The "triple helix" model is setting the university-industry-government relationships in order to increase innovation and knowledge capitalization. The evolution of the research process revealed that the relationships between government, universities and industry switched from a bilateral one to triple one. Moreover, in addition to those existing three parties, an increasing attention sets for a fourth element: the society. In this case, we can talk about a **quadruple helix**, in which the society takes part in the process of knowledge creation (Reichert Sybille, 2006)

Starting from the work of Etzkowitz and Leydesdorff (2000), Dooley and Cork (2007) introduced two models of the triple helix, Mode 1 and Mode 2.

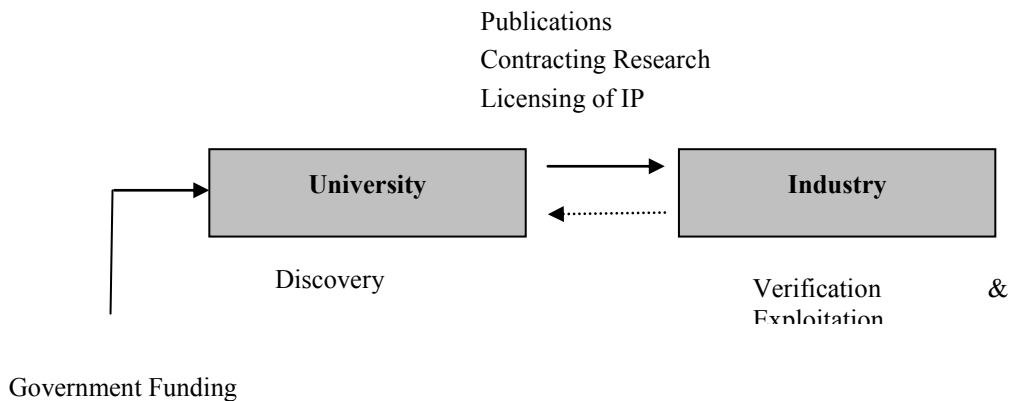

Figure 1 University research under Mode 1. Adapted from Dooley and Cork (2007)

Mode 1 presents the university with 2 functions: education and discovery research, and the government is the main funder. The results of the research are a public good and it is available to everyone in the market. This is also the vision captured by the Romanian Strategy of R&D.

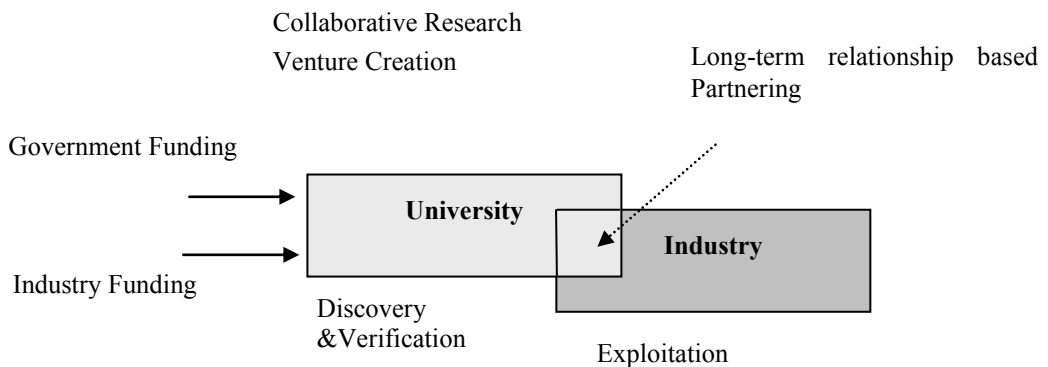

Figure 2 University research under Mode 2. Adapted from Dooley and Cork (2007)

Mode 2 is a model that increases the interaction between university and industry, which allows a better feedback between those two. Using mode 2 by the universities implies an adaptation of the research capacity with the industrial partner demands. The role of the university is in this case to test and to verify the product. The interaction between industry and university has a positive impact among both: the industry benefit from outsourcing the verification activities, and the university benefits from the new knowledge generated.

Research methodology

This study is the outcome of research project “The development of interdisciplinary academic research aimed at boosting Romanian universities’ competitiveness on a world scale” financed by CNMP. This exploratory research wants to study the relationship between academic and business environment from the academics point o view. The research method used was a qualitative one, the focus group. In order to capture and to compare experiences we conducted one focus group with researchers from 2 prestigious universities from Bucharest: an economic one, and a medical one. The focus groups used the same interview guide. The focus group with researchers from the economic university consisted of 8 members, and the one from the medicine university consisted of 5 members. The participants selected for the focus group discussion had experience in collaboration with business environment. The interviews were conducted during February and March 2008. The themes followed in the discussion were related to the academics’ evaluation of the relationship between academic research and business environment and the perspectives of the future collaboration between academic environment and business environment in the view of academics.

Major findings

How do you evaluate the relation between academic research and business environment?

In this topic, both groups agreed that the relation with the business environment is a poor one. The group with researchers from the economic university agreed that “the business environment is not interested in our work, because they have other options” and another important aspect revealed was that “the companies do not trust the academic research, they think that we don’t have the capacity solve their problems”.

On the other group (the doctors), the discussion started by defining the business environment for them: “you understand something different by business environment than we do”, that is because in Romania “there are few private hospitals”. The relation of academia and companies in health domain is not perceived as a research project: “the company that distributes materials or instruments comes, distributes

its products or maybe organizes some training lectures for a technology, or a new material". However, those kinds of activities have to be institutionalized because of the law.

How do you see the collaboration with the companies in the future?

Both of the groups agreed that academia and business sector should collaborate much better in the future. The researchers from the economic university said that is very difficult to achieve this goal because until now the collaboration was made by "personal relations". In order to pass from this some opinion were shared: "to elaborate position documents that defines the intentions and potential in R&D of the academia", "to invite company representatives at our conferences", "to generate some research proposals to the companies". An important aspect mentioned by all participants was the "institutionalization" of the research with the business environment: "we need a structure", "there is a vice rector in charge with this activity", "we can write down a number of intentions for collaboration, but there has to be a department to take them further to the companies". The other group (the doctors) mentioned that "the products from the drugs companies and from suppliers for the medical sector are let too easy into the market", and the "role of the university can be the one to evaluate the effects of the products". There were situation in which companies introduced directly products on the market, not tested by universities and they proved to fail in treatment: "there was a drug which was put on the market without putting it to the test, and it was gave to Romanian patients and other countries too, and at the end it was put out from the market, because it was proved inefficient". But participating to such research project involves many ethical issues: "this stands on the involvement of each researcher and its character" and "there are people that let them bought and others that don't". The role of the research here is to "certify that what companies are saying about their products (recommendations), what is it put in the CV of the product is real". However, this activity should be made in a regulated environment: "the government should issue a law".

Conclusions

The research activity is starting to gain field into the Romanian universities. Several laws and regulations sustained this process: including research projects as a condition for academic promotion, increase of public funding of the research. The research with the business environment is in an embryonic stage. Even though the issue presents a real interest, a certain defensive attitude among participants was noticed.

Beside the specific of each research activity, there is a difference regarding the support from the university on such projects. In the economic university, the projects funded by companies are considered for promotion as research project, instead in the medicine field they see as a research project only those funded by the Government through national research programmes and gained through competition.

Another aspect that differentiates the two groups is related to research ethics. In medicine, the research with the business environment involves many ethical issues, because companies want to put on the market as soon as possible their products.

ELEMENTS OF MARKETING IMPLEMENTATION IN RELIGIOUS ORGANIZATIONS IN ROMANIA – A QUALITATIVE RESEARCH APPROACH

Strâmbu-Dima Andreea

Romanian integration in European Union stresses the necessity of marketing evolving toward social and cultural fields and, in the same time, brings a new interest in analyzing religious field and modernizing its approaches, in order to have a bigger contribution to the development of Romanian society.

The present paper lies at the convergence of these trends, recommending the use of religious marketing in Romania, in order to solve some problems appeared in religious organizations or society, at large. This idea, presented in other papers as well, is now enriched with the first reactions of Romanian clerics over the religious marketing. These reactions will be analyzed varying their main cultural organization features.

Keywords: religious organizations, organizational culture, religious marketing

A question that concerns religious leaders is “What can we do to make our message relevant for the modern society?” Within a debate on the applicability of marketing in religious organizations, some clergymen expressed their concern for the moral state of the society and their hope to find a solution. Marketing can be used by religious organizations at all levels in order to fight against this situation, by promoting religious values and concepts in a systematic and scientifically manner (based on research, models, strategies etc.). This way, Romanian Churches will be able to fulfill their objectives and, in the same time, they will have a more effective contribution to the development of Romanian society. Religious marketing faces sometimes strong critics, but if there would be a constructive collaboration between clergymen and marketing specialists in order to develop operationally the religious marketing, the result will be a useful and effective tool in service of the religious organizations.

Defining religious organizations culture

Alfred Kroeber and Clyde Kluckhohn (1952) have compiled a list of more than 100 definitions of culture. We will try to offer a preview of the meaning of culture and especially of organizational culture, in order to create the premises for our discussion over the organizational culture influence in accepting the religious marketing.

The term **culture** comes from the Latin *cultura*, stemming from *colere*, meaning „to cultivate”. It „generally refers to patterns of human activity and the symbolic structures that give such activity significance”. In *Primitive culture: researches into the development of mythology, philosophy, religion, art, and custom*, Edward Burnett Tylor, writing from the perspective of social anthropology, described culture this way „Culture or civilization, taken in its wide ethnographic sense, is that complex whole which includes knowledge, belief, art, morals, law, custom, and any other capabilities and habits acquired by man as a member of society.”

But, the culture is not only an individual or macroeconomic culture. It has also microeconomic components. Marketers are often interested of an appurtenance group’s influences over an individual, but in fact the influence lies in the culture of that group. Organizational culture, a very important subject lately, has a strong impact over the organization’s actions and relationships, as well as over its members. UNESCO (2002) has defined culture referring to social groups – „culture should be regarded as the set of distinctive spiritual, material, intellectual and emotional features of society or a social group, and that it

encompasses, in addition to art and literature, lifestyles, ways of living together, value systems, traditions and beliefs”.

Referring to the organizational culture, Edgar Schein gave the next definition – „The culture of a group can now be defined as: A pattern of shared basic assumptions that the group learned as it solved its problems of external adaptation and internal integration, that has worked well enough to be considered valid and therefore, to be taught to new members as the correct way to perceive, think, and feel in relation to those problems”.

Practically, the organizational culture is formed by a set of opinions, values, norms, models of action, attitudes, common for all the members of an organization, which shape its personality. Culture is transmitted very fast to the new employees and adjusts the intern and extern behaviors of the organization, including the reactions at new things. Unfortunately, culture is very difficult to assess, although you can feel it from the moment you contact the organization, because of the way employees are receiving you, of the inside and outside design etc.

Culture helps the organization in its development to face two great challenges: (1) to assist new members in adapting to the organizational climate and (2) to relate in a constructive manner with external environment. Patricia Wittberg asserts that „religious groups - parishes, denominations, religious orders, and the like - also have these longstanding cultures, ideological systems by which they explain their identity and purpose to themselves and to outsiders.

Differences between the religious organizations

The experts opinions about the differences between the religious organizations state that these are determined by their history, management, the structure and the size of the organization, level of information technology development, economical status, phase from the life cycle in which it is, notoriety etc.

From a *historical* point of view, the Christian Churches are very similar – all of them have evolved from a mother-organization due to the discovery of new biblical principles and later on, all of them have faced the rise of factionalism among them. Therefore, although this element has its own relevance for the religious marketing, from a historical point of view, the differences between them are rather theological.

From a *managerial* point of view, of highly importance is the organizational structure, because it can facilitate or block the decision-making process, and the personality of the leader or leaders who are oriented towards new or tradition. This later aspect is hard to be extended to churches other than the Orthodox Church and the Roman-Catholic Church, as there is a higher number of religious leaders involved in the decision-making process.

Regarding the *size* of the organization, it is important not only the size of a church at national level, but also at the international level. The *level of information technology* development within the religious organizations is very high, according to their spokesmen. The *economical status* is very hard to be assessed for each organization: usually, economic figures and results have only an internal circuit not being publicised. In terms of the *phase from the life cycle* in which the organization currently is and, also, the specific level of notoriety, there should be conducted more in-depth studies for each of these.

Therefore, in the context of the qualitative research conducted, analysis of the Romanian religious organizations will be developed based on their specific managerial structure and organizational culture.

The management of religious organizations in Romania

As Viorel Dima affirmed, “churches with a higher hierarchical pyramid have an organizational culture oriented toward power, being more authoritarian. More flattened the hierarchical pyramid is, the more democratical will appear”. Marketing implementation seems to be easier, on the other hand, when hierarchy is less flattened and the leader is stronger and open-minded. In fact, this aspect is visible even in Romania, where the openness toward modernity of the new-elected Patriarch was noticed in the previous months. Being concerned to enhance the communication, after a very short time after his election, the Patriarch introduced Trinitas Radio at national level, updated the internet site of the Orthodox Church and started Trinitas TV.

Regarding the form of organization, the Protestant Churches are sinodo-presbyterian Churches, that is the local church is led by presbytery, a council of lay people. The presbytery is led by a priest/pastor, helped

by a churchwarden who has financial-administrative responsibilities. Usually, at national level, they are led by a synod, led by an episcopate or a lay director, composed from clerics and people in 1 to 1 rate. In most of the cases, in order to ease the coordination between the synod and the local churches, there is an intermediate organism, called protopopiat.

Within the congregational religious organizations, marketing implementation seems to be more difficult, because the local churches have a greater degree of independence and the councils of leadership have, generally, the role to represent organization interests in front of the state's institutions. However, the religious leader from The Brethren Assemblies presented a positive example regarding the importance of a leader's orientation towards modernity. He told that a new church has started evangelism without to make a research in order to understand which the best target-group from that town is. The results were not satisfactory and he explained to the church that it has to ground its actions on scientific methods. Another example of good practice is The Evangelical Alliance, who promoted the leadership courses of John Maxwell with the help of different associations and not only within certain denominations.

Elements that reveal the organizational culture

The culture of religious organizations is revealed through the Mission Statement, other official statements, objectives, values, norms and politics, symbols, beliefs, internal myths, habits and rites, behaviors, language, climate, ceremonies etc. that are visible in the organization.

Among all this we will refer to only three, which we consider of most importance for our study:

- **existence of official documents**, expressing the orientation of religious organization such as mission Statement, other official statements;
- **internal climate**: expressed by the relationship with clergy – communication, relationships with the parishioners (language, adapting to their needs the religious goods and services etc.), parishioners participation to religious organizations' life, way of getting the appartenance - native or elective;
- **strategic objectives and policies**: including strategic orientation toward inside or outside, orientation toward organizational development and orientation toward the level of competition.

Romanian churches' reactions at their contact with religious marketing

It has been conducted an exploratory qualitative research project intended to produce information regarding attitude and behavior of the churches active in Romania in terms of the knowledge, implementation and results generated by the marketing concepts and tools. Representatives from all the churches and religious organizations have been invited to participate within the focus-groups conducted.

The strongest reactions we could identify is the absence of two churches: first, in spite of numerous invitations, the Orthodox Church (its absentee can be compared with a certain lack of interest of toward its smaller competitors); second, has been Jehovah's Witnesses, which appears to be uninterested in contacting its external environment. Absentees, but expressing their interest on the topic, have been Reformat Church and Baptist Church. Unitarian Church did not answer to the our invitation.

It appears that some churches had already been accustomed with the idea, even if they weren't aware of everything that religious marketing implies. In this sense, we discovered that Evangelical Church of Augustan Confession encourages at its higher level the implementation of marketing and Brethren Assemblies already discussed about using some marketing instruments.

Probably Roman-Catholic Church practices marketing at its best as its representative stated that his church wants to present as well as possible their faith, using modern instruments, which are very necessary. He referred to the local churches which practice marketing, saying that they are a visiting-card for Roman-Catholic Church.

Some critics came out too: first, the term of marketing, referring to the market, has been considered as having nothing in common with the church. Yet, religious representatives presented plenty of reasons to introduce marketing into their activity. They asserted the necessity of promoting their faith, principles, programs, creed, intentions, ideologue, doctrine etc. Two of them (Seven Day Adventist, respectively Roman-Catholic at the second) reminded the biblical verse: "For the people of this world are more shrewd

in dealing with their own kind than are the people of the light” (The Gospel according to Luke 16:8). Therefore, the religious leaders expressed their availability to consider the themes treated with wisdom by the “people of this world”, as long as they don’t run counter their fundamental teaching.

A danger that has been presented by the religious leaders is forgetting about God intervention, which often makes the result bigger than they could ever expect or foresight. They fear that marketing, through its fixed process – research, strategy, implementation, and evaluation – favors forgetting the non-human capabilities.

Another sensitive topic has been the adaptation to the specific needs of the parishioner. When it has been approached, the participants have discussed about compromise and manipulation. Still, they have agreed that there are areas where this adaptation is possible without affecting their fundamental values. More, they have supported the opportunity provided by a potential segmentation of the public and an adapted approach for each of the resulting categories.

Another criticized aspect regarding the marketing applied in the religious context was related to the implementation of a win-lose principle while religion demands a lose-win relationship as the clergy is acting in the service of the parishioners. It is to be said that there is not a win-lose relationship within the religious marketing due to its inclusion in the social marketing. Non-profit organizations do not win against those soliciting financial or material support. More, there is a win-win relationship within marketing and this approach should be considered in the religious field too. If marketing concepts and tools will be thoughtfully considered and carefully implemented as to contribute to the reaching of specific objectives of each religious organization, gains will be obtained by the church, through fulfilling its mission and the parishioners that will receive better outputs (services, products and values) in terms of their quality.

The concern for strategic aspects of the religious organizations, even without a strong marketing connotation, is relatively well-known as well as the interest for communication at the level of the Christian religious organizations. The relatively surprising element has been represented in this context by the marketing research approaches developed by some organizations. Thus, some Christian Evangelical Churches are conducting surveys among their parishioners. Also, Evangelical Church of Augustine Confession conducts research activities aiming to find what is the image of the church, what are the parishioners’ expectations and spiritual demands from the church, what is the level of understanding associated to the language of the seventeenth century used by the church. The Adventist Church employs a longitudinal and selective quantitative approach to get information about the relationship between young parishioners and the Holy Book, family, priest and church values.

Most churches practice marketing just in a partial manner paying attention mainly toward communication and, sometimes, research without having a holistic approach. It can be expected that a formal, systematic and scientific approach could bring them significant advantages and support their efforts in fulfilling the specific mission. Still, marketing has also generated several negative effects, mainly in the business environment and from an ethical perspective, when it has been misused: that is why the role of the persons doing marketing and these persons themselves are essential for the marketing effectiveness and its finalities.

Conclusions

The ***Roman-Catholic Church*** use marketing at an international scale, its representative having airiness and availability toward this subject. In spite of the fact that the appurtenance is native, there are favorable factors in adopting the marketing vision, like the concentrated source of power and the efficient way to send messages at inferior levels. The marketing view is reflected into the process of adapting the religious product to different identified target-groups.

The ***Evangelical Church of Augustine Confession*** is the next denomination from the point of view of receptivity to the religious marketing. It enjoys a tendency to marketing at the international level, the other influential factors not having a significant contribution either favorable or unfavorable. The ***Eastern Christian Orthodox Church*** opens itself more and more to communication with the external environment, beginning to promote the concepts of marketing, adapting them to its own peculiar system. The ***Seventh-Day Adventist Church*** seems to be the closest to the category of the churches accepting marketing, although it is obvious that we are now in a different category – the churches which still have restraints toward marketing.

The *Pentecostal Church* has different papers on religious marketing at the international level. Its representative had a rather negative approach although has presented some advantages derived from the usage of marketing in the religious environment. The very high level of adaptation to the believers' needs and their involvement into the organization's life are good premises for a holistic approach of marketing, as soon as its dimensions will be understood and adapted. The *Brethren Assemblies* seems to be divided in two sections — the traditional churches on one hand and the newer local churches, which use marketing techniques, on the other hand. Due to its congregational type of organization, it is difficult to promote a new concept and to hope to be accepted at national level. However, in spite of their congregational type of organization, the churches composing the Evangelical Alliance (The Baptist Church, The Pentecostal Church and the Brethren Assemblies) have the positive experience of promoting leadership principles through the organizations developed by John Maxwell.

The *Greek-Catholic Church* and the *Evangelical Sinodal-Presbyterian Church* hold similar opinions. Their representatives did not express a very definite argument pro or con the usage of marketing in the religious environment. The criteria to compare them does not demonstrate a significant potential of interest for this – the appurtenance natively, the internal orientation, the defensive approach regarding competition etc.

Therefore, we can say the Romanian Churches presented balanced opinions, as if they have expected more details on religious marketing, in order to support or combat it. However, the views expressed until now were rather favorable, probably due to the international trends, but also because of the minority position held by most of the religious denominations in our country.

Abstract: The post is unanimously acknowledged as an essential public service that meets a fundamental need, namely the ensuring of the right to communicate. Poșta Română (Romanian Post) is the responsible entity for fulfilling the obligations resulting from Romania's joining the Universal Postal Union. Thus, it has to ensure the conditions of integrating the national postal services in the international ones and adopt the latest technology in the field. As a result of these trends and modifications, we consider as opportune the analysis of Romanian Post's image in order to know, quantify its results and establish a competent management imposed by Romania's integration into the E.U.

Key words: image, satisfaction of target public, strategy

Introduction

In the framework of service carrying out one may speak of services for enterprises and services for population. The economic growth is influenced by the development of services for enterprises. Services for population are the services that population pay through the intermediate of documents of sale and purchase. This category of services include transports, post, telecommunications, insurances, tourism, public food, education, health, cultural and sports activities, fixing and maintaining goods, laundry works, dry cleaners, barber's, hair salons, beauty parlours. The development of market services destined to population is the natural consequence of the whole evolution of the economy, being correlated with the tendency of the economic-social development's main indicators, such as gross domestic product, people's real incomes, unemployment rate, inflation rate, endowment with goods of long-term use, degree of urbanization, duration of spare time etc. Poșta Română is the national operator of postal services that is in charge with the issuing, printing, commercialization of stamps and postal effects and is also a supplier of added-value services such as: software development, currency exchange, consultancy services, and transport services. The postal activity has known profound transformations lately, due to technological development, as well as to the evolution of the society and vision on public services.

The postal service is considered more and more as an economic activity developed on competition basis, in a free market. Many countries changed their internal legislation in order to liberalize the market and to create authorities of regulation to guarantee the observance of competition rules. For ensuring coherence on a long term of the sectoral strategy and necessary predictability to investors, one takes into consideration the evolution till 2025. This horizon has surpassed the date of integration in the E.U. (January 1, 2007) and even the date settled for the next revision of the European directives in the field of postal services (2009). This takes also into consideration the necessity of a stable sectoral policy during and after the adhesion to the EU, as well as during the negotiations regarding the postal services in the framework of the new round of service liberalization, promoted by the World Trade Organization (WTO). The postal activity has transformed a lot the last years, due to technological development, as well as to the evolution of society and vision on public services. The European Union plays the part of pioneer in promoting competition in postal services and is especially concerned with the universal service.

2. Practical study about the image of Poșta română on the market of Galati

For the research, analysis and evaluation of customers' satisfaction degree regarding the services offered by the Romanian Post on the market of Galati, it was carried out a market research on the basis of a questionnaire, on a representative sample of 100 people. At the first question regarding the types of postal services used for the last 30 days, it is noticed that besides company's traditional services, most of the individuals prefer to pay their bills of different utilities, the Romanian Post having concluded contracts with companies such as: Electrica, Distrigaz, Romtelecom, Vodafone, Orange etc.

At the second question regarding the quality of service performance of the front office personnel, for analysing the opinions of interviewees regarding front office personnel, one calculates the score obtained for each assertion using the semantic differential. After receiving answers from individuals, it is noticed that it is needed the improvement of office workers' attitude towards customers. Customers want more amiableness and professional training, but in a higher proportion they want to be more efficiently served and receive more pieces of information about services.

As for the time of waiting at the pay office, the results are the following: 36 % of interviewees have waited for 20 minutes in order to benefit from postal services, 17% have waited between 15 and 20 minutes, 19 % between 10 and 15 minutes and only 6 % have not waited at all. The time of waiting at postal pay offices is especially long for most of the individuals. By using the semantic differential it was estimated the individuals' opinion about: post office's location, aspect and environment, the adequate performance of the solicited service, satisfaction of the target public's needs and their access to information regarding postal services (folders, posters, forms models). The results of the research proved that only the access to information is adequate, while the rest of the analysed problems reflect customers' discontent, which imposes the organization a series of improvement actions.

Regarding postal services' tariffs, one may notice that 66% of the individuals consider that they are accessible, only 14% believe they are not, and the rest of 20% did not have any opinion or abstained from answering. Using Likert's scale one analysed the image of the public interviewed about four statements regarding the distribution of postal parcels. As a result of the obtained global score, it is noticed that the distribution at the right address and arriving of parcels in good condition is in agreement with customers' opinions. Unfortunately, it is noticed that parcels do not always arrive in time. Also postal services beneficiaries do not agree with the attitude of the postman. As for the analysed public's motivation in choosing postal service it was analysed: the safety of dispatch, quickness of dispatch, tariff accessibility, office accessibility, diversification of service offer, extension of territorial network, employees' attitude, level of employees' professionalism. It is noticed that a significant percent of 28% of the respondents are satisfied with the tariffs of postal services, which they consider as acceptable. The post office where it took place the research, being downtown, is preferred by many customers. 11% of the subjects use the post due to the diversification of postal services. A smaller number of respondents have considered as strengths the safety and quickness of dispatch, the wide territorial network, employees' attitude and level of professionalism.

To the question: If you had the possibility to choose for the carrying out of your services, what would we choose? 28% of respondents answer they prefer banks, and a percent of 31% prefers service companies, while only 41% want to benefit from services offered by the Romanian Post. To the question if they consider that the services of Poșta Română should be improved, most of them in percent of 70% considered that it is necessary to improve them, 12% of the subjects were satisfied, and the rest of 18% did not have any opinion. In the relation with Poșta Română only 17% of subjects may do without postal services, while the rest of 83% consider these services as a necessity. The improvement of postal services is considered by 36% of the respondents as a problem regarding the time of waiting at the pay office, a smaller percent, but quite impressive – 23%- want an improvement of pay desk organization inside the post office, 17% want the improvement of the manner of serving customers and the office's environment, and only 7% want more professionalism from employees.

Respondents are of ages between 19 – 45 years old, namely 44%, 36% are 46 – 65 years old. People over 65 years old are only 8% of the total. The young under age are represented by 18% of the respondents. As for the occupational situation, the people interviewed are part of different categories of occupations, but in very close percents. 21% are workers, drivers etc; 22% technicians, office workers, medical assistants etc; 19% students, pupils, unemployed; 17% specialized personnel with higher education; 12% retired people and 8% employers, managers, share-holders. As for the level of education we notice that most of the

respondents have average education, a smaller percent have superior education, the rest having college or gymnasium studies and only 3% having attended only the elementary school. As for life environment, 88% live in urban environment and only 22% in rural one. Most of the respondents – 25% - have an income between 800 – 1,500 lei and only 14% have an income of over 2,500 lei.

Conclusions

Under the conditions where the market of postal services suffered modifications, through the regulations that allowed the liberalization of this market, it took also place the competition growth, The National Company Poșta Română losing its status on the market of postal services, a market characterized by pure monopoly. Liberalization of postal services market is one of the reasons that led to the considerable change of current and potential customers' behaviour. As a result of the research regarding the attitude of postal services consumers in the framework of Romanian Post, we noticed that it is necessary to know their behaviour, the manner in which the decisional process of service performance develops, to allow the organization to achieve a postal offer in accordance with market demands. The orientation towards customers ensures their attracting and renders them loyal, and implicitly leads to profit increase and improvement of organization's image. Any marketing activity cannot find its economic and social end without putting in the centre of its preoccupations the buyer and their problems, without trying to explain the decisional buying process. One noticed that more and more customers become more concerned with the quality of services they benefit from, and the manner in which they are treated by organization's personnel during service performance. An aspect that leads to the making up of a company's not very good image refers to the time of waiting to the counters, most of the customers considering that they wait too long for the respective service.

Generally customers are content with the postal offices location; in exchange one cannot say the same about their aspect and environment, about the access to information referring to postal services that need numerous improvements from customers' viewpoint. Even if Romanian Post has low prices at most of services, customers would not hesitate to go to a bank or other company that performs postal services. Thus, a significant number of customers keep with the Romanian Post only a relation of necessity, because they do not have other options. Although postal services consumers come from different environments, have different ages, a different status in society regarding the level of education, professions, and incomes, most of them are sensitive to the manner in which they are served, as well as the way their problems are solved. That is why the interest in the investigation of their behaviour should concern more the organization management. In order to improve the quality of services, the research of consumers' behaviour must be carried out at the same time with customers' education, with the help of promotional policy, as well as the research of competition behaviour.

Customers' satisfaction and image improvement should begin firstly by permanently training company's employees. Through the development of the training system the company wants its employees to acquire managerial abilities, organizational culture, and knowledge about postal services. An important part is played by the communication between the contact personnel and customers. The performer must know how to address, behave, and show honesty, altruism, the wish to help the others, treat complaints very carefully, know their specific activities. Also, employees should be freer in offering solutions to discontented customers and be able to take certain decisions without appealing to hierarchically superior personnel.

Depending on customers' traffic, diversity of services, the organization's competent departments must decide the staff necessary for each headquarters. Also one must take into account the organization of personnel that perform services for important customers – legal persons. The maintenance of long-term relations with these customers is very important. The customer and performer come to a mutual understanding and in time the performance becomes superior qualitatively speaking. The employee must know precisely what their attributions are, what people expect from them, how their work will be evaluated and what compensations and penalties are applicable.

In order to avoid agglomeration inside post offices, it is necessary a better internal organization of pay offices, by supplementing their number in crowded periods, as well as during the month. Another reason of customers' discontent is the change of shifts at noon. This presupposes that customers wait for 15-20 minutes the change of shifts. With an adequate endowment, with necessary instruments, such as computers, printers, this might be carried out in offices specially arranged, which means pay offices should not close.

In crowded offices one may set special boxes that would allow buying stamps and postal effects by self-service. For a better quality of postal services more offices must be included in the informational system, be modernized and arranged, as well as be brought to a standard of endowment and functioning as high as possible. The achievement of a modern and efficient communication system becomes more than a necessity, respectively an incontestable demand for the Romanian Post to gain and maintain an important position in the market.

As for the distribution policy, an important part is played by the diminution of dispatch time, necessary for letters', parcels', money orders' distribution etc., through investments into infrastructure, periodical replacement of car park with modern vehicles. An essential condition for the development of the national postal infrastructure is represented by the ensuring of the financial resources necessary to investments. These sources may be banking credits on commercial bases, for the implementation of national projects with priority, external financing for research elaboration, for the preparation, organization, implementation and ensuring of important projects' logistics referring to the development of infrastructure etc. Customers need to be permanently informed, to know better the products and services they want to benefit from. This may be realized through a well-conceived promotional policy. In the framework of Poșta Română, postal products and services must be promoted with the help of advertising messages through press, television, internet or directly.

Regarding the internet, the site of Poșta Română needs numerous improvements, such as enrichment and permanent updating of content, as well as a faster downloading of the site, so as visitors would not wait for too long. A better informing about postal services may be carried out through distribution of folders which would contain, besides company's brand, the site address and a telephone number, where people should be able to permanently obtain the necessary information.

Abstract

The nowadays globalization process has been generated some significant changes in the field of the international marketing research projects. More and more international market studies must solve specific issues in terms of communications, methodological approach, translation of the market research material and define the type of information based both on the field and desk sources. In this context the authors emphasize on the high value of the direct market research.

Key words: globalization, research project, international project, methodological approach, direct market research

Process triggered a few decades ago, the globalization of consumption and production increased considerable in the last few years due to substantial mutations recorded in world economy and especially, in certain areas of the world, as a consequence of the cold war ending. Multinational companies have extended themselves and today there's no amazement for nobody that, for example, a USA company produces certain goods in Sweden, which then sells them on the markets of Central and Eastern European countries.

Such mutations have been followed continuously by changes in the way to tackle and study the market, which was adjusted to the new information requirements and decision fundamentals. Today is also studied on the national markets, it is true, but it is also studied on market groups, considered to be the 'local markets', and also several national markets, which are tackled, through the marketing activities and considered to be a specific market.

In this context, market study has obtained new values and so the designers and accomplishes of marketing studies have been obliged to solve new methodological and organizational problems. Of course, these problems are numerous and almost each new study project brings yet something that need to be solved. It does not exist in this moment unique solutions or already prepared recipes, but practice has brought to specialists attention certain elements and characteristics, which can be generalized and theorized. This is also the purpose chased in downward steps. We will try, therefore to repeat further some of the most significant problems imposed to market study by the globalization of consumption and production and based on the gathered experience, to give answers to some questions, which already combine the specialists consent.

What do international projects represent in the market study area?

International research projects are basically market studies done simultaneously in several countries with the same purpose and the same marketing instruments. Of course, in temporal perspective, an international research project can be accomplished actually in the same period of time, or with a certain gap, as a consequence of certain restriction of logistic directions or generated by specific elements of a certain market.

The designing of an international market study starts from the formulated requirements of a certain client (usually an multinational company, an international organism, a groups of firms, etc), which asks several marketing research networks to elaborate the research methodology and to design the project, until the

preparation of the research report. Several times, such a client can provide with the methodology project, if he possess a marketing department with professional researchers. It is mentioned that, in present, it exists networks specialized marketing studies, which have branches and associates in considerable number of countries. A question can be asked: why does the client addresses itself to several research networks (usually a minim of three)? The answer is simple: in the market environment the network which offers the most attractive methodology and the most attractive cost is preferred. It must be underlined that not the cost is, in fact, the most important aspect of the choice, but the report between methodology performance and the involved costs.

In return, the specialized in marketing studies network, which was chosen by the client, after the elaboration of the methodology project, must find the material and human resources adequate in each of the countries involved in the study. This is at all easy, inclusively for the big specialized in marketing research networks, because not even these have subsidiaries or associates in all the countries that the client is interested in.

The named network proceeds in a similar way to the client for the selection of the partners from each country: asks for costs, based on the elaborated methodology, from several specialized firms (usually a minimum of three). It is mentioned that the specialized firms are not obliged to cooperate automatically with their subsidiary or with the associated firm from a certain country. It can be chosen any other specialized firm in market research, which presents a more attractive offer for the accomplishment of the project. In this way it is done the study in all the involved countries.

Theoretically, depending on the size of the research project, two or three specialized firms from a certain country, can be chosen for the realization of it.

What are the main problems, which require to be solved in order to elaborate the international market researches?

A first problem, which needs to be overcome is at the communication level and has two main components:

- It refers to the international connections available in each country referring to phone, fax, e-mail, express mail etc. These means of fast communication are not at the same level in all the countries and those in charge of international projects have sometimes difficulties in this area. Additionally, referring to computer use for these sort of communication means (fax, e-mail), it exists numerous incompatibilities of available programs.
- Furthermore, in the communication field are induced some inconvenients caused by the differences of the time zones. Sometimes, contacts and answer are needed immediately, in few hours and the difficulties are obvious, if in a project are countries like Australia, some European countries, SUA and countries from Latin America. The practical solution for these situations is the creation of time reserves, if it is possible, to communicate in an adequate way.
- Another problem, which needs to be solved, in order to proceed with a behavior international research is that, of ensuring a methodology unit of the project. The countries involved in the project distinguish themselves through many things and that is why, the guarantee of a methodology frame is not at all easy. In this sense, the researchers responsible for international projects are confronted with the next most important aspects:
- The insurance of an unitary frame, of comprehension in the same way and spirit, of the different research instruments used (questionnaire, lists, instructions, conversation guides etc). Here appear numerous confusions and conflicts generated especially by the linguistic differences between countries. It is required a great experience in the market study and a perfect knowledge of the national frame, for the realization of adequate translations, practice demonstrating that a lot of times mistakes have been committed, even by professional translators. In this sense, it must be taken into account the fact that, assuming that the questions from a questionnaire are not enough to be translated into the academic form, as they need to be understood in the same way those who are meant for meaning the big audience - the consumers. Things are yet more complicated in the case of the slogans from different advertisements, which almost never, cannot be translated word by word, but in their spirit. That is why, translations from this field are very difficult and they suppose numerous efforts,

taking part at these specialists from the academic areas and experienced researchers from specialized firms in market research.

- Another very important problem related to the metodological homogenization of international marketing studies, refers to the structure of patterns of consumers that will be used in research. Also in this case there are great differences between countries, meaning that, some countries have very well organised patterns: person lists, household lists, firm lists etc., details concerning territorial repartition, the dimensions and characteristics of certain consumers segments are known etc. ,and the acces to this sort of data that is vital for building up the patterns is unlimited. However, in other countries, either this sort of data is not structured so it can be used, or it does not exist at all. Considering this, the ones responsible for projects from the designated networks have encountered numerous difficulties,that are dealt with individually in each country, at least at their first contact with the local market research firms. Later on, as they obtain suitable results, their work is improved.

Finally, between the problems that must be passed in order to accomplish the international research projects, we can count that of the stock and process of information, gathered from the consumers. The main difficulty of this sort is pure technical: the modern software programs for data processing (for example: SPSS, probably the most used in present) are not available in all the countries and then the research networks need to processes in centralized way the data. These are introduced in a special manner called 'a code in a column', in each country that participates at the research, and further at the headquarters of the named network, these to be transferred in adequate programs, with the purpose of being processed.

Information needed for international market research

The research, based on scientific grounds, of international markets is inconcievable without knowing a serious amount of information regarding the processes and mechanisms of a consumers' behavior. That is why researchers have taken into great consideration possibilities of collecting sources of information regarding the study of the consumers' behavior; this led in time to the development of a real „methodology” in this sense. The categories of information needed in order to study consumers' behavior must permit the presence of certain aspects, as follows:

- **Past behaviour**: What has been bought? How much? How? Where? When? In which situation? Who has bought? etc.;
- **Scheduled behaviour (future behaviour)**: What are the intentions of buying? How accurate are they? What sortiments are preferred? From which shop? etc.;
- **The motivation to buy or not to buy**: Why do people buy? How do they buy? Why is something not bought? etc.;
- **Consumers attitudes** regarding goods and services: to which do favourable attitudes exist? How did those attitudes form? Which are the unfavourable attitudes and What determined them? etc.;
- Social-demographic and economical **consumers'characteristics**, those of their families and households and the environment in which they live in etc.;

In this sense, specialists have proposed the grouping of information needed for market and consumer research according to their **source of origin**, as a fundamental criterion, and according to every source, taking into consideration more relevant subcriteria. In essence, the proposed categories are as follows:

A. Desk research:

- ⇒ **after the information bearer**: from statistical evidences, from financial-accounting evidences, from technical-expeditious evidences, from studies, situations, reports, synthesis;
- ⇒ **according to the expression form**: in physical, natural expression, in value expression, in words;
- ⇒ **according to the aggregation rate**: at a microeconomical level and at a macroeconomical level;

B. Field research:

- ◆ **After the place where the collection takes place, information obtained:** in peoples' homes (headquarters of economic agents), in stores, during fairs, shows etc.;
- ◆ **After the period of time it refers to:** permanent, periodical, one time only (ad hoc);
- ◆ **After the observation unit, information that refer to:** a person, a household/ family, a enterprise, institution, store, or any collectivity of this nature;
- ◆ **After the collecting procedure, information obtained through:** interview operators (face to face), selfadministration, email, telefon, combination of procedures mentioned above, telemathic surveys;
- ◆ **After the collectivity from where they are gathered, informations obtained through:**
 - statistical surveys and exhaustiv research;
- ◆ **After the expression form:** in physical, natural expression, in value expression, in words;
- ◆ **After the structuring and aggregation level:**
 - at a microeconomical level and at a macroeconomical level;

Ways to approach international market research

Specialists in this field have proposed two major ways to approach the study of consumers' behavior:

- Indirect study, based on desk research;
- Direct study, based on field research;

Each of this ways of approach have certain particularities, advantages and disadvantages, which enforces the need to take decisions of applying them through each market research according to specific attended goals .

For the better understanding of performances produced by these ways of approaching market research, some important frequencies referring to them are considered useful.

Thus, **indirect research** shows a series of:

- **advantages:** it is relatively easy to make, it has a high level of efficiency, involves, usually, relatively low costs, in comparison to direct research, it doesn't require strictly specialised staff;
- **disadvantages:** it does not cover entirely the problematic area of behavioural mechanisms and processes, it has a descriptive character, being a *post facto* research, it refers exclusively to medium levels of behavioural processes and dimensions, it depends on past situations, being insufficient, when modifying actions of certain factors etc.

As to the application of indirect research methods, the usage of chronological or time series has proved to be very useful in terms of comparing indicators and variables, especially in order to find out trends and certain modifications of different behavioral processes.

Direct research produces information substantially different from the ones existing in chronological series, because of its' particularities:

- it relies on the collection of data directly from the consumers, mainly through statistical surveys. For the projection and accomplishment of this statistical surveys important methodological and organizational aspects need to be adequately solved, on which the quality of the gathered information depends;
- it requires using a specialized staff with a high level of qualification, sometimes even superspecialized;
- it requires the application of sometimes specific methods and technics, for the gathering and the analysis of the information;
- it allows the approach of practically all behavioural processes and phenomenon;
- many times it is the only possible way to apply, because indirect research cannot simply be used for approaching some behavioural processes and phenomenon;
- it requires, regularly, relatively high costs;

Direct research has developed in two **main directions:**

- a first direction, which is linked historically to the beginning of direct research, consists of approaching it in a „cross section”, by realising a thorough study of consumers’ behaviour in a certain moment or period of time. In this way real „photographs” of behavioural manifestations of consumers are obtained, but this fact is usually insufficient for the research goals that need to be followed.;
- recently direct research of *longitudinal type*, as well as *experimental and quasiexperimental* research have been assessed;

This way of direct research study the market and consumers’ behavior as a processes that develops in time, not as an isolated act, „the film” produced by these approaches being much more close to the reality of behavioral processes and manifestation associated to consumers.

Between these two main directions of direct research there are no essential methodological differences, the centre of gravity of the differences locating itself on the analysis, interpretation and quantification of the information.

The combination of the two direct research methods mentioned above proves to be pragmatic and efficient for the market study, on the theoretical, conceptual plan, as well as practically, by the possibilities it offers for the fundamentals of marketing decisions of all categories of economic agents.

Operational situations of international market research

As a result to the numerous applications realized in this field, specialists have reached benefic conclusions as far as the research part goes, in the way that they have highlighted that, on a practical level, the approach of studying the market starting from several operational situations in which the researcher might find himself is useful.

In conclusion, it is all about the following situations:

- The situation in which no information exist or very little aspects regarding certain sides of the market are known. This situation is not particularly common in practice because there are relatively few cases in which no information about a certain aspect or process of the market is available;
- The situation characterized by knowing some aspects regarding different processes or market phenomena, but which require a more profound analysis and a more thorough explanation. In this situation one might refer to the application of numerous methods, technics and investigating procedures: projective testing , scalar analysis, discriminating analysis, typology analysis and segmentation, markovian procedures etc.
- Finally, the situation in which, besides from the analysis and evaluation of behavioral processes and phenomenon, extensive market tests are needed, representative, including market foresights, and a more complex handling of the subject, with significant results for large groups of consumers. In this situation too, the methods and technics one can refer to are numerous: statistical survey, chronological series analysis, elasticity coefficients, factorial analysis, correlation and regression analysis, statistical-mathematical models of foresighting, statistical analysis of comparative type etc. Of course, extensive market testing leads to representative results, both qualitative and, especially, quantitative.

In the context presumed by these operational situations sequential treaties are also useful or even the exclusive approach of several processes or mechanisms of consumers’ or markets’ behavior. However, those that have a great performance are the integrative approaches, because they allow a deeper knowledge of the acts, processes and behavioral and market processes.

In the case of both types of approaches, sequential or more complex, the adoption of a systematic vision over the market processes and phenomenon has to be imposed, in order to accurately place the obtained results in their natural context.

Competition of Brands by Positioning

Todt Horst

cristian.dabija@econ.ubbcluj.ro , 0740-189659

A very specific but quite common modelling of brand competition is analysed where the properties of two goods are represented as points in the two-dimensional Euclidian Space. The analogues of the Cournot and Stackelberg case are considered. The remarkable point about this situation: There is no equilibrium. Competitors are forced to permanently reposition their brands.

Key words: brands, positioning, competition, Cournot, Stackelberg

The problem

A well-known formal description of competition between brands, each characterized by two “properties”, rests on the following modeling:

Assume a two-dimensional Euclidean Space, where each dimension represents a continuously varying property. Then a brand is a point in this space. Assume further that consumers can be represented by their preferred combination of properties; total demand can then be described as a distribution over the Euclidean Space. The properties may be “price worthiness” and “quality” or alternatively “modern style” and “durability” or any other combination.

Figure 1. Space of brands

The following assumptions are made:

1. **Any distribution of demand is admissible** (continuous, discrete, or mixed continuous-discrete). It must be, however, restricted to a bounded subset of the E^2 . For plausibility a further restriction to the positive quadrant is possible but not necessary.
2. **Total demand is fixed.** This is a harmless digression from reality; it might be interpreted as a short-run discussion
3. **Demand goes always to the next brand (Euclidean Distance).**

4. If two (or in general more) brands are in **equal distance**, then they get equal **shares of demand**. This assumption proves irrelevant. It is introduced to prevent obvious questions.
5. **Repositioning is costless**. This assumption simplifies the argument but is not essential for the main conclusions.
6. **Positioning of their brand is the only strategic parameter of the competing firms**. This, of course, is not realistic; yet it seems justified to highlight the effects of brand positioning. Economists often scrutinize price effects neglecting all other parameters – and have no bad conscience.
7. **Competitors try to reach a market share as high as possible**. This seems reasonable. It might, however, be in conflict with profit maximization.

The appropriate method to discuss the problem is game theory. It is actually a “two-person-constant-sum-game”. The possible strategies of both competitors are the points of the E^2 . Theory tells us that such games have always at least one equilibrium point in “mixed strategies”. Mixed strategies, however, do not make sense in the given context. They would in general imply the choice of several brand positions with probability, and would therefore not give an answer to the question, which position the brand should hold. Hence a reasonable solution is only an equilibrium point in pure strategies, i. e. – in plain language - a **definite brand position**, (possibly several **alternative positions**). The question is,

- whether such an **equilibrium exists**,
- and how it may be determined.

Both questions shall be answered. For short “**equilibrium**” stands for “**equilibrium point in pure strategies**”.

There are two cases to be distinguished:

1. Both competitors choose the position of their brand **independently** from one another. Each of them knows that he will have just one competitor, but has no knowledge of what the competitor will do. This can be interpreted as a situation, where both enter the market **at the same time**. This corresponds to a **Cournot Duopoly** in the case of price competition.
2. One competitor chooses his position knowing what the choice of his competitor is. The competitor knows this, and tries to make the best out of it. This can be interpreted as a situation where one competitor enters the market first (so that his brand is publicly known), and the other follows. This corresponds to a **Stackelberg Duopoly** in the case of price competition.

The Genealogy of the Problem

II.1. General Remarks

The depicted problem is closely related to two famous problems of the history of economic thought. Both are illuminating theories of economic location decisions. In addition to that they have found application in many other fields. The two problems look quite different. Nevertheless it appears that they are related to one another, too. They are known as the **Hotelling-Problem**²³² and the **Launhardt-Weber-Problem**²³³.

II.2. The Hotelling-Problem

The **Hotelling-Problem** is a special case of the above described situation; insofar as (put in the given context) the case is considered where just **one property** – instead of two - varies by **intensity** (see Fig. 2).

²³² Hotelling Harold: "Stability in Competition", Economic Journal, 1929

²³³ Launhardt, Wilhelm, „Die Bestimmung des Zweckmäßigsten Standortes einer Gewerblichen Anlage“, Zeitschrift des Vereines Deutscher Ingenieure, 1882 ; Weber, Alfred, “Über den Standort der Industrien“, Tübingen 1909

Figure 2. Intensity of property

The solution is the **Median**: Both competing brands will be in equilibrium if they are positioned such that the demand on the left side is equal the demand on the right side. The brands would not be distinguishable – a case not close to reality! The flaw of the conception, of course, is the assumption of only one property. In this case the brands are not noticed as different by customers.²³⁴

II.3. The Launhardt-Weber-Problem

The **Launhardt-Weber-Problem** – again related to brands – allows of the representation of **two properties**. The distribution of demand has to be discrete – no relevant restriction. There is, however, **only one brand** – not really a competition problem! Nevertheless it gives the answer to a reasonable question: **What is the brand position closest to demand?** If demand decreases proportionally with the distance to the brand position (contradicting the above assumptions) the **median generalized to two dimensions** is again the solution.

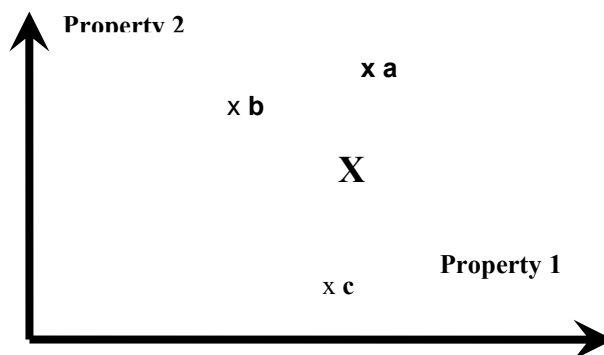

Figure 3. Launhardt – Weber – Solution

In **Fig.3** the demand is concentrated on three locations (a, b, c) in the property space and **X** the solution. **Launhardt** (1879) and later **Weber** (1910) solved the problem for three locations of demand. The **Kuhn algorithm**²³⁵ provides the **generalized median** for an arbitrary number of demand positions.

The Solution of the Competition Problem

III.1. The Existence of a Cournot Point

The starting hypothesis to be checked is the following: **The generalized median is the Cournot point.** This hypothesis, however, proves wrong.

The generalized median does always exist; the Cournot Solution exists only for a number of very special cases of no practical relevance:

²³⁴ See Chamberlin, Edward Hastings: “The Theory of Monopolistic Competition”, 1933 for the case of three competitors, where no equilibrium exists

²³⁵ Kuhn, Harold and Klienene, R.E.:” An efficient algorithm for the numerical solution of the generalized Weber problem in spatial economics”, Journal of Regional Science, Vol. 4, 1962, p. 21-33.

- If total demand is concentrated on a straight line (Hotelling case) or if demand comes “close” to such a situation;
- If demand is “very regularly” distributed on polygons with an even number of edges.

In all other cases (i.e. realistic cases) **there is no Cournot-Solution.**

Theorem 1: If the Cournot-Solution exists it coincides with the generalized median.

The proposition provides a simple check for the existence of an equilibrium point (in pure strategies).

Rule:

Determine the generalized median in the property space (by the Kuhn algorithm). Then it is easy to check, whether it is a Cournot Point, by the criterion of the next section.

*III.2 A Criterion for a Cournot Point*²³⁶

Figure 4. The Cournot Point

The basic idea to determine an equilibrium point can be demonstrated by **Fig. 4**. To simplify the argument we assume that demand is continuously distributed over an area **D** with a density that is nowhere zero, yet otherwise arbitrary. This assumption may be relaxed (see Section I, assumption 1) at the cost of a more complicated argument. The origin **O** is chosen such that it lies in the (unique) generalized median of **D**. Suppose the abscissa **X** divides total demand in two equal parts (through any point in **D** there is at least one such straight line). Suppose further that there are two other straight lines, **G1** and **G2** that divide demand in **D** into two equal parts (**dividing lines**).

Now it follows:

- If a brand (say brand a) settles **outside** a dividing line, then the competitor (say brand b) has the chance to get more than one half of the market share (see **Fig. 5**)

²³⁶ Todt, Horst: „Wettbewerb durch Standortwahl in der Fläche. Die Cournot- und die Stackelberg-Lösung“ in Todt, Horst (editor) Beiträge zur Standortforschung, Schriften des Vereins für Socialpolitik. Neue Folge 1994

Figure 5. Equilibrium

- If not all dividing lines intersect in the same point (X , $G1$, and $G2$ in Fig. 4) then any brand will settle outside some dividing line. Hence any brand can improve. There is not equilibrium.
- Only if all dividing lines cut one another in the same point, is there an equilibrium point possible: The point of intersection.

The case of a unique point of intersection is possible. Take the case of a constant density of demand on a circle or a square. Usually, however, there are several points of intersection. If there are only two then there is no Cournot point. This is the criterion required.

Theorem 2:

If and only if all dividing lines of the brand space intersect in the same point then this point is the Cournot Point.

From theorem 1 we know, that the Cournot Point – if it exists – coincides with the generalized median. Notice that the generalized median is not necessarily a Cournot Point. The hypothesis of proposition 2 is also required, i.e. a very regular distribution of demand. More laxly formulated:

Rule:

The Cournot Point does normally not exist.

III.3. The Stackelberg Point

The **Stackelberg Problem** has always a solution: **The generalized median is the Stackelberg Point.** If a new brand enters the market it is rational to position it in the generalized median. The next competitor will certainly have the chance to get at least as much a market share as the pioneer in the market did. His success will, however, be at a minimum if the pioneer has settled in the generalized median.

The problem of a normally not existing equilibrium has not become less pressing. Once a second competitor is present in the market there is (normally) no longer an equilibrium realized. The successful intruder may again be attacked by the pioneer and so on.

Conclusion

The final conclusions of all this is the following:

- In real world there exists **no equilibrium** for two competing brands.
- The brands have to be repositioned continuously in the course of a competition process.
- The necessity of repositioning does not depend on changing tastes. Even if people do not change their attitudes need competing firms the help of marketing experts.
- **Hence dynamics without equilibrium is the normal case for brand competition.**

One might object that this is a very special case where just two brands and two dimensions are considered. Without a strict proof at hand plausible arguments stay against the possibility of equilibrium for a greater number of competing brands. A fortiori a greater number of properties would rather increase the tendency to disequilibrium. The chance of a competitor to improve his position in any situation will rise with the number of competitive brands that can be attacked. The sceptic may, however, ask the question, whether customers see themselves in a situation as described.

ROMANIAN AGRO-ALIMENTARY MARKET'S EVOLUTION FROM THE POINT OF VIEW OF THE REQUIRES MANIFESTED BY POPULATION

Țimiraș Laura Cătălina

University from Bacau, Faculty of Economics , Spiru Haret, no. 8, Bacau, tzimirash@yahoo.com, 0234/516345

Using as research sample – the secondary data investigation sources, the article presents the Romanian agro-alimentary market's dimension and dynamics by means of few characterization indicators of population's demand. The latest official statistical available data have been used, noticing, after their analysis, that in the 2001-2006 period, the agro-alimentary market from Romania known an ascendant trend, for some categories of products being registered even doublings of the manifested demand. Different rates of change for demand from the different markets also testify changes at the level of alimentary consumption behaviour of Romanian population for the considered period.

Key words (agro-alimentary market, effective demand, potential demand, consumption expenses, expenses for agro-alimentary products, drinks and tobacco)

Using as research sample the secondary data investigation sources, the present article displays the evolution of some characterization indexes of Romanian agro-alimentary products' market, respective characterization indexes of population's demand for this category of products.

An emphasizing indicator of population's demand's evolution for agro-alimentary products' category is the turnover realized by detailed activity enterprises with such products. It is noticed that, during 2001-2006 period, the turnover of the detailed activity enterprises in unspecialized shops with main sell of aliments, drinks and tobacco, registered an increase in real terms with more than 85%. On this basis, the strict specialized shops has diminished, market that after a period of decreases surpassed the level of 25% (in 2001-2004 period), entered during the last two years of the analyzed period in a slightly ascendant trend.

There are noticed, therefore, changes at the level of purchase habits with the meaning of population's reorientation towards those commercial spaces that offer a diverse range of consumption goods (including the alimentary ones), in the detriment of strictly specialized units that involve a quite long period of time for supplying.

Specification	2001	2002	2003	2004	2005	2006
	Millions lei current prices (RON)					
Detailed trade in unspecialized shops, with main sell of alimentary products, drinks and tobacco	7555	9760	13100	16965	21269	26033
Detailed trade of alimentary products, drinks and tobacco in specialized shops	2316	2098	2464	2714	3238	3723

Figure no. 1. Real dynamics of the turnover of the detailed activity enterprises for alimentary products, drinks and tobacco, in Romania, during the 2001-2006 period (2001 = 100%)

Referring to total²³⁷ consumption expenses of population for agro-alimentary products, it is noticed that in dynamics there have had a positive evolution. Therefore, in average, in 2006 a household spent approximately 139 RON for purchasing aliments and nonalcoholic drinks and 19,7 RON for alcoholic drinks and tobacco, aspect that in real terms constitutes an increase of approximately 11,2% and respective of 37,2% with respect to 2001. On the total amount of alimentary products and tobacco an increase in real terms of the total consumption expenses was noticed, with 13,8% during the analyzed period²³⁸.

In what the percentage of the aliments and nonalcoholic drinks is concerned, from the total population's consumption, these have met a major decrease during the analyzed period. But, the expenses with alcoholic drinks and tobacco, on the basis of population's purchase increase in Romania, have maintained on certain scale the percentage held in population's total consumption expenses, the increase rates of the two indexes being relative equal. This aspect may be explained by the fact that aliments and nonalcoholic drinks answer on a greater extent to some primary type of needs, whereas, alcoholic drinks and tobacco enter in the pleasure of consumption sphere.

Starting form the idea that in the total value of expenses the self-consumption's counter value from own production is included, the evolution of this indicator does not render a truthful image of the effective market's dimension and dynamics. For the agro-alimentary products case the total consumption expenses index constitutes more likely a measure of the effective and potential demand manifested on the market (appreciation that takes into consideration the physiologic nature of needs to whom the agro-alimentary products are addressed).

