the increase in the level and quality of life, the economic and social cohesion and the solidarity between the member states. With the purpose of achieving these objectives, art. 3 of the Maastricht Treaty shows that the actions of the member states and of the Community must consider the implementation of an economic policy based also on the close coordination of the member states' economic policies. In addition, art. 103 specifies that the economic policies of the member states are "a problem of general interest and must be coordinated".

2. Doctrinary approach

The economic doctrine often addresses the issues of how conducting economic policies and economic policies coordination. At the risk of gross oversimplification, two main schools of thought can be emphasized.

The first is represented by the Keynesian economists. They emphasize market failure and thus the need for an activist management of the economy. Price stability and growth are seen as conflicting objectives, at least in the shorter term, and macroeconomic policies are directed at guiding aggregate demand in order to achieve an optimal trade-off. The focus is on cyclical stabilisation of the economy. Both monetary policy and fiscal policy are called to contribute to this task, which imposes the need for close coordination in order to obtain the maximum results.

The reference model which allows the analysis of the monetary policy coordination with the budgetary policy, elaborated by the Keynesian economists Hicks and Hansen, is the IS- LM model. The IS- LM model reflects the interdependency relations between the equilibrium on the market of goods and services and the money market equilibrium and allows the analysis of the possible interventions of the state, either through the fiscal- budgetary policy for influencing the real sphere, or through the monetary policy for influencing the money sphere, or by combining the two types of policies. The fundamental conclusion resulting from the IS- LM analysis is the following: coordinating the monetary policy with the fiscal-budgetary policy would have a higher efficiency compared with the situations when the two economic politics instruments would be used singularly.

By contrast, the neo-classical economists highlight the potential for government failure and are more sceptical on the effectiveness of policy intervention. The long-run neutrality of money is stressed. Instead of short-run stabilisation greater emphasis is placed on appropriate incentives and credible institutional design for long-run stability. From this perspective a stable economic environment (and price stability in particular) is regarded as pre-conditions for growth. In this context, the coordination between fiscal and monetary policies would be needed for ensuring the stability of the economy.

These two main schools of thought have exercised their influence in various ways over time, both within the academic environment and in policy circles. The 1960s were no doubt the heyday of keynesians. Faith in macroeconomic demand management was then severely affected in the 1970s and 1980s, both by the theoretical assault of new classical economics and incurrance of stagflation. The Maastricht Treaty and reforms aiming at better control of public finances in a number of countries around the world in the 1990s reflect the new consensus and the lessons learned from the earlier experience.

2. The necessity of economic policies coordination and particularities in EMU

The coordination of the economic policies within the Economic and Monetary Union and especially of the common monetary policy with the national budgetary policies is imperative as a consequence of the interdependences that exist between the member states and of the presence of collective (public) goods within the union.

As regards the first aspect, the increase in the economic interdependences between the member states, it generates an enhancement of the external effects, first of the negative ones, produced by the policy promoted by one member state on other member states. For instance, the aggravation of the budget deficit of a member state may generate an increase in the interest rate on a long term, which eventually will be covered by all the governments when they pay their public debt. Moreover, taking into account the priority objective pursued by the European Central Bank, namely the stability of prices, it is possible that the aggravation of the budget deficit or the public debt of a member state may lead to an increase in the interest rate on a short term by the monetary authority, and the effect would be suffered by all the member states of the Monetary Union. Consequently, it may be ascertained that whereas the economic policy promoted by one of the member states is perceived as unsustainable, there may appear reactions from the markets and the European Central Bank that will be suffered by all the member states of the union. Of course, besides the external negative effects, there are also positive effects in the Monetary Union that are many times neglected or minimized, such as the diffusion of the technical progress, the training of manpower, the creation of some common transportation or telecommunication networks etc.

Concerning the second aspect – the presence of collective goods in the Economic and Monetary Union – these goods are represented by the monetary stability, the credibility of the monetary policy of the European Central Bank, the sound management of the public finances, the stabilization of the euro area's economy etc.

With a view to limiting the negative external effects and to expanding the positive ones and preserving the collective goods, special importance is granted – within the Economic and Monetary Union – to the coordination of the economic policies and particularly to the common monetary policy with the national budgetary policies.

Generally, regarding the coordination of the economic policies, two perspectives stand out [3], namely:

- the so-called "coordination – public good", which would have as an objective the creation and preservation of international public goods that are based upon rules. For instance, the Stability and Growth Pact is considered a coordination instrument of the national budgetary policies in the euro area and intends to contribute to the preservation of a stabile and non-inflationist monetary union, through the "control of the public finances".
- the second perspective considers the coordination as a response to the external effects of the national economic policies and would have as an objective the maximization of the collective welfare. Such coordination is called "strategic coordination" and is based on the capacity of governments of exercising discretional policies, based on mutual agreements. This form of coordination is, nonetheless, more difficult to achieve, as it implies the co-operation of the participating parties with a view to elaborating an assembly of policies based on the differential use of the available economic policy instruments.

Therefore, it is estimated that the simplest coordination form is the one based on rules or constrictions, as they could preserve a certain decisional independence, or at least the illusion of such independence.

Within the Economic and Monetary Union, since the national budgetary policies are under the responsibility of the member states, it was considered indispensable to set budgetary rules (provided both by the Maastricht Treaty and the Stability and Growth Pact), which – by ensuring the budgetary discipline – may contribute to a balanced and durable economic growth. The arguments invocated in favour of a set of budgetary rules focus on the display of contagion (contamination) effects, on the background of the promotion of an inappropriate budgetary policy by a state, both between the member states of the union and between the budgetary policy and the monetary policy. Nevertheless, the coordination through budgetary rules shows certain disadvantages that are in fact present in relation to any kind of rules. Thus, it is estimated that a "good" budgetary rule should respond to all exigencies, among which it should: be simple and transparent, be constantly modified, be in conformity with the budgetary results and be constrictive. Besides these exigencies, the specialized literature [4] invokes other conditions as well: the rules should offer certain flexibility to the public authorities and favour – to a certain extent – the economic growth. The flexibility condition implies the fact that, in applying the rule, the implications of some events should be kept in mind (such as fluctuations of the economic growth, unforeseen shocks) on the budgetary results. As for the conditions of favouring the economic growth, it would imply no conflict whatsoever between the application of the rule and the action of the public authority in favour of the economic growth. Taking into account these exigencies that should be met, the construction of a "good" rule is difficult to achieve. For example, the increase in the flexibility reduces the simplicity of the rule, and it is hard for a simple and transparent rule to consider the favourable effect of the action of the public authority on the economic growth. Consequently, the budgetary rules will be eventually a compromise between different exigencies.

With a view to correcting some drawbacks of the budgetary rules, in 2005 (March) the Stability and Growth Pact was reformed, which brings significant changes regarding the preventive and corrective procedures from the original pact. At the same time, the new pact pays more attention to the co-operation between the member states of the union, the European Commission and the EU Council and improves the surveillance of the observance of the budgetary rules.

The amendaments brought to the Stability and Growth Pact (which make the budget laws be more flexible, but also more complex) aim at a better management of public finances, but the manifestation of the positive effects will finally depend on the manner of applying the new framework by the member states of the Union, the European Commission and the EU Council.

One of the most concerning issues and at the same time difficult in the matter of economic policies within EMU is represented by ensuring an efficient coordination of the common monetary policies with the budgetary politics of the 15 member states. In the euro area, the common monetary policy has as priority objective maintaining the stability of prices (defined as an annual increase of under 2% of the harmonized index of the consumer price) on medium term. However, the economic divergences which exist between the member states of EMU make the impact of the common monetary policy become non-similar. For example, the common monetary policy can appear as being too restrictive for the countries which register an increase of the GDP under the increase of the interest rate (such as Germany or Italy), while for other countries, where the increase rate of the GDP is superior to the interest rate (for example Ireland) the common monetary policy is perceived as being expansionist. As a result, the transmission of the common monetary policy has asymmetric consequences since the national financial systems, the economic structures and the shock adjustment mechanisms are different.

Perceiving differently the interest rate established by the central bank also appears in the case of the USA where Fed establishes the interest rate for all the member states. However, we appreciate [6] that the main difference between the Euro area and USA consists in the high degree of mobility of the working force in the USA and the capacity of the American federal budget of promoting the resource transfers between the states. Such elements do not appear within the European Union where the federal budget has a small percentage (under 1% of the area GDP), and the language barriers, the non-recognition of degrees etc. limit the mobility degree of the working force. At the same time, according to some, the skepticism which is manifested towards the euro currency would mostly be due to the ECB monetary policy, which would not support the economic growth and the structural reforms (such as it is the case of the USA or Japan).

In this context, there were several proposals [6] of modifying some articles of the Maastricht Treaty. For example, the modification of article 105 of the EU Treaty is supported so that the common monetary policy to have as objective, besides the stability of prices, the support of the economic growth and the occupying of the working force as well.

Under the current conditions, EMU is characterized by a bigger number of member states- of different sizes and with different economies from the structural point of view – and also by manifesting some behaviors of the type "clandestine passenger" [5]. Such behaviors appear from the small states, which, especially under the conditions of a macroeconomic shock, benefit from the economic policies for sustaining the economic growth promoted by the bigger states without supporting any cost or take advantage from the interest rate decrease without having a lower inflation. In this context, achieving collective actions which would ensure the economic growth in EMU and would also counter-attack the opportunist temptations, would be of high importance.

3. Conclusions

The economic divergences which exist between the member states of the UEM, and also the asymmetrical consequences of transmitting the common monetary policy call for an efficient coordination between the common monetary policy and the national budgetary policies as well as for important structural reforms for the achievement of a stable and durable economic growth in the Euro area. The history of the international monetary systems proves that the lack of a real coordination of economic policies is the source of the most important monetary instabilities.

THE STRENGHTENING OF ROMANIAN LOCAL FINANCIAL AUTONOMY’S LEVEL IN THE EU CONTEXT

Rusu Elena

Universitatea „Al. I. Cuza”, Iaşi, Facultatea de Economie şi Administrarea Afacerilor, B-dul Carol I, Nr. 22, CP 700505, e-mail: elena28072001@yahoo.com***, Tel. 0232-201652***

The Romanian local public finance should be continuously improved by the time it will correspond totally to the requirements of European Union, taking into consideration that the consolidation of public finance at the level of territorial public administration depends on the measure of decentralization and of the strengthening financial autonomy’s level. At the same time, local government must be in accord with European Union legislation as Maastricht Treaty and. European Charter of Local Self-Government

This study is primarily intended to provide the stage of Romanian financial autonomy in the context of European Union with the help of its relevant indicators and the establishments of legislation limits.

Key words: Romanian integration, European Union, local public finances, local financial autonomy, local budget, own revenues, expenditures, competences

Introduction

Local authority financing is currently at the heart of the political debate. All the European Union’s member states are faced with the challenge of reconciling the need to control and reduce public spending with greater financial autonomy in local government. They are accordingly seeking ways of achieving an equitable distribution of financial resources among the different levels of government in a context of budgetary cutbacks at every level of public administration. At the same time, local fiscal policy has to be judged in the light of the Maastricht criteria which say that candidates for the monetary union must – among other things – not run an excessive deficit (a general government deficit of more than 3% of national gross domestic product and a general government debt of more than 60% of national gross domestic product).

1. Revenues indicators

For the analyze of local financial autonomy are relevant the realized revenues and not the forecasted revenues. In this context, local authorities must avoid the differences to big between forecasted revenues and realized revenues. A healthy autonomy level supposes, also, a good forecasting of local budget.

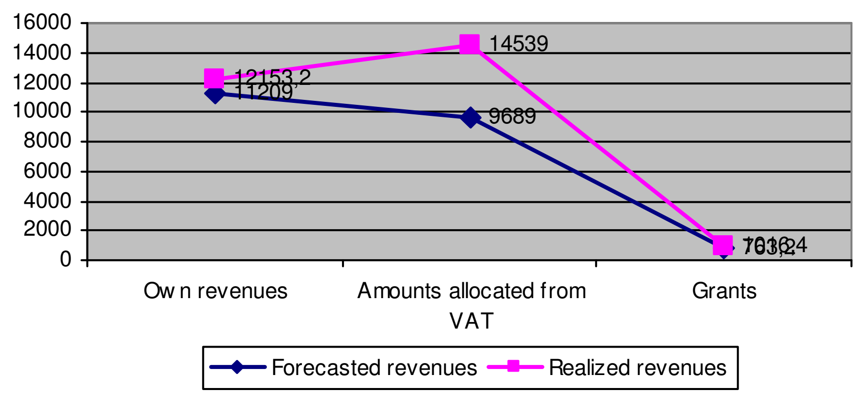

Figure 1: Local public revenues in 2006 (mil. Lei)

Source: www.gov.ro and Romanian Statistical Yearbook 2005 – 2007

Local authorities succeeded to make a good forecasting for own revenues and grants, but there are big differences at the amounts allocated from VAT. The percentage of realized revenue from VAT is 150%. In this context, it is relevant the local authorities must try to be more independent and do not depend by the transfers from the state budget, because the transfers are insecure.

a) The level of financial autonomy

In accord with principle of subsidiarity [The Treaty of Maastricht, Title II, Art. G, 3b], local government must try to resolve its own problems and for these it needs own resources. High own resources give independence to the local authorities in the way haw there are spent the own resources, demonstrating financial autonomy.

The level of financial autonomy, as an indicator of revenues, is determined with the relation:

The level of financial autonomy = Own revenues / Total local revenues * 100

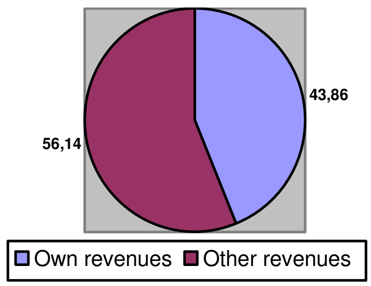

Figure 2: The level of financial autonomy in 2006 (%)

The level of financial autonomy forecasted is 51,7 %, but the level of financial autonomy realized is 43,86%. Being under 50%, the local governments still demonstrate the dependence from the state budget transfers. This dependence suggests a low local financial autonomy and it is absolutely necessary to rise the own revenues. In the same time, Romania's situation is better than the average of EU-15 member states in 2004, when local tax revenues from total tax revenues represented 17,7%.

Until 2003, Romanian own revenues represented 25% - 30% from total local revenues, but after the new rules established by The local public finances Act, own revenues have grew up (own revenues includes also quotas from income tax) [The local public finances Act, Art. 5(1)]. Another way to rise the own revenues is given by Fiscal Code – local authorities can rise local tax with 20%[Fiscal Code, Art. 282] and can - but generate a high fiscal level and local governments avoid to use this method.

b) Percentage of local public revenues

The local financial autonomy is bigger if own revenues in total local public revenues are bigger (local tax and quotas from income tax)

Revenues	**2004**	**2005**	**2006**
Own revenues	46,8	45,93	43,86
Amounts allocated from VAT	47,43	47,31	52,47
Grants	5,77	6,76	3,66

Table 1: Dynamic of local public revenues percentage in 2004-2006 (%)

Source: Romanian Statistical Yearbook 2005 – 2007

The year 2006 keeps the same rate of quotas from income tax mentioned by the new local finances act [The local public finances Act, Art. 32 (1)]. Quotas from income tax , 7550 million lei, represent 62,12% of total own revenues in 2006, towards 2005 when quotas from income tax were 4799 million lei, represented 51,1% from total local own revenues. The transfers from the state budget to local budget eliminate the amount allocated from income tax, but keep amounts allocated from VAT and grants. The amounts allocated from VAT in 2006 are bigger than previous years, but grants are smaller.

For obtaining bigger own revenues, were raised building tax, transport tax, yacht tax in 2006.

c) The amount of state transfers to local budget in total state revenues

The amount of state transfers to local budget in total state revenues show the level of state implication – central administration – in the sustaining of local budget. As a rule of local financial autonomy, is indicate this amount to be smaller.

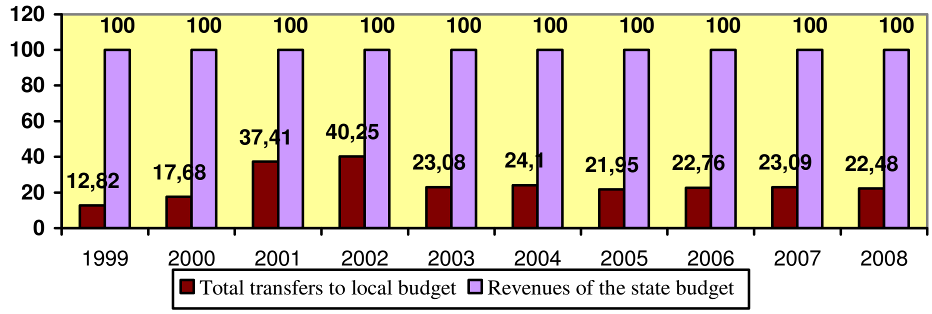

Figure 3: The evolution of state transfers to the local budget in total revenues of central public revenues (%)

The total transfers from state budget to local budget in Romania show big fluctuations over years, about 12,82% in 1999, 40,25% in 2002 and 22,66% in 2006 and 22,48 in 2008. These fluctuations are possible as a result of the decentralization process which supposes the reducing of transfers and the sustaining of exclusive competences from own resources.

The quotas from income tax are considered as own revenues. The income tax is collected at the state budget. At the end of the month, central authorities transfer 47% to local budgets, 13% to county budget and 22% in a special account of general departments of county public finances for the equilibrium of local and county budgets. The sum of percentages (47+13+22 = 82 %) demonstrates that to the state budget remain only 18% from the income tax.

d) Fiscal revenues

A relevant place in total local revenues belongs to the fiscal revenues. Local public revenues are collected using local fiscal policies, which are part of national fiscal policies. The tax redistribution is used to assure fiscal revenues to local authorities. The disadvantage of the redistribution system is the state consideration - if it shares its revenues with local authorities, it has the right to control haw the resources are used (specially, the opportunity of local authorities' decision-making). Another disadvantage is local taxes are established by national law and, so, local public administration doesn't enjoy of a real local autonomy.

Fiscal revenues have risen over the 2004-2006 period. The evolution is shown in the following charter:

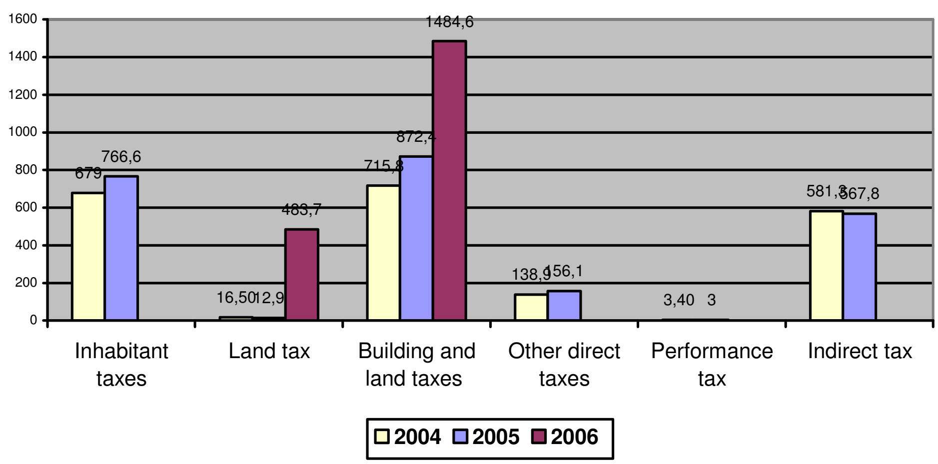

Figure 4: The evolution of local fiscal revenues in 2004-2006

Land tax is an important source of local fiscal revenues in Romania, but also in majority countries of the European Union. The transformation of land fee in land tax in 2006 generated a rising of these revenues. Indirect tax registered regress.

In general, the evolution of fiscal revenues in Romania is a positive one and this contributes to the implementation of local autonomy financial principle. If local administrations have the capacity to generate own revenues, they will succeed to detach from the state budget transfers.

e) The ratio of local public revenues to gross domestic product (GDP)

In Romania, total revenues of the local budgets represented 27708,6 million lei in 2006, meaning 8,4 % from GDP. In the same period of time, in the EU-27, the ratio of local tax revenue to GDP represented 11,2%.In this context, the ratio of local tax revenue to GDP in Romania is not faraway to the average of EU-27.

2. Expenditure indicators

a. The level of covering local public expenditures with own revenues

The impact of decentralization process can be analyzed using the level of covering local public expenditures with own revenues indicator:

The level of covering local public expenditures with own revenues = Own revenues/Local public expenditures * 100

This indicator is preferable to be big because local public administration can demonstrate its capacity to cover local public expenditures with own revenues and, so, its financial autonomy.

	2002	**2003**	**2004**	**2005**	**2006**
The level of covering local public expenditures with own revenues	24,45	28,09	24,39	46,57	47,86

Table 2: The level of covering local public expenditures with own revenues in 2002-2006 (%)

Data table shows a low capacity to cover the local public expenditures with own revenues in the period of time 2002 – 2004. Starting with 2005, this indicator raise to 47,86% in 2006. This rising demonstrates a good start for implementing the local financial autonomy.

b. Ratio of local expenditures

In Romania, the capital expenditures in local public budget imposed by the necessity of development of local public investments must rise as a condition of local public autonomy. The current expenditures are still too big. In 2006, the capital investments to local expenditures represented 19, 72%. In the same period of time, the average of EU-27 of capital investments to total local expenditures was 12,7%.

	Romania (million Lei)	**EU-27 (million Euro)**
Total expenditures	28761	1322956
Intermediate consumption	7076	331259
Compensation of employees	11608	453157
Interest	330	22186
Subsidies	16	44349
Social benefits	2998	196180
Other current expenditure	1061	76483
Capital transfers payable	0	29912
Capital investments	5672	168419

Table 3::The ratio of local expenditures in EU countries in 2006

Source: Eurostat

c. Local public expenditures to GDP

A relevant indicator for the level of taxpayer satisfaction is local public expenditures to GDP. This indicator allows estimating the amount of local public expenditures in accord with the economic and social development of each state. In 2006, local public expenditures represented 8,4% of GDP in Romania and 11,4 %of GDP in EU-27.

d. Local public expenditures to total public expenditures

Local public expenditures to total public expenditures is another important indicator for the ocal financial autonomy. In 2006, local public expenditures represented 41% of total public expenditures in Romania and 44,70% in EU-27.

	Romania (million Lei)	**EU-27 (million Euro)**
Local public expenditures	28761	1322956
Total public expenditures	68498	2959098

Table 4: Public expenditures in 2006

Source: Eurostat

Conclusion

Local public authorities in Romania, in accord with local autonomy principle, subsidiarity principle have big competences and the power to make expenditures established by Local public finances Act and Decentralization Act. The local financial indicators show the presence of financial autonomy in Romanian reality, but the funds are insufficiently for to perform good local public services as in others European Union countries. In spite of this, financial autonomy and the decentralization process make progresses as a result of the experience of local authorities in the funds management.

THE INFLUENTIAL FACTORS ON THE EXCHANGE RATE IN ROMANIA

Sandu Carmen

„Al. I. Cuza" University of Iaşi, Faculty of Economics and Business Administration, Adress: B-dul Carol I, nr. 22, Iaşi 700505, E-mail: sandu_carmen@yahoo.com, Telephone: 0740/852.842 & 0752/018.030

Abstract: The exchange rate between foreign currencies is a variable which depends on internal and external factors. By their nature, actors which influence the exchange rate can be economic, monetary, financial and psychological.

The stability of the exchange rate determines the predictability, homogeneity and continuity of the macroeconomic policies, whilst a greater volatility in the development of the national currencies exchange rate not only affects the accuracy of the forecasts but enhances its sensitivity as well, respectively the effect of its internal or external factors. In the following, I intend to highlight and to ascertain the fluency of these factors over the exchange rate in Romania, before and after its adhesion to the European Union.

Key words: exchange rate, influential factors (of influence), foreign currency, balance of payments, inflation rate, currency depreciation, currency appreciation.

1. Introduction

The exchange rate is one of the most synthetic prices in the economy, the expression of a generalized balance on the real market, the monetary market and the capital market. The development of the exchange rate is influenced by the degree of economic growth, by the evolution of prices on the asset an services market (inflation), by the national economies' ramified structure, by external competitiveness and international openness as well as by the political stability and the governments ability to solve the internal crisis which an economy may have to face at a given time. The number of factors that directly or indirectly influence the exchange rate make it difficult to model such a complex and dynamic economic variable. But at the same time, the existent links between the foreign currency market, the monetary and the capital markets make that the short term, medium or long term evolution of the exchange rate itself has an influence over the global economic balance.

The exchange rate is not a static measurement but a dynamic one. The evolution of the exchange rate is determined by a number of factors which do not have a linear influence, but a particularly complex and inconsistent one, a single factor being able to neutralize the influence of others or several factors may act in the same direction.

1. One of the most important factors that influence the foreign exchange rate is the *position of the balance of payments.* The equilibrium external balance of payments depends on the import and export value, on the product efficiency and competitiveness, on the level of the prices, on international services and international market conjuncture. In return, the exchange rate influences the equilibrium of the external balance of payments, as a consequence of the connection between them. The depreciation of the foreign currency stimulates export growth, reduces imports and generates a tendency equilibration of the balance of payments.
2. *the ratio between the foreign currency demand and offer* has an influence over the foreign exchange rate, since the demand in foreign currency depends on the loan value, on the international services needed, on the credit reimbursements terms and on the interest rate;
3. *the increase in the circulating monetary mass* contributes to the depreciation of the national currency, and the actions to restrict monetary mass determine the appreciation of the national currency;
4. *credit encouragement or limitation* influence both the national economy and the exchange rate;
5. *increased interest* discourages credit demand, diminishes the circulating monetary mass and generates positive effects on the national currency's exchange rate. Decreasing the interest facilitates access to the credit, determines implicitly the growth in the circulating monetary mass and national currency depreciation;

6. the ratio between the export prices and the prices of imported assets influences the foreign exchange rate;
7. *the increase in internal inflation* determines the national currency depreciation, and the decreasing inflation index reflects positively on the national currency rate;
8. budget deficits and surpluses;
9. *tax policy and the structure of the budget expenditure* stimulate or restrain domestic production, public sector input;
10. *economic policy measures* which favor or enclose economic trades;
11. banks buying or selling foreign currency on the foreign currency market;
12. increased *output* reflects in competitiveness, export growth and insuring the internal balance;
13. investments directed towards high productivity and efficiency areas;
14. the degree of coverage of imports over exports.

The analysis of the determining factors of the foreign exchange rate evolution also implies knowing an issue particularly difficult to define, and that is if the analyzed determining factors of the foreign exchange rate themselves have not been influenced by the evolution of the foreign exchange rate. Thus, economic theory and practice show that the active or passive balance account of the current balance of payments or of the capital determines the foreign currency demand and offer, and through the mechanism of foreign currency demand and offer, the balance influences the exchange rate development. But is also true that economic theory and practice proves that the development of the exchange rate can stop or encourage import or export, stimulate or decelerate the input or issue of foreign capital in a country.

2. Influential factors on the foreign exchange rate in Romania in the period pre and post adherence to the European Union

In Romania, there have been a series of changes regarding foreign currency and international transactions. It started from one of the lowest GDP/per capita level in Europe (1985- 1989). The ROmanian New leu (RON) had an exchange rate set on three currencies (dollar, pound, german mark), but, in the context of accentuated inflation, this system overcharged the exchange rate with undesirable implications: decreasing competitiveness on the external market, deteriorating the net exchange index.

Starting from 1991, the ROmanian New leu “internal convertibility in the current account” has been introduced, but the parallel foreign currency market maintains. A decision has also been taken (which later proved to be damaging) to convert in Romanian leu dollar deposits to the internal banks. The decision was revoked shortly afterwards. At the end of 1991, the exchange rate regime is managed floating (BNR intervenes to amortize fluctuations).

Ever since the beginning of the transition period, the interdependency relationships between the exchange rate, the inflation rate and the imbalance of the foreign balance of payments have constituted controversial issues of the Romanian economy. In establishing the role that the ROmanian New leu exchange rate has in redressing the macroeconomic imbalance, there have been two options: that of anti-inflationist anchor and that of an influential tool of the external balance of payments. The extent to which one of the two options prevailed reflected in the evolution of the exchange rate.

Generally, there has been an attempt to maintain the balance between the necessity of ROmanian New leu depreciation in order to stimulate export and avoiding prices to increase. In the Romanian economy, marked by serious structural imbalances and by an important corrective component of the inflation, the exchange rate has been one of the determining factors in the price movement, but not the most important one.

The import structure on groups of merchandise, defined by the great importance of the interchangeable component (raw materials, energy) contributed to the fact that the import demand has a reduced flexibility comparing to the price. The GDP, import, export, investment and input evolution in Romania in the 1989-2006 period is according to the table below:

Tabelul nr. 1. The evolution of the main macroeconomic indicators in Romania during 1989-2006

(Values=millions RON)

Year	GDP	Export	Import	Investments	Input
1989	80.000	16.780	13.500	23.640	56.390
1990	74.652	11.585	18.467	14.669	59.190
1991	59.468	9.217	11.608	8.473	45.130
1992	54.376	12.607	1.671	8.014	41.870
1993	45.690	8.611	1.071	6.435	34.744
1994	70.186	14.488	15.516	11.289	53.405
1995	79.602	17.892	21.567	14.341	64.734
1996	76.605	17.556	23.163	14.731	63.256
1997	70.759	16.976	21.107	12.347	61.161
1998	74.377	16.825	22.795	12.041	67.148
1999	70.147	19.654	23.044	10.790	62.259
2000	73.429	24.135	28.269	11.418	62.842
2001	81.869	16.908	33.629	14.317	69.743
2002	90.155	31.947	37.086	16.173	75.748
2003	103.056	35.775	43.514	18.597	88.277
2004	117.626	42.262	52.919	21.414	100.296
2005	126.583	41.693	54.785	23.979	110.932
2006	143.488	46.474	63.857	25.287	126.607

Source: Processing of the Statistic Yearbooks data and data on www.insse.ro

From the analysis of the data taken from the Statistic Yearbooks one can observe that the evolution of Romania's GDP during 1989-2006 is an oscillating trend. Thus:

1. in the 1989-2003 period there is a decrease in the Romanian GDP, that concurs with the beginning of the social movements; the yearly maximum decrease is registered in 1991;
2. the years of 1991 and 1995 mark a national GDP growth;
3. the period between 1995-1999 represents a period of decrease of the national GDP, except for 1998 when there is registered a slight appreciation;
4. starting with the year 2000 one can notice that the Romanian GDP has entered an ascendant trend, registering for the first time a GDP greater than during the communist period in 2002.

The evolution of the prices on the external market for import, respectively export, difficult to anticipate and incontrollable by the national authority, strongly affect the exchange rate of an economy, such as the Romanian one. Moreover, they have deprived the Central Bank from quantifiable and predictable elements in defining the exchange rate policy. In the context of Romania's import and export commercial inflows, those products whose prices formed on the exchange market are exogenous variables (oil products, cereals, chemical compost) have an increased weight, and the Romanian economy remains a receptor of these external trends.

In the actual conditions of the Romanian market, liberalizing prices imposed itself as an objective requirement for the setting on economic fundamentals, on one hand of the ratios in the internal prices system, and on the other hand of the ratios between the internal and external prices. Concurrent to that, there has been the need to develop the restructuring process at a macroeconomic level, and the syncope and the inconsistencies have amplified the otherwise inevitable inflationist phenomenon.

The actual dynamics of the exchange rate reflected, with few exceptions, an overvalued level. The nominal depreciation index reveals an evolution systematically under the dynamics of the inflationist process (according to the price indexes calculated by the National Statistics Commission). Given the inflationist potential of every sudden movement in the exchange rate, the monetary authority pursued a “nominal target” using the methods specific to the ROmanian New leu managed floating.

Overestimating the exchange rate generated distortions in the economy, equaling a subsidy given to the importers, respectively a tax bared by the exporters. Despite this, depreciation cannot be automatically accepted as a balance lever in reestablishing the equilibrium trade balance. Given the structural nature of the imbalance, solving it can only be made by using a macroeconomic policy mix (fiscal, budgetary, commercial, and monetary) corroborated with the reorganization of the real sector.

The exchange rate balance lever acts like an exogenous stimulus with limited effects over time. It cannot be efficiently used to correct some temporary imbalances. On a long term, the determining factor is economic competitiveness, in which productivity plays an essential part. Beyond the direct effect of the national currency overvaluation reflected in the balance of payments, there are also indirect effects that appear and which are less noticeable. Not being able to appropriately evaluate the production factors, the price system is the first one being affected. The typical case for the Romanian economy was that of the oil products.

In the foreign currency market area, overvaluation generated serious dysfunctions whose final consequence was the irrational distribution of resources and the input of inflationist forecasts. The monetary policy has been globally affected negatively, in that direction that dysfunctions induced by the exchange rate have been counteracted by increased interest levels.

During the first 10 months of 2005, the Romanian foreign trade continued to register an increased pace of growth of 16,9% on export and respectively 24,1% on import.

A positive aspect is noticed in the evolution of the net exchange rapport index (the ratio between import and export unitary value indexes) which has been of 103,5% during the first 10 months due to the more accentuated growth of export prices comparing to the import ones for most of the merchandise groups, representing an improvement by 3,5%. The ratio of gross exchange (the ratio between the physical volume of export and import indexes) was of only 98,6%, the increase in the physical volume of export and import) outmatching the export one by 6,1%.

By analyzing the exchange rate evolution corresponding to the two main currencies that prevail in the foreign exchange reserves, meaning ROL/EUR and ROL/USD, afferent to the period between 31.01.1995 – 31.05.2006, the following aspects were noticed:

1. since the putting into circulation as a scriptural currency (in 1999) and until its circulation (in 2002), the single European currency had an increasing trend;
2. a modulation point in the evolution of euro has been in 2003 when euro became a nominal anchor for monetary policy promoted by the BNR. Since that moment, the dollar lost ground against the single European currency. The national currency rate no longer follows a managed, linear trajectory comparing to the two other foreign currencies.
3. after the adoption of the direct inflation targeting regime and on the grounds of a free foreign currency quotation, a component of the current account’s complete liberalization policy, the national currency knew historical appreciations comparing to the two currencies composing the foreign currency reserves: the euro and the American dollar. This appreciation has also been encouraged by the success of BNR in fighting against inflation.

3. Factors of influence over the foreign exchange rate during Romania’s adhesion to the European Union

Romania adhered to the European Union the 1st of January 2007. Even if we have been members of the European Union for over a year, the nominal and real convergence process towards the euro zone will have to continue, perhaps even faster than before. Romania’s objective is to enter the Exchange Rate Mechanism (ERM2) and to subsequently adopt the euro. In order to accomplish this objective, the inflation rate will have to decrease substantially in the following years. This mission may be considered difficult considering the inflation persistence and the inflation rate forecasts in Romania.

January 2008 brought an increase of 1,6 % in the industrial production, comparing to December 2007, and by 6,1% comparing to last January, an increase maintained by the electric and thermal energy, natural gas and water, which increased by 5,1% and by the processing industry which increased by 2,4%.

After the 2007 progress, constructions have increased their weight in the GDP from 7,4% in 2006 to 9,1%, outranking for the first time agriculture, which went from 7,8% to 6,6% in 2007. For the year 2008, signals show a sustained progress of the sector in which Romania is the European leader, since the increase registered in January was of 29,5%.

Regarding the utilization of the gross domestic product in 2007, the population's input contributed the most, with 8%, to the economic growth, both as a consequence of the proportion as high as 77% that it holds, and also on the account of its increase in volume. If last year, the GDP forecast reduced the proportions held by the current account and budgetary deficiency to 13,9% of the GDP, and respectively 2,33% of the GDP, the forecast for this year is not as optimistic, even if January is the second consecutive month when the pace of export growth exceeded the import one. The import growth decelerated by 11,3% comparing to January 2007, while exports increased by 16,9%. As a consequence, the evolution of the trade balance deficit decelerated to 2,8%, until 1,4 milliards of euro, comparing to over 80% in January 2007.

Experts estimate that the pace of export growth will maintain more alert this year comparing to 2007, especially in the capital goods and high value-added products area. The weight of the commercial deficit in the GDP will position itself to aproximately 16% of the GDP at the end of the current year, while the BCR prognosis indicates a current account deficit increase up to 15% of the GDP.

Surprisingly, a solution to save the economy at a loss would be the registration of an agricultural year favorable both to the progress of the GDP, the equilibrium trade balance, and to the inflation. The satisfactory agricultural production would impose a slower pace of imports in this segment and implicitly lower inflation "costs", thus reaching the maximum rate in the last two years. Reaching the maximum of the inflation rate in the last two years, 7,97 % in February, forced the National Bank to increase the monetary policy interest to 9,5% per year.

The inflation target of the National Bank is of 3,8 % with a margin of plus/minus a percentage point, but BNR revised the inflation prognosis to 5,9%, from 4,3 % in the previous version. Practically, 2008 is the second year when Romania misses the inflation targeting. Analysts stipulate the decrease in the prices of food products in the second part of the year, after the issue of the new agricultural harvest, so that inflation will decrease fewer than 6% towards the end of the year, and the pressure on the ROmanian New leu would diminish. The national currency would have a closing rate of 3,5 RON/euro at the end of the year.

A practical solution and at all neglectful might be the depreciation of the ROmanian New leu in order to dilute these deficits, and a lower rate than 3,7-3,8 RON/euro would be beneficial to the balance of payments. This might be possible if one considers the fact that in April, the ROmanian New leu – euro registered a very low level. The ROmanian New leu rate has not reached such a low level since the 27th of December 2007, when BNR had listed a reference exchange rate of 3,5282 RON/euro. But the ROmanian New leu has appreciated significantly comparing to the dollar as well, by 0,54% up to 2,2350 RON/dollar, a level which it has not reached for almost eight years, since the 15th of August 2000, when BNR had listed a reference exchange rate of 2,2349 RON/dollar. In Romania, the RON gained value during the last days of the month of April, on the grounds of foreign exchange repatriations from abroad before holidays and of the fact that large international companies operating locally bought domestic currency in order to pay the taxes to the state.

National Prognosis Commission experts (CNP) made some estimation for the period between 2009 and 2013. Some of these examples might be:

1. the GDP growth will be of 5,9% in 2009, the GDP increase for 2010 being estimated to 5,8%, 5,8% for 2011 and of 5,7% for 2013;
2. the industrial production will increase by 5,3% in 2009, by 5,5% in 2010 and in 2011, and in 2012 and 2013 it will increase by 5,4%;
3. the yearly average inflation is estimated to 3,4% for 2009, for 2010 to 3,3%, for 2011 to 3,0% , and for 2012 to 2,7%, and for 2013, CNP maintained its forecast of 2,5%;
4. the current account deficiency will maintain at over 10% of the GDP during 2007 – 2013;

5. the average of the foreign exchange rate will be of 3,25 RON/euro in 2009, 3,20 RON/euro in 2010 and of 3,15RON/euro in 2011, and during 2012 – 2013, the exchange rate is estimated to 3,10 RON/euro.

4. Conclusions

In conclusion, the exchange rate represents one of the criteria of nominal convergence, the criteria regarding the inflation rate depending on its accomplishment. With respect to the stability of the foreign currency exchange rate, the national currency must fit a fluctuation band of maximum +/- 15% for two years before Romania's entry into the Exchange Rate Mechanism 2(ERM 2).

TURNAROUND MANAGEMENT AND BUSINESS ADVISORY SERVICES PROGRAMMES

Simen Antoneta

Lucian Blaga University of Sibiu, Facutatea Stiinte Economice, Adresa: Fagaras, str. I.M.Klein nr.14, e-mail: antonetasimen@hotmail.com, tel: 0744483009,

Abstract: In this paper I present the link between TAM and BAS Programme and EBRD financing. The purpose of the TAM and BAS Programme is to promote economic transition through advice and mentoring at the enterprise level and to develop a sustainable infrastructure of business advisory services. There are strong parallels between the work of TAM and BAS and investments of the EBRD, which may invest in companies after a TAM /BAS project ends. The EBRD and its financial intermediaries have invested 722 million Euro in 163 enterprises that have received funding from TAM and BAS programme. This funding has contributed to a total project value of 1,66 billion Euro.

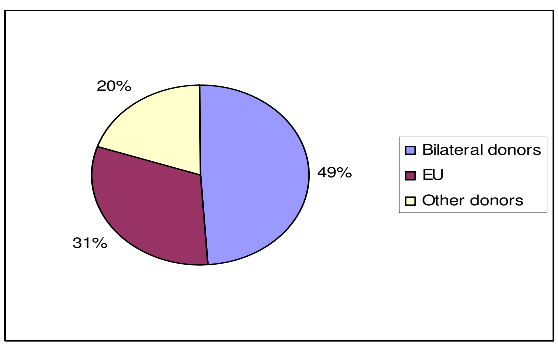
Key words: TurnAround Management , Business Advisory Services, European Bank for Reconstruction and Development, micro, small and medium – sized enterprises

Business Advisory Services (BAS) Programme

The EBRD's TurnAround Management and Business Advisory Services Programmes are complementary schemes aiming to help enterprises adapt to the demands of a market economy. Both TAM and BAS work directly with individual enterprises, providing industry specific advice. These include restructuring of the business, improving its products, reducing operating cost, advising on local and export markets and helping to develop business planning skills at managerial level.

The TAM and BAS Programme is administrated by BERD and partly funded by EBRD and partly by donors. The biggest single donor is European Union, which has provided funding through the European Agency for Reconstruction, EuropeAid, Phare and Tacis. Bilateral donors include Austria, Belgium, Canada, Denmark, Finland, France, Germany, Greece, Ireland, Italy, Japan, Luxemburg, the Netherlands, Norway, Spain, Sweden, Switzerland, the United Kingdom and the United States. The Programme is also been funded by multilateral donors, including the Baltic Technical Assistance Special Fund, the Central European Initiative, the EBRD's Early Transition Country and Russian Privatization Center. The following chart shows the sources of funding for TAM and BAS since 1993.

Chart 1: Sources of funding for TAM and BAS since 1993



The BAS Programme works with micro, small and medium – sized enterprises from agribusiness to manufacturing and tourism to define their business need and to identify services to be provided by local consultants. By using local consultants BAS combines the dual role of assisting SMEs in their business expansion with contributing to the professional development of local accredited business consultants.

The Programme's aim is to raise awareness of the benefit of using external consultants and to directly improve the supply and quality of local advisory services. In order to be qualified for consideration under BAS, enterprises should meet the following conditions:

- be majority privately and locally owned
- have been in existence for at least two years

- have little or no previous experience of using external consultants and do not have resouse to finance a complete project
- be able to demonstrate potential for growth and a capacity to absorb the assistance given
- operate in all sectors except banking and financial services, military product or services gambling.

The consultants involved in Programme must have the relevant experience, capacity, resources and general competences to undertake the assignment successfully. They are evaluated and accreditation will be granted for a specific advisory service types and sector of competence. The BAS programme provides a grand of about 50%, on average, of the total net project cost to a maximum of 10000 Euro

From its inception in 1995, BAS has carried out about 6000 projects and utilizing over 66,5 million of donor funding. Currently, BAS operates in 18 countries through 29 office and working with 1765 local consultants approved by local offices. Some 82 companies which have been selected for BAS assistance have subsequently mobilized 209 million euro in loans and investment, of which 51% were invested by EBRD and EBRD – related financial intermediaries.

Business Advisory Services (BAS) Programme in Romania

The Programme started in Romania in 2006.Until 2007 September has undertaking about 35 projects for micro, small and medium – sized enterprises with nearly 230,000 euro of donor funding. The total advisory project value is nearly 500,000 euro.

The following charts show the distribution of BAS projects by sector in Romania and the distribution of BAS projects by consulting areas.

Chart 2: The distribution of BAS projects by sector

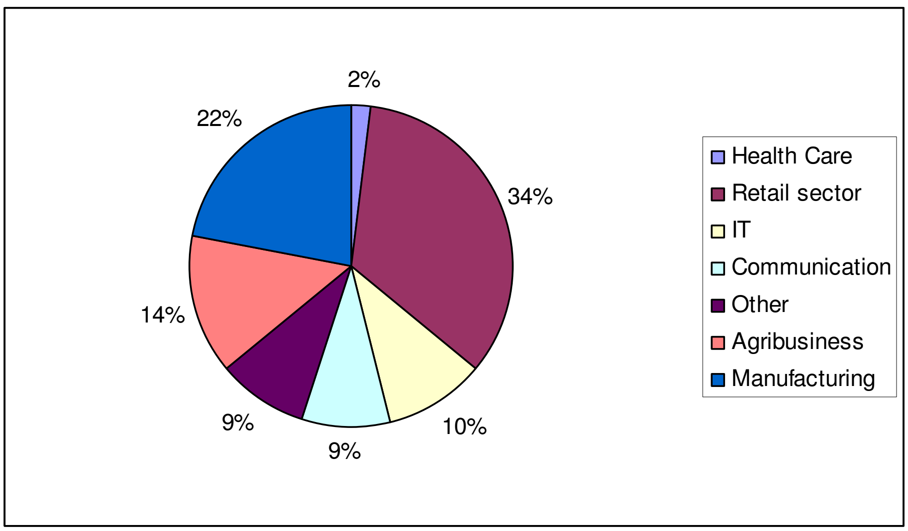


Chart 3: The distribution of BAS Project by consulting areas

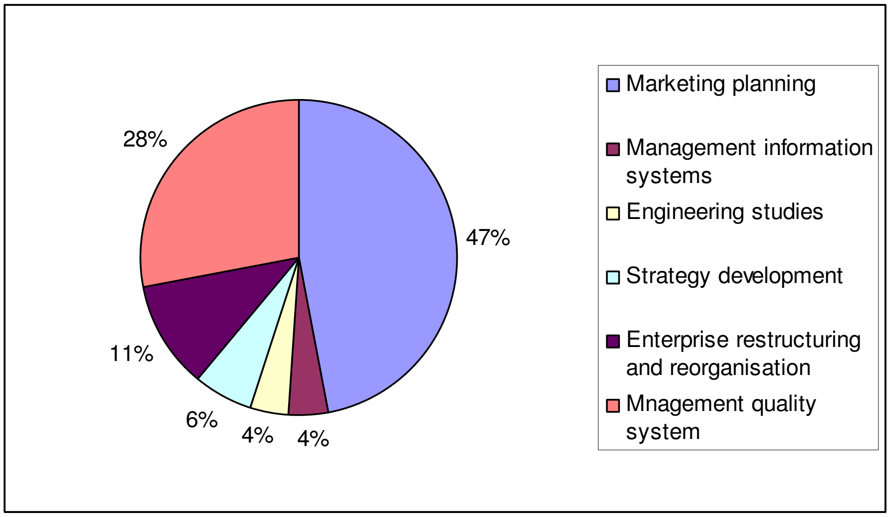

TurnAround Management (TAM) Programme

The objective of the TAM Programme is to support economic reform by helping enterprises of all size to transform themselves so that they can operate successfully in a free market economy and help to develop new business skills at senior management level so as to be able to survive and compete in market economy.

TAM Programme work with experienced directors and senior managers from economically developed countries to improve technical and commercial know – how in local companies. They help to introduce a new management culture and to improve management skills. Projects involve extensive restructuring, encompassing all aspects of an enterprise's activities. The strong management skills developed by each company receiving TAM support is a new and sustainable resource that continues to evolve once the project is completed. The skills developed by managers can also help to restructure and revitalize particular industry sectors. The TAM Programme has the following objectives:

- Build the confidence of SME to operate successfully and adapt to international markets
- Assist SME to comply with industrial legislation and develop sound environmental practices
- Establish strategic direction and attract external investment and finance
- Help management prepare a business plan based on international business practices.
- Improve SME competitive position with marketing strategies and network of international contracts
- Introduce new and industry specific business skills directly to the senior management of SME
- Achieve sustainable results by changing the enterprise business culture and improving business viabilit

Since 1993, TAM Programme has carried out about 1500 enterprise restructuring projects in all of the EBRD's countries of operations, involving over 96 million euro in donor funding. Some 97 companies which have been selected for TAM assistance have subsequently mobilized 1,6 billion euro in loans and investment. About 41% of this have been provided directly by EBRD or by banks that act as intermediaries for EBRD financing.

Conclusions

Following EBRD investments, TAM senior adviser are able to assist in investment monitoring and to act as non executive broad members for EBRD equity investments and BAS consultants are able to provide advice for specific post – investment problems.Some EBRD investments were made with enterprises that undergone both TAM and BAS projects. The EBRD and its financial intermediaries have invested 722 million euro in 163 enterprises. This funding has led to co- financing with a total project value of 1,66 billion euro (see Chart 4).

The evaluation of the future levels, that the different shares quoted on the stock exchange will be traded at, is a complex activity, which involves gathering and processing a high volume of information and also experience and a little flair in their interpretation. ***The Technical Analysis*** *is a statistical method for estimating the evolution of the shares prices depending on the past evolution of these and on the volume of the transactions. It relies on using the charts for prices and volumes of the shares and also on a series of measures based on these. Its aim is to forecast the evolution on short term of the stock prices by considering the hypothesis that the historical trends reiterate in time and that there is a logical explanation regarding this evolution.*

Key words: Technical Analysis, shares, stock exchange, candlestick chart

1. Introduction

The evaluation of the future levels, that the different shares quoted on the stock exchange will be traded at, is a complex activity, which involves gathering and processing a high volume of information and also experience and a little flair in their interpretation. When establishing the shares that have to be bought, two analysis methods are used by the investors on the stock exchange: the fundamental analysis and the technical analysis. In addition, market information regarding the future events that will influence the price of a specific share are to be considered.

The technical analysis is a statistical method for estimating the evolution of the share prices depending on the previous evolution of these and on the volume of the transactions. It relies on using the charts for prices and volumes of the shares and also on a series of measures. Its aim is to forecast the evolution on short term of the stock prices by considering the hypothesis that the historical trends reiterate in time and that there is a logical explanation regarding this evolution. The selling/buying decision is influenced by quantifiable financial factors, but also by emotional factors, which are not quantifiable (the fear, the uncontrolled desire to gain) which leads to mistakes. Such mistakes tend to repeat in time, which provides behavior models that can be apprehended after a rich practical experience only.

In order to carry out its objectives, the Technical Analysis relies on the use of charts, but also on statistical indicators.

The charts are made both for prices and for transactions' volume. On a price chart you can see three essential elements: the evolution trends, the thresholds and the patterns.

The trends of price evolution must be followed on long term or short term, depending on the investor's profile. In case of long-term trends, the chart should be drawn for a period of 3-5 years or even for the entire transaction's period. This way, we can identify the general trend of that share, but also the eventual cycle oscillations.

Another important element the charts provide are *the thresholds or the levels*. These represent minimum values (support level) and maxim values (resistance level) of the prices repeatedly reached in a specific period.

Regarding *the patterns*, these represent an estate of different trends or a combination of trends and levels. Generally, a share evolution trend is repeating in time under the influence of some psychological factors. The investors know that a long period of time with low decreases of a share price is followed by an accelerated growth on a short period, situation which increases the chances for such a model to repeat itself. The identification of a behavior model of a share price helps the investors to estimate its future evolution.

2. Chart Types

The technical analysis uses more ***types of charts***, such as: simple or line charts; bar charts; candlestick chart; point and figure chart; volume histogram. The first four types of charts show the evolution of trade prices, while the fifth one regards the transactions' volume.

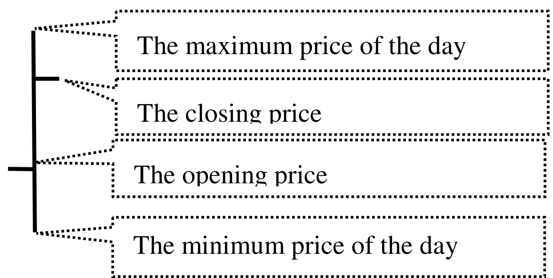
1. The Simple Chart

It is used to follow the trends on long and medium term. The chart is drawn by the union with a continuous line of the closing price level for every day of trading. Between the advantages of this type of chart we can underline its simplified elaboration and interpretation, and as disadvantages we can notice the lack of any information regarding the price oscillations during a trading session.

2. The Bar Chart

A vertical line is drawn for each trading day, on which four elements are represented:

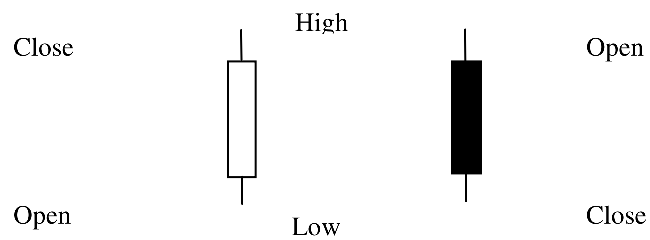
- The top of the vertical line represents the maximum price reached in a trading day;
- The bottom of the vertical line represents the minimum price reached in a trading day;
- The short horizontal line to the left shows the opening price of the day;
- The short horizontal line to the right shows the closing price of the day.



- As compared with a simple chart, this one provides more information through the four characteristic prices of the day.

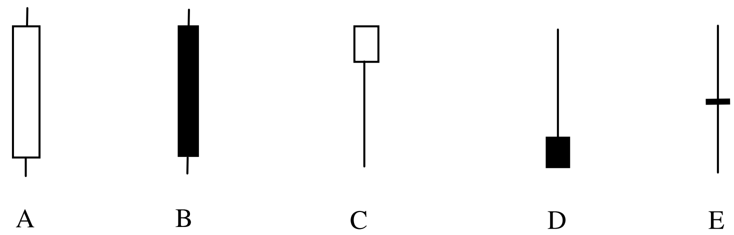
3. The Candlestick Chart

It offers information on the evolution of a price during a day, but also information regarding the movement direction. The representation of the price chart for a trading day is done with the help of a "candle" which has two elements: the body and the shadow (wick) of the candle. This is represented like this:



The body of the "candle" is different painted depending of the price evolution sense, as white or green if the closing price is bigger than the opening price and black or red in vice versa situation.

The price changing during a trading day forms a chart shape which allows the observation of the trends.



A – Known as “the bull sign” reflects a constantly increasing trend, in which the market is opening near the minimum and it is closing near the maximum;

B – “The bear sign” shows a constantly decreasing trend, in which the market is opening near the maximum and it is closing near the minimum;

C- “Without top wick” (Shaven Head) shows an increasing trend, which generally appears after a decreasing of some days. Usually, after the appearance of this sign, it will appear an inversion of the price decreasing trend.

D – “Without bottom wick” (Shaven Bottom) shows a decreasing trend, which usually appears after a few days of growth, symbolizing an inversion of the increasing trend;

E – “Doji Star” represents a body in which the opening and the closing are the same. It can represent a signal of trend change or of indecision of the investors. For many times the appearance of this shows a trend inversion.

4. The Point & Figure Chart

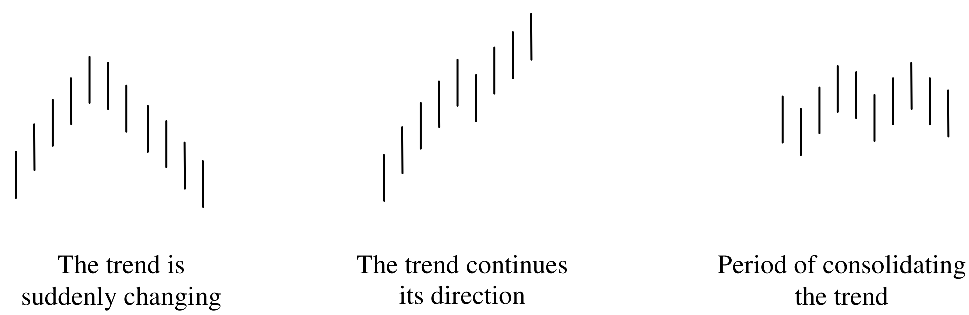
This chart is more rarely met, in which the price increasing is represented by increasing rows of “X”-es, while the decreasing is represented by decreasing rows of “0”-es.

5. The Volume Histogram

For the estimation of share selling price its trend should be correlated to transactions volume. A correlated analyze of the prices and volumes is often more useful than a simple price analyze. The prices and volumes correlated analyze is realized by the combination of a price chart with a volume histogram.

3. The Returning Signals and Patterns

The shapes that different types of charts take offer clues regarding the next evolution of share price. When ***interpreting*** these, the users of the Technical Analysis start on the assumption that the history is repeating. For this reason they looked for the identification of some *returning signals* and *patterns* on which it can be anticipated the future evolution of the share trading price. On a chart, three possible situations can be identified:



The returning signals appear in the first situation, when the trend direction is changing.

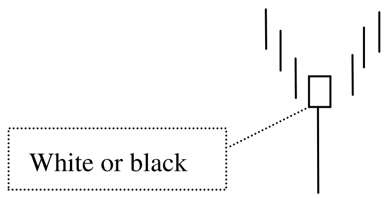
Examples of returning signals identified with the help of the charts:

Hammer & Hanging Man

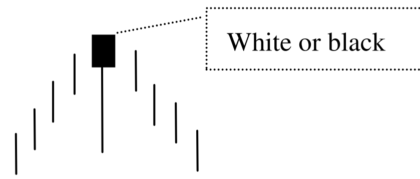
The increasing signal is given by the appearance of the *hammer* lay-out (the end of the decreasing trend), and the falling signal by the appearance of the *hanging man* lay-out (the beginning of the upward trend). Both lay-outs can be recognized after three criteria:

– the real body is very little, so the day opening price is close to the closing price. Its color is not important;
– the down wick is two times bigger than the body height, so that a little minimum price is reached during the trading session;
– the up wick doesn't exist or is very little.

Graphically, the two lay-outs are described as:



Hammer

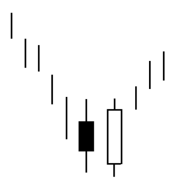


Hanging Man

Engulfing Pattern

More signals looking for a possible trend change are obtained by the combination of more lines on the chart. A first such combination, known as engulfing pattern, combines two lines of different colors, as:

– A smaller black body followed by a white body who covers the little body, meaning the beginning of an upward trend (A);
– A smaller white body followed by black body that covers the little body, meaning the beginning of a decrease trend (B).



A

B

The recognition of this kind of lay-out is based on three requirements:

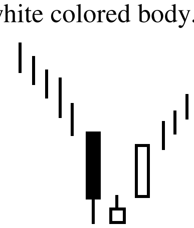
– the existing of a trend clearly defined, of an increase or a decrease, even if this one is on short-term;
– the existing of two bodies of different colors that compose the lay-out engulfing. The exception of this rule is when the first body is very little or is a Doji star;
– the second body must cover the first one and to define the trend direction.

Star

The Star lay-out is represented by a little body that precedes a big size body. It can have four representations: morning star, evening star, doji star and shooting star.

The Morning Star

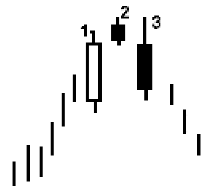
It shows the beginning of an upward trend. It is composed of three bodies: the first is a black one, followed by a small sized body, and in the third day a white colored body.



The Evening Star

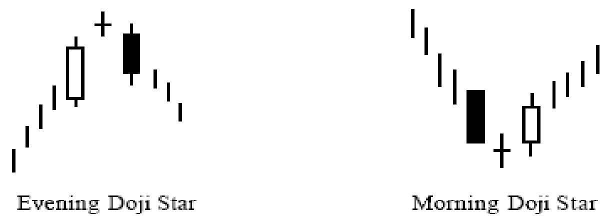
It shows the beginning of an heir trend. It is composed also of three bodies, the first is a white colored one, and the others are black. Besides, it must be accomplished also three conditions:

- to exist a gap between the first body and the second one;
- the third body must close more lower than the closing of the first body;
- to exist a smaller volume in the first day of transaction than in the third day.



The Morning & The Evening Doji Star

It is met when it appears a Doji sign situated above the transaction ceiling price from the day before on a bullish market (the evening doji star) meaning the end of the upward trend, or when appears a Doji sign situated below the floor price from the day before (the morning doji star) meaning the end of the heir trend.



The Shooting Star

It is a configuration made of a little body (white or black) with a long wick up, showing the change of the upward trend. The signal of changing trend it is more powerful if between configuration body and the others bodies exists a gap.

Regarding the patterns, these can be identified by closely watching the charts for a bigger period of time.

The Head-Shoulders" Pattern

It signalizes a future descendent trend for a specific share. The chart has three tops, the central one being higher than the extremes, which have about the same height.

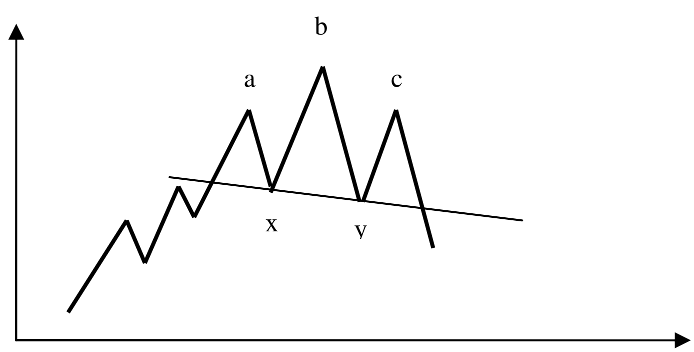


Fig. 1: The "Head-Shoulders" pattern

a – left shoulder; b – head; c – right shoulder.

The signal for changing the trend is the line of the “neck” that unifies a minim of the left shoulder (x) with a minim of the head (y).

The Double Bottom pattern

It is contrary tot the Head-Shoulder model and signalizes an ascending trend for the share. The chart has a “W” shape, with two minimum values recorded in a period of a few weeks, with a maxim level inserted between them.

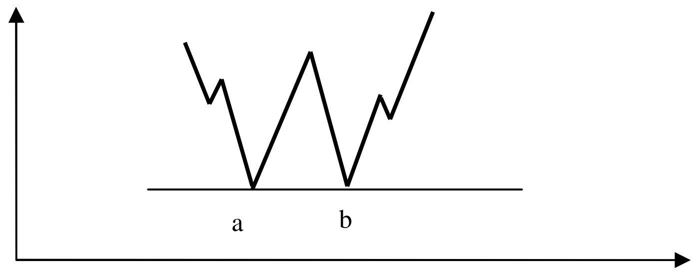

Fig. 2: The Double Bottom Pattern

The increasing trend is more powerful if the second minim is smaller than the first one, because the uninitiated panicked investors will exit the market.

FISCAL POLICY AND WELFARE STATE IN THE ENLARGED EUROPEAN UNION

Slavin Mariana

Universitatea de Vest Timisoara, Facultatea de Stiinte economice, Str. Pestalozzi nr.16, Email: slavinmariana@yahoo.com

Abstract: It is considered that fiscal competition is able to determine a reduction of tax rates, a greater efficiency in the use of public funds and a better allocation of equity. On the other hand, fiscal competition can affect the transfer effects of taxation on the economy impeding the normal functioning of international trade and capital markets. The bitter competition inside Europe, following the elimination of the borders, of the free goods, services, and individuals' flow, produces a huge pressure on the national protection systems in order to reduce social costs. Taxation can contribute to development and to welfare through three sources: the firstan foremost the tax system must collect enough funds in order to finance public services and social transfers at a high level of quality. Secondly, taxation influences the economic decisions and should offer incentive for more employment and for an efficient and lasting use of the natural resources.

Keywords: fiscal policy, welfare state, tax competition

1. The welfare state in European Union

In order to induce the people's welfare, the social state welfare state acts in the following directions: pensions' system and benefits for descendents, healthcare and transfers in cases of illness or disability, the system of family supports, the social assistance area and the unemployed support. The social politics' main instrument is the social insurance system. The public system's social insurance benefits are financed by employees, employers and state's contributions. The corporations and the insurance agents, with self-administration, perform programs based on occupational insurance schemes. Today the welfare state manifests itself differently; each country adapts and/or reforms the social politics starting from the two classical models: the residual one, the achievement model and the redistributive one. At this moment, the great majority of documents issued by the European Institutions make reference to the *„European Social Model"*. Presently, in Europe there are as many social models as number of member states. The literature dealing with the welfare state makes a distinction between four models: Nordic, Continental, Mediterranean, and Anglo-Saxon, the later is also named the liberal or the residual model. Anglo-Saxon states, UK and Ireland have economies focused on the free marked in assigning resources, promoting the decrease of the state position and the markets liberalization. These states resorted to cut-off in wages combined with a policy based on diminishing the social rights for those unemployed; diminishing the providence-state budget's costs were accompanied by a powerful tax relaxation, which offered advantages in the global tax competition. The Anglo-Saxon countries have a less extensive welfare state where social assistance is seen as a last resort and primarily oriented to people in working-age. The Continental European states, more conservatives - Austria, Belgium, France, Germany and Luxembourg – promoted the insurance based on labour and on bended rights. The politics which were promoted in those countries had to realize the concern's harmonisation of the busiest (beneficiary of a large system of social security) and of the not-busiest (more and more numerous and very dependent on the first category). Scandinavian states – Sweden, Denmark, Finland and Nederland - insist on the generality of social welfare and on solving politically, then economically, the society's evolution. The Mediterranean countries, including Greece, Italy, Portugal, and Spain, focus their welfare spending on old-age pensions and typically concentrate on employment protection and early retirement to exempt groups of the working age population from participating in the labour market. Strong labour unions in the formal sectors have compressed the wage structure. In Europe there is a social submodel in transition, where neither the neo-liberal solutions, nor the social state built in Occident are applicable. The Eastern Europe needs a social model which has to provide a new type of sustainable balance between the social security and the economic competition. The growth of the investments in infrastructure and in research-development are elements of public politics compulsory for the Eastern countries, and especially for Romania. These elements will bring to the society's general development, to the consumption growth, to business development and the most important, to more and better paid employment positions (jobs). The concept of this principle remained intact during all the crises which affected those states, proving in the same time the resistance towards external transformations. At the end of the last century, a new program entered the European Institutions' agenda. In 2000, the European Council met in Lisbon and adopted a series of needed measures in order to have *„the most competitive economy the world had ever known",* the central binominal being the two dimensions: *economic dimension and social dimension.* One year later, in Gothenburg, to those two dimensions it was added a third one, thus referring to the environment protection.

From the realities of great importance with which the Union economy deals and which put their print on the political decisions from Brussels, we mention: The European Union passes an economic recession period; the social inequalities are growing; the providence-state is less and less capable to reduce inequalities, due to the fact that it has difficulties to finance social projects (their financing supposes tax growth; but this action affects the competition of the European economy); a process of population ageing with an ascending trend; environment protection supposes high costs, more and more difficult to support.

The bitter competition inside Europe, following the elimination of the borders, of the free goods, services, and persons' traffic, produce a huge pressure on the national protection systems in order to reduce social costs. „The solution" which came from the European Institutions in order to remove the competition considered to be unfair proved to be that of *„national social regimes harmonisation",* first of all regarding the right to work. Certainly, after the new member states integration, the tax competition of the East led to pressures regarding the diminution of the taxation in the EU of the 15 countries. This competition can be also considered unfair. In this sense we can forecast two scripts. The first script is considered to be tax harmonization at direct taxation level (we mention that the majority of indirect taxation depends already on the union politic), so to avoid cross-border corporate mobility and, implicitly, problems of labour forces in the tax inactive states. A second scenario, which we considered better, would be to adopt at the level of the first member states a politic of tax relaxation. In this way a pulse of the aggregated offer will be given to the economic growth.

2. GDP and the social protection expenditure

Economic progress is ultimately measured by the gross domestic product (GDP) of a country. GDP is the central measure of national accounts, summarising the economic position of a country or region. GDP is equal to the market value of all final goods and services produced in a given period of time. GDP per capita in purchasing power standards (PPS) may be used to measure the material living standards of a country, one way of determining wealth. The PPS is essentially an artificial currency, whose exchange rates with the euro and other European currencies are calculated using purchasing power parities (PPP). One PPS buys the same volume of goods/services in all countries. Thus, use of the PPS eliminates price level differences between countries, allowing a fairer comparison of living standards. To the level EU-25 in the year 2005, GDP per capita is of 23500 euro. The new members states NMS-10 have the values much more (euro per capita): Latvia 11000, Poland 11700, Lithuania 12200. The states with the values most big (euro per capita) am: Ireland 32299, Denmark 29900, Netherlands 28900, The Austria 29700. Is remarked Luxemburg with eldest value, 58000 euro per capita. Romania and Bulgaria have most little values scilicet 8100 respectively 7500. If social protection expenditure is expressed in terms of. Outside EU-25, expenditure is highest in Norway (9154 per-capita PPS (purchasing power standards), the PPS), just below Luxembourg differences between countries are more pronounced. Within EU-25, Luxembourg had the highest expenditure in 2004 (12180 PPS per capita), followed by Sweden (8756 per capita) and Denmark (8470 per capita). The countries with the lowest expenditure is the Baltic States: Latvia (1220 per capita), Lithuania (1448 per capita), Estonia (1625 per capita). In Romania the social protection expenditure in 2004 is 1089 per capita. The disparities between countries are partly related to differing levels of wealth and also reflect differences in social protection systems, demographic trends, unemployment rates and other social, institutional and economic factors. In 2004 gross average social protection expenditure accounted for 27.3% of GDP in the EU-25 countries. In 2004 the EU countries with average or above-average ratios (27.3% or more) accounted for 42.2% of the EU population, the group with between 22% and 27.3% for 32.7% of all EU inhabitants, those spending between 17% and 22% of their GDP on social protection for 23.6% and countries spending less than 17% of their GDP for only 1.5% of the EU population. The countries with the highest ratios — Sweden (32.9%), France (31.2%), Denmark (30.7%), Germany (29.5%), Belgium (29.3%), Austria (29.1%) and the Netherlands (28.5%) — spend (in relation to GDP) more than twice as much as the three with the lowest ratios — the Baltic countries Latvia (12.6%), Lithuania (13.3%) and Estonia (13.4%). Taking the EU-15 countries as a whole (for which long series dating back to 1990 are available), after peaking at 28.7% of GDP in 1993, social protection expenditure fell to 26.9% by 2000. This ratio then rose continuously from 2001 to 2003 (27.7%) to end on 27.6% in 2004. Over the period 2000-2004, expenditure on social protection as a percentage of GDP in EU-25 was about 0.3% lower than in EU-15. Significant rises were recorded in Belgium (26.5% to 29.3%), Ireland (14.1% to 17%), Luxembourg (19.6% to 22.6%) and Portugal (21.7% to 24.9%). The situation was somewhat different in countries which continued to show strong GDP growth. In 2004 in particular, the share of social protection expenditure in GDP decreased in the Estonia (14% to 13.4%), Latvia (15.3% to 12.6%), Lithuania (15.8% to 13.3%) and Slovakia (19.3% to 17.2%). This increase reflects faster growth in social protection expenditure than in GDP, which slowed down in the European Union in 2003 in comparison with 2002 and speeded up in 2004 in comparison with 2003. Social protection expenditure goes to areas that either are not particularly affected by the economic situation (such as health expenditure and pensions) or are in fact countercyclical (unemployment or social exclusion). In 2004 out of the total EU-25 expenditure on social protection, social benefits accounted for 96.2%, administration costs 3.1% and other expenditure 0.7%. The structure of social protection expenditure in EU-25 in 2004 is following: old age (39.9%), sickness/health care (27.2%), family/children (7.5%), disability (7.8%), survivors (4.3%), unemployment (6.3%), housing (1.9%), administration costs (3.1%), social exclusion (1.4%) and other expenditure (0.7%).

3. Fiscal policy in European Union

Tax systems have, from the historic point of view, a national character, being drown in the specific conditions of the national economy. Thus, the volume, the structure, and the tax rates correspond with the allocated levels of stabilization and of redistribution. Tax systems can contribute to the increase of capitals mobility, to the development of financial markets, to the growth of competition, to a more efficient allocation of material and financial resources, with consequences on the economic development. Globalization amplified the elasticity and the mobility of tax bases but, raised a series of new problems regarding tax administration in the new conditions. Some countries reacted at the negative effects determined by globalization; they reformed the tax system, through the implementation of new profitable treatment measures for capital incomes, so that the capital wouldn't immigrate to other states. Taxation can contribute to development and to welfare through three sources: the first the tax system must draw enough funds in order to finance public services and social transfers at a high level of quality. Secondly, taxation influences the economic decisions and should offer incentive for more employment and for an efficient and lasting use of the natural resources. Thirdly, the taxation system reallocates the income, and this action must be done in a way it bonds the effective demand and the social balance through covering some gaps in income distribution. The tax systems of the EU member states suffered major changes from this point of view, by implementing various tax reforms. The measures regarding taxations, which raise much the inequality and strangle the demand, will hardly contribute to a dynamically growing economic region as called for in the Lisbon Strategy.

3.1 The consequences of tax competition

The question is if the EU Member States take advantage for the implementation actions of tax policy, which contributes to coordination in the EU, or accept the tax systems which are less and less distorted due to tax competition. If the capital is mobile and the taxation level defers from state to state, multinationals can use a full set of tax optimization strategies. The methods used are two: the transfer for profit shifting in low taxation areas and the implementation of some financial departments in fiscal paradises for financing investments. These types of strategies of non-payment of taxes put pressure on governments, because the states with a higher tax rates lose incomes and subsequently small or medium-sized companies (SMEs) hang back, because they can not use similar strategies; but with all this they take part to the competition on the same market. When the multinationals don't use profits, but the productive investments in order to use the tax differences between different states, the pressure grows further, in order to reduce finally the tax rate. This process, known under the name of tax competition, doesn't appear in the domain of corporate taxation. Due to the fact that the financial welfare is also more mobile as the invested capital from a productive point of view, the same logic can be applied to the taxes on personal capital income or on capital gains. Generally, labour force is less mobile than capital and labour force with a poor qualification is less mobile then labour force with a high qualification. A very immobile tax base is consumption, especially the consumption of primary commodities. Consequently, tax competition drives to an essential change in the tax structure. Governments are blackmailed regarding the reduction of tax level for factors with a high mobility and to raise the fiscal burden on sources less mobile, in order to protect the revenues. In the situation of a tax competition, taxes will shift, consequently from taxes on income and goods to taxes on consumption. The main results of the taxation evolution in EU during the last decades confirm exactly the fact that this phenomenon happened.

3.2. The evolution of taxation in EU

Indeed, statutory tax rates of corporate income decreased drastically. From the evolution of statutory rate on corporate income tax (CIT) in the period 1995-2006 we can observe a decrease of these rate for the EU of the 15 member states (except Spain which maintains a statutory rate at the level of 35%) from an average of 38,0 % in 1995 to 29,5 % in 2006. We exemplify a decrease of the statutory rate in Ireland from 40% to 12.5%, Portugal from 39.60% to 27%, Greece from 40% to 29%, Luxembourg from 40.90% to 29.63%, Italy from 52.20% to 37.25%, Germany from 56.80% to 38.64%. At the level of the new member states we can also see a considerable reduction of the statutory rate for the corporate income during the period 1995-2006: in Cyprus from 25% to 10%, Latvia from 25% to 15%, Lithuania from 29% to 15%, Poland from 40% to 18%, Slovakia from 40% to 19%, the Czech Republic from 41% to 24%, Romania from 38% to 16%. But Malta (35%) and Slovenia (25%) kept the same statutory rate.