In what the evolution of total monetary expenses for alimentary products and drinks is concerned, it is noticed that there have encountered a more emphasized real dynamics than the total consumption expenses' evolution, thus in the period of the 6 analyzed years an increase with 28% was observed. The mentioned differences are mainly generated by self-consumption's counter value percentage decrease in

²³⁷ Total consumption expenses enclose the monetary consumption and the self-consumption's counter value from own resources.

the total consumption expenses, the dynamics of the latter being sustained by supplementary monetary expenses and not by own production consumption decreases. Therefore during the 2006 year, in average, a household consumed agro-alimentary products form own production in a value of 221 RON, and in 2001 in a value of 1288730 lei, aspect that in real terms constitutes a decrease with 6,6%.

Figure no. 2. Real dynamics of total and monetary expenses for alimentary products, drinks and tobacco – monthly averages per person-, in Romania, during the 2001-2006 period (2001 = 100%)

At the present moment, the agro-alimentary market's dimension expressed by means of monetary expenses generated by aliments and drinks purchase is quoted to 25.637.7 million RON (in increase with 19,7% as with respect to 2001). This increase is exclusively due to population's expenses increase for agro-alimentary products purchase (intensive increase), in the frame that Romania's population registered a decrease during the considered period.

Figure no. 3. Real dynamics of monetary consumption expenses for alimentary products and drinks, in Romania, during the 2001-2006 period (2001 = 100%)

Referring to market's evolution of the main groups of agro-alimentary products it is noticed that these have known different evolutions testifying therefore changes in population's alimentary consumption behaviour. Thus, during the 6 analyzed years, an increased demand for all types of analyzed products is noticed, the increase data varying from few percentages up to doublings of the markets' dimensions. From this point of view is remarked:

- sparkling water and nonalcoholic drinks market and the one of meat cans – case where the markets' dimensions met a doubling;
- fish and fish products, as well as fruits, sweets, meat and meat products, as well as alcoholic drinks – where the increases approached or have even surpassed the 50% level.

On the other side, the markets of some alimentary products with relative big percentages in the total of the alimentary expenses (cereals and products of cereals, dairy products, vegetables) have not registered major positive evolutions.

Figure no. 4. The dynamics of (real) physic and value purchasers among the main categories of alimentary and drinks products, in Romania, in 2006 with respect to 2001 (year 2001 = 100%)

In conclusion, there can be appreciated that the agro-alimentary market from Romania registered an ascendant evolution during the last period. A major increase of agro-alimentary products it is noticed in the frame of consumption countervalue of products from own resources. The most spectacular increases were registered on the sparkling water and nonalcoholic drinks market, the one of meat cans, as well as on alcoholic drinks; for some of the products mentioned registering even doublings of the demand during the six analyzed years.

A NEW GENERATION OF AGRO-ALIMENTARY PRODUCTS ON ROMANIAN MARKET – NUTRITIONAL PRODUCTS

Țimirăș Laura Cătălina

University from Bacău, Faculty of Economics , Spiru Haret, no. 8, Bacău, tzimirash@yahoo.com, 0234/516345

The present study constitutes a succinct description of the evolution status of nutritional products on Romanian market, as well as the context of its appearance on the market. Constituting the latest generation of agro-alimentary products, the nutritional products are adapted to metabolic needs of different segments of consumers. Appeared relative late on the Romanian market, nutritional products' penetration in consumption constitutes, at the present time, one of the tendencies manifested in agro-alimentary marketing at the level of European Union, as a result of increased interest of consumers for alimentary safety and security, interest manifested (even though with a more reduced intensity) at the level of the Romanian market also.

Key words (agro-alimentary market, nutritional product, competitive advantage, alimentary safety and security)

There are considered to be nutritional or functional products those products that have suffered certain modifications of their chemical composition, materialized in diminishing, adding or replacing of one or more components, with the purpose of obtaining benefic effects on the health state, physical performances and/or psychic consumer's state. In this frame, nutritional products do not address to market as a whole, but are adapted to metabolic needs of different segments of consumers.

Nutritional products' appearance

With time passing, in the hierarchy importance that diverse agro-alimentary products had in quality appreciation, numerous changes were registered. Not long ago, quality was appreciated, especially, on the basis of sensorial value of products, and the hygienic-sanitary one. Under these circumstances, processors from alimentary industry focused their efforts towards sensorial products characteristics' improvement, on diversity, on maintenance period's increase and providing offers also out of the seasons. All this were possible due to transformation technologies' improvement to an industrial level of agricultural products. But, the results of such processing that supposed a high number of interventions on the raw material, determined a series of unwanted effects, generated especially by the changes produced on the biologic value of agricultural products. There were obtained, thus, very attractive products, with sensorial and hygienic-sanitary proprieties, with a high energetic value, less perishable and easy to prepare. Agro-alimentary products' biologic value reduction, the results of multiple processing operations at industrial level, was materialized in diminishing the vitamins and minerals content.

Processed products consumption increase, with low content of vitamins, mineral elements and alimentary fibers and fruits and fresh vegetables consumption decrease, lead during the last decades, especially in the developed countries, to the appearance of nutritional diseases.

As an answer to these problems, agro-alimentary markets of the developed countries met a series of mutations generated by increased exigencies of consumers, of public opinion, in generally in what alimentary safety and security is concerned. In this frame and with the purpose of further assuring a sensorial and hygienic-sanitary high value of the agro-alimentary products, the producing firms oriented towards the so-called nutritional products, that, even though are submitted to a big number of transformations at an industrial level, there are better adapted to physiologic needs of human organism. Therefore, by means of nutritive value correction of agro-alimentary products, on a significant extent, the nutritional value of raw introduced material is reconstructed (even not on total), the risks for consumers' health being therefore, reduced.

Even though it first appeared in the developed countries, where consumption of products with a high processing degree and low biologic value had a big percentage from the total consumption of population,

and the consumers were more preoccupied and conscientious of the purpose that alimentation has on health and peoples' safety, nutritional products appeared and expanded at the level of other markets also (on a rather low developing level).

Nutritional products categories

Starting from chemical correction procedure of agro-alimentary products the following nutritional products categories are distinguished:

- Nutritional products obtained by nutritive value diminishing
 - It supposes the partial or total reduction of one or more components of the product. There were obtained therefore, products with a diminished content of sugar or without: sugar, caffeine, fat, salt, alcohol. These products are much better adapted to certain segments of consumers: children, elderly people, persons who suffer from different diseases.
- Nutritional products obtained by nutritive value of agro-alimentary products enrichment
 - This procedure follows, especially, the insurance of a surplus of vitamins, mineral elements, and alimentary fibers, materialized in an alternative for traditional products consumption, products poor in such elements. These elements regard the reduction of nutritional disease risk, resulted as chronic uncovering of physiologic needs of human organism for a certain nutritive substance and also answer to physiologic needs of some segments of consumers that lay down physic and/or intellectual effort or that presents certain metabolic affections.
- Nutritional products obtained by replacing some nutritive components with others
 - A significant percentage in this category is held by products, where sugar was replaced by other sweeteners.
- Nutritional products obtained by multiple interventions on chemical composition
 - These kinds of products are: degreasing milk with calcium additive, carbon-gaseous light with vitamins addition, etc.

Nutritional products' competitive advantages

Starting from the presented aspects the competitive advantages of nutritional products may easy be noticed, elements that also justify the ascendant evolution of its market:

- there are products that answer alike to necessities concerning the sensorial aspects but there are also balanced from a nutritional point of view, aspect that is not valid for other products with a high level of processing;
- there are products adapted to metabolic necessities of different categories of consumers: the ones that make physical and/or intellectual effort, consumers with certain metabolic affections, the ones that pay special attention to health state, to silhouette, those who want to maintain "in shape" physically and mentally speaking.

Nutritional products' evolution on Romanian market

In parallel with the expansion registered in Western Europe (especially), the market of the products potential benefic for health is in incipient shape in Romania. Actually, all these products, frequently called "healthy products" – where nutritional products are included – constitute on agro-alimentary products relative new products.

The penetration of these categories of products on Romanian market started especially after 1990, even though at the present moment there can be talked about quite toilsome "beginning", "braked" by very low level of knowledge of Romania's population, in rapport to importance of alimentation for health. Concerns in these directions are noticed especially on consumers' categories that suffer from certain affections or that regards silhouette. For the rest, in most cases the importance of alimentation for population's health is not known, the information from the label or wrapping often are not read, and even read, only in few cases and only partially it reflects the "truth" concerning consumption benefits.

From this point of view (of the measure in which the consumers are interested in the information from the label), a study realized in 2006 at the level of Bacau239 county highlighted that the information from the wrapper are read, partially, by 68,8% from the surveyed persons, only 20% read it fully and 20,2% do not read it at all.

Another major problem that breaks the market of nutritional products development is the consumers' reticence towards what is new. Therefore (in a greater extent than with other products) agro-alimentary products consumers are relative reserved in what "new" is concerned, in the context in which, on a significant percentage, alimentary consumption habits are transmitted by filiation, and the "horizontally" loaning is generally met only with the young consumers category.

Thus, the results of the same study prove that in what agro-alimentary products consumption that have a character of newness (there were considered new from the consumer's point of view those products that were not consumed up to that moment, no matter of the moment of appearance on the market), its frequency being relatively low, the consumers preferring the products that have already experienced. From the total of 950 agro-alimentary products purchasers surveyed, over 70% do not or very rarely consume agro-alimentary products that have never tried. At the opposite level, those who often consume new products (once or many times a week) represents only 17,5% from the total of the investigated persons. Major differences for the interest point of view for the new products is manifested on environments, ages and on categories of population according to incomes, more oriented toward newness are youngsters, with high incomes, from urban environment.

With all "obstacles" generated by low interest of Romanian consumers for information, as well as reticence for what is new, during the last years among the Romanian consumers and public opinion, a higher interest for a healthy alimentation is noticed. Therefore, starting with 2002 the E-s problem (preserving, stabilization, colors, etc), of genetic modified organisms (GMO) started to be more discussed. This has marked the beginning of some changes in consumers' mentality and behavior (or at least at the level of certain consumers segments), in the sense of an enhanced attention (next to price and expiration date) to new concepts such as: ecologic product, biologic, balanced alimentation, etc. Not at least an enhanced attention should be granted by Romanian consumers to these aspects that justify on the basis of horizontally loaning of purchasing and consumption habits, the undertaken studies testifying that at least population with high income categories manifesting real similarities with tendencies registered at the level of purchasing and consumption habits on EU level.

On the basis of the tendencies manifested at the level of public opinion from Romania (of granting a big importance to healthy alimentation), on the national agro-alimentary market appeared also nutritional products. Thus, it is noticed an improvement of "healthy" agro-alimentary products offer in generally and especially of nutritional products offer.

Few aspects that come to strengthen this fact:

- for instance next to white flour some producers offer dark color flour, with a high content of ash, fibers, minerals and vitamins;
- there exist a diverse range of bread and bread specialties with high content of fibers but with cereals adding benefic to different segments of consumers;
- the offer for diary products was made more varied, existing products with low fat content, with adding of vitamins, minerals, essential ferments, fruits, etc;
- the offer for the other cereals for breakfast was also made more diverse – musli cereals, with adding of alimentary fibers, etc;
- it appeared and made diverse the dietetic sweets range (with low sugar content and/or fat, with low calories content, reach in alimentary fibers, sweets that do not contain raw material of animal origin), etc.

Actually, the offer's diversification of agricultural producers by proposing the nutritional products may offer real competitive advantages in the context where the option for this category of products constitutes

²³⁹ Direct research, with exploratory character, on a sample of 950 respondents, using the sampling on quotas as selection procedure of units in the sample

the adopting of an anticipatory vision as with regard to market dimension and confers a real element of difference in rapport to the offer of the other players from the market.

In spite of these, the offer from Romanian market is net inferior, as compared to western markets. Thus, Romanian consumers are restricted to manifesting their preferences, especially because of the reduced diversity of these products. For instance, in the case of dietetic sweets on Romanian markets, especially sweets for diabetics, rich in alimentary fibers are presented. But, products with a low content of carbohydrates or without gluten, ice-cream, fresh pastry or confectionery products without sugar or with a low fat content are either inexistent or present on reduced quantities on markets.

For characterizing the development level reached by a certain market really relevant is the knowledge of penetration degree in consumption of the respective product. Further on, there are presented few of the results of the same research realized among purchasers at the level of Bacau market.

The consumption of agro-alimentary products is a habit for 32,7% of the surveyed persons. It can be noticed that the tendency to use such products is distinct for different population categories depending on a series of criteria such as: age, income, social setting, gender or the presence of children in the household. As far as age is concerned, one notices a greater proportion of younger consumers of such products compared with the situation for persons in the older age groups (it is widely considered that young people are more open to the new than old people are). Similarly, the extent of the orientation towards such products is greater among persons with higher income compared with those with lower income, among persons residing in urban areas compared with those living in rural areas, and also among the female population compared with the male population.

Habitual consumption of nutritional products	Total	on averages		on genders		on ages (years)						on incomes(RON monthly / person)				
		urban	rural	male	woman	18 -24	25 - 34	35 - 44	45 - 54	55 - 64	65 and over	under 300	300 - 600	600 - 900	900 - 1500	over1500
yes	32.7	38.7	26.7	28.5	36.7	37.4	39.6	31.3	31.7	29.4	25	29.4	30.5	46.3	47.3	38.5
no	67.3	61.3	73.3	71.5	63.3	62.6	60.4	68.7	68.3	70.6	75	70.7	69.5	53.7	52.7	61.5
Total	100	100	100	100	100	100	100	100	100	100	100	100	100	100	100	100

Table no. 1. The structure of agro-alimentary products' purchasers in terms of the nutritional products consumption habits on total and on environment, gender, age, income (%)

- data resulted after a direct researched undertaken at the level of Bacau county, on a sample of 950 respondents -

Chief among the nutritional products that have penetrated consumption by the population are: products without sugar, products with added vitamins and minerals, products without caffeine, low-fat products, products without alcohol, products containing fibers, and products without salt. First in terms of the extent of the market penetration are the products with no sugar, followed by products with vitamins and minerals; over 50% of the surveyed persons who declared that they are consumers of nutritional products consumed such products. Products without salt and with fiber respectively account for the lowest number of consumers (under 20% of total consumers of nutritional products).

Figure no. 1. The degree of penetration in consumption of various nutritional products – data resulted after a direct researched undertaken at the level of Bacău county, on a sample of 950 respondents -

In terms of the intensity of consumption, among the consumers of nutritional products (who make up 32.7% of the total 950 surveyed buyers of agro-alimentary products), the largest part (46,3%) are those for whom the consumption of this type of products accounts for 25 – 50% of total food consumption. For 42.8% of the persons, the consumption of nutritional products accounts for fewer than 25% of total food consumption, while 10.9% stated that over 50% of their food consumption is made up of nutritional products. In conclusion, there can be estimated that the agro-alimentary market of nutritional products is on an incipient level in Romania, the products from this category being presented recently on the market and on a low range diversity. Nutritional products' appearance is tightly connected to interest increase for assuring a good state of health and of becoming aware of the alimentation's importance for population safety and security. However, the penetration of these categories of products on the Romanian market, starting especially after 1990, was slowly realized, the causes that "braked" this process being the relative low knowledge level of Romania population concerning the alimentation importance for nutritional products category that penetrated in population consumption, and are especially noticed: products without sugar and those with vitamins and mineral adding.

In this paper it is presented the marketing strategy development for a company that offers recruitment and selection of personnel services. This company is addressing, mainly, to the customer (companies) which are having the intentions of having top positions in large, and well coated companies.

The recruiting company accomplishes the head-hunting process for finding the best candidate for working successfully at the recommended job. For this recruitment process to be the most efficiently and the most effectiveness, the companies that are offering this type of services must be aware of the existing marketing politics and they also have tot tray to use them talking in consideration their resources and their needs. So, in this paper I have developed the marketing mix specific for the recruitment and selection of the personnel services (the 8th P).

Key words: candidates, services, employers and employee.

Introduction

When you are talking about enouncing the market strategy for different products, indifferent of their nature, you must consider the four basic elements: the product, the price, the placement and the promotion.

For services, these four elements - 4P, aren't enough because the services have many particular things, like: intangibility, heterogeneity (or variability), inseparability, and perishability, too.

The specific nature of the recruitment and selection of the personnel services, especially aspects like involving the clients into the production field and the importance of the time factor, demands that other strategic elements to be included.

That's why in the development of the mix of marketing for the recruitment and selection of the personnel there have been used the 8th P of the services marketing, that are describing the eight variables, very useful in talking the decisions for the recruitment and selection of the personnel services (according to Christopher Lovelock and Lauren Wright).

The mix of marketing in the recruitment and selection of the personnel service

For the recruitment and selection of the personnel services there had been developed the 8th components of the integrated services marketing, these being present in the following:

- a) The product elements
- b) The place, space and time
- c) The promotion and the instruction
- d) The price and other using expenses
- e) Process
- f) The productivity and the quality
- g) People/Personal
- h) Physical elements (tangible)

The right name of the recruitment and selection of the personnel company that we have been studied is not calling it: The X Company.

a) **The product elements** (offered services) are being represented by all the services performance components, which are creating the value for the customer. The managers must select the characteristics of the main product, but also the supplementary package of offered services, about the advantages that it is wanted by the customer and about how well are will compare the services performances with the competition once. In the recruitment and selection of the personnel services, the main product is being represented by the recruitment and selection of the personnel services, which other has to be according with the client specifications (the company that wishes to hire him). Outside the basic service, the recruitment and selection of the personnel companies may offer other elements that may be seen as an added service, such as: a high quality level, that may be given mainly by the quality and the adjustment of the solicited candidate; making a “brand name” in the recruitment and selection of the personnel market, so that the clients may trust into the offered services; the guaranty offered to the customer, concerning the adjustment of the candidate with the job and his integration into the working team, but also the hiring company; instruction services and training offered to the persons that are in the data base, and also at the other companies employees.

This company can be offers the following kind of services:

The recruitment and selection of the high quality personnel services (executive research);

The company that is being studied is focused, mainly, on the head-hunting for top or middle management positions, or on the rarely specialist positions. The head-hunting it is about the best specialists that are in the leading positions. These ones are being hunted by the company consultants for the similar positions in other companies. The potential candidates are being contacted by consultants; it is being presented to them the offer for the job they might be interested in and then are invited to a meeting for a detailed discussion. In this case it means that the candidate:

- is on the recruitment of personnel company list;
- the job and his specialization are being searched on the labour market at that time;
- he/she is good;
- they have a chance, even if its not looking for one, to chance the working environment and his incomes;
- if they are not interested in either of these ones, they remaining with the competence level testing and the expending of the relationship circle.

Audit and consultancy in human resources

Its relatively new service in the human resources field, Romanian and multinational companies are looking for these type of services (consultancy in the human resources):

- The audit of the human resources function means;
- The development and evaluation centers;
- The creation and implementation service of the performance evaluation systems
- Executive coaching;
- The leasing of the personnel/ the contracts of the personnel

Training

The X Firm is starting its cooperation with the companies it is working with the identification of the reasons for which they want to offer their employees training programs and the expectation they have from the employees at the end of the class.

If the training “product” is not the most suitable for what they want, then there are recommended some alternative solutions: The organizational diagnosis, the development and evaluation programs, coaching, recruitment or management style adjustment.

A company is offering classes for its employees to help them develop or /and consolidate their knowledge and abilities, to improve their attitude.

The X Firm offers a serial of classes for the employees' motivation and recommends them especially the ones for the managers, of which role is essential into team development.

The leader is establishing the organization culture and the holding back politics and decides what motivational decisions are applying into the company and if they are applied.

b) Place, space and time

The marketing decisions about when, where and how the client's services will be distributed. The product elements distribution towards the client it involves, decisions about the time and place of the distribution, and the type of the distribution channel: physical and/or electronically, it depends of the nature of the service that it is offered. During the recruitment and selection of the personnel services both types of channels may be used, because the clients can contact their potential employees, through face-to-face dates but through electronic channel also with the internet help.

The mail services and the internet allow the delivery of these services based on information which are distributed through the telephones or the computer, but anywhere and anytime are welcomed for the clients. The recruitment and selection of the personnel services the recruitment and selection sites, but even the human resources compartments may occupy directly with finding the ideal candidates or they can appeal at intermediaries, which means other recruitment companies that have data base with candidates, a lot more, or they can appeal to the other firms services for posting the hiring announcement. When it is about intermediaries these may get a commission for the made services. The client's expectations, about speed and indolence become decisive into the service delivery strategy. The most frequent selection method is the direct approach, combined with the activation of the (networking) contact area.

The activation of the contact area, called networking, is not necessary referring at the data base, but at the activation of all the existing contacts in the data base and as well of the each consultant contacts. It is trying to find detailed information; it is like some information net. Here there are meeting the information from the personal nets of each consultant. The direct approach suppose the accomplish with the client of a target list, a list of companies that have a similar profile, or which could offer candidates with a great potential for the position from the client's company.

The site of the X firm was the first site from Romania supported by an experienced company in the human resources area. The company site offers, company and candidates, a large amount of information about the human resources and it is a reference point for all what means the latest news on the market labor, concentrating especially on the consultancy part.

At this address the candidates may learn more about the carrier opportunities to create a CV, or modify the one that is already in the data base. Here they also find advices, about the interviews for getting a job, and information about the actual tendencies on the labor market.

The site is very easy to be used, and it answers to almost questions about such a vast domain as it is the human resource.

c) Promotion and education

No marketing programs can succeed without an efficient communication program.

This component has three vital roles:

- giving information and necessary advices;
- convincing the clients about the merit of a specific product;
- their encouragement of encouragement of acting at a certain period of time.

In the process services marketing, more communication means education, especially for the new consumers. The companies should learn these consumers about the benefit of these services, where and when to get them and how to participate efficiently at the service process. The communication may be realized individually, throw the sales personnel and trainers or throw the sales personnel and trainers or throw the media such as: television, radio, newspapers, periodicals, etc. The X Firm is using the direct

communication method in the client's relationship applying at the business – to – business method, and the potential candidates are contacted applying at the direct marketing.

d) The price and other expenses of the consumer

This component causes at the consumers the obtaining of the benefit from the service. The responsibilities are not limited at the traditional activities of establishing the sale price towards the consumer, which includes procedures given by the market and establishes the accreditation terms. The recruitment and selection of the personnel companies admit that in practice they are looking to minimize the costs and they are staking and the customers (clients) which might use the service, including the additional financial expenses, time, mental effort and psychological effort, and negative sensorial experience. The recruitment service price: is called a payment (service), (favor) or a practiced tariff, which varieties between: 20% - 50% from the hired person's salary, at which it is adding the recruitment and selection expenses.

At the X firm, the short list has, in generally three persons – the most suitable ones, the pluses and the minuses of each one (in the consultant vision). The decision belongs to the client, and the fee is paid completely by this one.

The sum has nothing to do with the candidate salary; it depends though of the recruitment method selected by the consultant and of the work volume evaluation.

The collected tariff (tax) of the X firm, for the recruitment and selection of the personnel, it is being found as a payment at the end of the service (job). The payment is established by taking in consideration the jobs complexity and how easy the suited candidates are being found.

For the leasing service there is a monthly administration tax or, if the recruitment process for that certain person it exist, then it is finalized a contract for the recruitment and one for the leasing.

e) The process

The process is a private functioning method and serial actions, which involves steps that need to find themselves in a stated succession.

The creation and distribution of the product elements towards the clients, needs the type (model), and the realization of an efficacious process.

One process it describes the method and the sequence in which the current services are doing their jobs into the system. The functioning process of the recruitment and selection of the personnel services that is being developed in most of the recruitment and selection of the personnel companies is sketched into the following in Figure 1.1.

The principles after which the X firm is guiding the X firm are bringing, to the looking for the candidates process, quality but it is admitted the fact that each search is different, so:

9. The analyze of the position and it's specification;
10. The research;
11. Looking – recruitment;
12. The candidates evaluation;
13. Verifying the references;
14. Taking the decisions (in the case of the best candidate);
15. Following the reaching of the objectives.

The firm must understand the client organization, of the specific request, the correct evaluation of the project, are elements without whom the candidates selection process, so it's relation with the hiring company to last, could not succeed. A successful relation can have a good final result only if there is a well trust level between the two, and if the needs are suited. In this process, not just the candidate is evaluated, it very important the initial part, of the project evaluation.

About the candidate, the first criterion (in a chronological order), of selection is obviously, the one of the functional competences. The main difference between the candidates is the profile of the organizational culture of the client. It is being offered to the client a short list of candidates which are the best for him, and

not the best for what the theoreticians from the organization behavior area think that it is the most less wanted from the possible organizations.

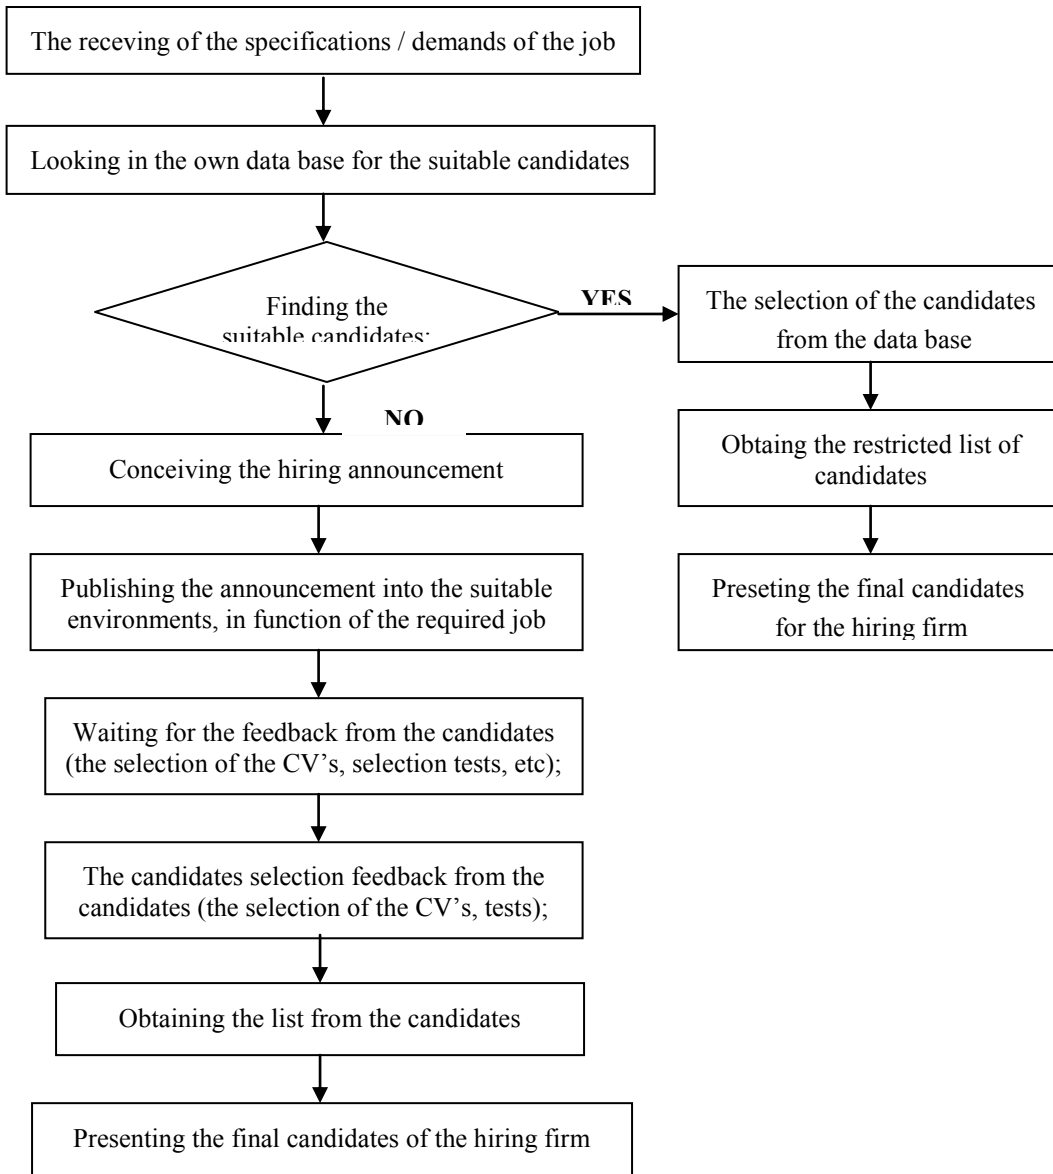

Figure 1.1. The main steps of the production process for the recruitment and selection of the personnel services

f) The productivity and the quality

These are showing how efficient are the entering which are changing themselves into exists and which are giving a value added to the clients (customers). These elements often are treated separately, but it is very good if they can be seen as being two sides of the same coin. No selection and recruitment services firm cannot allow treat the two elements separately. The improving of the productivity is essential for keeping the costs under control, but the managers must avoid making inadequate reductions (costs), in the quality level of the offered services to the customers (also about the employees). So, if the costs are rapidly growing, the services firms are forced to increase the presentation productivity, thing that may be accomplished in many ways. The providers of recruitment and selection of the personnel services may train better the actual employee or they might hire another ones, who would work a lot more, or with a lot more skill. Another way would be that the providers of services to increase the service partially renouncing at the

quality, a way less agreed through. The providers of recruitment and selecting personnel may “industrialize” the service by supplying the endows and by the standardization of the service process, or they may put to work the technology force, with the help of an computerized performing system, might realize rapidly the selection of the candidates from the data base, may rapidly send answers to the appliers, may administrate efficiently the entire recruitment and selection process.

On the other side, a web site hold by the recruitment and selection of the personnel agencies, may allow the clients to obtain the information they need, to explain themselves about the entire recruitment and selection process, practically all the details the clients need might be showed on a well realized site. One of the main ways throw which a company that offers recruitment and selection personnel services might be different from the competition is throw constant supplement of a higher quality than the one offered by the competitive firms.

As well as the product marketers the service providers must identify the client’s expectations that are being watched about the quality of a product. Unfortunately the quality of a service is harder to define, than the quality of a product.

Into the recruitment and selection of the personnel services, also, is not very easy to find a definition of quality of the performance of these services. The keeping of the client’s rate is probably the best measurement of the quality of the service – the capacity of a firm of keeping its clients it depends of the showed consistency in giving the value. The recruitment and selection of the personnel companies must secure themselves, which the clients are benefiting constantly of a higher quality of the prestation service. Even if some problems cannot be stopped from appearing the company may learn to resolve them.

For the growing of the services quality the following aspects ate the most important:

1. The capacity of improving the defficitary service;
2. The authorization of the employees of the contact with the clients for these ones to notice and to be concerned about the needs of the client.
3. The necessity of some higher quality standards of the service.
4. The strict surveillance of the performance in the serving – the own performance as well as the competition one.

g) The people

Lot’s of services depend directly of the personal contact between the clients and the firm employees. During the recruitment services, the firm consultancy is interacting with the clients even since the moment of the request defining for the vacant job.

The consultant must prove professionalism during the pecking the information about the culture of the organization, the values and its objectives, the personality of the one that would be hired for to eliminate any unfitness, adjustment or any problems of this kind.

The recruitment, consultancy and training firms receive the evaluation from that firm. For having success the firms that are offering recruitment and selection of the personnel services make important efforts to recruit, train and motivate the personnel, which especially are in direct contact with the clients.

The X firm is an experimental crew with professionalism abilities that has a strong background in business, psychology, philology and engineering. The consultants have lots of experience in leading the human resources, project consultancy for companies that act in several areas.

The X firm consultants are not specialists in the business area, but they know how a marketing department looks like, which are the attributions of a sales manager of a financial one, they understand the business model of the customer: some are specialized in the backing area, other in IT, and telecom, etc. The quality of a consultant at the recruitment is given of the quality of its own net, the quality of its company. From the personnel relation that they are having with lot of people from the “market” you can find out the most useful information. Each one of us has the duty to develop its own net.

To the contacts net is being added the companies experience on the market (there are between 5 and 15 recruitment projects in the same time), the advices and the guarantee that are being offered to the customers (including the responsibility of replacing the chosen person). Over 70% of the clients are returning as clients at the X firm.

h) Tangible elements

The building perception, the environment, the vehicles, the equipment, the staff members and the other visible clues, all of these are giving a tangible perception about the firm, its style and the quality that it is giving as well. The services firms must build, carefully all these perception because they can have a strong impact on the clients. A discussion between two persons might symbolize the safety that the client might have into the recruitment and selection of the personnel company.

Conclusions

It is very important to be established the relation between the services marketing, operations and human resources. As it had been showed into the components of the model of the 8P, the marketing cannot function isolated from other functions in a services organization. The specialists, who usually have the responsibility of improving the productivity and the quality control, are leading the process that is necessary for the creation and the delivery of the service. Similar, the employees are recruited and specialized by the managers. Even the ones that have direct responsibilities with the clients often are reporting to the managers.

The contact between the client and the recruitment and selection of the personnel service is the time period during which the customers are interacting with the recruitment and selection personnel service. In some cases, the entire service of recruitment and selection of the personnel may be reduced (minimized), at only one contact with the client, involving the command, the payment and the contact might be made through the simple interaction between the client and the employee.

21th century advertising might just be the most powerful weapon a marketer has and a quite efficient one if we think about the way it changed our world. But all that power comes with great responsibility: used accordingly by planning everything in the smallest detail possible it can be the best thing that ever happen to a company, used without any kind of strategy it can very well be a large scale disaster. Because of the great costs that advertising is much too often associated with and also the long term affects it has on the consumer a company should never start an advertising campaign without knowing every single last detail concerning their product and consumers. The study of the promotional message will show its capacity to gain the attention of the targeted audience, to stand out from other messages, to be associated with the product/service it promotes, to generate a positive reaction towards that specific product/service and to encourage its purchasing.

marketing, research, advertising

Marketing research in promotional policy issues is the most developed field of research from all the other marketing mix components research fields. The studies, in this field are primarily focused on advertising, being oriented on three main topics: promotional message, promotional channels, and evaluation of advertising efficiency.

The message itself is a pathway to reaching a goal, a way for the marketer to communicate with the consumers, to listen to them, to learn from them and a way to let the world know that the particular product/service is available with all its numerous advantages. In a world dominated by accessible technology is quite hard to be different or to remain unique through the products/services offered and advertising is just the tool to transform an ordinary product or service into an idea as close as possible to the desires and needs of the customers.

The study of the message itself it is being done in two different ways depending on when it is taking place: before or after testing the message. The study of the message before testing it will show its capacity to gain the attention of the targeted audience, to stand out from other messages, to be associated with the product it is supporting, to generate a positive reaction towards the product and to encourage the purchasing of the product. Regarding the method chosen to deliver the message (press, TV, radio...) we can identify the following methods for analyzing the message previously to testing it:

a) **Singular testing** analyzes the effects generated by exposing the subject to only one message and has the following approaches:

- The subjects are being confronted with different forms of the title of the announcement and they are asked to choose the one that they consider as the most interesting. Afterwards they will receive the rest of the announcement and some questions regarding it will be applied. This way the researcher can identify the way in which the title of that announcement gains the attention knowing the fact that in real life the title is the one responsible for standing out in the eyes of the consumer, only afterwards (and if this condition is satisfied) the consumer will actually read the entire message text

- Before being presented with the announcement the subject will be asked regarding their actual intention of purchasing that particular product. This variable will also be analyzed after the exposure to the message in order to establish the way in which the message influenced the purchasing intention for that specific product on that particular consumer. A particular attention should be given to products with a high grade of dedication (like high level electronics, professional tools and equipments) that stand out of the general consumer product category for which the purchasing intention is quite hard to be changed.

b) **File type testing** consists in a set of 6 to 8 announcements among which the one being analyzed, each one printed on a different sheet from the same copy-book. This copy-book will be handled to the subjects to look into and afterwards they will be asked what brands they can remember to be promoted inside and to evaluate the announcements without looking over the copy-book. The next step in this method is showing (again) the announcement being analyzed in order to determine in what manner the respondent trusts the message, is being attracted by it and how clear he understood it. Some of the main advantages of this method are: the short time needed to apply it, low costs, easy understanding of the results and as problems the fact the memory effect depends also on the interest shown by the subjects towards that specific product and not exclusively on the announcement itself. Again it is necessary to know the respondent and its interest towards that specific market product or service, his knowledge in the field being one of the strongest influence factors for the memory effect.

c) **The imaginary magazine method** consists on making a couple of magazines containing some rather interesting subjects and advertisings so they will appear as real as possible. The announcements that represent the subjects of the test will be inserted in some of the magazines which will be distributed thru the postal service or through some designated operators to families from different geographical areas. The respondents will be asked to read the magazine in a usual manner in order to rate the publication. The analyze will be made thru a form that the respondents will return after completing it and which includes among other things (questions regarding the articles and the advertisements in generally) some questions designated to the announcement being analyzed. This last type of questions will determine the memory effect, the way respondents are being attracted by it, the way they trust it and the attitude towards purchasing the promoted product. The questions regarding the product can be used to compare the answers given by families on which the message was tested on and families on which the message was not tested in order to see the effect that the announcement had. As in any research method based on respondents acting on their own, without any assistance from the researcher it vital for the value of the entire research that the selected respondents will behave as instructed and that all the responses received will be analyzed firmly before being taken into consideration.

d) **The consumer panel test** consists on 50 to 100 people that are being presented with a couple of announcements promoting the same brand in order to make a classification after their preferences, their interest towards the message and the influence it had on their purchasing intention. Standard questions for this sort of research will also focus on identifying the way the consumer sees the message transmitted through the announcement, on the way the message is being presented and on the most appreciated parts of the announcement. The test can be applied on individual or group interviews, in the respondents' home or in special prepared rooms. Among the limitations of this particular method there are the influences between individuals in group interviews and the potential classification errors when confronted with a large number of announcements.

e) **The D.A.R. test (Day After Recall)** consists in transmitting a commercial on TV in 3 or 4 designated localities. From those localities the next day after transmitting the commercial the researcher will select a number of people that watched the TV program. They will be asked on the phone if they saw the spot and, if so, to tell what they can remember from it. After this they will be asked to rate the message by its capacity to inform, its credibility and its clarity. The evaluation of the efficiency will be done by comparing the scores obtained from the respondents with other standard scores like the ones obtained by similar products. Also, an interesting thing to test when using this method is what other similar commercial is the one in question being associated with and in what manner this association affects its image and message

f) **The theatre test** consists in inviting a group of consumers in a theatre room under the pretext of watching a pilot TV program. Before the show the subjects will be presented with a list of brands among which the one being tested and asked to chose their favorite one under the pretext of a lottery and they could win the chosen product (the quantities of products will be chosen in such manner that their general

value to be as close as possible). After this moment the consumers will be presented with the actual TV program in which there will be inserted a couple of commercials representing the brands from the lottery including the brand being tested. At the end of the TV show the respondents will be asked again to mention their favorite brands (for another lottery, to increase their chances or to increase the quantity of the product chosen earlier). This way the researcher can measure the way in which viewing the commercials influenced the attitudes of the respondents. In order to maintain the story of a pilot TV shows the respondents will also be asked about the program and other commercials.

In order to analyze the messages before testing them a series of measures based on various equipments and technologies that test the physical reaction of the human body are also available. These methods are based on the fact that the emotions generated by a particular message will provide physical reactions that can be measured and therefore deduce some of the attitudes of the respondents towards the message they were presented with. Such methods are:

a) **The G.S.R. test (Galvanic Skin Response)** uses a device named the galvanometer that analyzes the physiologic reaction of the individuals presented with particular messages. The subjects will be connected with measuring probes (electrodes) to a measuring monitor while different commercials will be running. With the help of the measuring probes the monitor will record the perspiration on the inside of the palms of the subject that is considered as an important indicator for the intensity of the emotions felt. This particular method is not a very popular one due to the fact that it is not able to make the difference between a positive reaction and a negative one and it needs time to adjust the equipment to the body of each individual. Also the way people sweat depends on a large variety of factors such as room environment compared to the outside environment, skin properties, different anti sweating methods used by each person. Because of this is very important for the researcher to normalize the room temperature, to ensure the same conditions for all the respondents, and to establish the normal behavior (the base) for each individual being tester.

b) **The ocular receptor** is an observation technique based on a high sensitivity video camera that follows the movement of the eye retinas when the subject is being presented with the message. By using this technique the researcher can identify the parts of the message that were the most viewed by the respondent and the order in which he read it. The main disadvantage of this method is that it is not able to tell if the respondent is being attracted by the message (if he is actually reading it or looking at some parts of the announcement) or if he is just confused and looks at the message in a random manner. For types of messages that are known to have a standard form (like web pages, articles...) the respondent will be tempted to follow the same known pattern and will be confused when being confronted with something different. Also, when being confronted with color rich graphics the way the respondents react to the black and white form often differs from their reaction to the full color one. The researcher should be informed if some of his respondents are having trouble seeing one or more colors or textures (as an ocular medical affection) and if they are using eye glasses to enhance their sight (if so, what are the differences when viewing the message with and without the glasses)

e) **The PDR test (pupil dilatation response)** measures the degree of pupil dilatation of a respondent when he is being presented with a certain commercial. The theory behind this method says that in similar conditions of lightning in the environment and distance to the screen the way pupils react can show the measure in which the respondent is interested on a part of the message. Studies show that a commercial with a bright white background will score much more than a dark background one no matter how interesting the last one is. Therefore the scores are being normalized with the quantity of light the commercial generates to counter the independent physical reaction of the retina. Also the reaction time of each individual must be carefully tested and recorded to normalize the scores obtained in the real test. The researcher should not look for perfect healthy subjects because that is rarely the case in real life and by doing that the research results will not be that rich.

d) **The diaphanometer test** is based on transmitting a message starting from an unclear presentation and gradually increasing the quality of the transmission in order to measure the reaction of the respondent in different stages of this presentation. Counting on the particularity of the commercial the scrambling of the message can be audible, visual or both. In some variants specialists are using real noises to simulate the normal conditions (traffic noise, colleagues speaking at work, children playing at home, a construction site nearby, rain, sun, graffiti, or other problems affecting the print). Here for the researcher will use as scrambling methods sounds and print alteration simulations specific to the environment where the respondents come from and to the environment where the messages will actually meet the general public.

e) **The tachistoscope test** is about playing the same commercial at different speeds in order to determine the elements memorized by the respondent at different stages. This way the specialist can determine the minimum time needed to send the message with maximum effects and also to determine the elements of the commercial that stand out. The main idea here is to see which is the minimum time needed for the main parts to be understood by the respondent due to the ever increasing price of advertising space. Also a variant of this test was used to determine how fast can a banner go pass the respondent eye so that it will be seen accordingly (the banner print can be on a bus or the respondent might pass it at different speeds and distances). As a result of this technique the very interesting animated frame ads were developed (the coca-cola subway advertisement is a good example here).

Analyzing the promotional message after testing it determinates the effects it had after being practically applied to the consumer through one or more specific media types for which it has designed. The evaluation methods used here can be classified into three main categories: the recognition test, the memory test and the triple association test.

The recognition test, developed by Mr. Daniel Starch, evaluates the degree in which the message gains the attention of the subject when printed in a publication (newspaper, magazine...). The moment on which the test is being applied depends on the frequency of that particular publication. For the publications that are being published weekly or twice a month the test will begin after three to six days after the publication is sent to the shops and for the monthly publications the test starts after about two weeks and can take about three weeks. The selected respondents are readers of the publication, the size of the panel will be between 100 and 150 people. The basic questions used in this method generate the following categories:

- Subjects that do not remember seeing the message
- Subjects that can only remember seeing the message previously
- Subjects that remember seeing the message and associate it to the product/brand it is promoting
- Subjects that read at least half of the announcement

Contrarily to the easiness of using this method there are a number of limitations like: the interest showed by the respondent can also be influenced by the previous interest regarding that subject, the possibility that some confusions regarding the understanding of the message might appear, the situation in which the subjects read more than one magazine with similar adds and the fact that recognizing a product from the add does not mean that the respondent will go ahead and buy it.

The memory test consists in accessing a panel of respondents that were exposed in a particular moment with a certain communication channel (press, TV, radio...) and asking them to speak about the commercials seen or heard. In this sense there is: **unassisted remembering** when the subjects do not receive any information regarding the particular commercial and **assisted remembering** when such information are provided. In the case of assisted remembering the main purpose will be the analysis of the popularity of the message by presenting the respondents with different publications that they read and asking them what ads they can remember from those publications. One of the techniques specific to this method of analysis is the Galup-Robinson technique which has the following steps²⁴⁰:

- a) the respondent must remember and describe correctly at least one article from the publication that is being analyzed;
- b) the respondent is being presented with a number of paper pieces with the names of some brands that were advertised in the publication and also some that were not present in the publication. He is asked to select the brands that he remembers being advertised in the publication
- c) for each brand remembered correctly the respondent is interviewed in order to establish the accuracy and the strength of the information remembered (how many details he remembers and how precise they are)
- d) afterwards the magazine is opened at every ad that the respondent remembered and he will be asked if that is the ad he was referring to when answering the questions and if is the first time he

²⁴⁰ Serbanica, A., Cercetări de marketing în sprijinul politicii de comunicații a întreprinderii, Teză de doctorat, ASE, București, 2005, pp.94-95;

sees it. If that is the first time the respondent sees the add the paper containing that brand will be disregarded in order to focus only on the brands clearly remembered

- e) Finally the information is classified accordingly to the gender, age, education and other socio-demographic data regarding our respondent

The triple association test is based on analyzing the association capacity between three sets of information regarding the distinctive category of product, brand, and promotional message. The respondents are being presented with information regarding two categories and they should provide the third one to complete the set.

Another area in which marketing research is used to assist the decisional process regarding the promotional strategy is the study on the potential message transmitting methods. Such researches help in the substantiation of the decisions regarding choosing the proper communication methods (TV, radio, and press), establishing the channel selection criteria (entertainment, business or news oriented) and choosing the most benefic type of programs when the advertising spots will be transmitted.

The fields covered by this type of research are: the message distribution methods (for example the number of TVs or radios), the people who watch/listen to them, the exposure to the messages, the efficiency of the message. The types of studies vary on the method used to distribute the message.

For the written press the main interests are the distribution of the publication and the main characteristics of its readers. The distribution of the publication means the number of printed issues, the number of sold issues, territorial coverage, the profile of the selected location for the distribution, the fate of the unsold issues (donations, free issues, paper recycling plants...). The profile of the readers of a publication represent the total number of persons who got the chance of reading it even partial and does not limit to those who actually purchase it. The analysis of the readers of a publication is being done through three main characteristics: number of readers (the number of persons that read the publication), structure of the readers community (socio-demographic, psychological and behavior related characteristics of the panel), level of exposure (how many times does a person read the publication, for how long he reads it, number and types of articles read...) ²⁴¹. The general term reader used here there will be understood a person that reads that particular magazine completely or partially in a certain interval of time from the moment it went out on the market, one day before the interview for daily papers, 7 days for a weekly publication... (Practically the interview will be done before the next issue will be out).

The information regarding audience is obtained through inquires. In Romania, these kinds of studies are being developed under the direct supervision of BRAT (The National Biro for Circulation Auditory) as a part of the National Auditory Study research program. This study involves people living in cities with over 50.000 inhabitants with ages between 14 and 64 years. The interviews are taking place in the residence of the respondent, face-to-face, by recording the answers in a printed questionnaire. The field activity is divided into two research campaigns that were established by BRAT after a selection from the offers received: CSOP – the Centre for Marketing Research and Opinion Studies and IMAS – the Institute for Marketing Research, each with 50% of the interviews ²⁴².

In television the audience can be measured through various methods like: random phone call method, people meter an the journal method.

The random phone call method consists in calling random phone numbers and asking them if they are watching TV in that particular moment. If so, they must say what channel they are watching and the TV program that is running at that precise moment. This method is not really proper for evaluating shorter TV programs because there is rather hard in obtaining o representative panel during the show. Also the shows running early mornings or late at night are not suitable for this type of research.

The people-meter is a device that is connected to the TV of each household involved in the research that records the total time in which the TV is on, the time spent watching each program and the number of family members watching. In order for th device to work properly each family member must press a button when joining the other viewers and again when leaving the room, this way the people-meter records not only the time spent watching TV but also the structure of the viewers. The recorded information is sent in

²⁴¹ Haskins, J., Kendrick, A., Successful advertising research methods, NTC Business Books, Lincolnwood, 1993, p. 244;

²⁴² <http://www.sna.ro>

real time to the main server that stores the data from all the panel members and measures the general audience. As good as it might sound in theory this method has a big limitation due to the difficulty of getting all the family members to cooperate by pushing their button each time they enter or leaving the premises of the TV.

The journal method involves asking the selected respondents to register in a journal the chosen channel, the viewing period and the programs watched. The journals are not made for each viewer in part but for the TV no matter who is watching it. This method is cheaper but is often affected by the fact that the respondents will forget to write down some aspects of their behavior or will do so in order to avoid being judged for the programs they watch. Also by using this method there will be a rather big delay between the moment when the behavior happens and when it is recorded in the data server and analyzed.

For radio audience measuring the random phone call and the journal method are also being used. Marketing research plays a crucial role also in evaluating the efficiency of the advertising campaigns using qualitative (interviews, focus-groups) and quantitative research methods for this purpose (the investigation).

*Resume: This paper is the result of some marketing researches about organizations informations needs. For identifying the needs of marketing informations of the organizations in the south region of the country, a series of qualitative research where made, totalizing two focus groups and 5 in-depth interviews. From the research were detained aspects about: present informations sources, needs of informations, and utility of a new portal with marketing information named **INFOMARK** and the trust in it.*

Key words: Marketing research, information needs, organization from Bucharest, Muntenia and Oltenia

For identifying the needs of marketing informations of the organizations in the south region of the country, a series of qualitative research where made, totalizing two focus groups and 5 in-depth interviews.

The two focus groups took place in the following days Friday the 7th of December 2007, at 18 o'clock and Saturday the 8th of December 2007 at 10 o'clock, in the marketing laboratory "Prof.univ.dr. C. Florescu" of the Academy of Economical Studies fro Bucharest.

The participants were part of the management personnel, with decision attributes in the marketing domain from different companies from Bucharest (mostly) and from the near by districts.

The fifth in-depth interviews were carried on with the participation of the representations of a non-lucrative organization fro Bucharest, a multinational distribution company from Bucharest, as well as the managers from 3 medium firms from Ploiesti, Pitesti and Buzau. The interviews took place either at the firms' quarters or in one case in ASE.

From the analysis of meaning of the in-depth interviews, were detained the following aspects:

a) regarding the present informations sources

- "a sportive Romanian organization can obtain new informations about marketing in sports only from foreign specialized books , from that we can draw the conclusion that the rest of the informations (specially the ones from the Romanian market) are not presenting a highly degree of novelty" (The Romanian Sports an Olympic Committee)
- "at our company level does not exists an allocated budget for purchasing the marketing informations. When it is a obvious need for a specific information, the information is looked in the free sources" (The Romanian Sports an Olympic Committee)
- "the available informations are the ones focused on the price evolutions for: the rough materials, the labor force, the utilities and the offers of our society" (medium firm from Ploiesti)

²⁴³ This paper is based on the dates gather for the first phase of the research project "Research regarding the development of an complex and interactive integrated system for the assistance of marketing decisions in the Romanian organizations in order to rise competitiveness" - Grant CNMP Partnership no. 91-066 / 18.09.2007, Coordinator ASE Bucharest, 2007-2010, amount 2.000.000 RON);

- “the firm does not have a well developed marketing department and for that matter the marketing informations are pretty reduced” (medium firm from Ploiesti)
- “in the present the means for obtaining the marketing informations are modest” (medium firm from Ploiesti)
- “our main source of informations is represented by the specialized publications (like books or articles on the internet)” (medium firm from Ploiesti)
- “the informations used by our company are obtained from the next sources: surveys, discussions with clients, specialized magazines, and others sources of informations specialized in economics domain, Internet, participations at exhibits nationals and internationals. The types of informations used are: statistical ones from the National Statistical Institute reports, analysis and previsions of the specialists from the specialized publications, reports and informs from the Owners Organizations – FEPAIUS, worksheets presented by the participants al symposiums from the textile domain” (medium firm from Pitesti)

•

b) regarding de needs of informations:

- „I especially need informations regarding the sponsorship possibilities our organization could benefit from” (The Romanian Sports an Olympic Committee)
- “The organization might need access to an integrate informatics system, witch ensure the access to different detailed sectorial studies and reports, analyzed and truthful, having as reference the Romanian market.” (medium size firm from Buzau)
- “Would be relevant the informations related to the strategies and policy adopted by different firms from both the Romanian and the international market.” (medium size firm from Buzau)
- “The informations we are in need at this moment are the ones regarding the internal market, the evolutions, and the market shares of the main competitors on the segment. As regards the external market, the dates available at this moment there are some materials available on internet about some synthesis and analyses, but not so recent and without having the certainty of an official source. About the Romanian textile market the most recent data found are from the year 2004-2005, the actual situation being complete change, both on national and on international level”. (medium size firm from Pitesti)
- “A study for which I would clearly pay is a monitoring study of the competition prices” (multinational distribution company from Bucharest)
- “The political-legislative situation in general is at interest to as, but not essential, because here you can not change the economical terms, being in the UE.” (multinational distribution company from Bucharest)

c) concerning the utility of INFOMARK and the trust in it

- “You can make studies on one theme, on one market, in-depth studies, not only general ones, to see something related to the consumer behavior. And then it is OK.” (multinational distribution company from Bucharest)
- “A firm, lets say in theory understand that ASE in good, but in practice ASE is for students... it doesn't appeal. It is the reason that a firm makes all its research through other firms that are responsible towards yours projects. A firm that didn't deliver or the delivered product isn't a qualitative one I will not pay it, and I can also ask for damages.” (multinational distribution company from Bucharest)
- “I do not thrust it and others will think alike. You do not have the means to control; I say again, the people when they are not paid, they won't do the job right.” (multinational distribution company from Bucharest)
- “Your men are going to teach the ones from that firms how to do it, people that know only theoretical methods, and the other ones having only the practice. Your people being smart will look in the practice and will see how to integrate the practical dates into the theoretical

models that they know, in order to generate new and useful informations.” (multinational distribution company from Bucharest)

Also, from processing the informations resulted from the focus groups some position standing and some interesting conclusions were acquired:

a) regarding the present informations sources

- The large companies are making direct researches, are buying the results of general studies. The small and medium firms do not have the money to spend on direct research, they are resuming to the official statistical informations, and mostly one the intern (reports from the selling forces, the sales analysis).
- Another information source is the feedback received from behalf of the clients – informations received from the public relations department (if its’ exists), from the sales agents, from the services or form the consumers discussions forum analysis, or the analysis of some blogs.
- “I hade the surprise in doing a research for a product and the result to be a really different one that the one resulted from the customers forums and blogs analysis.”
- “There were also decisions taken on the filings and the personal sense of the managers, even if there were dates from research that stated other else. Even thou, those decisions were a real success.”
- “For advertising you can find money, to convince the bosses to spend money on researches is much more difficult.”
- Large companies are having subscriptions to official statistical publications.

b) regarding de needs of informations:

- “I am having access to dates about competition, but I would want informations about what’s in the consumers mind (the consumer motivations)”
- “I am having good access to informations, and also a peaty good budget for that, I would be interested in informations about the financial stability of the competition, their objectives and strategies, and informations about the political-legislative environment.”
- There is also interest into: Firm image; Consume behavior; Needs, motivations, attitudes; Trends regarding the conduit; Life style;

c) concerning the utility of INFOMARK and the trust in it

- Large firms would rather pay a monthly subscription to have access to a portal like INFOMARK, and would give their approval to participate to researches related to general situations in the market;
- They are afraid by the free of charge information and by the intoxication information given by the competition in order to frighten.
- Would be well received informations about failure that took place in the past in order for them not to repeat the same mistake in the future.

Starting from the content analysis of this study, it was pointed out the actual situation of how Romanian organizations collect their marketing information, the necessity of such information and the openness of the Romanian organizations towards market analysis as a starting point in the marketing activity, and the opinion regarding the utility of the INFOMARK portal. The majority of the organizations declared their interest in this project, one of the information solicited in the content of the portal being those related with presenting some theoretical aspects of the marketing activity, new things in the marketing field, studies regarding consumers buying behavior, presenting research methodologies on studying the competition or consumer loyalty.

The managers mentioned the utility of forecasting the market and its potential from the buying intentions for the next 3-5 years, at local and regional level, demographic indicators, consumption, the amounts of money spent in different kind of goods, consumer profiling and market segmentation using different criteria, retail audits. Other information needed is that related to participating to fairs and expositions (the way a fair is chosen, number of presentation tables, etc), the way a visual identity manual is created, the way the strategy of export is chosen, the distribution channels. There considerate useful statistics related to

import and export in the same branch, studies regarding the profile of audience of the communication mediums. In addition, they need data by which they can verify the potential success of the future projects. The marketing objectives are based mostly on the previous performance of the company and to the market trends and less on the achievements of the industry. The sources for information used by the managers in assisting the marketing decision process are: previous experience, the internet, the company site (contacts, no of visitors), specialized publications (newspapers and magazines), professional associations, market studies, market observations and competition observations, statistics (INSSE), company partners (clients, distributors and suppliers), internal reporting procedures, Finance Ministry web site, web sites of Commerce Chamber, golden pages, yellow pages, e- auction, fairs and exposition, specialized books. Most of the respondents say that the information they have is insufficient. The main printed journals read by the managers are Săptămâna financiară, Capital, Ziarul financiar, Wall Street. The web sites of governmental institutions are less utilized because they tend to be vague and hard to interpret.

The information about competitors are obtained from the clients (in one case, for obtaining the information the company gave a discount to the client), from the internet (with the fact that the internet research consumes lot of time and energy because of the unstructured information) or direct from the competitors. Information about clients and suppliers is obtained from Golden Pages, the internet using search engines, outdoor panels. Most of the interviewed companies do not realize market surveys or if they realize some in house studies, they make them in a rudimentary matter. Only big companies realize such studies in a professional way. However, all the companies consider that market surveys are necessary. The information necessary to forecast is obtained from the press or other internal sources (sales evolution). The manager understands the necessity and utility of forecasting in sales and in consumer behavior. The internet, the fairs and expositions internal and international provides much of the information about new technologies, but also the external partners or suppliers. The companies consider as a necessity the existence of sectorial databases regarding the European funding opportunities, in the financial and accounting field. Most of the companies, especially small ones, don't have a marketing strategy or a marketing plan, don't have a budget for marketing data, but they are willing to invest 3-5% from sales in this area (with a condition that sales have to rise in the future). The respondents suggested that the portal should be divided into domains and sub domains of activity, a search engine being also useful. The portal has to offer information to managers about their suppliers, competitors, distributors and legislative trends. In addition, information about macroeconomic indicators on the sector of activity and geographical area, theoretical information about marketing strategies and practice of marketing should be present on the portal. The managers also mentioned newsletter as an important instrument to keep them informed about the latest information put on the web site. The participants agreed that the portal will work much better if the access to the database should be made on a subscription, because the maintenance team will be in this way motivated, and the information will have a better quality. In many cases, and, in special, in small firms, marketing values are not known, they do not have a corporate culture, and marketing information when they exist is incomplete or not useful. A good point is the fact that the majority of the companies are aware of the necessity of developing marketing activities. The companies want to find more information regarding the market (domestic and abroad), some of the companies developed forms of collaboration with companies from the same industry and they are willing to set a budget for developing the marketing activity in the company.

The companies are interested also in the trends of the market in which they activate, on the consumer behavior and factors that influence it, for these activities, they are willing also to set a budget. From all the interviews conducted, the idea of realizing a web portal was very good received. If the marketing activity in the companies that participated at the discussion the thing are not that clear, all the participants agreed that is important to be informed, in detail, when they have to make a decision regarding the development of their business.

Big companies make their own market research; buy results of some general survey. SME's do not spend money on market research; they use only official statistics, and mostly internal data (sale force reports, sales analysis). Another source of information is the feedback received from the clients, information received by the client service department (where it exist), from the sale agents, from service or by analyzing the users forums, or blogs.

Big companies are willing to pay a monthly subscription in order to have access at an internet portal like INFOMARK, and they would participate at studies regarding general situations of the market. However, large companies are reluctant in using a free portal. The free information is considered of poor quality and

they consider it as a way in which competition wants to scare them. They consider useful information of company failures, things that went wrong in the past, in order not to make the same mistake.

Qualitative research methods tend to be used more and more in academic research. The cost for these methods is quite low and the results may be very interesting and useful for many fields of study. However, the utility and the characteristic of qualitative research methods differ from subject to subject and from discipline to discipline. This paper comes close to a comparison of two qualitative research methods (focus-group and in-depth interview) used in investigating the opinion of academics, analyzing by comparison the results founded in a research conducted in the Bucharest University of Economics using focus group and in-depth interviews. The conclusions of the study reveal that apart of the limits states in the literature, there are other elements that can contribute to obtaining unrealistic results.

Key words: Qualitative research methods, focus group, in-depth interview, academic research

Introduction

Rapid social change and the diversity of the world have contributed on a large scale to the diversification of research methods. Limits of quantitative research methods have determined orientation to the qualitative instruments which are more reliable in certain circumstances. There are many virtues of qualitative research that determine a lot of researchers to manifest preference for these kinds of methods: are the correct choice of appropriate methods and theories, the recognition and analysis of different perspectives, the researchers' reflections on their research as part of the process of knowledge production, and the variety of approaches and methods (Flick, 2002:4). Qualitative research explain how it may be useful for exploring "why" rather "how many".

There are various types of instruments used to collect data for qualitative research. Focus groups and in-depth interviews are among the most utilize instruments that researchers are using in collecting their data.

Focus group implies a group discussion in order to identify perceptions, thoughts and impressions of a selected group of people regarding a specific topic of investigations (Kairuz, Crump and O'Brien, 2007). Discussion should be perceived by the participants as no-threatening and free to express any kind of opinion, no matter if this opinion is shared or not by the other participants. Focus groups generate valuable information, especially when the participants represent small groups of interest, ignored by the quantitative research or when the area of investigation.

The in-depth interview is a technique designed to elicit a vivid picture of the participant's perspective on the research topic. During in-depth interviews, the person being interviewed is considered the expert and the interviewer is considered the student. The researcher's interviewing techniques are motivated by the desire to learn everything the participant can share about the research topic.

In depth interview is an effective qualitative method for getting people to talk about their personal feelings, opinions, and experiences. It is also an opportunity to gain insight into how people interpret and order the world. We can accomplish this by being attentive to the causal explanations.

The results obtained through these two qualitative methods varied (among others) according to the subject investigated. As a general rule, in depth interviews, the participants are more confident, more relaxed and they feel more encouraged to express the deepest thoughts about a certain subject. In focus group the

participants act according to their personality; it is the risk that in some situation those with a weak personality to follow those with a stronger personality. There are also some situations when the issue discussed is incommode and the participants are not confident in expressing their real opinions. They are more preoccupied by the image that the other participants will build up on them that to express what they really think about that subject.

The case study

This study tries to identify the limits of using focus group comparing with in-depth interview in identifying the opinions of academics regarding some aspects of academic research. The aspects evaluated through these two qualitative methods were related to the connection between academic research and business environment and to the performance of the academic research.

Both issues are quite very important for Romanian academics and universities management. The performance of academic research (through the results of the research process) is perceived as almost similar with the performance of the university.

Cooperation between academic research and business environment is considered to be one of the proofs that academic research is in the benefit of society, a confirmation of the market utility of universities. Academic research is considered to be efficient and social valuable if it offers solution to real problems that companies confront on. Students seem that are not willing to sacrifice functional expertise in favor of generalist expertise. (Schelfhaudt and Crittenden, 2005)

From universities point of view, collaboration between business environment and universities is an important source of casuistic for the teaching process. It is also an important source of financial resources for universities, and many times sponsorship activity is determined by the implication of business environment in the academic activity. There are cases when industries developed in a perfect harmony with universities (Silicon Valley).

From the students' point of view, those universities with strong connection in business environment are very attractive. It is a proof of the fact that they will have better opportunities to find a job and a confirmation that higher education does not offer only theoretical knowledge, but also practical skills and abilities.

In Romania it is still believed that universities are more oriented to theoretical approach than to practical direction. Universities considered that business environment does not have positive reception for academic research. Business environment is not convinced that universities have necessary abilities to find correct answers for their problems.

Methodology

The purpose of this paper is to present the differences between focus group and in depth interview using these qualitative methods on a subject regarding the academics' evaluation of the performance of academic research and the relation between business environment and academic research. Both focus group and in-depth interviews were conducted in the same university, following the same conversation guide. Some of the academics interviewed by in depth interview method were present in the focus group. The structure of focus group was similar with that of in-depth interviews. Academics were grouped in three categories, according to age and involvement in research. Group A, below 30, group B between 30 and 50 (with two sub-groups, B1 with little involvement in research and B2 with involvement in research) and group C, over 50 (also with 2 sub-groups: C1, with little involvement in research and C2 with involvement in research).

The structure of the conversation guide was around three major themes: *what do you consider about the present evaluation system of academic research, why the performance of academic research in Romania is considered to be low and how do you appreciate the relation between academic research and business environment*. In order to discuss the comparison between these two qualitative methods were selected two questions: the first one, *what do you consider about the present evaluation system of academic research*, and the last one, *how do you appreciate the relation between academic research and business environment*. The reason of selecting these two questions is given by the fact that the first two question offer similar information from this paper's goal point of view.

Also, literature review was used in order to determine the place of this study among other researches. At the international level it is a constant preoccupation in analyzing both the virtues and the limits of focus

group and in-depth interview and some of these studies were consulted in order to sustain the conclusions of the present paper.

Major findings

What do you consider about the present evaluation system of academic research?

On this question, the answers gained in focus group and in in-depth interview were quite different. If both in-depth interviews and focus group all of the participants complained about the present evaluation system, the motives of complains were different.

The participants' attitude in focus group was rather favorable to the research aspects. Nobody mentioned in the focus group pecuniary aspects. All critics expressed by the participants in focus group were related to the relativity of the criteria established by the Ministry "why they are asking for publication in ISI journals, when we don't have such journals in Romania" (X12), to the high pressure that exist on the professors "students are asking for a good professor, evaluation system asks for a good researcher. It is quite difficult to be good on both" (X3, X9, X11). All participants in focus groups agreed that publication should be a criterion of evaluation, but not in this way. A lot of vague aspects were revealed, as "originality of the research", or "the contribution to the field", criteria which are difficult to evaluate and nobody explained what it mean.

In in-depth interviews the critics were very acid. The attitude against research activity was evident. "When I was hired, nobody told me that I supposed to be a researcher. I was thinking that I will be a professor" (X9, X6). "Which is the difference between research institute and universities? We should educate people, not to research" (X12, X10). Financial aspects were also among those reasons invoke the most. "They should first look to our wages and then they should ask us to have similar performances as the western academics" (X2, X7, X5).

The differences between the attitude expressed in focus group and in in-depth interviews have different reasons. One reason is given to the fact that all academics acknowledge that research is an important part of the academic activity and they don't want to admit "in public" that they do not agree with it. The complaints are related to the way of establishing criteria not with the criteria. In in-dept interview, they felt more confident and they expressed their concerning and their rejection regarding an activity which is considered too difficult or unnecessary (for some) from their point of view.

Another reason is given by the differences between generations. Those over 50 are more reserved than those under 30. But those over 50 have more official authority, so they abstain to express negative opinion in order to preserve their image.

How do you appreciate the relation between academic research and business environment?

This issue is one on which focus group and in-depth interviews were convergent. Both in focus-group and in in-depth interviews a certain defensive attitude was revealed. The academics consider that business environment does not offer credit to academic research. "They are not interested in what can we offer. Managers are suspicious; they consider us a sort of spy (X1)". "If you know someone in a company, than you have chances to develop some relation with them, otherwise is almost impossible"(X2). "Let's be realistic. What can we offer? Why should they be interested in our researchers' abilities?" (X7) "They don't need research; they definitely don't need academic research"(X5).

Other opinions consider business environments hostile to collaboration with academic environment. "Our students have many difficulties in finding companies for internship and those which accept students ignore them and do not allowed students to be involved in their current job. "All the time, we receive the same answer from the students when we ask them: what have you done in the company? I answer to the phone; I typed something on computer, things like these....(X6)"

From in-depth interviews, many additional comments appeared in link with the relation between academic environment and business environment. Almost all of them were in the same spirit of malfunction relation, which has roots both in the communist regime mentality and in the perception that universities are mostly oriented towards theory, not towards practice. "In communism, the collaboration between so called 'business' and universities were compulsory and nobody could say no, therefore, it was a formal cooperation, especially in the economic field. Maybe for engineering it was different but for us, it was

totally formal, without any kind of practical results.”(X20,X24, X2) “Companies do not appreciate academic environment because they consider that universities offer only pure theory. Many students are working today and they are saying that what we are teaching them doesn’t apply in practice”(X31).

Why on this question the results were similar? Why the both methods lead to the same conclusion, that business environment is hostile and is not interested in the research that could be provided by academics?

One explanation states in the fact that the collaboration between business environment and academics is a difficult one. Every academics confronted with this difficult cooperation between universities and business environment, mostly through students’ internship activity. As one of the interviewed academics said, it is somehow frustrating to ask the students all the time the same question: “What have you gained from your internship and to receive the same answer over and over again: “Almost nothing because they didn’t allowed me to involve in their business”. It is a real situation given by the insufficient maturity of business environment, on one side, and the struggle of academics to prove their business utility on the other side. We have to accept that Romania is still learning market economy and all the actors are in the middle of a radical transformation process. Business environment in Romania, in general, gives no real attention to the research activity. Many things are done “per se”. Romanian companies are too poor and multinationals prefer to involve specialized companies in their researches, not academic environment. This is not a secret, and academics are aware of this aspect. Therefore, the same opinions are reflected by the focus-groups and in-depth interviews.

Another explanation could be offered by the question itself. Apart from the other two themes, this one is about “somebody else”. It is a subject that concerns all of us, but it involves another “entity”, an abstract one, “business environment”. In focus group nobody was worried that his/her opinion is misunderstood or that the expressed opinions will have any kind of negative consequences. Furthermore, as all of them expressed the same thoughts, there was no fear of a “bad” image perceived by the other participants.

Another motive could be given by the fact that the cooperation with business environment is not necessary assimilated with the personal academic performance. If an academic does not publish, this could be interpreted as a lack of skill or a low performance, but not being involved in cooperation with business environment could be the results of many external factors, which does not necessary should be related with personal abilities or personal performance.

Conclusions

The use of qualitative research methods is considered to be a solution in investigating “Why?” especially when the need to generalize the results is not necessary. Qualitative research methods are also preferable when the investigation is oriented to determine motivation, perceptions or believes.

Focus-group and in-depth interview are among the most used methods. There are some advantages offered by these instruments: low costs and valuable information, which are difficult to obtain from a quantitative research.

The inconvenient of these methods are determine by their limits in generalization the results. Also the results can be altered if the instruments are used in an improper manner. This case study shows that interviews are also especially appropriate for addressing sensitive topics that people might be reluctant to discuss in a group. The question regarding the present evaluation system of academic research was a sensitive one and the results demonstrated that on question like this in-depth interviews are more indicated. On the second question the results were similar using both methods because the subject discussed was suitable for a group discussion too.

ECONOMIC INFORMATICS

AUTOMATIC MERGING OF WORD DOCUMENTS

Anton Viorel Mihai

Universitatea din Oradea, Facultatea de Științe Economice, str. Fluierașului nr.14, cod 410230, E-mail: mike101200@gmail.com, Tel: 0743.072234

In this article I have presented a tool designed by me to help in multiple document concatenation. I made it available in two flavors, VBA and VB.Net 2.0, both having the same basic functionality: to unite multiple documents automatically. For VB.Net version I used the Shared Add-in technique and also created a menu button in the fluent UI (ribbon). It offers users more options related to how they can merge the selected documents (order, page breaks).

Keywords: Visual Basic for Applications, Visual Basic .Net, Microsoft Word 2007, Fluent UI, Ribbon customization, Shared Add-in, Form, Button, List, Word Document, Document Template, Page break

Introduction

Microsoft Office is the most used office suite both because of its functionality and its integration in the Windows operating system (the most used operating system). The document editing mode is intuitive and with the appearance of Office 2007, the menu system made a big step ahead, practically the menu items becoming lively colored buttons on the fluent ribbon. Another one of the benefits of this new version is the possibility to preview the changes before applying them. This can be easily observed when choosing a different font size, while moving the mouse pointer over the different font sizes we can see how the text is resized automatically, but if we do not choose a different size our text comes back to its original format.

Making the tool

Despite these facilities we can say that this application does not satisfy all needs. There are many cases when we need to automate some processes. Just like automation is needed in many domains, it is needed also in document editing. Of course, we have 'mail merge' for some tasks and many other great features. Sometimes we need specially designed tools for special needs. For example: in the case of scientific sessions we get lots of documents for publishing. This requires ordering, extracting parts, uniting. For exemplification we will consider as the ordering key the file name. It happens that the documents number is in the order of hundreds and because of this, the people involved in this process spend many hours doing repetitive actions.

What are they doing?

They have to open each document and extract the abstracts. Usually they copy them in a centralized document but it happens that they make mistakes in ordering correctly. Also when centralizing the whole documents they need to create a centralized document that will contain all the documents for publishing. So they have to use a lot of copy and paste. Anyone can see how difficult this task is because of its repetitiveness.

In this document I present how to make a tool designed to help in such a case. I succeeded in obtaining different versions of this tool which have the same functionality, but the way that the problem is solved is different.

Before continuing with the making of this tool I will present its functionality. The two versions have a small aspect related difference but in rest they are identical. In the followings I will present you the version created in VB.Net 2.0. To run this tool we go to the Add-ins menu and we chose Combine. The interface looks like in Fig.1.

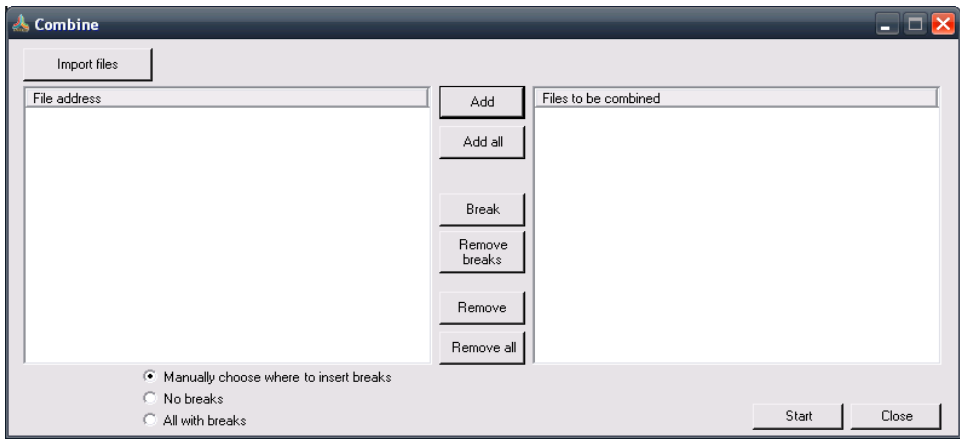

Fig.1 – Main window

The list in the left side contains the documents from which we can choose those that we want to merge. The right side list contains the documents that are going to be merged.

The button  is used to add new files to the left side list. When we push the button another window appears:

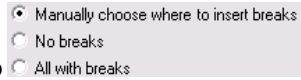

Fig.2 – Import files

With its help we can choose those documents that we want to work with. Ones imported we can find them in the list from the left side.

To move the files from the left sided list to the one on the right side we use the  button. It moves one item at a time. If we want to move all items at once we can use the  button. As you can see we can use for deleting from the right side list either the  button or the  button, depending on one what we need.

The button  is used to manually add page breaks between two documents and the  button is used to remove all added page breaks from between documents.

In the bottom-left corner you can see the following option group. The default option presumes that the application takes in consideration the page breaks introduced manually. The option 'No breaks' tells the application that we do not want to take in consideration the breaks introduced and the option 'All with breaks' means that the application will insert breaks between each two documents. After choosing the desired options and moving all the needed documents to the list from the right side of the window we push the  button which triggers the merging process. To close the application can use any of the following buttons: , .

This version was created using Visual Basic .Net 2.0. I chose to create a Shared Add-in Project for Microsoft Word and let Microsoft Visual Studio to do its job and create all the start files that we need.

The VB.Net version needed coding a button on the fluent ribbon. This code is presented under:

```
Public Sub OnBeginShutdown(ByRef custom As System.Array) Implements  
Extensibility.IDTEExtensibility2.OnBeginShutdown
```

```
On Error Resume Next
```

```
btnStart.Delete()
```

```
btnStart = Nothing
```

```
End Sub
```

```
Public Sub OnStartupComplete(ByRef custom As System.Array) Implements  
Extensibility.IDTEExtensibility2.OnStartupComplete
```

```
Dim oCommandBars As Microsoft.Office.Core.CommandBars
```

```
Dim oStandardBar As Microsoft.Office.Core.CommandBar
```

```
On Error Resume Next
```

```
oCommandBars = applicationObject.CommandBars
```

```
oStandardBar = oCommandBars.Item("Standard")
```

```
btnStart = CType(oStandardBar.Controls.Item("Combine"),  
Microsoft.Office.Core.CommandBarButton)
```

```
If btnStart Is Nothing Then
```

```
btnStart = CType(oStandardBar.Controls.Add(1),  
Microsoft.Office.Core.CommandBarButton)
```

```
With btnStart
```

```
.Style = Microsoft.Office.Core.MsoButtonStyle.msoButtonCaption
```

```
.Caption = "Combine"
```

```
.Tag = "Combine"
```

```
.OnAction = "!<MyCOMAddin.Connect>"
```

```
.Visible = True
```

```
End With
End If
```

```
oStandardBar = Nothing
oCommandBars = Nothing
```

```
End Sub
```

This is the code I used to initialize the add-in:

```
Public Sub OnDisconnection(ByVal RemoveMode As Extensibility.ext_DisconnectMode, ByRef custom As System.Array) Implements Extensibility.IDTExtensibility2.OnDisconnection
```

```
On Error Resume Next
```

```
If RemoveMode <> Extensibility.ext_DisconnectMode.ext_dm_HostShutdown Then _
```

```
Call OnBeginShutdown(custom)
```

```
applicationObject = Nothing
```

```
End Sub
```

```
Public Sub OnConnection(ByVal application As Object, ByVal connectMode As Extensibility.ext_ConnectMode, ByVal addInInst As Object, ByRef custom As System.Array) Implements Extensibility.IDTExtensibility2.OnConnection
```

```
applicationObject = CType(application, Microsoft.Office.Interop.Word.Application)
```

```
addInInstance = addInInst
```

```
If (connectMode <> Extensibility.ext_ConnectMode.ext_cm_Startup) Then _
```

```
Call OnStartupComplete(custom)
```

```
End Sub
```

```
Private Sub btnStart_Click(ByVal Ctrl As Microsoft.Office.Core.CommandBarButton, ByRef CancelDefault As Boolean) Handles btnStart.Click
```

```
Dim combine As frmCombine
```

```
combine = New frmCombine
```

```
combine.application = applicationObject.ActiveWindow.Selection
```

```
combine.Show()
```

```
combine = Nothing
```

```
End Sub
```

OPTIMIZATION AND LAUNCH OF A GOOGLE ADWORDS CAMPAIGN

Băndoi Anca

Universitatea din Craiova

Dănciulescu Daniela

Universitatea din Craiova

Abstract: *The case study was performed for a company that develops its activity in the baby articles sale field. The respective firm decided that, besides the sale it had developed in the 7 own shops in Florida, it would pass on to the online sale, considering that this market offers it a real development possibility. The company's decision was that the web site should remain in the initial form and that it should be opened a new site for the online sale (decision that significantly delayed the results in the natural search motors).*

Key-words: *on-line sale, commercial, pay-per-click*

As the online Developer shop was new on the online market, its optimization for the natural search motors was to develop in the next few months, the results for the natural search in terms of traffic being estimated to appear only after 8-12 months. Thus appeared the need to substitute, at least partially, the lack of the natural traffic by traffic generated by the PPC (pay-per-click) system.

It means that, the purpose of the PPC campaign was, on the one hand, the substitution of the lack of natural traffic (which, at that moment, was the objective of the company) and thus the increase of the sale volume (otherwise almost inexistent in the same period of time), on the one hand, and the email addresses collection of the potential clients with the end to create a data base, which were to be used subsequently for sending the newsletters/special offers. At the basis of taking the decision of creating the data base it stood the consideration that it is harder to win a new client than to maintain a relation with the already existing ones (especially if the last ones are also pleased of the services they have benefited of). As the purpose and the location of the campaign are settled, it was passed to the implementation stage of the campaign.

Audience Selection. The first step: **choosing the audience**, *the selection of a public-* the identification of the best potential purchasers. The audience selection was based on the principle more does nor always mean better; it was chosen a middle way: the selection of the **search syndication**. The three possible levels are: **1)** The first level: **no syndication** – the announcements appear only on *the result pages of the search motors*. **2)** The second level: **syndication of the search** – the announcements appear on *the result pages of the search motors* and on a chosen group of search motors, which have associated (for Google AdWords: AOL, AskJeeves, Netscape, Froogle). **3)** The third level: **syndication of the content** – in the case of Google AdWords the announcements appear contextually on partner sites, such as: *howstuffworks.com, business.com* and *nytimes.com*. The syndication of the content also means that the advertisement may be added to the email messages for the users of the GMail services from Google as well as in the letters based on the permission request sent to the company's subscribers like *iVillage.com*. And, of course, the announcement can also be displayed on each of the numberless sites associated to the chosen (in the case of Google and of Google AdSense).

Geo-location. Both the web site and the campaign were performed in English. Due to the large number of Spanish speakers from the United States, it was suggested the creation of a version in Spanish language, but the firm did not take that into consideration. On the other hand, both the campaign and the sale politics are limited to the USA borders; the company has not disposed (and does not consider it necessary) the extension abroad.

Search Words Selection. With or without a position on the first page of the search motors, a PPC campaign offers a way of improving the business, offering a relatively constant number of visitors – potential clients. As most of the articles it bases its activity on have relatively low prices (\$5-\$25), with a profit equally reduced, the PPC type advertisement has proven not to be useless, but inefficient; the effort to bring visitors/potential clients on the site was converted in a very low profit. Therefore, for the PPC campaign, it was decided the removal of the accent on the products that could offer a higher profit, thus

justifying the effort and the expenses. After a valuation of the list of the products that the company disposed of, the situation was as follows:

Table 1.: Gross Examination of the /Products/Potential PPC Campaigns

Produse	Pret mediu/produs	Click-uri/zi (Estimare grosiera)	CPC Mediu (Estimare grosiera)	Cost/Zi	Pozitie medie
Baby bathtime skin care	\$7	< 0.1	\$0.05	\$0.00	1.0
Baby books	\$8	28.0	\$0.24	\$6.62	3.2
baby cards	\$5	18.0	\$0.19	\$3.35	2.4
baby carriers	\$45	7.0	\$0.24	\$1.68	5.9
baby clothing	\$17	290.0	\$0.24	\$70.52	2.9
Baby towels	\$6	< 0.1	\$0.05	\$0.00	1.0
Baby Toys	\$18	64.0	\$0.25	\$15.77	3.8
strollers	\$140	600.0	\$0.25	\$148.32	4.0

Excepting the cloths products and the prams, the rest of the products represent the generation of a relatively low traffic, and even worse, of a truly dangerous profit limit. Taking into account the above mentioned, it was passed to the analysis of the possibility of deploying a PPC campaign for prams. It must be remarked, at that moment, the firm was selling the following brands: Graco²⁴⁴; Peg Perego²⁴⁵; Bugaboo²⁴⁶. It was passed to the analysis of the search terms and of the possible generated traffic, by using the 2 instruments: Yahoo! Search Marketing Keyword selector tool (previously Overture, previously Goto.com)²⁴⁷ and WordTracker²⁴⁸.

Table 2.: Estimation of the search frequency and terms derived from the keyword "strollers"

Search Terms Analysis. The search terms analysis was performed individually, based on: Report product price/CPC; Report Profit/CPC; Competition valuation; Traffic possibilities valuation; Moreover, taking into account the fact that it was intended the implementation of a AdWords campaign, the estimations were, primarily made in the light of the tool offered by Google (Google Traffic Analyze Tool) and only afterwards based on the instrument provided by Overture (at the respective moment it was Overture): **1)** The use of the negative terms in order to make the campaign more efficient. The elimination of the terms that may lead the campaign in a “wrong” direction. a) “review/reviews/testimonials” -although these elements usually help the increase of the traffic, they are terms generally addressing those in search for *information* that are not yet in the proper purchase stage, having a pretty high share in the conversion dilution; b) “wholesales”; c) “Reebok” - term, especially associated with “jogging strollers”, which is not in the company’s offer; d) “triple/twin” – though a heavy traffic can be observed, as being generated by these terms, this traffic is more likely the result of curiosity, than of the desire/determination to buy, so they were excluded; e) “dog/pet/cat” – refers to a different category of products; f) “car seat” – similar; g) “doll”. **2)** It was intended to cover all the possible variants: synonyms inclusion, singular/plural terms, frequent spelling mistakes (e.g: *stroler, Gracco, Bugabo, Bogaboo*) and separate words. **3)** Though it proved not to be significantly relevant in the search based on these terms, it was decided to include those words that urged to action: “buy”, “find”, “discount”, “cheap”. Choosing the matching time: it was chosen the “*Exact match*”, but also the *Phrase match*.

Creation of Advertisements Group. *The advertisement grouping on categories is important for the management of the company. It was chosen the advertisement grouping based on the selected search terms (more exactly, on brands: Graco, Peg Perego, Bugaboo and Jogging Strollers). Once the search terms were split into groups, it was looked for their division, based on the estimated traffic (Yahoo! Search Marketing Keyword selector tool (formerly Overture, formerly Goto.com)²⁴⁹ and WordTracker²⁵⁰). There was a selection of the terms that should have a search frequency: more than 1000 searches/month and less (the limit may vary depending on the reference field), as follows:*

Table 3.: Search words/phrases selection (and negative terms emphasis) for the term “graco strollers”

GRACO STROLLERS> 1000	GRACO STROLLERS< 1000
7559 graco stroller	666 graco travel system stroller
3072 graco double stroller	443 graco metrolite stroller
1217 graco baby stroller	437 graco duoglider stroller
	361 graco doll stroller
	290 graco twin stroller
	286 graco mosaic stroller
	226 graco stroller part
	222 graco quattro tour stroller
	214 duo graco quattro stroller tour
	200 graco car seat and stroller
	181 duo graco ionic quattro stroller
	173 graco quattro stroller
	161 graco snugride stroller
	141 graco duo stroller
	140 graco duoglider double stroller
	136 graco sit and stand stroller
	133 graco literider stroller
	127 ashley graco laura stroller
	126 graco baby doll stroller
	108 graco jogging stroller

In a similar way, it was performed the search term selection for the other campaigns: **Peg Perego, Bugaboo and Jogging Strollers**, taking into account each one’s specifications. Moreover, in certain contexts, there were combined “action” words.

Advertisements Writing. It is obvious that, according to the recommendations and specialty studies, the advertisements were written by taking into account a few important elements: 1) As a general rule, the repetition of the search word in the title and, depending on the possibilities, in the text of the advertisement has a significant positive impact over the person initiating the search, strengthening his conviction that the link he is about to enter is the one he was looking for. 2) The first line of the advertisement text describes in short, the product/service offered: “Save 7% on with coupon GRACONOW” – an excellent service/offer. 3) The second line of the advertisement text presents the possible benefits: Guarantee Quality & free Shipping. 4) The second advertisement, the one dedicated to the term “Jogging Strollers” presents another particularity: it was passed from a logical cumulating of the 35-35 characters, actually resulting in a single line (logical) of 70 characters. “Full line of high Quality Jogging---Strollers”. 5) Still, it seems that in the advertising field, usually the title/description/benefits are the optimum solution, just the way it was settled...80 years ago by Claude Hopkins²⁵¹.

Advertisement Testing. *The system “Split testing” is implemented including as part of the Google AdWords campaign, which proves the fact that it is not optional, but even necessary. It is worth mentioning that, when performing the test, the option “Google automatic ad optimization” was switched on OFF, in order to get a relevant data set; otherwise the Google AdWords system had the tendency of showing more than once the advertisements with a higher CRT. In general, the testing was performed for a number of 25*

⁶<http://searchmarketing.yahoo.com/rc/srch/> For additional information:

http://en.wikipedia.org/wiki/Yahoo%21_Search_Marketing

²⁵⁰ www.wordtracker.com

²⁵¹ http://en.wikipedia.org/wiki/Claude_C._Hopkins

repetitions/variant, which was considered sufficient to issuing pertinent conclusions, related to the respective advertisement.

Dynamic Keywords Insertion. When a PPC advertisement is written, it is extremely important that the terms, the search is performed on, were identifiable in the text of the advertisement and especially in the title²⁵². For exemplification, if there was performed a search for “graco metrolite stroller” the advertisement should look like:

For this option implementation, the syntax is: {*Keyword*: *Default Title*}

Where *Keyword* must be written just as it appears, and *Default Title* is replaced by the title, which desired to be general, by means of this syntax, it was succeeded the automatic insertion of the desired terms, so that they have fused with the performed searches. If the search terms overpass the admitted limit (title – 25 characters or description – 35) the Google AdWords system will use the term declared *defalut*.

Campaign’s Budget. Due to the fact that the firm that was going to roll PPC advertisements had never operated online before, it was not known the conversion rate of the virtual shop, so that it was passed to an estimation of the conversion rate based on the previous cases, where it had varied between 10-14 %. For more safety, it was worked at the budget estimation with an average ratio of 11.8%; during the tests it raised up 12.3%, and, during the first three months, by continuing the successive testing, both of the landing pages and of the search advertisements/terms it reached 12.9%. The calculation formula for the maximum sum attributed for a price offer: **Net profit /sale x conversion rate = maximum amount for price offer.** For example, for a net profit of \$21, with a sale rate of 11.8% we have concluded a maximum admitted value of \$2.44/offer. Anyway, the value is established under this sum, in order to also be able to get a profit, in the end.

Advertisement Positioning. Once the estimation of the maximum price payable for obtaining a visitor was complete and once the daily maximum budget was calculated, in the “Graco” campaign case it resulted that:

Table 4.: Traffic estimation – Google AdWords

Estimates for the maximum CPC: \$1.22 USD and daily budget \$400.00 USD

Keywords ▼	Predicted Status	Estimated Avg. CPC	Estimated Ad Positions	Estimated Clicks / Day	Estimated Cost / Day
Search Network Total		\$0.85 - \$1.22	1 - 3	52 - 68	\$50 - \$90
-accessory					
"ashley graco laura stroller"	Active	Not enough data to give estimates. ?			
[baby graco stroller]	Active	Not enough data to give estimates. ?			
-car					
-doll					
-double					
-duo					
[graco baby stroller]	Active	\$0.72 - \$1.08	1 - 3	0	\$1

²⁵² According to a study from 2002 of a marketing company AC Nielsen, almost 50% of the persons are inclined to click on an online advertising generated by the PPC system, at the time it advertises the search terms both in the title and in the description.

"graco stroller"	duoglider	Active	\$0.80 - \$1.20	1 - 3	0 - 1	\$1
"graco stroller"	jogging	Active	\$0.86 - \$1.23	1 - 3	0	\$1
"graco stroller"	literider	Active	\$0.78 - \$1.17	1 - 3	0 - 1	\$1
"graco stroller"	metrolite	Active	\$0.78 - \$1.17	1 - 3	1	\$1
"graco stroller"	mosaic	Active	Not enough data to give estimates. ?			
"graco stroller"	quattro	Active	\$0.72 - \$1.08	1 - 3	0	\$1
"graco stroller"	quattro tour	Active	\$0.71 - \$1.06	1 - 3	1	\$1 - \$2
"graco stroller"	sit and stand	Active	Not enough data to give estimates. ?			
graco stroller		Active	\$0.86 - \$1.22	1 - 3	49 - 64	\$50 - \$80

and using the following list of negative terms: double, duo, twin, doll, part, parts, car, seat, review, reviews, testimonial, testimonials, replacement, accessory, accessories, toy. It can be seen that the real situation is varying, which "Google's Average Cost-Per-Click" estimates to be wrong most of the time, as the traffic rate is higher than the one being declared.

Landing Page Variants Testing and Results Pursue. This stage assumes both the advertisements testing and the landing page variants testing. Thus, for the landing page presentation there were performed more page variants. It was set out from the "Success" formulas, taking into account the data organization method already proven efficient; in all the page variants there were included key elements for favoring the sale.

Fraud in the PPC System. SEMPO (Search Engine Marketing Professional Organization) published a study²⁵³ related to the way this problem is being considered by the campaigns' initiators. It is worth noticing that, though the fraud problem in the PPC system has been acknowledged as important for more than 70% of the adversaries, only 25% of them have tried to pursue the problem in their campaigns as part of the different testing. "The traffic generated by the search motors is the most valuable (traffic) for a web master, due to the psychical state (preparation) of the person performing the search. The fraud in the PPC system, the payment for the traffic that does not convert, may poison the world ..." Kevin Lee, SEMPO.org²⁵⁴. In order to test the vulnerability of the system offered by Google as part of the campaign, there was performed the following experiment: it was created a campaign displayed for search "ppoppuiuyy"; this way, the attempt for fraud could not alter the other Google AdWords participants' results (as there is no one else search campaign4s this search term). Thus, there were noticed the following:

Table 5.: Simulation of a Fraud Attempt on Google AdWords

Fraud attempts on Google AdWords system		
Fraud attempts	Successive clicks	Clicks registered by Google

²⁵³ <http://www.sempo.org/press/click-fraud.php>

²⁵⁴ <http://www.SEMPO.org>

Individual click on an advertisement	25	0
Individual click on an advertisement using proxy	10	1
Click on an advertisement using another computer, the same IP address	10	1

As a result of this experiment, it was noticed that the system cannot be influenced by usual, common methods, by an individual or a group of individuals. Although, pleasing enough, this experiment do not answer the much more elaborated fraud problem from the sophisticated systems/technologies or from the uninterrupted human labor (the cheap manpower from the countries considered “the third world”²⁵⁵). Moreover, experiments performed by dedicated firms tend to demonstrate that the real results are different. As a result of some experiments performed by SEMPO, the organization using INCUBETA²⁵⁶ application, there were deduced the following: Approximately 30% of the clicks generated are fraudulent; The fraud possibility is increasing on the measure of the offer increase; Google detected only a small part of the fraudulent clicks.

We can deduce the fact that (intuitive and predictable – this experiment) the fraud in the PPC system is a major problem of all the participants to the system, trespassing the admissible limits of the search motors. In order to emphasize the fraud there were settled the following measures: 1) To attentively monitor the possible rapid conversion collapse, especially related to the pinnacle of the increase in the company’s costs. Such a rapid change in the company’s figures could, most of the time, mean manipulation attempts. 2) To implement pursuing applications. 3) To follow the “click-through rate” and this the fraud over the advertisement display numbers. 4) To follow the search terms which were deactivated during the proper campaigns due to a low CTR conversion, especially if the respective company rolled with good results for a time and, suddenly, the search phrase has been deactivated; this could be a fraud sign. 5) To report any fraud in order to take measures at the level of the system (in our case, Google AdWords). 6) To daily monitor the traffic. 7) As a general observation, the more the PPC motor depend on the affiliation network, the less safe the traffic.

Conclusions. Although, at a first glance, it does not look like a special business opportunity, the calculations demonstrate that, in the case of Graco campaign: **1)** The conversion rate started from an estimation of 11,8% and, as a result of the successive testing, reached 12,9%. **2)** Net profit/sale: \$21.00. **3)** The estimated traffic is 68 visitors/day, but in this practice it is 75 (still, the calculations will be performed for 68). **4)** Maximum cost for bid/day is \$1.22. **5)** Maximum estimated cost per day: \$82.96. **6)** Sales/day: For a conversion rate of 11.8%: 8.25; For a conversion rate of 12.9%: 8.77. **7)** Income/day: For a conversion rate of 11.8%: 8.25x21=173.25; For a conversion rate of 12.9%: 8.77x21=184.17. **8)** Profit/day: For a conversion rate of 11.8%: 173.25-\$82.96=90.29; For a conversion rate of 12.9%: 184.17-\$82.96=101.21. **9)** Profit/month: For a conversion rate of 11.8%: 90.29x30=2708.7, For a conversion rate of 12.9%: 101.21x30=3036.3. Extrapolating the other 3 campaigns’ results (though the data varies, the results may be linearly multiplied), it resulted: Profit/all the 4 PPC campaigns/month: For a conversion rate of 11.8%: 2708.7*4=\$10834.8; For a conversion rate of 12.9%: 3036.3*4=\$12154.2. This may not be the most profitable business, but, taking into consideration the fact that it is a net profit and that the company performing the service is not a very large corporation, the results were very good. Furthermore, the limitation imposed by the product range offered is for the company’s disadvantage; after only 5 months of PPC campaign, it diversified quite significantly its product range and rolled in no less than 8 PPC campaigns at a time. In addition to that, the PPC advertisement is a relatively stable market and does not vary in terms of the so frequent indexation modifications/algorithm, being a very good alternative and a business increasing method.

STRATEGIC AND FINANCIAL PERFORMANCE USING BUSINESS INTELLIGENCE SOLUTIONS

Boldeanu Dana Maria

Academia de Studii Economice București, Facultatea Contabilitate și Informatică de Gestiune, Piața Romană nr. 6, sector 1, București, CP 010374, Email: danabolde@gmail.com, Telefon: 0721803603

In order to achieve better strategic goals, business intelligence has to provide employees with the right information at the right time. To make this happen, a business intelligence solution should be comprehensive, secure, integrated with all operational systems (in both ways, as capture of data and as feed-back is concerned) and always available. In concrete terms, business intelligence process manages to help decision makers by providing data models, statistical analysis and forecasting for comprehensive data analysis. Improved sales and financial performance is a major objective of a global sourcing strategy.

The research is trying to present the way of transforming existing data, gathered from different data sources in powerful managerial information, integrating “business intelligence” solutions in Romanian’s companies, with the help of some famous companies which create BI products.

Keywords: Business Intelligence, business performance management, decision support systems.

Introduction

Today, the time available for making operative decisions in a business environment is decreasing: decisions must be made within days or even hours. Just two decades, similar decisions still took weeks or months (Tiemeyer, 1995).

The process of decision making, regardless of the size of the company, is a rather complex one, implying data processing, information and knowledge. Usually, the data inputted in the IT systems of the company are very numerous, sometimes heterogeneous or provided from heterogeneous sources, are widespread into the system, and their transforming in information which can be analyzed for taking decisions is, in most cases, a lengthy and difficult process. The data warehouse (DW) and business intelligence (BI) systems, as well as the Decisions Support Systems (DSS) are designed to help the companies to answer in real time to complex questions. There are more different techniques in this respect, and the choice of the right instrument leads to finding the relevant answers for a certain company. The process is a dynamic one, and these answers are changing along with the business strategy of the respective company.

Many organizations do not have well-developed global sourcing measurement strategies in place, and thereby lose out on attractive business opportunities. Realizing these opportunities requires a detailed understanding of global sourcing performance, which can be facilitated through Business Intelligence (BI) concepts applied in other areas of supply chain management.

The present article is structured in two parts, which include:

- a presentation about the significance of business intelligence (BI), why is so important to have a business intelligence solution in your company, what can we do with a BI solution and which are the types of problems that BI can resolve;
- the second part describes some BI solutions used in these days in Romanian companies.

1. Business Intelligent – overview and importance

It is difficult to give an exact definition to a complex solution which can vary depending on the analyzed context. In an abstract way, it can be said that BI is the process of „combining” the information from several sources, and presenting the result in a form which can be used in taking the business decisions. This aspect is more obvious if we are going to analyze the iterative character of the business intelligence processes, where the steps of analysis, planning and improvement need the harmonious join of the information from the data base offered by the business intelligence with the right managerial decisions taken on the basis of all this information.

„Understanding the business or the intelligence of the business”, the translation mot-à-mot of the Business Intelligence expression is obtained precisely through the analysis and refining of the data regarding the operations of a company. It is a process which results from the data collected at the company level from various internal activities (marketing, sales, production) and/or external (customer behavior or competition behavior as a reaction to the internal activities). This collection is iterative and cyclical and this is why the collected data should be organized to facilitate their transformation in information (reports, queries, analyses or presentations). The final purpose of these processes is a set of decisions which affect the functioning and the productivity of any business, and the solutions which sustain this process are extremely important and have decisive effects, but they cannot guarantee the effect if a lot of elements (organizational, technical, procedural) are not properly set up.

BI applications include the activities of decision support, query and reporting, online analytical processing (OLAP), statistical analysis, forecasting, and data mining” (Sauder School of Business, 2000).

A business intelligence solution brings information to the hand of the users that need it: analysts and experts (multidimensional analysis, statistics), consumers (dynamic queries and simple analysis) and information users (reports). (Microsoft, 2004)

According to a study published by **Data Warehousing Institute** in 2000, (Data Warehousing Institute, 2000), named: *“Harnessing Customer Information for Strategic Advantage: Technical Challenges and Business Solutions”* the technologies DATA WAREHOUSE and BUSINESS INTELLIGENCE allow the companies to collect, to integrate and to analyze the information related to customers so that this will enable the companies to understand the intentions and the behavior of the customers. Being aware of these information and knowledge flows, the companies can optimize the interaction with the customers at all levels, which will lead directly to the increase of revenues and profit.

BI applications allow the ability for aggregate and summaries on specific and detailed categories at the same time. As part of the analysis of different processes, these kinds of applications show exact information and expel moreover elements. Thus, the managerial team can monitor the business performance variables. As an example of the various categories of variables, which we can see in the table below, we can mention: the value or the volume of sales on a specific region (area), on product, on spell or the rate of products return for different reasons, the rate of discard from the guarantee period, the analysis of the customers behavior in a specific situation or in a predefined context.

Type of BI application	Activities that can take place / Questions that can be answered
Product analysis	<ul style="list-style-type: none"> • Which is the product which has the highest profit margin or the highest contribution to the absolute value of the profit? • Which are the products which bring the lowest profit margin (unprofitable products)?
Marketing analysis	<p>Demographical analysis using information about customers and sales data, price sensitivity (elasticity of demand), consuming preferences. For example: • Which are the products preferred by consumers belonging to the market segment with a monthly income lower than a certain level?</p> <p>Using this information we can estimate the efficiency of the publicity campaigns and of the marketing activity.</p>
Sales analysis	<p>Identifying trends, season analysis, and association of complementary products (buying a package of products).</p> <ul style="list-style-type: none"> • Which is the sales tendency (trend) in the stores from a specific demographical area? • Which are the products with growing sales and which are the customers that buy products like these?

Retail analysis	Data analysis regarding retail orders, supplies analysis, stocks analysis. Through these analysis it will be possible to estimate stocks better, to schedule deliveries better, to make proposals for the price promotions for certain products and for the delivery calendar.
Financial analysis	The analysis of the profitability on departments, category of products, geographical locations, seasonality. A particular case is represented by financial institutions (banks, assurance companies) where the financial analysis plays a key part in carrying on the activity: defining bank's packages of products and services, scoring analysis as a method of synthesizing of information about the financial situation of a certain customer, in an aggregate criteria of evaluation as rating or score type on the basis of which it is possible to obtain a credit facility
Budget planning	The increase of the efficiency of a manufacture process by costs reduction, increasing the production, planning the next fiscal year (forecasting the balance sheet of incomes and expenses, cash-flow statement, etc)
Balanced scorecard	Defining performance indicators from a specific area, calculated from the existing information from the system. We can follow the entire performance of the company or the performance of some groups as against others from the same area.
Project management analysis	The analysis of the resources way of allocation, analysis of projects portfolio.

Table 1 - Activities and questions in terms of BI application's types

2. Business Intelligence solutions

Once we have distinguished the importance and benefits of BI, we can move on to present and point out the features and attributes of specific BI solutions. In this way, we can say that in Romania the continuous increasing of the competition between market sectors makes a must to adopt BI solutions adequate to the business specificity. The companies are interested in finding out which are the best products on the market, the most profitable customer and which are the new products they need to be more profitable. Alongside competitively, as a generic element, to adopting BI solutions contributes also the necessity to optimize processes and to take better decisions, the bigger volume of data accumulated in operational systems and the European and international standards addressed to different industries.

We are going over some BI solutions presented also in Romania and trying to point out their strengths in the area:

- a) Microsoft is one of the companies which offer integrated, powerful and comprehensive solutions of business intelligence which allow performing data mining analysis, reporting solutions with the support of Microsoft SQL Server Analysis and Microsoft SQL Server Reporting Services. Here we talk about **Microsoft SQL Server 2005**, fated by his technical resources to provide new and comprehensive possibilities of exploring data in order to offer companies an effectively competitive advantage, to help taking decisions that will make it in direct advantage.

The solutions of business intelligence are conceived to include multiple data sources, from a large area of operations, easy to integrate with the support of Integration Services ready to explore and improve data, getting an integrating vision of all analyzed data and building extended business analysis as OLAP (On Line Analytical Processing), data warehouse, data mining (finding patterns and applying them over the business operations, using a flexible and accessible platform), tools for data extract, transform, and load using multiple and different data sources (ETL tools), balanced scorecard, etc, with the support of Analysis Services.

The **SQL Server 2005 BI Workbench** suite is made of five basic tools (Monaco, 2004):

- SQL Server Relational Database – used to create relational database;
- Analysis Services – used to create multidimensional model (measures, dimensions and schema);

- Data Transformation Services (DTS) – used to extract, transform and load data from sources to the data warehouse or schema;
- Reporting Services – used to build and manage enterprise reporting using the relational or multidimensional sources;
- Data Mining – used to extract information based on predetermined algorithms.

Analysis Services Architecture

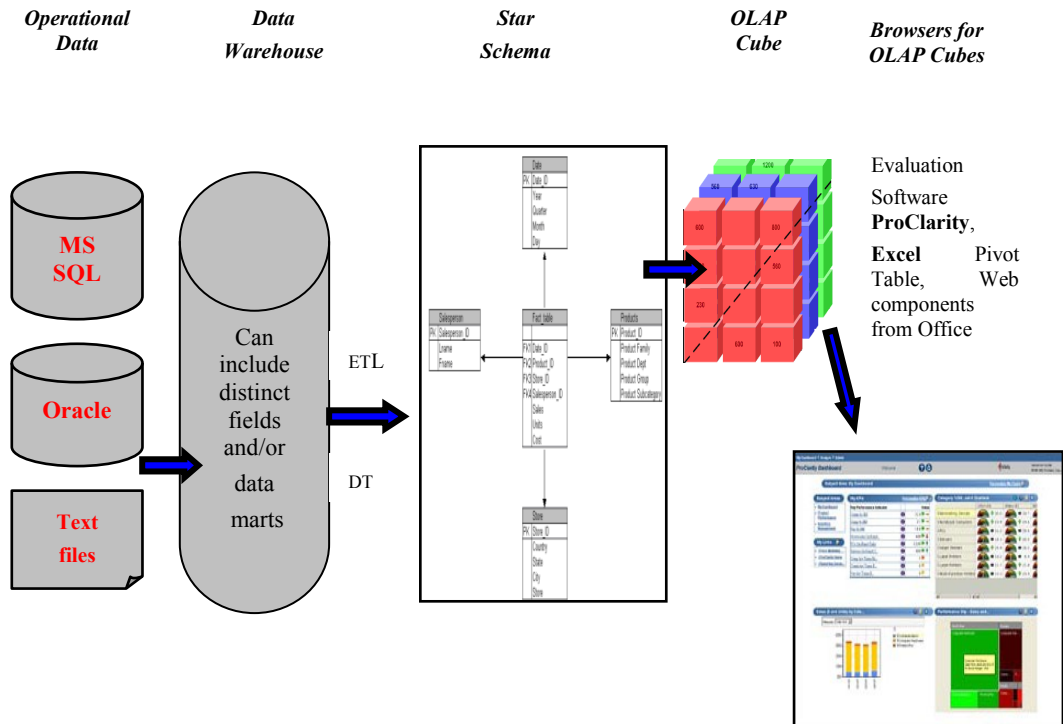

Figure 1 - Analysis Services Architecture: relationships between different technologies levels involved in Analysis Services (Source: processed after Monaco, 2004)

- b) **Cognos 8 Business Intelligence** is the only BI product to deliver the complete range of BI capabilities needed for corporate performance management: scorecarding, reporting, analysis, dashboards, and business event management as well as data integration, on a single, service-oriented architecture (SOA). Author, share, and use reports that draw on data across all enterprise sources for better business decisions. (Cognos Corporation)

Complete BI capabilities in one product, BI platform contains: accessing quality data, system administration and management, architecture and software environment. Both for the business and for IT users the product includes a framework manager, an administration console and a good integration with Microsoft Excel (Cognos Corporation).

Cognos 8 Business Intelligence has a lot of customers, over 23,000 and we can mention among other IBM, Tyson Foods, Inc., BearingPoint, etc.

- c) **BISS – Business Intelligence Software Solutions**, part of RomSys group offers a complete suite of tools, named Business Objects Portal: Crystal reports, Web intelligence and OLAP intelligence. Among BI platform products we can distinguish: BusinessObjects Enterprise, BI platform, Crystal Report Explorer, BusinessObjects Auditor, etc.

BI platform has a set of services for distributing and administrating business intelligence facilities. Users facilities include access to business intelligence portal, ways of interacting with the shown content and the administrating facilities must include security components, data access and audit.

The products and services of BusinessObjects Enterprise Information Manager allow the integration and the improving of performances. Corporate performance management (CPM) is the area of business intelligence involved with monitoring and managing an organization's performance, according to key performance indicators (KPIs) such as revenue, return on investment (ROI), overhead, and operational costs. For online businesses, CPM includes additional factors such as page views, server load, network traffic and transactions per second. CPM is also known as business performance management (BPM) or enterprise performance management (EPM).

Figure 2 - Performance management from Business Objects Platform

(Source: <http://www.businessobjects.ro>)

Each of the IT solutions presented above has its advantages, records an impressive number of customers and is continuously developing from 1 day to another, through the addition of new packages of analyse and reporting which to guide the persons in charge in order to take the best decision at the proper moment.

3. Conclusions

A Business Intelligence platform large enough to comprise and integrate all data, to analyze them and report them in customized way can help any company to move from the desire to obtain performance to action through better and faster decisions.

More and more business solutions are emerging and their efficiency is increasing, as they try to answer to a larger number of questions about the performance of the companies. No matter what solution you may choose, the business intelligent system must help the top management to make better, more informed business decisions, to increase their competitive edge and to respond more quickly evolving customer needs. Many advantages can rise from a BI solution wise chosen, so that the management will be able to answer in real time to complex questions, to maximize profit and to take appropriate decisions based on all relevant information and will also allow it to monitor the impact of its decisions with timely correction and adjustments.

SOLVING THE PRODUCER-CONSUMER PROBLEM USING C ω

Boriga Radu Eugen

Universitatea Titu Maiorescu din București, Facultatea de Știința și Tehnologia Informației, Calea Văcărești nr.187, sector 4, București, radu.boriga@utm.ro, 0724.565.388

C ω is an extension of the C# language with two new concurrency constructs based on the join calculus: asynchronous methods and chords. We will describe both of them and we will apply to solve some variants of the Producer-Consumer Problem.

Keywords: Producer-Consumer Problem, asynchronous methods, chords

1. C ω Language Overview

The C ω language was designed in 2002 by a team from *Microsoft Research* led by *Nick Benton* and *Luca Cardelli*. The new language is described by *Microsoft* as a strongly typed, data-oriented programming language to bridge *semi-structured hierarchical data (XML)*, *relational data (SQL)* and the *.Net CTS (Common Type System)*. Additionally, C ω extends C# with new asynchronous concurrency abstractions, based on the *join calculus* [2,5].

The language provides a powerful, and yet simple, model of concurrency which is applicable both to multithreaded applications running on a single machine and to the large event-based applications communicating over a wide area network.

The *.NET* execution engine provides a multi-threaded execution environment with synchronization based on locks [4]. The C# language includes a lock statement, which obtains the mutex associated with a given object during the execution of a block. Also, the *.NET* libraries implement a couple of traditional concurrency control primitives such as semaphores, mutexes and reader/writer locks, as well as an asynchronous programming model based on delegates. However, there is a serious mismatch between the 70's model of concurrency on a single machine

(shared memory, threads, synchronization based on mutual exclusion) and the asynchronous, message-based style that one uses for programming web-based applications and services.

Conventional methods, inherited from C# language, are *synchronous*, so the caller must wait until the call is completed. In opposite, if a method is declared *asynchronous* then any call to it is guaranteed to complete immediately. Asynchronous methods never return a result or throw an exception.

The asynchronous methods are declared by using the *async* keyword instead of *void* in the header of the method. The call of an asynchronous method is like sending a message or posting an event. Since asynchronous methods have to return immediately, they can be used to schedule for execution a method which needs a long time to be completed. This usage is actually rather rare in C ω . More commonly, asynchronous methods are defined using *chords*, as described below, and do not necessarily require new threads.

A *chord* consists of a header and a body. The header is a set of methods separated by '&'. The declaration of a chord must include at most one synchronous method (which must be first written in the header) and at least one asynchronous method. The body is only executed once all the methods in the header have been called. Method calls are implicitly queued up until/unless there is a matching chord.

Let's consider, for example, the class below [2]:

```
public class Buffer
{
    public async Put(string s);
    public string Get() & Put(string s) {
        return s;
    }
}
```

The code above defines a class *Buffer* with two instance methods, which are jointly defined in a single chord. The method *string Get()* is a synchronous method taking no arguments and returning a string, and method *async Put(string s)* is asynchronous, so it returns no result and takes one string argument.

If *b* is an instance of class *Buffer* and the call of the synchronous method *b.Get()* occurs, then we have two possibilities:

1. if there was previously an unmatched call to *b.Put(s)* then there is now a match, so the pending *Put(s)* is dequeued and the body of the chord runs;
2. if there are no previous unmatched calls to *b.Put(s)* then the call to *b.Get()* is blocked until another thread supplies a matching *Put()*.

Conversely, if a call to the asynchronous method *b.Put(s)* occurs, the caller never waits, but there are two possible behaviors with regard to the other threads:

1. if there was previously an unmatched call to *b.Get()* then there is a match now, so the pending call is dequeued and its associated blocked thread is awakened to run the body of the chord;
2. if there are no pending calls to *b.Get()* then the call to *b.Put(s)* is simply queued up until one arrives.