The process is far of being closed. Now, Germany prepares the new tax reform for corporations, carrying downwards the statutory rate under the level of 30%. Denmark intends to reduce this rate from 28 to 22%. These initiatives will certainly contribute to intensify the pressure on other countries. Due to the fact that the term „high-tax location " is a relative term, it isn't foreseeable a "race till the finish". It is known that the tax base differs from state to state; the fiscal authorities decide a number of deductions, exemptions, etc. This is why the tax base is changed, like the tax rate, and so result the effective tax rate. The literature supports the existence of some possibilities of calculation of the effective rate: a) using the data with a historical character b) anticipated approach. The effective rate obtained using data with a historical character are based on macroeconomic data (national accounting books) or from the aggregation of financial information offered by the corporations. The anticipated approach considers that the future forecasted taxes will be paid according to the corporations' development projects. Two methods of calculate effective tax rates are formed of the effective average tax rate – EATR and the effective marginal tax rate - EMTR. These rates are generally more reduces then the statutory rates, but these also followed a descending curve since the mid-1980s.According to the Institute of Fiscal Studies, the EATR in the EU-15 declined between 1982 and 2005 by 11.0 percentage points, while the EMTR fell by 10.0 points. The figures provided by the Zentrum für Europäische Wirtschaftsforschung point to an even more pronounced downward trend, with an average decline of the EATR in the EU-15 of 13.6 points from 1984 to 2003. The fact that tax revenues from corporate income have remained broadly stable as a proportion of GDP (gross domestic product) (3%) in EU in 1995 is often taken as evidence against the hypothesis of harmful tax competition. From this can result the fact that the competition determines a growth of the corporate income tax rate but states broaden their tax base. It can not be determined an evident relation between a reduction of the statutory tax of the corporate income and of the collected incomes from this taxes. In the case of the new member states the diminished tax rate are accompanied many times by a low level of the corporate incomes related to the GDP, in opposition with the EU of the 15. One of the most frequently used indicators in order to express the real tax burden or effectively direct or indirect imposed on different types of economic income or on activities possible to be taxed by the member states are represented by the implicit tax rates. Implicit tax rates are different for each economic function. These are calculated as the ratio between total tax incomes coming from a category (consumption, labour and capital) and a representation of the potential tax base defined using the data about production and incomes from the national books. These rates allow tracking the tax burden level during the ages and in different states. The implicit tax rate (ITR) on capital that reached a value of 27.3% in 2005 for the EU of the 27 is is lower in the new Member States, like Lithuania (11.4%), Slovakia (14.4%) but, also, Germany (23.3%) and Greece (8.1%) record a low level of capital tax. But Sweden (46.5%) records the highest level.More and more EU Member States are starting to introduce a dual system of income taxation. While labor income remains to be taxed progressively, a flat tax that runs far below the top rates of labor income taxes is applied to capital income. Since capital income is much more concentrated than labor income, the shift towards dual income taxation corresponds to a large tax relief in favor of the wealthiest. As acknowledged by the EU Commission, the tax burden on labor income displayed an upward trend until the mid-1990s. It was recorded a level of about 36% in the EU of the 15 and has remained rather balanced since then. In 2005 the implicit tax rate on labour at the level of the EU of the 27 was 35.2%. Sweden (46.4%) is the state with the highest labour tax followed by Italia (43.1%), Belgium (42.8%), France (42.1%), Finland (42%), the Czech Republic (41.3%), Austria (40.9%), Hungary (40.4%). The lowest level of ITR on labour can be noticed in Malta (22.1%), Cyprus (24.6), UK (25.5%), Ireland (25.6%), Romania (26.7%). The analyse of the implicit tax rates evolution for the period 1995 and 2005 in EU shows a substantial growth of the implicit tax rate on labour starting with the first period of the '70 and till now, while the implicit tax rate on consumption kept balanced. The average effective capital tax fluctuated sometimes significantly from a year to the other. The implicit labour tax rate was always higher then the implicit rate on capital and consumption, and the difference grew during the analysed period. These ITRs are computed only in this report and are commented in detail in the next chapters. They are here juxtaposed to highlight three main facts: first, that average effective tax rates on labour remain well above those for consumption and capital; second, that the decline in labour taxation is slow and has indeed shown signs of slowing down; third, that nevertheless there seems to be some convergence between the ITRs as that on consumption and that on capital show signs of an increasing trend since their 2001 trough. During the ages, the worries concerning more and more the unsatisfied general performance of the EU labour market brought in light the high tax burden on labour and led to repeated calls to reduce it. The statutory tax rate on personal incomes diminished arriving in 2007 to 38.68% at the level of the EU of the 27, value which confirms the tax shift from individuals with high incomes to those with low incomes. Several member states had even introduced a general flat tax on personal incomes, (e.g. Romania 16% in 2005). In most EU states, the social contributions have a great impact at the ITR level on labour then the personal income tax (PIT). The exception is made by Denmark, Ireland and UK where the personal income tax has a greater weight then the social contributions. In Denmark the part of social contributions is very small so that the welfare costs are financed through general taxation. From the states with the highest weight of social contribution (but with a PIT not to small) we mention the Czech Republic, France and Italy. An other group of states would be Romania, Poland, Slovakia and Bulgaria who have a very high level of social contributions, but also the personal income tax under the level of 20% from the total of labour tax . Starting from 1990, the VAT was the first of the indirect taxes which grew, in order to equal the public revenues. To exemplify, member states with lower VAT level have used the existing corridor of between 15 and 25%, allowed by the European Directive with reference to VAT, in order to approach the upper limit of the spectrum.. Obviously, the share of VAT revenues in total taxation has been rising. Moreover, the tax burden on resources like energy or gasoline grew. The ecological effect of these taxes depends on whether the user has indeed a possibility to seek alternatives. Taxing the energy use of certain industries is most likely justified on ecological grounds, since energy-saving technologies are often available and become more attractive this way. In many other cases, however, the so-called „green" taxes have no other effect than to burden low-wage earners in particular, because poorer households spend a higher percentage of their income on energy bills and heating costs. As shown, the general predictions about the consequences of tax competition are confirmed by empirical proof. The main result is not so much a decline in total tax revenue, but a structural change in the tax system. This change primarily concerns the distributional impact of tax policy. All considered changes relieve high-income earners while raising the tax burden on the lower end of the income scale. This is true particularly for the shift from direct to indirect taxes, but also for the cuts in top personal tax rates and the trend to introduce a flat rate on capital income. Instead of reducing social contrasts the tax system further widens the gap between rich and poor individuals.

TAX COMPETITION AND CAPITAL MOBILITY BETWEEN OLD AND NEW EU MEMBERS STATES

Slavin Mariana

Universitatea de Vest Timisoara, Facultatea de Stiinte economice, Str. Pestalozzi nr.16, Email: slavinmariana@yahoo.com

Abstract: Accession of new member states with lower corporate taxation has raised fears on tax competition within enlarged Europe. The fiscal systems can contribute to the intensification of capital mobility the development of financial markets, competition intensification, and the better allocation of resources having positive effects on the economy. The flow of capital worldwide, including Foreign Direct Investments (FDI), is subject to diferent conditions and determinants of the host countries. Beside the comparative or competitive advantages given by the economical environment, the labour costs, the financial market developments, etc. fiscal policy is ready to contribute to the attraction of foreign direct investments.

Keywords: tax competition, foreign direct investments (FDI), corporate taxation

1. Tax competition in the European Union: theory and empirical evidence

1.1. Theories of Tax Competition

The literature on the topic of tax competition could be distinguished into two main ways. The first one, beginning by Tiebout, assesses tax competition in positive way because it leads to more effective using of public funds and limits non- productive activities such as rent seeking. The second one, beginning by Oates, professes the tax competition as a harmful because the decline of tax revenues leads to the decrease of providing public services below optimal welfare level. Oates says that the result of tax competition could be a tendency to lower volume to and lower efficiency of public services providing. If governments decrease the taxes to attract mobile capital, public expenditures are below the level when the marginal benefits of these expenditures equal their marginal costs. The expenditures cuts concern especially on programmes which don't provide enough benefits to business environment. Oates's conclusion, that such a governments behaviour is not effective, is based on the presumption that no government gets competitive advantage in the struggle. The result is a welfare decline in all communities or countries. Sinn emphasises the characteristics of services provided by public sector and not efficiently provided by private sector. Competition amongst government leads to a decline of providing such services. Sim adds that tax competition doesn't have to lead to the under-dimension of public services but it has strong redistribution effects.

Following Oates's discussion of tax competition, it was not until the mid-1980s that economists began to build formal models based on his ideas. Zodrow and Mieszkowski and Wilson have derived in a formal way the dynamics and the consequences of tax competition in what are known today as the basic models of tax competition. In their models, tax competition for mobile tax bases will lead to a "race to the bottom" in tax rates and leave the competing jurisdictions with too little revenues to be able to provide public services at a socially-optimal level. This basic result has also led to the fundamental question whether capital taxation – and for what matters corporate taxation – can survive in the long-run. Wildasin notes that the tendency toward under-provision of public services attributable to tax competition can be offset with a subsidy to each of the local governments, provided by a higher level of government.

A rather different perspective is taken by the public choice literature. Brennan and Buchanan argue that tax competition improves welfare, because the size of government would be excessive in the absence of this competition. Edwards and Keen examine this view formally in various "Leviathan models," where governments are concerned in part with maximizing the size of the public sector.

New considerations arise when regions differ in size. Bucovetsky and Wilson analyze "asymmetric tax competition" between a "large" region and a "small" region, as distinguished by the number of residents, each possessing the same endowments of capital and labor. Assuming that they are large enough to affect the after-tax rate of return to capital in the union, the larger jurisdictions tend to have higher equilibrium tax rates than the smaller jurisdictions, since the former are less concerned about tax-induced capital outflows. The resulting tax differentials cause an inefficient reallocation of capital from larger to smaller jurisdictions and thus potentially strengthen the case for tax harmonization. However, such differentials can also create political opposition to tax coordination, as small jurisdictions may benefit from the capital inflows (and higher service levels) attributable to tax competition.

Over the last twenty years, economic research has attempted to remove the strict assumptions of the basic models of tax competition and has come with a more contrasted picture. The consequences of tax competition are indeed rather complex, do not necessarily lead to a "race to the bottom", need to take into account the public expenditure side of the problem, and depend on various characteristics.

The degree of (a)symmetry in the size of countries or the asymmetries in endowment of factors between jurisdictions will also influence the outcome of the tax competition. The geographical location and the concentration production, such as the existence of a core-periphery model may lead to different optimal levels of taxation between regions. In addition, the existence of trade between the members of a union or with the rest of the world may lead to specialization and hence different equilibrium levels of taxation. The availability of multiple tax instruments besides capital taxation, the existence of economies of scale in the provision of the public service international spillovers in public goods , the possibility for the public sector to provide public input goods that will reduce the private cost of production , or that will reduce income uncertainty via redistribution are also elements that will influence the effects of tax competition. The degree of mobility of the factor(s) of production, the complementarities between mobile and immobile factors a possible home bias in investment, the degree of citizens demand for social insurance , the presence of cross-border loss offset , and the possibility to export the tax burden on foreigners are further features that will determine the equilibrium effect of tax competition.

1.2. Tax competition in EU: Do European Members States compete over tax rates?

A important question is whether EU Members States compete over corporate tax at all. Over the last 25 years, Europe has experienced declining statutory tax rates both for mobile bases and less mobile ones. In the analysis of the evolution of statutory tax rates on corporate income in 1995-2007, at the level of the EU-15 countries, we notice a decrease for all the countries . For instance, the corporate tax rate decreased in Ireland from 40% to 12.5%, Portugal from 39.60% to 26.5%, Greece from 40% to 25%, Luxembourg from 40.9% to 29.6%, Italy from 52.2% to 37.3%, Germany from 56.8% to 38.7%. At the level of the countries NMS-12, we notice a more considerable reduction of statutory tax rates on corporate income in 1995-2007. For instance, the corporate tax rates decreased in Cyprus from 25% to 10%, Latvia from 25% to 15%, Lithuania from 29% to 18%, Poland from 40% to 19%, Slovakia from 40% to 19%, the Czech Republic from 41% to 24%, Slovenia from 25% to 23%, Bulgaria from 40% to 10%. On the other hand, Malta (35%) preserved their rates as such. And in Romania the statutory tax rate on corporate income tax decreased from 38% in 1995 to 25% in 2002, then to 16% in 2005.

Over the last decade both old and new member states decreased statutory corporate income tax rates and broadened the tax bases, but while this was associated with declining tax revenues in the NMS, they remained broadly stable as proportion of GDP in EU-15. For old member states effective tax rates fell for profitable projects but remained fairly stable for projects that just break even or make low profits. In 2007, average nominal tax rate in the NMS is by nine percentage points lower than in the old member states, with the difference growing over the last decade. During 1995-2007 the average statutory rate in old member states fell by 5.8 percentage points and in NMS by 13.9 percentage points. One of the reasons was the motivation of NMS to adjust their tax systems and cancel these tax incentives which were in conflict with the European Law. The NMS pattern of capital allowances and treatment of losses was converging to EU practices. There were some differences in valuation of inventories for tax purposes, although they have also decreased. NMS granted various tax incentives to foreign investors, but as far as most of them were in conflict with the European law, they had to be abandoned. With this remark in mind, the fall in statutory rates to some extension had to compensate for broadening of the tax base.

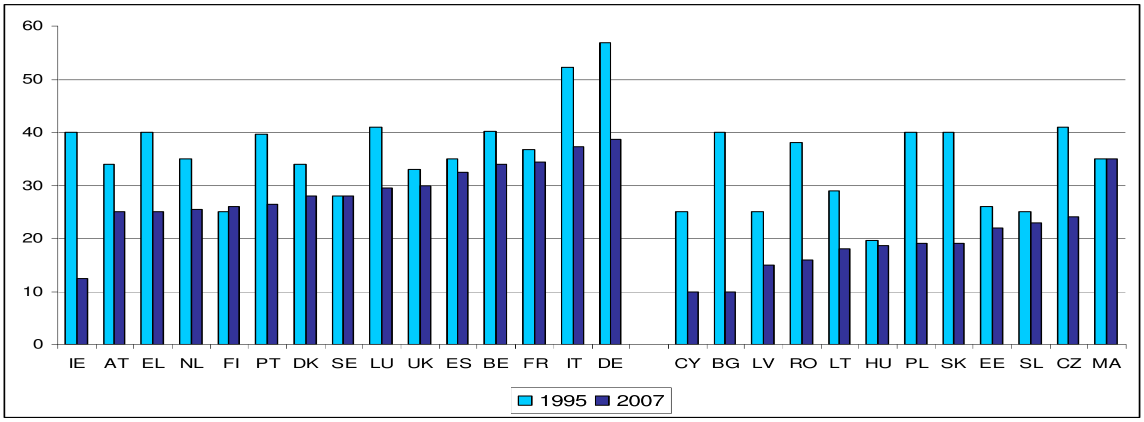

Figure 1 Statutory tax rates on corporate income 1995-2007 in EU (%)

Source: European Commission, 2007

The trend to decrease statutory rates continues. In 2007 some old MS lowered their corporate taxation level, specifically Greece, Spain, Netherlands and Portugal cut their rates. Moreover, Estonia reduces its rate by 1 pp annually to achieve 20% in 2009. Slovenia, which resisted the pressure for tax cuts for decade in 2007 decreased it by 2 pp. Judging by numbers one could note that we observe some kind of "race to the bottom" in corporate taxation. The dynamics of this process accelerates. Accession of Romania and Bulgaria in 2007 increases the competition for investments and jobs as the corporate taxation rates in these countries are below the EU level: in Bulgaria the government reduced the corporate tax rate from 15% in 2006 to 10% in 2007 and in Romania a flat rate of 16% for income and corporate taxes was introduced in 2005. Although the cuts in statutory corporate rates are significant it is not clear if result in higher capital inflow.

There is no clear link between statutory corporate income tax rates and revenues raised from corporate taxes, what indicates the role of effective taxation. The good example is Germany with high tax rates and limited revenues and on the opposite Ireland with low rates and relatively high revenue level. It indicates the potential role of effective taxation in generating budgetary revenues. However, the effective tax rates are not observed and therefore do not influence the common perception of the real tax burden.

Statutory rate is only one factor among all determining tax burden. Regulations concerning the tax base are even more important as they provide instruments to differentiate between types of activity and operations. To capture real effects of corporate taxation one should apply the nominal rates to real tax base. The purpose of computing taxable profits, income may be subject to adjustment for exemptions (income excluded from the tax base), allowances (amount deducted from the gross income to arrive at taxable income), rate relief (a reduced rate of tax applied to a class of taxpayers or activities), tax credits (amount deducted from tax liability), and tax deferral (a relief which taxes the form of a delay in paying taxes). It is common to apply all above mentioned measures. As a result the tax base is influenced by depreciation schemes, treatment of losses and valuation of inventories among others. Another factor determining real tax burden is efficiency of tax revenue office. Thus, effective corporate tax rates differ from announced statutory rates.

2. The impact on tax competition on foreign direct investments

Companies are affected differently by the taxation in each country. Thus, the small companies are more sensitive to the fiscal policy than the bigger ones because the levies are significant in their cost structure and they do not have the possibilities to envisage tax avoidance strategies. Big companies are able to negotiate fiscal treatments and the funds they pay to the budget. Under these circumstances, multinationals have several alternatives to structure and finance the investments, considering the host country's characteristics. A very important aspect concerning taxation is that multinationals are able to locate branches in countries with low taxation setting up strategies to avoid taxation. Companies are tempted to declare a higher profit in countries with low taxation or adjust the repatriation of dividends according to the tax legislation in the country of origin. Given these behaviour agreements concerning double taxation avoidance are very important for each country's tax regime.

The governments have several fiscal instruments at their disposals useful in influencing the actual tax rates and the local orientation of multinationals. Traditionally the literature sums up the following instruments useful in attracting the FDI: the reduction of corporate taxation to competitive level, deference of taxes or exempts from corporate taxation, exempts from duty or local taxation. These instruments are used on a large scale though their applicability was restricted by international conventions.

The FDI can be appreciated by using several indicators: net FDI inflows, and as ratio of the GDP. FDI have reached historical levels due to their effort to create a competitive framework designed to attract FDI. Though there are significant differences, all CEE countries have managed to implement sufficiently attractive measures for the foreign capital. The major determinants were: a stable economic environment, without major crisis or convulsions, the privatisation of state companies, a positive evolution of financial markets, bank intermediation, relatively good infrastructure and communication systems, modern payment systems.

2.1. FDI inflows into new member states

The issue of tax competition can be examined indirectly by looking for the responsiveness of foreign investment to corporate tax rates. The empirical literature on the effects of taxes on FDI focuses almost exclusively on the US and the EU-15 data. There are only a few studies on FDI determinants in the NMS. Carstensen and Toubal apply difference between statutory rates of two countries as variable determining FDI flows for the sample of 1993-1999 and CEECs and conclude that estimated parameter value is small and not significant at the 5% level. The potential explanation was that they did not take into account special tax regimes designed to attract FDI. application of effective tax rates would address these shortcomings. Tax rates were also examined as FDI determinant by Edmiston who apply two variables: number of special tax rates and the highest statutory profit tax rate. The results indicate that imposition of an additional special tax rate reduces FDI as a percent of GDP and higher tax rates lead to lower inflows of FDI in FSU and CEECs. Again, the variable applied is statutory rate Lahreche-Revil adds data on some of the current new members to their EU15 sample, and tries to separate the effects of corporate taxation in the new members for the sample 1990-2002. Tax measure determines the sample: statutory rate, implicit tax rates (Czech, Hungary and Poland) and EATR (Czech, Hungary, Poland and Slovakia). The only strong and general conclusion of the Lahreche-Revil paper is that taxation may drive relocation, but only within EU15. This factor is rather irrelevant when outflow of FDI from old to new members are considered. Anyway, the approach seems to be very useful in analyzing capital flows from old to new member states.

Along with progress in development, foreign investment flows into NMS boosted in 2005, in some countries reaching over EUR10 billion a year. UNCTAD reports that even in 2000-2002, when overall FDI flows were shrinking each year reflecting slowdown in world largest economies, inflows to NMS increased. Indeed, these inflows have been steadily increasing year after year. In the euro terms, the average annual dynamics during 1995-2004 was 9%.

EU-15 countries have been very active in acquiring assets in NMS until 2001, often winning large privatization tenders. New inflows have been declining from that year. However, it seems that the accession of the new members in 2004 boosted FDI from the EU-15. What more, it seems that the increased flows into NMS in 2004 were at the expense of other FDI outflows from "old Europe". FDI flows into the NMS increased even more dynamically in the following year. Nevertheless, the significance of direct investment flows to the NMS was negligible for all outward FDI of Western European economies. Even the high results of 1995-2001 and 2004-2005 were only about 3-5% of total outward FDI investment into equity capital and loans of the EU-15. In 2002-2003, EU-15 investment into equity capital and loans in NMS were only around 1% of total outward EU-15 FDI.

Germany is the largest EU investor in the group of old members states, with reported FDI outward stock in 2003 of nearly EUR37 billion in 2004, followed by the France (EUR25 in 2004), the Netherlands (EUR18 billion in 2005), Austria (EUR13 billion in 2003), United Kingdom (EUR8 billion) and Sweden (EUR7 billion). Inflows of direct investment from Western Europe constituted around 75% of total incoming FDI to EU in 2001-2002, and in the case of smaller countries have been significant part of overall investment outlays. FDI flows among new member countries are still small (3% of total FDI stock in the CEE region in 2005), yet increased in recent years.

2.2. The evolution FDI in Romania

In Romania, during the last 10 years since market liberalisation, several changes went on, the FDI encountering ups and downs. During 1996-2000 the FDI volume barely raised to 6 billion USD (2 billion USD from privatisation of state companies). Compared to the capital inflows into Poland (39 billion USD), Hungary (21,5 billion USD), Czech rep. (12,5 billion USD) the investments were incomparable low because of the political instability, unfavourable laws, small scale of privatisation and the reluctance to create the legislative framework favourable to foreign investments. Obviously, analysing the investments flow in the mentioned countries, the main determinants for FDI entry were: the host countries political willingness to attract FDI, a payment system adapted to modern needs and connected to the real time payment system already existing in developed countries, a flexible foreign exchange system, a friendly business environment, stable tax system, possibilities to withdraw profits, etc. The trend of FDI flows were reversed in 2000 when economic growth resumed, Romania being regarded as an attractive country for the foreign capital. The evolution of FDI indicators shown in the table below:

mill. Euros

Indicator	1996/2000	2001	2002	2003	2004	2005
Net FDI	5695	1312	1194	1910	4153	5213
Gross FDI	5857	1457	1448	2782	4561	5957
Net FDI/capita EUR	264	61	55	88	192	236
Net FDI/GDP (%)	3,3	3,3	3	5,5	7,0	8,34
Gross FDI/GDP (%)	3,4	3,3	3,0	5,5	7,7	9,53

Figure 2 Foreign direct investment indicators in Romania

Source: NBR

The FDI inflows during 2005 mounted to 5213 mill euros consisting of: foreign capital participation to equity formation (51,6%), reinvested profits (22,3%), net loans (26,1%). The FDI were directed towards manufacturing industries (37,3%), food industry (26,1%), transportation (5,1%), trade and commerce (15%), banking and insurance (14,5%), communication (10,9%). A rather low contribution was brought to the textile industry, despite its' great potential (2,6%), hotels and restaurants (0,2%). From the point of view of FDI types Greenfield investments represent 42,2% of the total FDI at the end of 2005, the difference being acquisitions (brownfield investments). The spread of investments the largest amount was directed toward the Bucharest region (60,6%), the South Eastern part of the country (8,4%), the central regions (7,4%), the western regions (6.8%). The most important part of FDI come from The Netherlands (19,5%), Austria (15,4%) Greece (8,5%), France (8,4%), Switzerland (7,1%), Italy (6,9%).

This brief study attempts to analyse the effect of fiscal rates on foreign direct investments. Considering the old, more developed members of the EU as well as the countries that have recently acceded to the EU. We find that the fiscal rates are important, but not the most important determinant in attracting FDI. In spite of the speed up of investments flow in the newly acceding countries the more developed, stable economies are the favoured destinations. Besides the economic growth characterising the new member states, the financial market development, the low inflation, loans availability and economic perspectives are among the most important determinants.

EVALUATING DISCRETIONARISM OF ROMANIAN FISCAL POLICIES BASED ON STRUCTURAL BALANCE

Stoian Andreea

Bucharest University of Economics, Faculty of Finance, Insurance, Banking, and Stock Exchange, Piața Română. No.6, Bucharest, andreea.stoian@fin.ase.ro***, 021/3191901, ext. 264***

Abstract: Structural balance represents a useful fiscal indicator to evaluate the efficiency of fiscal policy from discretionarism point of view, also, giving some relevant insights on long run sustainability. According to estimated results for Romania's case, it could be noticed only 2 episodes of fiscal adjustment. Based on the size of structural balance from following years, it could be emphasized some inconsistency of Romanian fiscal policy. On long run, the main challenge is related to achieving fiscal sustainability.
Keywords: fiscal policy, discretionarism, structural balance, GDP gap, Hodrick – Prescott filter, fiscal sustainability

Introduction

Assessing sustainable fiscal policy requires active measures of increasing taxation or reducing budgetary expenditures, independent of business cycle. Those particular actions are part of *discretionary fiscal policies* implemented by governments in order to improve their fiscal stance. In order to investigate the dicresionarism of fiscal policy, it could be used some fiscal indicators out of which the most relevant is *cycle abjusted balance* (CAB) or *structural balance* (SB) (see in that sense, Muller and Price, 1984). Based on that fiscal indicator, it could be measured fiscal stance changes from one period to another, which, within the main literature stream, are known as *fiscal impulse* (Alesina and Perotti, 1995).

Structural balance represents an important fiscal indicator often used in order to evaluate the efficiency of fiscal policies on short, medium, and long run. It is mostly used by international organizations, such as Organisation for Economic Co-operation and Development (OECD), but, especially by governments within European Union (EU) area which are under the constraints of Growth and Stability Pact. Moreover, Giorno, Richardson, Roseveare and van den Noord (1995) consider that changes of structural balance give mportant insights on the incidence of fiscal policy on aggregate demand.

Many authors consider structural balance as an important indicator for identifying and measuring the discretionarism of fiscal policy. For instance, Chouraqui, Hagemann and Sartor (1990) consider the relevance of SB as an indicator for evaluating the discretionarism of fiscal policy, taking into account the following aspects[178]: (i) on one hand, based on SB, it could be made the distinction between cyclic component and non-cyclic component of budgetary balance, and, therefore, it could be used in order to estimate the incidence of fiscal policy promoted by governments; (ii) on the other hand, taking into consideration the consequences of public finance policies on long run, based on the changes of SB, it could be obtained some relevant insights on future orientation of fiscal policy. But, there were also some critics in that sense. For instance, Muller and Price (1984) consider that SB could give some insights on fiscal stance changes caused by public finance policies and not by business cycle.

The necessity of estimating *structural balance* consists in the fact that under a growing structural balance, public debt could become unsustainable and, therefore, active measures of fiscal policy are requested. Fiscal imbalance could be influenced by permanent factors, as well as by temporary factors (Blejer and Cheasty, 1991; Hagemann, 1999), and such an impact is reflected by the size of fiscal imbalance. It is considered as being *temporary factors* those effects on budgetary expenditures/revenues due to the deviation of GDP from its normal trend (e.g. rising social transfers, especially unemploylement transfers), while, *permanent factors* are represented by normal evolution of budgetary expenditures/revenues in the absence of some external shocks, when the economy operates on its full employment capacity[179]. Consequently, the relationship between fiscal balance and business cycle could be considered from two

[179] It is considered when the unemployment rate lies between 5 – 6%, according to Dornbusch and Fisher (1990) and when inflation rate is stable.

perspectives: (i) based on *discretionary changes* of fiscal policy; and (ii) based on *induced changes* due to business cycle.

The aim of this paper is to investigate the discretionarism of Romanian fiscal policy based on changes on estimated structural balance. The structure of the paper is the following. In Section 2, it will be presented methodological aspects on estimating structural balance. Section 3 consists in applied methodology for estimating Romanian structural balance. Section 4 is devoted to the analysis of Romanian fiscal policy and their efficiency from sustainability point of view, and also consists in concluding remarks.

Methodological background on estimating structural balance

In the main stream of literature, there have been identified two main approaches of estimating structural balance (see for instance, Mendez-Camba şi Lamo, 2002):

First approach lies on two stages. On the first stage, it is estimated the gap between the effective output and the potential output based on Hodrick-Prescott filter, or based on a production function. On the second stage, there are estimated elasticities of budgetary expenditures/revenues on GDP. The mentioned method is commonly used by international organizations, such as International Monetary Fund (IMF), European Comission (EC) or OECD, but it has some drawbacks steamed from the estimation of GDP gap (Brandner, Diebalek and Schuberth, 1998). For instance, OECD uses a Cobb-Douglas production function, while IMF does not apply the same methodology for all the countries. There are cases where production is estimated based on a general equilibrium model within NAIRU, and other cases where production is estimated based on statistical methods. On the other hand, EC uses Hodrick-Prescott filter, which is mostly used because of its simplicity.

The second approach relies on SVAR model where budgetary deficit and GDP percentage change are the variables. Compared to the forst approach, the second one has some advantages because it does not imply estimation of potential production, nor elasticities, but it is difficult to be implemented in tha cases with short time series (e.g. Romania's case). Moreover, based on SVAR approach, Dalsgaard and de Serres (1999) estimate structural balance values which go to a conventional balance of 3% of GDP, according to Maastricht Treaty requirements. This method could be extended in order to analyse the reaction of fiscal policy to different shocks.

Generally, estimation of structural balance is based on conventional balance (D) determined as a difference between budgetary revenues (R) and budgetary expenditures (E):

$$D = R - E \qquad (1)$$

In order to identify and then eliminate the business cycle influences, it will be estimated *output gap*, as a difference between effective real GDP (Y), and potential output (Y^*), as percent of potential GDP:

$$GAP = \frac{Y - Y^*}{Y^*} \cdot 100 \qquad (2)$$

The next stage consists in estimation of budgetary revenues/expenditures elasticity related to GDP. The previous studies show that there are taken into consideration only those components of revenues/expenditures which could more probably be influenced by business cycle (taxes and social government spending).

In that sense, it is considered that taxes have a constant growth rate depending on GDP, and, therefore, the percent of potential fiscal revenues (R^*) in effective fiscal revenues (R) is given by the following relation:

$$\frac{R^*}{R} = \frac{k_0 (Y^*)^\alpha}{k_0 Y^\alpha} = (\frac{Y^*}{Y})^\alpha \qquad (3)$$

where:

α = fiscal revenues elasticity related to GDP, $\alpha>0$;

k_0 = constant.

The cyclic component of fiscal revenues as percent of potential output is given by the first approximation of a Taylor serie:

$$\frac{R-R^*}{Y^*}=\frac{R}{Y^*}-\frac{R^*}{Y^*}=r-r^*=\alpha\frac{R}{Y}GAP \qquad (4)$$

The cyclic component of budgetary expenditures is estimated the same as in the case of fiscal revenues, but taking into consideration only those social transfers related to unemplyment ($E_{unemployment}$):

$$\frac{E_{unemployment}-E_{unemployment}{}^*}{Y^*}=\frac{E_{unemployment}}{Y^*}-\frac{E_{unemployment}{}^*}{Y^*}=e-e^*=\beta\frac{E_{unemployment}}{Y}GAP$$

(5)

where:

β = social transfers expenditures elasticity related to GDP, β>0;

Based on the relations from (1) to (5), it could be estimated structural balance (d^*), which could have been obtained where effective output would be equal to potential output. Structural balance is conventional balance (d), adjusted with the cyclic effects of budgetary revenues/expenditures:

$$d^*=d-(\alpha\frac{R}{Y}-\beta\frac{E_{unemployment}}{Y})\cdot GAP \qquad (6)$$

where:

$$d^*=\frac{D^*}{Y^*};d=\frac{D}{Y^*}$$

Estimating structural balance on Romania's case

In Romania's case, National Bank of Romania (NBR) makes publicly available information related to the size of structural balance. But, according to its methodology, 'structural balance is estimated as a difference beteen conventional balance and privatization revenues, considered as being financing source and not an effective budgetary revenue'[180]. Within the main stream of literature (see in that sense, Blejer and Cheasty, 1991), it is emphasized that in tha case of transition countries, due to numerous distortions which could have some influence an macroeconomic aggregates, it could be estimated a *core deficit*, which eliminates such distortions. In that sense, privatization could be seen as a transitory process which could have some effects on some particular macroeconomic variables, but, estimating structural balance only by taking into consideration a simple difference, could be considered as being not relevant. Therefore, I propose within this paper a different approach of structural balance estimation, which it is more complex and could go to more relevant results.

Estimation of structural balance in Romania's case is based on the methodology presented within previous Section, but by taking into account some particular features of Romanian economy, further discussed:

1. estimation of *output gap* is based on relation (2) and by applying a Hodrick – Prescott filter[181] on GDP in 1990 constant prices.
2. in order to identify and isolate the transitory effects of business cycle, only fiscal revenues and unemployment social transfers are taken into account. But, there are, also, studies (see for instance, Lane, 2003) whichi investigate the impact of business cycle on different government expenditures/revenues components: current expenditures, government consumption, salary expenditures, capital spending. In Romania's case, business cycle could have much more influence on the total amount of budgetary expenditures/revenues than on their components. Moreover, in the case of transition countries, structural adjustment policies, could be considered as having transitory effects on budgetary revenues/expenditures because of their public financing, and, therefore could be asmimilated to the effects of business cycle[182].

[180] National Bank of Romania, Annual Report 1999, pp.43.

[181] It represents a decomposition technique, where timer series are decomposed into a trend component and a stationary component (Enders, 1995).

[182] Blejer, M. I; A, Cheasty (1991), „The Measurement of Fiscal Deficits: Analytical and Methodological Issues", *Journal of Economic Literature,* Vol.XXIX (December 1991), pp.1644-1678, pp.1654.

Consequently, it is considered as being more relevant to identify and isolate the cycle component within budgetary revenues/expenditures, rather than of their components.

3. according to the structural balance estimation methodology, fiscal revenues and social transfers are considered to grow on a constant rate, *α*, in the case of revenues, and, respectivly, *β,*in the case of expenditures. Elasticity estimation relies on two models, which consider budgetary revenues/expenditures growth related to output growth (see in that sense, Brandner, Diebalek and Schuberth, 1998; Braconier and Holden, 1999): (i) for fiscal revenues growth, it is considered the following relation: $R_f = k_0 Y^{\alpha}$, and (ii) for social transfers (unemployment), it is considered, on a first stage, their growth related to unemployment rate $E_{unemployen\,t} = k_1 U^{a}$, and, on a second stage, based on Okun model, it is established the relation between social transfers and output, according to: $E_{unemployme\,nt} = cY^{\beta}(Y^{*})^{\beta}$ (Braconier and Holden, 1999). In Romania's case, it was taken into account, on one hand, the relationship between budgetary revenues and GDP growth $R = k_0 Y^{\alpha}$, and, on the other hand, the relationship between budgetary expenditures and GDP growth: $E = k_1 Y^{\beta}$. Applying natural logarithm on both relationships, it will be obtained the following regressions: $\ln R = \ln k_0 + \alpha \ln Y = c_1 + \alpha \ln Y$ and, respectively, $\ln E = \ln k_1 + \beta \ln Y = c_2 + \beta \ln Y$. Using OLS, it will be estimated *α* and *β*. Taking into account the difficulty of estimating Cobb-Douglas production function, the methodology applied within this study is often used (see in that sense, Lane, 2003). The estimated elasticities are presented in the table below:

Explanatory variables	**Equation 1** **Dependent variable: budgetary revenues[*)]**	**Equation 2** **Dependent variable: budgetary expensiures[*)]**

Table 1. Government expenditures and revenues elasticity

The estimated elasticity for budgetary revenues, *α,* is about 0.83, and estimated elasticity for budgetary expenditures, *β*, is about 0.81. Based on the previous results, it will be estimated structural balance, according to relation (6) (see, Table 2):

Year	**1990**	**1991**	**1992**	**1993**	**1994**	**1995**	**1996**	**1997**	**1998**	**1999**	**2000**	**2001**	**2002**	**2003**	**2004**	**2005**	**200**

Structural balance (% GDP)	-1.4	-5.2	-0.3	-0.3	-2.2	-3.3	-4.5	-5.1	-5.5	-3.7	-4.1	-3.2	-2.6	-2.1	-1.0	-1.5	-1.8

Table 2. Estimated structural balance

The analysis of Romanian fiscal policy discretionarism and concluding remarks

Taking into account the evolution of estimated structural balance, it could be noticed some inconsistency of Romanian fiscal policy within the considered period. For instance, for 1992, it could be observed the efforts of Romanian government to reduce the large deficit from previous year in order to prevent the consequences on inflation rate. Even so, in the next few years, inflation rate was on its highest, despite the reduced budgetary deficits. Moreover, in the next few years, structural balance rose again, and the next episode of fiscal adjustment could be observed in year 2001. This episode could be considered as being more efficient than the previous one, because structural balance reduced consequently in the following years. Obviously, this moment could be related to the efforts of Romanian government to assess the requirements of Maastricht Treaty referring the constraints imposed for budgetary deficit. Also, it is important to emphasize the growing trend in the last year (2006). Momentarly, Romanian budgetary deficit, still, lies between the accepted limit, and a continous growth could raise some distortions on fiscal sustainability. Much more, analyzing the evolution of estimated structural balance, it could reach to another significant conclusion, regarding the inertia of authomatic stabilizers, and the fact that fiscal adjustments focused only on reducing the large size of fiscal deficits, but had no effect on aggregate demand.

Structural balance represents a useful fiscal indicator to evaluate the efficiency of fiscal policy from discretionarism point of view, also, giving some relevant insights on long run sustainability. According to estimated results for Romania’s case, it could be noticed only 2 episodes of fiscal adjustment. Based on the size of structural balance from following years, it could be emphasized some inconsistency of Romanian fiscal policy. On long run, the main challenge is related to achieving fiscal sustainability.

Abstract: The mandatory private pension represents a step forward in order to improve the quality of future life. Due to the problems occurred in the public pension system and the continuous debate regarding the number of participants, the lottery organization and schedule, the legal framework for the minimum rate of return, the possibilities of transfer between funds, we focused on the most developed market in the region, the Polish one, hoping to find the classical pattern for success.

Keywords: Mandatory private pension, investment policy, Polish market.

1. The most important goals of the study

As we have previously emphasized, we look forward to define possible correlations between the Romanian and the Polish pension funds markets. Starting with the evolution of the funds number, the legal framework, we hope to rely on the polish second pillar success in order to outline a profitable experience for our market.

Depending on the different phases of evolution, we should carefully appreciate the changes occurred in the last ten years for the Polish markets.

Another issue is the flexibility of this market, because we have already faced problems regarding this phenomenon for the Polish first Pillar. For example, Marcin Kawiński & Dariusz Stańko (2007) found out that due to labour market flexibility and (macro) pension finance sustainability there is a proposition to change the pattern of the 1st pillar to guarantee a minimum and universally available anti-poverty pension (that would be probably means tested) rather than keeping up high standard retirement based on fixed condition (i.e. period of contribution)[183]. Even this isn't our aim for the present study, we can easily predict that a change in the architecture of the first pillar will determine different behaviors for the second and third pillars.

2. The input data and the methodology of the study

The analyzed period was April 2002 – November 2006, using monthly data made public by the Polish Committee of Insurance and Pension Fund Supervision (KNUIFE).

We tried explaining the evolution of the private pension funds with the help on an econometric model:

$$AU = \alpha + \beta TB + \lambda S + \varepsilon$$

Where: AU = accounting unit

TB = bonds and treasury bills weight in investments portfolio

S = shares listed on a stock exchange weight in investments portfolio

ε = residual

---

[183] Marcin KAWIŃSKI & Dariusz STAŃKO, Labour flexibility and pension schemes in the European Union , 5th International Research Conference on Social Security, "Social security and the labour market: A mismatch?" , Warsaw, 5-7 March 2007

α = constant

β,γ = determinative variables coefficients

To simplify the model we considered the following hypothesis:

- we did not took in account the inflation level and the economical growth;
- the political decisions were not included;
- We left aside the fact that some of the second pillar funds managers are also managers of the third pillar funds (sometimes a manager asks the competent commission for a dual authorization). In this case it occur the problem of setting different investment policies, depending on the existence of multiple choices, one second pillar fund and one third pillar fund. Additionally, it should be underlined that the Polish Commission approved from the beginning the possibility for a manager to establish two mandatory private pension funds;
- the existence of a minimal rate of return;
- There are two kinds of lotteries, one similar with the Romanian existing one (everybody is provided a number of undecided in respect to the former market share), and another one, established since 2004 in Poland (the lottery participants are selected on financial criteria). So, at present, only the selected funds participate in the lottery – those which have generated rates of return higher than the weighted average rates during the two past accounting periods and whose assets have not exceeded 10% of the total value of all funds. All funds meeting these criteria participate in the lottery to the same extent. The lottery is carried out on the last working day of January and July every year by the ZUS. As a result, the largest funds (Commercial Union – known in Romania as AVIVA, Polsat, and ING N-N Polska) haven't had the access to new more members. A similar approach was tried in Romania by Aviva, the British insurer hopping to bring much more members by eliminated from the Lottery the two biggest pension funds: Allianz Tiriac and ING.