2. The Producer-Consumer Problem for a Running Belt with Finite Length

Firstly, we review the terms of this variant of the *Producer-Consumer Problem*: "*A producer makes objects and places them, one by one, at an extremity of a bounded running belt. At the other extremity of the same belt the consumer takes objects, one by one too, and uses them. The producer cannot place an object on a full belt and the consumer cannot take an object from an empty belt. At any time, either the producer or the consumer can access the belt.*"

The program below solves this problem, using the concurrency constructs which are provided by the language *Cω*, starting with the theoretical solution described in [1,3]:

```
public class Belt
```

```
{
    private async FreePlaces();
    private async OccupiedPlaces(int x);

    public Belt(int length) {
        for (int i=0; i<length; i++) FreePlaces();
    }

    public void Put(int x) & FreePlaces() { //First chord
        Console.Write("P " + x + " ");
        OccupiedPlaces(x);
    }

    public int Get() & OccupiedPlaces(int x) { //Second chord
        Console.Write("C " + x + " ");
        FreePlaces();
        return x;
    }
}
```

```
public class Test
```

```
{
    private static Belt b = new Belt(3);
```

```

private static Random r = new Random();

private static async Producer() {
    int i=10;
    while (i<100) {
        Thread.Sleep(r.Next(10));
        b.Put(i++);
    }
}

private static async Consumer() {
    while(true) {
        b.Get();
        Thread.Sleep(r.Next(30));
    }
}

public static void Main()
{
    Producer();
    Consumer();
}
}

```

The Producer and the Consumer act in the following manner:

1. the constructor of *Belt* class makes a number of calls of the asynchronous method *FreePlaces* equal with the length of the belt;
2. the Producer can place an object on the belt, calling the synchronous method *Put*, if the belt isn't full. In this case the body of the first chord is executed, which will make a call of the method *OccupiedPlaces* to update the configuration of the belt;
3. the Consumer can take an object from the belt, calling the synchronous method *Get*, if the belt isn't empty. In this case the body of the second chord is executed, which will make a call of the method *FreePlaces* to update the configuration of the belt.

3. The Producer-Consumer Problem for a Running Belt with Infinite Length

Firstly, we review the terms of this variant of the *Producer-Consumer Problem*: "A producer makes objects and places them, one by one, at an extremity of an infinite running belt. At the other extremity of the same belt the consumer takes objects, one by one too, and uses them. The consumer cannot take an object from an empty belt. At any time, either the producer or the consumer can access the belt."

The program below solves this problem, starting with the theoretical solution described in [1,3]:

```

using System;
using System.Threading;

public class Belt
{

```

```

    public async Put(int i);
    public int Get() & Put(int i) {
        Console.Write(" C" + i);
        return i;
    }
}

public class Test
{
    static Belt b = new Belt();
    static Random r = new Random();

    static async Producer() {
        for (int i=10; i<100; i++) {
            Console.Write(" P"+ i);
            b.Put(i);
            Thread.Sleep(r.Next(20));
        }
    }

    static async Consumer() {
        int i;
        do{
            i = b.Get();
            Thread.Sleep(r.Next(30));
        }while (i !=99);
    }

    public static void Main()
    {
        Producer();
        Consumer();
    }
}

```

In this variant, the Producer can make any number of calls of the asynchronous method *Put* (due to the infinite length of the belt). When the Consumer will invoke the synchronous method *Get* the body of the chord from class *Banda* and he will get one object from the belt. It's easy to see that the body of the chord can be executed only after a minimum one call of the method *Put*, so the Consumer cannot try to take an object from an empty belt.

4. Conclusions

The concurrency is an important factor in the behavior and performance of modern programs: these type of programs are difficult to design, write and debug. Moreover, most popular programming languages treat concurrency not as a language feature, but as a collection of external libraries and this fact has undesirable consequences. The *Cω* language advantage is that it has such features embedded in the language, so the

compiler can analyze them, and can produce better code and warn programmers of potential and actual problems.

On the other hand, asynchronous events and message passing are more and more used at all levels of software systems and very often we find situations where there are many asynchronous messages to be handled concurrently, and where many threads are used to handle them. Threads are still an expensive resource on most systems, so the it's a big advantage to use the messages and threads behind a language mechanism, because a compiler may optimize the generated code.

For these reasons we suppose (and hope) that the *C ω* language will be used on a larger scale in the development of distributed applications.

AUTOCHTHONOUS APPROACHING IN THE MANAGEMENT OF THE SECURITY RISK

Burtescu R. Emil

Universitatea “Constantin Brâncoveanu” – Pitești, emil.burtescu@yahoo.com, 0722-736.647

An optimal management for a corporation, no matter what size the corporation is, it must contain the management of the security risk. On the importance that is given to the risk management can depend the well functioning of the corporation. An important role in this process has the owner of the business and the way that this one understands the risk. A good understanding of the risk by the owner will have as effect the allocation of sufficient funds to implement controls meant to bring the risk level in order to be an acceptable one. The autochthonous corporations, in a great part even because of the inexistence of reglementations in this domain, have an empiric approach of the phenomena.

Keywords: approaching, autochthonous, controls, resource owner, risk, risk analysis, risk level, risk management, security, vulnerability.

The restriction to the data access must be a permanent concern of the corporation. Completing or not this will have benefits upon the corporation or, by the contrary, negative effects. The absence of the security measures can be as harming as having too much security measures. A security policy permitted for own users and for the collaborators or clients can have as effect covering security deficits that can be used by the malefactors. Using too many security measures will have as effect complicating the work of its own employees and even the collaborators or clients. What a corporation has to do to maintain an optimal security level of its own data? Can the corporation assure and maintain this security level? Do the owners of the business understand the necessity of the security of data?

For many people the security of data represents the only method for maintaining the business of the corporation, ignoring the other potential threats: the economic environment, the natural environment, the financial environment, public environment, technological environment, etc. In the next lines, we will refer at risks as being only security risks.

For assuring the security measures in a corporation, this can be based on people (preparation, responsibilities, knowledge, and organization), processes (policies, procedures, standards) and technologies (infrastructures, applications)

The risk security management in a corporation represents the process to determine an acceptable level of risk and maintaining or reduced, as is possible, the risk level. The confusion between the risk management and the risk analysis must not be done. Risk analysis has as purpose identifying and classifying the risk in the corporation, and works only in one phase, while the risk management is a permanent process.

The corporations must adopt a risk management formed on four stages (or three in some cases) (figure 1):

1. Risk evaluation.
2. Coordination of the decisional process.
3. Implementing controls.
4. Measuring program effectiveness.

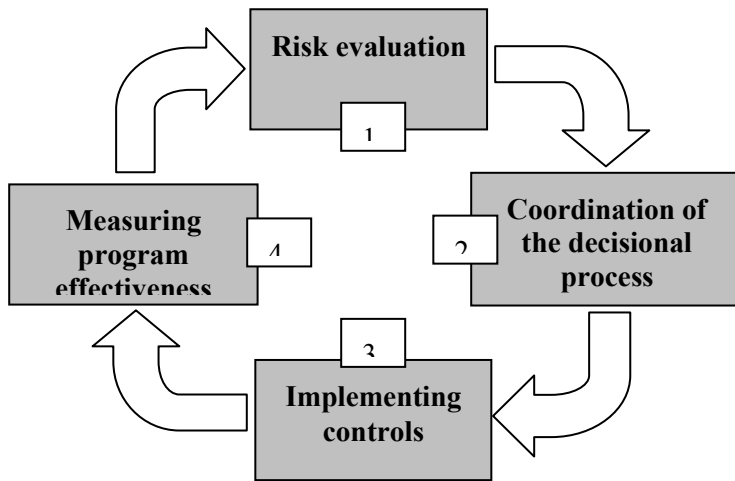

Figure 1. Risk management cycle

Risk evaluation will contain activities meant to identify and classify risks that can affect the corporation's business.

Coordination of the decisional process is meant to identify and evaluate the measures and the control solutions taking account of the report costs-benefits.

Controls implementation means implementation and developing control measures meant to lower or to eliminate risks.

Measuring efficacy, analyzing the efficacy of the adopted control measures and checking if the applied controls assure

the established protection level.

It is necessary for the corporation to work permanently and periodic the operations from the risk management cycle to assure at least a controllable risk level.

As concerning the level touched by the risk management, this can be situated in one of the next levels:

1. **Inexistent** - the corporation doesn't have security policy well defined and documented.
2. **Ad-hoc** - the corporation realizes the risk. The risk management efforts are made in a hurry and chaotic. The policies and processes are not well documented. The projects of risk management are not coordinated and chaotic, and the results can't be measured and evaluated.
3. **Repeatable**- the corporation has knowledge about the risk management. The process of risk management is repeatable but immature, insufficient documented. There is no formal instruction or a communication concerning the risk management, responsibility being left to the decision of the employer. The corporation does efforts to get better.
4. **Defined** - the corporation adopts a formal decision for the implementation of the risk management. The objectives and the ways to measure the results are clearly defined. The employees are formally instructed at a base level
5. **Controlled** - the risk management is well known in all the compartments and levels of the corporation. There are well defined control and lowering the risk procedures. Efficacy can be measured. The personnel is instructed. The resources are sufficient. The benefits are viewable. The risk management team works to improve permanently the processes and instruments that they use. A large part of the risk evaluation processes, of identifying controls, of analysis of cost-benefits are manual.
6. **Optimized** - the process of risk management is well understood and atomized using specific instruments developed in the corporation or taken from corporations that are specialized in this domain. The sources of risk are identified and are taken measures to limit their effect. The employees are differentially instructed. It is worked on optimizing the processes.

The ideal thing would be that corporation should be at least on the **repeatable** level and to do efforts to gain the **optimized** level. Accessing one of the indicated levels, even if they have to represent a priority for managing the corporation, in many cases, for the autochthonous corporations, this desideratum is hard to gain.

The owner of the business has an important role in this case. He takes part in **two important moments** of the cycle of risk management.

The first moment is the one from the beginning when they must establish what is important for the corporation, that means to define an acceptable risk for the corporation.

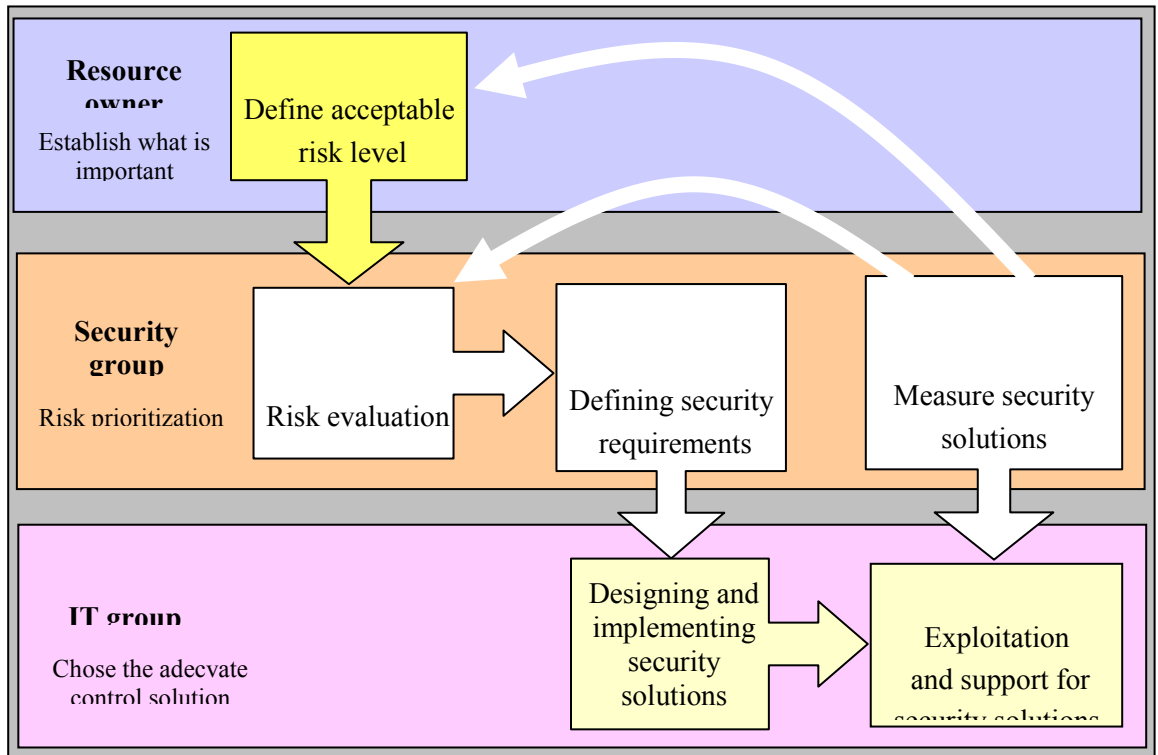

Figure 2. Rules and responsibilities in the security risk management process.

The second **moment** is the one when they **will be able to allocate funds to implement, maintain and improve security**. Because of this it is important for the owner of the business to understand firstly what security risk implies and the fact that this can be lowered or eliminated by investing money. *I consider that the greatest risk that a corporation can have is the risk not to understand the meaning of the risk.*

In this situation a **first** approach of the owner of the business, referring to risk could be:

- this can't happen at my company, and on risk analysis is made and the investments in security are equal with 0, risk management being inexistent.
- the necessity of security is partially understood but because having no money, it's not invested in security, just like the situation that we mentioned earlier.

The **second** approach goes from the premise that something must be done. In this way, all the job must be done by the IT group, if there is one. If there is no IT group, all the work must be done by the person that has in charge the IT section and who has only elementary knowledge about security. We can't even talk about risk analysis anymore. In this situation we can say that the company has an Ad-Hoc type of risk management (chaotic would better suite this situation).

The **third** approach will lead to a repeatable risk management level, that tends to be defined. We meet this situation when the owner of the business is not made only by one person, but by a group of people, and these people can cooperate, not totally, necessity of security. In this case the investments in security exist, even if these investments do not cover all the security deficits.

The **fourth** approach has constrictive aspects or it has important elements. This will lead to a controlled risk management level and even optimized. The defining elements in this situation are:

- the company belongs to a domain in which security has priority;
- the company is in a collaboration process with another company that has an optimized risk management process;

- the company, even if it is autochthonous. Has an external management.

If the company belongs to a domain in which data sensitivity has priority, then there are strict regulations that the company has to obey to function in the domain. In this category there are included companies or organizations from the defensive, internal affairs, banking population evidence domains. For the companies and organizations from the United States there are regulations mentioned in Orange Book of Security.

In case of collaboration with a company that has an optimized risk management level, it is necessary that the company should obey at the security demands proposed by the partner. No company that has a high level of security and a controlled or optimized management will not risk to share data with a partner that has a lower level of security.

There are companies that even from the beginning take measures for lowering the risk. This situation is met in the most cases at the companies that come with a management from western countries.

This last approach is based on a very well understanding of the risk and of the necessity of security, that will generate enough funds for investments meant to reduce the risk level for the company.

The main reason for which autochthonous companies do not invest in security is represented by the costs. There are situations when, even if all the steps for developing controls that are meant to lower the risks were made according demanding in domain and by specialized personnel, the sum that was allocated was lower than it was demanded. In this case we can talk about a **financial enforced security**. The group named to implement controls had to do different things to be able to have enough money, sometimes some vulnerabilities being left discovered.

The second reason is represented by the fact that even if this thing is demanded there are no companies or specialized personnel for such a thing. Preparing your own personnel is extremely expensive because of the initial prepare and payment but even with the ulterior costs. Companies that are specialized in this domain are few and not known. Lately these companies began to be seen on the market. Demanding specialized companies presents many advantages: the existence of specialized personnel and lowering the costs by externalizing security services.

The next facts must be understood in order to assure an optimal security level:

- Investments in security do not create direct benefits but have the great advantage because they lower the potential loss. In many of the cases, 20% of the costs are reflected in 80% of the benefits, concerning lowering the risk and assuring security.
- Assuring the corporation's data security is like an "insurance policy" in case of a disaster.
- A minimal security level is preferred in case any kind of level does not exist. A minimal level of security does not represent the optimal of security.
- Assuring the security must be a continuous process, implemented by the strict risk management cycle.

KM AND LEARNING ORGANIZATIONS

Butuza Antoaneta

West University of Timisoara, Faculty of Economic and Business Administration, antoaneta.butuza@fse.uvt.ro , 0256.592.505

Hauer Ileana

West University of Timisoara, Faculty of Economic and Business Administration, ileana.hauer@fse.uvt.ro, 0256.592.505

The Knowledge Management (KM) infrastructure is essential to support learning organizations. A learning organization has embraced a KM initiative and is moving towards becoming a knowledge-based organization. KM infrastructure (tools and technologies) provide the platform upon which learning can be built. Effective learning is associated with increased information sharing, communication, and understanding. There are essentially two key contributors that can create learning organizations-people and technology. The importance of learning organizations and the dominant role of such organizations in a knowledge economy is only just being understood.

Key words: knowledge management, learning organizations, knowledge economy

Introduction

The nations that will lead the world into the next century will be those that can shift from being industrial economies based upon the production of manufactured goods to those that possess the capacity to produce and utilize knowledge successfully (Porter, 1990).

The new organizational form will rely on clusters of self-organizing components collaboratively investing the organization's know-how in product and service innovations for markets, which they have helped to create and develop. Such organizations can best be described as cellular, suggesting a living, adaptive organization, able to respond rapidly to new demands (Bukowitz & Williams, 1997; Nonaka, 1991).

In such a dynamic environment, the concept of a learning organization, one that continues to change and adapt to the demands of its environment, is critical if the organization is to survive and thrive (Popper & Lipshits, 2000). Hence, greater attention needs to be given by organizations towards building learning organizations. Learning is connected with a company's ability to adapt to a rapidly changing environment. Essential to learning is the gaining of germane knowledge and the increasing of the existing extant knowledge base (Ellerman, 1999; Ellinger, Watkins & Bostrom, 1999; Wickramasinghe & Schaffer, 2005). Through learning, organizations are better equipped to react faster and to fully exploit opportunities thereby placing themselves in a position of competitive superiority.

Theory Fundaments

Learning organizations: definitions

Learning is defined as acquiring new knowledge and enhancing existing knowledge (Huber, 1991).

The concept of the "learning organization" to the business world was introduced by Senge in 1990 (Senge, 1990) Such a learning organization represents a complex interrelationships of systems composed of people, technology, practices, and tools designed so that new information is embraced (Simon, 1999). Learning organizations are organizations that have embed institutionalized learning mechanisms into a learning culture (Popper & Lipshits, 2000). Every organization has the potential to become a learning organization; some organizations learn explicitly address both the learning and unlearning that is needed for keeping abreast with the changing dynamic reality of the business environment (Senge, 1990, 1994).

A learning organization is an organization that has an enhanced capacity to learn, adapt, and change (Levine, 2001). Learning takes place at two levels - individual and organizational. Learning within organizations, as with individuals, is evidenced through the change or growth of the extant knowledge base (Wickramasinghe & Schaffer, 2005). While organizations do not have brains per se, they have cognitive

systems and memories that play a key role in organizational learning activities (Popper & Lipshits, 2000). As individuals develop their personalities, personal habits, and beliefs over time, organizations develop their views and ideologies.

A learning organization consists of employees who are continuously enhancing their capacity to learn in the corporate culture (Huber, 1991; Popper & Lipshits, 2000). It is here that learning processes are analyzed, monitored, developed, and aligned with the organization's goals (Kapp, 1999). Most companies underestimate the importance of intangible assets such as knowledge, creativity, ideas, and relationships; yet all these account for more value in a knowledge economy than the more easily measured and highly prized tangible assets (Probst, Raub, & Romhardt, 2000).

Organizations are growing more knowledge-intensive in order to learn from past experiences and from competitors to reshape themselves and to change in order to survive and prosper. Organizations need to utilize knowledge across processes and functions, to become knowledge-driven organizations or learning organizations (Nevis, DiBella & Gould, 1997). Hence, the organization that becomes a learning organization will have a significant advantage over its competitors because of its ability to learn faster and thereby adapt faster and more successfully to its environment. Learning organizations are generally described as those that continuously acquire, process, and disseminate knowledge concerning markets, products, technologies, and business processes (Roberts, 2000). This knowledge is often based on experience, experimentation, and information provided by customers, suppliers, competitors, and other sources (Ellinger et al., 1999; Senge, 1990, 1994).

Learning organizations have to continually expand their capacity to be creative and innovative. The only way to sustain competitive advantage is to ensure that your organization is learning faster and more effectively than the competitor is. Organizations are realizing that their human capital (people power) and structural capital (databases, patents, intellectual property, and related items) are the distinguishing elements of their organizations.

Types of learning

As with knowledge, organizational learning is not a homogenous construct. At its very simplest, there exist two types of learning (Argyris, 1977; Argyris&Schon, 1978, 1996; Huber, 1990):

- Incremental: learning that is characterized by simple, routine problem solving and that requires no fundamental change to your thinking or system.
- Radical: Breakthrough learning that directly challenges the prevailing mental model on which the system is built.

Learning can be further classified as adaptive and generative learning (Argyris, 1977; Argyris & Schon, 1978, 1996).

Adaptive learning and generative learning

The current view of organizations is dominated by the perspective of adaptive learning, which has its roots in biological sciences where organizations learn and adapt to survive in their environment (Huber, 1990; Senge, 1990).

According to Senge (1990) increasing adaptiveness is only the first stage; companies need to focus on generative learning or "double-loop learning" (Argyris, 1977).

Generative learning emphasizes continuous experimentation and feedback in an ongoing examination of the very manner in which organizations set about defining and solving problems. In Senge's (1990) view, generative learning is about creating- it requires "systemic thinking", "shared vision", "personal mastery", "team learning" and "creative tension".

Generative learning, unlike adaptive learning, requires new ways of looking at the world. Generative learning requires seeing the systems that control events. When we fail to grasp the systemic source of problems, we are left to "push on" symptoms rather than eliminate underlying causes. The secret of the learning organization is to find the leadership, institutional arrangements, and culture elements that result in generative learning as a continuous process. Table 1 provides the 10 steps of systems thinking that have been designed to support generative learning (Senge, 1990).

Step	Description
1	How is the system defined?
2	What business or businesses is the corporation in?
3	How is the corporation organized?
4	How does the corporation actually operate?
5	What are the policies, practices, strategies and tactics currently in place?
6	What is the management style?
7	How has the corporation performed in the past and how is it performing now?
8	What/who are the corporations stakeholders?
9	Who are the competitors?
10	What are the laws and governmental regulations and how do they affect the corporation?

Table1. Ten steps of systems thinking

Source: Senge, 1990

One of the characteristics of a learning organization is that it moves beyond simple employee training to more of an environment that stresses problem solving, innovation, and learning. Organizations that embody the traits of such an environment consist of live areas, or disciplines, that make a learning organization what it is (Senge, 1990):

- Personal mastery. This discipline allows people to clarify and focus their personal vision, focus energy, develop patience and see the world as it really is. Employees who possess a high level of personal mastery can consistently generate results, which are important to them through their commitment to lifelong learning.
- Mental models: These are internalized frameworks, which support our views of the world, beliefs in why and how events happen, and our understanding of how things, people, and events are related.
- Building shared vision: Developing “shared pictures of the future” together so that people are genuinely committed and engaged rather compliant.
- Team learning: Teams as a vital element of a learning organization. Hence there is great significance in the ability of teams to learn (Price, 2000).
- Systems thinking: People in an organization are part of a system. Systems thinking is a discipline which integrates the other disciplines in a business. It allows the “whole” (organization) to be greater than the parts (people, departments, teams, equipment, and so on).

The five disciplines are connected to one another. By themselves, they do not provide guidance on how to build a learning organization. In order to transform an organization from a goods and services producer, for example, to one with a focus on integrating learning in their business practices of producing goods and services, a commitment must be made to establish a learning infrastructure. Learning must be institutionalized (Buhler, 1999; Dodge, 1991).

Discussions

Importance of KM for learning organizations

KM is inextricably linked with capitalizing on an organizations human skills, expertise, and intellectual assets (Duffy, 2001; Lee, 2000; Thorne & Smith, 2000). Taken together, these intangible assets including human capital (tacit knowledge and competencies), structural capital (intellectual property, methods, and policies), social capital (relationships), and organizational capital (customer relationships and agreements) provide an organization with its key unique strengths. Building on these unique strengths there are then two

levels of organizational learning – the contribution level (where people learn, collaborate and innovate) and the multiplier level (where what comes from the contribution level is passed along to the rest of the organization through processes such as mentoring, networking and inspiring (Brown & Druid, 1991; Clegg, 1999; Davenport & Prusak, 1998).

To remain competitive, organizations must efficiently and effectively create, locate, capture, and share their organization’s knowledge and expertise. Hence, the KM infrastructure is also essential to support learning organizations. It is indeed fair to say that a learning organization is one that has embraced a KM initiative and is moving towards becoming a knowledge-based organization. Thus, KM infrastructure (tools and technologies) provides the platform upon which learning can be built. As has already been discussed, the KM infrastructure includes repositories for unstructured data, structure data (data warehousing, generation, and management), and groupware that supports the collaboration needed for knowledge sharing. It also includes tools like e-mail for other forms of interpersonal communication required for the efficient, time and location-independent exchange of information (Croasdell, 2001; Davenport & Prusak, 1997, 1998; Davenport, Jarvenpaa & Beers, 1996; Duffy, 2001; Garvin, 1993). From the standpoint of a learning organization, it is the interaction of knowledge workers with the KM infrastructure that ensures that organization learning both single and double loop takes place.

Organizational learning vs. learning organization

Organizational learning and learning organization are terms that permeate much of the business literature and are often used interchangeably. However it is important to note that organizational learning is the ability of an organization to gain insight and understanding from experience through experimentation, observation, analysis, and a willingness to examine both successes and failures (Brown & Duiguid, 1991) and thereby a process. In contrast, a learning organization described an organization that supports the process of organizational learning, has implemented KM initiatives and is or is transitioning to become a knowledge-based enterprise (Sharma, Wickramasinghe, & Gupta, 2004; Wickramasinghe, 2003). Figure 1 highlights these differences and the connection between KM and both organizational learning and the concept of a learning organization.

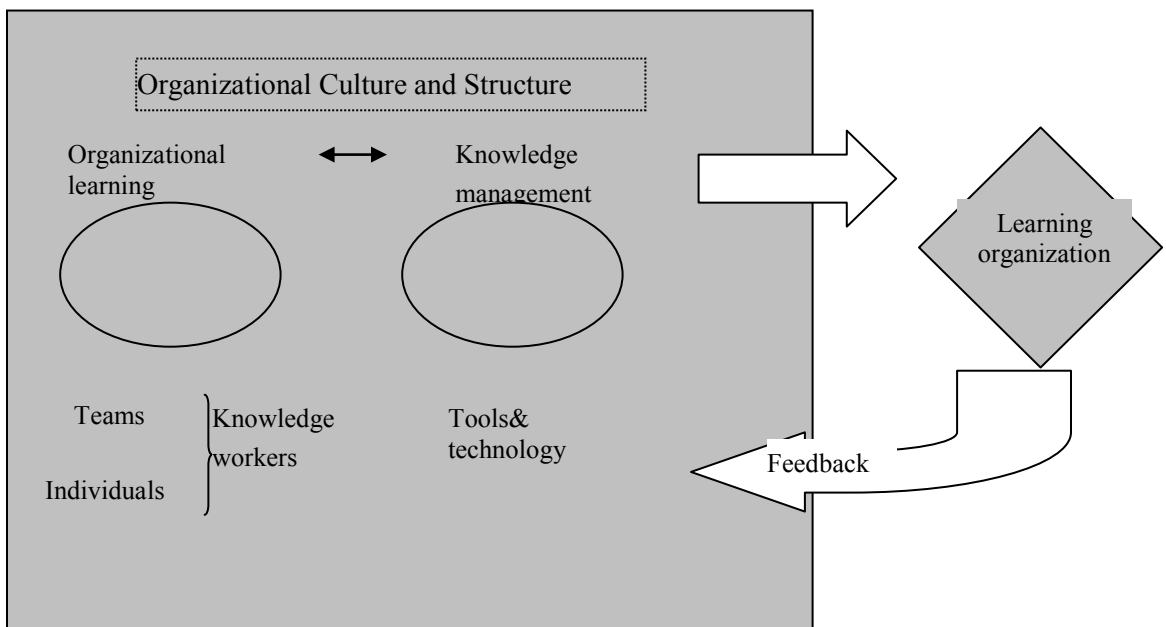

Figure 1. The fundamental elements for building a learning organization using knowledge management

Source: Wickramasinghe, von Lubitz, 2007

CONCLUSIONS

The concept of a learning organization that strives continually to develop its people and processes will be an accepted philosophy of all competitive organizations in the future. Within business, learning is a conscious attempt on the part of organizations to improve productivity, effectiveness, and innovativeness in uncertain economic and technological market conditions. Effective learning is associated with increased information sharing, communication, and understanding. It is for these reasons the concept of “learning” is probably more pronounced in business than any other area.

These are essentially two key contributors that can create learning organizations- people and technology. It is the combination of these two factors with new business processes and business models that will underpin success in the next decade. The power of learning from customers, employees, and suppliers will provide considerable advantage to learning organizations and play a vital role in establishing and maintaining a competitive advantage. The importance of learning organizations and the dominant role of such organizations in a knowledge economy is only just being understood. However, what is of most significance is that it is not possible to have a learning organization without incorporating KM, it is not possible to support the process of organizational learning without KM nor is it possible to have a truly successful KM initiative without incorporating the processes of organizational learning or developing a learning organization. Hence, a knowledge-based business is also a learning organization.

In this work, we'll show some theoretical and practical aspects about operational game such as modern method for optimization of decisional act.

Operational game is a simulation way wherein there are observed, in artificial conditions, the people who take the decision in reality.

The utility of operational games as optimization methods is limited but they can represent an efficient heuristic instrument for the development of models of some situation which demand the meeting of several people.

Keywords: *operational game, simulation, similarity, analogical model.*

1. GENERAL ASPECTS CONCERNING MODELING OF CONFLICT CASES

Into an environment of concurrence, taking decisions cannot base only on intuition and experience, being known that adopting of every decision is accompanied by a risk produced by unfavorable events which make changes of waited profit or of the relations between business and partners.

In mathematic programming, graph theory or scientific management of stocks, there are used mathematical models which allow finding of optimal decisions in a certain time. In such cases there is only a side interested in knowing optimal solutions; that is the manager.

Within market economies there are often cases whereat least two parts participates to: physical persons, collectives, directed systems, with interests which are in bigger or smaller disagree called „conflict cases”. In these cases, there are at lease two sides interested in optimal solution. Interest conflict is quasi-present in concurrence economy, in social and politic life or in military problems.

Starting from the study of society games, E. Borel and John von Neumann founded mathematical bases of the study of conflict situations and/or cooperation. However this science of human behavior in conflict or only competition cases concerned, under several aspects Kepler, Galilei, Pascal, Fermat, Bernoulli and, recently, Polish mathematician Hugo Steinhaus, first book „*Theory of Games and Economic Behavior*” appeared in 1944 having as authors J. Von Neumann and the economist O. Morgenstern. After this date, numerous works appeared which contributed to development of competitive case theory and its applications in very many domains [1, 10].

Competitive situation between two economic agents having economic relations based on a statute – a protocol – can be considered as a game with two rational opponents but there are economic competitions wherein one of the partners isn't rational but his behavior is established by a happen set of rules. This partner named nature, influences human's activities through overflows, droughts, or certain conjuncture cases like, for example, govern dropping, work breaks, war starting, launching of a new product etc.

In these games, called „games against nature”, nature is considered to take the most unfavorable state for the opponent. For this reason, as the player – statistician – not to be more in complete ignorance, he has in most cases, possibility to get certain information about nature strategies through the experiences he can make and which give him the possibility to decrease the losing which nature reserve to him. In these cases, the games are named statistic, and their mathematic theory is due to A. Wald (1951).

Statistician can decrease the risk to take wrong decisions (because of not knowing nature strategies), making experiences. This thing is fenced by the following circumstances: experiences need time, in most cases decision must be taken fast and on other side, experiences imply expenses that can be bigger than the advantage brought by knowledge excess which experiences deliver it [6].

But there are cases wherein the risks wherewith decisions are taken can be not known either at least in likelihood and these are named situations of whole incertitude. There is decision theory that analyzes such cases. It must be mentioned that „nature” that acts wholly random, is not perforce against the man.

2. OPERATIONAL GAME AS SIMULATION METHOD

Under the conditions of the growth of structural and functional complexity of enterprises, of rising of technical level of installations, and corresponding to some strong specializations of the professions, new problems have been put, the decision person having to take optimal or almost optimal decisions

Thus, additionally to traditional procedures relied on intuition and experience, a series of scientific, modern, taking decision procedures are necessary, which are characterized by o theoretic foundation based on mathematic methods, with keeping of a general directing, practice and realist. Within this action, production process modeling and simulation is an upper stage, absolute necessary to decision act optimization [2].

Modeling represents reality and simulation imitates it. A simulation method wherein decisions are taken by one or more real persons is named operational game. The term is sometimes used only for the situations that imply participation of two or many persons.

Last decade, the games began to be used on a bigger and bigger scale in the study of the complex military and industrial operations. Nowadays, they are also used in the research of some problems of administration at municipal or national level and even in external politic. The games are used since many years ago in military domain but their using as research instrument is relatively recent. The games began to be used more and more to stuff selection and training, for his familiarization with operations which occur in a complex system or for explain the ideas which are in the base of these systems [12].

In research problems, games can be used in the following three scopes:

1. at the elaboration of a decision model;
2. at the finding of optimal solution of the model;
3. at the evaluation of purposed solutions for the problems modeled through a game.

Games can help to model building, offering a base for test degree of importance of the variables and functional form of the model (of the relations between variables). Also, sometimes „games” allow us to discover mew action possibilities or to compare several found solutions. In some cases, we can get from the model only partial description of the strategy but not a complete one; the effect of the strategy will be able to be established, however, by the helping of a game.

Operational games are, essentially, experiences wherein it is viewed decision person’s behavior in checking conditions. They are different form the most of psychology and sociology experiments only because they have place outside the lab, in condition that to allow us a better knowledge of certain circumstances. Hence, intentionally, experimental situation is built so to represent an intuitive or analogical model of real case which interests the researcher.

Often, games have been elaborated without have a clear idea about the kind of how they could or would have to be used. Occasionally, it proposed effort reasoning but generally models have been built either as a scientific exercise or as for explore eventual applications. It pretended that games are useful in stuff selection and training or for describing of complex system operating but till now, nothing about the efficiency of these applications is known.

Some researchers largely exposed methodological problems about games using as research mean. Despite of the lack of a logical and rigorous foundation, operational games give whose use them an outstanding trust in their results. Sometimes, a result a little believable is accepted even for this reason with a strong satisfaction. Believable results are often taken without a critic analyze [8].

In a game formulation, we are in the evidence of contrary objectives which make us to hesitate in our exigencies formulation. On a side, game solution must be as right to conflict situation we study, as possible. This demand encourages adding other details too, in the hope of approaching more and more to

real case. On other side, the game must be able to be solved, at least having demanded rightness degree. This condition imposes to abandon more and more details.

General tendency which represents futile embarrassment of operational games, can be other example that to show how wrong „reality approaching” is understood. This is a trap within there is easy to fall. To research „reality essence” is a difficult and embarrassing thing, and the recognition of the objective is difficult. Often is thought that through the incorporation of more and more details into the model, essence reaching is surer. If, so how it happens about operational games, the increasing of solving difficulties escapes from attention, temptation to develop the model becomes stronger and stronger [11].

But right in games case, it would be able to put against this tendency, otherwise disillusion won't be late. Not only the solving efficiency is reduced to half, but, as a consequence of excessive charging of model, even solution study becomes difficult. There is the tendency to forget that the game doesn't represent the reality itself. Reality appearance, so useful in teaching process, becomes dangerous in applications.

3. ANALOGY AND ANALOGICAL MODEL

In usual application of operational games there is the tendency to confound the notions of analogy and analogical model. They aren't the same thing. Analogy generally allows us to get a few results (when it is possible), but whose sometimes it grants them a trust that they would worth only if they have been deduced by the means of an analogical model.

There is important to understand the difference between analogical model and analogy, in the sense wherein these terms are used here. In both cases, we use a case as model of other case. The difference consists of what we know about the correspondence between model and „real” case. In analogy, there is known whether the two cases have certain common properties but we know nothing about the correspondence existing between their features [5].

In consequence, in analogy, we don't know the function F which establishes the link between variables and result and therefore we don't know how well or how bad is represented the structure of real case. Within an analogical model, we consciously introduce a feature that, on analyze or experience base, we consider it acceptably fitted to the real one.

The structure of a game corresponds to that of modeled situation, in the sense that the same decisions bring in both cases to the same results. We must insure of the existence of this correspondence before can draw conclusions about the reality, relied on the game.

The existence of a correspondence between properties doesn't prove that it would exist also a correspondence between features. We can build a game and act over its feature till the same data will bring to the same results like in real case. So, the game might be used for the exploration of structural relations which produce certain dependence between data and results. But in an established value domain, the same dependence between data and results can be produced by a big number of different features. Hence, there would be dangerous that, relied on this dependence, to draw conclusions about the results for data outside the domain wherefore it was established. Therefore, it is also important to clarify the limits within data can vary for gotten structure to generate corresponding results to real case. Last observation is similar to the affirmation that a *S-shape curve* can be well approximate as a line, in certain domain of its variation, but outside it, the approximation is bad [4, 5].

The more the game represents several features of reality, the more difficult becomes structure analyze of it (that is structure representing through a mathematical model). On other side, if the model doesn't contain enough relevant aspects, it cannot be a correct reflection of reality. The right rapport between simplicity and complexity cannot be gotten than experiencing over the game itself. Building of a game, to prove good for solving studied problem, needs much more time than game using, after it has been gotten.

If a game doesn't adequately correspond to reality or if there is difficult to establish how large this correspondence is, the researcher remains interest in this game more for his own pleasure than to use it as analogical model. In this case, the game becomes a usual „experiment” or it is used for other scopes, for example, for stuff training but not for research.

4. OPERATIONAL GAME USING FOR GETTING PRACTICAL CONCLUSIONS

Some games have been built as, on their base, to be deduced an approximate solution of a real problem. These games are generally easy and imply the existence of a mathematical model, which to enfold the most part of „real” case. In the following example, there is formulated a game which to contribute to solving of a non-competitive problem [7, 9].

In a problem it must be established the order wherein several products follow to entry in fabrication. Organization expenses, associated to every product, depend on the last product existing in fabrication. The problem, consisting of the minimization of the sum of organization expenses, with some restrictions demanded by the stocks, can be represented as a matrix containing organization expenses corresponding to every pair of products. The matrix is not symmetric because making of *A* after *B* implies different expenses to those needed for making *B* after *A*. There is viewed that there is got an „bagman’s asymmetric problem” Studying the problem, we can identify a series of decision rules that, apparently, would bring to expenses reducing, in rapport to the cases wherein production planning is made based on intuition and experience. Found rules don’t show what decisions must be taken in all cases, thus the intervention of enterprise management is still necessary.

The researchers have re-planned the production of last three yeas using gotten decision rules and taking themselves the decision when management intervention was necessary. Comparing real expenses with obtained results, there has been observed a clear decay of these ones. It remained to view whether who managed in reality production planning, would have been able to get such improvements.

There was made a game wherein it has been demanded to decision stuff who established the order of making products, to re-plan last three year’s production. The results gotten by them, have brought to the same improvements as those found by researchers team. On this base, the new rules have been adopted and then, a continuous improvement of results has been observed, comparing to those found applying the old method.

We don’t argue that result improvements, observed through the application of decision rules in proposed game, would be a logical warranty that the same improvement would make in reality if those rules have been applied.

4. CONCLUSIONS

Making, modeling and finishing of a game needs long time (measured in years) and also, a big amount of work from a complex team consisted of economists, mathematicians, engineers, informatics stuff, programmers.

Main inconvenience of operational games used now, consists of that it cannot establish a strong link between game and reality. A model, either game or equation, is always a simplification of reality and even for this reason, it is useful in science. It is important to know the nature and the means of this simplification because only thus, the conclusions gotten basing on the model will be valuable in reality. The large game which to surprise more and more real cases, can be realized only by helping of electronic computer.

We can consider the implementation of an operational game as an investment, in the sense that it implies big sums of money and time at staring, previewed results appearing after several years.

Within an operational game, Monte Carlo simulation method can be used when random variables or Forrester’s simulation techniques occur, besides the large form of operational research or statistic-mathematic methods. Operational games allow dynamic simulation of some sequential decisions. Among main scopes of operational games using is that of formulation, at management stuff, of the skills in solving real cases wherewith they meet often in practice.

Another aim is that of the development of complex approaching skills, systemic of simulated process. By the means of operational games, experts can test a series of hypothesis about the nature of the decisions fallowing to take, with establishing of probable effect of several decisions. In this sense, we can say that the game offers the possibility of amount experience in problem, before real development of economic processes, allows anticipation of the consequences of using resources in the most different cases, of course, without their effective using.

When we refer to operational game advantages, we needn't neglect psychological effects of them over participants, who can entirely show their personality, to check assimilated knowledge, power of generalization, of phenomena abstraction, power to ration correctly, all these directed for development of response feeling for taken decision, of the implication of it for enterprise „destiny” and enterprise good financial-economic way.

This paper was developed within the research Project „*Development and the Implementation of the Integrated Management System (DI - IMS)*”, no. 2387/2007, PNCDI_II.

DATA SETS (BASIC 2008)

Cosma Emil

“Ovidius” University of Constanța, Faculty of Economic Sciences, Telephone 0766/221615, E-mail: ecosma@univ-ovidius.ro

The most important thing to know about data sets is the fact that they are organized into tables. Every single table contains rows and columns, also called information fields. Every row/line within a table has the name of record. The data that are organized in such manner (into independent relational tables) are relational data. The software application used for arranging data in such way is called relational database. SQL (Structured Query Language - programming language for querying) is the most frequently utilized programming language, being used for the retrieval and management of data stored in relational databases. The Visual Basic controls for databases play a significant role in establishing the connections between applications and data. Every table contains a primary key, which is used for the unique identifying of database's recordings. In other words, the value of a primary key within a table can not be duplicated throughout the recording processes. For instance, a primary key could stand for a personal identification number, an e-mail address or another unique identifier (the persons' names are not usually chosen as primary keys because there might be the possibility of a repetition).

Keywords: Basic, Connect to Database, Tables, SQL Server

In order to initiate a database working session, this has to be activated. For connecting to an existing database or to create a new one, the *Server Explorer* Window might be utilized (if it doesn't appear, one may need to launch the window from the menu: *View, Server Explorer*). One needs to use the *Add Connection* option from the contextual menu by using the *mouse right-click* on *Data Connections* (the system *Tools* menu could also be accessed, followed by *Connect to Database...*). Using this dialogue one may select different types of databases, such as: *Microsoft Access, SQL Server Database File, Oracle Database*. Because the *Visual Basic's* native database is *SQL Server Database*, one may specify the name of such database which exists within the personal computer or create a new one (*Personnel* for example, fig. 1):

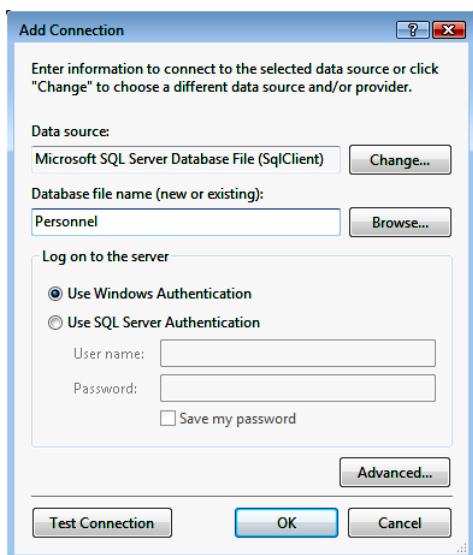

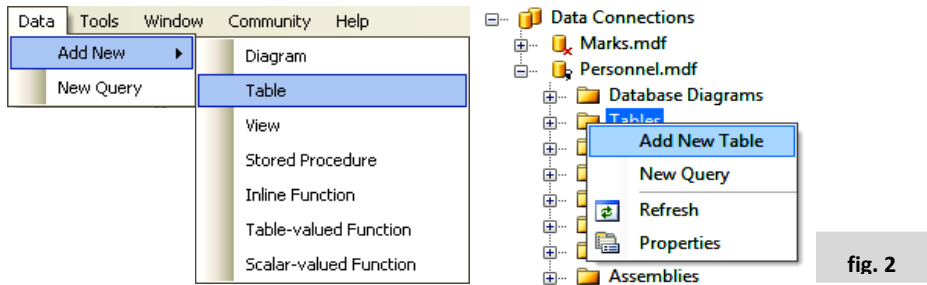

fig. 1

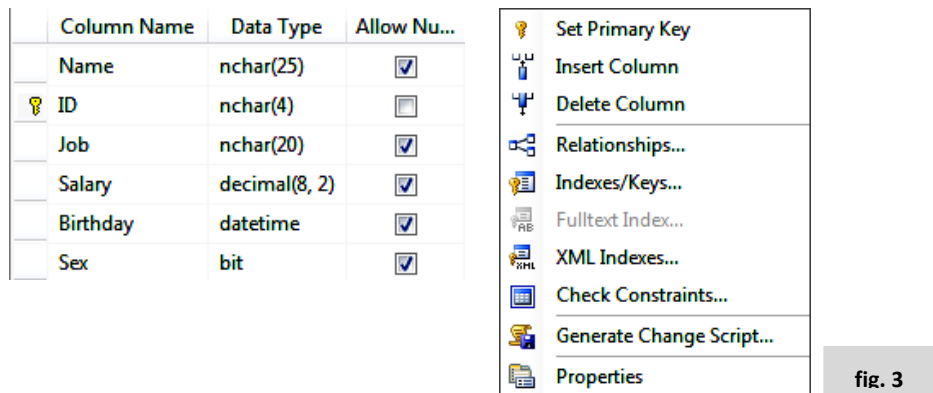

One may add a new table within the database (*Personnel.mdf* here). The *Data* option appears in the *Visual Basic* menu, but the contextual menu might be also utilized when *right-clicking* on *Tables* (fig. 2).

Data table's structure definition (Table Designer)

Within the *Table Designer* window one may define (*Table Definition*, fig. 3):

- the field names names (*Column name*);
- *Data Type* within the field (character lines, decimals, date time, logical, etc.);
- the number of characters which is required for typing the field values;
- the number of decimals needed for the numerical data- for instance: *decimal (8,2)*;
- the fields which don't require a completion (*Allow Nulls*);
- the primary keys (Set Primary key) – right-click on the field name.

Example:

- ✓ The *Employee* table will be defined in the *Personnel.mdf* database (fig. 4):

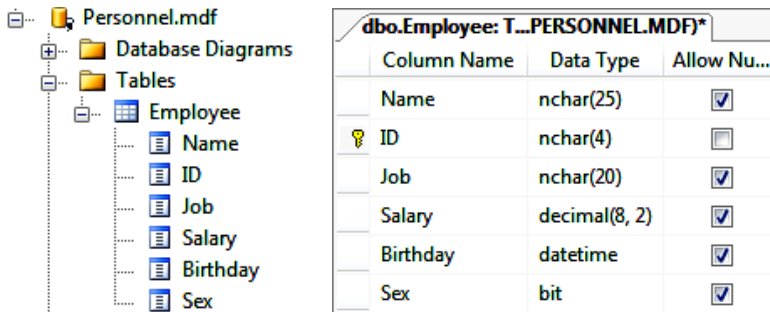

fig. 4

- ✓ The ID field is defined as a primary key.
- ✓ In order to define the data table's structure (*Open Table Definition*) or its content (*Show Table Data*), one may utilize the contextual menu or the *Data* option from the main menu (fig. 5).

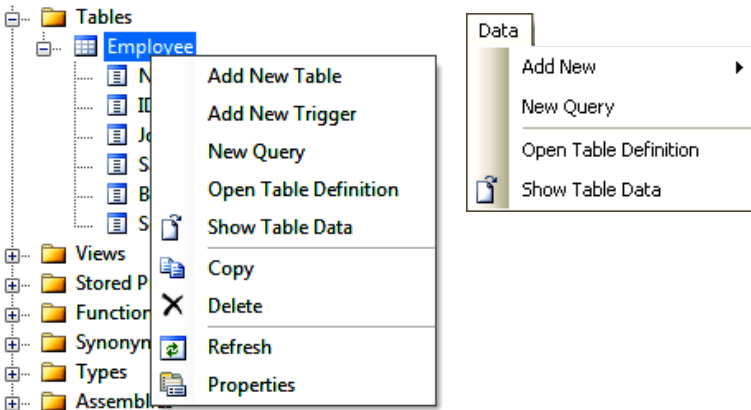

fig. 5

- ✓ Table's content (fig. 6):

Employee: Query...SPERSONNEL.MDF)						
	Name	ID	Job	Salary	Birthday	Sex
	Pop Stefan	157	President	4500,00	12.12.1950 ...	True
	Popescu Constantin	158	Accountant	2017,00	11.01.1968 ...	True
	Dumitache Florina	161	Secretary	960,00	25.06.1971 ...	False
	Toma Dumitru	163	Referent	1230,00	06.06.1953 ...	True
	Petriu Stefan	177	Engineer	2100,00	12.02.1968 ...	True
	Vasiliu Alina	202	Secretary	950,00	13.01.1970 ...	False
	Musat Luminita	204	Secretary	979,00	26.03.1973 ...	False

fig. 6

- ✓ In order to visualize the form's data (introduced within the project) one should activate the *Add New Data Source...* link for establishing a *New Connection...* with the *Personnel.mdf* database (fig. 7):

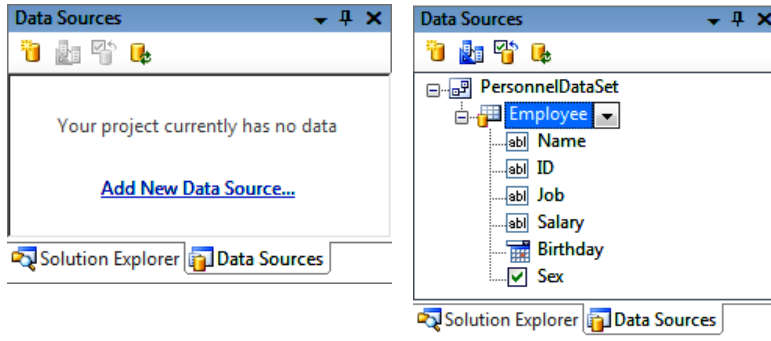

fig. 7

- ✓ The *Solution Explorer* window contains the project's elements. Please notice the *PersonnelDataSet.xsd* element – data set, database's copy, on the local computer (fig. 8):

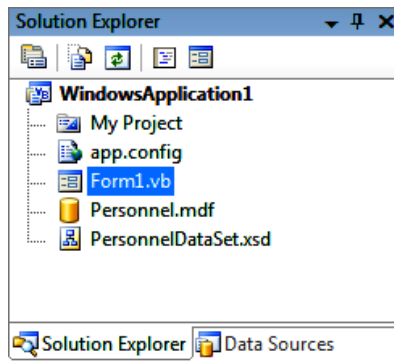

fig. 8

- ✓ *Visual Basic* creates automatically the **BindingNavigator** and the **DataGridView** objects by dragging (using the *mouse*) the tables from *Data Sources* into the form. It also creates: **DataSet**, **TableAdapter**, **BindingSource** and **BindingNavigator** (fig. 9):

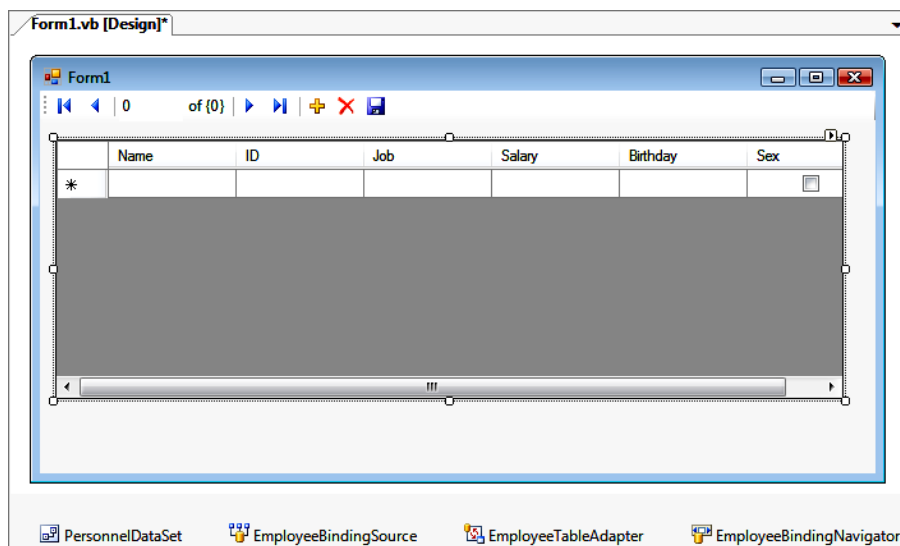

fig. 9

The program memorizes the data within the **DataSet** object which represent the entire database (fig. 10). The **TableAdapter** object copies data between database and **DataSet**. It also includes methods to facilitate the operations in relation to the database (the selection, the insertion, the update, the deletion of recordings). The **BindingSource** object encapsulates all data from inside the **DataSet** and controls the data movement actions, as well as the procedure of elements' addition and deletion.

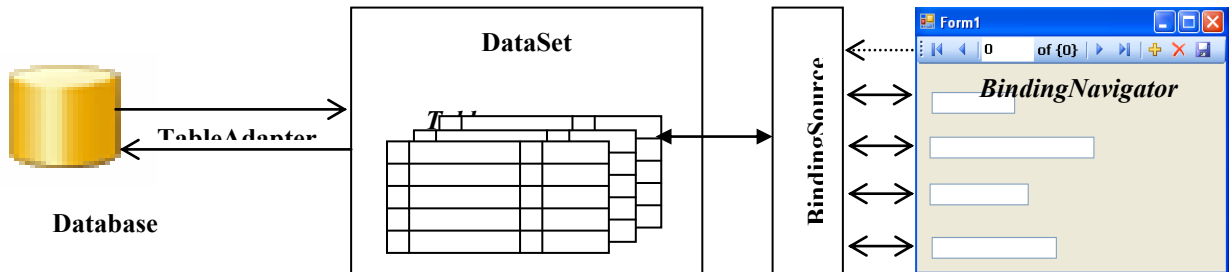

fig. 10

BindingNavigator offers the interface through which the user may interact with the data source.

Visual Basic generates automatically code sequences. When loading the form, these instructions intermedate the data copying (through the **TableAdapter**) from the database into the **DataSet**. The **StudentiBindingNavigatorSaveItem_Click** event (control from **Binding Navigator**) allows the tables' modifications to be saved in the database.

```
Public Class Form1

Private Sub EmployeeBindingNavigatorSaveItem_Click(ByVal sender As...
    Me.Validate()
    Me.EmployeeBindingSource.EndEdit()

Me.EmployeeTableAdapter.Update(Me.PersonnelDataSet.Employee)
End Sub

Private Sub Form1_Load(ByVal sender As System.Object, ByVal e As...
    'TODO: This line of code loads data into the
    'PersonnelDataSet.Employee' table. You can move, or
remove
    'it, as needed.

Me.EmployeeTableAdapter.Fill(Me.PersonnelDataSet.Employee)

End Sub
End Class
```

By using **DataGridView** and **BindingNavigator** controls, one may visualize on the form, data within the *Personnel* table (fig. 11):

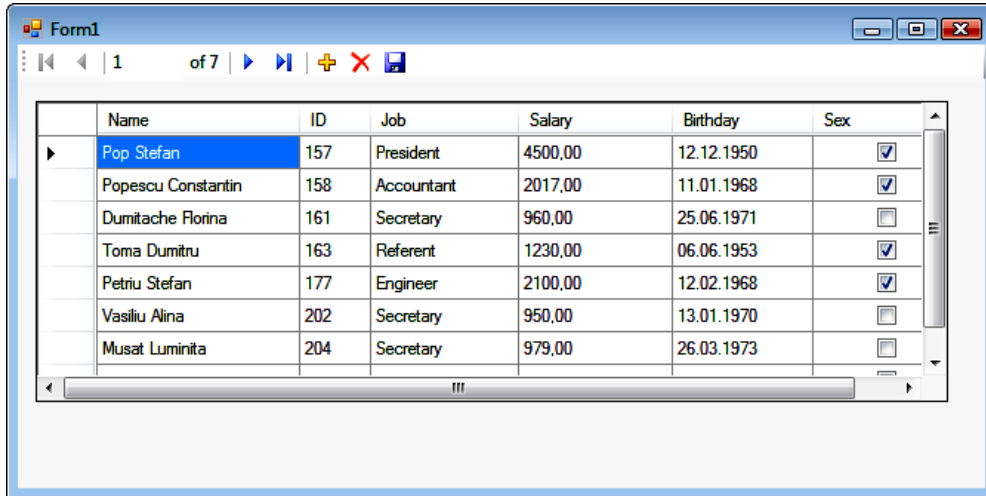

fig. 11

One may add other controls on the form, for instance, a button that displays the income tax. The recordings within the table can be scanned sequentially, from the first to the last, each field's values being available (fig. 12).

```
Private Sub btnIncomeTax_Click(ByVal sender As...
    Dim i As Integer, name As String
    Dim Salary, IncomeTax As Integer

    For i = 0 To PersonnelDataSet.Tables("Employee").Rows.Count - 1

        name = PersonnelDataSet.Tables("Employee").Rows(i).Item("Name")
        Salary = PersonnelDataSet.Tables("Employee").Rows(i).Item("Salary")
        IncomeTax = Salary * 0.16

        MessageBox.Show(name & " " & IncomeTax)

    Next

End Sub
```

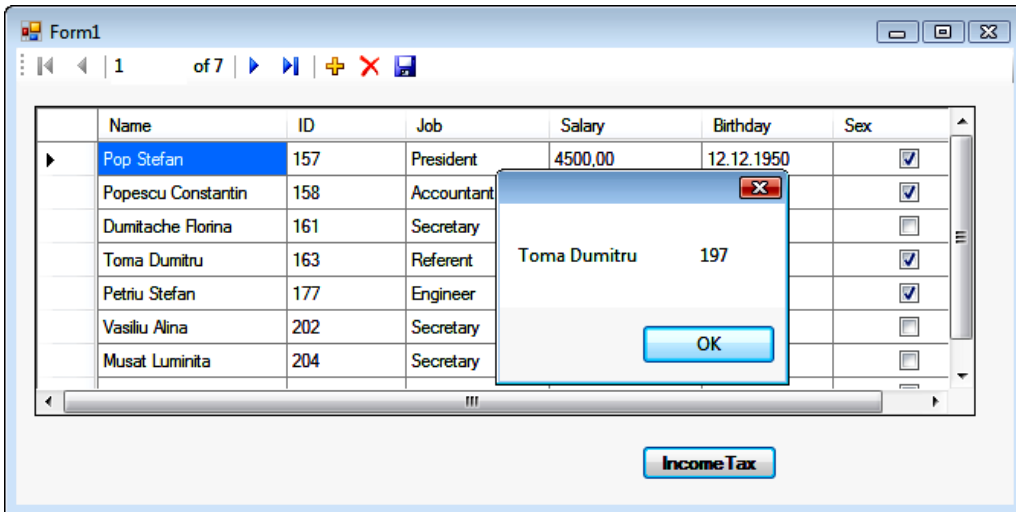

fig. 12

Even if it may be perceived as a difficult manner at the first sight, in order to grant access to the elements within the data set, one should demand a hierarchical class structure (collections and properties) that is to be represented in the following way (fig. 13):

fig. 13

The application steps should be followed in the prescribed order:

- The form loading (*FormLoad*);
- The execution of the **Form1_Load** event procedure where the connection with the database is established and where the *Fill* method is used for filling the local data set.
- The database interrogation should be executed and the result is sent in the **PersonnelDataSet**.
- When pressing the *Income Tax* button the recordings within the local set are examined and the fields' values are displayed.