The election of the determinative variables (TB and S) was made considering that the weight of these two assets in investment portfolio is overcoming 90%. Even the Romanian pension funds didn't start the investments (there are not, for the moment, transfers from the public budget), the probability for those two types of assets is sure to be high.

3. Empirical results

To remove the influence of those pension funds that disappeared and the new ones that appeared during the analyzed period, we chose to take only those which were active the entire period, which are: AIG OFE, Allianz Polska OFE, Bankowy OFE, Commercial Union OFE BPH CU WBK, OFE „DOM", OFE Ergo Hestia, Generali OFE, ING Nationale-Nederlanden Polska OFE, Pekao OFE, OFE Pocztylion, OFE Polsat, OFE PZU „Złota Jesień", OFE Skarbiec-Emerytura.

The eliminated pension funds were small ones, such as Winthertur OFE, that had a market share of 3.50% in 2004.

Considering the accounting unit growth, which is the most eloquent vision of each pension found profitableness, this was around 198% - 171% for the five analyzed years and in the year 2006 the 15% average increase in the value of an accounting unit was the best annual result ever achieved by pension funds.

Ordering the pension funds by the average rate of return (Table no. 1) we can see that the best rate of return was obtained by ING Polska and the lowest rate of return by Allianz Polska, fact which can be explained through the investment portfolio structure.

In this analysis considering the bills and treasury bonds and shares listed on a stock exchange weight we noticed a slight difference between the weights of the two assets in the investment portfolio of ING Polska – where the shares weight is higher the shares weight in Allianz Polska investment portfolio. This could be an explanation for the obtained rate of return.

Pension Fund	**Annual rate**

	of return
Allianz Polska	12.9
Pekao	13.6
Skarbiec-Emerytura	14.1
Ergo Hestia	14.4
Pocztylion	14.4
Commercial Union	14.7
Bankowy	15.1
Polsat	15.3
PZU Złota Jesień	15.3
Generali	15.6
AIG	15.9
DOM	15.9
ING N-N Polska	16.1

Table no. 1[184]: The average rate of return for the pension funds

Before going to estimate the regression parameters the multiple regression hypothesis there were verified. The regression model $AU = \alpha + \beta TB_i + \lambda S_i + \varepsilon_i$ could be written with the matrixes help:

Y = aX + e, where $Y = \begin{pmatrix} AU_1 \\ \dots\dots \\ AU_n \end{pmatrix}$; $X = \begin{pmatrix} 1 & TB_1 & S_1 \\ \dots & \dots & \dots \\ 1 & TB_n & S_n \end{pmatrix}$; $a = \begin{pmatrix} \alpha \\ \beta \\ \lambda \end{pmatrix}$; $e = \begin{pmatrix} e_1 \\ \dots \\ e_n \end{pmatrix}$

The multiple regression hypotheses are[185]:

- Hypothesis no 1. E(e) □;
- Hypothesis no 2. $Var(e) = E(ee^T) = \sigma^2 I$;
- Hypothesis no 3. *X* is a not - random matrix
- Hypothesis no 4. *rank* (*X*) = *2*+1 < *n*
- Hypothesis no 5. e ->$N(0, \sigma^2 I)$

With the help of E-views statistic tests we verified the hypothesis.

Coming back tot the first model, from its confidence point of view, there were 6 pension funds: DOM, AIG, Commercial Union, Ergo Hestia, Skarbiec-Emerytura and Pekao, for which the obtained rate of return is in strong connection with the bills, treasury bonds and shares weight in investment portfolio.

The model confidence was appreciated examining the determination coefficient (Multiple R – which shows the percent in which the determining variables are influencing the determinate variable), the Fisher - Snedecor test (F test – shows the model global confidence; for values grater then 1 of F test confirm true the hypothesis H_1: $\beta, \gamma \neq 0$) and not least the values of *t* test and p – value for α, β and γ. All this results, statistical speaking, are showing the model credibility.

Pension Fund	Multiple R	*F* test	*Significance*

			F
DOM	0.692648	3.227685	0.101557000
AIG	0.659642	2.696096	0.135464228
Commercial Union	0.800375	6.238438	0.027830797
Ergo Hestia	0.683449	3.067868	0.110472112
Pekao	0.772090	5.166000	0.041867081
Skarbiec-Emerytura	0.621773	2.205918	0.180758574

Table no. 2[186]: The model confidence

The model showed it self as being partial accurate, meaning that the treasury bills and shares weight is explaining only a part of the accounting unit evolution (about 50%), for 5 others pension funds, which are Allianz Polska, Bankowy, Polsat, PZU Złota Jesień, ING N-N Polska.

Pension Fund	Multiple R	F test	*Significance F*
Allianz Polska	0.586263	1.832967	0.229006
Bankowy	0.498617	1.158092	0.367714
Polsat	0.520270	1.298994	0.331293
PZU Złota Jesień	0.486967	1.087978	0.387761
ING N-N Polska	0.563279	1.626580	0.262931

Table no. 3[187]: The model confidence

For the two others pension funds Generali and Pocztylion, the model did not work as expected, in other words, the weight of the considered assets does not represent the most important impact on the obtained rate of return. The Multiple R values (about 30%) show clearly that there are other important elements, which are explaining the accounting unit evolution that we did not take initially in account.

Pension Fund	Multiple R	F test	*Significance F*
Generali	0.382011	0.598035	0.575735838
Pocztylion	0.306191	0.362082	0.708537644

Table no. 4[188]: The model confidence

Conclusions

In conclusion, beside the two pension funds: Generali and Pocztylion, the model that we built-up showed itself as being confident. The rate of return obtained by the analyzed pension funds is in a strong relationship with the investment portfolio structure and as mentioned we can strongly say that the more risky funds (a bigger weight for shares in investment portfolio against other funds less risky) had accomplished a bigger rate of return.

Discussing the rate of return, we support the idea of a relative minimum guarantee, due to the Polish reality, market that is “facing” nowadays a rate of return between 12% and 17% for the past five years.

[186,4], [5] Surce: authors processings

Indeed, we shall have no provided data for the next two years, but this is similar to other markets and should not represent an issue to worry for.

Abstract_The pension system reform in Romania initiated in 2000 is based on three pillars: 1) the public redistributive mandatory pillar; 2) the private mandatory pillar; 3) the private optional pillar. The paper tries to answer a few questions concerning the juridical and technical problems raised by the implementation of the last two pillars. The method used is that 'of scenarios', and the simulations are made separately for men and women, given that the duration of contribution payment and also the life expectancy at retirement are, at least in the present, different for the two categories of beneficiaries.

Keywords: private pension, universal pension funds, accumulation, deccumulation.

1. The Organization and Functioning of Universal Pension Funds

Together with the mandatory component (Law 19/2000 concerning public pension system and other social security benefits), the reform started in 2000 included other components, namely:

a) mandatory private component;

b) optional private component;

These components will be functioning on other principles and regulations, as follows:

a) Mandatory private component:

- is based on mandatory contributions;
- the universal pensions funds will be established based on contributions, which are to be invested and capitalized accordingly to the special regulations adopted for this purpose;
- the contributions and the interest from investing them are kept in individual accounts;
- the pension funds of this component are administered by private institutions.

b) Optional private component pillar III:

- is based on optional pension plans (contributions are not mandatory);
- cumulated funds of this component are to be invested and capitalized;
- the contributions and the return on the investments made from the contributions are kept in individual accounts;
- the pension funds of this component are administered by private institutions.

The reason for introducing the universal pension funds are, besides the increase of the replacement income, by supplementing it with a pension received from the private system, the reduction of the importance of the public pension system, the insured's possibility to choose and assume responsibility for the fund they are insured at and for the age they plan to retire, and also, the development of financial markets.

Regarding the second pillar of the pensions system (the mandatory private component), in October 2004, Law 411 was adopted. This Act stipulates that the pension funds are to be managed privately by a non-commercial entity, the participants of the fund beginning the same time members and shareholders. The functioning model is that of mutual funds. Shareholders of the pension fund (the insured) are individuals aged less than 35 years who contribute presently to the public pension system. They must contribute to one of the pension schemes privately managed. There is another participant category, those aged between 35 and 45 years presently contributing to the public pension system. For them, participation to the private pension schemes regulated in the second pillar is their own option. For each of the members of the private pension funds, an individual pension account will be opened, monthly contributions to the private pension together with the profit from investing these amounts being accumulated in these accounts. In the first year of contribution to the scheme, this will be 2% of the gross income (the same calculation base used in the public pension system). In 8 years from the beginning of participation, the contribution share will increase with 0.5% each year, beginning with the 1st of January of each year, reaching 6% of the gross income at the end of the 8 years. The contributions to the private pension funds are lower than in other Eastern European countries. The explanation for this fact is the decrease of the social security budget's financial resources because of re-direction part of the contributions to the public system towards private funds, situation that might unbalance social security's budget a seriously affect public pension system's functioning. Pension funds can be invested in several financial instruments such as bank deposits, treasury bills, shares traded on the regulated capital markets of Romania or EU, mutual funds, etc, precise maximum proportions of each of them being stipulated in the fund's prospect. *The conclusion* that can be drawn from this is that the managers of private pension funds can invest the financial resources in financial instruments with minimum and medium risk, fact that offers a higher security for the investors.

Regarding the third pillar of the pension system (the private optional component), the participants are not obligated to participate to this pillar, contribution to such a pension fund being optional. Contribution payment for the private pension schemes can be shared between the employer and the employee, according to the stipulations in the collective working contract or, if this doesn't exist, according to a protocol between the employees' representatives. For the contribution to the private pension there is a fiscal exempt up to the equivalent of 200 euros per year, both for the employer and the employee.

Managers of the optional private pensions can be insurance companies and other companies allowed to manage pension funds but, all of them have to get a license in this respect. Their activity will be monitored by the Private Pensions Surveillance Committee (CSSPP).

According to the legislation, the right to receive an optional private pension will be given at the request of the participant, but with the compliance of the following cumulative conditions: the participant must be at least 60 years old; he had been paid at least 90 monthly contributions (about 8 ½ years); the optional private pension calculated is at least equal to the minimum optional private pension according to the CSSPP regulations, exempts from this rule being applied in case of death of the participant or in case of permanent invalidity. In case of both pillars (second and third), private pension funds can not be declared bankrupt.

2. Possible scenarios of accumulation and deccumulation of universal pension funds

The need to supplement the replacement income obtained from the public system was motivated above. Given the fact that during the accumulation phase the funds are collected in the individual accounts the problem that appears, though, is what level of replacement income can an insured expect and how long will be the deccumulation phase. The questions persist, mainly because the computations based on average values, concerning the accumulation values in the individual accounts and the level of the annual pension that could be obtained, are not relevant. Concerning these aspects, there is a major difference between men and women because, considering that the incomes used as basis for the contribution to the pension system over the entire accumulation period are equal for both gender, the standard accumulation phase and life expectancy at retirement, are different. Thus, according to the law, the standard accumulation phase is 30 years for women and 35 years for men, fact that, evidently, has an influence on the funds collected over the accumulation phase. Starting from the normal retirement age, i.e. 60 for women and 65 years for men, as far as life expectancy at retirement is concerned, the difference is even bigger, of 13 years for women (from 60 to 73) and of about 2 years for men (from 65 to 67). These figures will have a strong impact on the length of the deccumulation phase and, implicitly, on the level of pension that can be obtained. For these reasons, in the present paper, we proceeded to different computations for men and women.

a. Possible scenarios. Second pillar. The mandatory private component.

Working premises

In order to compute the insurance fund obtained in the accumulation phase (Fa) we used the compound interest formula:

$$S_n = S_0(1+i)^n \quad (1), \text{ where:}$$

- *So* is the annually invested sum in a pension fund. We used a monthly base of 300. For its calculation we began with a monthly base of 300 euros, the equivalent of the present average salary in the first year of privately administered funds. Starting with the second year, we considered an annual 5% increase of the salaries. To compute the contribution to the pension funds the lawful percentages were applied: 2% in the first year, and increasing the contribution for the following 8 years by 0,5 pp/year finally reaching 6%. Using this percentage the contribution for the entire period was computed. The resulted contribution is considered as a gross one being composed of a net contribution of 90% of the gross contribution invested for the contributor, and 10% is the added value meant to cover the administrator's costs.

-*Sn* is the annually invested sum at the pension fund together with the yearly fructification

i- is the level of compound interest during To simplify the computation we considered the i factor as unchanged (4%). This value is realistic given that the low and medium risk financial instruments the fund legally invests in. **-**n is the number of years for each contribution

The total sum obtained on the basis of annual contributions being fructified is given by the net yearly added contributions together with the fructification:

$$F_{a=}\sum S_{nt} \qquad (2)$$

The result of or simulation is summarized bellow: Tabel 1

Scenario for men	**The age the contributor accedes to a fund**	**Contribution period**	**Fructifying factor**	**Resulted fund**
SC1	22 years	43 years	4%	50.346 EURO
SC2	35 years	30 years	4%	19.106 EURO
SC3	40 years	25 years	4%	12.477 EURO
SC4	45 years	20 years	4%	8.351 EURO

Tabel 2

Scenario for women	**The age the contributor accedes to a fund**	**Contribution period**	**Fructifying factor**	**Resulted fund**
SC1	22 years	38 years	4%	35.297 EURO
SC2	35 years	25 years	4%	12.477 EURO
SC3	40 years	20 years	4%	8.351 EURO
SC4	45 years	15 years	4%	4.371 EURO

It can be observed that for women a smaller value is accumulated at the end of the contribution period, all the other variables being unchanged.

The next issue is the computation of the possible pension computation, according to the accumulated funds at the time of contribution to the system considering the life expectation at the time of retirement E(X) different for men and women, i.e. 2 years for men and 13 for women. Considering that the rent $Pa=X_{1}$, is paid on an annual basis at the end of the period.. To determine the annual pension rents obtained in the deccumulation phase we used the actual value of serial equal payments[189]:

[189] Şeulean Victoria, *Protecţie şi asigurări sociale*, pag 148-149, Ed. Mirton, Timişoara, 2003.

$$S_{VA} = X_1 \cdot \sum_{t=1}^{n} \frac{1}{(1+i)^t} \qquad (3), \text{ where:}$$

X_1- is the value of the obtainable pension considering life expectancy for men and women, resulting:

$$X_1 = \frac{S_{VA}}{\sum_{t=1}^{n} \frac{1}{(1+i)^t}} \qquad (4), \text{ where:}$$

t- is the deccumulation period, i.e. the period the pension is received computed as a difference between the life expectancy and the standard retirement age;

i- is the actual factor during deccumulation. We maintained a constant 4% level.

The scenarios for the deccumulation phase are:

Men

Tabel 3

Scenario	**Contribution period**	**Resulted insurance fund**	**Fructifying factor**	**Yearly payable pension**
SC1	43 years	50.346 EURO	4%	26.923 EURO
SC2	30 years	19.106 EURO	4%	10.217 EURO
SC3	25 years	12.477 EURO	4%	6.672 EURO
SC4	20 years	8.351 EURO	4%	4.465 EURO

Women

Tabel 4

Scenario	**Contribution period**	**Resulted insurance fund**	**Fructifying factor**	**Yearly payable pension**
SC1	38 years	35.297 EURO	4%	3.533 EURO
SC2	25 years	12.477 EURO	4%	1.248 EURO
SC3	20 years	8.351 EURO	4%	835 EURO
SC4	15 years	4.371 EURO	4%	437 EURO

Obviously, the results are based on presumed determinants there evolution being subject to changes, and therefore our extrapolation is slightly different from real life situations. The computations can be detailed increasing time factor by one year or monthly but the conclusions are not significantly different. The contributor can also choose a different rent system than the one considered in our scenarios. Although, considering that data used for computation is realistic and according to the legislation at the moment of the study, we can draw several conclusions**.**

The first conclusion is that the difference between pensions obtained by men and women in the private pension schemes is significant. The reasons, briefly, are connected with the accumulation phase, shorter for women than for men and the difference between life expectancy (73 years for women and 67 years for men), given the fact that the principles of accumulation and deccumulation are the same.

The second conclusion is that if in the public pension system, based on the redistribution of funds between the generations the positive discriminations for women because of the earlier retirement with 5 years will not affect the replacement income, in the case of private pensions, each participant, man or woman, can expect a pensions that depends only on the contribution to the pension scheme and on the contributing period. In case that, at retirement, the insured opts for a yearly rent, its amount will also depend on the life expectancy of the insured at the retirement.

The third conclusion, which is in fact a corollary of the previous two, is that, considering the actual data regarding the eligibility requirements of the retirees in the public pension system ant the life expectancy at retirement, higher for women than for men, we can expect that in the future there will be an equalization of conditions for the contribution stage and the normal retirement age for the two categories of beneficiaries. Such a decision would be the first premise towards equalization of the replacement incomes obtained in the private pension system. Considering this, it is not surprising the fact that many countries, developed or developing, proceeded to modification and equalization of the normal retirement ages and of the contribution stage for women and men.

b. The third pillar. The optional private component.

Starting with the functioning principles of this component that have been presented above, we chose the following scenario:

The annual contribution to the system : 300 euros, equal for women and men; accumulation stage : 10 years, 15 years, 20 years, 25 years, 30years and 35 years , both for women and men; the actualizing factor is 4% , constant all the stage; the deccumulation stage, respectively life expectancy at retirement is 7 years for men and, respectively 11 years for women, closer to that in the EU countries. For computation of the pension fund obtained in the accumulation stage (Fa) we used the formula of equal payments series in future values:

$$S_{vv} = (1+i)^n \cdot X_2 \cdot \sum_{t=1}^{n} \frac{1}{(1+i)^t} \quad (5), \text{ where:}$$

Svv – accumulated pension fund; X_2- the value of the contribution to the system in the accumulation stage, considered as one single payment made at the beginning of the period; *t*- the accumulation stage, in years; *i*- the actualizing factor in the accumulation stage.

For determining the value of the annual rents that will be obtained in the deccumulation phase we used the formula of actual values of equal payments series, explicitated above.

In these circumstances, the resulted scenario will have the following configuration:

Accumulated pension fund for men and women Table 5

Scenario	**Accumulation period**	**Actualization factor**	**Accumulated pension fund**
SC1	t= 10 years	4%	Fa_1= 3.603 EURO
SC2	t= 15 years	4%	Fa_2= 6.006 EURO
SC3	t= 20 years	4%	Fa_3= 8.934 EURO
SC4	t= 25 years	4%	Fa_4= 12.495 EURO
SC5	t= 30 years	4%	Fa_5= 16.824 EURO
SC6	t= 35 years	4%	Fa_7= 20.001 EURO

Annual pension –Pa- obtained in the deccumulation phase Tabel 6

Scenario	**Men**		**Women**	
	Pension payment period	**Annual pension - Pa**	**Pension payment period**	**Annual pension - Pa**
SC1	E(x)= 7 yrs	Pa_1= 577 EURO	E(X)= 11 yrs	Pa_1= 369 EURO
SC2	E(x)= 7 yrs	Pa_2= 962 EURO	E(X)= 11 yrs	Pa_2= 616 EURO
SC3	E(x)= 7	Pa_3= 1.431EURO	E(X)= 11	Pa_3= 916 EURO

	yrs		yrs	
SC4	E(x)= 7 yrs	Pa_4= 2.002 EURO	E(X)= 11 yrs	Pa_4= 1.281 EURO
SC5	E(x)= 7 yrs	Pa_5= 2.696 EURO	E(X)= 11 yrs	Pa_5= 1.725 EURO
SC6	E(x)= 7 yrs	Pa_6= 3.205 EURO	E(X)= 11 yrs	Pa_6= 2.051 EURO

We can observe that, considering equal eligibility conditions in the private pension schemes, for women and men, the difference in the replacement income decreases, the only factor responsible for the difference between the two categories of beneficiaries remaining the life expectancy at retirement of 11 years for women and 7 years for men.

The calculations performed in the study, regarding the value of the accumulated funds and, based on them, the value of the pension rents obtainable, start with a monthly income equivalent to the average income. Serious problems will occur in case of participants with the income equal to the minimum income or, in any case, lower than the average income. In case of lower contributions the accumulations and rents in the private pensions system will be lower. Also, their low income will not allow, most of them, to contribute to the third pillar of the pension system. For this category of participants the support from the government will be probably necessary in the future.

Based on the scenarios sketched in the paper, there have been solved, at least at a regulatory level, a series of problems concerning the functioning of the second and third pillar of the pension system, as viable alternatives to the public pension. Among them, we can mention: 1. express authorization of the universal funds managers, that should be able to provide solid financial situation indicators; 2. the surveillance of investments made by the universal pension funds and limitation of these investments to financial instruments with low and medium risk; 3. separate management of universal funds actives by those managers that also administer other funds.

The insurance market represents a significant part of the economic development. The Romanian market, even it is an emergent one, have tried, for the last 10 years, to improve the expectations regarding the main indicators of welfare: gross written premiums for both mandatory, but especially facultative insurance policies, total assets, equity, the number of insurance brokers and agents. The progress can be viewed with eyes wide opened, but we address the question whether this trend is sufficient the decrease the gap between the Romanian market and the most important insurance ones from European Union. To achieve this goal, we summarize some correlations between Romanian and Polish market, and the results are promising.

Key words: Insurance, Pearson correlation, gross written premiums, equity.

1. The most important goals of the study

This study consists in a comparison between the Romanian and Polish insurance markets, for the period 2003-2005. The main goal of this study is to define if there are signs of improvement in the Romanian P&L insurance market by a detailed comparative analysis of a developed insurance market, the Polish one.

Even this seems to be inappropriate (in fact, there are more advanced insurance markets) the first step should be an intermediate level. However, this Polish market is enough for the moment. For example, gross written premiums in 2004 were 13602665 polish zlots (4 billions euros) for Poland and 26,975,746,721 lei (745,000 millions euros) for Romania. This is the starting point for the analyses and should be kept in mind for the following ideas, conclusions that can be drawn up as a result of our comparison.

2. The input data and the methodology of the study

The input data were provided by the Insurance Supervision Commission (ISC) yearly reports and Insurance and Pension Funds Supervisory Commission (KNUIFE), which were improved from one period to another, with more and more information. The analysis was made for P&L insurance market[190].

This study is based both on indicators provided directly by ISC and KNUIFE and on determined values of various elements, obtained from these insurance authorities reports, such as: equity, gross written premiums, gross paid claims and number of authorized insurance classes.

For both computational databases we eliminated those insurance companies with irrelevant activities (not diminishing gross written premiums, but ceasing activities, withdrawing authorisation, etc) and lack of technical information for the entire three years analysed period. From this point of view, the next insurance companies were eliminated: IF TU S.A. (liquidation), TUwRiGŻ Agropolisa S.A. (the lack of activity in 2004), FIAT Ubezpieczenia Majątkowe S.A. (the lack of activity in 2004), and HDI Asekuracja TU S.A. (the lack of activity in 2003)[191].

In the mean time, we excluded the main branches operating on Polish insurance market (Elvia Travel Insurance Company, COFACE AG, and Cardif-Assurances Risques Divers S.A.); due to insufficient

[190] This polish market is known as: Zakłady pozostałych ubezpieczeń osobowych i ubezpieczeń majątkowych.
[191] We presumed the Romanian insurance market to be a well-known one.

information on our market or the fact they are concluding business by new established insurance companies.

The Pearson correlation coefficients matrix was used as the statistical support of the dynamic analysis.

3. Empirical results

The following two tables illustrate the results, more specific, the values of the correlation coefficients for the P&L insurance classes, for the period 2003-2005.

Table no.1

Correlation coefficients between the financial variables for Romanian P&L insurance classes

YEAR	2005	2004	2003
Number of classes / Gross written premiums	0.8295	0.5954	0.8046
Number of classes / Equity	0.5444	0.343	0.5529
Number of classes / Gross paid claims	0.5862	0.503	0.571
Equity/ Gross written premiums	0.544	0.475	0.659

Table no. 2

Correlation coefficients between the financial variables for Polish P&L insurance classes

ANUL	2005	2004	2003
Number of classes / Gross written premiums	0.2524	0.2533	0.2481
Number of classes / Equity	0.4459	0.4652	0.3950
Number of classes / Gross paid claims	0.2459	0.2435	0.2307
Equity / Gross written premiums	0.1645	0.1733	0.2048

A more general conclusion from the comparative analysis between the two insurance markets is that The Polish market seems to be more stable than the Romanian one. The Pearson coefficients for the Polish insurance market had no significant changes during this period of time, but for Romania, with an emergent economy and an insurance market insufficient developed, the variation from one year to another are much more significant.

The second important conclusion is that the values for the Pearson coefficients are grater for the Romanian market, compared with the Polish one. This means a higher degree of dependency between all these variables, as a final remark of our particular insurance market. Even the lack of strong competition can be seen for many insurance classes, the higher the number of classes for an insurer, the bigger the turnover. After this short dissemination, it is the moment of a more detailed analysis.

Furthermore, it was performed a more specific analysis for this financial variables, for both countries.

The financial analysis for the period 2003-2005 revealed the following conclusions:

A. Correlation between the number of classes and the gross written premiums

For the Romanian insurance market, a strong correlation could be observed between these two variables, maybe too strong for an emergent market, as the Romanian one. Another argument for the emergent quality of the Romanian insurance market is the statistics revealing that only 4% of the whole number of buildings is insured. So, we could presume that this is acceptable for one insurance class, it will have some important clients and the effects in earned premium will pay off. The correlation could be much stronger if the Romanian insurance market had harsh competition[192]. A total different conclusion could be stated for the Polish insurance market. The values for the correlation coefficients are modest, around 24%, which emphasised a weak but positive relationship between these two financial variables. A grater number of classes, in Poland, do not have, as a direct consequence, a grater and significant level for revenues, such as gross written premiums. This is an expression for a more stable insurance market, with an intensive competition between underwriting companies.

It can be also stated that even the increasing competition won't be able to "squeeze" the coefficient. In fact, many foreign insurers have concluded mergers and acquisitions with or of Romanian insurance companies, but the market share for the P&L insurance market still remains the same. Indeed, some of them are hard to dethrone and their position is quite outstanding, but the hope is the last to die. If we want a certainty, we should demand the date when the strongest Romanian insurance companies shall collapse. The answer is difficult to predict, but we believe the answer to be "never". One way or another, the Romanian coefficient is at a high level, mainly due to the relative insufficient strength of the most important companies.

They aren't able to absorb the demand for insurance products, so they leave an important piece of the "cake" for the smaller ones. We intend to believe this reality to be a positive one, the concentration of a market being a point of start for a future duopoly or monopoly for a specified class of insurance.

Additionally, it can be easily concluded that this kind of markets tend to increase the insurance price due to the limited possibilities of an insured person. We have had, a few years ago, this kind of problem with the Romanian market, when many insurance companies developed a concerted practice regarding the price of green card[193], a type of insurance that is, nowadays, comprised in third party motor liability insurance.

From another point of view, this is considered to be the sign of a competition market, but what can we expect to happen the moment these less important insurance companies face the truth of bankruptcy? How this liaison can be possible? It's very simple. These companies are interesting from the insured point of view, because they often charge less than a powerful company. Yes, but what will happen with the claims, if the company has insufficient funds to pay the damages. Indeed, this is going to be a delicate phase of a company business cycle.

Despite this fact, everybody is considering lucky to have a "piece" of the Romanian market, to be recognised by the clients, till the moment they deal with his claim management problems, which they always pretend to be temporary.

B. Correlation between the number of classes and equity

The result was not very surprising because it is the result of the continuing efforts for the Romanian Insurance Supervision to increase the level of equity. This trend was much obvious in the year 2004, when the number of classes decreased from 8 to 5 and the medium level for equity raised from 22.43 million to 33 million Ron. However, it is not a reflex response to increase the equity when the number of insurance classes increased. Some Romanian insurance companies (e.g. Nationala), had 4 classes with an issued capital of 25 billions ROL, and, on the other hand, other companies (e.g. Petroas) had 15 billions ROL equity for 7 classes.

A weaker, but also positive correlation could be observed for the Polish case, due to different regulations and, again the same conclusion, a more stable insurance market: from 32 companies, analysed in the period 2003-2005, only one of them changed the number of insurance classes. Comparing to the previous correlation coefficients, it seems that the two countries are more similar.

C. Correlation between the number of classes and gross paid claims

For Romanian insurance market, the correlation coefficient revealed a strong link, as the result is, somehow, reasonable since the level of gross paid claims increased every time when ISC approved new insurance classes. The analysis must be performed for a minimum of 10 years together with the correlation between the number of classes and the financial result, since both theory and practice proved that the risk will be diminished and the portfolio will be diversified through the number of insurance classes.

[192] Dragota, Mihaela, Serbanescu, Cosmin, Pele, Dan, Traian, *Portfolio Diversification and Market Share Analysis for Romanian Insurance Companies*, publicata in volumul intitulat Risk Management and Value. Valuation and Asset Pricing, publicata in volumul 3 al Revistei *World Scientific Studies in International Economics*, 2008.

[193] The third party motor liability insurance for the foreign territory.

For the Polish insurance market, the correlation is positive, but weaker than for the Romanian P&L insurance one, which revealed that the grater level of claims is not significantly determined by the number of underwriting classes. The database showed a variation for the number of classes between 1 and 18, with an approximately average value of 14 classes and a median value of 17 and a standard deviation around 5. By the contrary, for the gross paid claims, the gap between minimum value and the maximum one are much more greater, from 1532 zlots to 4297311 zlots (for the year 2005), with an average value of 259966 zlots and a median value of 36151 zlots. The level for standard deviation was, for the same year 2005, around 775.600 zlots.

These values bring to light an insignificant change in the number of classes from the year 2003 to the year 2005, concomitant with major variation in gross paid claims. These data explained the unimportant role of number of classes on the changes in gross paid claims.

For the first two years of our analyses it can be concluded that the Romanian markets finds itself still at the beginning, because those values (0.503 and 0.571) explain a stronger correlation between gross paid claims and number of classes. Or, this is the proof for an emergent market, still searching for its ideal path. Otherwise, it is difficult, even impossible, to describe the pattern or this stronger correlation. In fact it shows that the greater the number of classes, the higher the amount of claims to be paid. The first cause is explained by the expansion of business and the increment of gross written premiums and consequently of indemnities. But, there is a second thought that this result was brought, has appeared due to bad management policies. Since there is no evidence of management distress for the chosen companies, we may conclude the first item to be the explanation for the mathematical conclusion.

As a comparison, the Polish market seems to be less inflexible, the coefficients ranging around 0.24. As an example, it can be found that PZU S.A., the biggest insurance company, with a share in non-life branch premiums of 60.55% has reached the highest level of claims paid: 4,443,207 polish zlots (approximately 1,315,000 euro), TUiR WARTA S.A. (market share – 13.32%) reported 900,000 polish zlots (approximately 266,000 euro) and STU Ergo Hestia S.A., the third polish insurer of the P&L insurance market (market share – 6.61%) an amount of 615,000 polish zlots (approximately 182,000 euro). Meanwhile, AIG Polska TU S.A., with a market share of only 0.24%, had chosen to practice all 18 classes and the result for the gross paid claims was 18,301 polish zlots (approximately 5,400 euro). The goal of this example cannot be fulfilled without an insurer with few classes, but relevant claim ratio: TU PZM S.A. 72.02%.

D. Correlation between equity and gross written premiums

The correlation is positive, but weaker, from the year 2003 to the year 2005 for the Polish insurance market.

The result is normal because the level of equity, it is not a guarantee for an appropriate level of the gross written premiums. If the specific regulation established by the Insurance Supervision Commission (ISC) is taken into consideration to increase the level of equity, the result could be easily understood. This indicator provided a greater stability, the image of a stable company, but some significant events could generate, even for these important insurers, a non-suitable level of gross written premiums.

The results for the Polish market revealed a weak correlation, mainly because of heterogeneity of these two variables. In practice it can be demonstrate a pattern for the equity level, depending on gross written premiums, the results for the Romanian market expressing rather the need to capitalize the insurance companies in order to achieve the legal framework, then the willingness to over capitalize the company.

4. Conclusions

The Romanian insurance market has more steps to achieve, in order to compete with the solid western markets, the existing gap between the countries analysed above being a living proof.

Even the foreign insurers have “invaded” our market, the poverty of many social categories represents a hand brake for the expected development, but for sure it will be easier with well capitalised insurers, much more classes and growing premiums.

The competition should not be hold guilty for the progress of the Romanian market. The Polish market proved to be highly developed, compared to the indigene one, even if the first three insurance companies had a market share of more than 80%. Mean while it can be stressed out that the Polish market has only 32 P&L insurance companies. As a final conclusion, the Romanian insurance market is able to improve its performances by a qualitative management, the number of foreign insurers penetrating our market being of real help, due to their experience on developed markets.

THE COMPUTATION OF SOME PRIVATE PENSIONS

Tănăsescu Paul

A.S.E. Bucureşti, CSIE, Str.Mihail Moxa nr. 5-7, mirceaiulian91@yahoo.com, Tel.0724.02.10.38

Abstract: The aim of this study is the development of few models for the private pensions such as retirement pension, disability pension and the widow pension. We also provide a numerical application of the elaborated models.

Key words: Single net premium, computational functions, private pension, lifetime rent, disability pension, widow pension.

There are multiple problems regarding the pension systems. Due to the difficulties existing on the social pensions system, new products have erected products that assure incomes equal to insured wages for disability occurrence (approximately 90%) and an income correlated to the contributions and performances reached by the private pension fund administrator, for full time retirement.

A few months ago, the mandatory private pension system (the so-called second pillar) was implemented. For the excepted persons of the second pillar and for those who desire another pension, the third pillar (the facultative one) is also an alternative. Contributors to a facultative pension system should realize incomes and pay contributions to the social public system. Of course, depending on the envisaged pension, there are some requirements to fulfill, such as the age of 52 years and 6 months (at the maximum) and the payment of 90 monthly contributions, if the goal is a lifetime pension, starting the age of 60, which represents the legal retirement one.

As for the facultative private pensions, the contributions are also added to the participant's personal account. If he dies before he reached the legal retirement age, the cumulated amount shall be transferred to his legal heirs' account. The contribution flexibility is also an advantage for the facultative private pensions, the insured person having the opportunity to raise the contribution (up to 15% of the taxable income) or to cease the payment of contributions the moment he does not realize incomes, but with the possibility to restart the contribution, once he will obtain them again. There is also an advantage the fact that the legal framework for private pensions is stable and the field of activity under continuous supervision.

The pension prediction still remains a complicate issue. Obviously, it can be an answer such as "the pension depends on contributions". But this is totally vague and the hard work is switched to later computation (the moment all the data are known). There are a lot of variables to evaluate: commissions, taxes, penalties, investments and accompanying risks, transfer possibilities, payments of pensions. However, it can be obtained a perspective on cumulated amount from contributions by comparison to life insurances with accumulation paid as lifetime rents. We should also mention that the private pension represent a way of saving money for old age, meanwhile a life insurance with capital accumulation is mainly o protection product (mixed insurance) and secondly a saving opportunity. As a consequence, a pension plan means contracting annuities or postponed lifetime fractionalises or certain benefits according to the contributions on the active life.

The most simple mathematic method for full time pension is the one that enables the insured person, x years old, to pay for the following r years, m times a year, a net premium P, in order to obtain from the insurer, over n years $(r \le n)$, a k times a year a pension S till t years. We note $a_x^{(b,c)}(\alpha:\beta)$ the actual medium value of a series of fractionalises (which represent an annually monetary unit) made for the period $[\alpha,\beta]$, where b indicates the anticipated or posticipated payment (A, P) and c the annual fraction.

As a result we obtain the equation: $m \cdot P \cdot a_x^{(b,m)}(:r) = k \cdot S \cdot a_x^{(d,k)}(n:t)$, where $b,d \in \{A,P\}$.

For the disability insurance, we shall consider three possible states: the „a" state means active (apt or valid) for a named job, the „i" means disable for every job and the „d" state (deceased). We presume the decease as the only way to eliminate the "i" state. We note with : l_x^i the number of living individuals in "i" state, at age x; l_x^a the number of living individuals in "a" state; l_x^{ai} the number of living individuals changing the „*a*" state in „*i*" state at age $y \in (a, x)$ and remaining in this state until the age of x; $p^{ii}(y, x)$ the probability that the individual in state "i", at age y will be in the same state at the age x; $p^{ai}(y, x)$ the probability that the individual in state "d" at age y will pass and remain in state "i" until age x. We note with l_x^i the surviving function for disabled persons and with q_x^i the decease annual rate. We will use the commutation functions (numbers):

$$D_x^i = l_x^i \cdot v^x,\ N_x^i = \sum_{y=x}^{\omega} D_y^i,\ C_x^i = \left(l_x^i - l_{x+1}^i\right) \cdot v^{x+\frac{1}{2}},\ M_x^i = \sum_{y=x}^{\omega} C_y^i .$$

For an "n" years survival insurance for a disabled person *x* years old, the single net premium for an insured amount of one u.m. is: $E_{x,n}^i = p^{ii}\left(x, x+n\right) \cdot v^n = \frac{l_{x+n}^i}{l_x^i} \cdot v^n = \frac{D_{x+n}^i}{D_x^i}$.

For one u.m. rent, postponed *r* years and limited to *n* years, paid annually and anticipated to a disabled person of *x* years old for the time he is alive, the single net premium is: $a_x^{i,(A)}\left(r:n\right) = \frac{N_{x+r}^i - N_{x+n}^i}{D_x^i}$. For the anticipated life annuity, arithmetical progression of rate 1 *u.m.* and first term 1 u.m., postponed *r* years and limited to *n* years, the single net premium is:

$$Ia_x^{i,(A)}\left(r:n\right) = \frac{S_{x+r}^i - S_{x+n}^i - \left(n-r\right) \cdot N_{x+n}^i}{D_x^i}$$

We shall determine now the single net premium paid by an active individual, *x* years old, for an insurance that offers him as soon he is getting disable, an annually anticipated life rent, with the annuities of 1 u.m., immediately and unlimited, but only in case the event occur between *x* + *r* and *x* + *n* years. We shall note this premium to $a_x^{ai,(A)}\left(r:n\right)$. Later, we shall obtain the single net premium paid by the *x* years old active person, in order to receive, immediately and unlimited, an annually anticipated life rent, but only in case the disability occur between *x* + *k* and *x* + *k* + 1 years. We shall note this premium $E_{x,k}^{ai}$. Presuming the disability cases uniform distributed through the year, we may conclude the moment an active person become disable to be the middle of the year. In this case, the value for the disability pension at that moment is $a_{x+k+\frac{1}{2}}^{i,(A)}$. We have: $E_{x,k}^{ai} = \frac{l^{ai}\left(x+k, x+k+1\right)}{l_x^{aa}} \cdot \frac{v^{x+k+\frac{1}{2}}}{v^x} \cdot a_{x+k+\frac{1}{2}}^{i,(A)}$.