MENUS (VISUAL BASIC 2005)

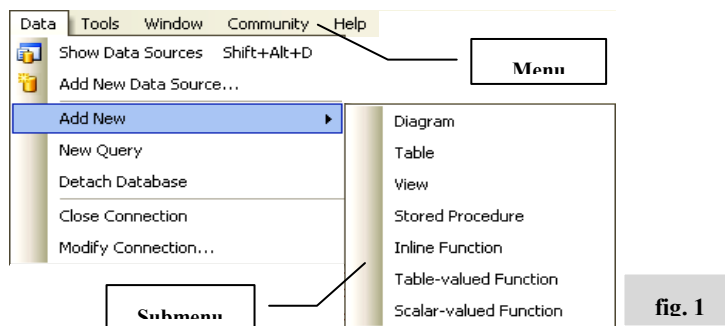

Cosma Emil

“Ovidius” University of Constanța, Faculty of Economic Sciences, Telephone 0766/221615, E-mail: ecosma@univ-ovidius.ro

The **menus** are interface objects that offer the user a series of options, which allow the selection and running of some processing operations. In one way or another, almost every graphical interface contains a menu. A menu appears usually at the top of the application windows, has a standard structure, and, generally, every operation that could be executed within an application must have a corresponded in its menu in order to perform. The user creates for him/her a mental model of the application's structure by simply analyzing the menus and the menu articles, the menu representing a way through which the user communicates the system what operations to do at a given time.

Keywords: Basic, Financial Functions, Menus, Submenus, MenuItem, MenuStrip

A menu usually consists of a bar – (*Menu Bar*, zero level menu), which contains many elements (options). Every menu element can have an own list of menu elements that groups within a submenu. The elements included in a submenu can also have their own submenus (in this case, the submenu has sometimes the name of menu). Those are connected to a vertical submenu that is going to be activated only when choosing the option. The user's choice of vertical menus options may launch a processing operation or the display of a new vertical submenu (fig.1).

Although there is no theoretical limit to the number of submenus that may be introduced when running an application, it results practically that there is a limit of two submenu levels that succeed the main menu. When a menu element contains a submenu, an arrow appears on its right side. The corresponding submenu appears when placing the *mouse* cursor on that particular menu element.

■ Main menus

Internal, the zero level menus consist of the *MenuItem*s collection of the *MainMenu* control. The menu items create another *MenuItem*s collection, each of it being attached to the menu it belongs to. Regarding the visual aspect, the zero level menus are also *MenuItem* type objects, just the same as every element included within a menu or a submenu situated within a lower menu hierarchy.

Example:

- ✓ When having an opened form within the design environment (*Text Property: Financial Functions*), one should select the *MenuStrip* control from the *Toolbox*. This will be added to the form, having the name of **MenuStrip1**, but it may change (*Name Property*) to a suggestive name (ex. **MnuFunction**). One may type the menu's text value after selecting the *Type Here* box within the form, which stands also for the menu's title (here *Function*). After introducing the text related to

the first menu, a new *Type Here* box will appear for adding either an element from submenu, or another zero level menu (fig. 2):

fig. 2

- ✓ Within the zero level menu, one should introduce successively the desired options in the *Type Here* box (fig. 3).

fig. 3

■ Submenus

Example:

- ✓ The submenus have to be introduced (fig. 4):

fig. 4

■ Menus Up to Date

- The introduction of a new element. One may select the menu element that is located at an inferior position to the new element's location. *Mouse* right-click on: *Insert*, *MenuItem* (fig. 5).

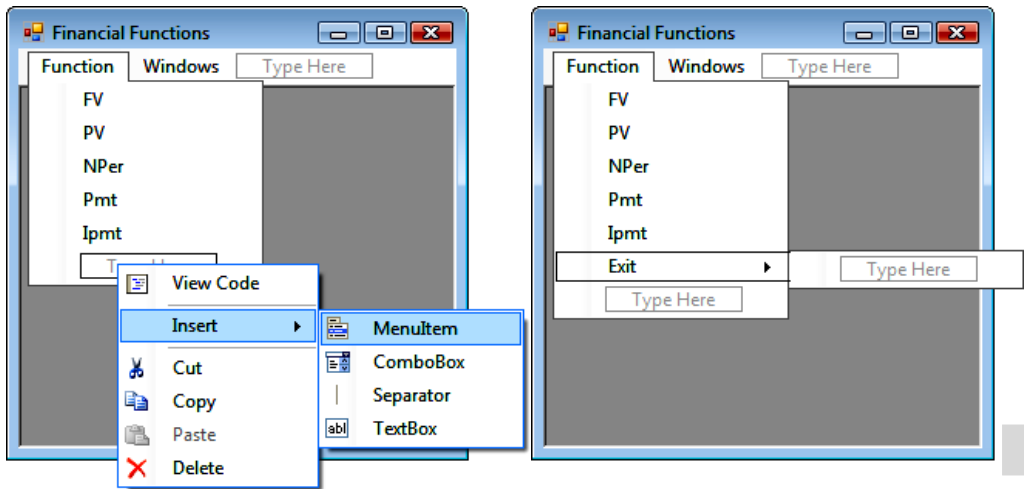

fig. 5

- The deletion of an element. One should select the menu element, *mouse* right-click, *Delete*.
- The introduction of a separator. One may select the menu element that is inferior to the place where the separator will be located. *Mouse* right-click: *Insert*, *Separator* (fig. 6).

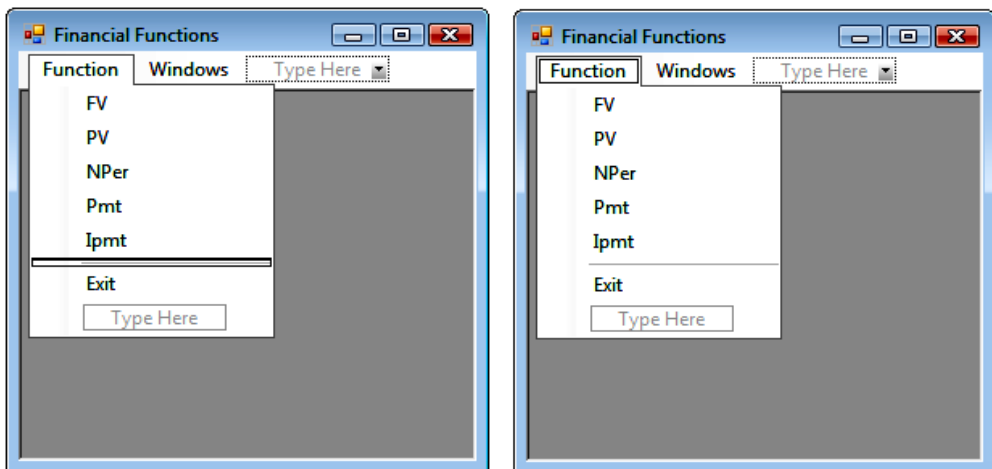

fig. 6

■ The addition of a contextual menu

Example:

- ✓ A *Button* type control should be added to the form. This button will be connected with the contextual menu, therefore the elements included in it will become visible when the user right-clicks on the button.
- ✓ One should add the *ContextMenuStrip* control from the *Toolbox*. The control will be visible in the reserved area that is located inferior to the form.
- ✓ The text value of the first contextual menu element should be introduced within the text box that is situated under the *ContextMenuStrip* location, and afterwards, other elements could also be introduced.
- ✓ Within the *Properties* window, for the introduced button, the *ContextMenuStrip1* value has to be placed within the *ContextMenuStrip* property (fig. 7).

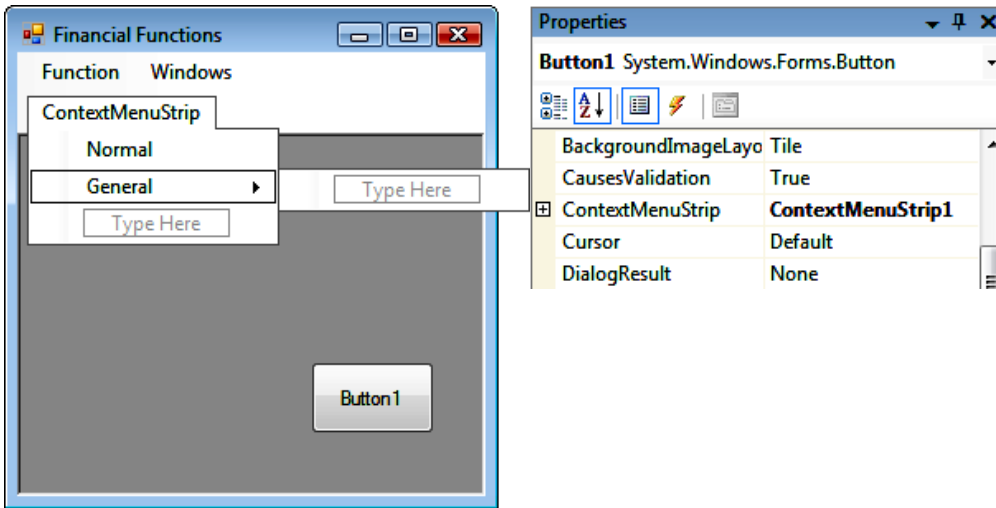

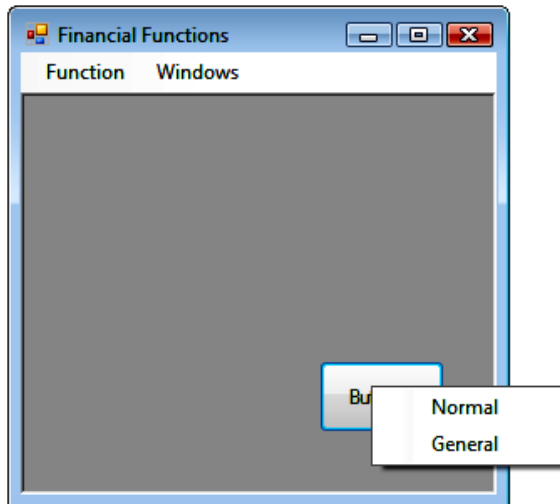

fig. 7

MnuFunction ContextMenuStrip1

When running the program, the contextual menu elements will be displayed if one right-clicks on the *Button1* control (fig. 8):

■ Access keys

fig. 8

The access keys allow the user to run over a menu hierarchy by pressing different keys together with the *Alt* key. For instance, if the access key of the *Function* menu is *F*, and the access key of the *PV* element from the *Function* menu is *P*, then the *Alt+F* keys combination followed by pressing the *P* key, has the same effect as selecting, using the *mouse*, the *PV* menu element from the *Function* menu. When introducing the text value of a menu element, if one places an *ampersand* (&) before the letter, this will be defined as an access key and therefore will appear underlined (fig. 9).

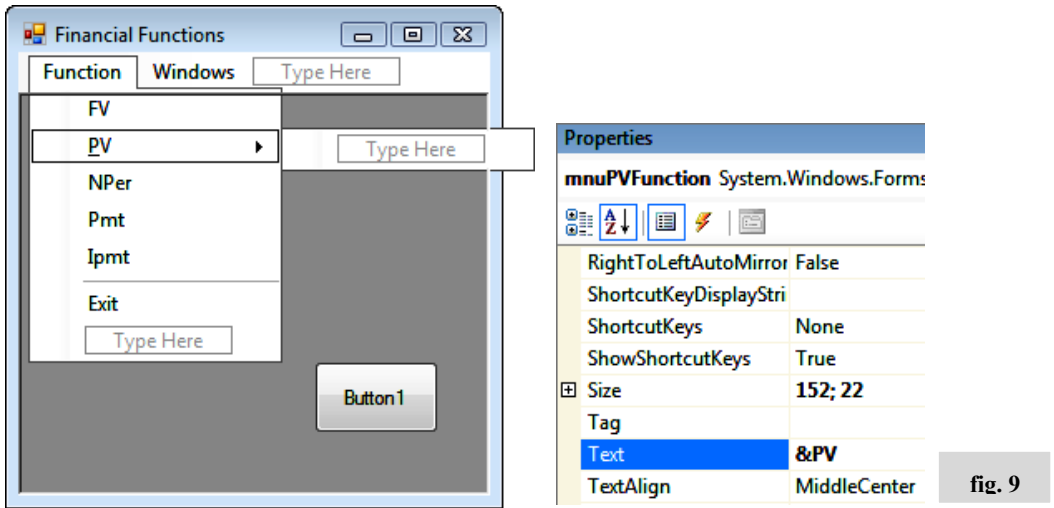

fig. 9

The standard principle of the graphical interface utilization is the fact that every menu element should be accessible by means of using an access keys combination. The access keys for the zero level menu should have no duplicate and all access keys for the menu elements belonging to each individual menu should also be unique. Although the access keys are mostly consisted of the first letter of the menu element's title, in order to avoid the duplicate, one may use another letter within the word. For example, using *E&xit* in the *Exit* option, allows the *Alt+X* key combination to become the access key for the *Exit* menu element.

■ Shortcuts

Keyboard's *shortcuts* (**ShortcutKeys** property) invoke the menu elements' functionality. Shortcuts are actually keys combinations; for instance, *Ctrl+P* is the combination for the *PV* option of the *Function* menu (fig.10).

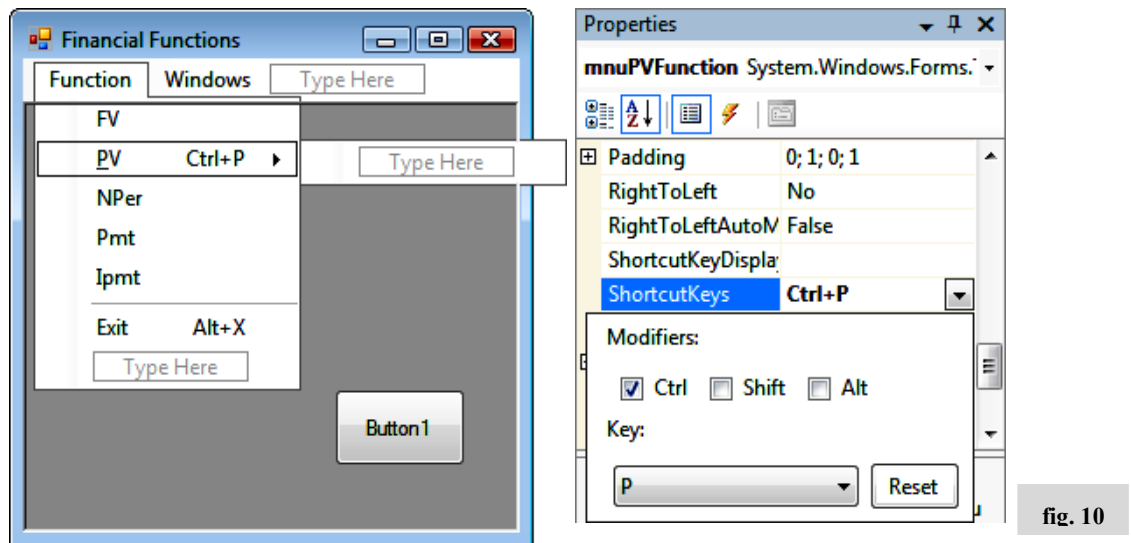

fig. 10

Shortcuts are composed of the control keys (*Ctrl*, *Shift*, *Alt*), the functional keys, the letters and the ciphers. For instance, the shortcut for the *Exit* element could be defined as the *Alt+X* combination.

■ The names of the menu components

The text values that are introduced within the *Type Here* boxes do not actually represent the name of the menu or of the menu elements. These text values – as *Function* or *Windows*- are just the menu elements' titles, namely their visual impress. On the other hand, the *name* of a menu element is an identifier used in the program sequences of the *Menu* object and it is never seen by the users. It is not recommended to

utilize the names of the menus or of the menu elements given by the *Visual Basic* programming environment (the name of every menu or menu element is formed by the concatenation of the word *ToolStripMenuItem* together with a number representing the order in which that particular menu or menu element has been added to the form).

A better approach would be to give some significant names to the menu elements – at least to those introduced within the program code. A helpful convention for menus would be the utilization of the *mnu* prefix, followed by that particular menu's title – for example, *mnuFunction* and *mnuWindows*. Regarding the menu elements, the element's title will be attached to the menu's name – for instance, the *PV* menu element of the *Function* menu has the name of *mnuFunctionPV* (fig.11).

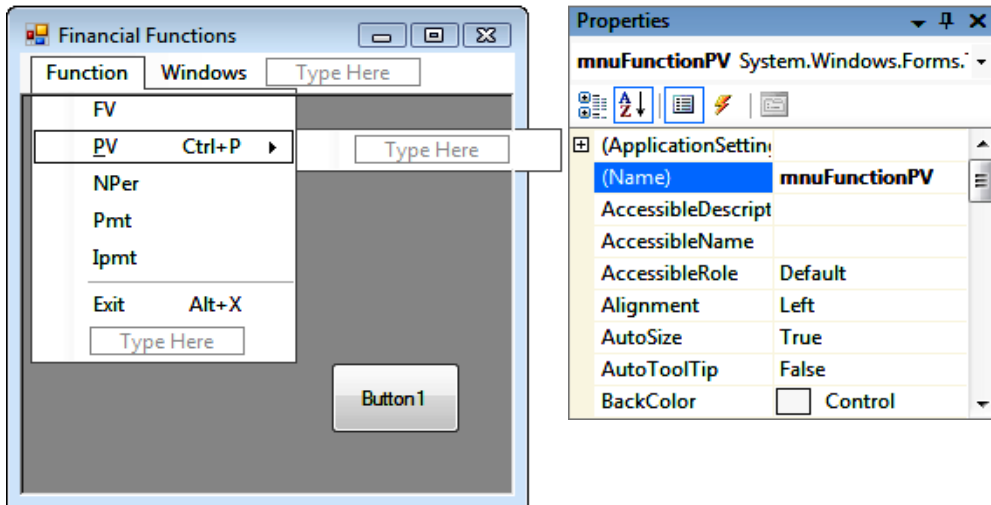

fig. 11

■ Events launched through menu

When the user selects a menu element (**Click** event), one code sequence may be activated just the same way as the click event is generated by a button type control. The event procedure of the *Exit* element (the name **mnuFunctionExit**) may be edited using the code editor (double-click on the menu element) (fig.12):

```
Private Sub mnuFunctionExit_Click(ByVal sender As ...  
    MsgBox ("Exit!")  
    Me.Close()  
End Sub
```

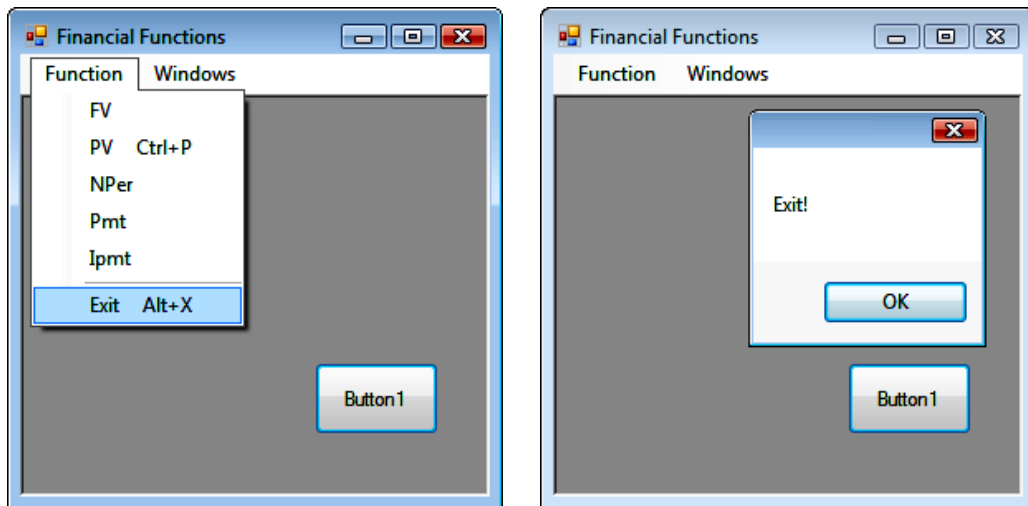

fig. 12

OPTIMIZATION METHODS FOR PPC CAMPAIGNS

Dănciulescu Daniela

Universitatea din Craiova

Băndoai Anca

Universitatea din Craiova

Abstract. *Generating traffic has not been an exclusive matter of optimization for natural search purpose for a long time. The PPC (pay-per-click) method generates an important amount of traffic, especially for the online large-size business. Many PPC services tendered are by far GOOGLE (by means of the Google AdWords service), Yahoo! Search Marketing (the former Overture) and MSN AdCenter. The system assumes that, depending on the search terms, the result of the search will preferentially advertise/will favour the beneficiaries of these services, the clients that pay for the respective search terms. The payment depends on the number of the received CPC (Cost Per Click) clicks, each listing position corresponding to a price that is established according to a bidding, which may reach amounts of 10-12\$/click for premium positions (1-3).*

Key words: *PPC (pay-per-click), CPC (Cost Per Click), marketing*

Optimization of the Advertisement Text

The writing of advertisements for the PPC site is especially aggravated by the standard structure of the advertisement, that also comes accompanied by the limitation of the number of characters. In Google AdWords system, it consists in 3 lines: the title– 25 characters, the body of the advertisement– 2 lines maximum 35 characters each, followed then by a URL address, which normally is the domain's address, even though the address, which is referred to, supports up to 250 characters.

As directory lines, it is advisable to go straight to the situation presentation, being no space for the artificialities used in the classic advertisements. The important thing is that the communication to the potential client was accomplished. In the light of John Steinbeck, American novelist "*Your audience is a single reader*", every individual that read the ad and is a potential client must be taken into consideration; it means that the advertisement must be written in order to direct towards this specific unique person,

Anatomy of an Advertisement. Each advertisement launched in the PPC campaign must respect the following sections: 1) Title of the advertisement: - 25 characters for Google and Microsoft adCenter, 40 for Yahoo!. 2) Search Marketing, 50 for Miva and 60 for Mirago and Thomson's WebFinder. 3) The content of the advertisement, usually divided into two columns: The presentation line of the product/service/offer. The second presentation of the benefits/assuring the quality and another advertising opportunities. This section may have 70 de characters for Google and Microsoft adCenter, 190 for Yahoo! Search Marketing, 200 for Miva, 180 for Mirago and 140 for Thomson's WebFinder. The fourth line is reserved for the URL address. It will consist in an address that will be annexed (normally the domain of the web site), but actually the link will lead to another page, dedicated, that can be found on the respective site.

Testing the Search Terms: Implementing the Specific Search Phrases

In order to perform the searching term testing, in the case of a PPC campaign, oriented towards selling, it starts from the considerations that: 1. In order to optimize the results, it must focus especially on the visitors/clients that are in the searching process stage and 2. In order to focus on the above mentioned visitors/clients, it is advisable the implementation of *specific search phrases (long tail keywords)*. **Which are the specific search phrases and why are they so important?**

The specific search phrases are those groups of words (normally made up of 3-4 words) which endorses directly and punctually the object of the PPC campaign. That is how, every time a client uses a *specific search phrase*, he tends to be looking for exactly what he has the intention to **buy**. In all these cases, these specific searches have a higher conversion rate than the *generic* searches, which tend to adapt more to the investigation type that the customers use in the first stages of the purchase process. Thus, it is well known that, in order to determine a sale: 1) The customer becomes informed about the product. 2) The customer is

looking for information about the respective product, getting ready for a possible purchase. 3) The customer evaluates the alternatives to the product (characteristics, price, etc...). 4) The customer performs the acquisition choice. 5) The customer completes the transaction (most of the time, in the Online environment, with a credit card). 6) The customer evaluates the purchased product and decides if he desires to keep or to return it. Using the six steps process pattern, as part of a company using PPC, by means of *specific search phrases*, the one that is taken into consideration is the customer who already is in the 4 item, *The customer that makes the decision to buy*, because once he decides he wants to **buy** something, he starts using specific search phrases, in order to find the looked for product. Moreover, these phrases **tend to be easier to classify and emphasize** than the generic phrases, made of one or two keywords. For example, let's say that the web site for which the PPC campaign has been organized is selling trips in the Tirol Region, during the whole year: **Tyrol Ski Accommodation**. In an initial stage, it may seem that, hinting for a word like: **Ski**, is the solution for gathering as much traffic as possible. If it had gone on like this, the site that performs the campaign would have been in direct competition with *ski.com*, *IfYouSki.com* or *goSki.com*, etc. It is not very likely that the site leading the PPC campaign were as big as they are and, that is to have a budget as large as they have, affording more a branding campaign than a sale one. Secondly, this is not even wanted to happen. Even more important, *ski* is not the best search word to be looking for. And that's because everybody, who is searching, using this search term, refers to the type of *ski equipment*, *ski areas*, or just make a general search related to the place where they would like to spend their winter holiday. Even though more specific phrases were hinted, like *ski accommodation*, it would still remain in competition with much stronger competitors, such as *hostelbookers.com*, *Hotels-And-Discounts.com* or *travelocity.com*. It is then obvious the necessity of the services offered, with which it may begin the cataloguing, the traffic and the immediate sale generation.

These are just few of the example. There could be found many others, for certain, but: 1) The long tail keywords are **much** easier to catalogue. 2) The persons searching, by using long tail keywords, may very likely become buyers! 3) Even though, individually, they are not going to bring an impressive traffic, the combining power and their specificity convey to a large conversion ratio.

Landing Pages Optimization. A landing page is a web page that can be accessed as a result of a click on a link displayed as part of a PPC campaign. This page may be developed in order to serve exclusively a PPC campaign, may be one of the pages of the site or, though entirely in disagreement, may be the main page of the site. In order to obtain the best results, the landing page must contain the exact elements described in the advertisement that was clicked on and the content of the landing page. Let's say that a *Ginkgo Biloba* nutritional supplement advertisement is being rolled. Some one, who have just clicked on the advertisement, is interested in buying – or at least to receive information about the respective product. You do not send him to the home page, forcing him go around the site, looking for the product. Send him directly to a page that contain data about *Ginkgo Biloba* in all its greatness, with letterheads, characteristics and the benefits described in the advertisement, clearly displayed. By doing this, it is created a sense of continuity, safety and satisfaction for the client, **the landing page being the vivid expression of the advertisement itself**. When the client clicked on the advertisement, he created a bond. The last desired think is the interruption of the continuity. That is the reason why it is important that they present a page, which harmoniously continue from where the advertisement has left them. The landing page can do this. Here is an example of three web sites that roll PPC campaigns Google AdWords and Yahoo!Search Marketing competing on the searching term: *Ginkgo Biloba*:

1. WholeHealth.com
(http://www.wholehealthproducts.com/index.cfm?fuseaction=product.display&Product_ID=87&CFID=320680&CFTOKEN=21224494)
2. PhysicianFormulas.com
(<http://www.physicianformulas.com/store/Scripts/prodview.asp?idproduct=263&name=Ginkgo-60mg>)
3. OrganicPharmacy.com
(<http://organicpharmacy.org/search.php?searchterm=Biloba&imageField.x=18&imageField.y=15>)
4. Drugstore.com
(<http://www.drugstore.com/search/search.asp?search=gnc+ginko&aid=336064&aparam=xsp111157>)
5. HerbalRemedies (<http://www.herbalremedies.com/herbal-remedies-usa/>)

In the first two examples, the landing pages include a photo of the product, followed by information about Ginkgo Biloba, and an easy and obvious way to purchase.

- In the first case, the ways the client could be distracted to some other part of the site are minimal, *WholeHealth.com* being an example of page sale optimization.
- In the case of *PhysicianFormulas.com*, though the site respects a visitor's needs, the presentation of certain alternatives (the right side column, above the selling area) may be confusing for the potential client, who may pass from page to page, and thus, the purpose of his visit is diluted (paid on the site, anyway).
- Cases 3 and 4 offer a page with many related products, the potential client having more dimensions and productions available, but also a higher possibility of being disoriented and leave the site, not being able to decide over the desired product. Ideally, it is intended the restriction of the client's choice range from the landing page and the attraction of the attention towards the performance of the so called *the desired response (MDR –Most Desired Response)*. It seems that, at least in this specific case, *WholeHealth.com* created an ideal landing page, succeeding in leading the client towards to the shopping basket in a minimum number of steps.
- The last case, *HerbalRemedies.com* advertises for the term „Ginkgo Biloba”, but send the visitors to a generic nutritional supplements page, the identification of the product for which the click has been made being practically impossible. Now, the client is forced, redirections his efforts in order to find the product he is looking for and use the search motor of the site. All these distract from the purchase process. It is a sad fact that, many of the business still send their clients to the home page, where the client is left alone to find whatever he is interested in. Let's not forget that a visitor offers us approximately 7-8 seconds for a web page, which means little enough, unless we capture his attention.

The home page is not a “landing” page. Generally speaking, the home page is the public face of the company. It is the place where people go for an overview of what the business offers. In opposition, a landing page is entirely dedicated to completing a sale of a certain product. It must encounter the expectations of a precise audience that has clicked on the advertisement, looking for information or for a specific product. As a rule, the landing page does not need to be part of the main site; it could be an independent page. It offers the possibility of being creative in marketing, without causing integration problems. In certain case, such as the short-term offers, promoted by PPC campaigns, it is advisable to avoid the index of the pages. Thus, when the offer expires, the PPC campaign may be stopped and the page may be dropped without possible losses from the point of view of the traffic.

Characteristics of the Selling Pages. Besides the continuation of the conversation started with the client by means of the campaign's message, it is compulsory the observance of some crucial characteristics:

- **Concentration on a Single Objective**

Regardless of the conversion methods taken into consideration, the landing page must contribute to the accomplishment of the determined objective. The visitor must not be distracted with irrelevant products and offers. Normally, **the fewer the links on the landing page, the better**. It is desired the leading of the buyer towards a specific action, not following a link that could direct him somewhere else, to an irrelevant part of the site, or worse, to a totally different web site.

Elimination of the Disorder. Navigation towards the rest of the landing page sites is not necessary. What is intended is the limitation of the clients' options and not the enlargement. Any element on the landing page, *which was not created* to require this reaction, diminishes the ability of the landing page of fulfilling its purpose. There is just one exception: **a page – a response**. Not every client that reached the landing page is ready for an acquisition, no matter how good the selling copies are. But, if, as an exchange, there can be gathered e-mail, then he could be closely followed afterwards. It allows establishing a relation with the potential client and his information concerning the product or service. Of course, a motive needs to be implicated for him to send the e-mail address, and this is a domain where the testing is essential. Notifications concerning the deductions, informative bulletins, the affiliation to a club, comparative studies about the product, and so on, may be included in a prospect list to which the clients have no access unless they have registered first. The principle is: **It is offered something with a high perceived value, but with an effective reduced cost. The higher the prospector perceives the value of the product, the wilier he**

is of giving his personal data (for example, his email address). That is why **testing is essential** in this case, too. By testing it can be determined the change formula to which people respond better. In the end, it is obtained the contact information along with the permission to keep in touch. Remember that the *observation value* is the key. Everything offered need to be *useful*. People will not register just for receiving advertisements – and if this is everything they receive, they will not stay registered for a long time. It must be supplied something valuable for the prospector *while* he is converted in a purchaser.

• **Advertisements that Emotionally Urge and Detonate an Action.** Good advertisements determine people to take part in the action. It is made an appeal to their emotions, desires (to be better, smarter, richer, prettier, happier, healthier, safer, stronger, more loved – these are the main reasons). It is said that *man is spending most of his time trying to improve his nature. The desire* to do that is intrinsic in the human nature – and the advertisement needs to communicate the ways in which the product or the service leads to the fulfillment of their desires. If there is a „secret” in making good advertisement, this is it! While it is true that not everybody can be a famous author, it is also true that most of the techniques of creating good advertisement can be taught. There are both elementary information, which may be known, and formulas that simply function. It is obviously that the range of possibilities cannot be covered, but some of the “tricks” used by the professionals are: **Title:** it is the most important element of an advertisement that sells well. The title (and the subtitle) must emphasize the beneficiary of the product as well as *the unique sale phrase*. The title must also fit the advertisement that brought the prospector on the sale page – it is the continuation or the reaffirmation of the AdWords advertisement. **The Use of an Attractive First Sentence** - which captivates the reader and determines him to listen to the story. The opening paragraph should help him see that his pain is understood and clearly suggest that the solution for what he is searching is found. **Presentation of the Whole Story** - all and entire story!...and the creation of a perspective of being in his shoes. There are displayed the benefits, the comparison of the characteristics and different confessions. If the person is interested indeed, he will be pleased to read the whole story, *as long as it is not boring*. **Re-elaboration of the Unique Sale Proposal**, (Example: Get 20%off. Use coupon). **Establishment of the Credibility.** the use of the confessions, the company’s references, trust, certificates and membership seals. **Re-elaboration of the Offer.** Clear elaboration. Include each detail related to what the purchaser could expect to receive and how every single detail is applied in order to help him improve his possibilities. **Establishment of the price in Terms of Accessibility.** The compensation of the product cost with benefits that will be derived in terms that should demonstrate that the price deserves much more than the published price. **Assurance of a Bonus** with a high perceptive value but a low price. Example: Order until [date] and will receive [something with a high perceptive value]. **Addition of the Urgency.** It must be drawn the attention about the limited stock. Set up a *response until* a date related to a bonus with a high value of distinction. It must be created a *plausible* reason for buying now, risking to lose the offer in case of delay. **Elimination of the Risk** to warrant any time possible. The warranty is established so that the product or service purchase implies no risk from the part of the client and so that it could not be ignored. **Preparation of the Conversion:** the sail must go smoothly and in fewer steps. This is the last chance of appearing interruptions during the sale process. A good selling modality will have all these ingredients, each time for an example that includes all these ingredients, there can be visited the GoogleCash²⁵⁷ sale page).

Management of a Page Use. The use studies have shown that when a client arrives on a page for the first time, he rapidly scans the left up corner of the display, then on the length of the page on the right side before turning back and stop in the centre of the page. All these last no more than a second. That is how it happens when people *scan* a page – usually with no conscience of the fact. On the whole, it means that the *acronym* should be placed up in the left corner, in order to help the clients orient, but not that prominently as to distract them from the *title*, which is *the most important element* of the selling page. The information, necessary to assure the client, but nor essential for the product sale (such as the recommendations and the safety seal), may be discreetly placed on the right side of the display, alongside with a link, maybe, to the shopping basket, but carefully **not** to distract the attention from the title or from the advertisement, which should be displayed prominently, from the top to the bottom, in the centre in the lower part of the page. The studies have proven repeatedly that there is a small window of opportunities in order to draw the attention of the client, once he arrived on the landing page. In a few seconds he cannot be convinced that he is on the right site, there are big chances that he will click somewhere else and thus he would be lost as a potential client. The fastest way of letting the client know he is in the right place is **exposing the title use**

²⁵⁷ <http://hop.clickbank.net/?plansen/googlecash>

in the advertisement they initially clicked on. Anyway, as there is so much space on the landing page, the re-elaboration must not be repeated word by word – the goal should be the creation of a powerful sense of continuity from the *advertisement* to the *landing page*. The same logic applies to the characteristics and benefits. If there were well enough to determine someone to click on the initial advertisement, then assure yourself that they are prominently displayed on the landing page, in front and in the centre. If you have a long presentation page, position the information so that the client did not have to roll in order to find the re-elaboration of those benefits and characteristics (even though they are on a display resolution of 800x600). After the best advertisement has been placed on the display, there must be included **photos, prices and technical specifications** of the product, applicable anytime. Neglecting any of these items, give the client an extra-reason not to finish the sale (remember: there must be told the *whole* story). Here will be placed all the ingredients of a successful business, mentioned above. If the price cannot be specified, it often happens that when there are offered business-to-business services (such as consultancy), it must be specified a price range. It helps to the elimination of the prospectors who do not afford these services anyway. The so called **negative qualification** helps filtering the clients that would never buy anyway. Ideally, the negative qualification should start from the AdWords advertisement that means that filtering those prospectors *before* they click on the advertisement, which includes a cost. The AdWords shopping basket button – *Order now!* – should always be placed at the end of the sale presentation. Controversially, it can be placed up, in the right side of the page for those who already know what they want to order. Additionally, it could be found a proper location in the middle of the presentation – at an item where “the sale” could be a logical choice for prospectors that “have read enough” in order to know how they desire to acquire. It is advisable to be prominently placed closed to the end, where the people are expecting to see it. It must be easy to find. The trust certificates, the contact information of the company and the putting down of the copyrights must be placed in the low part of the sale presentation, as the visitors are not interested in this information until AFTER they have decided to become clients. Only *then*, the contact information of the company, alongside with the trust certificates will become an important element in the sale equation. If it is not a giant respectable corporation, with a prominent brand name, it is a premature habit to present this information earlier during the process.

Page Testing. The most useful testing method has proven to be the split testing A/B (A/B split testing). It is tested separately, both variants of the advertisements of the PPC campaign, and variants of the landing pages. At the A/B split testing of the advertisement, there are applied different titles, patterns, images and offers, but not all at once. Once again, with the purpose of gathering significant information from the testing, it is advisable that each component were tested individually, making sure that you have a clear idea of what defines the success. Is it desired an increase of the sales, whenever a new title is tested? Or maybe more email addresses? The duration of such testing depends on the results obtained. If the tests do not roll long enough, we will not have enough information to finally conclude which of the test pages should be *kept* and which should be removed. If one of the page versions sells more than the other, then it can be known is about 20 impressions (10 for each of the two testing versions) which of the landing pages are good and which are not. These results are seldom significantly different. Under these conditions, in order to have a consistent result, it is considered the testing of at least 50 impressions (25 for each page).

Conclusion. In addition to that, the PPC advertisement is a relatively stable market and does not vary in terms of the so frequent indexation modifications/algorithm, being a very good alternative and a business increasing method.

Hierarchical organization of information, in relational databases

Demian Horia

University of Oradea, Faculty of Economics, No 1, University Street , 410087, Bihor, Tel. 0259 408 796

email: horia_demian@yahoo.com

Abstract: In this paper I will present different types of representation, of hierarchical information inside a relational database .I also will compare them to find the best organization for specific scenarios.

Keywords: hierarchy, relational databases

In many situations it is necessary to organize information like a tree. The classical tree looks like the one presented in the figure below

To represent this information inside of relational databases we need, a table with the following structure:

Nod	idNod	idNodPrec	Nod
idNod	1	1	Node A
idNodPrec	2	1	Node B
Nod	3	1	Node C

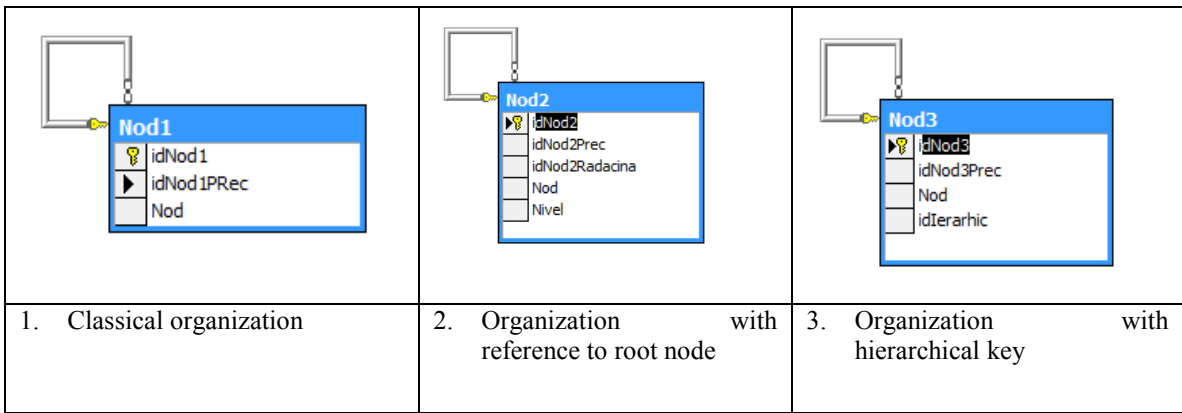

Fig. 2

In my studies I will try to find other methods for organization of hierarchical data, and I will compare them, to find the best solution. In practice there are a few very necessary operations. These operations were used in my tests.

For these tests I used three methods of representation:

1. Classical organization
2. Organization with reference to root node
3. Organization with hierarchical key

To better understand these types of organization I will present the table structure for each one

Data looks like this:

1. Classical organization

idNod	IdNodPrec	Nod
1	1	Desktop
2	1	Horia
3	1	Public
4	1	Computer
5	4	Local Disk (C:)
...

Fig. 3 Organizarea tabelara a unui arbore

2. Organization with reference to root node

idNod	IdNodPrec	idNodRadacina	Nod	Level
1	1	1	Desktop	1
2	1	1	Horia	2
3	1	1	Public	2
4	1	1	Computer	2
5	4	1	Local Disk (C:)	3
....				

3. Organization with hierarchical key

idNod	idNodPrec	Nod	idIerarhic
1	1	Desktop	1.
2	1	Horia	1.1.
3	1	Public	1.2.
4	1	Computer	1.3.
5	4	Local Disk (C:)	1.3.1.

...	
-----	-----	-----	--

One of the operations which I have tested was to obtain a sub tree beginning from a specific node.