Introducing the commutation functions: $D_x^{aa} = l_x^{aa} \cdot v^x$, $N_x^{aa} = \sum_{y=x}^{\omega} D_y^{aa}$, $S_x^{aa} = \sum_{y=x}^{\omega} N_y^{aa}$, $D_x^{ai} = l^{ai}\left(x, x+1\right) \cdot a_{x+\frac{1}{2}}^{i,(A)} \cdot v^{x+\frac{1}{2}}$, $N_x^{ai} = \sum_{y=x}^{\omega} D_y^{ai}$ and $S_x^{ai} = \sum_{y=x}^{\omega} N_y^{ai}$ we obtain: $E_{x,k}^{ai} = \frac{D_{x+k}^{ai}}{D_x^{aa}}$ and $a_x^{ai,(A)}\left(r:n\right) = \frac{N_{x+r}^{ai} - N_{x+n}^{ai}}{D_x^{aa}}$.

Let's consider the insurance by which a valid person, x years old, is going to receive between *x* + *r* and *x* + *n* years, as long as he is an active person, a life time anticipated annuity of 1 u.m. Noting with $a_x^{aa,(A)}\left(r:n\right)$ the single net premium for this insurance, we have:

$$a_x^{aa,(A)}\left(r:n\right) = \sum_{k=r}^{n-1} \frac{l_{x+k}^{aa}}{l_x^{aa}} \cdot v^k = \sum_{k=r}^{n-1} \frac{D_{x+k}^{aa}}{D_x^{aa}} = \frac{N_{x+r}^{aa} - N_{x+n}^{aa}}{D_x^{aa}}$$

Generally speaking, for the disability insurance we introduce a lack term and the progressive variation of the life time rent in consideration with the number of contributing years. We shall forward consider the case when the rent increases unlimited, in an arithmetical progression. This means that for a lack term of k years, the active insured person, x years old, recently contractor of this insurance, in case of disability between $x + k + 1, x + k + 2, \ldots$ shall receive a disability pension in arithmetical progression of step β and first termα.

We presume that the insured contracted the insurance *t* years ago. We note the medium actual value for this insurance with $AIN_{x,k,t}$, for *t* = 0, this being similar to the single net premium for the insurance.

1. In case $0 \le t \le k$, we have:

$$AIN_{x,k,t} = \sum_{j=0}^{\omega-x-k+t-1} (\alpha + j \cdot \beta) \cdot E_{x,k-t+j}^{ai} = \frac{\alpha \cdot N_{x+k-t}^{ai} + \beta \cdot S_{x+k-t+1}^{ai}}{D_x^{aa}}$$

The net single premium for the insurance is: $AIN_{x,k} = \dfrac{\alpha \cdot N_{x+k}^{ai} + \beta \cdot S_{x+k+1}^{ai}}{D_x^{aa}}$.

2. In case $t > k$, we have:

$$AIN_{x,k,t} = \sum_{j=0}^{\omega-x-1} \left[\alpha + (t-k)\cdot\beta + j\cdot\beta\right] \cdot E_{x,j}^{ai} = \left[\alpha + (t-k)\cdot\beta\right] \cdot \frac{N_x^{ai}}{D_x^{aa}} + \beta \cdot \frac{S_{x+1}^{ai}}{D_x^{aa}}$$

We consider now that the growth of the rent is limited to a specified number of years, and then this is set constant to the attained level. In this case, the new insured person shall receive after the lack period of k years in case of disability, a pension with the following anticipated annual values: α, $\alpha + \beta$, $\alpha + 2 \cdot \beta$, ..., $\alpha + n \cdot \beta$, ...

We use the medium actual value with $AIL_{x,k,n,t}$.

1. In case $0 \le t \le k$, we have:

$$AIL_{x,k,n,t} = \alpha \cdot \frac{N_{x+k-t}^{ai}}{D_x^{aa}} + \beta \cdot \frac{S_{x+k-t+1}^{ai} - S_{x+k-t+n+1}^{ai}}{D_x^{aa}}.$$

The single net premium is: $AIL_{x,k,n} = \dfrac{\alpha \cdot N_{x+k}^{ai} + \beta \cdot \left(S_{x+k+1}^{ai} - S_{x+k+n+1}^{ai}\right)}{D_x^{aa}}$.

The moment the insurance and the lack term are the same, $t = k$, we have: $AIL_{x,k,n} = \dfrac{\alpha \cdot N_x^{ai} + \beta \cdot \left(S_{x+1}^{ai} - S_{x+n+1}^{ai}\right)}{D_x^{aa}}$.

2. In case $k < t \le k + n$, we have:

$$AIL_{x,k,n,t} = \frac{\alpha \cdot N_x^{ai} + \beta \cdot \left[S_{x+1}^{ai} - S_{x+k+n-t+1}^{ai} + (t-k) \cdot N_x^{ai}\right]}{D_x^{aa}}.$$

3. In case $t > k + n$, we have:

$$AIL_{x,k,n,t} = \sum_{j=0}^{\omega-x-1} (\alpha + n \cdot \beta) \cdot E_{x,j}^{ai} = (\alpha + n \cdot \beta) \cdot \frac{N_x^{ai}}{D_x^{aa}}.$$

For the widow pension, we note a_y^w the medium actual value of an annuity paid to a widow, y years old and $L_{\frac{x}{y}}$ the number of married men, x years old married to wives, y years old and L_x the number of individuals, x years old. Consequently, it results that the medium actual obligation of an insurer, due to the active person's decease, x years old, is: $W_x = \dfrac{\sum_y L_{\frac{x}{y}} \cdot a_y^w}{L_x}$.

If I_x is the number of active person, becoming disabled between x and $x + 1$ years old, then we shall note a_x^{iw} to be the medium actual obligation of an insurer to provide a pension for the disable's widow (the deceased was x years old). Considering the deceases to be uniformly distributed during the year, we shall obtain: $a_x^{iw} = \sum_{k=0}^{\omega-x} \dfrac{d_{x+k}^i}{l_x^i} \cdot v^{k+\frac{1}{2}} \cdot W_{x+k+\frac{1}{2}}$.

Making use of the commutation functions: $D_x^{iw} = d_x^i \cdot v^{x+\frac{1}{2}} \cdot W_{x+\frac{1}{2}}$ and $N_x^{iw} = \sum_{k=0}^{\omega-x} D_{x+k}^{iw}$, we have: $a_x^{iw} = \dfrac{N_x^{iw}}{D_x^i}$. Noting a_x^{aw} as actual medium value for the widow's insurance for an active person, x years old, we have:

$$a_x^{aw} = \sum_{k=0}^{\omega-x} \left(\frac{d_{x+k}^{aa}}{l_x^{aa}} \cdot v^{k+\frac{1}{2}} \cdot W_{x+k+\frac{1}{2}} + \frac{I_{x+k}}{l_x^{aa}} \cdot v^{k+\frac{1}{2}} \cdot a^{iw}_{x+k+\frac{1}{2}} \right).$$

Introducing the commutation numbers: $D_x^{aw} = v^{x+\frac{1}{2}} \cdot \left(d_x^{aa} \cdot W_{x+\frac{1}{2}} + I_{x+k} \cdot a^{iw}_{x+\frac{1}{2}} \right)$ and $N_x^{aw} = \sum_{k=0}^{\omega-x} D_{x+k}^{aw}$, we obtain: $a_x^{aw} = \dfrac{N_x^{aw}}{D_x^{aa}}$.

In order to illustrate the previous elaborated models, we shall present an example. We shall consider an active husband, 32 years old, concluding an insurance contract, as it follows:

a) if he becomes disable in 10 years, he will receive a disability pension equal to 40% of his wage, pension that will increase for every work year by 3% of the wage (in 30 years is equal to the wage);
b) Beginning 62 years old, he will receive a full time pension, equal to the wage;
c) If his wife dies, he will receive a pension equal to 50% of his wage, unless his working period was less than 10 years. For these rights he is paying an annually contribution, equal to a percent p of his wage, as long he is healthy till the age of 62. We shall determine the p percent of the insured's contributions considering his wage to be constant for the rest of his working life. We shall note with S the insured's wage and with x (x = 32 years) his age. The insurer's actual obligation is compound of:

– The actual value for the disability pension:

$$V_1 = \frac{0,4 \cdot S \cdot N_{42}^{ai} + 0,03 \cdot S \cdot \left(S_{43}^{ai} - S_{63}^{ai} \right)}{D_{32}^{aa}} = 0,74905 \cdot S.$$

If we cease the disability pension, once he will obtain the full time pension, then:

$$V_1 = \alpha \cdot \frac{N^{ai}_{x+k} - N^{ai}_{x+k+n}}{D^{aa}_x} + \beta \cdot \frac{S^{ai}_{x+k+1} - S^{ai}_{x+k+n} - (n-1) \cdot N^{ai}_{x+k+n}}{D^{aa}_x},$$

Where $\alpha = 0.4 \cdot S$, $\beta = 0.03 \cdot S$, $k = 10$ years the lack term and $n = 20$

We obtain:

$$V_1 = \frac{0,4 \cdot \left(N^{ai}_{42} - N^{ai}_{62}\right) + 0,03 \cdot \left(S^{ai}_{43} - S^{ai}_{62} - 19 \cdot N^{ai}_{62}\right)}{D^{aa}_{32}} \cdot S = 0.40746 \cdot S.$$

- The actual value for the full time pension: $V_2 = S \cdot \frac{N^{aa}_{62}}{D^{aa}_{32}} = 0{,}591715 \cdot S$ u.m.
- The actual value for the widow pension: $V_3 = 0,5 \cdot S \cdot \frac{N^{aw}_{42}}{D^{aa}_{32}} = 0{,}23013 \cdot S$.

The actual value for the insured's contribution is:

$$V = p \cdot S \cdot \frac{N^{aa}_{32} - N^{aa}_{62}}{D^{aa}_{32}} = 13{,}789864 \cdot p \cdot S \quad \text{u.m.}$$

So, in case of addition of full time pension and disability pension, we have:

$$p = \frac{V_1 + V_2 + V_3}{13,789864 \cdot S} = \frac{0,74905 + 0,591715 + 0,23013}{13,789864} = 0,114 = 11,4\%.$$

If the payment of disability pension is ceased, the moment the person receives full time pension, we shall have:

$$p = \frac{V_1 + V_2 + V_3}{13,789864 \cdot S} = \frac{0,40746 + 0,591715 + 0,23013}{13,789864} = 0,089 = 8,9\%$$

Obviously, the high percent of contribution is determined by the level of important requested benefits. In case of separate treatment of the two previous pensions, the contributions decrease at least two percent.

THE COMMON CONSOLIDATED CORPORATE TAX BASE – A NEW APPROACH IN THE CORPORATE TAX FIELD

Toma Elena

„Alexandru Ioan Cuza" University, Faculty of Economics and Business Administration, Iasi, telephone no.0744429256, e-mail: suman_elena@yahoo.com

Abstract: The Common Consolidated Corporate Tax Base, abridged „CCCTB", represents a new concept in the fiscal theory, which in the future will become a reality of fiscal practice in each EU's member states. The year 2007 represented a significant step in shaping the principles which will gouvern the CCCTB, as a result of the great meetings at the level of European Commission on the matter. We intend analyze the impact of the legislative initiative and also to describe, it's containt.

Key words: Common consolidated corporate tax base, fiscal competition, fiscal policy

1. Introduction

The problem of harmonising the Common Consolidated Corporate Tax Base, abridged „CCCTB", has been discussed within the framework of the European Commission, even since 2004. Though a better approach of this problem, when the stakes which concern the primar aspects to be harmonised in this area, occured in september 2007. Harmonising the common consolidated tax base remains a priority on the list of the Europeen Commission. Its foundation consists of the following motivations, at least.

2. Why the Common Consolidated Corporate Tax Base?

First of all, achieving a common consolidated corporate tax base represents a reaction of adapting the common legislation to the evolution of the globalization process. Extended in all the areas of the economic life, this process has no physical boundaries to stand in the way of the world wide expansion and development of the grand companies, and has marked the economy in the whole wide world.

As a second answer to the „Why the common consolidated corporate tax base?" question we find the basic idea of the European Union's construction through which they wished to find a unique economic frame, including common fiscal legislation. They also wish to create an attractive european economic space in order to place the foreign investments (where a harmonised legislation may constitute an advantage of localization).

In the third place a common consolidated corporate tax base would remove the world wide's groups trouble: the cost for managing the tax will remarkably diminish if we take into consideration the fact that now, a multinational group, which activates in all the member states, needs to work with 27 different systems of the corporate tax.

By comparison, in this case, the steps started early, even since 1977, when through the 77/388/CEE Directive, which concerns harmonising the indirect taxes such as VAT and of the excises duties at the European Union level, they proceeded to harmonise the VAT's tax base available for all the member states. The process of harmonising the VAT started to improve since 1 January 1993 along with the new created Unique Market.

The stated process has as foundation the fact that this tax represents, in the first place, the most important fiscal sourse as weight in GDP, in which the commom budget is being also formed. This process has also aimed to one of the four fundamental liberties such as the free circulation of merchendise and services, knowing that the VAT represents a fundamental element of this prices.

The things stand differently regarding the profit taxes of the economic agents which, now, stand on quite mobile and different principles. Until now, the fiscal politics in the domain have been orientated and limited to defining the general aspects in corporate tax' s domain and in adding rules regarding avoiding the double constraint. In conclusion we talk about 27 different techniques of the profit's constraint: each member state having its own system of taxing the economic agent's profit.

From the money politic's point of view, the member states sort of lost their sovereignty because they mostly took over this privilege from the European Central Bank. Concerning the fiscal political side, we can say that each Govern can establish its own objectives and fiscal strategies; this way, the fiscal politicy and especially the one in the direct taxes domain, became an operating device in creating teritorial attractivities for the potential investors, starting with 2004.

Througout the 10 new commers in 2004, the tendency manifests also in Romania's and Bulgary's case. Their governs juggled with the level of the part tax or with some fiscal facilities which aim the investments or the reinvestments of the profit, concerning the profit tax. The other member states were forced themselves to reduce the level of the corporate tax in order to keep the important investors already localised on their own teritory or the potential new investors. In this way, they reached a sort of fiscal competition between the states with unwanted effects (the example of the Nokia Company being the most relevant in this case).

We can conclude by analizing all this, that the European Commission's legislative proposition of harmonising the common consolidated corporate tax base has as motivation this phenomenon of „fiscal competition" along with the other three motifs mentioned before. There is no doubt that this legislative measure was considered important imediatly after the member states have diminished their corporate tax rates, in 2005 and 2006.

2.1. The analysis of the Corporate Tax Rates, beging whit 2005's

This fiscal competition, sometimes camouflaged, in the sense of lowering the tax rates, is not to blame because the new commers must fit into the catching-up process of the member states with high performance at the level of macroeconomic meter, such as: rythm of economic development, unemployment rate, general price meter, etc (this process was initially used by the new commers and after that by the other member states). This phenomenon of diminishing the interstates ecarte, reporting on the level of economic development, comes as a purpose itself for the creation of the European Union. This new created space aims to be an international economic power in competition with the other economic forces of the world.

Starting with 2005, we witness a general process of reducing the corporate tax rate.We can notice in the following table that a number of 17 countries have reduced their tax rates as it follows:

Table no. 1 : Corporate Tax Rates in Europeen Union 27

Country	2004(%)	2005(%)
Austria	*34*	*25*
Belgium	34	34
Danmark	*30*	*28*
Finland	*29*	*26*

Source: modified by „ KPMG's Corporate and Indirect Tax Rate Survey 2007", p. 5 -11, http://www.kpmg.com/Services/Tax/Business/IntCorp/CTr

In 2007, the average of the corporate rate taxes, which concerns the European Union, was 24.2 %, lower with 3,6 % than the registered average at OECD, with 3.8 % than the registered average at Latin America and with 5, 9 % lower than Asia-Pacific, according to a study of KPMG.

From chart number 1 we can observe a descendent trend regarding of the average corporate tax rates, but in 2005 we can notice a more sudden drop then in the other years, as a result of legislative measures taken by the 17 member states of the Union to reduce the corporate tax rate. The descendent trent has maintained in 2006 and 2007 as a consequence of the lowering of the corporate tax rates in the following states: Portugal has modified, starting with 2007, to 25 % the corporate tax rate, Spain has lowered to 32.5%, Czech Republic to 24%, Cyprus to 10%, Bulgaria to 10%, and Slovenia to 23%.

3. A short discussion about technical elements of the „CCCTB”

It was enforced a new way of thinking the profit constraint system because of all these many reasons, in elaborating a Common Consolidated Corporate Tax Base “CCCTB”, materialized in a working document which is to be found on the priority list of the European Commission, in the moment of speaking.

The history of this legislative first step begins in july 2004, when the European Commission elaborated the draft-document on the edge of this problem. This document was analyzed later on, within the framework of ECOFIN, in september 2004. Elaborating a common fiscal tax base, in taxing the profit of the companies, joined a common timetable of development in the area of the competition between the enterprises of the European Union. The efforts of the European Union in what concerns the common consolidated corporate tax base shaped in a new document named „The common consolidated corporate tax base: the draft of the technique background".

Throughout this document they accomplished to trace the corporate tax base as a sequel to the arguments of the European Commission’s experts with the collegiate and business environment.

Between the formative elements of the fiscal tax base of the corporate tax, the taxpayer draws our attention. Moreover, the companies which carry on their activities on the Union’s teritory will have the possibility to choose the common consolidated corporate tax system, wether if they are resident in a member state or if they have a permanent etablishment. Only the fiscal consolidated companies have the compulsoriness to use this new system, starting up 2010.[194] Talking about the fiscal consolidated companies, we have to underline the fact that the document defines them as a group in which over 75% of the suffrage are owned by the parend company. In the other cases in which the group is not being fiscaly consolidated, the option for common consolidated corporate tax base is being used by all the companies which are members of the group or by neither of them.

The option remains valid for at least five year. It also quietly renews itself for another three years if the tax payer hasn’t manifested his denial in writing. In order to make possible a continuity in applying the system corporate tax in case that the tax payer who already uses the stipulations of the tax base is being taken over by a company which hasn’t chosen this system, will continue to calculate the owed tax until the end of the 5 or 3 years period, respecting the stipulations of the common consolidated corporate tax base.

The document elaborated by the Commission stipulates the general rule of calculating the taxable profit and also gives a list of the main taxable or exempt income, deductible and non-deductible expenses. In detail, the taxable income represent all the acquired income of the society from all the sources: monetary or non-monetary, of exploitation, financial or exceptional. That leaves us with the exempt income and the investment income which diminishes the acquisition or the production price of the assets like dividends. The deductible expenses represent all the expenses made by the society in order to accomplish the activity object. On the list of non-deductible expenses we fiind the following: corporate tax expenses, penalties, expenses for the shareholders or/and the personnel, liquidating the fixed assets from the luxury goods category, entertainment and representation costs (only 50% of them being recognized).

Concerning the fiscal depreciation, are being considered fixed assets those which have a usage period bigger than a year and have an entrance value bigger than 1000 EUR. What looks different than the usual fiscal practice is the Commission’s wish to calculate the fiscal depreciation variously in categories of fixed assets (named pools) in case that all these are utilized on medium or short term, or individual fixed assets if they are utilized on long term. In case of the long term fixed assets we need to bookkeep them separatly in order to combine all the following rules: entrance value of minimum 5.000.000 EUR and usage period of minimum 25 years. The buildings will be depreciated with a rate of 2.5% per year, while the other long term fixed assets will be depreciated with a rate of 4%. We consider this change a favourable one, especially when it comes to the price of managing the corporate tax which will be reduced allong with the physical time affected by the depreciation’s calculation.

The income and the expenses’ will be registered after the bookkeeping of engagement principle and the bad debts provisions are totally educible by respecting some certain conditions. On the other hand, the fiscal losses will be recovered from the upcomming profits, in an unlimited time period, while the former profit recuperation is forbidden. The common consolidated corporate tax base would result from the sum of

[194] www.ec.europa.eu.int, in “Groupe de travail sur l` assiete commune consolidee pour l` impot sur les societes” (GT ACCIS), p.28

the individual profits obtained by each group's daughter-company with no concern for the member state which gave it (mentioning that it will be allot and taxed with the legal rate from that state).

It's also important to mention that the European Commission's legislative proposal aims to create a new fiscal tax base but not a unique rate tax; it also has been harmonised the base of VAT's of application without a unique rate, but qith a minimum threshold.

At the september 2007 debates they drew the most important rules of profit's apportionment. Moreover, the apportionment will took place by taking into consideration the next five key-elements: salaries, fixed capital values, sales level, incorporation criterion and the possible sector formula. It also came to an intermediate form of the profit's apportionment. This profit makes possible the three following key-elements: work factor (with two elements: salaries and number of employes), asset factor and sales factor.

The tax base of each taxable entity will be calculated with the following formula[195]:

$$CCCTB_A = \left(\frac{1}{3} \left(\frac{1}{2} \frac{PayRoll_A}{PayRoll_{Group}} + \frac{1}{2} \frac{NoEMP_A}{NoEMP_{Group}} \right) + \frac{1}{3} \frac{Assets_A}{Assets_{Group}} + \frac{1}{3} \frac{SalesT_A}{SalesT_{Group}} \right) \times C$$

Where: NoEMP = number of employees;

The impact of introducing the system will be major, especially when it comes to reducing the red tape (this one being an obstacle in the way of placing the foreign investments, though it creates an attarctive european economic space for the potential investors from out of Europe) which works with one specific law and remarkably reduces the administration tax price.

The idea of a unique common consolidated corporate tax base has the support of 78% of Union's experts (according to a 2006 boring made by the European Commission); the most fanatic advocates were the ones from Cehia, Denmark and Spain with a maximum percent of 100; in Italy the proposition was sustained by 96% of the questioned ones, while in Greece, Louxemburg, Polland, Slovenia and Sweden only 90% agreed. The least bit enthusiastic were those from Great Britain with only 62% in favour of changing the system, while in Ireland and Slovakia 50% opposed to the initiative of the European Commission.

In Romania the project was sustained by 90% of those questioned; the people noticed the positive impact over the red tape's reduction, a steel present disaster of the administrative romanian system[196].

4. The „ CCCTB" – Impediments and possible solutions

An obstacle in the way of functionality of the common consolidated corporate tax base consists of the inconsistently bookkeeper's system at the level of the member states, pointed out by the European Commission. At the moment, there are 27 accounting systems either of anglo-saxonic origins or french continental origins. The differences between the accounting systems of the member countries are related to the degree of independency between bookkeeping and fiscality. If in Great Britain the fiscal legislation does not „contaminate" the accountancy (which offers the investor a real information on the patrimony), in the other member states, the fiscality leaves it's mark on the accountancy, in different proportiones, it's purpose being to supply the information for the fiscal devices. Another alternative would be eliminating from the accountancy area the way of calculating the owed corporate tax . A possible solution is adoption of the International Financial Reporting Standards (IFRS) by the EU's member state. Anyhow, the European Commission has left the problem opened to discution, so that the member states can make propositions on the matter.

We add to this the eventual government's reticence to introduce in the national fiscal legislations the common foresight by subjective or objective motifs.

The making of an unique framework of corporate tax does not represent the solution in order to attract foreign investments, but only one of the factors which can contribute to the creation of the location advantages, along with the other factors such as: the existence of a well done infrastructure, fiscal and

---

[195] www.ec.europa.eu.int, in „Annexe au document CCCTB/WP/060, Synthèse des règles de répartition éventuelles", p. 1

[196] "Tibuna Economica" Review, no. 42/2007, p. 60

monetary stability, the lack of red tape. All these factors contribute to transform the state into an attractive teritory for the investors.

In Romania, such a legislativ project would be usefull taking into consideration the ascending rythm of developing the foreign investments, but it will incounter obstacles in the stated process, like in most of the states.

On the course of harmonising the fiscal legislation with the common legislation in the area, Romania has already made progress, now being in full process of introducing the IFRS. This way, the Fiscal Code has been elaborated taking into account the preadhasion's conditions which are to be found in „Assessment", chapter 10, also partially adopting a series of international standards. Partial encounters of the International Accounting Standards were included into the Order No. 94/2001 and No. 306/2001 of the Minister for Finance. These regulations belong to the romanian accountancy system and are mantained nowadays in the new Order No.1752/2005 Minister for Finance which canceled the regulations mentioned before.

The new order No. 1752/2005 has been written according to the european directives; all the judicial persons who develop their activity in Romania are obliged to submit this regulation. Moreover, starting with 2006, through the Order No. 907/2005 of the Minister for Finance, the credit institutions are obliged to make „a distinctive set of financial situations coresponding to the IFRS for their own necessities of informing the users, other than the state institution", meanwhile the public interest entities can chose the preparation of financial situations according to IFRS.

Starting with 2007 the companies listed are also obliged to draw up financial situations according to the IFRS. It's imposed to mention that through International Standards of Financial Reference we understand „International Standards of Financial Reference" (IFRS), International Accounting Standards (IAS) and afferent Interpretations (Interpretations SIC-IFRIC), the amendments that follow those standards and the relevant interpretations, the standards and the future afferent interpretations, just as they are approved by the European Union, translated and published in romanian."[197]

5. Conclusions

In conclusion the legislative initiative of the European Commission , once adopted and added to the national level represents another step closer in the direction of unrolling the unifying process which aims also the fiscal legislation area.

ENLARGEMENT OF THE EUROZONE – CHALLENGES AND PERSPECTIVES

Toma Ramona

Universitatea „Lucian Blaga" din Sibiu, Facultatea de Ştiinţe Economice, Sibiu, str. Calea Dumbrăvii nr. 17, E-mail: torasib@yahoo.com, Telefon: 0269/210375

Abstract: EU enlargement is not complete without the new member countries joining the eurozone. This paper makes an economic analysis of some theoretical and empirical aspects on which the success of the European Monetary Union enlargement will depend. Because the new EU member states are characterized by asymmetric shocks and low flexibility on the labor market, the new eurozone cannot be classified as an optimum currency area. Our study underlines the challenges of eurozone enlargement, considering that the monetary union can be undermine if the Eurosystem continues to apply the slow and incomplete reforms that are needed to revigorate the euro area economies.

Key words: eurozone, enlargement, challenges

The classical theory of **optimum currency areas** developed by Mundell (Mundell, R., 1961), McKinnon (McKinnon, R., 1963) and Kenen (Kenen, P., 1969) defines the optimum currency area as being a geographical region within which member states must use fixed rates of exchange on a single currency. Robert Mundell has identified a set of requirements that a country must meet in order to become part of an optimum currency area: symmetry of external shocks, mobility of the labor force, openness of the economy, the level of economic diversity. These criteria are still in use; for example, if a certain country is relatively open in terms of trade to another one or to a regional block, but its labor force mobility is insignificant, its economy is not very diversified and it has to face asymmetric shocks, a flexible rate of exchange is a good choice.

The explanation of the criteria of optimum currency area is that, generally, in an economy that has to face external shocks, real adjustment takes place if nominal rigidities are available. Thus, the only asymmetric shock would be the flexible rate of exchange. The shortage of capital mobility requires another method of adjustment. Even though Mundell has failed to unveil another benefit of the fixed exchange rate (lower transaction costs), he supposed that if adjustment costs are not very high (if the requirements of optimal currency area are met) the best choice is a fixed rate of exchange, which would stabilize the currency.

The criteria for optimum currency area are extremely important especially when a country is determined to peg its own currency to another one, defined as an anchor. In order to fight hyperinflation and constrain economic policy, the Argentine has chosen the currency board arrangement on the US dollar. Thus, the US dollar became a monetary anchor but, given the lack of a well-built fiscal policy and efficient institutions, this decision proved catastrophic. The result was deterioration of trade, increase in foreign debt, decrease in investments and slowdown in economic growth.

Recent specialized literature defines the concept of **impossible trinity** (the "Triangle of Impossibility"), namely the impossibility of having in the same time a fixed exchange rate, a free capital movement and an independent monetary policy (Frankel, J. A., 1999). Therefore, a flexible exchange rate, under greater free international capital mobility, enables the monetary authority to introduce an independent monetary policy. Nevertheless, if the monetary authority is not able to use the independence of the monetary policy appropriately the right choice is to give it up in order to import stability from other countries.

Most specialists have rightly concluded that European Union ***is not an optimum currency area***, because business cycles are not well synchronized, wage and price flexibility is low and fiscal transfers and labour migration is not welcome.

The enlargement of the European Monetary Union brings forth the costs and benefits it involves. We should find out the degree to which **"the new euro area"** will be an optimum monetary area. The traditional theory on the monetary area developed by Mundell (Mundell I) brings on a little skepticism. Because heterogeneity will increase in an enlarged euro area, the probability that asymmetric shocks should occur will increase as well. This is the reason why such enlargement is not recommended (De Grauwe, P., Schnabl. G., 2004).

There are still voices that recommend the adoption of the single currency after more than two years from the EU accession (De Grauwe, P., Lavrac, V., 1998). Their arguments are based on the fact that a country recently entered in the EU must cope with the competition existing on the single market and the challenges of the global capital markets. On the other hand, these countries are characterized by different levels of development, lower than those in the Union, and they have to obtain nominal and real convergence.

Nevertheless, three countries joined the euro area: Slovenia on January 1, 2007; Cyprus and Malta on January 1, 2008. It is no accident that the smaller countries are the first to join. For them the common currency is good protection against fickle financial markets. Their exposure to external trends is so much greater because of the relatively small size of the domestic economy.

The explanation should be found somewhere else the traditional framework of the optimum monetary area. As Mundell states in his work, in a world in which expectations are always changing, the fluctuations of the exchange rate do not work as stabilization tools used when facing asymmetric shocks. In this convention, called Mundell II, immediate entrance into the euro area could be the optimal solution.

The decision on the accession to the euro area depends on the assessment and perception of benefits and costs. The traditional theory of Mundell and McKinnon reveals three criteria that quantify the costs and benefits of participating in monetary union: asymmetry, flexibility, and openness (integration). Mundell does not recommend integration into a monetary union when a country faces strong asymmetric shocks and a lack of flexibility on the labor market. McKinnon introduces the openness degree, because eliminating the variability of the exchange rate reduces transaction costs and the volatility of internal prices.

While Denmark and Great Britain could negotiate in order to remain outside the eurozone, the new member countries have to accept the conditions stipulated in the Maastricht Treaty that is to prepare for the currency union and to adopt the single currency when they consider they are ready. On the other hand they meet the criteria of an optimum currency area to a lesser degree than the old EU members did. These countries are of small dimensions, have more or less developed trade relations with the EU and they expect benefits from the introduction of the euro.

De Grauwe and Melitz (2005) point out the fact that although the process of monetary integration in Europe has been regarded with skepticism, today's success of the euro brings new valences for a possible constitution of some monetary unions in other regions, too. Focusing on the enlargement of the eurozone, they draw attention to its effects on the labor market reforms, on the empirical validation of the hypotheses regarding the endogenous character of the criteria for the optimum currency area and the process of monetary integration of Central and Eastern European countries.

Dabrowski and Rostowski (2006) consider and argue that the EU enlargement is not complete without the new member countries joining the eurozone, the failure of the monetary integration of these countries creating a two gear Europe and determining a fundamental change in the EU political and economic architecture, sharpening the already existing differences between the center and the periphery.

Smidkova (2004) explains the Czech Republic government's cautious position regarding adoption of the euro. The expectation of a quite late euro adoption date is predominantly due to persistent large fiscal disequilibria and the priority assigned to strengthening real convergence before adopting the euro. Csajbók and Csermely (2002) analyses the economic benefits and costs of introducing the euro in Hungary considering that have a permanent impact on Hungarian economic growth through numerous channels. Of the five Maastricht criteria, those relating to inflation and the budget deficit will require the greatest efforts in terms of economic policy. Meeting these two criteria automatically entails convergence of long-term interest rates. Polanski (2004) analyzes different scenarios for euro adoption in Poland. He notes that while Poland has already made significant progress in some convergence criteria (inflation and interest rates), it is seriously lagging behind meeting the budget deficit criterion. The author also links nominal convergence with real convergence and concludes that further nominal convergence is increasingly subject to real convergence. In the Polish case, he sees no contradiction between the two.

The convergence criteria imposed on prospective members for joining the monetary union have to do with what have been called "nominal convergence". Low inflation and sustainable budgetary policies are desirable whether or not countries want to join a monetary union. The decisions of the ECB will systematically be felt by many member countries to be the wrong ones at the wrong time, leading to conflicts and tensions in the union.

Some euro-candidate countries will have higher inflation in the union because of the Balassa Samuelson effect. But there is nothing to be worried about. These countries will continue to have structurally higher inflation in the monetary union, without this creating problem of losses of competitiveness. Others may have lower inflation in the future, and yet be hit by an asymmetric development and a lack of flexibility that makes their membership very costly.

Countries that pass the budgetary convergence requirement have no guarantee at all that they will be successful members of the monetary union. But even if the budgetary numbers are a truthful they are irrelevant to predict if countries will experience more benefits than costs from their membership in the monetary union.

The eurozone enlargement will have extensive practical implications for the functioning of the eurozone. Asymmetric shocks will increase significantly: some countries may experience a boom and inflationary pressures while others experience deflationary forces. In this context, the ECB will not know whether to increase or to reduce the interest rates. As a result, member countries will often feel frustrated with the ECB policies that do not take into account the different economic conditions of the individual member countries. To minimize the potential risk of a future disintegration of the enlarged eurozone, an important measure that have to be taken should focus on making labour markets more flexible.

The strategy of the European Central Bank could represent a model, but this solution is not guaranteed because it was adopted considering the features of the euro area. The optimal monetary and exchange rate strategy for the transition period before joining the euro area should be selected according to the features of the country that aims at such an objective.

Abstract: The European East Emerging countries represent an interest research topic both in terms of macroeconomic environment and corporate finance decision. Their evolution within the process of nominal and real convergence process requires a challenging analysis of the way the main macroeconomic environment affects corporate segment. This analysis will focus in a first stage on the macroeconomic environment, highlighting out the way it evolved during the transition process from the centralized and planed economy to the market oriented one. Secondly, the focus will be oriented on the corporations based in these countries. Their finance decision will be analyzed in comparison with the corporations located into the emerging countries and moreover a deep interest will be granted to their leverage, especially from the point of view of the way finance mechanisms can be valorized based on their balance sheet data.

Key-words: rating, sovereign risk, idiosyncratic risk

JEL Classification Numbers: G21, G30, G33

Introduction

There are 50 emerging markets at the worldwide level. In order to get a deeper insight of the importance of these countries in the global economical architecture, a few statistics must be highlighted out: 1/5 of the global out put is produced by them, 4/5 of the total population lives in these countries and 8,5% of the stock market capitalization at the global level belongs to these countries. The BRIC countries (Brazil, Russia, India and China) will be the largest economies by 2050 and in 2007 their cumulated GDP represents 48% of the global GDP.

The strongest points that are always pointed out as for the emerging countries imply strong currency, budget surpluses and a high rate of local consumption. The lack of correlation between their financial systems and the largest capital markets enabled specialists to conceive them as an important element in case of financial crises since investors have the opportunity to direct the capital inflows towards them in order to get a higher protection. The negative aspects imply higher volatility, lack of transparency and liquidity. At the global level, there is a keen interest directed towards emerging countries because of the potential growth perspectives offered to the multinational companies and to the low labor cost. Outsourcing became one of the most important strategies developed by all world-wide level corporations.

East European emerging countries imply a different research effort in terms of macroeconomic analysis because of the specific features determined by the transition process to the market-oriented economy. Their strategic geographic position and their growth perspectives have been pointed out as two of the main advantages offered to the other developed European countries. Overall, their global market can be valued at more than 50 billion EUR which represents a huge opportunity for the companies of the developed countries in terms of products valorization.

Corporate segment is the most important growth resource for the East European emerging countries. It is appreciated as being the most important welfare mobile owing to the fact that it contributes in a fundamental way to keep up a decent living standard level. Thus it is important for the enterprises to have all the finance mechanisms opportunities in order to expand. But macroeconomic environment is a key factor in their case since it has been acknowledged that as for the emerging countries, the correlation between country and corporate rating is more substantial than in the case of the developed countries. The stability of the macroeconomic environment as well as the degree of economical growth, the inflation rate or the level of the capital market liquidity and transparency affect corporate segment. This paper is related to the work of Xianghong and Zhao who studied the impact of the macroeconomic environment on the corporate default, but also to the work of Revoltella, Haiss and Fink and of Berglof and Pajuste who highlighted out the particularities of the corporate governance systems within Central and Eastern Europe. Similar research efforts on this topic have been made by Cavallo and Valenzuella and also by Huang and Kong, Peter and Grandes, Borensztein who studied the relationship between corporate and sovereign spreads having as point of reference the corporate default premia limited to the case of publicly traded firms. This study is more closed to the work of Borensztein who underlined the specific aspects of the corporate finance within emerging markets, but we propose to be mode analytic in our research; we will concentrate on the micro-level approach, taking as point of reference the financial data corresponding to the enterprises located both into developed and East-European emerging countries.

The paper is structured as follows: section 2 is dedicated to the case-study which contains a deep analysis both in terms of descriptive statistics of the financial structure specific to companies located into East European emerging countries and also in terms of capital structure determinants. Last section is dedicated to the conclusions.

Section 2

This section focuses on the corporate finance decision within East emerging countries.

There will be tested 3 relationships between capital structure and various financial indicators reflecting liquidity, profitability and activity of the enterprise in order to highlight out potential specific features of the finance mechanisms characteristic to companies located into East European emerging countries.

2.1 Database and methodology description

The sources the information was obtained from were the following:

- Hewlett-Packard Credit Division containing information relative to the Financial Statements of various companies located both in emerging East European countries (Poland, Slovenia, Slovakia, Bulgary, Czech, Romania);
- Economic Intelligence Unit site regarding the macroeconomic environment of the emerging East European countries.

The assembley of financial indicators that will be analyzed is the following: Current Liquidity ratio (I_1), Quick Liquidity ratio (I_2), Short Term Debt Cash-Flow Coverage (I_3), Return on Tangible Net Worth (I_4), Earnings before Taxes/Total Assets (I_5), Operating Expenses/Net sales (I_6), Debt/Tangible Net Worth (I_7), Interest Coverage (I_8), Short Term Debt/Total Debt (I_9), Leverage multiplier (I_{10}), AR turnover (I_{11}), AP turnover (I_{12}), Working Capital Turnover (I_{13}), Total Assets Turnover (I_{14}), Altman Z-score (I_{15}).

The methodology that will be followed up is based on the analysis of the output regression built up by the OLS procedure.

The dependent variable will be represented by 2 financial indicators reflecting the capital structure of the company: leverage multiplier and the weight of the short term debt into the total debt. Leverage multiplier represented by the report between total assets and equity has been selected in order to get an insight into the self-financing policy of the enterprise. This variable is significant for the East European emerging countries because it reflects the internal finance resources. Indeed, in the context of capital market and banking system underdevelopment degree, internal finance resources are valorized to a high extent; moreover, since companies located into these countries are perceived as riskier, their internal finance resources are very important in order to get additional external resources.

The level of assets usually perceived as an indicator reflecting the size and the activity dynamic has been perceived lately by the finance resources providers as a covenant for the company and its importance becomes much higher in the case of the companies located into East European countries.

The independent variables which are considered to exert an influence on the capital structure and on the finance decision are Earnings before Taxes/Total Assets (I_5), Operating Expenses/Net sales (I_6), Debt/Tangible Net Worth (I_7), Working Capital Turnover (I_{13}), Total Assets Turnover (I_{14}), Return on Tangible Net Worth (I_4).

The output statistic will be analyzed in order to highlight out the impact of every indicator on the capital structure.

2.2 Descriptive statistics analysis of the financial indicators

It is obvious that most of the companies located into emerging countries had adopted financing structures based on long term debt since a higher weight of the short term debt into the total debt will make them being perceived as riskier. The financial effort implied by the long term debt is considered to be softer than the one implied by the short term debt.

The standard deviations corresponding to the financial indicators of the companies located in emerging countries are high.

Table no.1– Descriptive statistics of the corporate rating for companies located in emerging countries

Source: own processing

The instability conferred by the macroeconomic environment is dominant in the case of the emerging countries.

The variance corresponding to the leverage multiplier is 57.23; the Altman Z-score has also a high variance -3.341,502.

From this perspective, we can assume that macroeconomic environment had a strong impact on the corporate rating. The macroeconomic volatility implied by the emerging countries environment affects the evolution of the financial variables.

2.3 Statistical perspective on the corporate finance decision within East emerging countries

In order to get a deeper insight regarding the particularities implied by the finance decision within East emerging countries, there have been performed three regression test. The regressions conceived the corporate rating as dependent variable and all the other variables as independent ones, including the country rating.

The first statistical test focuses on the relation between the leverage multiplier and indicators reflecting the profitability (I_5) and the size (I_6 and I_7) of the enterprise.

This relation can be modeled as:

L = -0,03726*P + 0,585511*NS – 0,10551*T

Where

L = leverage multiplier

P= EBT/TA

NS= Operating expenses/Net Sales

T= Debt/Tangible Net Worth.

Analyzing the output of the first regression, it is obvious that there is not a deep correlation between the leverage multiplier as an indicator of the capital structure and the liquidity and dynamic activity indicators for the companies based in the emerging countries.

Nevertheless, the Earnings Before Taxes reported to total Assets and the Total Debt reported to Tangible Net Worth are correlated negatively with the leverage multiplier. The second negative correlation is in line with the assumption that as for companies located into East European countries, their finance decision is based mainly on internal financing and they are reluctant to indebtedness. As far as they focus on self financing, equity level is high.

Source: own processing

The second correlation strengthens the idea that finance decision of the companies located into East European countries does not imply automatically the reinvestment of the profit although internal resources is dominant as finance mechanism.

This assumption reflects the fact that self financing implies mainly contributions brought by stockholders while the profit is distributed as dividends and not reinvested.

The positive correlation is established between the dimension of the company and the level of equity. As far as the company manages to have a high level of sales, its equity will increase.

The second regression conceives the weight of the short term debt into total debt as dependent variable (I_9) and as independent variables there have been used the same as in the case of the first regression.

The correlations are the same as in the case of the first regression. The weight of the short

term debt into the total debt is correlated negatively with profitability and the weight of the fixed assets and positively with the size of the company.

The relation can be modeled as follows:

$$S = -0{,}25637\,P + 0{,}248579 \cdot NS - 0{,}03599 \cdot T$$

Where:

S = short term debt reported to total debt

P= EBT/TA

NS= Operating expenses/Net Sales

T= Debt/Tangible Net Worth

The output statistic reflects the fact that their financing policy does not imply a differentiation between the short term and the long term approach. The financial indicators are correlated in the same way both with equity level and short term debt.

For the period to come, it is obvious that this differentiation will be implemented under the context of stock exchange development.

The third regression conceives the short term debt reported to total debt as dependent variable and as independent variables working capital (I_{13}), accounts receivables turnover (I_{11}), current liquidity ratio (I_1) and return on tangible net worth (I_4).

The relation can be modeled as follows:

$$S = -0{,}06308\,Lq + 0{,}000467 \cdot RT + 0{,}086124 \cdot AR + 0{,}309613\,WC$$

Where

S = short term debt reported to total debt

Lq = current liquidity ratio

RT = return on tangible net worth

AR = accounts receivable turnover

WC = working capital turnover

Source: own processing

Output statistic highlights out a negative correlation between liquidity ratio and the weight of short term debt into total debt which is in line with the assumption that a high level of indebtedness determines outflows of liquidities.

The positive correlations are established between the accounts receivable turnover, working capital turnover, the return on tangible net worth and the indebtedness indicator which reflects the fact that an increase of the activity of the company will be supported by a more aggressive financing policy based on external resources.

Conclusions

The article concentrates on the particularities of the finance corporate decision within East emerging countries.

The statistic output highlights out the short term approach of the financing policy. There has been no differentiation between the correlations established at the level of various financial indicators and the short term debt/long term debt.

For the years to come, in the context of the capital market development, there will be a switch from the short term approach of the financing decision to the long term one.

The intensity of the negative correlation between liquidity indicator and indebtedness degree will decrease since the financing policy will be conceived having as reference the long term approach which will reflect higher projection degree.

Their financing policy focuses mainly on internal resources valorized by the practical contributions brought by shareholders within the company while profit is mainly distributed as dividends and not reinvested.

THE INTERNAL AUDIT AS A COMPONENT OF THE PUBLIC ENTITIES' INTERNAL CONTROL SYSTEM

Țară Ioan Gheorghe

University of Oradea, Economic Science Faculty, 1, Universitatii Street, Oradea, ioantara@yahoo.com

Abstract: The internal control system is usually considered a lever into the hand of the management system to achieve their aims. Without having a good system of control it is not possible to overlook the economic and financial processes especially when they might not function well. The internal financial audit is thought to look into internal control aiming at disclosing its weaknesses. But is it possible as long as the internal audit is a part of internal control? The International Standards of Audit say that it has to be independently organized so as to be able to bring additional value to management process. Some methods to improve the internal public audit independence might be: a reduction of the state interference regarding public audit organization and its exercise as much as possible, methods to reduce the dependence of the internal public audit on the internal management system and methods to increase the responsibility of managers towards the entire internal control system.

Keywords: internal control system, internal public audit, financial audit, management system, international standards of audit

Theoretical aspects

The International Standards of Audit basically represent examples of a good practice in financial audit throughout the world so as to be unitarily practiced, both as organization and exercising. They refer to the principals of the organization of the entire financial system and also to the rules of practicing so that all the auditors are able to professionally understand with each other.

According to The International Standards in the domain, financial audit represents a verification and certification independently carried out by a responsible professional as far as the annual accounts and financial statements of any company are concerned aiming at expressing their opinion connected to the accuracy of information issued by these companies' synthetic documents.

- Following this definition, the main characteristics of financial audit are:
- the independence as far as both its organization end exercise are concerned
- it refers to the information coming from financial statements
- it is practiced by the highest competitive professionals in the field
- it aims at expressing an opinion regarding the accuracy of the information issued from financial statements

All these requirements being met, the financial audit may increase the credibility of the information. This is, actually, the extremely important purpose of the financial audit or, in other words, its vital function.

As it is known, the basis in financial audit is well established by the followings:

- International STANDARDS of financial audit
- International STANDARDS of accounting.

They have mainly been issued by two of the most representative international organizations in financial, accounting and audit field such as: INTOSAI-International Organization of Supreme Audit Institutions and IFAC-International Federation of Accountants.

There are more possibilities for the financial audit to be regarded by using more criteria in order to classify its multiple forms. Thus, such points might be:

- the object of audit
- the organizational structure involved in its exercise
- the position towards the audited company
- the area of its activity

Regarding **its object the** financial audit can be **public**- that concerns of how public funds are made up and used. As a general rule, it is organized by the state only, both beside the Parliament, as an external audit, and inside of the public entities that is usually called “internal public audit”. There are also financial **auditors privately organized** as both physical and legal persons.

Taking in account **the organizational structure involved** in its exercise we can revealed more institutions which are in charge with such an activity as the following:

- internal audit offices that exercise audit especially for both the state’s agencies and private companies where they are organized. They serve these entities’ purpose.
- inspections of audit are organized inside of Finance Ministry in order to verify the legality of spending public funds.
- Financial Auditors Chamber which gathers all the independent auditors either physical or legal persons. They practice the financial audit activity independently for all entities.
- Court of Accounts is considered the supreme institution of financial audit being in charge with the formation and utilization of public resources. It is organized as an “of Parliament” organism. Therefore its independence is possible to be much more than of those structures belonging to Government.

According to the **place of its setting-up** it appears as an activity at the companies’ level, within their managerial systems and , on the other hand, like a system working for companies from outside. Thus, it is called either internal or external audit.

The most important point of view consists in seeing financial audit as the followings: an audit of systems (when its area of activity refers to either one or all of the companies’ systems), as an audit of the performance (when are taken in account the economicness, efficiency and effectiveness of economic and financial transactions) and finally, as an audit of regularity (when it is exercised upon the way of respecting the laws and all the other rules).

Regardless of what kind of financial audit an auditor exercises it is extremely important his mission’s results to be credible. For that, the chief thing is supposed to be **the independence**. Even though other requirements, such as: objectivity, integrity and professionalism would be met, the lacks of the independence will lead to those conclusions and, as a result, recommendations which are always suspected to be unfair and, therefore, useless.

The internal public audit is, as The International Standards of Audit recommend, a component part of what is called the internal control system and it is set up to be subordinated to the manager of public entity. Due to this position, its independence seems to be affected. Sometimes the managers are tempted to interfere in the financial auditor activity from the position of being entitled to do that. For instance, they wish to decide upon the objectives which have to be or not allowed to be planned for control. Other times, the organization connections with other types of control inside a public entity lead to an objective temptation of involving financial auditors in different other activities than financial audit. Therefore, one may say that the internal public audit has a relative independence.

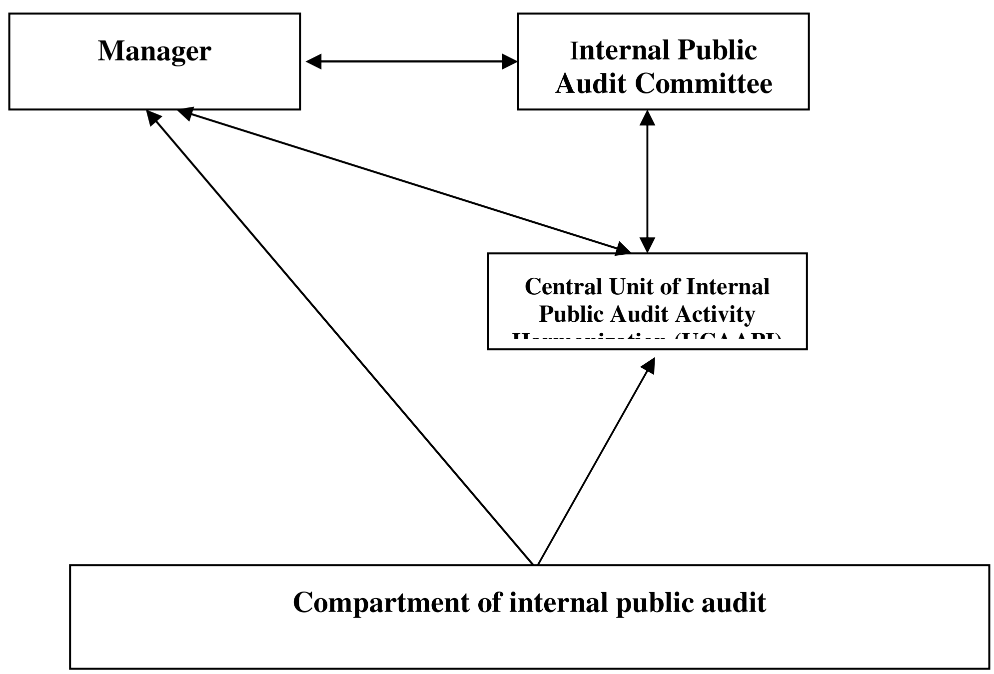
In order to increase the independence of the internal public audit, the state took a decision to subordinate it doubly, both to the public managers and to a state specially- created organism. In this way the state thought of increasing the organizational independence of internal public audit and of controlling the activity of the internal auditors as well. But how wide is, actually, its independence? We will take a notice of some aspects of internal public audit organization. The International Standards of Audit recognize a certain relativity of the independence of internal audit. When it comes to the methods to increase its independence the standards recommend any methods but nobody ever may interfere in its exercising process. Although it seems to be normal for the state to take care of its fortune organizing an effective control on all aspects, it is also strongly necessary to take in account that an effective audit can only be obtained by setting it up as independent as, at least theoretically, it can be. The more independent the internal public is, the more effective it is and fewer wrong decisions would be taken regarding the handling of public money.

The organization of the internal public audit

According to the law and targeting to the wider independence of the internal public audit, it has been organized in the following way:

- it is the responsibility of all the managers in the public sectors to organize the activity of the internal public audit. The managers are in charge of ensuring the organizational and functional conditions inside any public entity.
- As it can be seen below, (fig.nr.1) the basis in the organization scheme of internal public audit are the compartments which are set up at the level of every public entity. They are doubly subordinated as it follows: the manager of the public entity, who directly subordinates the activity of internal auditors and, at the same time, is in charge with making sure that their activity performs properly. On the other hand there is a specially created structure which works inside of Finance Ministry being a state's representative within public audit system that is called Central Unit of Internal Public Audit Activity Harmonization which is operatively led by The Internal Public Audit Committee.

Fig.nr.1



Taking in account what the law says these organisms, from outside of the public entities, are in charge whit both administrative problems and methodological guidance of the internal public audit. Basically, the state representatives are careful and purposely watch over whether the law is respected both by the auditors and public entities.

- There is the possibility for the small public entities, which do not have enough money, to renounce of organizing internal audit and their financial statements are audited either by the compartments belonging to the hierarchical superior entity or by the external auditors coming from Finance Ministry, namely, from the state, as well.
- The area of internal public audit refers mainly to all economical and financial activities and also to the systems of the entire entity. The financial statements are considered the basis of the internal public auditors' activity.

- The activity of the internal public auditors is annually planned and always approved by the general manager. The objectives of audit are partially decided by the auditor himself but there are also demands from the entire system of management.
- The internal public auditor reports his findings, conclusions and recommendations not only to the general manager but to all the component parts of the management system (people or functional structures)

The feed-backs of the internal public organization

All the aspects above prove, in my opinion, that the requirements of the international standards are generally respected. But this assertion is very real when we talk about the statements of the law only. Although the law says, quite perfect, how to apply its statements, the reality proves to be different so far.

Thus, the interference of the state by its representatives might be considered correct, at least, in a certain way, as long as it refers to the way of respecting the law by those two parts: auditors and entities. But, as the standards say, the auditor must be free to be able to express his opinion without any confinement. Or, being controlled by the state it is supposed he can not always say why an entity or an activity goes wrong when it comes to the flaws of the law.

There are also difficulties for some managers to properly understand the importance of the independence of auditors when it comes to issuing the annual plan or to putting it in practice. Many of them consider they are right to change their employees' plan of audit, to ask for other missions or to decide on forbidding certain previously planned actions.

In order to express an opinion upon the accuracy of the information issuing from financial statements, the internal public auditors need to be able to apply all their competences during the year. At the end of the year the financial statements have to be professionally certified before being sent to the Finance Ministry and becoming public. Never should Finance Ministry get the annual financial statements without being certified by the auditors. But it has not always happened so and therefore some wrongly drown-up balances are mistakably centralized. Eventually, the general execution account of the national public budget is not real. Then, ought Finance Ministry to demand for a professional certification of annual balances? The answer is obviously "Yes".

The connection between internal financial audit and internal control system

According to the international standards and also by the Romanian law the internal control system represents the ensemble of the control forms within a public entity including the internal audit as well, which are set up by the management to serve their purpose in order to make sure the public resources are efficiently, economically and effectively spent. It also includes all the functional structures of the entity, as well as, the methods and procedures of its exercising. As we can notice the internal audit is considered a component part of the internal control system.

Taking in account the same standards, the internal public audit represents an independent and objective activity which gives assurances and advice to the management in order to get a good administration of public funds. It helps the public entity to accomplish its objectives by a systematic and methodical approach which assesses and improves the efficiency and the effectiveness of the management system taking in account the risks and the internal control handling. It is obvious that the most important mission of the internal public audit consists in watching over the internal control system so that it would be able to provide for the management system assurances and advice in order to reach their purpose.

Due to the internal audit position, both as a component part of the entire internal control system and as an independent activity aiming at providing the management system with advice and assurances that internal control works properly, there seem to be some difficulties in putting in practice all its functions. It depends on the managers; on how much they are interested in having an effective audit and whether they are really conscientious about the importance of the internal control towards helping them to handle public money with the biggest performance.

The practical activity proves that:

- there are situations when the public managers do not simply organized internal audit considering that it is useless

- others think of it as if it were something compulsory to be done and therefore they do something to simply organize it but no more than that
- some managers confound the internal audit attributions with those of the other types of internal control and so they cannot obtain from the internal audit the most important thing: support in making sure that all economical and financial processes work as they were previously planned
- there are managers who are aware of the importance of their mission regarding the public money and therefore they organize the internal audit according to the international standards as a component of the internal control system and, at the same time demand to it to watch over the entire system of internal control and over all the other systems inside the entity. They are also aware of the fact that it is not at all allowed to interfere in the planned activity of auditors and look forward to hearing their activity results: conclusions and recommendations.

Taking in account what The International Standards of Audit (I S A- number 400) says, the internal control is an object of the financial audit, both internal and external. From this perspective internal control can be useful for the activity of financial audit as well. Thus, when financial auditors check the internal control and find out that it is well organized and works properly, they can decide to rely on the internal control and, as a result, their samples are smaller in size and fewer in number. By contrary, when the internal control needs to be improved both internal and external audit make such recommendations to the management system after checking it and widening the samples.

In my opinion, it does not matter that the internal audit is considered, by the international standards, a part of the internal control system as long as its independence is not affected. But its independence might be really affected by the will of the legislators by not issuing the law in accordance with the best international practice and also by the behavior of the managers.

Conclusions

The international standards of audit consider the internal audit as a part of the internal control. As a consequence, the internal public audit is a component of the internal control's public system. The Romanian law states the same. Due to its organizational position, being directly subordinated to general manager and, at the same time, as a part of internal control system, the internal public audit is recognized as having a relative independence. But the independence of the financial audit must tend to maximum. Although the internal public audit is considered relatively independent, on behalf of the management system it should be improved. Some ways to do it might well be the followings:

- o doubly subordinate it but not both parts to be the representative of the state especially of the executive power. As it is now, both managers and specially organized structure to deal with internal public audit (UCAAPI) are state representatives. Consequently, they are supposed to take care of the state interests only and the ones of the financial audit in itself is easy possible to be ignored. Therefore, our suggestion would be to find the second part to subordinate to the financial internal audit from another direction than the state such as: The Chamber of Financial Auditors as an independent, professional and privately organized structure or The Court of Accounts as an independent and professional organism of audit not belonging to the executive power. Either of them would be able to look after the independence of the internal public audit more objectively.
- The managers from public system should be aware of the importance of their activity in the public money field. This might be done by improving the managerial law system so that they compulsorily take care of the internal audit organization and exercising.
- The Finance Ministry should get the annual balances from the public institutions certified only. In this way the responsibility of the managers towards the internal public auditors' activity would increase.
- The selection of the internal public auditors might well be done more professionally in order to be hired merely the ones who prove enough professional experience concerning the finance, accounting and financial audit. At the same time, a permanent process of professional training both for managers and for internal auditors would be useful.

GOING PUBLIC IN ROMANIA: A REVIEW OF IPO ACTIVITY, COSTS AND PRICING

Ursu Silviu

„Alexandru Ioan Cuza" University of Iasi, Faculty of Economics and Business Administration, B-dul Carol I Nr.22, 700505, Iasi, E-mail: silviu.ursu@uaic.ro, Telefon: +40232201449

Abstract: This paper analyses the process of going public in Romania via initial public offerings of shares to investors. Various features of the domestic IPOs that took place over the period from 2002 to 2007 are discussed, with an emphasis on the volume of new listings and its explanatory factors, the costs of going public and the initial returns of the IPOs.

Keywords: Initial Public Offerings, IPO Underpricing, Bucharest Stock Exchange

Introduction

Going public is an important step in the life of a company, because it provides access to a large amount of equity for an indefinite period of time and helps the company to raise finance for its expansion. Moreover, it brings indirect benefits such as increased trustworthiness and reputation for the company, higher value for employees that enables their involvement and their willingness to participate in the future development of the company, and the ability to obtain more and cheaper finance through new securities issues or even bank loans, given the higher transparency of the company which regularly provides information on which it is evaluated.

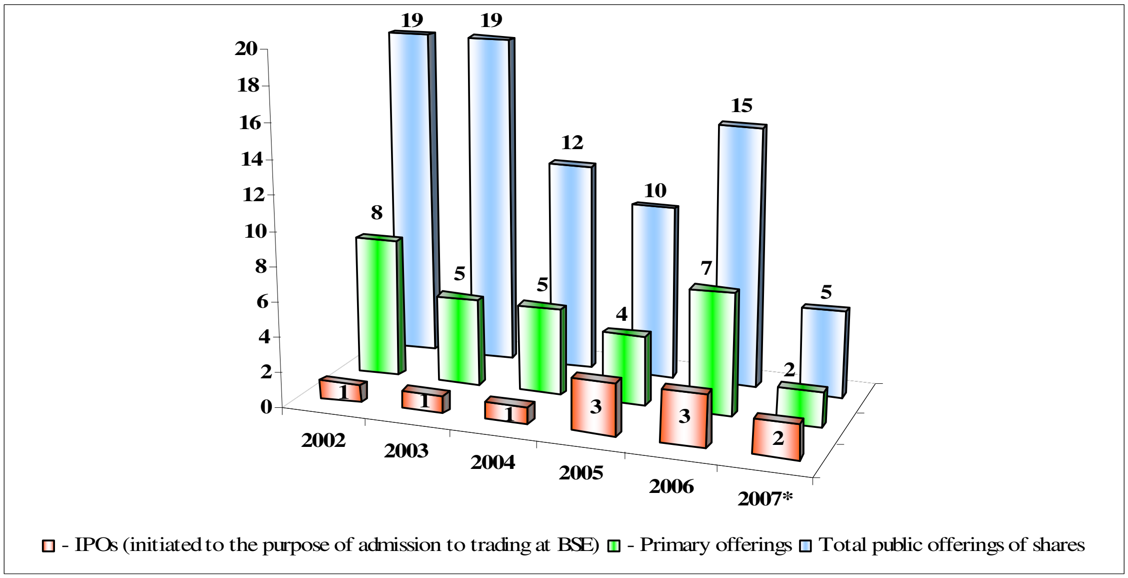
Most companies that go public do so via an initial public offering (IPO), which is a commonly used term for the primary public offering of shares by a company related to its entry to the stock market and the listing of its shares on the stock exchange.

Given the benefits of being public, an increasing number of companies around the world consider the IPOs as an important way to raise financing for new investments. Over the past five years, the IPO markets have witnessed an unprecedented level, with a record of $246 billion in 2006 in the amount of capital raised worldwide by companies going public (Ernst & Young, 2007: 5). The growth of IPO markets is a global trend reflected by all the main regions in the world – Europe, America and Asia. However, a further analysis at country level shows large discrepancies. For example, the IPO activity in Europe is mainly driven by deals in the most prominent European exchanges, with London Stock Exchange, NYSE Euronext, BME and Deutsche Borse as leaders by the number and offering value of the new listings, while, on the other side, Central and Eastern European primary markets, with the exception of Poland, are lagging far behind those from the most developed European countries.

Overview of the IPO Activity in Romania

The Romanian IPO market, as most of the EU NMS markets, is underdeveloped. According to the statistics provided by the Romanian National Securities Commission (NSC), over the period 2002 - 2007, only 80 prospectuses for public offerings of shares were approved by NSC, most of them secondary (62%), which gives support to the idea that going public is not a real option for the Romanian companies in need of financing.

Figure 1 shows the total number of domestic public offerings of shares over the past six years (2002-2007) by pointing out the number of primary offerings and, among these, the number of the initial public offerings initiated with the goal of listing the company on Bucharest Stock Exchange (BSE).



General source: Romanian National Securities Commission Annual Report 2006

Source (2007): List of the prospectuses for shares sale offerings approved by NSC in 2007 (NSC website)

Figure 1. Number of public offerings of shares in Romania (2002-2007)

As data from figure 1 clearly shows, only 11 of the primary and secondary offerings approved by NSC since 2002 were initiated to the purpose of admission to trading at the stock exchange, which supports the previous statement about the insignificance of the domestic IPO market. Moreover, when considering only the companies that were actually listed on BSE, following their IPO, the previous number contracts significantly by 33%, since two IPOs closed unsuccessfully and other two postponed this further step.

Table 1 reports the companies that listed on Bucharest Stock Exchange between 2002 and 2007, following an IPO, and the main characteristics of their offers.

Table 1. Initial Public Offerings* in Romania (2002-2007)

Company (trading symbol)	Year of subscription	Total value of offering (RON)	Intermediation		Subscription level
			Method	Costs

* Only the IPOs that closed successfully and were followed by the company listing on Bucharest Stock Exchange

** Total costs including the NSC and BSE fees

*** Includes only the NSC and BSE fees, since the underwriter was the company itself

The scarcity of IPOs in Romania can be explained by several factors, such as the "historical inheritance" of the privatization process, the competition from other stock exchanges and institutional investors, and the "perpetual" lack of knowledge about financing through primary capital markets.

The mass (or "voucher") privatization program (MPP), carried out in 1995-1996, was one of the major methods used in Romania in order to increase the speed of privatization. In order to create liquidity for the newly issued vouchers, the MPP was followed by a massive listing on the Bucharest Stock Exchange of most of the privatized companies (6000), which determined an "overcrowd" effect that deterred more companies to access the capital market. This approach was very different from Poland's privatization program that focused mostly on IPOs and helped to create an IPO culture.

The competition from other equity providers is another factor that can be used to explain the rarity of domestic IPOs. Over the past years, many firms from Central and Eastern Europe, including Russia, were raising funds on other European exchanges, among which London Stock Exchange was the main destination. Nevertheless, with only one local company, A&D Pharma, listing on the Alternative Investment Market (AIM) of LSE, the stock exchange competition doesn't quite help to understand the current situation in the Romanian IPO market, although it can be considered as a real factor in the near future, since many domestic firms expressed their interest for foreign capital markets. The competition is not limited only to stock exchanges, but to other equity providers as well. The small number of domestic IPOs can be attributable to institutional investors, such as venture capital and private equity funds that developed a strong presence in the financing of firms from emerging countries.

On the cost side, the average IPO intermediation fee is less than 2%, well bellow the "seven percent solution" first documented by Chen and Ritter in 2000, and is mainly a reflector of the low level of involvement of investment firms, given the prevalence of the fixed-price mechanism and the best efforts method. Even when considering the indirect costs - the NSC fee following the approval of the prospectus (0,1% of the offering value), BSE fee for trading the shares on POF Market section (0,09% of the value of the sales), and BSE fee for the admission and promoting to trading (RON 1200, excluding VAT), the IPO cost is beyond any doubt an incentive for domestic companies to go public.

IPO Pricing in Romania

The topic of pricing is one of the most studied areas in the IPO literature. A well-accepted result is that, on average, the IPOs are underpriced, which means that the first closing price or the closing price observed a few days after the initial trading is much higher than the IPO price.

The first documentation of the underpricing can be traced back in '70s in the studies of Stoll and Curley (1970), Reilly (1973), Logue (1973) and Ibbotson (1975), that found a systematic increase from the offer price to the first day closing price (Welch and Ritter, 2002: 10). Since then, this 'underpricing discount' has averaged around 19% in the United States, although it fluctuated significantly, averaging 21% in the 1960s, 12% in the 1970s, 16% in the 1980s, 21% in the 1990s, and 40% since 2000 (Ljungqvist, 2004: 1).

The underpricing in not specific only to the US IPOs, but to all countries with primary capital markets, with no exceptions (Welch and Ritter, 2002: 10). A recent survey of European IPO markets shows that the average initial underpricing amounts to 22% over a pan-European sample of 2000 companies between 1995 and 2004 (Gajewski and Gresse: 2006: 2), which is close to the level found for US markets. However, when observed in each of the 15 countries in the sample, the level of underpricing varies notably from one domestic market to another, with the lowest average initial return of 5.36% in France and the highest of 46.68% in Greece (Gajewski and Gresse: 2006: 32).

In Romania, given the small number of IPOs that actually reached the goal of listing on Bucharest Stock Exchange, the data sample is limited to only seven companies which makes very difficult the process of drawing significant information about the pricing of local IPOs. Therefore, no conclusive studies focused on the underpricing of local initial public offerings. However, some descriptive empirical results can be computed and this can be considered as a first step for a further more insightful analysis.

In order to determine the level of underpricing, two measures widely employed in the IPO literature will be used (Gajewski and Gresse: 2006: 27):

- **the raw initial return**, determined as the difference between the post-IPO equilibrium price (EP) and the final offering price (OP), divided by the offering price:

$$U = \frac{EP - OP}{OP} = \frac{EP}{OP} - 1$$

– **the initial return adjusted for a market index return**, determined as the difference between the raw initial return and the market index return:

$$U_m = \frac{EP - OP}{OP} - \frac{I_1 - I_0}{I_0} = \frac{EP}{OP} - \frac{I_1}{I_0},$$

where I_1 is the market index closing price on the first trading day and I_0 is the index closing value the day before.

To address the problem of first day of trading market illiquidity that affects the process of obtaining the equilibrium, I will use as the equilibrium price (EP), the closing price observed in the first day, but also over a five, ten days and one month horizon.

Moreover, Bucharest Stock Exchange Composite Index (BET-C) will be used as the market index proxy.

Table 1. Initial returns of IPOs in Romania (2002-2007)

Company symbol	Raw initial returns (%)				Adjusted initial returns (%)			
	1st day	5 days	10 days	1 month	1st day	5 days	10 days	1 month
ALU	95,65	80,43	76,09	73,91	93,93	79,07	72,92	73,21
BRK	158,71	164,52	172,90	205,16	159,05	169,28	171,18	200,72
FLA	5,22	4,35	3,04	7,39	5,72	0,08	-0,93	-0,85
GDP	42,86	233,33	161,90	68,57	41,24	233,63	157,67	58,80
TEL	35,71	58,93	66,67	69,05	35,95	56,66	64,01	64,46
TGN	43,03	42,77	34,59	25,57	40,87	38,38	36,47	26,00
VNC	10,00	3,33	-1,33	-10,67	9,89	-0,62	-4,59	-17,75
Mean	55,88	83,95	73,41	62,71	55,24	82,35	70,96	57,80
Standard deviation	54,11	85,61	70,51	71,08	54,10	88,22	70,33	71,73

The table reports a substantial underpricing of Romanian IPOs, irrespective of the used measure - raw or adjusted initial return. The mean return on the first day of trading for the companies composing the sample is about 54%, which is a very large value when considering other empirical evidence about IPO initial performance in Europe. Only few studies documented similar values, such as Goergen et al. (2003) that found a 1st day initial return of 86.07% for Dutch companies that went public between 1996 and 2000 (also using a small sample of only 11 companies), Levis (2004) – 60,1% for 240 UK IPOs or Gajewski and Gresse (2006) – 46,68% for 183 Greek firms that listed following an IPO between 1995 and 2004.

These abnormal raw and adjusted returns do not disappear in the short run. In fact, they grow significantly in the first trading week and stay at high levels until the end of the first month of listing in more than half of the cases. At the same time, standard deviations are almost equal to the mean values, proving the heterogeneity of the IPO initial returns.

The most important negative effect of the IPO underpricing consists of “money left on the table by issuers”, defined as the number of shares offered multiplied by the raw initial return (Ritter: 2006: 1).

On the positive side, the huge initial returns of the domestic IPOs, together with the oversubscription level (842,94% in average and increasing over the years) are an indicator of the financing potential of the Romanian capital market. Nevertheless, this is not an argument that going public is a sure thing in Romania. It depends also a lot on company financial data and perspectives, as suggested by the IPOs that closed unsuccessfully over the analyzed period.

Conclusion

Based on data from companies that listed on Bucharest Stock Exchange following an initial public offering, the paper analyses briefly various features of the Romanian IPO Market.

First, with only seven companies that issued new shares between 2002 and 2007, IPOs play an insignificant role in the financing of domestic companies.

Second, the costs of going public are very low, mainly because of the use of fixed-price mechanism and best efforts method by the underwriters (SSIFs), and also because of the efforts of financial markets institutions to reduce the indirect costs.

Third, the Romanian IPOs are highly underpriced and oversubscribed, which strongly suggest the increasing interest of the investors and the potential of the local primary capital market of financing the domestic companies.

As Romania's economy will continue to grow and the activity of the Bucharest Stock Exchange will increase, there is a positive expectation that more and more companies will see the advantages of raising additional financing through an IPO and will access the primary markets.

Abstract: *The paper points out the main issues on the integration of the Romanian and the Bulgarian capital market in the European financial services market and the position that these two emergent markets can reach near future.*

Keywords: capital market, Romania, Bulgaria, market capitalization, European integration.

4The Romanian Stock Exchange has a long institutional history. The first, French inspired, law regarding the Romanian capital market appeared in 1881, and was modified in 1929, when the so-called "Madgearu Law" was enacted. The years between 1934 and 1945 saw some intense activity, with 56 listed companies, some of which were also traded on other, renowned, European exchanges (Paris, Anvers, Frankfurt, Amsterdam, Basel and Zurich).

Unfortunately, the communist regime caused the exchange's shut down. It did not resume activity until 1995, operating under Law 52/1994. In April 1995, 24 brokerage firms decided to reopen the Bucharest Stock Exchange, which was to supply efficient and transparent trading mechanisms for shares issued by local and international companies, investment funds, the government and local authorities.

What has driven the Romanian stock market's development? Firstly, there was the Romanian government's mass privatization program, in the early 1990s, which created thousands of private companies and shareholders. Unfortunately, just a few (8 or 9) companies were listed in '95-'96, due in my opinion to their managers' lack of interest in the stock exchange mechanisms, and weak corporate governance. Later, though the listed companies number increased, with a high mark of 130 in '98-'99, market transparency was still an issue. Consequently, the Bucharest Stock Exchange decided in 2000 to raise transparency and corporate governance standards among listed companies, with the aim of achieving a qualitative transformation of the stock market, and gaining a competitive advantage over the open-market exchange, the RASDAQ.

Another interesting feature is the rapid increase in the number of brokers, from 28 in 1995 to 173 in 1998. Their ranks were gradually diminished, though, due mainly to decreasing traded securities, as the Asian and Russian crises of 1998 made many investors wary of the emergent markets.

A quick review of the Romanian stock market's past shows a sinuous evolution, with significant variations both in the number of listed companies, and in the volume and value of traded shares. Yet, in spite of the difficult last 12 years, the Romanian stock market has grown step by step. An important milestone was the introduction in 1998 of the BET index, covering the 10 most liquid shares. Also of importance was the enactment in August 2001 of the Corporate Governance Code, drafted in accordance with the principles of OECD, which has had an effective contribution to a more transparent stock market in Romania. Another contribution to the market's development was the issuing, at the end of 2001, of the first municipal bonds (for Mangalia and Predeal), and the launch in the same year of the electronic platform for fixed income shares.

The year of 2003 was a turning point for the Romanian stock market, as the brokers' community adopted a new strategy for market development. Thus the framework was in place for achieving a climate improvement for investments.

The main objectives of this strategy were:

- National stock market growth through attracting new issuers to the market;
- Strengthened integrity and liquidity of the BSE;
- The introduction of new financial instruments;
- The adoption of the Corporate Governance Code by more issuers;

– The BSE's alignment to European stock market trends, etc.

The BSE's legal status underwent an important change in January 2005, as it went from a public institution to a profit-oriented public company, with 67 former exchange members as shareholders.

Concerning market capitalization, I find the following chart very relevant, as it shows its growth from a near-insignificant level in 1996, to almost 25 billion Euros in 2007.

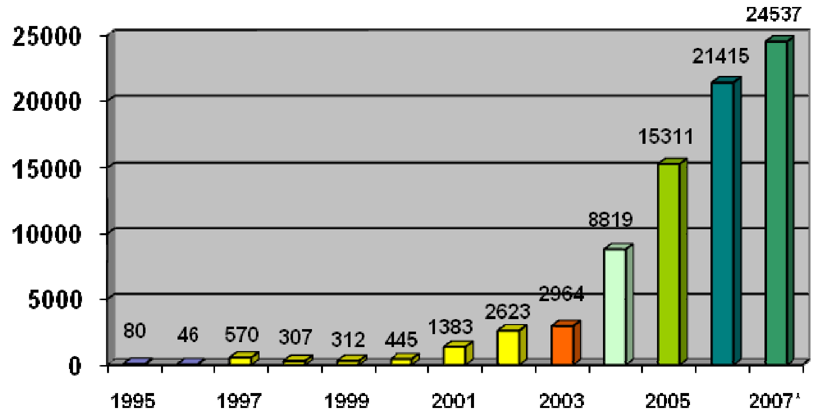

Figure nr.1 The evolution of the market capitalization in billion euros

The daily traded value average also increased significantly, to almost 10 million Euros, while we observed the exchange management's desire to maintain the image of a secure, transparent and efficient market, and increase investor trust in the stock exchange mechanisms.

Romania's intent to join the EU has also influenced its stock market. Given the serious commitment to the membership race, especially since after 2004 this was a realistic target for 2007, adopting the European stock market regulations became a necessity. Thus, a new Exchange Code was introduced in 2006, bringing clarifications to many issues essential for an efficient stock market. Among these new measures were:

– Clear delisting mechanisms on the regulated market;
– Shorter suspensions for issuers following an event in the company;
– Regulations for margin trading and short selling;
– More flexible price limits (+-15%) per trading session

Another important step was the development of the BSE's electronic trading platforms, and the introduction of the Arena trading system. This allowed for faster operational trading, and a significant improvement of the back-up system.