1 In case of classical organization and organization with reference to root we need to create a function like this one

```

CREATE FUNCTION dbo.FN_NOD1_ARBORE ( @idNod1 INT)
    RETURNS @ARBOREDEST TABLE (
        IDNOD1 INT
        ,IDNOD1PREC INT
    )
AS
BEGIN
    DECLARE @ARBORENOD TABLE (
        IDNOD1 INT
        ,IDNOD1PREC INT
    )

    DECLARE @ARBOREPREC TABLE (
        IDNOD1 INT
        ,IDNOD1PREC INT
    )

    DECLARE @KOD SMALLINT
    SET @KOD = 0
    --INSERAREA NODurilor DE PLECARE(cele de ultim nivel pentru care exista produse publicate)
    INSERT INTO @ARBORENOD
    SELECT
        N.IDNOD1
        ,N.IDNOD1PREC
    FROM
        NOD1 N
    WHERE N.IDNOD1 = @IDNOD1 --nodul de la care pornim

    INSERT INTO @ARBOREDEST --ACEASTA VA CONTINE DOAR parintii
    SELECT
        IDNOD1
        ,IDNOD1PREC
    FROM @ARBORENOD
    WHILE (@KOD = 0 ) BEGIN
        --CAT TIMP MAI EXISTA NODURI CE FAC REFERINTA CATRE NODURI DIN PARINTE
        CONTINUAM PARCURGEREA ARBORELUI
        DELETE FROM @ARBOREPREC --GOLIREA BUFFERULUI DE noduri parinte
        INSERT INTO @ARBOREPREC --ACEASTA VA CONTINE DOAR nodurile de nivel inferior ce nu au mai

Arbore3	302432	208064	11	0	2	99	3	4	1.95	

Situation 2.

Observations:

1. When the space used by data is not important, the second method of organization hierarchical data was the best choice.
2. If space used for data need to be very small, the classical organization of hierarchical data was the best choice.
3. The third method gave us very good performance in situation in which we need to obtain a sub tree.
4. In each of this situation we obtain a very long time when we are trying to obtain the leaf nodes.

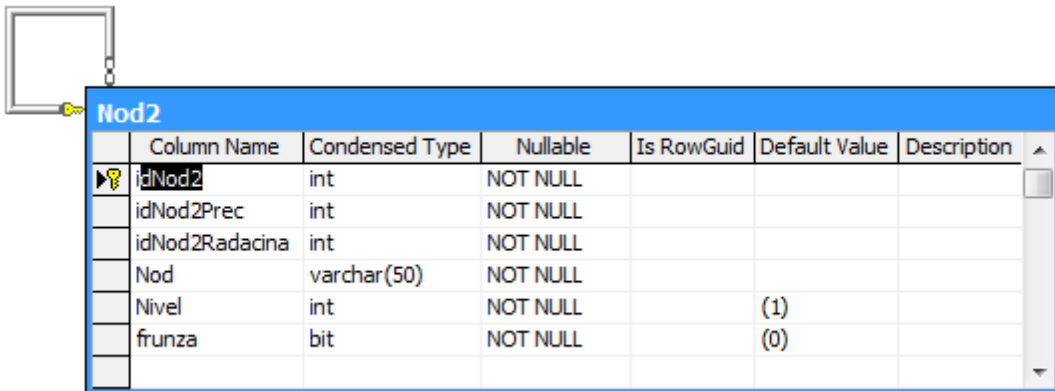

To improve performance I decided to try to reduce the time in which we obtain the leaf nodes. To do this we had to modify the structures of this table and to have additional information in these. I

THE PROTECTION OF THE ECONOMIC INFORMATION IN COMPUTER NETWORKS

Dăscălescu Ana Cristina

Universitatea Titu Maiorescu, Facultatea: Știința și Tehnologia Informației, Adresa de contact: Str. Grigore Moisil nr. 5, bl. 7 bis, sc. 2, ap. 116, sector 2, București, Telefon : 0721717162, email: dascalescu_anacri@yahoo.com

The Article „The protection of the economic information in computer networks” emphasizes the importance of securing the economic information in computer networks, the Internet network respectively.

It is described one of the most used encryption algorithms such as the DES algorithm ,also its improved alternative: the triple DES (3DES). In order to have a good understanding of the described algorithms, first there are presented the preliminary ideas from the cryptography domain, for example: the objectives aimed by a cryptographic algorithm, definitions, the criteria which must be accomplished so that the cryptographic system to be considered secure and efficient.

Main words : cryptographic system, computer networks, encryption algorithms

Preliminary Ideas

The beginning of the new millennium finds the modern society in an informational structure depending on the acceleration of the information and communications technology; the essential condition of the informational society success is the adoption of the information and communications technology in all the domains.

The new rules of the informational society are applied to the economic level, leading the new economy, as well as the political, social, administrative, cultural levels, transforming the reality into a new way of virtual perception; The used terms at the level of the modern society include: e-business, e-commerce, e-learning, e-mail, e-government, e-health, at the European level, as well at the Romanian level.

During the XX century, the biggest technological and in the same time social event was the setting up of the Internet as a concrete implementation, in big proportion, of the computer networks, concurring to the distributed exploitation of the economic information.

The development of the Internet obviously depended by the technology, but also by the social factors which had been combined with the technological factors, so that the Internet to become what is today.

In general, the computer networks, especially the Internet, do not represent only a technologic phenomena but also a social phenomena due to the users' participation to its present structure. The development of the electronic businesses such as e-business, as well as the existence of other Web services, led to a necessary new level of security which is a lot maximized. The Internet became the tool used by hundreds of millions of users, thus its vulnerability becomes directly a new and important vulnerability of the human society.

A component of the field „security of the information” is represented by the cryptography.

Its objectives are the followings:

1. *Confidentiality*: the quality of keeping the information secret in order to be used only by the authorized persons;
2. *The data integrity*: the quality of avoiding any kind of unauthorized modification of the information (insert, delete, substitute);
3. *Authentication*: The quality of identifying an entity according to the certain standards.

It is formed by the followings:

- (a) Authentication of one entity;
- (b) Authentication of the information source;
4. *Non - repel*: The quality which prevents the neglect of some previous events.

The other objectives concerning the information security (authentication of the messages, digital signatures, authorization, validation, the access control, certification, reception confirmation, revocation) can be derived from these.

The cryptography is the study of the math methods concerning the information security, capable to ensure the confidentiality, authentication and non-repudiation of the messages, as well as the integrity of the data.

The term „cryptography” means secret writing. The domain includes the encryption operation of a text, as well as the possible decipher trials and finding the crypt key. In some works the general work frame is named cryptology, the term „cryptology” meaning only the legal cipher and decipher.

The general situation of the cryptography is the following:

The sender would like to send a message to the recipient through a communication channel which has a high level of uncertainty. This uncertainty is represented by a cryptanalyst rival who wants – from unknown reasons – to know and eventually to modify the content of the message, even though the message is not intended for him.

This confidentiality requested by sender and recipient it is usually solved through the transformation of the message so that it can be understood by nobody. The respective transformation is named „encryption”.

The algorithm which realize the described operations it is called the „encryption system”.

The encryption system is a structure (P, C, K, E, D) , where:

- $P = \{w \mid w \in V^*\}$ is the multitude of” clear texts”, written over an vacuum alphabet (customary $V = \{0,1\}$).
- $C = \{w \mid w \in W^8\}$ is the multitude of” encrypted texts”, written over an vacuum alphabet W (customary $W=V$).
- K is the multitude of elements named keys.
- Each key $k \in K$ determines a encryption method $e_k \in E$, and a method of decryption $d_k \in D$.

$e_k : P \rightarrow C$ and $d_k : C \rightarrow P$ are functions which have the quality $d_k(e_k(w)) = w, \forall w \in P$.

In general, it is considered that $C = \{\alpha \mid \exists a \in P, \exists k \in K, \alpha = e_k(a)\}$.

The function e_k is obvious injective; if e_k is biinjective (so $d_k = e_k^{-1}$), the encryption system is named”symmetrical”.

In order to be considered good, the encryption system, needs to fulfill three criteria (stated by Francis Bacon in XV II century):

4. 1. Being given e_k si $\alpha \in P$, it is easy to determinate $e_k(\alpha)$;
5. 2. Being given d_k , si $w \in C$, it is easy to determinate $d_k(w)$;
6. 3. α is posibil to determinate from w , without knowing the d_k .

The last criteria defines – sunder a vague form – the ideaa of”security” of the system.

Bacon adds a forth rule to all above criterias:

4 The encryption text must be a trite text, without suspicious.

This condition is used today only by the strict sub domain of cryptography, named stenography.

The encryption system DES

In May 1973, The USA National Standards Office had launched in the Federal Registry (the official journal of the government) an appeal to the construction of the official encryption system which will be named Data Encryption Standard (DES). The company IBM built this system – published in the Federal Registry at 17 March 1975, modifying an older system named Lucifer. After many public discussions, at 17 January 1977 DES was officially approved as an encryption standard. Since then, it was revalued at each fifth year, presently being the most popular encryption system with symmetrical key.

The description of the DES system

The DES system encrypts a clear 64 bits text block into an encrypted text of as well 64 bits using a 56 bits key. The algorithm includes 3 steps:

1. Be α the initial clear text of 64 biti. It is applied an initial fixed permutation IP,

obtaining $\alpha_0 = IP(\alpha) = L_0R_0$. L_0 is formed from the first 32 bits of α_0 , and R_0 – from the last 32 bits.

2. It performs 16 itineraries (ways) of a function which will be specified later. At each way will be calculated L_iR_i ($1 \leq i \leq 16$) using the rule:

$$\begin{aligned} L_i &= R_{i-1} \\ R_i &= L_{i-1} \oplus f(R_{i-1}, K_i) \end{aligned}$$

where \oplus is or - exclusively (XOR) of two binary sequences, f is a function which will be specified later, and K_1, K_2, \dots, K_{16} are sequences of 48 biti calculated from the K key. It says that K_1, K_2, \dots, K_{16} are obtained from the diversification of the key schedule.

3. The initial permutation invert is applied to the block $L_{16}R_{16}$ order to obtain the encryption text $\beta = IP^{-1}(R_{16}L_{16})$.

The system of equation swchich defines the encryption at each tour can be inverted in order to obtain the equations of the decryption tours. These are:

$$R_{i-1} = L_i, L_{i-1} = R_i \oplus f(L_i, K_i)$$

The encryption function $f(A, J)$ has as arguments two binary sequences one of 32 bits, and one of 48 bits. The result is a sequence of 32 bits. The calculus steps of the function are:

1. The argument A is extended to 48 bits using an expansion function E. $E(A)$ includes the A's bits situated in a certain order, some bits being written twice.

2. It is calculated $B = E(A) \oplus J$ the result is divided in 8 subsequences of 6 bits each:

$$B = B_1B_2B_3B_4B_5B_6B_7B_8.$$

3. There are used 8 S – boxes S_1, S_2, \dots, S_8 , each of them being a picture of 4×16 with elements, whole numbers from the interval $[0, 15]$. For a sequence $B_j = b_1b_2b_3b_4b_5b_6$ will be calculated a number of 4 bits $S_j(B_j)$ such as: bits b_1b_6 give the binary representation of the index of a line r ($0 \leq r \leq 3$) from S_j ; the other bits $b_2b_3b_4b_5$ give the binary representation of the index of a column c ($0 \leq c \leq 15$) from the picture. Then $C_j = S_j(B_j) = [S_j(r, c)]_2$ ($1 \leq j \leq 8$). ($[x]_2$ is the representation in base 2 of the whole number x).

4. The sequence $C = C_1C_2C_3C_4C_5C_6C_7C_8$ – of a length of 32 – is rearranged using a fixed permutation P. The final result is $f(A, J) = P(C)$.

The diversification process of the key K includes 4 steps. K is a sequence of 64 bits, from which 56 define the key, and 8 bits from the positions 8, 16, 24, \dots , 64 are parity bits ,arranged in such a way that each octet to contain an odd number of 1. These 8 bits are ignored during the diversification process.

1. From the key will be eliminated the parity bits, and for the rest of the bits will be applied a PC1 permutation, obtaining $PC_1(K) = C_0D_0$ (C_0 are the first 28 bits from the sequence, and D_0 – the others 28 bits). The permutation PC1 is:

57 49 41 33 25 17 9
 1 58 50 42 34 26 18
 10 2 59 51 43 35 27
 19 11 3 60 52 44 36
 63 55 47 39 31 23 15
 7 62 54 46 38 30 22
 14 6 61 53 45 37 29
 21 13 5 28 20 12 4

2. For $i = 1, 2, \dots, 16$ it is calculated

$$C_i = \text{LS}_i(C_{i-1})$$

$$D_i = \text{LS}_i(D_{i-1})$$

and $K_i = \text{PC}_2(C_i D_i)$. LS_i is a circular rounding to the left with one or two positions, depending on the value of i : a position if $i = 1, 2, 9, 16$, otherwise the rounding is of two positions.

The permutation PC_2 is:

14 17 11 24 1 5
 3 28 15 6 21 10
 23 19 12 4 26 8
 16 7 27 20 13 2
 41 52 31 37 47 55
 30 40 51 45 33 48
 44 49 39 56 34 53
 46 42 50 36 29 32

The decryption is realized starting from the encrypted text β and using the same algorithm in revert order; it will be used in random order the following keys: K_{16}, \dots, K_1 .

Do to the length of the work key and the elementary operations used by the algorithm, there are nor special problems regarding the software; the only observation is that the algorithm is slow due to the way of working (with data sequences, with tables, etc.).The way of conception makes it an perfect hard (inside the cip), which was already realized, existing multiple variants of machine hard of coding.

Triple DES (3DES)

Triple DES (known also as 3DES or – rarely – DES – ede) is system derived from the DES, propose by Walter Tuchman (the team chief of IBM who built DES). The official name is FIPS Pub 46 – 3.

Officialy, 3DES is defined through the formula

$$c = \text{DES}_{k_3} (\text{DES}^{-1}_{k_2} (\text{DES}_{k_1}(m))).$$

where:

m is a clear text block (64 bits),

e is the resulted encrypted text block

k_1, k_2, k_3 are keys DES (of 56 bits),

DES_k : encryption DES with key k ,

DES^{-1}_k : decryption DES with key k .

The introduction of decryption at step 2 does not affect the algorithm's security. The advantage consists in using the DES implementation for 3DES.

Using three steps (*ede* or *eee*) is essential for protection against the attacks such as *meet-in-the-middle*. In case of a double encryption, this attack is efficient enough.

Indeed, we can consider an encryption system block where n is the size of the key. A double encryption with two different keys will use actually a single key with a length of $2n$. For a given clear text m , let's suppose that we can stock $e_k(m)$, for the whole possible K .

Be x an encrypted text after the formula $x = e_{k_2}(e_{k_1}(m))$, where keys k_1 and k_2 are secrets.

For each key p exists a unique key thus $d_p(x) = e_q(m)$. Particularly, exists exactly 2^n possible keys determined by the even (m, x) , keys which can be found in approximately $O(2n)$ steps.

If the number of the keys which can be stocked is $2^p < 2^n$, the algorithm can be modified in order to know all the possible keys in about $O(2^{2n-p})$ steps.

In case of one of the situations

$$k_1 = k_2, k_2 = k_3, k_1 = k_2 = k_3,$$

DES – *ede* is reduced to a simple DES, a thing frequently used in order to verify the compatibility.

The key for the Triple DES has $3 \times 56 = 168$ bits, at which can be added $3 \times 8 = 24$ parity bits; in total are 192 bits.

The encryption system 3DES is not yet broken that is why there are a lot of systems which are using it; as recent examples are the bank cards (MasterCard and partial – Visa) which are configured, since 2002, based on the encryption system. Moreover, the mobile system Zapp has as encryption system the system 3DES.

Résumé. L'implantation d'un ERP (acronyme pour "Enterprise Resource Planning systems") est un projet d'entreprise qui suppose la refonte du système d'information et surtout la remise à plat des procédures de gestion au sein de l'organisation. L'ampleur et la complexité des ces projets demande un cadre théorique et des « pratiques optimales » pour modeler et évaluer les facteurs clés de succès de l'implantation et analyser son impact sur la performance de l'organisation.

La problématique de notre communication se décompose en trois questions de recherche :

Quel cadre conceptuel pour l'implantation de l'ERP ?

Quel sont facteurs clés du succès l'implantation de l'ERP ?

Quel lien entre l'implantation de l'ERP et la performance de l'entreprise ?

Mots-clés : Entreprise Ressources Planning (ERP), changement organisationnel, intégration, Facteurs Clés de Succès (FCS), performance de l'organisation

1. Introduction

Les progiciels ERP, acronyme pour "Enterprise Resource Planning systems", connaissent un véritable succès auprès des organisations (privée ou publique) de toute taille et domaine d'activité. Le choix de l'implantation d'un ERP est motivé par : le remplacement des systèmes propriétaires fonctionnels; la simplification et la standardisation des systèmes; l'amélioration des interactions et de la communication avec fournisseurs, clients et d'autre partenaire d'affaires; l'acquisition d'un avantage stratégique; le lien avec les activités globales (Mabert & al., 2000). L'ERP remet en cause la conception d'une organisation fondée sur la spécialisation fonctionnelle. L'organisation devient transversale, elle n'est plus découpée par grandes fonctions mais par des macroprocessus qui traversent les principales fonctions de l'entreprise (Davenport & Short, 1990 ; El Amrani 2004).

L'étude empirique que nous avons réalisée auprès d'une population d'entreprises roumaines nous a permis de considérer parmi les déterminants de la réussite de l'implantation d'un ERP (Dumitru, 2007): l'implication du management, l'inclusion des promoteurs du projet dans le système décisionnel, la définition exacte des critères d'acceptance, la motivation des acteurs impliqués dans le projet, la définition claires et précise des latitudes décisionnelles, la formation des utilisateurs, la qualité du centre de compétence, l'approche processus et qualité totale, l'intégration de la dimension spatio-temporelle, la conduite du changement, la réalisation rigoureuse de l'étape d'analyse fonctionnelle, le choix d'une solution ERP et le management des risques.

A la base de ces déterminantes de la réussite de l'implantation on peut constituer un modèle d'analyse des facteurs clés du succès (FCS) de l'implantation de l'ERP.

2. Concepts et principes de base

Le concept ERP (Entreprise Ressources Planning) désigne un progiciel comprenant divers modules qui utilisent un référentiel unique (une base de données unique) et qui assure la cohérence organisationnelle entre les fonctions de l'organisation et les niveaux de gestion. Pérotin (2002) définit l'ERP comme un logiciel de gestion intégré regroupant un ensemble d'applications informatiques paramétrables et modulaires, qui visent à fédérer et optimiser les processus de gestion de l'entreprise en proposant un référentiel unique et cohérent et en s'appuyant sur des règles de gestion standard. Les dernières années, les ERP intègrent aussi les processus inter-organisationnel (management des relations client, management des relations fournisseurs) ainsi que les processus de business intelligence (BI) et de gestion des connaissances (KM).

L'approche processus, est l'un des principes de management de la qualité identifiés dans la norme ISO 9000:2000. Cette norme définit le processus l'ensemble d'activités corrélées ou interactives qui transforme des éléments d'entrée en éléments de sortie. Le management par les processus consiste à rompre avec l'approche verticale traditionnelle pour adopter une vision transversale de l'entreprise, par un alignement coordonné et un pilotage des différentes activités créatrices de valeur pour le client, ce dernier étant de plus en plus exigeant.

L'intégration implique l'existence d'une base de données unique partagée par toutes les composants de l'ERP (gestion comptable et financière, gestion des ressources humaines, gestions des achats, ...). Par l'intégration on assure que les données sont enregistrées qu'une seule fois tout en prenant compte, dès le début, de tous les traitements possibles à chaque étape du processus de la gestion. Les potentialités des technologies d'informations et de communications (TIC) ouvre la perspective d'intégration de l'information (figure 1) qui vise les données structurées et les données non structurées (le contenu).

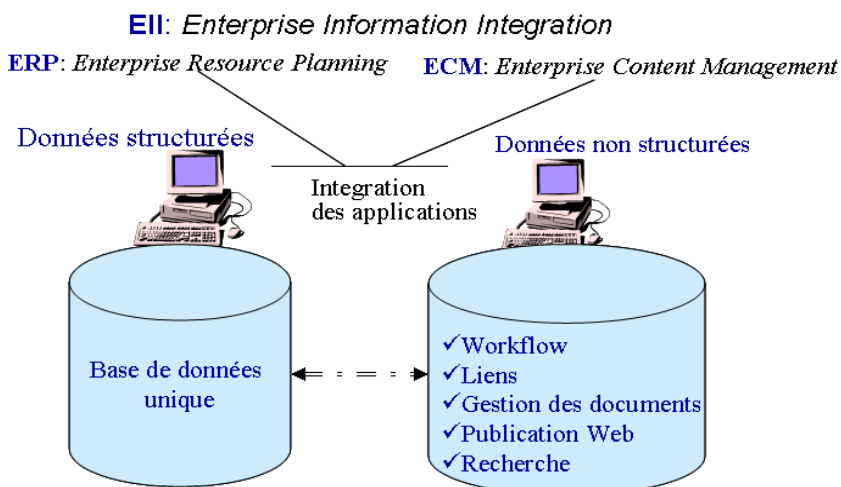

Figure 1. Intégration de l'information

Le changement doit être perçu comme une solution permettant à l'organisation de répondre au problème de management qualité et d'adaptation au regard aussi bien de son environnement que d'elle-même (Florescu & Dumitru, 2007). Un plan de conduite du changement est en mesure de réduire les résistances au changement dans l'organisation et de faire adhérer l'ensemble des collaborateurs au projet de l'entreprise.

La gestion des risques a pour objectif l'anticipation et la gestion des nombreux risques liés au projet ERP:

- Risques liés à la mobilisation des acteurs : mobilisation continue des équipes projets autour des objectifs, portage du projet par le management de proximité, capacité à mobiliser les ressources internes

- Risques liés à la taille et à la complexité du projet : nombre d'utilisateurs impactés, multiplicité des sites, déploiement vers des entités aux cultures et aux modes de fonctionnement différents, réactivité des processus de décision, prise en compte des disparités locales...
- Risques liés à l'atteinte des objectifs de performance : décalage outil/besoins, rejet de l'outil par les utilisateurs, modes de fonctionnement hétérogènes/attentes...
- Risques sociaux : sentiment de contrôle des activités, recherche de productivité, réduction des effectifs cibles, etc.

Le cycle de l'implantation fait référence aux étapes critiques à suivre dans le processus d'implantation de l'ERP (De Rongé, 2000) :

- le choix d'une solution ERP, l'organisation précise les besoins à combler par ses systèmes d'information et analyse les solutions offertes sur le marché selon des critères d'adéquation pertinents;
- l'analyse des processus de gestion, une analyse visant à comprendre pleinement le fonctionnement des processus organisationnels et les systèmes d'information en place ;
- Le réingénierie des processus, pour reconfigurer optimalement les processus avant d'entamer l'implantation du ERP;
- la particularisation des modules de l'ERP, pour son adaptation à des besoins particuliers;
- la mise en place, qui pose de difficultés de transition, de formation et de communication.

Trois principes de base caractérisent un ERP :

- le principe fondateur d'un ERP est de construire des applications correspondant aux diverses fonctions citées précédemment de manière modulaire sachant que ces modules sont indépendants entre eux, tout en partageant une base de données unique et commune au sens logique. Les modules peuvent être particularisés en fonction des besoins spécifiques de l'organisation par ce qu'on appelle paramétrisation ;
- l'usage d'un moteur de workflow, qui permet, lorsqu'une donnée est enregistrée dans le SI, de la propager dans les modules qui en ont l'utilité, selon une programmation prédéfinie ;
- la standardisation et l'intégration, la solution informatique ERP exige qu'on standardise l'information et qu'on y intègre les processus appropriés. La standardisation vise également l'interface avec l'utilisateur.

3. Les facteurs clés du succès de l'implantation de l'ERP

Les recherches relatives aux FCS de la mise en place d'un ERP relèvent l'importance de cinq dimensions (figure 2) sur lesquelles on analyse les facteurs clés du succès de l'implantation d'un ERP.

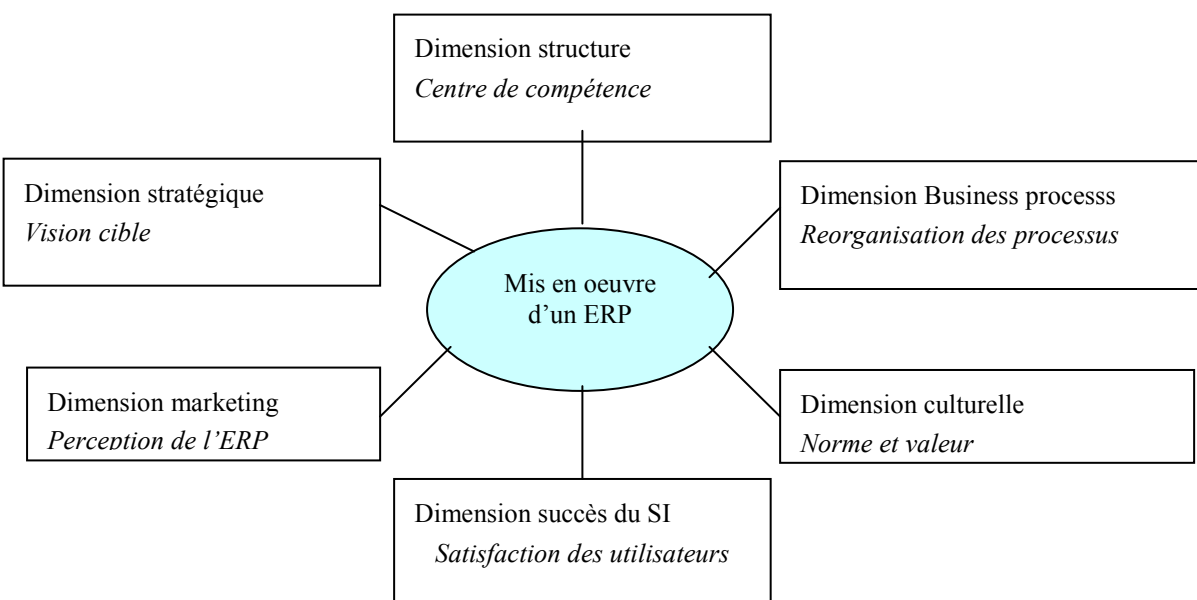

Figure 3. Dimensions de la mise en oeuvre d'un ERP

(Inspiré du modèle de Chaabouni (2006))

La dimension structure fait référence à l'organisation et au fonctionnement du centre de compétence constitué des membres de l'équipe projet ERP. Un centre de compétence apporte une réelle valeur ajoutée sur des projets dont la durée de vie est longue et qui seront amenés à évoluer fortement dans le temps. La mise en place d'un centre de compétence doit s'accompagner de la définition d'un contrat de services et d'indicateurs de performance.

La dimension stratégique fait référence à l'importance de la vision organisationnelle cible (El Amrani, 2003). Dans le cadre d'un projet d'implantation d'un ERP, la définition d'une vision organisationnelle cible consiste à tracer clairement les grandes lignes de l'organisation future et la direction que doivent emprunter les acteurs du projet pour l'atteindre.

La dimension Business process fait référence à la réingénierie des processus d'affaires. Il faut décider d'un changement des processus comme préalable de l'implantation de l'ERP. La mise en place d'ERP s'accompagne d'une standardisation des processus internes à l'entreprise.

La dimension culturelle part de l'idée que la principale raison de l'échec des projets ERP réside dans le fait qu'on prête très peu d'attention à la culture des organisations et à ses effets très importants sur les processus de planification, de l'implantation et de mise en marche du projet. Dans une culture de gestion de changement pour réussir la mise en place de l'ERP deux éléments sont considérés essentiels :

- la formation, pour assurer les compétences et la capacité des personnes à utiliser efficacement le système ERP. On part du principe que la compétence et la capacité des personnes à utiliser efficacement le nouveau système sont primordiales pour assurer le meilleur fonctionnement du système ERP ;
- l'implication des utilisateurs dans l'implantation de l'ERP constitue un facteur clé de succès pour la conduite du changement ;
- l'implication de la direction générale est considéré un des FCS de la mise en oeuvre de l'ERP (le projet d'implantation d'un ERP doit obtenir l'approbation et le soutien de la direction générale).

Il est important que le projet d'implantation d'un ERP devienne le projet de toute l'entreprise, du top management jusqu'aux opérationnels.

La dimension marketing fait références à l'intention d'utilisation de l'ERP. Le TAM (Technology Acceptance Model) a postulé que l'utilisation des TIC est déterminée par une intention comportementale d'utiliser un système, et cette dernière est conjointement déterminée par l'attitude des personnes et l'utilité perçue (Legris & al, 2003).

La dimension succès du SI fait référence à la satisfaction des utilisateurs afin d'assurer le succès de mise en place du système ERP. L'évaluation du succès des SI constitue un domaine d'intérêt pour la recherche en management du système d'information (DeLone & McLean, 1992 ; McGill, Hobbs & Klobas, 2000 ; Maaloul & Mezghani, 2003). Le modèle proposé par DeLone & McLean démontre que le succès des SI est évalué par : la qualité du système, la qualité de l'information, l'utilisation, la satisfaction des utilisateurs, l'impact individuel, l'impact organisationnel. Ultérieurement ce modèle a été ultérieurement enrichie, notamment par l'ajout d'une nouvelles dimensions : l'implication des utilisateurs et l'ingénierie du changement.

4. L'impact de l'implantation d'un ERP sur la performance

Dans notre travail de recherche nous avons opté pour une typologie de performance qui différencie : performance économique, performance organisationnelle et performance humaine (Florescu, 2007).

La performance économique, qui réside dans la survie de l'entreprise et sa capacité à atteindre les objectifs fixés, elle se mesure en indicateurs financiers. On parle aussi d'une performance économique non strictement quantifiable qu'on peut mesurer par la qualité totale et la position concurrentielle de l'entreprise. L'utilisation d'un ERP impacte positivement surtout sur la « *qualité totale* » et même sur la « *position concurrentielle* ».

La performance organisationnelle est étendue comme étant « la manière dont l'entreprise est organisée pour atteindre ses objectifs et la façon dont elle parvient à les atteindre ». Kalika (1988) et Chaabouni (1992) dégagent quelques critères d'évaluation de la performance organisationnelle : la qualité de la circulation de l'information, les relations entre les services, la coordination, la coopération, le degré de contrôle, la communication, la décentralisation, la flexibilité et l'intégration.

La performance humaine s'analyse à travers le résultat obtenu par les salariés sur les postes de travail dans un groupe, un service ou une entité entière. Par ces potentialités, un ERP constitue un vecteur de l'amélioration de la performance humaine, tant au plan individuelle que d'équipe.

L'investissement dans un outil ERP n'est pas en soi le garant de la performance de l'entreprise. L'ERP, comme tout système d'information, doit être considéré comme un actif de l'entreprise et non un support de ses activités.

5. Conclusion

Nous espérons avoir atteint l'objectif principal de notre travail de recherche : la compréhension de la problématique de l'implantation d'un ERP.

Nos recherches vont se poursuivre dans deux directions :

- l'enrichissement des modèles de recherches empirique de l'implantation de l'ERP
- la construction d'un référentiel de bonnes pratique pour l'implantation et l'utilisation des ERP dans les organisations.

Information Security Management System plays a critical role to protect the organization and its ability to perform their business mission, not just its IT assets. Risk Management and Risk Assessment are important components of Information Security Management System Risk management is the process of identifying risk, assessing risk, and taking steps to reduce risk to an acceptable level. Information and communications technology management and IT security are responsible for ensuring that technology risks are managed appropriately. The research starts with the conceptual framework of the Information Security Management System and provides an analysis of the IT risks management to the level of the financial institutions in Romania.

Key words: information security management system, risk management, risk assessment.

1. Introduction

The acceptance of an Information Security Management System (ISMS) constitutes a strategic decision of an organization, the development and the implementation of such a system being influenced by the needs and the strategic objectives of the entity in case. Practically, this system will assure an adequate and proportional selection of the security measurements to protect the information resources.

The research starts from the conceptual framework of the ISMS based on the requests of standards:

- ISO/IEC 27001(2005) “Information technology - Security techniques - Information security management systems – Requirements” and
- ISO/IEC 17799 “Information technology - Security techniques - Code of practice for information security management”.

These standards, recognized also to the level of the Romanian organizations, offer the methodological framework for developing and implementing an efficient security management system to the level of a certain organization. Concomitantly, the ENISA agency (European Network and Information Security Agency), through the Risk Management / Risk Assessment portal (<http://enisa.europa.eu/rmra>), offers a series of tools and methods for analyzing and assessing IT risks.

The present paper offers also an analysis of implementing IT risks management to the level of the financial institutions in Romania, underlining the most important IT problems pointed out by the respondents in the last year and the most efficient measurements taken by the top management for solving them.

2. The conceptual framework of the Information Security Management System

The information security management system (ISO 27001, 2005) is defined as that part of a global management system, based on a certain approach of the business risk, through which it is establishing, implementing, analyzing, monitoring and improving the security of the information. This system includes organizational structures, politics, planning activities, practices, processes and resources. Information security should be an integral part of the organization’s operating and business culture. In ENISA vision, the methodological view of developing an ISMS necessitates the covering of 6 steps (figure 1):

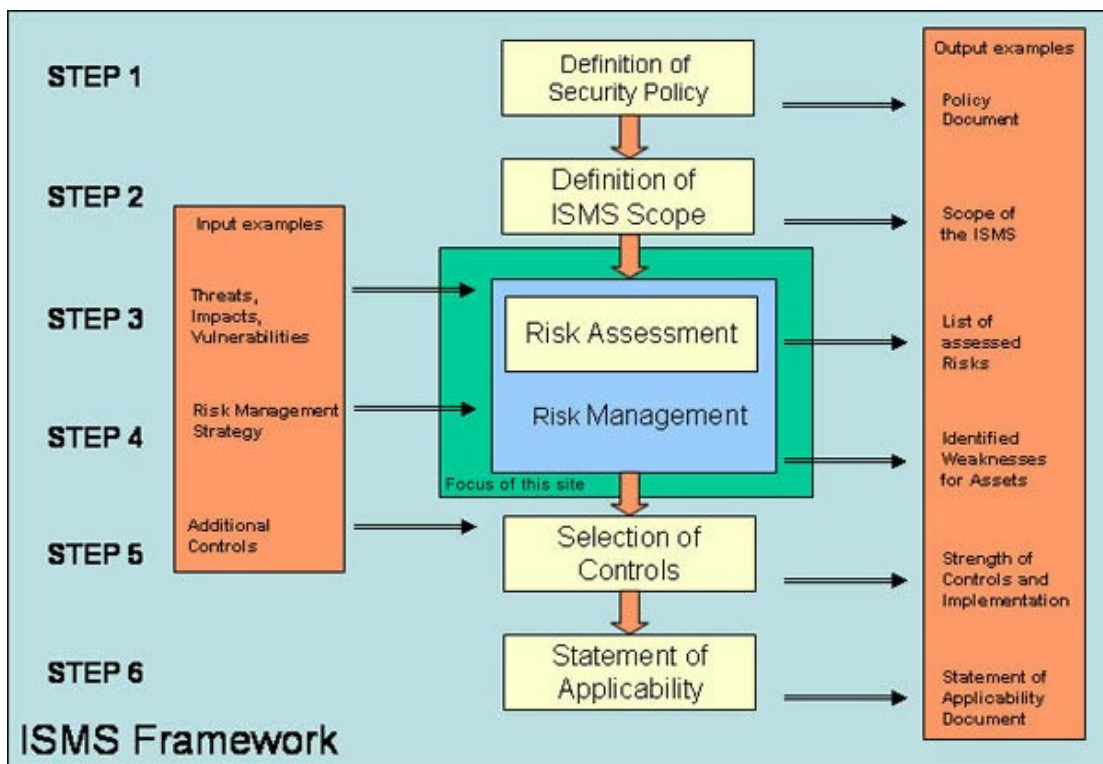

Figure 1. The steps of process developing of the information security management system
 (Source: <http://www.enisa.europa.eu>)

1. Definition of Security Policy,
2. Definition of ISMS Scope,
3. Risk Assessment (as part of Risk Management),
4. Risk Management,
5. Selection of Appropriate Controls and
6. Statement of Applicability

Steps 3 and 4, the Risk Assessment and Management process, comprise the heart of the ISMS and are the processes that “transform” on one hand the rules and guidelines of security policy and the targets; and on the other to transform objectives of ISMS into specific plans for the implementation of controls and mechanisms that aim at minimizing threats and vulnerabilities.

The processes and activities related to the steps 5 and 6 do not concern information risks. They are rather related to the operative actions required for the technical implementation, maintenance and control of security measurements. Appropriate controls may either be derived from existing sets of controls or mechanisms, usually included in information security standards and guidelines, or the outcome of a combination or adaptation of proposed controls to the specific organizational requirements or operational characteristics.

In both cases, step 6 is the documented mapping of the identified risks, applied to the specific organization with the technical implementation of security mechanisms the organization has decided to deploy.

Finally, although the ISMS is a recurring process as a whole, in most of the types of organizations mentioned above, steps 1 and 2 recur on a longer cycle than steps 3, 4, 5 and 6. This is mainly because the establishment of a security policy and the definition of the ISMS scope are more often management and strategic issues while the Risk Management process is an everyday operational concern.

Risk Management and Risk Assessment are major components of Information Security Management System (ISMS). Risk management can be defined as “the process of identifying vulnerabilities and threats within the framework of an organization, as well as producing some measurements to minimize their impact over the informational resources”. This process of the risk management includes some basic processes, as we can see in the figure below (figure 2):

1. *Risk Assessment* requires the covering of three steps: risk identification, risk analysis and risk evaluation. Every organization is continuously exposed to an endless number of new or changing threats and vulnerabilities that may affect its operation or the fulfillment of its objectives. Identification, analysis and evaluation of these threats and vulnerabilities are the only way to understand and measure the impact of the risk involved and hence to decide on the appropriate measures and controls to manage them.
- 7.
2. *Risk Treatment* is the process of selecting and implementing of measures to modify risk. Risk treatment measures can include avoiding, optimizing, transferring or retaining risk. The measures (i.e. security measurements) can be selected out of sets of security measurements that are used within the Information Security Management System (ISMS) of the organization.
- 8.
3. *Monitor and Review* is a process for measuring the efficiency and effectiveness of the risk management of the organization processes is the establishment of an ongoing monitor and review process. This process makes sure that the specified management action plans remain relevant and updated.
- 9.
4. *Risks Communication, Awareness & Consulting* means a process to exchange or share information about risk between the decision-maker and other stakeholders inside and outside an organization. The information can relate to the existence, nature, form, probability, severity, acceptability, treatment or other aspects of risk.

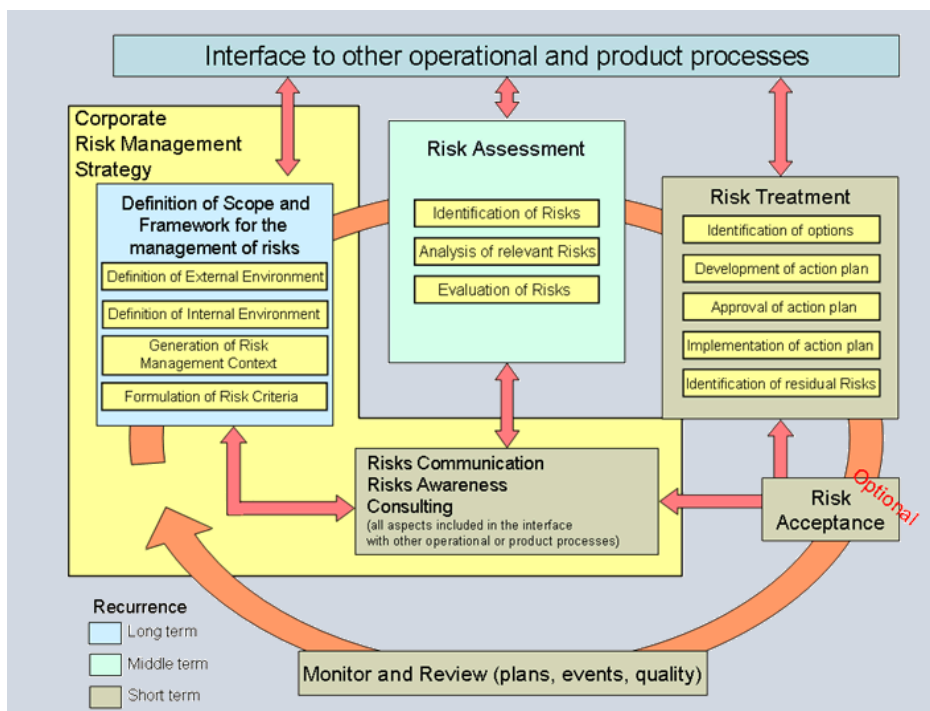

Figure 2. Risk Management Process

(Source: <http://www.enisa.europa.eu>)

5. *Risk acceptance* is the decision to accept a risk by the responsible management of the organization. For each risk area, the options are:
- reduce: lower the risk through controls, or technology;
 - transfer: offload the risk by placing it on some other entity;
 - accept: decide the risk is acceptable based on the benefit;
 - ignore: choose not to reduce, transfer or accept the risk - this is equivalent to accepting the risk, but without due diligence.

3. The analysis of the IT risk management to the level of Romanian's financial institutions

To the level of financial institutions in Romania, the European requests for Basel II implementation have had major implications in the governance way of the information technologies. For many information systems in the banks is absolutely necessary an architectural rethinking which will allow a consolidated and, also, flexible approach of the market, as well as the selling of some complex products and financial services adequate to the permanent change of the economic environment. Basel II involves a bigger responsibility in the well functioning of the banks informatics systems both for the IT department and for the management of the bank.

In our research, the analysis of the IT risk management has been based on the data gathered from a number of 30 subjects (financial institutions) through a questionnaire. The gathered information allowed us to point us the following:

- the most severe IT problems distinguished by the respondents in the last year,
- the most efficient measurements taken into consideration by the top management for resolving the pointed out problems.

As we can notice also in figure no. 3 the most severe IT problems pointed out in the last period (year 2007) have been bonded by the personnel (staff problems 24%) and high cost of IT with low improvement of ROI (19%). We can also mention between stringent problems serious IT operational incidents and low IT performances (both with 13%).

Figure 3. The most serious IT problems pointed out in the last year

The most efficient measurements taken into consideration by the management for resolving their problems have been the following: the alignment between IT strategy and overall strategy and a more efficient IT risk management.

Figure 4. The most efficient measurements taken into consideration by the management for issuing pointed out problems

In conclusion, although the last years have been remarked through rapid changes to the level of informational architecture of the Romanian financial institutions, which implicated major investments, the efficiency of the IT management risks is valuated and the real issues in the area aimed more the human side than the technical one.

4. Conclusions

Therefore the establishment, maintenance and continuous update of ISMS provide a strong indication that a company is using a systematic approach for the identification, assessment and management of information security risks. Furthermore such a company will be capable of successfully addressing information confidentiality, integrity and availability requirements which in turn have implications for:

- business continuity;
- minimization of damages and losses;
- competitive edge;
- profitability and cash-flow;
- respected organization image;
- legal compliance.

DATA QUALITY IN BUSINESS INTELLIGENCE APPLICATIONS

Gorgan Vasile

Academy of Economic Studies Bucharest, Faculty of Accounting and Management Information Systems, Academia de Studii Economice, Catedra de Informatica de Gestiune, Piata Romana, nr. 6, Bucuresti, 0724643651, gorganvasile@yahoo.com

To survive an organization must develop a strategy. To develop a successful strategy it must be capable to forecast the future circumstance. This is why nowadays business intelligence applications are essential for the success of a business. The decision support system is the eye through which the business strategist can look out on the organization's environment and detect behavior trends. Making decision on poor quality data can dramatically affect the strategy of the organization. This white paper addresses issues concerning data quality from business intelligence applications, the sources of poor quality data and possible ways to overcome these problems.

Keywords: business intelligence, data warehouse, data quality, ETL, data mining

Introduction

Business Intelligence is a broad category of applications and technologies used to collect, archive, analyze and access data, which helps users in decision making at an economic entity level. In fact Business Intelligence is an environment in which decision makers get reliable, consistent, comprehensible, easy to use and timeliness data. Using this data, decision makers can perform analysis that offers a broader view of the entity position in the past, present and the near future.

Therefore, why does an organization need Business Intelligence? To survive an organization must develop a strategy. To develop a successful strategy it must be capable to forecast the future circumstances. Understanding the past is the best method in trying to predict the future. This is the reason why information is considered the main ingredient of a strategy. The decision support system is the eye through which the business strategist can look out on the organization's environment and detect behavior trends.

Today the central element of business intelligence architecture is represented by the data warehouse, although there are people that use the terms "business intelligence" and "data warehousing" on an interchangeable basis. According to **Larissa Moss** business intelligence is a framework of *cross-organizational disciplines* and an *enterprise architecture* for the construction and management of an integrated pool of operational as well as decision support applications and databases that provides the business community *easy access* to their business data and allows them to make *accurate business decisions*" while "data warehousing is a subcomponent of and a vehicle for delivering business intelligence".

Issues concerning data quality in Business Intelligence applications

However the participants at the economic activity, the analysts and the clients set up an alarm signal about the decisions that are frequently made on the basis of data of low quality, data that is not set up to date because of the failure of the process of data cleaning. Knowing the impact of the poor quality of data it is "tormenting" to see the careless way in which most companies manage critical resources. Most of the companies don't create programs that produce quality data in a proactive, systematic and regular manner. According to a TDWI study, more than half of the companies don't have any plan to manage quality of the data.

The sources for the low quality data are uncountable. An important source is the process of data introduction that produces most of the problems and the systems interfaces. There is no wonder that the

employees at the introduction of data are blamed for most errors. In general the source of data errors falls into the following categories:

The lack of validation routines is a source responsible for bad data introduced on the Web or in the operational systems

Valid, but incorrect data: validation routines can miss the typing mistakes that respect the validation rules. A value can be valid but it doesn't mean it is also correct

Wrong syntax format and structure. The organizations try to introduce the data from more systems. In these cases, the ETL systems have to map these differences to a standard format before starting to clean the data.

Unexpected system changes. This situation occurs for instance when the database administrator adds a new field or a new code in the database and forgets to notify these changes to the systems administrator that makes the import

The multitude of interfaces. Complex architecture of nowadays systems leads to a multitude of interfaces which are difficult to update.

The lack of referential integrity check. In order to increase performance many administrators deactivate the check of the referential integrity when importing data.

Errors of data conversion. The programmers do not allocate enough time to understand the source and destination data model and, consequently, they write code that generates errors. One change in the migration program or in the interface systems can create thousands of wrong entries.

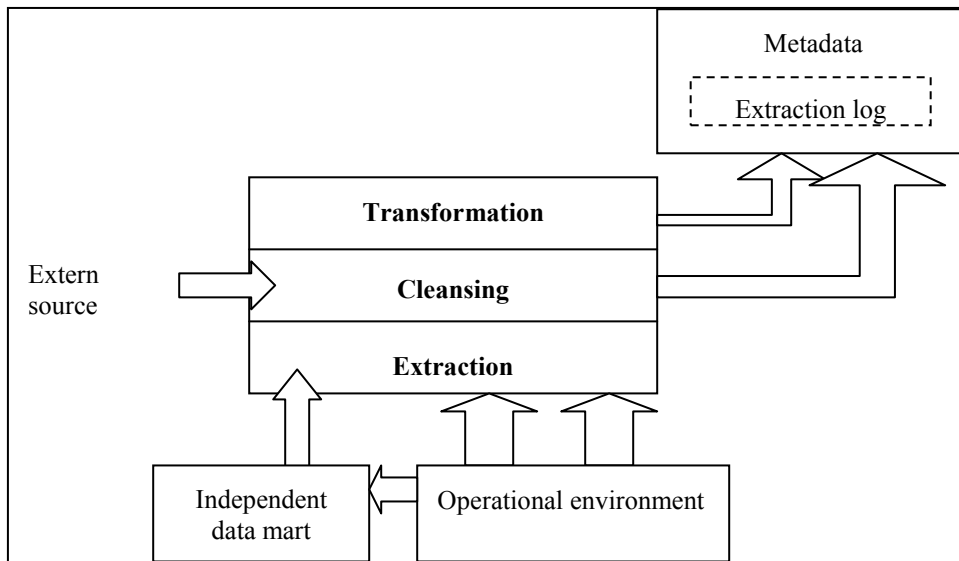

Fragmenting the definitions and the rules. A bigger problem comes from splitting the company into departments, divisions and operational groups, each of them with a different business process managed by distinct system. Slowly and unavoidable, each group starts to use slightly different definitions for common entities – “clients” or “suppliers” – and apply different rules for the computation of the same things – “net sales” and “profit before tax”.

Slowly changing dimensions. Slow changes in the dimensions can create data quality problems according to the expectations of the users that watch the data. For instance, if an analyst wishes to compute the total of the fixed assets bought from one company in the last year, but this company merged with another one from which we also bought goods, problems may appear.

The ETL process and its role in data quality

ETL processes in a data warehouse environment extract data from operational systems, transform the data in accordance with defined business rules, and load the data into the target tables in the data warehouse. There are two different types of ETL processes: *initial load* and *refresh*.

The initial load is executed once and often handles data for multiple years. The refresh populates the warehouse with new data and can, for example, be executed once a month. The requirements on the initial load and the refresh may differ in terms of volumes, available batch window, and requirements on end user availability.

Extracting data from operational sources can be achieved in many different ways. Some examples are: total

Figure 1 The ETL process

extract of the operational data, incremental extract of data (for instance, extract of all data that is changed after a certain point in time).

Data integration is the process of collecting data from the operational system in a central repository for analysis. Operational databases are the main source of a data warehouse and the integration process must assure a coherent environment for data used in analysis. The integration process consists of two operations: data transformation and data cleansing.

Data cleansing is the process in which errors are removed from the input data and it is a part of the integration process. It is probably one of the most critical steps of a data warehouse project. If the cleansing process is faulty, the analyst may not confide in the data warehouse and even a more serious scenario involve taking decision using bad data.

An efficient cleansing process can improve not only the quality of data from the data warehouse but also from the operational environment. The data administrator can verify the extraction log in order to identify the source of errors. Sometimes it is possible to detect errors that originate in the operational environment. Some errors can be generated by the original operational application or they can be simply typing errors. In both cases the data administrator must report these errors to the person responsible for data quality from the operational environment. Some errors can be generated by metadata, when the cleansing process doesn't intercept a metadata transformation or metadata used in the cleansing process are incomplete or incorrect.

There are debates concerning the actions that must be undertaken when input data mistakes are detected. Some consider this data must be returned to the operational environment in order to be corrected and send back to the data warehouse once the correction process is complete. Other thinks these errors should be corrected and integrated in the data warehouse whenever it is possible. Errors should be still reported to the operational environment. As a conclusion the data administrator must assure that there is a correspondence between data warehouse and operational environment. Otherwise a lack of confidence concerning the data warehouse can appear.

Data cleansing process cannot detect all errors. Some errors are simply typing errors. Other errors are more serious and put to test the data administrator competence. An example of such errors is the one in which the sales representative, instead of using each client unique identifier they use some generic identifiers that are accepted by the system.

Data cleansing is an important premise in a successful data warehouse project. The data administrator must have an active role in detecting and removing errors. While there is no ingredient that can guarantee the data warehouse success there are for sure some that can assure its failure. A faulty data cleansing process or a not very careful data administrator are certain premises of the failure.

Data transformation is the process in which data from operational systems are transformed into one consistent format. Each operational system contributing to the data warehouse must be analyzed to

understand data and their formats. Once these elements have been selected and defined, an integration process must be defined that will generate consistent data. Data transformation mainly concerns data description, data encoding, the units of measure and data format.

The ETL process is one of the most expensive and time consuming component of a data warehouse development process. If a decade ago the majority of ETL were hand coded, market for ETL software has steadily grown and the majority of practitioners now use ETL tools instead.

Joy Mundy identifies a series of advantages and drawbacks of ETL tools. The main advantages are:

Structured system design. ETL tools provide a metadata-driven structure to the development team and this is valuable for teams that build their first ETL system

Operational resilience. Unlike home-grown ETL which present many operational problems, ETL tools provide functionality and practices for operating and monitoring the ETL system in production

Data-lineage and data-dependency functionality. Most analysts expect to be able to see the way a certain value from a report was obtained (its source, its transformation etc). Unfortunately few ETL tools supply this functionality.

Advanced data cleansing functionality. Most ETL tools offer either advanced cleansing and de-duplication modules (usually for a substantial additional price) or they integrate smoothly with other specialized tools.

Performance. It is not proven that using an ETL tool leads to increased performance. It's possible to build a high-performance ETL system whether you use a tool or not

There are also presented some **disadvantages** of ETL tools: Software licensing cost which varies from several thousand dollars to hundreds of thousands of dollars Uncertainty seen as misinformed ETL teams that sometimes are uncertain about what an ETL tool will do for them and reduced flexibility.

The key element of a successful ETL system is the practice of designing ETL system before development begins. Efficient ETL system implements standard solutions to common problems but also offer enough flexibility to deviate from those standards where necessary.

Conclusions

In order to make decisions that support the strategy of a business, the decision makers must confide in data they analyze. A series of studies discovered that many business intelligence projects failed because the poor quality of data in the phase of data warehouse's feeding. In order to increase the quality of data a series of steps must be followed. Among that we remember: **the launch of a program of data quality, the creation of a team for the quality of data, the reviewing of the business processes and the data architecture, continuous monitoring of the data, the use of intelligent application that integrate data mining for the validation of data.** We insist on the last one of the steps presented because it presents a series of advantages. First, the validation decisions are taken without needing any code to be written. The data mining algorithms learn the functioning rules of the entity directly from the data, setting the user free from the concern of discovering these rules and developing specific code for their description. On the other hand the data validation is made in different ways for each client. Using the data mining the rules are deducted from the client's data generating logic of validity that is automatically specialized for each particular client. Also the data mining process allows the application logic to be automatically updated in a simple processing process. The rewrite, recompilation and deployment of applications are not necessary because they are always available, even in the moment of processing.

Abstract: The exponential increase in information, primarily due to the electronic capture of data and its storage in vast data warehouses, has created a demand for analyzing the large amount of data generated by today's organizations so that enterprise can respond quickly to fast changing markets. There are various tools that can be used to capture and codify knowledge, include databases, data mining techniques, and various types of artificial intelligence. The paper outlines these techniques, which dominate the technical tools for deriving knowledge from an organizations data assets.

Key words: knowledge management, data mining, knowledge, data assets

1. INTRODUCTION

Knowledge is increasingly being recognised as a vital organisational resource that provides competitive advantage. The role of information technology (IT) in knowledge management (KM), is an essential consideration for any company wishing to exploit emerging technologies to manage their knowledge assets.

Knowledge management (KM) tools encompass the technologies and techniques of collaborative computing and the soft issues of team work, cooperation, and group dynamics. Companies increasingly recognize knowledge management's potential to unlock corporate information resources- both implicit and explicit- as they seek to improve business practices and processes, deliver innovative products and services, and gain competitive advantages (Wickramasinghe, von Lubitz, 2007). Internet technologies provide the necessary competitiveness and interoperability, offering a low-cost, standardized, future-proof, backward-compatible network infrastructure- a so called intranet.

KM tools enable the collection, coordination, and distribution of information and knowledge so that team members can collaborate effectively in pursuit of a common goal. It is useful to think of major KM tools and techniques in terms of their social and community role of organization be it in:

1. the facilitation of knowledge sharing and socialization of knowledge (production of organizational knowledge);
2. the conversion of information into knowledge through easy access, opportunities of internalization and learning (supported by the right work environment and culture);
3. the conversion of tacit knowledge into explicit knowledge or information, for purposes of efficient and systematic storage, retrieval, wider sharing and application.

2. Theory fundamentals

There are various tools that can be used to capture and codify knowledge. These include databases and various types of artificial intelligence (AI) systems including experts systems, neural networks, fuzzy logic, genetic algorithms and intelligent or software agents.

2.1 Databases

Databases store structured information and assist in the storing and sharing of knowledge. Knowledge can be acquired from the relationships that exists among different tables in a database. These relational databases help users to make informed reliable decisions, which is a goal of knowledge management. Discrete, structured information is still managed best by a database management system. However, the

quest for a universal user interface has led to the requirement for access to existing database information through a Web browser.

2.2 Data mining techniques

The exponential increase in information, primarily due to electronic capture of data and its storage in vast data warehouses, has created a demand for analysing the large amount of data generated by today's organizations so that enterprises can respond quickly to fast changing markets. These applications not only involve the analysis of the data, but also require sophisticated tools for analysis. Thus, data mining techniques, and the newer techniques of business intelligences and business analytics, which basically combine the major data mining techniques with key business objectives, drivers, and outcomes critical to the generation of knowledge from data assets, dominate the technical tools for deriving knowledge from an organizations data assets.

The relationship between KM and data mining is depicted in figure 1.

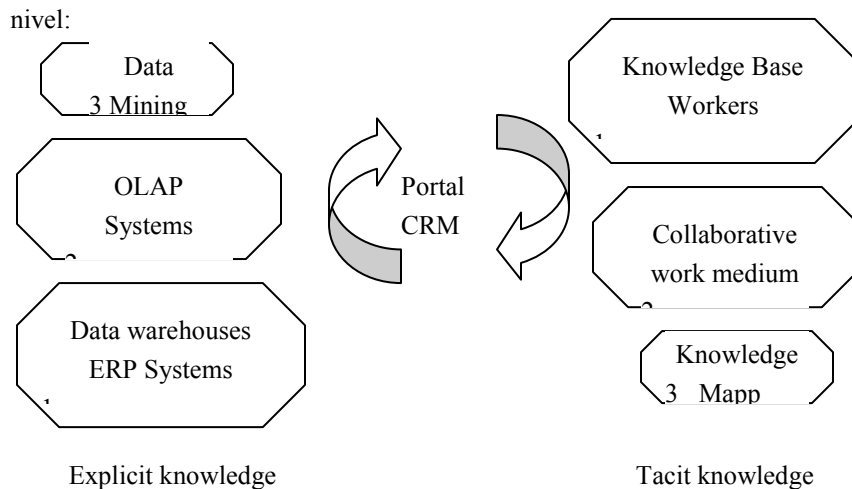

Figure 1. Relationship between KM and data mining

Source: Rosca, Bodea, 2006

For explicit knowledge, data mining is considered the higher level, because it needs data organized abilities (level 1), data querying and viewing (level 2), and learning automating technologies from artificial intelligence domain.

It is essential for a data mining process to discover new knowledge without previous states of assumptions. The goal of using data mining is not to verify assumptions, but the discovering of new unexpected and unintuitive knowledge, which can even be opposite with intuitive perception.

According to Fadlalla and Wickramasinghe (2005) there are four key data mining techniques:

1. Decision tree
2. Clustering
3. Neural networks
4. Association rule

The first two technique are used for exploratory data mining, the later two techniques are used for predictive data mining. In figure 2 are depicted the major techniques of data mining.

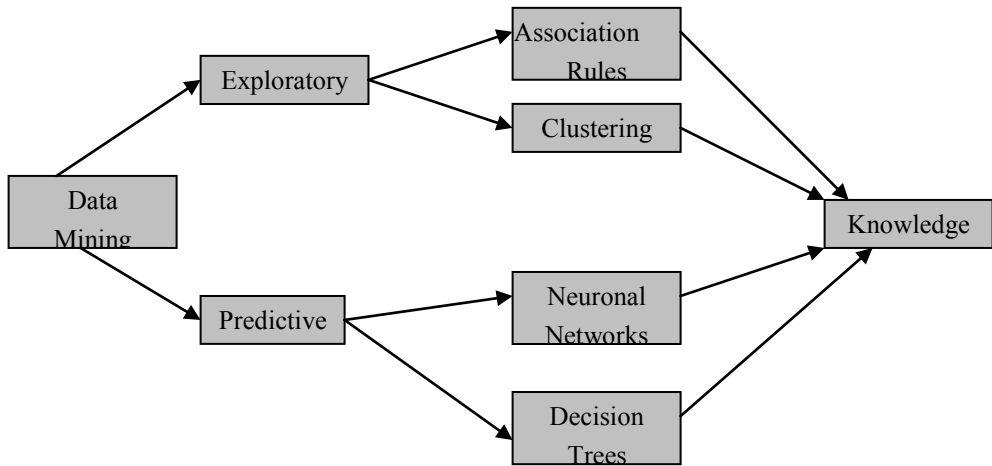

Figure 2. Major techniques of data mining

Source: Wickramasinghe, von Lubitz, 2007

Data mining is the non-trivial process of identifying valid, novel, potentially useful, and ultimately understandable patterns from data (Fayyad et al., 1996). Data mining algorithms are used on databases for model building, or for finding patterns in data. When these patterns are new, useful, and understandable, we say that this is knowledge discovery. How to manage such discovered knowledge and other organizational knowledge is the realm of knowledge management.

Data mining is a step in the broader context of the knowledge discovery process that transform data into knowledge. Figure 3 shows the knowledge discovery process, the evolution of knowledge from data through information to knowledge (Fayyad et al., 1996) as well as the types of data mining (exploratory and predictive) and their interrelationship. Data issues that data mining helps us wrestle with include huge volume of data, dynamic data, incomplete data, imprecise data, noisy data, missing attribute values redundant data and inconsistent data. Furthermore, data mining offers a wide variety of models to capture the characteristics of data and to help knowledge discovery including summarization, clustering / segmentation, regression, classification, neural networks, rough sets, association analysis, sequence analysis, prediction, exploratory analysis, and visualisation (Wickramasinghe, von Lubitz, 2007).

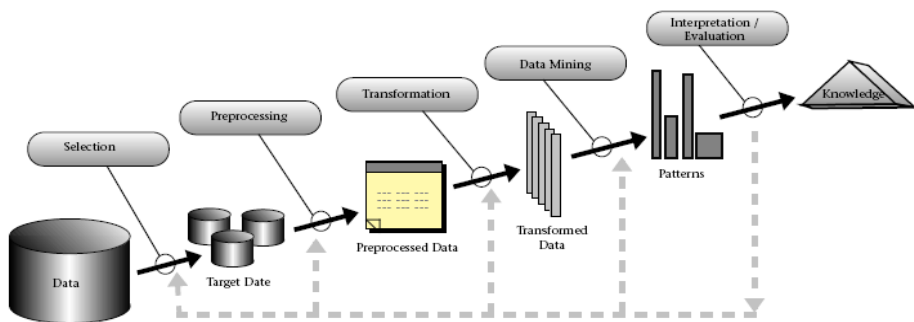

Figure 3. Data mining and the KDD process

Source: Fayyad, et al., 1996

The terms Knowledge Discovery in databases (KDD) and Data Mining are distinct. **KDD** refers to the overall process of discovering useful knowledge from data. It involves the evaluation and possibly interpretation of the patterns to make the decision of what qualifies as knowledge. It also includes the

choice of encoding schemes, preprocessing, sampling, and projections of the data prior to the data mining step. **Data mining** refers to the application of algorithms for extracting patterns from data without the additional steps of the KDD process.

We see in figure 3 that data extracted from the large pool of data is not the final outcome intended. It typically contains a significant amount of erroneous information that should be excluded prior to inputting the correct data to be processed by the data mining algorithms; thus, data goes through the following process steps before being used for any decision-making or prior to any of the previous techniques being utilized effectively (Fadlalla, Wickramasinghe, 2005; Fayyad et al., 1996).

- a) Selection: Selecting the data according to some criteria;
- b) Preprocecion: This is the datacleansing stage where certain un wanted information is removed which may slow down queries;
- c) Transformation: The data is not merely transferred across but transformed in that overlays may be added;
- d) Data Mining: This stage is concerned with the extraction of patterns data. It includes choosing a data-mining algorithm, which is appropriate to search a particular pattern in the data
- e) Interpretation and evaluation: The patterns identified by the system are interpreted into knowledge by removing redundant or irrelevant patterns, and translating the useful patterns into terms that can be understood by users.

3. The four data mining techniques

a. Decision Tree (Fadlalla, Wickramasinghe, 2005; Fayyad, et al., 1996)

Data mining techniques are used to find the most pertinent information and data to facilitate superior decision making. The decision tree technique achieves this by closing the gap between the facts and real understanding. Decision tree represents the knowledge or the available information in tree-like form and a method for treatment is selected. The decision is usually made on the choices of outcomes. Decision trees are built through recursive partitioning, which is splitting the data into partitions and subsequently splitting it further.

Advantages of the Decision Tree Technique:1. The decision tree as a whole is a graphical representation since visually the tree structure itself supports the location of the correct split or accurate decision. 2. The model of the decision tree helps in reasoning and can be used to examine and justify a decision choise.

Disadvantages of the Decision Tree Technique: 1.The Decision tree cannot predict a continuous response variable. Specifically, all the splits are dependent on the previous splits. Hence, the model has high order interactions. The decision tree cannot discover a single rule based on the ration when two values are given a new variable has to be defined to specify a simple rule.

b. Clustering (Fadlalla, Wickramasinghe, 2005; Fayyad, et al., 1996)

This technique is a type of undirected data mining. The purpose of undirected data mining is to find the structure as a whole and then the decision is made using decision tree or neural network technique. Clustering is a classification, which enables us to find specific factors. Clustering can also be used for maintaining the records about students. The most used method for clustering is k-mean. This is a geometrical method, which uses the average location of all members from the particular cluster. The whole field is divided into numbers and then these numbers are normalized. The value of each field is interpreted as the distance from the origin along the corresponding axis. Here the centers are initially defined and the adjusted using predefined algorithms. To start a clustering session, a random set of centers are chosen which are then adjusted by adding to and removing centers during analysis. The clustering technique is dependent on the two main criteria:

- The cluster must be homogeneous.
- Each group or cluster must be mutually exclusive.

Advantages of Clustering: 1. The main strength of clustering is that it is an undirected knowledge discovery technique. 2. The can be used as a preparatory technique for other data mining technique such as decision tree or neural networks.

Disadvantages of Clustering: 1. Clustering represents a snap shot of a data at a certain point in time and thus may not be as useful in highly dynamic situations. 2. Sometimes the clusters generated may not even have a practical meaning. 3. It is possible not to spot the cluster sometimes since you do not know for what you are looking.

c. Neural Networks (Fadlalla, Wickramasinghe, 2005; Fayyad, et al., 1996)

The technique of neural networks is modelled after the human brain and consists of many input nodes, one or more hidden (middle) layer nodes and one or more output nodes. The input and output nodes relate to each other through the hidden layer. The input layer represents the raw information that is fed into the network. The hidden layer represents a computational layer that transforms the inputs coming from the input layer into inputs to the output layer.

The most important application of neural network is pattern recognition. The network is trained to associate specific output patterns with input pattern. The power of neural networks comes into play in its predictive abilities (i.e. associating an input pattern that has not previously been classified with a specific output pattern). In such case, the network will most likely give the output that corresponds to a pre-classified input pattern that is least different from the new input pattern.

Some advantages of Neural Networks are 1. Neural Networks are good classification and prediction techniques when the results of the model are more important than the understanding of how the model works; 2. Neural Networks are very robust in that they can be used to model any type of relationship implied by the input patterns.

Some disadvantages of Neural Networks are 1. The key problem with neural networks is the difficulty to explain its outcome. Unlike decision trees, neural networks use complex non-linear modelling that not produce rules and hence it is hard to justify ones decision. 2. Significant preprocessing and preparation of the data is required. 3. Neural networks will tend to over-fit the data unless implemented carefully. This is due to the fact that the neural networks have a large number of parameters, which can fit well into arbitrary data set.

d. Association Rule mining (Fadlalla, Wickramasinghe, 2005; Fayyad, et al., 1996)

Association Rule are used to discover relationships between attribute sets for a given input pattern. Such relationships do not necessarily imply causation, they are only associations. These patterns (associations) are not easily to discovered using other data mining techniques. The support of an association rule is percentage of cases, which include the antecedent of the rule, while the confidence of the association rule is the percentage of cases where both the antecedent and the consequence of the rule are displayed. Only rules whose support and confidence exceed predetermined thresholds are considered useful.

Advantages of Association Rule: 1. The association rules are readily understandable. 2. Association rules are best suited for categorical data analysis.

Disadvantages of Association Rule Mining: 1. Generate too many rules and sometimes these are even trivial rules. 2. The association rule are not expressions of cause/effect rather they are descriptive relationships in particular databases, so there is no formal testing to increase the predictive power of these rules.

3. Applications of data mining techniques

a. Decision Tree

The Decision Tree helps select statistics or statistical techniques appropriate for the purpose and conditions of a particular analysis. Decision tree classifiers show a great deal of potential in many pattern recognition problems such as remotely sensed multisource data classification, medical diagnosis, speech and character recognition, to mention a few.