The Bucharest Stock Exchange was actively involved in the implementation of regulations for the Central Depository. Thus, the clearing activities were outsourced to the Central Depository, connected in real time. This is expected to increase the stock market's transparency, as required for alignment with the European regulations.

The BSE's future depends on how the Romanian stock market will be able to integrate with the European stock market. Investor perception of the BSE is as one of the region's major markets. This is confirmed by the listing in 2006 and 2007 of the first bonds issued by international financial institutions, the World Bank and the European Investment Bank. These bond issues contributed to the stock market's strength, and its image as a mature market, a requirement for international recognition.

2006 was a relatively good year for investment on the Romanian stock market. The BET index, which follows the average movement of the listed shares' prices, went up 22% in 2006. This represents a solid performance compared with the interest on bank deposits, which is almost three times smaller.

The value of shares traded on the BSE increased with 27% in 2006, from 223% in 2005, and 140% in 2004.

The index's evolution (and in fact the Romanian stock market's) was correlated in a large measure with that of indexes of other important markets in the region (Px –Czech Republic, WIG – Poland, BUX – Hungary). This correlation will obviously grow stronger, as the Romanian stock market matures.

2006 also brought other important events for the stock market. The merger between the BSE and RASDAQ was finalized. According to the new stock market legislation, and a new exchange code issued by the NSC, today the BSE operates a regulated market with three categories for shares and three for bonds (the practical equivalent of the old BSE) and will operate shortly an alternative trading system currently undergoing authorization by the NSC (RASDAQ's 'heir'). This involves definitively shutting down the electronic trading system used by RASDAQ, and migrating all issuers to the BSE's Arena system. The two markets' merger was one of the most important events on the Romanian stock market, and this consolidation improved its visibility regionally and internationally.

Unfortunately, this consolidation trend did not continue. The merger of the BSE and the SMFCE, under consideration for a long time, was rejected in 2006 by the BSE shareholders. In consequence, the BSE announced the launch of its own derivatives trading platform in the near future, which will use the SNCDD as a clearing house. On the other hand, the SMFCE announced also announced a trading platform. While this market fragmentation is not necessarily considered positive by experts, the two institutions will definitely present new platforms and financial instruments.

In the field of operations and new instruments, it was now possible for brokerage firms to offer margin trading to their clients. This became operational in the fourth trimester of 2006, but this kind of transactions is still under development. Under legal requirements, the guarantee deposited by the client, in form of cash or securities, must be at least 50% of the market value of the securities to be bought through margin trading.

By the end of 2006, 58 companied were listed on the BSE, with 2.8 bill. Euros in traded shares.

Corporate bonds had a good year in 2006. In September, the World Bank launched in Romania a 525 mil. RON public bond issue, the first issue of an international financial institution in our country, and the biggest one to that date. The issue was successful, with 635,948 shares subscribed, from 525.000 issued and allotted.

The EU membership is certainly an important step for the BSE. We expect a stronger and improved institutional framework, due to intensified cooperation among key institutions on the stock market, increased contact with the business community, and the support for institutions with a potentially positive effect on the quality of stock exchange activities: the Institute for Corporate Governance and the Brokers' Association. We can also assume an increase in market capitalization, probably to 40 billion Euros.

In the first two years from accession, market capitalization in the Czech Republic, Hungary and Poland grew with a 48% average rate per year, and the traded value with 77%. While these effects will not be immediate, they will certainly, given the increased visibility and trust, also manifest in Romania.

With the BSE's future relatively bright, and Bucharest increasingly a point of interest on the European stock market landscape, an analysis of the stock exchange in Bulgaria, neighbor country and simultaneous new EU member, is not without interest.

A first look at the Sofia Stock Exchange reveals a stock market split into official and unofficial operations. Shares from the A and B segment are traded on both market sectors, but some differences exist in the types of bonds traded. While government, corporate and municipal bonds are traded on the official market, the unofficial one deals in privatization cheques and other bond types. In April 2007 17 companies were traded on the official market, with a 2.8 bill. Euros market capitalization, compared with 339 companies and 7 bil. Euros on the unofficial market. The 9.8 bill. total capitalization is significantly smaller than the BSE's (approx. 25 bil. Euros). In 2006, there were 29 newly listed companies, 2 IPOs, 19 mutual funds and 28 bond issues. The beginning of 2007 brought 7 new IPOs, 10 bond issues and 6 new companies.

The Sofia Stock Exchange top 20 listed companies, aggregated by type of activity, contains:

- 43% financial brokers;
- 30% transportation, warehousing and communication companies;
- 20% production companies;
- 4% retailers and whole sellers;
- 3% tourism and food companies.

Active since 2000, the Sofia Stock Exchange enjoyed constant growth, evident both from the doubled daily average in the last few years and the SOFIX index' evolution (up 1300% from 2000 to 2007), and from the low capitalization level in 2007 (37% of the GDP, from 5% in 2000).

Trends and expectations for the Bulgarian stock market's near future include the concern for alignment with European requirements, by introducing legislation and the unique European passport. Also, the Sofia Exchange, like the BSE, is considering alliances with other European stock markets (7 of which have expressed interest), and multiple listing using a single issue prospectus.

What about investment opportunities on the Bulgarian stock market?

The Sofia Stock Exchange intends to encourage companies to be active on the stock market, and to increase the role of stock exchange mechanisms in attracting new financing. More precisely, this concerns raising capital through share issues.

Simultaneously, securitization is encouraged in key economic sectors: energy, electricity, central heating, banking, etc. Real estate is to be an important domain for the stock market. Also, small and medium companies are expected to be more actively involved in the stock market to fund new projects, occasionally even riskier ones.

Like Romania, Bulgaria is concerned with better corporate governance standards (aligned with the same OECD principles), and is drafting a special code, which I find very similar with the one in place in Romania.

The Bulgarian stock market shares the introduction of IT solutions as a priority, and technological innovations will be deployed rapidly, mainly in the existent systems – COBOS (Client-Order-Book-Online-System) and EX3 (automated single-point information disclosure system developed by the BSE, FSC and CSD).

Of course, as with the BSE, the Sofia Stock Exchange's management is aware of the limitations: a market still small, reduced liquidity, few IPOs, limited range of financial instruments, but there are great expectations. Introducing new legislation and finding important partners are the next period's main goals. Much is expected of the collaborations with the Deutsche Burse, OMX, Wiener Bourse, Hellenic Exchange, the Italian Exchange, the Warsaw Stock Exchange.

EU membership will for both Romania and Bulgaria, along with increased foreign funds' investments, more investment from domestic institutional investors.

Pension funds and insurance companies are stock market segments with great potential, and expected to become much more active in the future.

Thus, positive effects will surely manifest on both Romanian and Bulgarian stock markets, especially quantitatively, potentially making 2008 a more interesting year than 2007. At least in Romania, the listings of important companies like "Fondul Proprietatea" or Romtelecom will have an essential impact on both market size and attracting interest from potential investors.

The introduction of regulations following EU accession will mark a difference between 2007 and 2008, for both the BSE and the Sofia Stock Exchange. Of interest will be the increased competition as international operators enter the market, and the results (undoubtedly benefic) of this added competition for investors.

The financial instruments will certainly become more diverse. The BSE is developing a new derivatives platform, the introduction of which will be a major market event. The platform will start by supporting futures contracts in the first stage, so share options could be introduced in 2008. Margin trading could also significantly bolster traded values.

Bonds will continue to be an important market segment for Bucharest and Sofia. As many banks express interest for the stock market, corporate bonds will be a growing segment, and municipal bonds will also continue to consolidate. Investment firms in both countries are candidates for continued good performance, and we can confidently expect that IPOs will play an essential role.

Bulgaria must be seen as a serious, fast-approaching competitor, which cannot be treated with indifference. Consequently, finding strategic partnerships is most important in the future, as is the consolidation of the domestic market, and increased prestige on the international market. Speed is of extreme importance while introducing reforms and leading the competition in the region.

Regardless their nature, all the capitals have a cost. The cost is the highest risk element, which accompanies the capital, because, is in inverse proportion to the profit: a higher cost leads to a lower profit. For attracting the sources of capital, a firm must spend certain sums, which are proportional to their price. The content of this thesis tries an efficiency of financial structure for companies based on the minimizing of finance costs. In this case, it has proceeded to a deep analysis of financial source on long term. In the purpose of efficiency of financial structure has followed the costs for variant of financial structure through point out models of analyses and assemble the costs recommended by international and national specialty literature.

Keywords: financial structure, financial sources, capital cost, efficiency

The capital represents the ensemble of material values resulted from the human activity and all out financial values owned by a company, used with the purpose of obtaining a profit.“ (Encyclopedic Dictionary, 1993 edition.

The capital is defined to be „that production factor who in his ensemble of yields and used to obtain other goods and services, destined for sale, with an economic advantage, profit“.

The company’s capital, participating at these economic processes, upholding them, and turn into products and services, the management quality of their using, the company’s efficiency, liquidity, solvency, earnings, it’s chances of success in competition, it’s existence, it’s development and it’s one selfness.

The capital account represents the difference between the economic capital and the company’s debt, and the loan capital is, how the name seas, the capital drown from different financial sources, which the company has to pay and repay.

The form of propriety for the capital, they are frequently situation in which the capital account are much more expensive then the loan ones, situation that has generated the sentence “*is more profitable to work with someone else’s money then with yours”*.

This state of things arises from the financial risk and, from the so-called efficiency by the usherette to assume the risk. The placement in a company is more risky then that on a bank or any other zone, with fix payment, for at least two reasons:

- The payment of invested capital in company it is done by dividend from profits and the level of profit is the result of a sum of factors hard to administrate and multiply, a lot of them being unpredictable, derived from a state of specific uncertainty .
- The collection of advanced capital it’s conditioned by the economic-financial performance of company that keeps, at least the same state of things, restored at the first theme.

As follows, the capital holders place their funds in companies only if the offered dividend is much bigger then the interest offered by the bank or the payment offered by other financial forms, this difference carries to a much bigger capital cost.

Regardless their nature, all the capitals have a cost. The cost is the highest risk element, which accompanies the capital, because, is in inverse proportion to the profit: a higher cost leads to a lower profit.

The capital is a product with a price and a cost supported by the user. In the capital price and cost comes in a series of specific factors like: confidenciality, the utilization rate, the importance, the risk, the wangles, the guarantees and the loan categories.

For attracting the sources of capital, a firm must spend certain sums, which are proportional to their price. The respective expenses represent the average of the marketing cost of the sources of capital, i.e. of the loans and the authorised share capital and equity.

The cost of the equity is interesting for evaluating any investment project, both in financing from equity, as well as mix financing (equity and loan capital).

The cost of the loan capital varies with the capital demand and offer, the length of the loan, the importance of the credit for the one who needs it, etc. The sums, which are paid for loans, vary a lot, sometimes reaching very high rates.

The global cost of the capital (equity and loan), regarded as a hope for paying the capital investors (shareholders and creditors), actually expresses the market value of the firm.

We can conclude that the expenses or the cost of the loan capital are measured mainly by interest and the cost of the equity by dividends. Thus, the sum of the interest represents the cost of the loan capital, and that of the dividends is the cost of the equity, both forming the total cost of the capital.

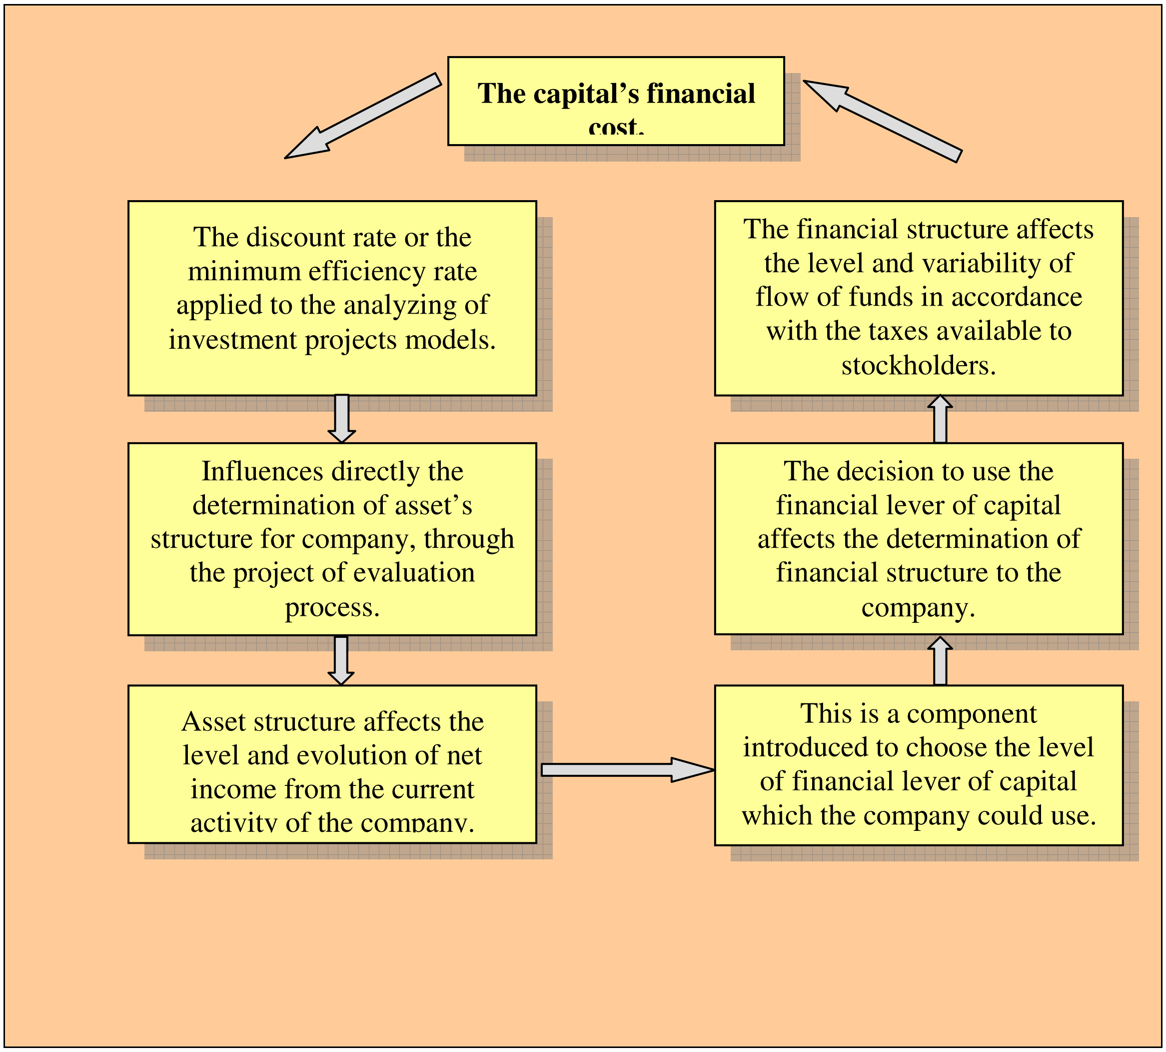
A problem of great importance in the analyzing and evaluation of financial sources constitute the financial lever effect of capital about the financial costs of company. *"Can the company affect their costs, in a favorable or unfavorable way, by the diversity of the financial sources used?[198]"*

The financial cost keeps a direct bundle between the elaborating of capital structure and his financial structure. Has economic sense that the company tries to minimize the financial cost. The capital costs and the other costs, share a common characteristic in that of they can reduce the dividend size paid to stockholders.

Having in view that the value of an asset depends on the financial results of investments. Now to keep constant all the factors that can affect the asset price is necessary of capital costs. If these costs would be minimized, the stockholder's dividend would be maximized. This thing will go to the maximizing of company's asset price.

If this financial costs can be affected by his capital structure, then the structure management capital is clear an important element of company's financial management. This thing is shown in the next figure[199].

[198] Burton A. Kolb, Richard F. DeMong, Principles of Financial Management, Irwin, 2005
[199] Leopold A. Bernstein, John J. Wild, Analysis of Financial Statement, Dow Jones-Irwin, 2005



The capital's financial cost

The manner of introduction for the analyzing investments of project models from the investments expenses point of view is represented by the financial costs of capital. Next it shall be examined the instruments used in determination of financial structure accordingly to the company. By studying the technical analyze of investments projects, from the investments expenses point of view, it has been reported a "risk" as being a variable associated with the expected income.

The cost of capital account concerns in evaluation of any investment project as much as integral financial from capital account, and mix financial.

The global cost of capital, looked as a capital investors payment hope express the market value of the company. Net cash flow cleared by the company serves for the payment of capital "suppliers". The creditors have priority to be paid with the interest agreed. The stockholders will be paid, in accordance with "rest role", with the positive difference left between net cash flow and paid interest, respective net profit. If the net cash flow is smaller or equal with the interest that needs to be paid, then, the value of capital account is naught.

In conclusion, the expenses or *the loan capital is measured through interests, and the capital account costs through the dividend*. Thus, the sum of interest represents the capital account costs, and the interest is the capital account cost, both form the sum of capital cost.

The indexes used to analyze the capital cost (as an efficiency rate claimed by the investors point of view) they are taken from the most known models from financial theory. Thus, for *the capital account costs* it is used the efficiency after the CAPM model, for the actualization rate (**k**) it is used the Gordon Shapiro model and the financial efficiency ($\mathbf{R_{fin}}$).

Thus, the analyze purpose is to offer points of view to ensure the manager's financial decision, and on the base of the investment, representing one of the fundamental index that guides the company's financial activity. In theory they are a lot of analyses under restriction assumptions, from, the analyses in oblige company, the analyses of investment project financed integral from capital account, the analyses of investment project on company's structure.

GORDON & SHAPIRO

$\mathbf{V_a}=\int_0^{\infty} \mathbf{D_t \times e^{-k\times t} \times D_t}$, available in continuous time

$\mathbf{V_0 = \sum_{t=1}^{n} \frac{D_t}{(1+k)^t}}$, available in discreet time.

$\mathbf{P_t = P_{t-1} + r \times b \times P_{t-1}}$, the profit formula.

When $\mathbf{n \to \infty}$, $\mathbf{k = \frac{D_t}{Cb} + \frac{P_{net} - D_t}{VN}}$, the value of capital cost in condition of available of the model (the profit growth rate).

Va – the value of the asset at the moment of foreseeing. The value will be the stock market rate of exchange, not taken count of the incorrect evaluation possibilities by the market. The deductive cost will be compared from the model with the ones obtained through other methods. It is observed that adequate to the calculation methods, the stock market exchange rate it is a future price, the market estimating the expectation of investors in the future flows manner offered by the company. In opposition the accounting value it is a reflection of past events from the company's activity. An eloquent comparison between these two values can be obtained through the comparison between capital cost with the formula from upstairs (k, when $n \to \infty$) and the financial efficiency decayed in accordance with the formula:

$$\mathbf{R_{fin} = \frac{P_{net}}{Cb} = \frac{D_t}{Cb} + \frac{P_{net} - D_t}{Cb}}$$

Dt – the dividend in t period. After the Gordon&Shapiro model the future dividend represents a progression based on D0- the dividend on past period.

g - increase rate of dividend. In fact, g is the only one from the model of which estimation raises problems. In the model, g represents the product of two terms:

b – the profit distribution rate;

r – the efficiency of reinvested profit rate, the same with the company's efficiency rate.

Taken in consideration, that it doesn't exist a constant in the same rate, it has been chosen g to be the medium increase recorded in a period of time by an action. Taken in consideration that the inflation influences the company's course just through the appearance of differences from reevaluation and the net profit it shall be ignored. Another solution would be the calculation of an index equivalent, taken in consideration the upstairs mentioned influences. The used formula for g will be:

$\mathbf{g = \sqrt{\prod_{t=1}^{n}(1+g_t)} - 1}$, where $\mathbf{g_t = \sqrt[t]{\frac{C_t}{C_0}} - 1}$.

The base parameter of Gordon&Shapiro model, the increase rate g it is very difficult to be obtained on the historic data base. A study on the most transaction companies at BVB example, it takes as to conclusion that they are very uncommon cases of companies with constant increases. The negative values of the increases met in the majority of cases it stumble us to put in practice the described methodology, in which is calculated the increase as a geometric average of a previous values.

Thus it has been chosen a simpler variant, but with more restrictedly and less credible assumptions, calculated as a product between the efficiency rate of reinvested profit and the distribution rate of these, having dough about the truthfulness of the conclusions because of big differences registered from one year to another. The data from the columns with financial efficiency and the capital cost of k can be used more in comparison between the market's rate of exchange and the accounting values of assets.

Another mechanism can be underlined on the data base from this table is the attribution method of dividend. In a country with capital market developed, the dividend is one of the principle demands of stockholders, and the companies pay sometimes the dividend from the reserves so that they wouldn't challenge variations of courses. The strict "mathematic" loses the value in Romania's case. Most investors on the Romanian capital market follow the rapid increase of course or they don't follow under any form a direct profit being strategic investors. Thus, in over 50% of cases, the dividends of the most important companies are 0. Sometimes the profit is missing, some other times because is insignificantly size that don't justifies the expenses shown on the occasion of their agreement.

All this difficulties can be suppressed through capital market development from Romania and the fundamental reorganization of these. The main premise necessary to be carried out is the increase of the investor's interest, an impossible thing to achieve without a base of viable companies, with an investment policy and transparent development. Thus, will be solved an important problem: market liquidity who through it's consequently affects the stock market. It has been believed that all of this will happen along with the economic development which will offer the fundamental of competitive capital market.

CAPITAL ASSETS PRICING MODEL (CAPM)

$$\mathbf{R_i = Rd + (R_{PB} - Rd) \times \frac{\sigma_i}{\sigma_{PB}} \times \rho_{iPB}} \quad \text{or} \quad \mathbf{R_i = Rd + (R_{PB} - Rd) \times \beta_i}.$$ [200]

Rd – interest rate at the bonds issued for three months. For the data compatibility it shall be transformed the data equivalent rates in annual percents. Another problem is the existence on the same period of two types of bonds: interest bearer and the discount issued ones. The problem is that an efficiency calculation for each of these bonds goes to different results. An explication would be the restrictive access of a type of bonds. If would exist issues of both types for each analyzed period it shall be chosen the average to be a possibility of an alternative investment. When the rates are different it shall be chosen an average rate.

RPB – the efficiency of stock market. As a principal index it shall be used the BET index value for the analyzed period. The efficiency it shall be calculated after the formula: $\mathbf{R_{PB} = \frac{I_t - I_0}{I_0}}$

Where: I represents the index value at different moments (0, t). This calculation sits at the compatibility base of this rate with the rest of indexes, all of the rates being expressed in annual percent.

$\mathbf{\sigma_i \times \sigma_m \times \rho_{im} sau \sigma_{im}}$ - Co variation between the market efficiency's evolution and that of the analyzed title. It will be calculated on the base of two series of data, one of the market efficiency rallied in weeks average, and one of efficiency calculated on the base of stock exchange rates after the market's efficiency model. The period taken in calculation is of 18 months, equal to almost 75 weeks indexes.

$\mathbf{\sigma_{PB}^{\ 2}}$ - The variation of market efficiency in the analyzed period.

β is obtained reporting the co variation of market title at the market variation. In the previous estimations is considered to be constant.

Ri – asked efficiency. This obtained efficiency from the CAPM model can be used at the establishing of a balance course which through it's comparable with the market ones can lead to results that can offer a serious base of analyzing the market parameters. In the normal way the fair value represents a reper for the market's future evolution and for manager's decisions.

For the application of CAPM model is necessary to take over the data about an efficiency analyze of bonds with a three months term, which can be adapted after a period of 40 weeks. A problem to be solved was a comparison calculation of the two efficiencies that intervene in CAPM and the chosen of a period when the

---

[200] Sharpe, Williams „*Capital assets pricing: a theory of market equilibrium under conditions of risk*", The Journal of Finance, vol. XIX, no.3, September, 1964;

market efficiency outruns the bonds. This choice restricts the application of correct payment assumptions of the risk by the market; it has been considered next the assumption that all the investors are sensible at risk and ask a payment accordingly to this one. The analyzed period can be chosen on the upper method (efficiency without risk is smaller then the market one) and after the actualization data, being chosen the last month that carried out all conditions.

It has to underline the situation of companies depending on the way of period chosen, a period much longer that could eliminate from the graph some companies, and another period could change completely the sample's configuration. Intuition, the companies from BET calculation would "resist" at any change, the others not appearing constant in the samples about the most transactionated companies.

The situation of the rate of exchange – accounting value report makes difficult the analyses of calculated costs after the Gordon&Shapiro method, but after CAPM too. At the calculation of these indexes the purpose was to find the capital casts that could be drowned from the market. As long as is out of discussion a financial source, because of the small price offered by the market for a new asset, the calculation doesn't find a practical utility, the calculated costs loses it's significance. More, the lose of market liquidity, materialized in the price difference of offer-demand, don't take in consideration the significance of the sum which the stockholders are willing to pay per asset. From most of ways, the rate of exchange formation mechanism is based on a level where the interest disappears for the asset's sale; in general the buyers follow the profit from the missing of liquidity's demand offering always smaller prices. Like an example, it is offered a rate of exchange differences registered at the public offers of buying, that overtakes at a price that outruns few times the market price. This differences increase the supremacy of diversity of interests about the investment one.

The CAPM study shows the influence of market evolution on the principal assets on the market. Important in this study is beta obtained for each asset. It's previous use of beta in calculation of efficiency asked explicit by investors doesn't offer any useful results for conclusions. The efficiency list obtained doesn't resist to any significantly testing. Comparing the normate efficiency CAPM with the ones obtained by investors it sees the weak connection materialized through the big dispersion of results.

The calculation of beta was established taken in consideration the two measurement indexes of market efficiency: the BET index and the BET-C index. The justified choice of the parallel measurement of market efficiency forms is given by the inconvenience met at the two market indexes: BET is a restrictive representation (only ten companies) and the BET-C has in his calculation a series of companies of which the liquidity is minimum, some not being transactioneted for markets. As expected, the results where completely different, each one reflecting a different face of reality.

In the calculation of beta's case on the co variation of assets base: with BET rate of exchange, all companies that comes in the index calculation have registered positive values and at near majority 1 (Dacia's- 0,890674, Terapia-0, 67948). At some assets the market increase period has dovetails with a faster growth of exchange rate, the beta value being more up then the normal level (ALRO Slatina-2, 48015, Arctic Găeşti- 4, 28626). In the other companies case the beta index has known a large scale of values, the conclusion being that not the evolution of BET index establishes significant variation in the assets rate of exchange.

When the market efficiency is considered to be the BET-C it is observed a bigger spreading of values, more than half mark evolution of exchanging rate in reverse way the market evolution. In an ensemble observation, the majority of companies negative correlated with BET-C are positive correlated with BET. A study of these two indexes specific feature on the analyzed period takes at the conclusion of a superior variation of the calculated efficiency on the base of BET index (0,040233) given by BET-C (0,009502), co variation between the two indexes being positive (0,01709). This aspect can be interpreted as a variation in the same way of indexes. The BET-C index being calculated on a bigger base of assets, lots of them having immobile rate of exchange, is less mobile then BET, has in essence only transactioneted assets.

In Romania, the transparency and the completitude of financial information are in continuous development, but they found in the incipient phase. Thus, to have a necessary detailed information for the elaboration of a global study must be taken real information of financial indexes that should dovedail in the fundamental way with the one asked by theory. The main problem that it has to meet and offered as an example is the publishing of data about the debt and expenses with the rates. Thus the debts are not detailed after their nature in financial and exploitation, the majority of information referring generic to the sum of debt. In the expenses case, from the total of expenses are distinguished only the exploitation expenses, but for a fundamental analyses of loan capital costs is necessary a detail at the credit contracts level with the banks, about what the data are practically non existing.

Debt financing of investment projects, used to complete internal sources, has benefits that increase company value (tax shields from interest payments deduction), but also implies costs of financial distress (bankruptcy costs and agency costs) that decrease market value of debt and company value. In this paper, we discuss how taxes affect financial structure choice and we estimate tax shields from debt financing for an investment in real assets, using four different models developed in financial literature.

Key words: real assets investments, debt financing, tax shields, marginal tax rate

Role of corporate and individual income taxes in choosing financial structure

Although all companies operating in a national territory face the same statutory corporate tax rate, *marginal tax rate* depends on tax shields that a certain company could obtain. We can define *effective tax rate* as the statutory rate multiplied with probability of having positive taxable income that allows tax benefits.

Mackie–Mason [1990] establishes a substantial effect of taxation on financial structure choise, which becomes more important as company approaches the point where tax benefits source exhausts. This means that deduction of every unit of interest must be appraised using a marginal tax rate as decreasing function of interest expenses.

Graham [1996] achieves important results in this research field. He builds a complex simulation methodology to estimate marginal effective tax rate (set as weighted average using probabilities of not paying income taxes), used later in his study in year 2000. The average net value from deduction of interest expenses is about 4.3% of market value of companies in the sample. They estimate net advantage from deduction of the last unit of interest payment to 13–25% for extremely profitable companies and 8–15% for profitable companies. Present value of tax shields from debt financing is about 9.7% of firm market value. Kemsley and Nissim [2002] reach to a similar result (10%). In this particular sample, tax shields represent about 40% of market value of debt. Graham [2001] returns to this item simulating marginal tax rates for thousands of US companies and supplies empirical evidence that tax benefits from debt financing are between 5 and 10% of market value for a company, reconfirming his previous results.

Empirical studies demonstrate that debt financing becomes more attractive to investors as effective marginal tax rate enhances. As tax shields from other sources than debt (for instance, depreciation) increase, marginal tax rate decreases and debt financing is discouraged. The two different sources of tax shields (operational and financial) are interchangeable.

Assessment models for tax shields from debt financing

Many authors propose alternative models to estimate the present value of tax shields from debt financing. Most frequently used formulas are presented in Table 1 (VA[a,b] is the present value of cash flow “a” discounted with rate “b”). We notice that discount rate for cash flows obtained because of interest expenses deduction is not the same for all models and it depends on kinds of risk attached to these cash flows.

Modigliani–Miller [1963] (from now on MM) consider that tax shields are not risky, so we can use risk free rate (r_f) as discount rate and the present value for these cash flows is $D \times \tau$. However, the taxation level of the income for individuals also influences tax advantage. That is why Benninga and Sarig [1998, pp. 259] consider corporate and individual taxation (Miller [1977]):

$$\text{PV (tax shields)} = \sum_{i=1}^{\infty} \frac{[(1-\tau_d) - (1-\tau_e) \times (1-\tau)] \times Dob_i}{[1 + (1-\tau_d) \times r_d]^i}$$

Myers [1974] notes that tax shields have the same risk with debt, so the discount rate is the interest rate r_d. In fact, only tax benefit for the first year is certain and we may discount it with rate of interest. For subsequent years, the debt value depends on the project market value V^L and the level of fixed leverage L ($L \times V_L$). Because of uncertainty of realizing tax shields from debt financing, its risk changes over time and the discount rate is cost of equity capital for unlevered company (r^U), which includes only the operational risk[201]. The amount of all these tax shields obtained in perpetuity is:

$$\text{PV (tax shields)} = \frac{D_0 \times r_d \times \tau}{r^U} \times \frac{(1 + r^U)}{(1 + r_d)}$$

Other cited authors are using cost of capital for unlevered company (r^U).

Authors	**Assessment models**
MM [1963]	PV [$D\tau r_f$; r_f]
Myers [1974]	PV [$D\tau r_d$; r_d]
Miles and Ezzell [1980]	PV [$D\tau r_d$; r^U]$\times(1+r^U)/(1+ r_d)$
Harris and Pringle [1985], Ruback [2002]	PV [$D\tau r_d$; r^U]
Damodaran [1994]	PV [$D\tau r^U - D\times(r_d - r_f) \times(1-\tau)$; r^U]
Fernandez [2004]	PV [$D\tau r^U$; r^U]

Table 1. Assessment models for tax shields from debt financing

There are isolated opinions that consider that the supplementary value coming from tax shields is not equal with the present value of tax shields. For instance, Fernandez [1994] emphasizes that estimating discount rate for these cash flows is a challenging task because the value of tax shields from debt financing (VTS) is given by taxes paid by unlevered company (G_U) minus taxes paid by levered company (G_L), while each of them has a different level of risk: VTS = $G_U - G_L$.

Cooper and Nyborg [2006] contradict this point of view. They demonstrate that the value of tax shields is equal with the present value of tax shields. The surprising result of Fernandez [1994] is due to wrong usage of an argument, valid only for MM [1963] model.

Case study

In this section, we focus on appraisal of tax shields from debt financing for a project in construction materials field. A rigorous and detailed analysis of the project, assessment of free cash flows and discount rate was performed before and it is not the purpose of this study. That is why we concisely present some elements, to create the basis for further analysis. We estimated free cash flows in USD because some cost elements are also specified in USD.

---

[201] PV (tax shields, year 1) = $\frac{D_0 \times r_d \times \tau}{(1+r_d)}$, PV (tax shields, year 2) = $\frac{D_0 \times r_d \times \tau}{(1+r^U)^2} \times \frac{(1+r^U)}{(1+r_d)}$,

PV (tax shields, year 3) = $\frac{D_0 \times r_d \times \tau}{(1+r^U)^3} \times \frac{(1+r^U)}{(1+r_d)}$ and so on.

Operating period for analyzed investment is ten years (2008–2017). The cost required to implement the project is 6,670 thousands USD, consisting of land (280 thousands USD), buildings (270 thousands USD) and technology (6,120 thousands USD). Working capital investment of 244.6 thousands USD for year 2008 depends on estimated turnover. Finally, nominal free cash flows are discounted with nominal cost of equity capital of 18.3%, resulting NPV of 2,733 thousands USD for analyzed project.

Internal financing source is 2,018.6 thousands USD (net income from previous years) and it is used to entirely finance land, buildings, working capital and 20% of technology value, while 80% of equipment purchase value (4,896 thousands USD) comes from debt financing. Valuation of the tax shields is similar, no matter what kind of debt we use. That is why we analyze a source of debt financing used for 10 years (life of the project). Debt refunding is done by 120 fixed monthly mensualities, starting in January 2008. Annual nominal rate of interest is 10.5%. The commission of 2% is retained from the loan, so that debt raised is 4,985.7 thousands USD (the commission represents 99.7 thousands USD of this amount).

Monthly rate of interest is 0.875% and value of a monthly mensuality is 67.27 thousands USD. Table 2 illustrates annual interest payments. The financial leverage, determined in concordance with the Fiscal Code, as annual average value of long term debt divided to annual average value of equity capital, does not exceed 3, which means that interest payments are entirely deducted in the same year.

Thousands USD

YEAR	2007	2008	2009	2010	2011	2012	2013	2014	2015	2016	2017

Table 2. Leverage and deducted expenses associated with debt financing

A company could not benefit from the tax shields from interest deduction if operating profit (EBIT) is negative or it is positive, but lower than the interest payments for debt. Because of the time value of money, such an advantage is less valuable if it is delayed.

Table 3. Net income and tax shields from debt financing

For our case study, EBIT for year 2008 is less than the expenses with interest payments and commission, so the tax shields is partly obtained in year 2009, when the net loss is recovered. Subsequently, tax shields are effectively realized in the same year when interests are paid, because operating profits have substantial positive value (Table 3).

In column (2) of Table 4, the interest and commission payments are "carried forward" in years when the tax shields are effectively generated. Corporate tax rate of 16% multiplied with interest expenses deduced from EBIT represents the nominal tax shields (column (4) – this procedure is valid only for the first three methods).

Present value of tax shields – Myers [1974]

Monthly effective interest rate of 0.9158% (annual rate of 10.9896%) is determined as the internal rate of return that equals the amount of capital borrowed with present value of the 120 mensualities: $4{,}896 = \sum_{t=1}^{120} \frac{67.27}{(1+\mathrm{RIR})^t}$. Present value of tax shields is 343.6 thousands USD (column (6) of Table 4).

Present value of tax shields – Miles and Ezzell [1980]

Tax shields adjusted with $(1+r^U)/(1+r_d)$ are discounted with the cost of equity capital (18.3%) and have a value of 295.7 thousands USD (column (8) of Table 4).

Present value of tax shields – Harris and Pringle [1985], Ruback [2002]

Benefits gained from tax shields associated with debt financing are liable only to operational risk, so the discount rate for unadjusted tax shields is still the cost of equity capital (18.3%) and have a value of 277.4 thousands USD (column (10) of Table 4).

Present value of tax shields – Benninga and Sarig [1998]

This method is preferable if external financing is gathered from individual investors that pay income taxes. For Romania, the three tax rates are equal to 16% and parameter used to adjust interest payments is $[(1-0.16)-(1-0.16)\times(1-0.16)]$ = 0.1344. In this situation, the tax shields have the same risk with debt and the adjusted discount rate is $(1-\tau_d)\times r_d$ = 9.23%. The present value of these cash flows is 363.7 thousands USD (column (13) of Table 4).

Table 4. Present value of tax shields from debt financing

Conclusions

Estimation results from Table 4 are quite different (from 277 to 364 thousands USD). As operational profits are high enough (excepting the first year) and allow interest payments deduction, the company faces only a financial risk, so the second and the third model are not appropriate in this particular case.

If the external financing proceeds from individual investors (bondholders) we can use Benninga and Sarig [1998] assessment model. If an institutional investor (a bank or a leasing company) provides financing, is more appropriate to use APV model of Myers [1974].

Anyway, the two values are close enough (364 thousands USD and 344 thousands USD) and represent about 13% of the project value, if it is entirely financed with equity capital. Because of the low corporate tax rate (16%), the present value of tax shields is only 7% of debt.

CONTROL ON PUBLIC INTERVENTIONS THAT CAN AFFECT THE ECONOMIC COMPETITION

Voicu-Olteanu Cristina

Universitatea din Piteşti, Facultatea de Ştiinţe Economice, Jud. Argeş, com. Bascov, nr. 58 B, e-mail: voltcristina@yahoo.com

Abstract: "State aid policy" represents the legal approach regarding state aids, meant to ensure the predictability and an increased transparency for the initiators and suppliers or state aid, for the business environment, as well as for the internal and international financing institutions, regarding the orientation of investments and of incentives they can benefit from, the definition of the conditions to access those financial incentives, as well as the obligations thereof.

Key words: State aid policy, low taxation, NUTS

Introduction

Article 87 of the Treaty stipulates that "any aid awarded by a Member State or from state resources, in any way, affecting or menacing to affect the competition by favouring some enterprises or the production of certain goods, shall be considered, whether affecting the commercial relationship among the Member States, as incompatible with the common market", so it has a detrimental potential when: it grants an economic advantage to the beneficiary, it is offered selectively to certain companies or for manufacturing certain goods, it can affect the competition or the commercial relationship among the Member States.