b. Clustering techniques have been applied to a wide variety of research problems. Hartigan (1975) provides an excellent summary of the many published studies reporting the results of cluster analyses. Clustering algorithms can be applied in many fields, for instance:

- *Marketing*: finding groups of customers with similar behaviour given a large database of customer data containing their properties and past buying records;
- *Biology*: classification of plants and animals given their features;
- *Libraries*: book ordering;
- *Insurance*: identifying groups of motor insurance policy holders with a high average claim cost; identifying frauds;
- *City-planning*: identifying groups of houses according to their house type, value and geographical location;
- *Earthquake studies*: clustering observed earthquake epicentres to identify dangerous zones;
- *WWW*: document classification; clustering web log data to discover groups of similar access patterns.

c. Applications for Neural Networks

Neural networks are applicable in virtually every situation in which a relationship between the predictor variables (independents, inputs) and predicted variables (dependents, outputs) exists, even when that relationship is very complex and not easy to articulate in the usual terms of "correlations" or "differences between groups.

- *Detection of medical phenomena*. A variety of health-related indices (e.g., a combination of heart rate, levels of various substances in the blood, respiration rate) can be monitored.

- *Stock market prediction*. Fluctuations of stock prices and stock indices are another example of a complex, multidimensional, but in some circumstances at least partially-deterministic phenomenon.

- *Credit assignment*. A variety of pieces of information are usually known about an applicant for a loan. For instance, the applicant's age, education, occupation, and many other facts may be available. After training a neural network on historical data, neural network analysis can identify the most relevant characteristics and use those to classify applicants as good or bad credit risks.

- *Monitoring the condition of machinery*. Neural networks can be instrumental in cutting costs by bringing additional expertise to scheduling the preventive maintenance of machines. A neural network can be trained to distinguish between the sounds a machine makes when it is running normally ("false alarms") versus when it is on the verge of a problem.

- *Engine management*. Neural networks have been used to analyze the input of sensors from an engine. The neural network controls the various parameters within which the engine functions, in order to achieve a particular goal, such as minimizing fuel consumption.

d. Application of Association Rule Mining

It is widely used in hospitals to maintain patient's records.

4. Conclusions

The exponential increase in information, primarily due to the electronic capture of data and its storage in vast data warehouses, has created a demand for analyzing the large amount of data generated by today's organizations so that enterprise can respond quickly to fast changing markets. Knowledge discovery technologies, in particular the techniques of data mining, are the essential technologies that help to analyze data, find significant relationships between data and then help to find reasons behind observable patterns. Such new discoveries can have a profound impact on design business strategies.

REAL-TIME MANAGEMENT AND ANALYSIS OF DSS PROJECTS

Hancu Lucian

„Babeş-Bolyai” University, Cluj-Napoca, Faculty of Economic Sciences and Business Administration,
Str. Lacul Roşu nr. 1/36 Cluj-Napoca, E-mail: lhancu@softproeuro.ro, Phone: 0264-411.935

The management and analysis of student projects become a real challenge for the teaching assistant, when dealing with a large number of students during an academic semester. Detecting fraud and guaranteeing students' originality tends to be considered a difficult human task. The use of Web technologies can significantly ease the gathering, the management and the analysis of these projects. The application we have built serves as a facilitator for increasing the student projects' originality and reduce the similarity with the sample projects discussed during the teaching classes. The Web application deals with Decision Support System projects generated from Microsoft Excel and InfoHarvest Criterium DecisionPlus, but can be easily extended to be an interface to other DSS generators.

Keywords Project evaluation, Decision Support Systems; Fraud Detection

1. Introduction

The evaluation of the students' projects has always been a challenge for the teaching assistant when facing an increased number of students. Assuring originality and reducing fraud tends to decrease with the number of students attending a teaching class. For this reason, academia is continuously searching for possible solutions in order to improve the students' originality, which can be a preamble of their innovativeness later in their lives.

A commonly encountered problem when dealing with students' projects as evaluation assignments is the fact that they tend to be conformed to the *Principle of Least Effort* ([1], cited by [2]). The use of materials discussed during the teaching classes, presented in a different format as individual student projects, does not guarantee the student's comprehension of the course's main concepts. Hence, the teaching assistant (which usually has the task of analyzing student's practical contribution to the academic course) must develop a technique for limiting fraud during project's presentations and increase the student's effort to develop original projects.

Recently developed researches [3, 4] employ data mining clustering techniques in order to point out students' behavior. The main disadvantage of these techniques is the fact they analyze the student's behavior *after* the behavior was completed, based on data gathered from students' surveys. In this article, we consider the case of analyzing the student's behavior *as it happens*, generating an output based on student's contribution and suggesting possible solutions to improve the quality of the student's assignment.

The paper is organized as follows: the subsequent section describes our research problem and the Web architecture we use to manage and analyze students' projects. The third section deals with discussing the findings resulted from analyzing students' project and measuring their degree of originality, whereas the fourth section points out the conclusions of our work and highlight future research directions in the field of the real-time management and analysis of the students' projects.

2. Materials and Method

Although it is still hard to believe that a fully automatic system can manage and analyze students' assignments and projects without human intervention, domain-specific approaches are an immediate solution to the problem of detecting students' fraud and increasing their contribution to creating original projects.

In this paper, we take into consideration the case of analyzing the projects assigned to students from the 3rd year's „Decision Support Systems” course. The fact that the projects were to be made using *Microsoft Excel* and *InfoHarvest Criterium DecisionPlus* [5] did not request for the use of automatic management and analysis methods. Instead, the number of students (around 400 in the whole year) implied the search for a semi-automatic technique that deals with the tasks of managing and analyzing the submitted projects.

Let us consider the case of collecting the projects. The use of a simple Web interface is sufficient for this purpose, as students are familiar with various Web mailing systems. The simple collection of the project

does not guarantee student's originality, as simple Web interfaces like the email ones allow the posting of any content without filtering or any prior verification. Thus, our system must also deal with a series of issues, like:

- collecting Microsoft Excel and InfoHarvest Criterium Decision projects and rejecting other types of projects;
- parsing posted projects and compute projects' similarity with previous posted projects;
- render mistakes and suggest possible corrections.

The **Figure 1** describes the resulted architecture of our Real-time management and analysis system's interface:

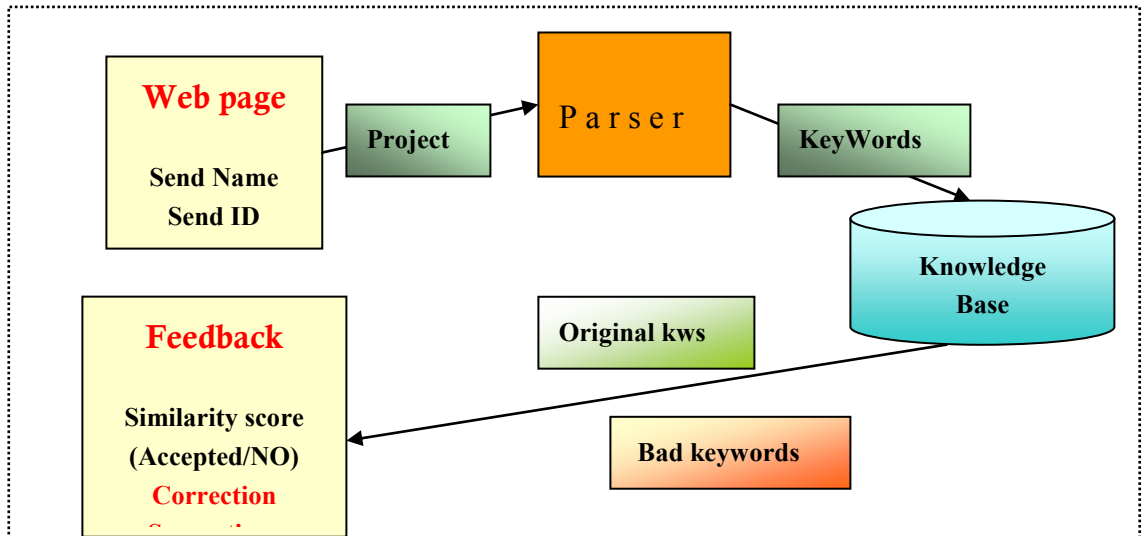

Figure 1. The Architecture of the Real-Time Management and Analysis of DSS Projects System

The Web-based system (available online at [6]) functions as follows: the student sends us his name, personal student ID and posts the project as text file. We have noticed that both *Microsoft Excel* and *InfoHarvest Criterium DecisionPlus* exhibit an *Export to text file* interface (*Microsoft Excel* provides the format *Text file -Tab delimited-* for saving worksheets). The project (saved as text file) is sent to the Parser, which computes the list of the keywords extracted from the project. We consider as keyword any text segment (formed by a word or group of words) that appears in a different Excel cell or in a different *Criterium DecisionPlus* project's goal, criterion or alternative. Furthermore, we query the Knowledge Base to classify keywords as *Original keywords* (keywords that did not appear in any previous projects) and *Bad Keywords* (keywords that did appear in previous postings). Based on the list of *Original Keywords* and *Bad keywords*, we compute the project's similarity score and conclude that it shall be accepted by the system in the case that the similarity score is below 60%. The Feedback page displays the total number of extracted keywords and the number of classified *Bad keywords* and highlights the keywords that should be changed to improve originality.

Before publishing the Web application, we computed two minimal *Knowledge Bases*, formed by the projects discussed during the lectures: we shall call them KB_E (for the Knowledge Base of the collected *Microsoft Excel* projects) and KB_C (for the Knowledge Base of the collected *InfoHarvest Criterium DecisionPlus* projects). The minimal *Knowledge Bases* shall be used to compare the students' projects with the one already discussed as teaching material. These *KBs* shall be updated with original keywords as students post projects, in order to further checking projects' originality between students' creations.

We should also mention the fact that we separately save different types of projects, as we would like to compare the results of both *Excel* and *InfoHarvest* projects. Thus, students' contributions conducts to the creation of the two datasets DS_E (containing DSS projects developed by use of *Microsoft Excel*) and DS_C

(containing decision models generated by *Criterion DecisionPlus*). In the next section, we analyze the resulted datasets and discuss the students' originality of the DSS projects.

3. Results and Discussions

On performing our research, we have considered two strategies for gathering student projects: for the building of the first knowledge base, we manually collect students' projects saved as exported text file (as a result to the above-specified option, available from Microsoft Excel) and pass them to the system one by one. For the second knowledge base, we make use of the Web application: students contribute with their projects to the update of the Knowledge Base. They are aware of the fact that the system has the capability to deal with unoriginal projects (to compute the degree of similarity with past-submitted projects) and their task is to contribute with original projects that adhere to the highlighted rules.

The results of the analysis are depicted in the subsequent table:

	KB _E	KB _C
Number of projects	75	75
Unoriginal projects	70	56
Unoriginality from didactics	54	39
Unoriginality above threshold	4	0
Extracted Keywords	1839	1266

Table 1: Results from the analysis of KB_E and KB_C

The unoriginality scores show a decrease in the degree of unoriginality of *Criterion DecisionPlus* scores, compared with the *Excel* projects. We explain this finding as the students were aware of the fact that their projects were to be analyzed in real-time by the Web application. Having the same number of input projects into the knowledge bases (75 *Excel* projects and 75 *Criterion DecisionPlus* projects), the degree of unoriginality decreases from 70 (93%) to 56 (75%). The degree of unoriginality derived by using parts of the projects discussed during lectures also decreases from 54 (72%) to 39 (52%), whereas the number of unoriginal projects which surpass the unoriginality threshold (60% of the keywords in one project can be taken from previously submitted projects) decreases from 4 to 0.

Despite the fact there are no unoriginal projects classified by the system as *unoriginal above threshold* in the second knowledge base, the number of unoriginal projects is still high (75%). The phenomenon is, to some extent, unexpected, but explainable: some students did not understand quite well how to deal with the Web system: they submitted a project, then obtain the results, then resubmitting the same project with minor changes. The system considers unoriginal the second project, even if it comes from the same student. The fact that the system allows the submission of any number of projects without restriction from any student contributes to the raise of the *unoriginality of the projects*. We plan to restrict this drawback with future upgrades to our system.

The unoriginality in terms of similarity with the projects discussed during the lectures also decreases. There are two factors which influence the result: the use of the real-time analysis system forced students to contribute with more original projects, as they were expecting to obtain a bad result when contributing with unoriginal material. The second factor comes from the building of the *Criterion DecisionPlus* project: it consists of only blocks, classified by the software as *goals*, *criteria*, *subcriteria* and *alternatives*, with a reduced number of extracted keywords, when compared with the number of keywords extracted from the *Excel* project. The last row of Table 1 depicts the numeric results of the fall in the number of extracted keywords, as *Criterion DecisionPlus* projects are more structured than the *Excel* projects and more restricted (the maximal number of blocks is set to 20 when using the Student Version of the software).

We also compare the most cited 5 projects, extracted from the data contained in the two knowledge bases. We call that the project *A* cites the project *B* if any of the keywords extracted from *A* were previously extracted from the project *B*. The following table highlights the results, which we discuss later on.

Most cited projects	Project ID KB _E	Citations KB _E	Project ID KB _C	Citations KB _C
1.	0378	54	5374612	24
2.	5334531	16	0482	18
3.	5397267	15	540465	9
4.	5402483	13	5412330	7
5.	5252489	13	5735631	6

Table 2: Results of the “Most cited projects” analysis

The table depicts the top 5 most-cited projects’ IDs, extracted from the knowledge base. To ensure the privacy of the students, we have previously encrypted the IDs. Our hypothesis was that without any prior information on the project restrictions, the students were going to use the projects discussed during lecture as the basic theme of inspiration (and unoriginality). The hypothesis is confirmed, the projects which starts with a 0 being lecture projects. We also notice the differences in citing the teacher’s project and other student projects (coming in the 2nd, 3rd, 4th and 5th place).

The last two columns of the *Table 2* highlight the results from the “*Most cited projects*” analysis performed on the second Knowledge Base. The results are surprising, as there is a project which surpasses in the number of *citations* the lecture project. We manually inspected that project and concluded that it contained an error: the student forgot to weight the *Goal* of her decision model with the criteria from the *second level* of the model. Being the first project electronically submitted to the Web system by a student and the first accepted project, her colleagues took it as an example of correctness and acted according to the accepted example. The number of citations of the *Criterion DecisionPlus*’ top level project shows how much the error propagated to the student projects, 24 of all the 75 projects containing the error. The error propagation is a well-known phenomenon in academics, uniformly distributed among the disciplines and the correction of the propagated errors becomes more difficult, as thoroughly discussed in [7].

4. Summary and Conclusions

We have presented the architecture of the Web-oriented Real-time Management and Analysis System of Decision Support Systems projects, which we have used during the DSS seminars. We have built two knowledge bases extracted from automatically processing the projects. The Knowledge bases highlight the unoriginal projects and the projects which surpass the admitted threshold of unoriginality (set at 60% of unoriginality).

The results show that our Excel project was the primary source of support for building the Excel projects, whereas a student error conducted to an error propagation among a significant part of students’ *Criterion DecisionPlus* projects. In the near future, we plan to extend the usage of the system to a larger number of students. We also plan to lower the *unoriginality threshold* for analyzing master students’ projects and investigate which threshold is better suited for both undergraduate and M.Sc. students.

Le développement durable, dans un contexte de globalisation, exige un pilotage des activités, celles de la direction système information (DSI) inclus, sur des critères de performance et de conformités. Les dernières années on assiste à l'intensification des recherches ayant pour thème la définition du cadre méthodologique et la construction d'un référentiel de bonnes pratiques pour assurer le manageant et le contrôle du system d'information des organisation en mettant en jeu les trois acteurs clés de l'entreprise : les actionnaires (le pouvoir Patrimonial), les administrateurs (le pouvoir Managérial) et les systèmes d'informations (informatiques).

Notre papier fait une revue de la littérature et présente nos réflexions au sujet de la gouvernance du système d'information (GSI) : (1) les concept de GSI, (2) principes de la GSI, et (3) les référentiels des bonnes pratiques pour la GSI.

Mots clés: Système d'Information, gouvernance du système d'information, alignement stratégique, management des risques informatiques, référentiels de bonnes pratiques, pilotage du SI

1. Introduction

La tendance actuelle à la mondialisation de la concurrence pousse les entreprises à conquérir sans cesse de nouveaux marchés et à mettre en œuvre des stratégies fondées sur la performance de toute activité et sur la conformité. Transformées en prestataires de services internes, les Directions des Systèmes d'Information se voient demander de justifier de leur efficacité, de leur productivité ou encore de leurs dépenses. La gouvernance du système d'information (en anglais, IT Gouvernance) devient un support important de la gouvernance d'entreprise (Corporate governance).

Selon le Cigref (2004) la gouvernance du système d'information peut apporter :

- Une meilleure prise de décision concernant l'ensemble du système d'information afin d'accroître son efficacité ;
 - Une clarification des rôles des différents acteurs afin de créer des synergies ;
 - Une meilleure définition des responsabilités des acteurs afin de faire prendre conscience des droits et devoirs de chacun ;
 - Une meilleure connaissance du processus clés liés au système d'information afin de faire partager la compréhension de la complexité de leur mise en œuvre.
- La mis en œuvre de la gouvernance du système d'information dans les organisations exige un cadre méthodologique de gouvernance (Chamfrault, 2005) et l'accompagnement par de réflexions et de plans d'action concernant l'alignement stratégique du système d'information, la valeur ajoutée du système d'information et l'urbanisation du système d'information.
- Le cadre méthodologique de la GSI s'appuie sur un ensemble des modèles, référentiels des bonnes pratiques (ITIL-IT Infrastructure Library ; COBIT- Objectifs de Contrôle de l'Information et des Technologies associées) et normes (Audit du système d'information de l'ISACA-Information Systems Audit and Control Association ; ISO 27001- Management de la sécurité de l'information ; ISO 19011- Management qualité et environnemental). Le contrôle du système d'information vise aussi sa mise en

conformité avec les - très - nombreuses réglementations de gestion des données financières (Sarbanes-Oxley Act, Loi de Sécurité Financière, Bâle II, ...) tout en assurant la transparence.

Notre travail de recherche a pour objectif d'assurer compréhension de la problématique de la gouvernance du système d'information : concepts, principes et référentiels de bonnes pratiques.

2. Les concept de gouvernance du SI

La GSI a pour mission fondamentale d'assurer aux dirigeants d'entreprise ainsi qu'aux actionnaires que la fonction système d'information est parfaitement gère. Le terme gouvernance du système d'information est maintenant fréquemment utilisé pour désigner les activités d'orientation et de contrôle relevant de l'instance administrative supérieure d'une organisation, soit celle qui tient le gouvernail. La Gouvernance du SI est vue comme un processus de management, fondé sur des bonnes pratiques, qui permet à l'entreprise d'optimiser ses investissements en « système d'information » dans le but d'attendre un ensemble d'objectifs (contribuer à ses objectifs de création de valeur, accroître la performance des processus informatiques et leur orientation clients, maîtriser les aspects financiers du système d'information, développer les solutions et les compétences en système d'information dont l'entreprise aura besoin dans le futur, garantir que les risques liés au système d'information sont sous contrôle) tout en développant la transparence (Leignel, 2006).

La « gouvernance du SI » est la transposition au niveau « SI » des principes de Corporate Governance (figure 1)

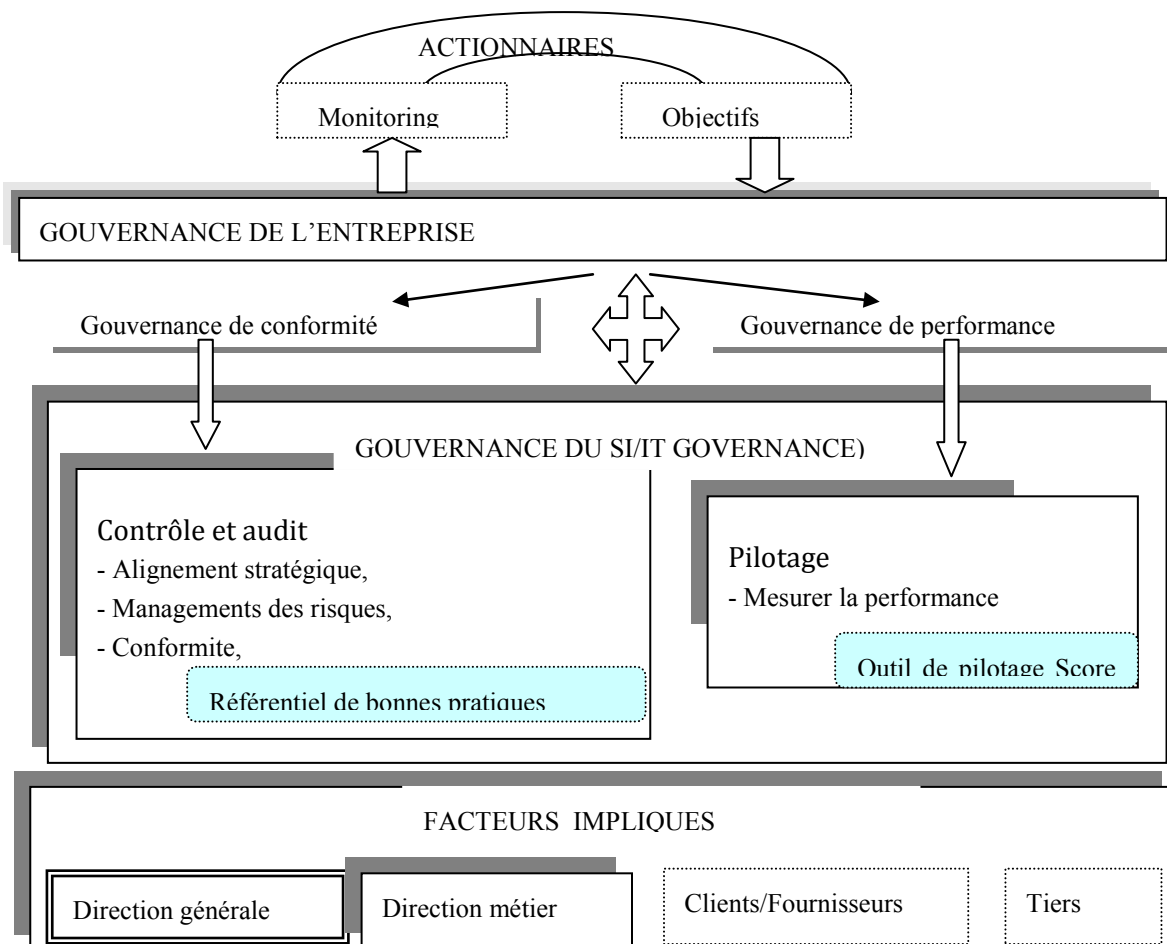

Figure 1. Cadre général de la ITGI

(source : Florescu & al (2007))

Les facteurs impliqués de la gouvernance du système d'information de l'entreprise sont :

- Les actionnaires (le pouvoir Patrimonial), qui fixent les objectifs et assurent le monitoring ;
- Les administrateurs (le pouvoir Managérial) avec de responsabilités pour la réalisation des objectifs en condition de performance et conformité et en toute transparence;
- Les services systèmes d'information (Direction SI), qui gère les ressources et les processus SI.

Dans le processus de la gouvernance on fait appel aux référentiels de bonnes pratiques (tel que le référentiel COBIT) et aux outils de pilotage (tel que IT Scorecard).

3. Les principes de la gouvernance du système d'information

La GSI est fondée sur cinq principes de base : alignement stratégique, la fourniture de la valeur, la mesure de la performance, la gestion des ressources et la gestion des risques (figure 2).

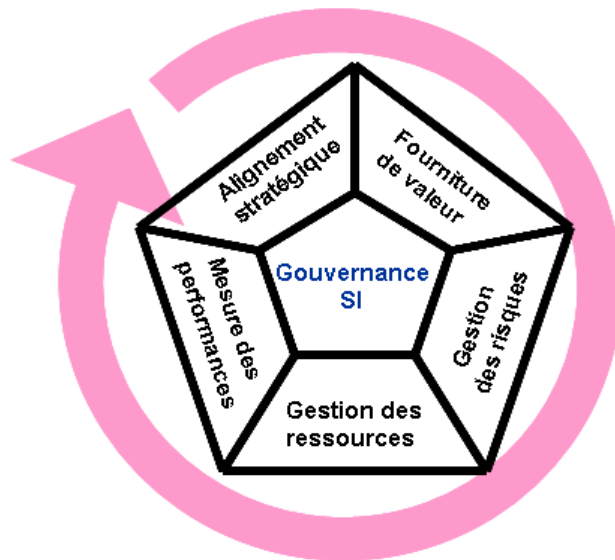

Figure 2. Principes de la gouvernance du SI

Source : Delavaux(2007)

L'alignement stratégique (IT Strategic Alignment), concerne l'alignement de la stratégie du système d'information à la stratégie d'affaires (Henderson & Venkatraman, 1993 ; Florescu & Tamas, 2006).

La fourniture de la valeur (IT Value Delivery), concerne l'amélioration de la valeur des services de l'entreprise par le biais du système d'information (Corbel & al.2004).

La mesure de la performance (Performance Measurement), concerne l'analyse des pratiques en matière de pilotage et de contrôle de gestion informatique (tableaux de bord, reporting, etc.).

La gestion des ressources (IT Resource Management), il s'agit d'analyser la connaissance et les principes de gestion des actifs matériels et logiciels, des ressources humaines, ainsi que des politiques de sous-traitance et d'externalisation.

La gestion des risques (IT Risk Management), il s'agit d'analyser la connaissance du risque pris par l'entreprise à travers ses systèmes informatiques (cf. cartographie du risque informatique) et ce, en termes d'impact métier.

Les principes de gouvernance du système d'information sont en phase avec les pratiques managériales fondamentales : établir une stratégie efficace, disposer d'outils de pilotage pertinents, démontrer la valeur et la contribution de ses actions, connaître les risques encourus et gérer le patrimoine informatique.

4. Referentiels des bonnes pratiques

4.1. Classification

La littérature qui traite de la gouvernance du système d'information cite plusieurs référentiels de bonnes pratiques, qui présentent d'intérêt pour la gouvernance du système d'information :

- ITIL (Information Technology Infrastructure Library), élaboré par les autorités britanniques et dédié à optimiser les services informatiques au sein de l'entreprise ;
- COBIT (Control Objectives for Business & Related Technology) développé par l'ISACA (Information System Audit & Control Association) *et* dédié à la gouvernance et l'audit des systèmes d'information ;
- CMMi (Capability Maturity Model intégration) dédié au développement de systèmes et logiciels (www.ssi.fr/html/presentation/cnmi.html) ;
- ISO 27001, norme pour assurer la sécurité du système d'information.

Dans ce travail de recherche notre intérêt porte sur les référentiels COBIT, le plus complet et à la fois intégrateur.

4.2. Le référentiel COBIT

A l'origine COBIT a été conçu ISACA (Systems Audit and Control Association (www.isaca.org) pour les auditeurs (figure 3).

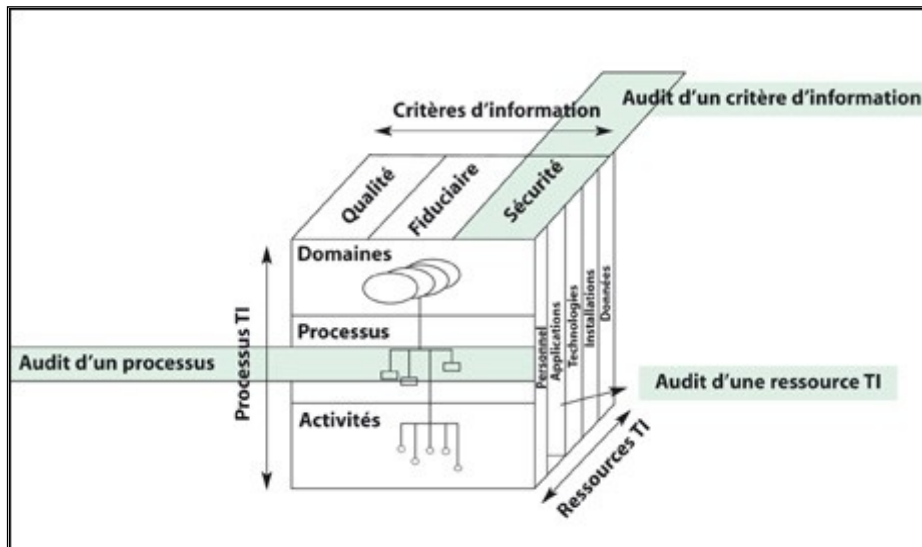

Figure 3. COBIT pour les auditeurs

(Source : Moissand Dominique, Doc. AFAI)

Ultérieurement l'IT Governance Institute (www.itgovernance.org) a développé COBIT (sa quatrième version de COBIT on assure l'harmonisation des termes et des principes pour faciliter l'intégration de COBIT et des référentiels ITIL, CMM, COSO, ISO 27001, 19011) qui est devenu ainsi :

- Un norme de gouvernance et un référentiel de bonnes pratiques à utilisés pour mettre en oeuvre la gouvernance informatique et améliorer les contrôles du système d'information ;
- Un modèle de maturité, on peut évaluer l'atteinte d'un ou plusieurs objectifs généraux sous forme d'une échelle ;
- Un outil de management, comprend des conseils pour les conseils d'administration et tous les niveaux de management ;
- Un outil d'audit du système d'information ;

- Un outil de conformité (voir la réglementation Sarbanes-Oxley).

Dans le cadre du référentiel COBIT les processus et les contrôles sont repartis en quatre domaines:

Le domaine Planification & Organisation, concerne la stratégie et les tactiques, l'identification des moyens permettant à l'informatique de contribuer le plus efficacement à la réalisation des objectifs commerciaux de l'entreprise.

Le domaine Acquisition & Mise en place, concerne la réalisation de la stratégie informatique, l'identification, l'acquisition, le développement et l'installation des solutions informatiques et leur intégration dans les processus commerciaux.

Le domaine Distribution & Support, concerne la distribution des prestations informatiques exigées, ce qui comprend l'exploitation, la sécurité, les plans d'urgence et la formation

Le domaine Surveillance et évaluer, permet au management d'évaluer la qualité et la conformité des processus informatiques aux exigences de contrôle.

Chaque domaine regroupe des processus qui sont décomposés à en activités.

Les bonnes pratiques à mettre en œuvre s'appliquent aux vecteurs suivant de la Gouvernance du SI (Leignel, 2006) :

- planification du SI et intégration dans le processus global de planification de l'entreprise ;
- gestion du portefeuille de projets orientée création de valeur ;
- alignement de l'organisation informatique par rapport aux processus métiers ;
- urbanisme et architecture d'entreprise ;
- transparence des budgets et des coûts et du contrôle de gestion ;
- maîtrise de l'optimisation de l'efficacité des projets ;
- fourniture de services d'information et optimisation des processus informatiques vis-à-vis des services aux clients ;
- gestion et maîtrise des risques liés au SI ;
- gestion prospective des compétences informatiques ;
- gestion et mesure de la performance du SI ;
- gestion de la communication relative au SI.

La mise en œuvre des bonnes pratiques pour chacun de ces vecteurs, dans une approche Qualité, permettra de tendre vers une bonne GSI.

5. Conclusions

Stratégie et gouvernance apparaissent comme deux vecteurs indissociables d'un changement induit par de nouvelles pratiques de management et de performance organisationnelle, recherchée par de nouveaux modèles de création de valeur dans les entreprises de toute taille. Dans le cadre du contrôle interne, le COBIT vient s'insérer dans le cadre des actions du COSO (Committee of Sponsoring Organizations of the Treadway Commission - Internal Control). L'ISO 27000 et l'ITIL peuvent être considérés comme des mises en application du COBIT dans le domaine du service SI et de la sécurité.

Une question inspirée de la littérature professionnelle traitant de la GSI: L'activité « système d'information » pourrait disposer d'un standard définissant les critères d'information à communiquer aux shareholders ?

***Summary:** Investment in informational technologies (IT) can represent the winning bet so much for Romania but also for the economical agents that will become aware of the importance of the implementation of performance informational systems in the context of high competition. The last years case reflects an obvious increase in the IT sector, thus in 2006, the value in the Romanian sector of the informational technologies and communication (IT&C), was 4.8 billions euro, having a 4,19% contribution in GDP (Gross Domestic Product). At the same time, the value of software & service exports was estimated at 380 millions euro for the year 2006. The firsts reports of 2007 confirm the increasing forecast of this sector, as a exemplification the IT services market only increased with 20%, reaching at over 210 million €, towards only 176,5 million € in 2006. The IT&C market is the most dynamic sector, analyses study realized by IDC, predicting also an increase by about 20% and for the year of 2008.*

***Key words:** Informational technologies, telecommunication, society knowledge.*

The IT&C market is the most dynamic sector, a analyses study of the economical impact of the IT industry, realized by IDC, at the Romania Microsoft Company order, estimates a medium rate of annual increasing by 10%, the forecasts for 2009 being 1,3 billion \$. The study analyzes the impact of the IT industry regarding at: creating new working places, establishment of new companies, local expenses for IT and taxes income.

The increase in software is significant at the level of the entire sector, shows the quotation study: until 2008, the Romanian software market will double toward 2003, reaching 200 million \$. At the level of the six countries analyzed (Romania, Bulgaria, Croatia, Macedonia, Slovakia, Serbia Montenegro) the expenses for software represents 16% from the total IT market in south-east Europe and are increasing by a 13% annual rate.

Regarding Romania, 1450 companies are involved in the IT domain. These have paid to the budget 122 million \$ under the form of fees and taxation. Summarized, the IT expenses in Romania, in 2004, were \$ 818 million. Over 45.000 persons are being engaged in the IT domain, and the local communication industry.

In Romania the employment in software industry represents 52% from the total number of working places in IT, estimating that in 2009 this percentage will reach 65%.

For the region countries Romania, Bulgaria, Croatia, Macedonia, Slovakia, Serbia& Montenegro, the economical impact of the IT industry is estimated as follows: between 2003 and 2009 the estimations are of about 35.000 new working places. As regarding the taxes at the budget in the next 5 years, these are estimated at \$.1.4 billion. The software expenses represent 15% from the total IT expenses. The number of persons from the IT industry will increase by 23%.

Roughly 50% from the total number of IT employees in south-east Europe are involved in developing software distribution and software services. Roughly 50% from the income collected from taxes in the IT sector derives from software connected domains.

So much in Romania as much as in the analyzed countries there are emerged markets. In those markets exists a community of IT experts, large as dimensions and big as potential. The engross capacity is yet frugal. Generally, the resources granted in world are strongly connected with the engross capacity.

The impact of the IT industry over the economical development of Romania can be resumed like this:

- the IT market records a transition to software and IT services;
- the process of brains migration from the IT domain has slacken;
- telecommunication market is completely liberalized;
- the Government is concerned and encourages the automatization of the public sector;
- there is a need and increase of the IT expense in the most vertical markets;
- IT services are recognized more and more often as activities with high added value;
- the process of the privatization in the energetic sector and other utility sectors unfolds at normal parameters (until the half end of this year the liberalization of this sector is anticipated);
- premises for the increase of foreign investments are created – which will have a strong impact over IT expenses.

Regarding the impact of the IT industry over the economical development in the region we can limit the next issues:

- the increase of the IT sector in the region is strong and will follow a upward trajectory also in the next period;
- the expenses with software represents 16% of the total IT consumption from the South-East Europe region and increases yearly by 13%;
- roughly 47% from the IT sector employees are involved in the creation, distribution, support or software applications maintenance.

Unique way – the knowledge society. Re-launching the Lisbon strategy

In Lisbon in March 2000 within the framework of The European Council Summit, the Presidents of the European Governments committed themselves to achieve until 2010 the objective of making from the European Union the most dynamic economy in the field of knowledge. On the occasion of this meeting it has been desired a more complex and deep approach, having as a discussion topic an economy based upon knowledge, as a whole and much too high objectives have been fixed. Romano Prodi, the president of the European Commission between 1999 and 2004, well known for its sharp declarations, states for the Financial Times at the end of 2004 that the Lisbon Agenda has proved to be “a Great Failure” and one from the main factors leading to this failure being the obstinacy of the European Union member states to use the veto against the economic initiative proposed by the European Commission. The former Dutch prime minister Wim Kok ended his report with the same conclusions as Prodi when speaking about the Lisbon Strategy.

The report entitled “*Confronting Challenges: Lisbon Strategy for the Growth and Occupation of the Labor force*”, published on the 1st November 2000 illustrated the fact that the spread between the USA technology and the European one instead of becoming smaller, it became larger. This report was an important issue for the Mid Term Review of the European Council in 2005. On this occasion it has been decided the re-launch of the Lisbon agenda, the main directions aiming the change of Europe into a space much more attractive for investments and working opportunities, the promotion of innovation and knowledge, the creation of new jobs. In order to achieve these objectives a better partnership between the European Union and the member states should be developed²⁵⁸.

Speaking about the information technologies, at the level of Europe there should exist a unitarian strategy. The idea is not very new. It has been stated since the Lisbon declaration. Starting form 1994, many personalities in the field of the science, business and politics, coordinated by Martin Bangemann (European commissioner responsible for the information industry and technology) draw up the report “*Europe and The Global Informational Society*”²⁵⁹. The document was adopted on the occasion of the reunion of the Heads of States in Corfu and represented a major step for acting in the direction of an informational Europe.

²⁵⁸ Commission Statement “Working together for growth and jobs. A new start for the Lisbon Strategy”.

²⁵⁹ <http://europa.eu.int/ISPO/infosoc/backg/bangemann.html>

The main points in the report are:

- *The informational society – new ways of living and working together*: The informational society is considered a huge challenge for the decision factors in any field of activity, politics, economy, culture, that should adapt to the information revolution as it is itself an expression of the human knowledge. This revolution adds new ways of acting for the human intelligence constituting the source of change in the way of living and working together.
- *The revolution determined by the market* – the group recommends to give up some policies based upon some old principles belonging to the period before the informational technology revolution took place and in some cases adapting them to the new market requirements: the liberalization of the communication instruments market, the annulations of the non-commercial policies and budgetary constraints existing inside the IT&C field.
- *The Information Society foundation*: there are ten applications proposed to constitute the base of this new society:
 - a) distance work – more work places, new work places within a more and more dynamic society;
 - b) distance learning – “long-life learning” within a continuously changing society;
 - c) the creation of some network centers for research and study within the universities – the Europe intelligence management;
 - d) distance services for small and middle enterprises – the SME are the “engine” of the European economy; by making at their disposal e-mail services, files transfer, electronic data exchange systems, video-conferences, distance learning, the economic growth will improve and the rate of unemployment will decrease;
 - e) a road traffic management systems – a road informatization for a better life quality;
 - f) the air traffic control – the creation of a integrate communication system at the European level for the air traffic control;
 - g) health services integration – lower costs and better quality services for the Europe citizens by integrated the divers health systems;
 - h) auction electronic systems – the creation of an electronic auction system at the European level by adopting of some electronic procedures for the public acquisition;
 - i) the interconnection of the public administration systems at the European level - a better administration with lower costs by the implementation of an electronic data exchange system between the administrative entities;
 - j) the implementation at the level of the cities of the informational highways – the creation of a high speed communicational infrastructure allowing the use of multimedia applications within a real time for the local, regional and national level.

The Bangemann report constituted the first step in establishing of a general action framework, many of its recommendations being also present in the *Lisbon Agenda*. Bangemann group has proved to be too optimistic as concerns the established terms for the actions to follow. The initiators of Lisbon Agenda proved not to be so aware of the fact that their optimism did not materialized in concrete actions. Thus after 10 years from the Bangemann Report and 5 years after the Lisbon Agenda it was necessary to re-launch the Lisbon Strategy (the ideal being that it does not resemble the Matrix, which was reloaded and it would be good that a third part should not be initiated, and if it would happen, this should be entitled the Lisbon Revolution).

The objective of Lisbon Strategy, re-launched in 2005, proposes the changing of the Union into a more attractive space for investments and work, the promotion of knowledge and innovation and the creation of work places more numerous and of a better quality. For the period of financial schedule 2007-2013, the member states were asked to allot some amounts coming from the structural funds which are to be received in order to finance the projects linked to the fulfillment of Lisbon Strategy objectives. Thus, each member state should elaborate the Reforms National Program for the Re-launched Lisbon Strategy.

The power horses of the IT industry. E-Readiness

E-Readiness measure the degree at which the world states are ready for the Information Society, their adapting level for the advantages offered by the IT&C field.

Economist Intelligence Unit, beside the *IBM Institute for Business Value*, a leader in the field of *e-business* strategies, have published an annual classification about the training level in the IT&C field of the largest economies of the world from 2000 until present day. The classification evaluates the technology, economical, political and social activities from 68 countries and their impact on informational economy.

The level of training in the field of IT&C is desired to be a deep analysis of the infrastructure of the new technologies of a country and of the consumer, business environment and governments' ability to use IT&C for their own benefit. Whenever at the level of a country there exist more "online" or wireless activities – the premise is that the economic activity will become more efficient. Our classification permits to the governments to measure the success of their technological initiatives in online operations a large approach of the most promising investments in the world.

The E-readiness classifications evaluate about 100 quantitative and qualitative criteria, classified into six different categories, each of them measuring the different components of the social, political economical and technological development of a country. The basic principle is that the digital affair stands at the core of the business and in order that the digital transactions be adopted at an extended level and become efficient, they should flourish within a holistic support environment. E-readiness does not only refers to the number of computers, broad band connections or mobile phones existing in a country (although they form an essential component of the classification) but it also depends upon the capacity of the citizens to use the technology with ability, business transparency and linked systems and of the governments decision to encourage the use of digital technologies.

It has only existed one step from e-commerce to the e-business because at present everything has become *e-something* (even the food we are consuming is full of *e.s*). We are already discussing about e-leaders when referring to those states that have already arrived at the level of implementing information technologies. The advantages these states obtain are comparable with the advantages obtained two hundred years ago by the countries which were the first making the step towards industrialization (and in many of the situations these states remain the same).

At the level of the year 2006 the hierarchies in the field of the IT&C are almost unchanged. It has been witnessed although an up-rising convergence among the countries situated in the top group of IT&C training. At the same time one may state that many from the countries situated in the low groups witness major progress. There is also a visible and quite rapid migration of the countries situated at different development stages towards the further generation connection.

"The economic progress is more and more depending upon the innovations concerning the use of IT&C technologies", states George Pohle. "Within the economies fully using the Internet and information technologies, the future competitiveness is motivated by the creation of new services capable to exploit the infrastructure. For the developing nations it still remains a necessity, a steady investment in creating the infrastructure. Those responsible to create strategies should concentrate themselves upon such educational approaches permitting in future the creation of a tight connected world.

Having more than 1 billion Internet users and 2 billions of mobile phone users in the entire world and with a permanent progress at the most qualitative development levels in the field of technology, the world at the beginning of the 2008 may be considered much more "e-ready" opposite to the previous periods.

Abstract: The economic entities, which now deal with the international circulation of capital and trading operations, have spread their operations through the globalization process of companies’ interests, process which is determined by multiplication factors, competitiveness and competition.

The new dynamic of their commercial and financial international activities and the integration of financial markets, which are mainly supported by the IT development, have brought out new organizational and operative issues.

The purpose of this paper is to highlight the connection between the evaluation of insurance contracts (according to IFRS4) – insurance contracts, accountancy and calculation of indispensable technical reserves of insurance companies, and the evaluation carried out by expert systems.

Keywords: technical provisions, expert systems, accounting standards, insurance contracts

A large number of financial companies were able to rapidly adapt to opportunities or threats of new market dynamics. The duty of reporting to national standards, which are different from homeland standards or those given by the Communitarian Legislative Institution, has lead to an increased need of general orientation; as for the internal and external information users, this lead to the need of an efficient informational system, realistic and appropriate, which should build a real support for the decisional process and for helping the companies to easily build internal and external relationships in the business environment.

The modern financial market, characterized by a high level of efficiency in using economical-financial informational system, has certain limits determined by its instability, threatening the trust of the investors and sets unfair current market values, leading to financial crises. A transparent and match able informational system accedes to an efficient functioning of global markets of capital and each internal national market, allowing fair price estimation of financial services, an efficient resource allocation, a simpler credit-financing and an increase of the investors’ trust over the market.

In conclusion, the elimination of the financial markets’ instability and an improvement on the informational system are now targets which no one should ignore. It is very important to internationally apply a set of accounting standards in order to draw annual financial sheets; but this comes with certain disadvantages, not only in theory but in praxis also. One can identify 3 main objectives that come with IAS/IFRS implementation:

- Guaranteeing a proper functioning of capital markets
- Common accountancy methodologies, avoiding trouble caused by false information

- ensuring the balance sheet receivers, the necessary information for the decisional process
- protecting the investors through an effective comparative process of data generated by the company

But what are there 2 symbols used for the international accounting standards? The IAS presents strictly the accounting character. In time, these principles have been partially modified by introducing the current standards (IFRS), which are able to guarantee the information transfer at a high quality level, having accounting and financial character for presenting and drawing annual financial sheets.

According to paragraph 27 from IFRS Introduction, the IFRS standards are accounting standards that set the evaluation, presentation and description requirements referring to transactions and events that are important when it comes to drawing financial sheets; they can also establish requirements for transactions and events in specific fields. The IFRS are generally based on a main frame that approaches the basic principles of the information needed for financial sheets.

The IFRS are established on an international procedure that includes: accountants, financial analysts, business environment, stock markets, legislative and controlling authorities, professors and other persons or organizations from all around the world.

In the perspective of globalization and integration of financial markets, harmonizing the financial-economical information at an international level is a main priority which should be immediately solved, in order to create a universal accounting language. We can state that the accounting globalization is already real, and the national accounting principles are progressively replaced with a set of international recognized standards and procedures.

At a communitarian level, the insurance segment has 2 types of accounting regulations:

- Accounting directives - 91/674/CEE Directive – referring to annual accounts and fixed accounts of the insurance companies. Directive IV (No 78/660/CEE) referring to annual accounts of certain types of companies, Directive VII (No 83/349/CEE) referring to fixed accounts
- The Regulation of European Commission No. 1606/2002 (IFRS Regulation) which states the compulsory character of certain types of IFRS at a communitarian level, through CE regulations, for quotable companies to draw their financial sheets, starting from 1st of January 2005

In our country, the insurance companies will have to apply the OMFP 907/2005 stipulations, according to which they will draw a set of financial sheets accordingly to IFRS and to Regulation No 1606/2002, which states that the stock market quoted companies would have to apply IFRS for their fixed financial sheets, starting from 1st of January 2007. The transition to IFRS will not only be available for the accounting segment, but it will have more complex implications, from basic activity planning, up to strategic management.

Technical provisions for general security and life insurance, assets that cover the technical provisions, and dispersion of assets that cover the gross technical provisions

Any insurance company must consider the investment of its assets, which will cover the gross technical provisions[6], safety and investment performance. When the companies invest their assets, they will have to ensure the dispersion of their assets. This dispersion follows certain rules and well established principles. At the most, the insurer can invest the following:

- a) 90% of its gross technical provisions in depots and disposable assets existent in credit institutions, but no more than 25% out of the gross technical provisions by one of the credit institutions. The gross technical provisions are the calculated technical provisions before the transfers into reinsurances. It is important to see that the biggest proportion of the investments from the gross technical provisions of an insurance company are depots and disposable assets existent by credit institutions, with a high liquidity ratio, which can be easily used by insurance companies to pay the insureds' losses, and it is also a investment that generates profits such as deposit interests.
- b) 50% of its gross technical provisions in stocks operated on a controlled and supervised stock market and participations by collective investment companies. This restriction is due to the fact that the stock investments have an increased risk level, but the profits can be also very high.
- c) 40% of its gross technical provisions in land and buildings, whereby 10% can be invested in any land or building(s) that are close enough to each other to be considered effectively as one

investment. The 10% limit is compelled as a measure of reducing the investment risk in that particular land property or building due to the possibility of the depreciation of their current market value.

- d) 10% its gross technical provisions in tangible assets, other than land properties and buildings, because the tangible assets are assets of greater value, that are for long-term use and their liquidity ratio is small
- e) 5% of its gross technical provisions in stocks and other titles such as negotiable securities, bonds, credits and other instruments emitted by the same entity, due to forethoughts in investments that have a high risk level.
- f) 5% of its gross technical provisions in unsecured loans, including 1% for any single unsecured loan, other than loans granted
- g) 3% of its gross technical provisions in cash-disposables. One can see that the insurance companies have strict rules in relation to the cash in hand; they can keep only 3% of their assets in cash, because keeping this money in cash is no investment, and it brings no profit.

Principles commanded by the Insurance Supervisory Commission

The principles commanded by the Insurance Supervisory Commission are referring to:

- a) Diversification and dispersion of assets that cover the gross technical provisions, so that there is no excessive usage of certain categories of assets, investment market or of an investment.
- b) Caution over investments in certain asset types that either have an increased risk level, nature of the asset, or the situation of the issuer.
- c) Limits over certain asset categories in the case of reinsurance contracts
- d) Operating with the assets of other branches is made similarly, when the assets include an investment in a branch that manages all or a part of the insurers' investments.
- e) The percentage of the non-liquid assets that cover the gross technical provisions must not exceed 10% of the total assets.

Principles used to determinate the technical provisions

The value of the technical provisions for the life insurance [7] is calculated through a prudent actuarial prospective evaluation, including all future engagements that are stipulated in the insurance contract, containing:

- a) All the guaranteed benefits, including the surrender guaranteed costs
- b) Bonuses for the beneficiaries of the insurance contracts, and all available options for the insured, based on the insurance contracts
- c) Expenses, including factorage, out of which one will subtract the cost of the future owned premiums

Referring to the evaluation of technical provisions, we can say that a careful evaluation is not an evaluation "according to the best estimation", but it will need to carefully carried out, due to certain elements that influence the value of the technical provisions.

The chosen asset evaluation method is also very important. It is vital to specify that the technical provisions are determined separately for each contract, although accepting a simplification and approximation of the result, on condition that the result is similar with the approximation. The life insurance contracts that stipulate the present of the insurance provider to the benefits obtained from the mathematical provision, one will need to calculate the benefit and return provision. The mathematical provision is calculated as net value. Another benefit-category is that of insured technical interests or other types of assurances; these benefits are included in the life insurances related to investment contracts that stipulate a complementary establishment of technical provisions for the cover of the benefits.

For a life insurance company, calculating the premium provision and loss provision is very important. The premium provision is calculated monthly by summing the shares from the gross underwritten premiums of the unexpired periods of the insurance contracts, so that the difference between the volume of the

underwritten gross premiums and this provision would reflect the gross premiums allocated to the fraction of risks that are no longer available at the calculation date, for each and every contract.

The loss provision is available for the losses that had already been reported, and it is calculated for each insurance contract whereby the event has been modified, event which had been formerly ensured by the insurance contract. The loss provision depends on the predicted expenses, which will be allocated for the clearance of those losses.

The expert systems are one of the most important achievements of the Artificial Intelligence. They support the human ability of solving problems, and the development of this particular field should be seen as an evolution of knowledge. The interest in expert systems technology and similar applications is constantly growing, even though the funds allocated to this field are rather small.

The last years show an improvement of the entire artificial intelligence field, which evolved as an active discipline and it is constantly growing. Nowadays, most research subjects are focused on Artificial Intelligence, especially on Expert Systems. The main research fields are the following:

- Causal configuration
- Strategic rationing
- Explanatory system
- Gathering and validating information
- Anatomic reasoning
- Temporary reasoning
- Intelligent training with computer assistance
- Integrating the natural language with medical expert systems

A large number of expert systems evolved in many medicine fields. At the same time, the expert system technology was applied successfully in other fields. This development brought to the improvement of the knowledge gathering process, by using genetic algorithms, and intelligent agents for creating Internet applications (intelligent search engines and Internet browsers) and for e-commerce applications (intelligent customers or sales, methods based on artificial intelligence for the agents' communication).

The developed countries are spending billions of dollars to plan and build the economical infrastructure: computer networks. This electronic and informational structure, which is frequently based on satellites, brings together entire companies, connecting them through computer networks and buyer-seller networks. Also there are other networks that are connected.

The man's intellect has always searched to improve his living conditions. Nowadays, the technology is so high-evolved, that man wouldn't even dream of such things in the past. And it will not stop here. A similar phenomenon corresponds to the expert systems. It's up to our imagination to see what these expert systems really are. But one thing is for certain: nowadays, the expert systems are highly important. This vast informational universe can be found in numerous fields. And so the purpose of this paper, that of the implications of expert systems, is only a starting point in their study.

The virtual world changed the way we think. That is why the economical entities must understand the increased importance of expert systems. Globally, one can identify the following trends of expert systems:

- Creating powerful KBS (Knowledge Base Editor- source / editor), that are perfectly adaptable to a particular field, based on which one can create expert systems
- Creating tandem system which combine knowledge based solutions with procedural solutions
- Setting standards to certain concepts and ideas
- Connecting the expert systems with the data bases

By introducing the artificial intelligence into a company, at a large scale, then the entire organization must be transformed. If we analyze the three most important factors: organizational structures, activity differentiation and decentralization, one can see a large impact. At the financial and accounting activity level, the differentiation must consider the transparency of the financial-economical information. Furthermore, one must consider setting standards to the decisional process and decision decentralization. By conducting a large number of surveys, one can reduce the expert system costs.

The ingenuity of the expert systems' methodology consists in the connection between the three main elements: knowledge basis, inference engine and user communication interface. The expert systems do not act isolated from the other elements of the exterior environment where they are implemented. It can be used by other external programs or it can send information to other programs. Most expert systems are interactive systems; this imply that their interface features communication channels with human users, it gathers information and data with the help of special sensors: form data base management programs up to table calculation systems or even programs that manage simple files. Furthermore, the expert systems are able to create and analyze data bases; they can draw reports or control various devices and instruments.

Creating the interface and integrating it in the environment is not always similar for all expert systems. That is why one needs different interfaces depending on the inputs and outputs necessary to the operating environment. Based on this fact, the expert systems are divided into 4 categories:

- a) Intern controlling systems
- b) Toll payment systems
- c) Financial planning systems
- d) Systems for law interpretation, other than laws that refer to toll payment

The expertise is an intensive knowledge and understanding of the specific field, knowledge gathered through training, reading or experience. The following knowledge categories are examples for what an expertise might include:

- Insurance facts
- Insurance theories
- Insurance rules and procedures
- Rules referring to what procedures should one follow in certain situations, for solving the occurred problems
- Global strategies used for solving insurance cases
- Metaknowledge

All these allow the experts to rapidly take better decisions than non-experts. It takes a long time and a vast experience to become an expert, and this way even beginners or intermediates can become experts. The main feature of an expert system is to be able to conduct an expertise, which is in fact the ability to execute the expertise at least at the level of a human expert. This includes not only the ability to solve the problem, but to solve it as fast as possible (faster than a human expert). An expertise implies that the knowledge base of the system must be comprehensive and rich. An expert from a certain field has always high proficiency in knowledge, as compared to a beginner. The experience is probably a major factor to be taken into consideration.

Conclusion

Given the existence of a modern and motivating management, experienced professionals, competent and motivated users, the premises of creating an expert system are similar to those of creating new investments. This will allow the expert system to be implemented as a practical, efficient, high-performance system which will help the economic entity in its activities.

In conclusion, an expert system can be created not only for simple and small problems, but also for complex ones. Small problems stress the human expertise less, whereby the knowledge base can be easily done. As for more complex issues, the human expert is more stressed and creating the knowledge base can take ever longer. This is why one must create an expert system that will solve not only small, but also complex problems.

THE IT AUDIT – A MAJOR REQUIREMENT FOR THE MANAGEMENT QUALITY AND SUCCESS IN THE EUROPEAN BUSINESS CONTEXT

Ivan Ion

Surcel Traian

ASE București Piața Romană 6, 0728884615, tsurcel@ase.ro

Amancei Cristian

ASE București Piața Romană 6 0740181433 cristian.amancei@ie.ase.ro

A requirement for the improvement of the quality management for the Romanian companies that are integrated in the European environment is represented by the development of an informational partnership between the actors involved in the company network. This partnership must be characterized by credibility, conformity, performance and security. The IT&C system represent the hardware and software support of this partnership, and the IT audit is the process that certify it's conformity. In the audit process, the main accent is on the security audit due to the importance of the vulnerabilities, threats and IT risk analysis. The list of measures that are proposed at the end of the audit to company management should be incorporated in the company security policy, that is the starting point for the ISMS – Information Security Management System, part of the company general management system. The implementation of the Business Continuity and Disaster Recovery Plan is one of the most important measures in order to increase the confidence level of the business partners and to provide safe environment for business continuance.

Key words: Management, IT&C Systems, IT Audit, ISMS, Security Policy, Business Continuity, Disaster Recovery Plan.

1. Management, informational partnership and IT audit

In the space of business environment extended at European level, between the multiple requests of a quality management, it retrieves the necessity of increasing of the competitiveness together with enhancing of the cohesion and cooperation between of the actors integrated in the company's business network logistics chains.

The business relations between suppliers, producers, outsourcing companies, transporters up to the final customer, the consumer, should be based on an informational partnership characterized by *credibility, conformity, performance and security*.

Credibility refers to the confidence in the results and reports provided by the company. The Sarbanes-Oxley Act, adopted in audit, states and straightness this mandatory condition for running out the normal economical processes.

Conformity refers to legislation, standards and norms conformity regarding the application of the best practices in the company's business activity.

Performance is regarded as the effectiveness and efficiency of the activity performed in the logistics system of the company.

Security refers to the plurality of the four attributes: information confidentiality, integrity, availability and no repudiation.

The IT&C systems provides the hardware and software support for the informational partnership between the company and the business network members developed by it. The IT audit certifies the quality of the informatics system and by this, the managerial quality of the electronic information.

The Romanian companies, members of the European economic environment are now obliged to approach the IT systems audit according to the international standards, the most used of them being CobiT developed

by ITGI/ISACA. In accordance to this, the BSI certification – British Standard 7799 for Information Security can be obtained.

The relationship between the management quality and the information security is important and it has three coordinates which illustrates the economic dimension of the information security. This three coordinates are: consolidation of the management capacity to protect the company structure and resources; development of the management ability to guarantee the business integrity and efficiency; assurance of a stable economic environment and continuity of the company business activity.