But not all state aids are forbidden. The main situation where the state aid is allowed is when it has a social character, being offered to the individual consumer, provided that these aids be compatible with the domestic market, such as:

- aid of promoting the development of certain activities or areas;
- aid for promoting the execution of a project of European interest or for repairing some serious disturbance in the economy of a Member State;
- fiscal subsidies admitted within the development programmes.

Regimes of preferential taxation

OCDE issued in 1998 a report "Competition affected by excessive taxation – a global problem". The key factors in identifying and assessing the regimes of preferential taxation:

a) Zero tax or the effective low taxation quota or an effective low taxation quota applied to relevant incomes is the starting point necessary to determine whether a preferential taxation regime is harmful. The zero tax or the effective low taxation quota can occur when the taxation graph rate is low or from the way a country defines its taxation basis.

b) The "restriction" regime: the restriction represents a clue that, through the preferential tax regime applied by the respective country, it has the potential to create harmful chain reactions. Thus, the restriction can be:

c) a regime that can exclude the resident tax payers explicitly or implicitly from benefiting from it;

d) the enterprises benefiting from this regime can be forbidden to function on the domestic market, explicitly or implicitly.

e) Lack of transparency: non-transparency is a wide concept including the favourable application of laws and regulations, negotiable tax provisions and inability to apply the available tax practices on a large scale.

State aid awarded in the EU Member States, 2006

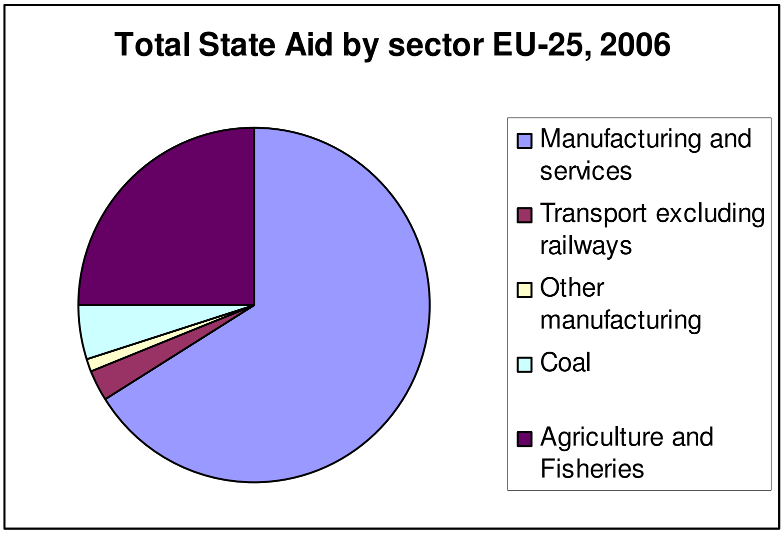
Source: European Commission, Economic forecast Autumn 2007, State Aid Scoreboard

In relative terms[202], State aid amounted to below 0.6% of EU Gross Domestic Product (GDP) in 2006. This average hides significant disparities between Member States: the share of total aid to GDP ranges from 0.4% or less in Belgium, Greece, Italy, Luxembourg, the Netherlands and the United Kingdom to 1% or more in Latvia, Hungary, Malta, Finland and Sweden. The high proportion in some of the EU-10 Member States is due largely to pre-accession measures which are being phased out under transitional arrangements or limited in time. In Sweden, it can be attributed to the very high amounts of aid for environment and energy saving which represents 86% of total aid. In Finland and Latvia, the explanation can be found in the relatively large amount of aid to agriculture which represents almost 75% for Finland and around 67% in Latvia. The EU average of State aid for industry and services expressed as percentage of GDP hides differences between Member States. The sharpest falls can be observed in Czech Republic, Cyprus and Malta, largely due to the phasing out of pre-accession measures, and in Poland due to the declining aid to the coal industry. Ireland, Denmark, Spain and Germany experienced also a significant decrease. In 2006, around 65% of State aid in the Member States was earmarked for the manufacturing and services sectors. A further 24% was directed towards agriculture and fisheries, 5% for coal and 3% to the transport (excluding railways) sector and the remaining 1% went to other non manufacturing sectors. The sectoral distribution is relatively stable over time with the exception of the coal sector which is clearly decreasing.



The state aid policy

“The state aid policy” creates the premises for a better orientation of state aids available to satisfy the economic development priorities of Romania in compliance with the adopted national and sectorial strategies. The document deals with the issue of state aids in compliance with the development objectives contained in the Lisabona Strategy, reviewed, and with the nationally adopted programmatic documents:

- The governing programme for 2005-2008;
- The National Development Plan 2007-2013;
- The Sustainable Development National Strategy of Romania “Orizont 2025”;
- The sectorial strategies adopted by the Romanian government.

“The state aid policy” contains the general objectives, the priorities that shall benefit from the respective support and also the community legislation applicable for state aid. The necessity of establishing a balance between necessities and available resources imposed the necessity of prioritizing the domains benefiting from support by granting state aids, thus establishing three categories of priorities:

- priorities identified by the National Development Plan (PND);

[202] For the purposes of the scoreboard, aid to the manufacturing includes aid for steel, shipbuilding, other manufacturing sectors, aid for general economic development and aid for horizontal objectives including research and development, SME's, environment, energy saving, employment and training for which the sector is not always known.

- priorities relying on financial instruments such as state aid granted only from state resources;
- priorities related to the privatization process.

By OUG no. 117 of 21st December 2006, the state aid national procedures were established in order to apply articles 87-89 from the Treaty of establishing the European Community and the secondary legislation adopted. Thus, the Competition Council shall be the contact authority in the relations between the European Commission and the public authorities, including the public institutions involved in the privatization process and other state aid suppliers and the state aid beneficiaries, involved in the state aid procedures. The phenomenon of distortion of the competitive relations among countries is favoured by their involvement in a process of concentration that can become dangerous and by the existence of state aids or by the persistence of some monopoles in favour of private companies benefiting from privileged advantages

The concept of state aid was construed by the Commission and by the Court of Justice very widely, so that it includes any public aid granted by central authorities, as well as the aids given by local or regional authorities. Moreover, the aid can come even from private bodies or other bodies on which the state, a public institution, a local or regional authority has, directly or indirectly, a powerful influence.

The range of state aids is larger than that of subsidies and contains all measures that, ia a way or another, involves the state resources. The selective character is vital for a tax measure to be considered as state aid.

In most cases, state aid creates discrimination between competitors. The form of the aid (tax deductions, guarantees for loans) or the reason for granting it, are not relevant. It is the effects generated by state aids on the competition on the market that counts.

In the opinion of the Commission and of the community courts there are four cumulative conditions according to which an economic measure or transaction in which the state is involved can be considered as concerning a state aid. They are:

- measure to involve the use of state resources;
- measure to award an advantage to the beneficiary company/companies;
- measure to distort or to threaten with distortion the competition at the cross border level.

Therefore, we can conclude that a measure shall be considered as state aid under the following circumstances:

1. Involving the use of state resources

Pursuant to Article 87(1) EC, the state aid can be granted "by the state or from the state resources". So, the form in which state aid is granted is irrelevant concerning the control of state aid: the effect of the measure is important. So, the distinction between "aid granted by state" and "aid granted from the state resources" is made to clarify that not only the aid granted by the central government, but also the aids granted by the local and regional state authorities and by the public or private bodies acting on behalf of the state are included in the exclusive control range of the Commission. As for the effective form in which the aid is granted, the state aid does not only refer to direct expenses made from the state resources (ie subsidies to the budget), but also to the indirect transfers of state resources (thus incurring revenue losses for the state), this concerning the generally accepted jurisprudence. Indeed, a revenue loss from taxation is equivalent to consumption of state resources, regardless of the level, regional or local, at which the loss is incurred.

2. Awarding an advantage to the beneficiary company/companies

The interpretation of the concept of "awarded advantage" proved to be vital in ensuring a large range of coverage for the community regulations concerning state aid. Starting from the first years of applications of the state aid community regulations, the European Court of Justice (ECJ) defined the notion of state aid as "including any measure, no matter its form, reducing the burden normally borne by a company, even if it is not a direct subvention *stricto sensum*, but it is equivalent to it in the virtue of its nature and effects". Accordingly, in Fiscal Aid Notice, the Commission only reiterates a well-known concept: a tax measure forgiving the companies of burdens normally borne from their own resources, measure satisfying the second criteria from the state aid definition. The Commission also gives some examples of tax measures awarding such an advantage:

- Measures reducing the tax basis (as well as special deductions, special or accelerated depreciation arrangements, inclusion of contingencies in the company balance sheet);
- Measures involving a partial or total reduction of the amount owed as tax (eg. tax exemptions or fiscal credits);
- Deferrals, annulment, even exceptional rescheduling of the debts to the budget.

Moreover, even the tax measures which ultimately are not equivalent to a loss of revenue for the state, as well as tax deferrals and payment deferrals to the social security budget, are also included in the state aid category, as long as this kind of facilities offer the beneficiary companies an advantage – allowing them to use amounts of money that would not be at their disposal otherwise.

3. It is selective

Article 87(1) EC is applied only to the selective measures, ie those which "favour certain activities or the production of some goods". The application of the selection criteria implies the assignation of a distinction between general application measures, ie those measures applicable to all companies and sectors, and the measures generating advantages only for certain companies or sectors. Though, many times it is difficult to put a clear line between the general support measures and the selective ones. The tax measures are difficult to be assessed according to this criterion and to the fact that community law considers that the selectivity of certain tax measures can be justified by "the nature or general sketch of the system" (such measures not being covered by the state aid EU regulations).

4. Affecting the commercial relationships between the Member State

The interventions involving state aid lead to the modification of commercial relationships between the Member States and to the distortion of competition. The two conditions are organically dependent; if granting an aid leads to strengthening the position of an enterprise compared to others acting in the community area, those who did not benefit from an aid are discriminated and affected negatively.

The EC Treaty deals with this in three articles, from 87 to 89 (the former articles 92 – 940. Article 87 (former 92), first paragraph, stipulates that "except the derogations provided herein, there are incompatible with the Common Market all aids granted by the state or from the state resources, regardless of their form, as long as they affect the changes between the Member States, distort or threaten to distort the competition, by favouring certain enterprises or activities".

As absolute forbiddance of aids would be impossible, the second paragraph of Article 87 mentions the situations where aids are compatible with the common market regulations, such as:

- social aids granted to individual consumers, subject to non discrimination related to the origin of such products;
- aids meant to remedy the damage caused by natural disasters or extraordinary events.

Also, the third paragraph mentions the situations where the aids can be considered compatible to the Common Market:

- aids meant to favour the economic development of the areas where life standard is very low or unemployment is very high;
- aids meant to promote the achievement of an important European project, or to remedy serious disturbances of the economy in a Member State;
- aids meant to make easier the development of certain activities or certain economic areas when not affecting the commercial and competitive conditions within the Community;
- aids meant to promote the culture and the preservation of the patrimony when not affecting the commercial and competitive conditions within the Community;
- "other categories of aids determined by the Council's decisions" (issued with a qualified majority, based on the Commission's proposal).

In Romania, the main aid plans involving financial aid are:

- the plan for disadvantaged areas (D areas) offering a series of tax facilities to companies which invest in the area;

- the plan for industrial parks offering a series of tax facilities to those companies specialized in rendering services to parks infrastructure;
- the plan for free areas offering tax facilities to companies which invest in the area.

Compatibility between the Romanian plans of regional aid and the acquis communautaire

The plan of D areas: the geographical coverage of this plan is more reduced than the eight "development areas" established at administrative level NUTS II (in fact, the 35 D areas covers territories corresponding to administrative areas NUTS IV, or even V), the concentration on smaller geographical levels can still be considered acceptable and pursuant to community regulations as long as they can be justified from the perspective of the regional development strategy;

NUTS is the acronym for Nomenclature of Territorial Units for Statistics, created by Eurostat in order to have a coherent and unitary territorial framework. It was used for the community legislation regarding Structural Funds starting with 1988 (at present, this nomenclature includes 15 EU countries, with 78 levels NUTS I, 210 levels NUTS II and 1093 levels NUTS III.

The plan for industrial parks: this plan does not identify particular issues concerning the compatibility with the community regulations. Industrial parks are confined area where they deploy economic activities, scientific research industrial production activities and services, activities of capitalizing the scientific research and/or technological development, with specific facilities, with a view to capitalize the material or human potential of the area. The industrial parks are based on the association in participation between public administration authorities, economic agents, research and development institutes and/or other interested partners. There are certain aspects regarding the future operation of the plan, as there can be problems regarding the compatibility with the community regulations in case the operating companies will offer services on preferential terms to different companies. These "preferential" services can affect the competition, especially if the companies in advantage belong to some "sensitive" sectors.

The plan for free areas: is incompatible with state aid EU regulations, as the income tax exemption for the entire period of existence of the area (of maximum 50 years) represents an operation aid (regarding the daily activity of the respective company and it is not related to supporting a new investment project). This facility is modified in practice so that it is strictly related to an investment project or to the creation of new jobs (modified so that it includes the conditions of approving the operating aids: temporary character, progressive reduction).

CORPORATE TAX COMPETITION IN UE

Voicu-Olteanu Cristina

Universitatea din Piteşti, Facultatea de Ştiinţe Economice, Jud. Argeş, com. Bascov, nr. 58 B, e-mail: voltcristina@yahoo.com

Abstract: The taxation of corporate income creates huge difficulties in an open economy; each government tries to take advantage by undercutting the tax levels of other governments or offering superior levels of public services. The existence of a strong interrelation implies that competition between countries, interested in capturing the tax base of the whole market, becomes more significant because capital will follow the maximisation of profits in the global market. The most competitive countries will have an advantage in terms of total revenue in the short run and a greater rate of economic growth in the medium-long term.

Key words :tax policy ,corporate income tax, CCCTB

Introduction

Fiscal degradation occurs through the erosion of the tax base resulting both from tax competition (the relocation of taxable bases to other countries) and from the development of the underground economy (the relocation of taxable bases towards the black market). The former depends on the differential between effective rates of taxation, the latter on their absolute level. Firms in Europe countries increasingly adopt global strategies and establish overseas sales, marketing, production and research units to cope with new competitive pressures. The notion of control allows all of a company's activities to be attributed to the controlling investor. This means that variables such as a company's turnover, staff or exports are all attributed to the controlling investor and the country from which he or she comes.

Elaborating the tax policy of a state is a very complex act of decision that should be based on the efficiency criterion. Thus, they have in view the reduction of fluctuations, of economic instability, the protection of incomes and the stimulation of economic development. Taxes and the other levies to the state budget modify the initial distribution of incomes, influencing the economic activity, the investments and the consumption. Fiscal degradation affects every major source of taxation (consumption taxes, business taxation, capital income taxation, social contributions), its effects differ greatly according to the nature of the tax concerned. Even consumption taxes, which are harmonized to a much greater extent than direct taxes, are not immune from the risk of fiscal degradation

As foreign investments stimulate the economic growth, the degree of unemployment, the transfer of technology and know-how, the increase of competition and the increase of revenues from taxes and duties, the countries strive to attract investors through their adopted tax policy. The tax policy is essential for all Member States, and the actions of a country can have an influence not only on that country, but also on the neighbouring countries. Therefore, on the European Union unique market, the Member States should cooperate and should not perform actions in different directions. The tax competition can be materialized also in measures considered as non acceptable al the EU level, such as:

- Attracting some funds from abroad and protection at the same time the funs of their own residents;
- The existence of some tax measures that can be considered isolated within the specific of the national economy;
- Granting some tax benefits if there is no effective economic activities, and others.

Using criteria like those mentioned above, the 1999 Primarolo report identified 66 harmful tax measures at the level of the European continent, such as: the regime of distribution centres in Belgium, the regime of coordination centres in the Basque country, the regime of the Luxembourg holdings established pursuant to law in 1929, the regime of the international financial services centre in Dublin, the regime of the Portuguese free areas in Madeira and Azore, the regime of the financial and insurance services centre in Trieste, the rules applicable to foreign insurance companies in Sweden, the tax treatment of the naval companies in Germany, Greece, France, Italy, Netherlands, the regime of the insurance companies in Gibraltar, the deductions for investments in mineral processing in Greenland etc.

The relation between the tax policy and investments establishes that, by its contents, the tax policy can favour the expansion of investments, and the investments, by their volume, have an influence on the tax incomes collected, thus determining the economic growth. Stimulating investments leads to the creation of new production capacities, expansion of the already existing ones, also to the increase of taxable incomes that largely contribute to the formation of state budgetary incomes. As the countries compete among them for investments, on international level, each government will try to implement a taxation rate at a reduced level.

Corporate income tax rate in OECD's European countries (2007)

Country	**Central government corporate income tax rate**[203]	**Adjusted central government corporate income tax**[204]	**Combined corporate income tax**[205]
Austria	25.0	25.0	25.0
Belgium	33.99	33.99	33.99
Czech Republic	24.0	24.0	24.0
Denmark	25.0	25.0	25.0
Finland	26.0	26.0	26.0
France	34.43	34.43	34.43
Germany	26.375(25.0)	21.9	38.9
Greece	25.0	25.0	25.0
Hungary	20.0(16.0)	20.0	20.0
Ireland	12.5	12.5	12.5

Source: www.oecd.org/ctp/taxdatabase

Thus, regarding the investors' taxation, we can see a discrepancy between the very low taxation quotas used by the new Member States compared to EU, as well as the existence of a narrow taxation basis (the case of Estonia) which was partially widened with the harmonization of the European economic policy.

The recently adhered countries benefit from a very low effective investment taxation level compared to the one used within the union. In some OECD Member States (the Czech Republic, Hungary, Poland and the Slovak Republic) the indicator tax/GDP decreased in 1999-2002, except for the Czech Republic, where it increased from 38.9 to 39.2. As for Hungary, this indicator decreased from 39.1 to 37.7, in Poland from

[203] This column show the basic central government statutory (flat or top marginal) corporate income tax rate, measured gross of a deduction (if any) for net central tax.
[204] This column show the basic central government statutory corporate income tax rate adjusted to find the net rate where the central government provides a deduction in respect of sub-central income tax.
[205] This column show the basic combined central and sub-central (statutory) corporate income tax rate given by the adjusted central government rate plus the sub-central rate.

35.5 to 34.3 and in Slovakia from 34.4 to 33.8.[206] In the last 14 years, the taxation level in EU decreased by 32%, reaching to 25.8%. These diminutions are especially due to the adhesion of the 10 new Member States in 2004.

Generally, the effect of the expansions in 2004 and 2007[4] was a decrease of the taxation average in EU, as in most of "old" Member States the taxation increased in 1995-2000. Except for Ireland, where it decreased from 33.1% in 1995 to 30.8% in 2005 – being one of the factors of the rapid economic expansion of the "Celtic tiger". Also, in the Netherlands it decreased by 2% from 40.2% in 1995 to 38.2% in 2005. The lowest taxation quotas of the company incomes are in Bulgaria and Cyprus – 10%, Ireland – 12%, Latvia – 15%, Romania – 16%, Lithuania and Hungary – 18%. The highest quotas are in Germany – 38.7%, Italy 37.3%, Malta 35%, and France 34.4%. The 27 EU average is 24.5%, and 28.5% in the Euro area. These taxation differences partially explain the delocalization phenomena of several production units towards to countries with reduced taxation, firstly because the new Member States rely more on indirect taxes rather than the direct ones, and secondly because of the tendency of Central and Eastern European countries especially to increase the competition in order to attract foreign investments. So, these implemented the necessary tax reform in order to modify the taxation of the income of soviet inspired investors[207], thus orienting the economy towards the modern policy trend.

The preparation of a coherent tax strategy should take into consideration the taxes that can occur regarding the operations of each company from the group in different tax jurisdictions, *ie* direct taxes (income tax, dividend tax, non resident income tax) and indirect taxes (VAT, customs taxes, excise taxes). The preponderance of different taxes and duties within the tax strategy is different according to the objectives of the performed project, the particular activity domain of such company and the areas of interest for the future (eg. expansion on international level, reorganization of distribution activity, sale of a business line, obtainment of significant financing, change of shareholders etc.).

The tax race is the reason that makes the EU to show concern towards the countries that establish very low taxation quotas. The taxation effective quotas take into consideration the statutory quotas, and also include aspects related to taxation basis, such as the provisions for accelerated tax depreciation, taxation credits etc. Thus, Baldwin and Krugman[208] published a theoretical pattern of industrial agglomeration s where the tax policy, even under the capital mobility conditions, does not lead to competitive taxation quotas due to rentals. Therefore, there will be no competition of excessive taxation quotas between "center" (old EU Member States) and "outskirts" (new Member States), but a "keen race" among the latter is not to be excluded.

The responsibility of adopting the tax policy within EU comes to the Member States' governments, this being the main reason why the tax harmonization is characterized by inconsistency (in most cases, unanimity is necessary to adopt decisions).

The tax measures providing a significantly low level of effective taxation, including the zero tax, compared to the quotas applied in general within the member States, are considered potentially harmful. The following aspects are considered when assessing the harmful potential of tax measures:

- Analyze if the advantages are granted only to non residents or only concerning the transactions performed by non residents, and if these advantages are protected on the domestic market so that they do not affect the national basis of taxation;
- Pursue if the advantages are granted without performing a significant activity on the Member States' market, thus establishing if these offer such tax advantages;
- Determine if the rules for profit determination regarding the activity of a group of multinational companies "are different from the internationally accepted principles, especially from the rules agreed within OCDE";
- Examine the tax measures from the perspective of the advantages offered, including the cases where the legal provisions are relaxed at the administrative level, in a non transparent way.

Approaches on tax competition

A great part of the specialty literature, including Wilson[209] deals with the basic pattern of tax competition. This supposes that the production of goods is determined by two factors: work that is immobile between areas and the capital which is mobile. Also, they are considered the zero commercialization costs and the fact that the companies face a perfect competition. Within this pattern, the authorities choose the imposition of the capital in a Nash game.

The standard approach supposes the comparison of balance rates when the capital is involved in migration operations or not. The intermediary result, called balance taxes, was modified and expanded by the researches made in the domain. In one of these approaches, in which the authorities assumed the deviation from the maximization of social satisfaction, the tax competition can improve the prosperity by moving the balance rates closer to the social optimum in a second-best approach.

Ludema şi Wooton[210] studied the impact of globalization on the enhancement of tax competition, starting from the fact that both factors, having an influence on the mobility cost and on the commercialization cost, change. Their conclusion is that the decrease of commercialization costs can attenuate the tax competition, and the reduced mobility causes multiple effects. These authors, together with cu Andersson and Forslid[211], Kind, Midelfart-Knarvik and Schjelderup[212] pointed out that the concentration will give birth to the need of space for deploying the activity. Therefore, the state benefits from the tax applied on rents for the mobile factor, thus compensating the decrease of the commercialization costs.

The growth of European admission is not a new development, the commercial and natural barriers being eliminated several times starting with the 40s. To achieve the comparison, they start from the fact that Europe is divided in two parts: a central part benefiting from developed economies and a peripheral part characterized by developing economies. Also, they established that the aggregate taxation, represented by the incomes from taxes and duties in GDP, suffered modifications as follows: in the 70s, the precipice between outskirts and center increased compared to the 60s, while between 80-90s the difference reduced significantly, the high taxation countries trying to keep up with the other countries where there was a tendency to decrease it.

Both the European Union and OECD[213] (Organization for Economic Co-operation and Development) introduced towards the end of the 90s initiatives meant to stop the tax competition considered as *harmful*. Fuest, Huber and Mintz[214] emphasize in their research that there is a powerful pressure exerted by the increase of competition on the governments concerning the reduction of taxation.

The economic theories support the fact that the authorities have at their disposal two instruments of determination: tax rate and tax basis. In the standard pattern developed by Zodrow and Mieszkowski[215], then resumed by Wilson[216], one instrument is used – the tax on income produced by investing the capital. The introduction of corporative tax in the Zodrow, Mieszkovsky and Wilson pattern supposes its equivalence with a tax on the income brought by investing the capital plus a rent fee of the production factors. In other words, the fixed factor is taxed with a statutory rate plus a rate on the earning brought by the capital (call the effective tax margin rate).

According to Baldwin and Krugman, the European Union countries should establish common rates for taxes in order to avoid a *keen race* [217] with possible effects of welfare for the states adopting low levels. The starting assumption is the following: the other factors of influence being equal, the producers will orient towards the countries with more reduced rates, and the absence of a firm coordination to try to

reduce the taxes in order to attract investors will determine a competition that will reduce the taxation even more. In reality, there are factors that allow the differentiation. The welfare countries offer the capital the advantage of the existing solid infrastructure and of accumulation of experience so that they allow a higher taxation. But the balance should be carefully maintained because, if the taxation is too high, the phenomenon of capital migration will occur.

The mobility of labour within the European Union is undoubtedly lower than the mobility of capital: the globalisation and the closer integration of the capital markets and the accelerated penetration of the new communication technologies have done much to encourage the international mobility of activities, in particular in the financial sector. While liberalisation of the financial markets has considerably improved the efficiency of resource allocation and reduced the cost of financing, it has also widened the scope for tax planning and increased the opportunities for tax avoidance and evasion and thus helped to erode the tax base in many countries in the world. This concern was recognised by the Council when it agreed that the liberalisation of capital movements should be accompanied by appropriate tax measures.

The need for a more co-ordinated approach in taxation policy

There is a clear contrast between the need for progress in tax co-ordination and the decisions adopted so far in this area, which has been substantially lagging relative to many other area of European integration. Tax co-ordination at the EU level has suffered from two main obstacles: the decision making rules and the lack of an overall perspective showing the economic and social downside of failing to reach decisions.

Under EU law Member States are largely free to design their direct tax systems so as to meet their domestic policy objectives and requirements. However, national tax rules designed solely or primarily with the domestic situation in mind may give rise to incoherent tax treatment when applied in a cross-border context. An individual or corporate taxpayer who is in a cross-border situation may suffer discrimination or double taxation or face additional compliance costs.

Coordination and corporate tax base harmonisation : this initiative is complementary to the Commission's ongoing legislative initiatives in the direct tax area. The Commission believes that the only systematic way to address the underlying tax obstacles which exist for corporate taxpayers operating in more than one Member State is to provide multinational groups with a common consolidated corporate tax base for their EU-wide activities. The Commission has announced its intention to present a comprehensive legislative proposal for such a Common Consolidated Corporate Tax Base (CCCTB) in 2008.

However, the CCCTB will only apply to companies which are eligible and opt for it. There is still a more general need to ensure better co-ordination for the benefit of individual and corporate taxpayers and to prevent erosion of Member States' tax bases through mismatches and abuse.

This initiative does not aim to replace existing national tax systems by a uniform Community system. It seeks to improve the functioning of the 27 national taxation systems in the Internal Market by improving cooperation between Member States and better coordination of their rules.

REGARDS ABOUT THE STATE INTERVENTION IN IMPROVING THE NEGATIVE EXTERNALITIES OF THE ENVIRONMENT

Vuţă Mariana

Academia de Studii Economice din Bucureşti, Facultatea de Finanţe, Asigurări, Bănci şi Burse de Valori, Piaţa Română, nr. 6, sala 1104, mariavuta@yahoo.fr, 021.3191900/264

Abstract: The environment has an important role in the economic activity and in achieving a sustainable economic growth, this is way the article aims to present, starting from the economical principles of the environmental policies, the possibilities that the state has to influence the economical activity in the sense of diminishing it's negative impact upon the environment. The authors have presented other economic principles then the polluter payes that can be used by the state to influence the environment policies. It is stated that applying the economic incentives supposes the acceptance of the economic instruments used by the organs of the competent administrations, the polluters community and lately by the non working organisations that are more and more affected by the damages produces upon the environment.

Key words: environment, externality, environment policy

The European Union Treaty, adopted in 1991 at Maastricht and entered in function two year later, is stating in the exclusive act as main objective, the integration of the environment in all types of European Union politics introducing amoung the polluator-payer principle the subsidiary principle and the prudence principle.

The Amsterdam Treaty is focusing on the adopting procedures of the environmental communion acts, these assuring in the European Union an harmonious, balanced and sustainable development of the economic activities.

The prudence principle was introduced in Germany in 1970 when the financial planning had a great importance. By appling this the state has to realize a carefull planning in order to avoid the environmental damages. In Germany this principle was applied in 1980 against the acid rains, global warming and the North See pollution. After it's introduction in the European Union Treaty it has been adopted in different international agrements like the Bergen Declaration of the United Nation Economic Commision for Europa and at Rio Conference. Starting from a radical definition the principle is including notions like:

- Preventive action: the existence of a minimax strategy that supposes the minimization of the negative effects. In case of uncertainty these actions are recommended because they are less expenses and have as results the limitation of damages;
- Adequacy of the damage spreading: every action has to be analysed from a double perspective – cost and efficacy;
- Paying the ecology debts: based on the extention of the notion of responsability of the current generation that id producing damages upon the futures ones.

In co-operation with this principle their are others like:

- the efficiency principle which has as objective finding the ways to achieve the environmental goals by minimizing the costs, which favors the utilisation of the economic instruments to internalise the costs;
- the equity principle is justified by the transfer of the revenues obtained from taxes, penalities and fines suported by the ones that are plluting the environment, revenus that are transfered in favor of the poor regions or to the social community affected by the damages.

The subsidiary principle is based on the maerican experience which supposes a precise definition of the different levels of intervention. In this sense the European Commission is defining the actors (the community, the local, regional ar international authorities, the firms, the public and the consumers) and the actions (economical growth, research, communication, market).

In Romania[218] the frame law regarding the environmen protection is setteling the principles and the stategic elements that are leading to sustainable growth: the principle of precaution in taking decisions, the prevention principle, the reduction and the integrated control of the pollution through using the best available techniques for the activities that are producing meaningful pollution, polluator-payer principle.

Putting in practice these principles is bases on different mechanisms. One one side we have the ones that think that the state should regulate the activities of the resources users or of the pollution factors, or limit the range of action of these one's. These limits can be used in simultaneously with other types of restrictions like fines and penalities in case the threshold are overpassed. On the other side we have the ones that think that the state intervention is leading to less satisfactory results then in the absence of any regulations. In this case the state can use the economic incentives.

The goal of these stimulants is to force the ***polluators*** to reduce the toxic emissions through: taxes,even financial aids or by creating the market for a negociable passes, that are offering the choice between:

- diminishing the own level of pollution;
- maintaining a high level of polltion but paying others to reduce their own level under the legal limit.

But will the economic incentives have effects in the developing countries?

First, the regulations regarding the environment in the develop countries are stating fines and/or jail time in case of fraude. In most of the developing countries the justice is not often brought into discussion. This atitude is well knowed but little is done to change it[219].

Second, these regulations are not applied in the developing countries because it is almost impossible to control all the dispersed operations that are causing pollution.

In the developing countries there is another problem that take the form of the gap between the level of the elaboration, control and practicability costs of the regulations, on one side, and on the either side, we have the constraints of the budget and of the administrative means existing in these countries. In the develop countries the environment regulations assume a high degree of competence and fiscal power of the local and central authorities that are decreasing the elaboration, control and practicability costs.

Third, the penalties are set to an tolerating level and are not able to change the behavior of the traspassers. This is way in the developing countries the possibility to detect a violation of the regulations regarding the environment is almost nule and furthermore the penalty level should be fixed higher then the advantage obtained by infringing. Most times the penalties level is not fixed according to inflation this is way their level is considered negligible.

Fourth, in the developing countries the regulations are often influenced by the individual behaviors according to their own profit. It is in the best interest of the transpasser to pay part of the penalty to the clerk, like a small "attention", the later beeing poorly remunerate[220]. Increasing the penalties or intensifying the control is leading towards the increase of the compensations rather then to the decrease of the degradation of the environment.

We state that the regulations are not enough to reduce the pollution and they should be combine with other types of instruments.

To better use the economic instruments there are some conditions that should be taken into account, condition presented in the following table, and that are including: a suitable knowledge base, a solid judicial structure, competitional markets, administrative capacity and a proper policy.

The conditions are different putting into light the problems that are met in the developing countries.

[219] OCDE, L'utilisation d'instruments économique pour la protection de l'environment dans les payes en développement, 1989

[220] T. Panayoton, Harvard Institute for International Development, 1989

Tabel no. 1 Different methods to efficiently use the economic instruments in the environment policy

Conditions	Essential characteristic
Knowledge	the way the economic activity is affecting the environment; the way the environment is affecting the economic environment; the way the environment programs are made up and put up in practice
Judicial structure	the guarantee of the existance of the property rights indisputable and executory upon the resources; ascribing the judicial competences for the use of the economic instruments;
Competitional markets	the existence of a resonably number of buyers and sellers; the price should be establish according to the rareness of the resources
Administrative capacity	the capacity to realize and put in practice programs of economic incitation; the capacity to control the concordance of the programs; the capacity to make the laws and rules obeyed
Policy practice	receptivity to the environment improvement and protection policies

Another important element in putting in practice the mechanism of reglementation of pollution is the system of the property right. This system supposes that the owners should be able to transfer the properties, control the access to the resources and endure the costs tied to their management.

The regime of the common property where all the access rights are very good define can be receptive to the economic incentives. In the developing countries these systems can act upon the demographic growth, the technological evolution and the market of the products base on natural resources.

Both in the develop countries and developing countires (especially amoung the Eastern European countries) it has been proved that the administrators that are under the state administration are not taken accountable when it comes to the cost of the environment pollution.

But in order for the economic incentives to be efficient, the prices and the competition have to play an important part in the economic structure and the decisions made by the actors that are polluting by creating the competitional market. In this case the economic incentives are more efficient then the direct regulations (if there is a large number of sellers and buyers). On other markets (for example credit markets) the responsability and the inssurance are playing an essential role in the use of the protection programs of the environment. On these market the enterprises have difficulties in creating the sources use to sustain the environmental programs.

From the administrative point of view we consider that we should take into consideration some condition, that are according to the capacity of the public power to:

- draw up and administrate the instruments;
- control the lay on of the instruments;
- applying the conditions for the use of the instruments;
- modifying the instruments according to the circumstance.

In conclusion, the policymakers should dispose by enough financial resources and personnel in order to put in practice the propose instruments. This implies a compromise between a simple model which implies limitative efforts but will not produce the desired reuslts and a complex model capabile to realize the optimal result but it is over the administrative capacity.

Applying the economic incentives supposes the acceptance of the economic instruments used by the organs of the competent administrations, the polluters community and lately by the non working organisations that are more and more affected by the damages produces upon the environment.

THE ANALYSIS OF THE RELATION BETWEEN THE EVOLUTION OF THE BET INDEX AND THE MAIN MACROECONOMIC VARIABLES IN ROMANIA (1997-2008)

Zoicaş Ienciu Adrian

Făt Maria Codruța

„Babeş-Bolyai" University Cluj-Napoca, Faculty of Economics and Business Administration, codrutafat@yahoo.com

Abstract: Starting from the conclusions which result from conducting some similar empirical studies on the great stock markets, in this work, we have set as our goal to analyze the return series behaviour of the main index of the Bucharest Stock Exchange (BSE) - the BET index, during different periods of time, compared to the evolution of some macroeconomic variables, like interbank interest rates, inflation rate or unemployment rate. The results confirm that there is a weak relation between these variables, in what monthly data are concerned.

Keywords: stock market, macroeconomic variables, empirical study

Analysis of the evolution of the BET index between the 19th of September, 1997 and the 7th of February, 2008

The evolution of the most important index on the Romanian stock market can be looked at on several time horizons, depending on the envisaged objective. Yet, in general, a fertile image from the point of view of the information contribution with intuititive character[221], of the evolution of an index, is given by the graphic of point levels recorded by this one, ever since its launching. Thus, by dint of a simple graphical representation, most of the descriptive characteristics of the index and, indirectly, of the Romanian stock market, can be identified: evolution tendencies, the intensity of ascending and descending gaps, possible annualized cycles, the delimitations between the phases of the stock exchange cycle (accumulation, growth, discharge, decline), possible standard formations (patterns), etc.

Figure 1 represents, on a logarithmical scale, the evolution of the BET index, since its launch on the 19th of September, 1997, until the 21st of March, 2008, the evolution comprising a number of 2.602 daily stock exchange transactions. In the graphic, we have delimited the main subperiods of homogenous evolution, corresponding to the BET index, respectively secondary trend turning points, the main trend being obviously a growing one, starting with 1999. By looking at the graphical representation, one can talk about the existence of several distinctive periods in the evolution of the index, delimited as follows[222:]

1. September 1997 – October 1998: accelerated descending trend, with a -53 degree gap (1);
2. November 1998 - July 2001: moderated ascending trend with a 17,61 degree gap (2);
3. August 2001 – May 2005: accelerated ascending trend with a 35 degree gap (3,4);
4. June 2005 – September 2007: moderated ascending trend with a 21,41 degree gap (5);
5. October 2007 – March 2008: accelerated descending trend with a -46 degree gap (6).

---

[221] We can note that "ardent" adepts of the technical or charter analysis consider the graphic of a financial asset as a source of information which is enough to undertake the most sophisticated analyses, due to the fact that it comprises all available or not available information for the public, the past, present and future ones.

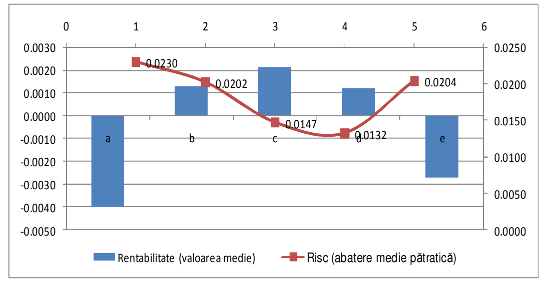
[222] At the end of the row which enumerates the subperiods, we have added in brackets the number representing those subperiods in figure 1.

If we were to characterize the five subperiods in relation to the classical phases of a stock exchange cycle, we can very easily place subperiod *a)* into the decline phase, subperiod *b)* in the accumulation phase, and subperiod *c)* in the growth phase. Somehow more subjective would be the placing of subperiod *d)*, in our opinion it represents a top discharge phase, or in the best case, a late phase of the growth period. Closely correlated to the evolution on international markets, subperiod *e)* obviously represents an adjustment tendency.

Figure 1: BET index evolution between September 1997 and February 2008

Source: Author's own manipulations in MetaStock.

Figure 2: The evolution of the risk-return relation in the case of the BET index



Source: Author's own manipulations in MS Excel

In order to quantify the differences concerning these evolution subperiods of the stock market, we will analyze the behaviour of the daily rentabilities of the index, by calculating the main characteristics of their distribution. By synthesising the values of the main characteristics

Table 1: Characteristics of the daily return series associated with the BET index on subperiods