The IT audit, according to the CobiT standard, performs a control examination of the IT entity. The audit, as it is presented by ISACA - International System Audit Control Association, is a process that is used for evaluation of the audit evidence, in order to determine if the physical protection of the IT&C assets (controls from the CobiT standard) and the management measures by which the data integrity is insured, leads to an efficient utilization of the company resources and carrying out the company goals.

2. Types of IT audit

Analyzing different methodologies and opinions of various authors, we consider that the audit missions performed in practice correspond to a complex typology. For this typology we recommend four criteria for structuring: the audit organization mode, the moment of the audit, the audit scope and the audit area it covers.

Regarding the audit organization mode, the way the audit activity is organized, it can be differentiate the *intern audit and the extern audit*. The intern audit represents an evaluation or an organized monitoring made by a company's own department, while the extern audit is performed by an independent auditor organization.

Regarding the moment when the audit is performed, it can be differentiate the *preventive audit and the corrective audit*. The preventive audit is defined as an examination of the operations made before they are effectively done, having the advantage that it can prevent a loss before it appears. The corrective audit is defined as an examination of the way the operations are made. It can lead to loss recovery; it can prevent the same mistakes to be repeated in the future thru establishing responsibilities for the guilty persons.

When establishing the scope of the audit, we can differentiate three audit categories: the conformity audit, the attestation audit and the performance audit.

The conformity audit certifies the responsibility regarding the transactions and the reports made based on the respective transactions. The attestation audit refers to the credibility of the final statements, attesting or not, if they present a fair view of the company and the transactions it realizes. The performance audit examines the performance in relation to the economic inputs and the outputs by analyzing the resource allocation under the economic efficiency principles.

The area covered by the IT audit are that the most important criteria. Regarding this criterion, the members of the audit team can handle the following segments of issues: *systems and applications, information processing environments, development systems, IT management and the Client/Server architecture*.

All these five audit segments focus on auditing the information security and refer to the following aspects: the physical security of the data centers and the logical security of the databases, the networks security and the applications security.

3. Risk analysis

The management – audit relation is best reflected by the management's responsibilities in the company regarding defining, implementing and monitoring of the internal controls that assure the decision processes feedback in the company.

The most significant problem regarding these controls refers to the analysis and risk management, especially due to the fact that the Internet contributes to an internationalization of threats and consequently to the risk exposure. IT risk is evident through its own components: threats, vulnerabilities and impact. The threats exploit the vulnerabilities of a system causing by its impact losses and managerial difficulties. Generally speaking, the risks associated to an information system regard:

- the physical security risk, regarding the existence of the security, detection and fire alarm systems, protection systems against tension fall-down, robbery, natural catastrophes, physical protection of the memory devices;
- the communication risk that may arise from connecting to the public network and it needs a firewall, antivirus protection, utilization of encoding techniques and the virtual private networks – VPN;
- the risk regarding the data and transactions integrity;
- the access risk regarding assurance of the information and network confidentiality, data and database integrity and their availability. The passwords management, monitoring and incidents resolving report is considered;
- the risk regarding the information system documentation and the personnel risk;
- the unpredictable situations risk management (the availability risk) is the risk associated to natural dangers, disasters, system fall-down that may lead to irrevocable data losses, in the absence of activity monitoring procedures and disasters recovery plans.

Only inventorying the risks is not sufficient, the IT audit should also contain a risk evaluation, the impact of the risks, from point of view of the losses they may cause. In practice, it operates with quantitative and qualitative methods to evaluate the respective losses.

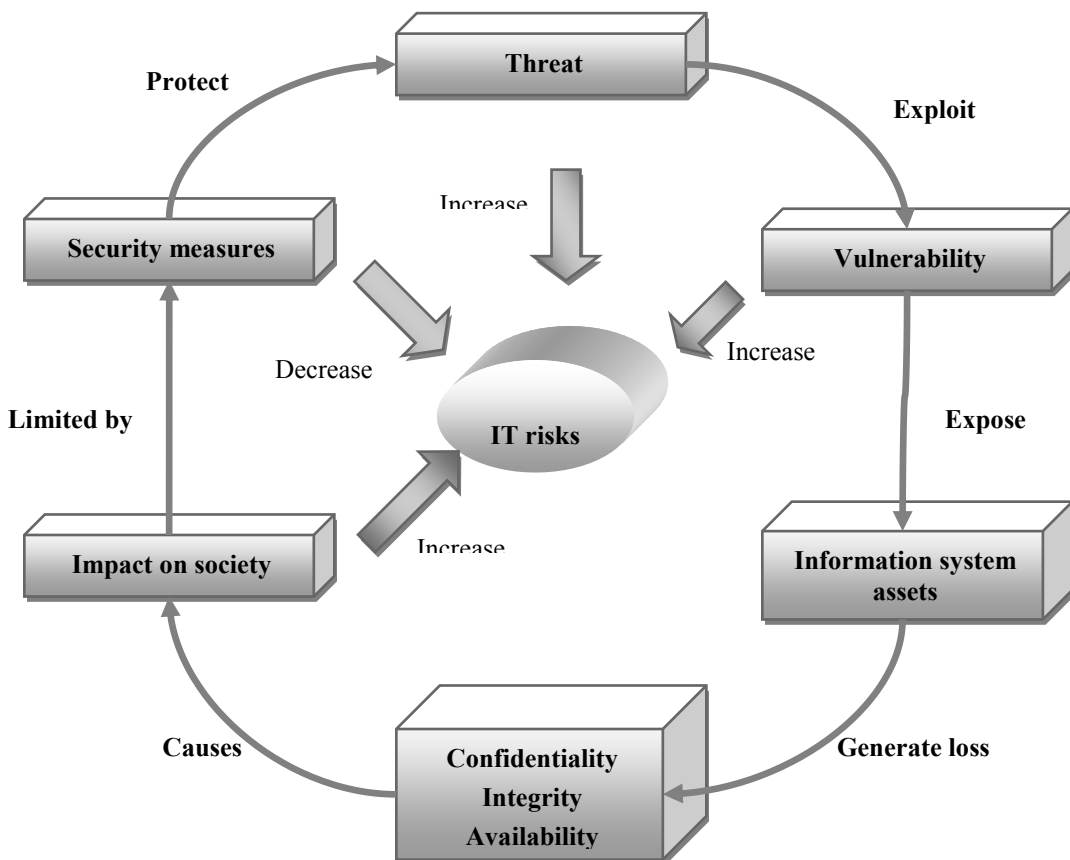

Fig. 1 IT risk components

4. Business Continuity and Disaster Recovery Plan

The most important measure recommended from the IT auditors to the company management, in order to lift up the partner level of trust and ensure the success undisturbed by the incidents. The principal reason for a company to develop a Business Continuity and Disaster Recovery Plan is the assurance of the company ability to operate efficient in the case of severe disruption of the normal operations. The severe disruption can appear from different sources:

- Natural disasters (fires, flows, earthquakes etc.);
- Equipment or processes fall-down (disks, programs, databases etc.);
- operating errors, sabotage;
- Terrorism or premeditated informatics criminality acts (for example, “denial of service” actions, hacking, viruses, worms, etc.);

The prevention of such events is not possible, but it is important to resume as fast as possible the essential operations of IT&C system. We should differentiate the loss prevention plans from the disasters recovery plans.

The loss prevention plans focus on minimizing the organizations exposure to the elements that may threat the normal operations. They basically contain activities planned on a regular basis like backups, authentication and authorization in the system, scanning for viruses and monitoring of the system usage.

The disasters recovery plans focus on a set of actions that must be realized by an organization in order to restore the normal services and operations in case of a serious loss. Generally, such plan will not describe the actions for every type of possible disaster, but it would search for common elements of the possible disasters, like information losing, personnel losing, equipment losing, the loss of access to information or facilities.

Conclusions

The projection into practice of these major requirements of a quality management in the European context means the implementation of a special component dedicated to the information security, called ISMS - Information Security Management System, in the informatics system of a company. The IT&C audit will focus on this system, without the resource consumption that is realized today for the classic IT audit.

ISMS is the frame for establishing, operating, monitoring, reviewing and developing controls and measures for assuring the information security in the context of an IT governance into an organization. ISMS become an organic component of the IT system and, as a consequence, a part of the general management system of the organization. ISMS is presented in ISO/CEI 17799 – 2000 standard, that has been taken over and adopted in Romania also by ASRO as an Information Technology Standard – practice code for the information security management SE ISO/CEI 17799 : 2004.

The security policy represents the central element of the ISMS. The security policy is made of a set of measures accepted by the management of the company, which states clear, but flexible rules that determine the standard operations and technologies required in order to assure the security. The security policy represents a document that states the main requirements or rules that must be known and implemented for assuring the security.

Audit certification, by obtaining the BSI Certificate awarded by the UK Accreditation Services – UKAS, even on-line, regarding the way an organization deals with the information security, respectively the control objectives, the security measures, the information security politics, procedures and processes, become a basic condition of an efficient management at European standards for the Romanian companies.

THE PATTERNS DEVELOPMENT PROCESS FOR E-BUSINESS APPLICATIONS

Lazărică Marinela

Universitatea "Constantin Brâncoveanu" Facultatea Management Marketing în Afaceri Economice, Brăila, str.Rubinelor, nr.16-18, mlazarica@yahoo.com, 0744330616

The main aim of this paper is to show how e-business represents an order of magnitude increase in the complexity and sophistication of systems used by large organisations, and how the IBM initiative can help address associated problems. The most significant contributing factor to this complexity is the high degree of integration required by virtually all the systems that contribute to the basic act of buying and selling goods and services.

In present, it seems likely that the ability to handle complexity, and deliver systems in a timely manner, will ultimately become business critical factors; the "Patterns for e-business" initiative is a frontal assault on proliferating complexity and integration.

Keywords: *e-business applications, patterns, best practices, integration of systems*

E-business applications

The specialists characterize these applications in this way:

- There is no longer a simple choice between buy and build. Systems architects and designers are faced with build, buy, rent, connect, or any combination.
- The consequence of errors and downtime with applications that interface to customers and trading partners are often major, and simply cannot be tolerated.
- It is often stated that Internet time runs several times faster than normal time. Speed of response is critical. If calling on accumulated experience means that a system is delivered significantly faster, then the business benefit will probably be very significant.
- E-business application development technologies are more complex and require very high levels of skill. The complexity of tasks means that Java and C++ are essential tools, and reuse of design components would reduce workloads considerably.
- The number of issues that systems need to address has become much larger. This includes availability, security, systems management, extensive integration with other systems, and increased application complexity.

Just as many other areas of business are using benchmarking and best-practice to establish a starting point for their activities, so IT professionals increasingly need a set of architectural and design 'best-practices' as a starting point for their activities. And the Patterns for e-business can be considered like this.

The importance of best practices in application development

The Internet is an excellent medium for communication, but, more importantly, it has evolved into a powerful business tool, a place where companies get real work done, establish real competitive advantage, and generate real growth and profits.

In March of 2000, Lou Gerstner, the chairman of IBM, predicted a major fallout in the Internet industry, not because the technology or medium itself was inherently flawed but because many companies experimenting with e-business were not adhering to sound business practices. The trends and new requirements proven *the importance of using best practices in the development of successful e-businesses.*

This rule of using best practices also applies when developing the applications and systems that run today's e-businesses. Application developers require proven techniques for building systems to take advantage of this new communications and business medium.

“Patterns for e-business” initiative of IBM

Patterns for e-business address a wider set of issues, such as design, development, integration, deployment, operation, and management for Web-based applications. These issues will become even more important over the next few years as systems architectures become more complex in response to the need for highly integrated, real-time corporate e-business applications. The complexity and variety of systems will ultimately expose businesses to unacceptable systems architecture risks, unless experience is gathered and abstracted as it is with the “Patterns for e-business” initiative.

The complexity of Web-based applications goes well beyond that of traditional enterprise systems. Security, systems management, interoperability, performance, availability, and many other issues are amplified in importance as soon as systems face into the external world. This is compounded by a need to integrate with existing legacy applications for processing of core transactions and for other activities such as on-line cross selling. The array of technologies needed to address these issues is bewildering and it is, of course, imperative that they all work together. This is why it is so important that “Patterns for e-business” addresses the runtime architectures with instantiations detailing actual products used. Simply knowing that a portfolio of products can work together is a highly valuable piece of information.

IBM has compiled the collective wisdom and experience gained from more than 20,000 successful Internet-based engagements and transformed that wisdom into the IBM Patterns for e-business. These Patterns provide the best-practice blueprints and tools to facilitate the application development process and enable companies to shorten time to market, reduce risk and, in general, see a more significant return on investment.

No matter the methodology driving an application development project, the major steps in successful projects are essentially the same.

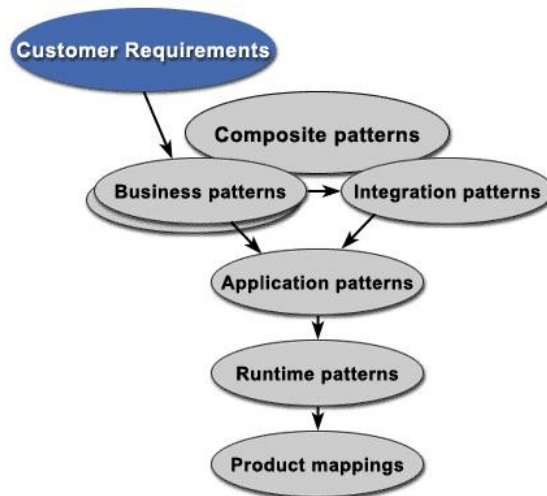

Fig.1. The Patterns for e-business layered asset model

Source - <http://www-128.ibm.com/developerworks/patterns/>

The Patterns provide assistance in all phases of the development process, beginning with requirements gathering. As a development team puts together requirements, the Patterns Web site helps match those requirements to the appropriate pattern, **Business pattern**. As the team refines the requirements and determines which existing systems, data stores and infrastructure will be integrated into the system, they can use the **Application pattern** to develop how application components and data within a business solution interact.

After choosing the Application pattern, the team can match **Runtime patterns** topology based on the existing environment and business needs. The Runtime pattern establishes the components needed to support the chosen Application pattern. Without advocating a particular vendor, this pattern defines the

logical middleware nodes, their roles and the interfaces among these nodes in order to meet business requirements.

Developers must now determine which products to use for the actual development. At this point, the Patterns provide a wide range of options and lend the developer significant assistance. Developers can access from the Patterns Web site **Runtime Product Mappings** that identify tested, optimal software implementations for each Runtime pattern. Associated with each Runtime Product Mapping on the Web site are best-practice application, design, development and management guidelines that have been gleaned in the process of developing these patterns. Developers can use them to access a wealth of information about other, similar development efforts.

Conclusions

The most significant contributing factor to this complexity is the high degree of integration required by virtually all the systems that contribute to the basic act of buying and selling goods and services. This integration is not confined to systems within the enterprise, but increasingly includes systems belonging to trading partners, third-party trading exchanges and perhaps most importantly those that face out to the customer.

The Patterns development process is a live project, ever-evolving and being updated as new products are released and are used in the building of real applications. IBM has constructed the Patterns and the Patterns Web site to enable development teams to work through the development process using their preferred methodology or the methodology suggested by consultants engaged to assist in the project.

Application development, regardless of the complexity of the project or the methodology, will benefit greatly by employing a best-practice approach to the process. While some aspects of an application development project may be unique, all development process generally follow the same major steps.

The IBM Patterns set the foundation for scalable e-business objectives. Companies can find the tools to build their first Web-based application, or link to additional services and products that will enhance even more complex projects. Using open-source standards, the Patterns take a vendor-neutral approach that accommodates today's complex environments and leverages the value of a company's existing infrastructure investment.

*Today, in the new economy, while the possibilities for software are seemingly limitless, so is the growing demand. The problem is that speed and quality have typically been opposing forces in software development, and they still are. In the past, businesses could sacrifice software quality to respect the deadlines, or compromise on software features to meet time-to-market deadlines. In the new Internet economy, it have no choice: the software developers **must produce higher quality software**.*

For this reason in the paper, we described the key points of software development process in the new economy, trends and major characteristics, the evolution of this process. In particular, the ecommerce system development methodologies which resolve the problems of e-business applications.

Keywords: *ecommerce systems, software development process, CMS-Content Management Systems, new economy, new business*

The major characteristics of new business

“Software is the world's most critical industry and will be for years to come. Yet most companies are spectacularly unprepared to create the software that will redefine how they interact with customers or that will help deliver their goods and services in new ways. “ – affirm Mike Devlin, Chief Executive Officer, IBM and Paul Levy, CEO, Rational [2].

Technology still drives the new economy, the e-economy. The difference is, the stakeholders in the new economy have remembered how important profitability is. The Internet - with the software and communications technologies that drive it - is changing everything.

But, software is everywhere, from the cars we drive to military equipment (today, 80% of a fighter jet's capability is performed by software, compared to 6% in 1960); to the cell phones that are allowing us more freedom and mobility. As software is becoming more present in more places, so too is the Internet impacting every business in this e-business world. become For businesses the world over, the Internet continues to drive more change and more opportunity.

Today, in the new economy, to be competitive, every business must embrace the technologies of its customers, its supply chain, and its partners. Software is increasingly used as the basis of this connection.

It has made so many surveys in this direction and the conclusions are:

- Software will continue to become increasingly complex.
- The new economy requires software that can be continuously updated.
- There are unlimited possibilities for software's growth.

Grady Booch has often said, *"We cannot reduce complexity in how we build software. The best we can do is manage it."* Today, the software developers are pressured to deliver more complex applications that require more mastery of more computing concepts and techniques than ever before. In building for the Web, the trend is toward even more concurrent, more distributed, and more connected applications.

In the past, most new software systems were developed by an internal IT organization, and the predominant value of software was in reducing the cost of doing business. Today, the new demands are competition, revenue and ever-faster cycles of development and upgrade. Indeed, the Internet has revolutionized the ability to both include the user during development and deploy software products transparently to a broad user base.

This need to support continuously evolving systems has driven today's software development processes away from the traditional sequence of waterfall development activities toward a highly iterative model. In the past, many software domains drew a distinct line between development and maintenance, but future software projects (legacy system upgrades, new applications, or some combination of the two) will not differentiate much between development and maintenance.

Iterative development and the Internet are also driving software engineering toward a more homogeneous software management approach. This includes process frameworks, advanced requirements and design notations, and Web-based architectural patterns.

Evolution of information system development methodologies, in particular ecommerce systems

First of all, the term *information system* is often used. A special type of information systems is *web information systems*. The development of complex, data-intensive web applications is becoming simpler due to the usage of content management systems [3]. Conventional information systems development methods as well as web application development methods do not cover the specific needs of a method for web content management implementations.

A large number of information system development methods are available (fig.1). Many specialists considered that web applications can be seen as a subtype of information systems. Using data-intensive Web applications raised new problems concerning consistency, navigation, data duplication, content audit and control, tracking of content and mapping the website workflows on the business processes [7].

The solution for these problems was found in content management. *A content management system* (CMS) makes it possible to create, archive, search, control and publish information from within a flexible and integrated environment [1]. A special type of content management systems are CMS-based Web applications, which are defined as Web applications for the management and control of information [5].

In academic and professional literature no specific methods on this subject exist. Currently, established information system and Web application development methods are being used, but these methods are not able to cover specific content management aspects.

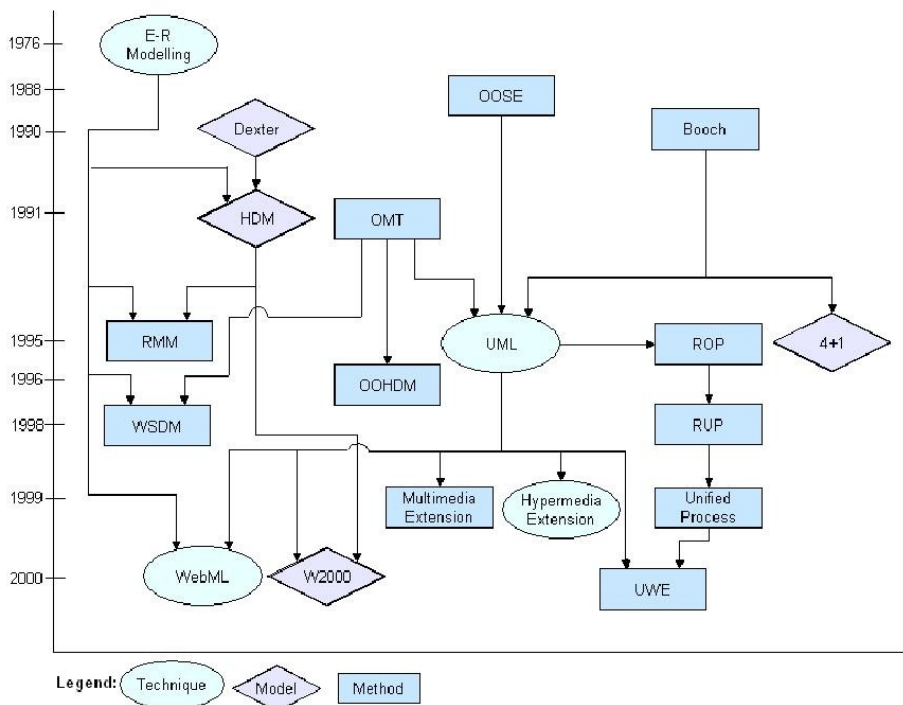

Fig.1. Relation between design method , model and technique

Source - Inge van de Weerd, *WEM: A Design Method for CMS-based Web Implementations*, technical report Utrecht University, 2005, pag.18

The software development process of ecommerce systems

IT professionals, web designers, engineers, IT managers or executives, everyone must understand how to apply software engineering concepts for ecommerce systems, for better integrate their software with the needs of their business. IT professionals need to establish a methodology that resolve all the problems of e-business applications. Those software developers who understand the concepts of analysis, architecture and design, will have the success in developing ecommerce systems.

It is important to understand the ecommerce systems that a new and unique form of software development which must not be build with the same methodologies necessary to build any information system. The development of successful ecommerce systems depends on powerful analysis, design and implementation.

The software developers must be able to understand the customer needs, provide user interface requirements, establish security, network architecture, ensure integration with legacy systems. Standard methodologies tend to depend on the existence of homogeneous conditions in business, but this fact didn't exist for ecommerce systems.

Because it doesn't speak about the information system analysis or design without the approach of software life cycle; for ecommerce systems, IT specialists must use a life cycle witch integrates creative design, advertising, marketing concepts (distinctive characteristics of the Web) and software engineering requirements. This life cycle must combine the traditional software life cycle with the spiral life cycle. The spiral approach develops each component of the total project independent, as such should have its own life cycle, each component can be middleware component, objects or reusable applications. The traditional approach is used for analysis, design or implementation.

In this way, it takes the best from both cycles.

Conclusions

Over the past two decades, the software industry has moved unrelentingly toward new methods for managing the ever-increasing complexity of software projects.

Two important remarks must mentioned:

- **Software will be the key differentiator for every business in the new economy.** It connects businesses to customers, suppliers, and partners. It empowers everyday devices.
- **Reduce complexity and improve processes at all levels of software engineering.**

The full integration of electronic communications and the business sector happened. Indeed, it is happening now as ever more modular ecommerce systems are being developed and deployed into the marketplace.

It is important to understand the ecommerce systems that a new and unique form of software development which must not be build with the same methodologies necessary to build any information system. The development of successful ecommerce systems depends on powerful analysis, design and implementation.

IMPLEMENTING E-MANAGEMENT IN SMALL AND MEDIUM ENTERPRISES

Maiorescu Iulian

*Academie de Studii Economice Bucuresti, Facultatea de Management, iulian.maiorescu@gmail.com
0744 575 345, www.mcode.ro*

This article presents the practical aspects of the e-management concept applied to SMEs (from Romania, but applicable to any new EU member): what is actually an e-management system, why to implement it in a SME and what are the key aspects to consider. The theory is demonstrated with several case studies (both positive and negative) to emphasize the importance of each step from the e-management implementation.

SME, e-Management, e-Commerce, e-Business, Internet, Management, IT

Understanding e-Management, e-Business and e-Commerce

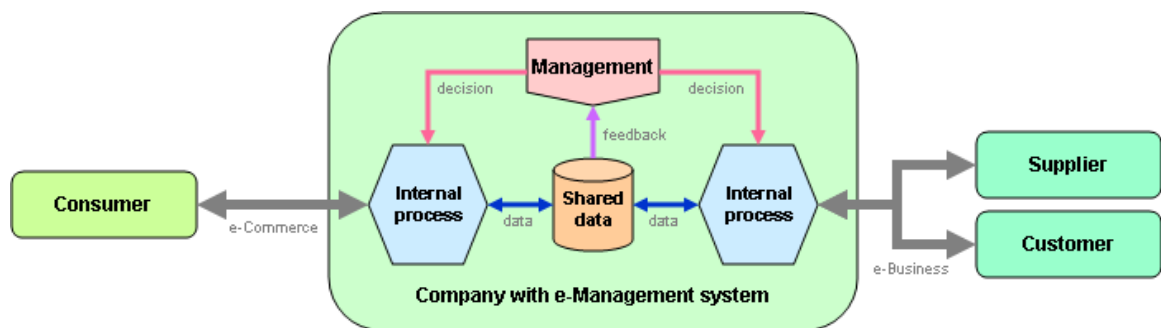

In the past decade there were a lot of discussions around those new terms, and they were marketed as the magic solution to all company problems. As any new technology they remain mostly only at theoretical stage, and were implemented first on large companies.

SMEs didn't use those type of technologies until recently, mostly because of implementation costs and lack of expertise on those domains. Since Internet and computers are now common things – like facsimiles once – it's trivial for any company to have at least a website. But a website is not any of those terms above, a website it's about marketing – or e-Marketing.

e-Management is about taking all the company's internal and external organizational processes to the next level: using software tools to centralize the data, to interconnect systems and customers and to use the feedback from those tools to take appropriate action. Using basic tools like "Microsoft Excel" or "Microsoft Access" is not quite e-Management, but is an intermediary step from paper-work to the true e-Management.

e-Management systems allow the interconnections of all SMEs suppliers, partners, customers and consumers, providing accurate measurements for all indicators required for an effective management decision – *you cannot manage what you cannot measure*.

Implementing an e-management system is not an easy – and not cheap, so accurate planning must be prepared before taking action. But the costs will be covered by the benefits if the company is expanding and the processes have an increased complexity.

Data flow in e-Management

e-Business is about connecting more companies using an integrated system, and this can be a part of the e-Management system. e-Business is the next level of fax and email orders, like connecting a company with a supplier or with an outsourced company.

e-Commerce is very common those days, and is about connecting the customer with the company. The typical cases are on-line stores from the Internet.

Using those new approaches is not mandatory for a SME, but since Europe become a single market exploring the new opportunities and meeting the new demands will soon impose e-Management as a new standard for any successful SME. Any Romanian SME working with other European companies which already have standards applied (ISO, TUV, etc) will have to implement an e-Management system.

Internet is usually the main channel where all the data flows, and due to mobile technologies, managers can have access to key information about their business anytime, anywhere – so travel times are no longer “dead times”, the manager can actively control the business even if they are not in the office.

E-Management provides the necessary support for a company to achieve the objectives using a clear path, measurable and predictable.

Arguments for Implementing an e-Management System

To implement an e-management system a SME must be first of all sure it needs one. Without a rigorous planning the new system can soon become a bottleneck and using it can cause disaster in the company.

Arguments to implement an e-management system:

- The company has many internal processes (manufacturing, shipping, customer support).
- Communication between the internal processes is performed using basic tools (phone, papers).
- There are many cases when production is delayed because of lack of stock.
- There is no (or poor) control of product’s life cycle (who manufactured it, who tested it, who packed it, when, etc).
- The management cannot identify the source of customer complaints
- Partners and customers are located in a different geographic region (country) or they use a different language
- There is a clear view of all processes and of metrics required from each process.
- There is a budget for e-management implementation (time costs, training, equipment, framework development).
- Employees, partners and customers have an acceptable technical IT level.

Arguments to not implement an e-management system – or to delay it

- The company has a limited number of customers, or the customer feedback is not vital.
- Customers and partners are located close to the company and they have very tight relations.
- There are few processes and they are simple and straight forward.
- There is already a simple process implemented for keeping record of production flow, which provides acceptable results.
- There is no budget for implementing a new e-management system, including the cost of staff training.

Steps to Implement an e-Management System

Any form of e-management implementation must go through the following steps. Skipping any of those steps can lead to future disasters in the company.

1. Documentation of all processes – all internal and external processes must be documented. For every process there will be described the actions performed, the responsible for every action, the information used (from other related processes) and the information provided to the next processes. A definition of metrics and performance indicators for every process is also required.

2. Definition of requirements – what SME management expects from the new e-management system: what global system indicators should be provided, when they will be calculated, and how those indicators should be calculated. A detailed descriptions of all capabilities will be also defined – in order to be more accurate, it's a good approach to describe also what the system should not do (this will avoid further confusions). The requirements will describe where and how the data will be presented – in a computer application, on the internet, will be sent by email, etc.
3. Provider selection: usually there are two main options: buy a (software) tool that meets the requirements or contact another company to develop a custom (software) tool according to the requirements. The decision here must consider several factors, besides costs:
 - How many requirements can be met by using the off the shelf products – most of those products meet some general requirements, but may not meet some key requirements which disqualify them.
 - What customer support is offered by the provider and what are the service terms. Training for all company staff will be required and those aspects should be treated with care, especially if the system will be implemented and customized by another company.
 - If there are options to develop and implement the system in several stages, for a flexible depreciation schedule.
4. Purchasing/development – if “of the shelf” products will be used for the e-management solution, they will be purchased in a custom configuration (if possible) with documentation and training programs. An extended support contract is useful. If the e-management tools will be developed by another company it's better to keep close relationship with the development team. For a successful final product, intermediate product snapshots can be tested during the development cycle, so adjustments can be made earlier.
5. Testing period – depending on the complexity of the e-management process, there will be a testing period of the new system. In this period there will be used both methods in all processes – the old method and the new one – to ensure the continuity of the production process and to check if the indicators provided by the e-management systems are reliable. This phase should be ended after all the staff is accommodated with the new system, the company went thorough all possible cases (including end of the year backups and reports), and after all requirements were successfully tested. The e-management solution should be modified if there are any discrepancies.
6. Future improvements and maintenance – during the e-management usage period new opportunities will be opened, and there will be some point when the e-management system should be improved, so the implementation process will be repeated with the same steps, with the amendment that this time provider selection can be the same as before, to ensure continuity and less effort and costs.

The steps above are a general description of e-management implementation. For an already established SME it's easier to define the goals and the requirements for the e-management system, but implementing it without major time costs and production delays can be a challenge, depending of the size and complexity of the SME.

For a new SME will be easier to implement an e-management system from scratch, but defining an accurate set of requirements, indicators and processes can be difficult without some management expertise. Lessons learned from other similar companies and case studies can help preventing future disasters: if wrong requirements are defined, the e-management system will be slow down the company growth.

Internet is usually the meeting point and the interaction platform for the e-management system, and special precautions must be taken to prevent data losses and to protect confidential information. Besides the bad publicity of the Internet environment (hackers, attacks, etc) it can be a safe place if some security

requirements are met. Those aspects should not be neglected when defining the requirements for the e-management system.

Case studies

Following there are several case studies of SME which implemented e-management systems.

Textile Company Case Study

This company produces textile subassemblies in outsourcing mode for its German partners, has around 15 employees and 12 production machines. The company manufactures several types of products, and the average number of pieces manufactured monthly is around 30.000 pieces.

One of the main management's challenges is to keep track of all products, which is a strong requirement of the German partners, which is an ISO certified company. All defects must be tracked and an archive of 5 years of all production must be kept. In order to integrate with the partners e-management system, the company has to provide monthly reports in a fixed electronic format with all production records (around 15 items for each product).

The other major challenge was stock management, especially handling different wire coil colors. The same color can have different shades which cannot be mixed for the same product, so precise management is required.

To keep up with those demands this company implemented a basic paper tracking system, which afterwards was manually translated to electronically format, send and archived manually. This system introduced many errors and the final reports were not accurate which caused a lot of complaints from the German partners. The stock management was poor, using some basic worksheets and manual operations, causing frequent chaos and production delays.

The company management contacted a software development company to implement a custom e-management system, which had to overtake all manually work. The main requirements were:

1. All production data to be centralized into a single electronic database, accessible from several production units and from management offices
2. All data inputs to be automated into a user-friendly software tool, with very strong proof (most human operators didn't have any computer-usage knowledge). The manual human inputs should be minimized, so inputs from weighting machine and bar codes will be automated.
3. Stock will be handled automatically – the only inputs will be just entries. Warnings will be issued when items are below thresholds and data aggregation with reporting features for the management.
4. Several reports and data aggregation will be available to the management, which will provide manufacturing status and times per machine and per human operator, number of defects, wire color usage, packed products and products ready to be shipped.
5. The data will be automatically exported to the format required by the German partners, and all information and reports will be automatically archived for future usage.

The system was developed and implemented in three months time, with two weeks of trial period. After several month since the implementation, the management feedback stated total control of stock with huge improvements in production times, a speed-up of the production and no delays or errors. Due to defect-orientated reports, the management could easily identify machines with high defect rates and replace the part in time to minimize losses. The German partners are also pleased with the accuracy of the data provided.

The company made a step further and implemented a production calculation feature to enhance short-term planning and future company strategy. The e-management system will be also the platform the ISO 9001 certification process.

Visual Effects Studio Case Study

This is a small company with 5 employees which provides visual effects and video animation services. The team works in the same time at multiple projects, and the challenge is to keep track of the time spend for each project, because there are many last-minute requests and changes from the customers.

The job specific requires a lot of customer reviews before the final delivery, so a team member must meet the customer and spend some time for reviewing and recording comments. This implies a lot of production time lost with meetings and travel. Customer communication was done by phone and by email, and after several communication sessions the track of customer requests is lost or misunderstood.

They contacted a company to develop an online e-management system with the following requirements:

1. Every team member will use an online website interface (for mobility) to keep track of all actions performed on a specific project (time spend, modification of requests, comments, prices offered, etc).
2. The team and the management will have access to visual reports for deadlines, resources load, total time spend for each project and other related information.
3. Customers will have a dedicated client area on the website, and they will be able to visualize their products online, with the ability to post comments. The team members will address those comments and will be able to respond, also online.

After the implementation of this e-management system the company management was able to invoice correctly for each project, according to the time spend for each project. The mobility and productivity of the team increased, since they didn't have to travel so much, and they could see from any location the status of the project and customers demands or comments.

Negative Case Studies

As stated in the previous chapter, not any form of e-management system is successful: a auto garage management wanted to implement a form of system for keeping track of employees time spend on each operation and to generate an invoice automatically. Because the garage management didn't contract a support service as well, the employees weren't able to handle the new system and it was soon abandoned because generated more delays than before.

Another SME from the logistics segment acquired an "off the shelf" system for an e-management implementation. But the system didn't meet an important requirement: accepting data input formats from partners, so without this key-feature it was soon abandoned.

Conclusion

e-Management is not rocket science and in the following years will become a requirement for any SME which aims for the European market and success. It will be something imposed both by the competition and by the customers.

Any SME management just has to realize that it needs an e-management system.

The events in the life of an organization flow rapidly and the socio-economic architecture changes while the managerial actions can modify the web of significances and the health of the business. The genesis and the consacrations of the market economy is a complex process that supposes mechanisms and institutions that guarantee values, norms and principles that are adequate for competition. The future imposes more and more the decrease of functional borders, promoting competition as a solution for ensuring success in a complex and dynamic environment.

Key terms: business health, socio-economic architecture, competition

Introduction

From the perspective of an enduring development, the management has as objectives creating jobs, reducing poverty, access to education and health services. The essence of competition is influenced nowadays by the correct way in which the management of the organization know and perceive the most relevant economic tendencies. These tendencies are determined by the essential transformations that occurred in the business environment (globalization, the increase of the services sector, competition based on a time factor, client's behavior).

Practice shows that the companies with the biggest success in business are those that focus their efforts on satisfying the needs of the customers while remaining profitable, searching for ways in which this objective can be achieved in a more performant manner than competitors.

A company survives and prospers when it satisfies the requests of the clients in a more profitable and efficient way than the competition. For doing this, the company has to elaborate a plan with strategic implications in terms of products and markets on which they focus their efforts with a special focus on identifying those elements that can ensure high levels of value as perceived on the market while bringing added value.

Companies can become performant only if the managerial system ensures conditions, by its decisions and actions, for identifying markets and categories of consumers. Managers can't ignore the importance of creating adequate price strategies and ways for promoting the products as efficiently as possible, while being connected to the specific of the conditions on the market.

In any organization, the management is based on information which shows that new technologies are not necessary to any manager, at any level of an enterprise in order to take healthy decisions, for choosing strategies and a certain policy. The availability of advanced technologies of information (computers with Internet or an Intranet network) ensure the communication between employees that is mainly written (information will no longer be truncated). The genesis and the consacrations of the market economy is a complex process that supposes mechanisms and institutions carrying values, norms and principles that are adequate for competition.

1. Diagnosing a business

The high dynamics of the IT society determines the organizations of any kind to continuously adapt to an environment in a continuous change. A periodical evaluation of a business represents a vital routine for its success. Either the organization employs a consultant or it does the evaluation internally, as a retrospective, it is necessary for finding the strengths and the weaknesses of a business

The management is continuously asked to answer the following questions:

- Which is the control panel structure of the management of the business?
- How are weaknesses of the business identified?
- How are computed and what is the significance of financial indicators?
- How can financial information be used to make the general management of the company more efficient?
- What is the role of the business plan?
- How are elaborated the budgets of the company?

In order to answer these questions the following will be used:

- Commercial diagnosis** through which is underlined the portfolio of clients and the types of projects implemented for these (or the products sold to them). It will also be attempted to approximate the degree of satisfaction. Thus, a structure of sales based on categories of projects/products/services sold/accomplished, the importance of various managerial decisions. Another aspect that has to be considered is the marketing policy of the company, underlining strengths (successes), weaknesses, opportunities and threats in a SWOT analysis.
- Diagnosis of the internal potential** in order to obtain an overview of the employees is needed to evaluate them at least annually. In this way there can be noted the positive aspects, the performances in the last period and the aspects that need to be improved can be identified. The evaluation has to be done by a constructive and open dialogue with the employee, so that it'll have as a result an improvement of his performances
- The organizational diagnostic of the company.** The following elements will be taken into account: the structure inside the company (how is the the communication between departments, who needs whom inside a project), the way in which decisions are taken regarding different projects, etc. The weakness of the organization of the company will be identified and how can these be improved. It is a good idea to create diagrams of the company with connections between departments in order to illustrate the above aspects.
- The cultural diagnostic** aims at checking if the team is working well together. The management of the company has to get involved in cultural aspects, creating team buildings, parties for employees etc. These things have to be mentioned in the global evaluation of a business.
- The technological diagnostic** attempts to verify if the company is making efforts to follow the international trends. Studying the IT infrastructure of communication can offer important information about the way a company works.

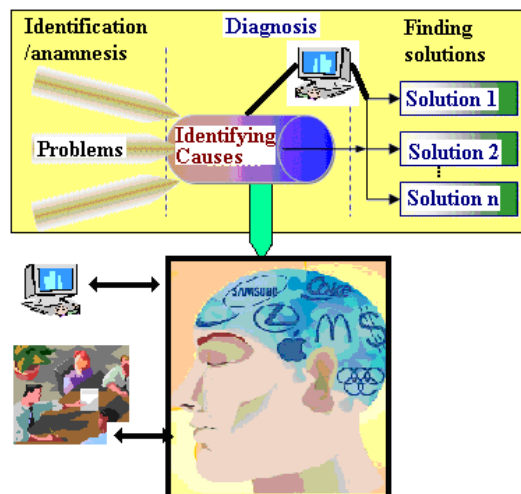

Figure 1 The process of diagnosis

- The financial diagnosis** of a company aims at studying the activity of the company statically,

dynamically and comparatively in order to evaluate the results obtained, the financial balances, the resources and their use, in connection with the efficiency of the invested capital.

In indexes computed based on accounting and financial information and the yealy financial situations allow drawing conclusions on the financial and economic state of the company. Starting from these indexes one can express the financial strength, the way in which capital is managed, liquidity and solvency, the efficiency of using the assets, the state of financial balance or imbalance, economic and financial profitability. By comparinf standard values with the results of the computations, based on real data, one can have a correct image over the economic and financial position of a company in its industrial branch and/or on the market share it refers to.

2. Information and communication technologies - supporting a business

Information management assumes performing some specific activities: designing and updating strategic information technology projects, applying coherent restructuring solutions, defining and following standards of aquiring, transmitting, processing and storing data, a high level assistance to final users.

In order to be successful and to be able to measure the level of success achieved, an enterprise has to establish some goals. The goals of the company have to take into account selecting strategies that would lead to achiving the objectives with the aid of a series of information and communication technologies.

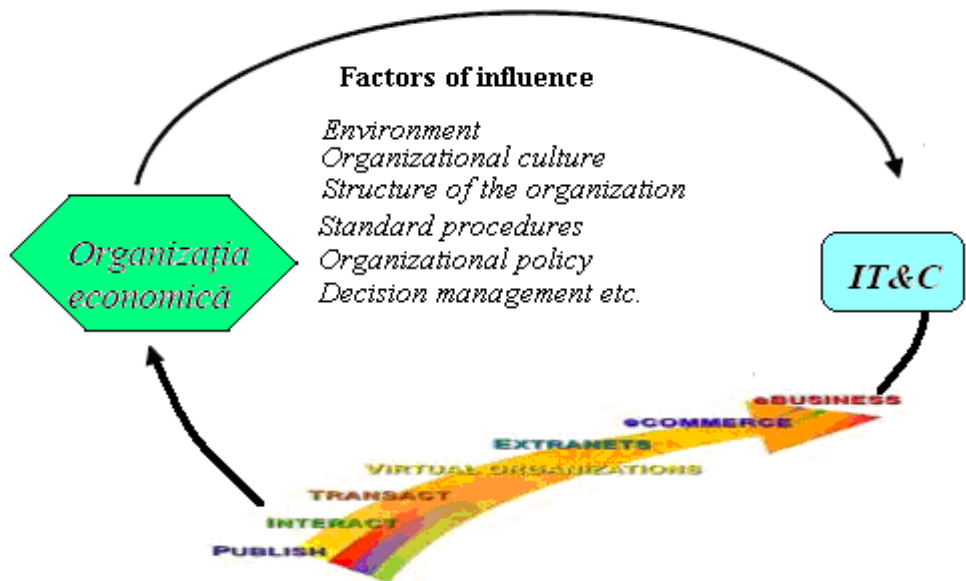

Figure 2 The relationship of information and communication technologies with the economic organization

The interactions between the informatic system and the members of the economic organization are extremely complex and in a continuous dynamic and in the future the functional borders will b reduced, promoting competition as a solution for esuring success in a complex environment.

Modern companies have to answer an increased need for „freedom”, of expression of the imagination, of fantasy and pleasure to work. That’s why organizations have to:

- Be temporary systems, capable of adaption and in a permanent change, depending on the evolutions of the environments and on individual needs.
- have groups of persons with different qualifications that would rapidly adapt to the changes in the internal and external environment
- Have a management that plays a role of connection between groups with a capacity of understanding the scientific language without asserting that he knows and directs the activity entirely.
- Have the management of the groups of specialists in an „organic” manner, rather than a „mechanic” one, the creation of groups depending on the problems that appear, and the command being given to those who are most capable of solving problems, not to those who have a certain rank.

The visions over the modern information technologies show that they represent a multidisciplinary domain that contributes to the creation and functioning of economic systems. For example the manager's success depends on his emotional competences and there is more and more research lately about the role of emotional intelligence in the professional activity.

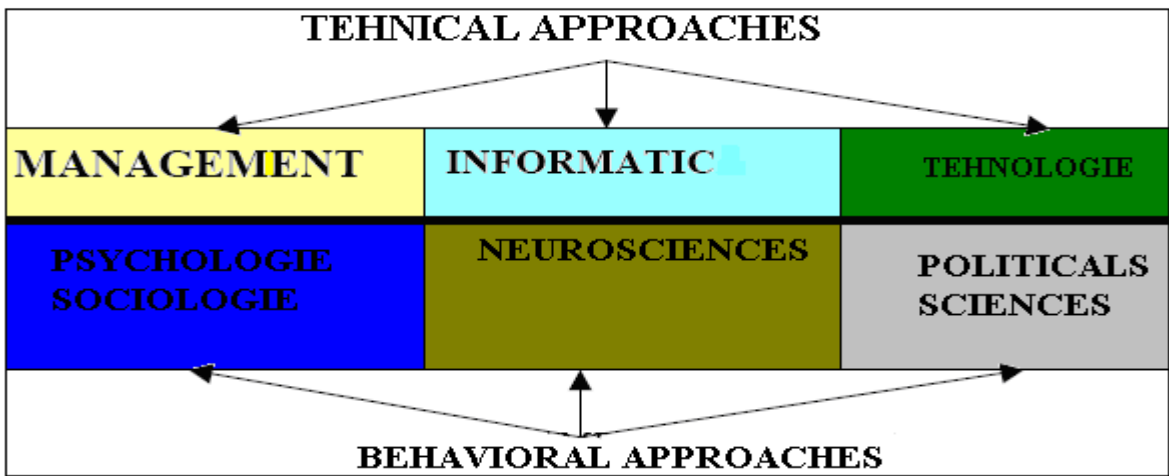

Figure 3 Interdisciplinary approach of information and communication

Another problem is what the technical or human limitation is until which web technologies can be applied for recruiting work force and in the same time it is extremely important to sense very early the intelligence level of a candidate to predict his chances of integration in the team and in the company.

The contemporary research is mainly transdisciplinary and less disciplinary, more experience based then experiment based.

3. Options for new network informations technologies

New technologies transform the way of communication between human and company entitites, simplifying and improving (or worsening) the relationship between people. The researchers are elaborating new communication technologies in an attempt to perfect the instruments (mainly multimedia) used for more and more people. Studies aim at obtaining a miniaturization, a simplified usage and the mobility of these technologies and component miniaturization (for example portable computers, mobile phones etc) in order to permanently maintain the connection with the workplace or the family. Thus we can easily make calls, we can send or receive facsimile or we can enter the Internet, from anywhere. For example a PDA (Personal Digital Assistant) represents a real communication center, combining the functions of an electronic agenda, a telephone agenda, a text processor, a facsimile and e-mail.

Neurosciences contributed to the new technologies as is the case of the tactile screens, computers where most functions are verbally transmitted or dictating a text directly or the new camera that focus automatically the image that the eye focused to.

In the same time, there are attempts to create programs that allow the control of the computer directly from the brain, that are use in the military and medicine.

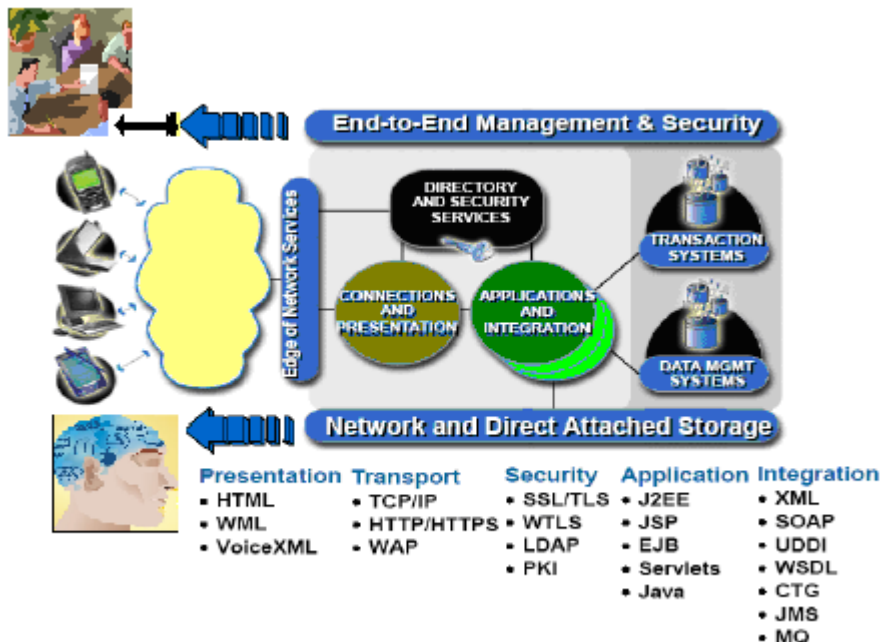

Figure 4 Types of NNIT

The most important technologies used in e-business and implemented by IBM Software Strategy for e-business are: Java, Extensible Markup Language (XML), Java 2 Platform, Enterprise Edition (J2EE), Presentation layer, Web application server, Integration server, Protocols, Objects, Struts, Eclipse, MVC pat-terns, Common Object Request Broker Architecture (CORBA), Transactions.

Many of these technology choices continue to evolve and expand as the open standards specification evolves to include a broader view of the enterprise architecture. The figure 4 demonstrates some of the common e-business technologies. Some technologies, such as Java and XML, can apply to more than one layer.

Conclusion

1. The direction toward Web services will particularly help “Net Generation” (companies that are born on the Web) to become successful by allowing their services to be easily discovered world wide and easily integrated with other services ranging in scale from other Net Generation services to enterprise-scale services.
2. The technological assimilation process resembles more the harmonisation of an orchestra to perform a concert rather than the individual study of a particular instrument. Individual virtuosity is a prerequisite, but on their own, an instrument and one musician only cannot replace the orchestra, the conductor, rehearsals and the continuous adjustments that are commonly agreed upon.

EXCELLENCE IN BUSINESS THROUGH THE NEW IT TECHNOLOGIES

Mareş Marius Daniel

Spiru Haret University, Bucharest, Romania, maresdaniel@yahoo.com, 0722704696

Mareş Valerica

Economic Studies Academy of Bucharest, Romania, maresvalerica@yahoo.com, 0721906108

Abstract No matter what branch of activity, dimension or maturity of its business, an organization should have a management framework to survive, to have success and to obtain excellent results in the domains of key performance as well as in the relationship with clients, personal and the impact on the society. Excellence supposes discussing the current situation as well as the implementation of a set of systems, processes and interdependent and relational data, which bring changes through learning, innovation, capitalization of the opportunities of improvement that bring added value using the new IT. Modern business aims at eliminating the geographical barriers for exchanging information, experience and communication with the decision centers.

Key terms: performance, added value, excellence, modern business, new IT.

Introduction

The economic actions require each other, are inter-conditioned, are complementing, extending and shrinking according to a behavior that is a consequence of the nature of the economic activities. In this way have grown the contemporary economies, as distinct entities, that vary from area to area, from country to country, but can be justified through their own extent of applying the existing legislation provided by the economic sciences.

The economic agents are trying to answer with as adequate as possible initiatives to key questions, by giving an interpretation of the functioning mechanism of the economy, through all its complexity: who produces? who consumes? what it produces? how much it produces? how much it consumes? how it produces? how it consumes? Overall, the economy has always answered these questions, but in different ways and with different results in various countries.

Starting from the criteria of belonging to the system of statistic evidence of the national accounts, the economic agents can be grouped in:

- agents that produce goods and services, such as companies
- consuming agents, as are the households
- financial agents, represented by the financial and credit institutions
- administrations
- the rest of the world, representing the agents belonging to other national economies

1. The relationship management - excellence

In the current phase of development of the market economy, the activity of the manager is a continuously ascending process. Depending on the mutations that occurred in the society, the management is called to solve compromises between the need for usefulness and the available resources, laying the basis of the policy and strategy, implemented by people, partnerships, resources and processes, with the aim of obtaining excellent results in the domains of key performances, as well as in the relationship with clients, personal and in the impact on the society.

Modern business are based on the sum of activities of study and analysis of the existing technical solutions, of the materials, technologies and costs, as well as in the elaboration of methodologies and computing procedures for the functional and dimensional preestimation of the adopted solution.

According to the international standards, the quality of a business is the sum of properties and characteristics that enable the third parties to satisfy some explicit or implicit necessities. We may note that

the notion of quality results from matching the sum of characteristics to the needs of the beneficiary. Quality can be expressed explicitly, using a set of special characteristics, as reliability, maintainability, availability and security, exactly defined mathematically.

Quality depends on several factors:

- conception
- production
- use

These factors form the conceptual model called “the quality loop”.

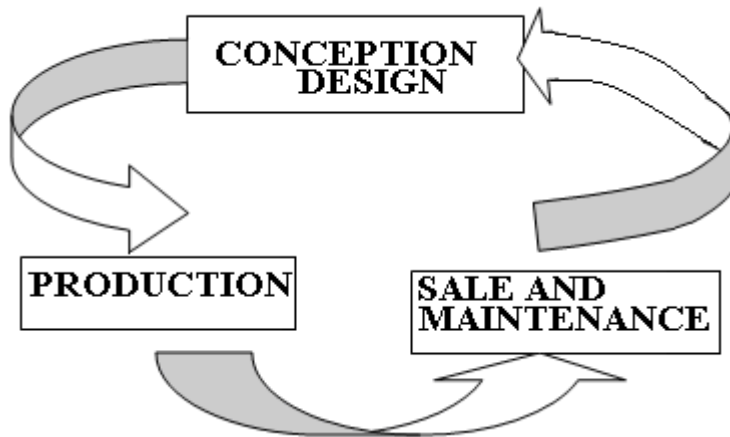

Figure 1 Quality loop

Based on the concept of quality loop, we'll consider the following as components of quality: design quality, production quality and sales quality to which can be added the elements of the reference to maintenance. A high quality of a business is the premise for obtaining excellent results based on a high management.

The values promoted by management are:

- Excellence
- Objectivity
- Empathy
- Determination
- Integrity
- Honesty
- Ethics

Some decision factors still believe that intuition and a set of rules represents the quintessence of a modern economical thinking, taking decisions that justify only the regulations from which result orders that are executed unconditionally.

The relationship between the management of a business and the excellence model is best reflected in the link with the clients, and the solutions aim at measuring and monitoring client satisfaction as an evolution from satisfied to charmed clients. The business success of any enterprise is determined by its capacity to identify the needs of the consumers and to offer products and/or services to satisfy them.

In order to increase clients' satisfaction the aim will be:

- achieving abilities in managing the relationships with clients;
- knowledge of the typology of the client and adopting an approach related to this typology.
- The excellence model is a practical approach that can be used in a variety of ways
- as an instrument of auto evaluation;

- as a means of Benchmarking with other organizations;
- to identify the areas of continuous improvement and to coordinate the various initiatives in the branch;
- as a basis for a common vocabulary and way of thinking;
- as a structure for the management system of the organization.

The excellence model allows various approaches for obtaining results in all areas and is based on the premise that the management of the company lays the basis of the policy and strategy, and these are implemented by people, partnerships, resources and processes, aiming at obtain results in the domains of key performances and in the relationship with clients, workers and in the impact on the society.

1.1 Fundamental concepts of excellence

Excellence refers to *determinant factors* and to the *results*. Determinant factors evaluate the activities performed with the aim for getting the results. The results are caused by determinant factors and the determinant factors are continuously improved on the basis of the **feedback** received from the results.

A business based on the model of excellence is (see figure 2)

- **oriented towards results.** Excellence means obtaining results that charm all the interested parties;
- **oriented towards clients.** Excellence means creating sustainable value for the clients and also added value;
- **leadership and excellence.** Excellence means a visionary leadership, charismatic and persevering;
- **management based on processes and data.** Excellence means managing the organization with a set of systems and data that are interdependent and relationated;
- **involvement and development of the worker.** Excellence means maximizing the contribution of the employees through their involvement and development;
- **learning, innovation and continuous improvement.** Excellence supposes discussing the existent situation and applying change through learning, innovation and using the opportunities for improvement;
- **developing partnerships.** Excellence means developing and maintaining partnerships that bring added value;
- **public responsibility.** Excellence means exceeding the minimum legal requirements for operating a company and the effort of understanding and answering the expectations of the interested parties from the society.

Figure 2 Model of excellence

1.2 The SWOT analysis (Strength-Weaknesses-Opportunities- Threats)

SWOT is one of the most used methods of analysis of the level of performance of an organization with the aim of analysis the position of an organization or of a department in relation with its competitors and identifying the major factors that affect the activity, with the aim of creating a future strategy (figure 3).

SWOT is an extremely simple to apply instrument which can be adapted to the requirements of various organizations. This analysis method helps identifying the strengths, the weaknesses, the opportunities and the threats characteristic to an organization or to certain elements inside it.

SWOT allows the identification of *internal and external factors* that affect the organization and quantifying their impact on the organization. The *internal factors* corroborated with the strengths and weaknesses are: the structure and the culture of the organization, its resources and shareholders. The *external factors* are related to the opportunities and threats represented by the clients and the competitors of the organization. We can also enumerate here other factors: political, technological, individual, economic and social problems.

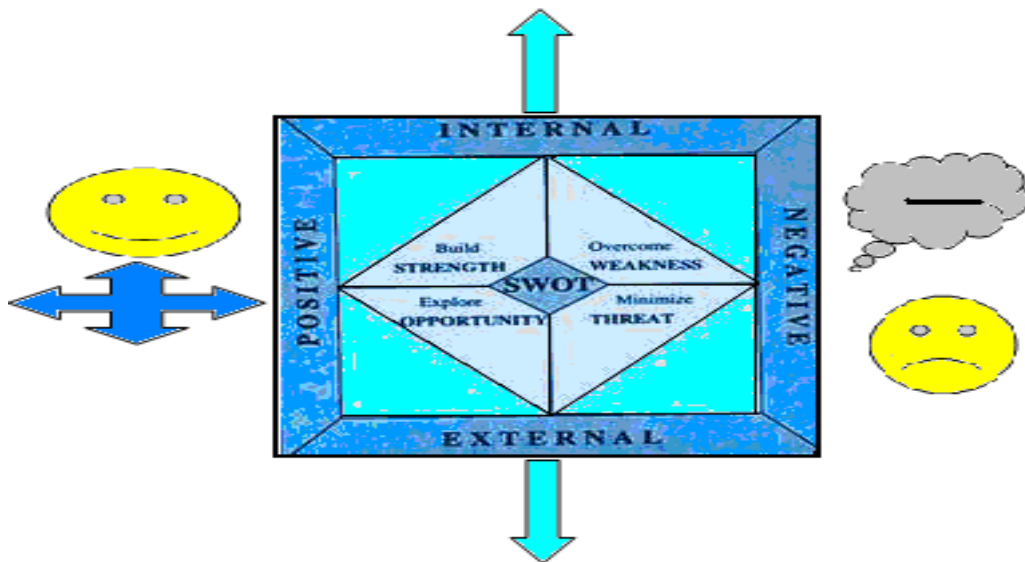

Figure 3 Factors of SWOT

1.2.1 The SWOT method

Applying the SWOT method supposes identifying:

Strengths are defined and measured in the domains in which the organization is excelling, that is:

- Witches are the strengths of the business?
- How strong is the company on the market?
- Does the company have the latest technology?
- Is there a clear development strategy?
- Is the culture of the organization favorable for a positive working environment?

Weaknesses are defined and measured by measuring the weaknesses by answering the following questions

- What can be improved in the activity of the company?
- What are problems faced by the company?
- Are there problems related to cash-flow?
- Is there a lack of financial resources for the projects?

Opportunities are defined and measure the opportunities, that is:

- Are there favorable circumstances on the market?

- Are there opportunities to extend to new markets?
- Is the integration of new technologies a priority for the company?

Threats are defined and measure the threats to which the company is exposed

- Which are the obstacles the society can face?
- Can rapidly changing technologies affect the market share?
- What are the changes produced in the companies of the competitors and how can these affect the company?
- Can changing policies in the field and changing laws affect the activity of the company?

1.2.2 The SWOT matrix

The SWOT analysis can be a synthesis of the key strengths and weaknesses of a society in a matrix. First of all it groups the problems and the advantages in four SWOT categories, allowing a simple identification of a strategy and of some ways of developing a business. Moreover, the method can be easily adapted to the specific needs of various business processes. The SWOT analysis can contribute to creating a strategy and rapidly adapting them to the excellence requirements.

	Strengths Favorable characteristics and the advantages of the used situations and techniques	Weakness Negative characteristics and the disadvantages of used situations and techniques
Opportunities	Strengths analysis - Opportunities How can strengths be used to develop opportunities?	Weaknesses analysis - Opportunities How can be overcome the weaknesses taking into consideration the development of opportunities?
Threats	Strengths analysis - Threats How can strengths be used to counteract the threats that have a tendency to block attaining objectives and following opportunities?	Weaknesses analysis - Threats How can be overcome weaknesses to counteract the threats that have a tendency to block attaining objectives and following opportunities?

Table 1 Matrix of SWOT

2. Managerial intelligence as a key factor for the success of a business

Managerial intelligence represents the global capacity of knowledge, rational thinking as well as the capacity of coping with the changes of the economic, social and political environment. Adapting the individual to the environment in which he lives can be achieved through cognitive elements as well as non-cognitive elements. The non-cognitive aspects of intelligence include emotional, personal and social factors, essential for the success of the individual and are essential for predicting his abilities for success.

Measuring intelligence is equivalent to measuring the rate of adaptations that allow a good understanding and solving of problems. If assimilation is superficial and adaptation (information processing) is done in a slow and insufficient manner, then the intelligent equilibration is insufficient.

Psychologists evaluate that together with the intellectual factors, there are non-intellectual factors that determine an intelligent behavior and shape *multiple intelligence*. All psychologists appreciate that starting from the adaptive role of the affectivity, it has been noted that people that have a high IQ or a well developed academic intelligence cope well in time, and another category of subjects, although they have a lower IQ compared to the first category, have better results in practice, given by the abilities to solve problems, verbal abilities and social competition.

The difference between the two categories of persons is done by:

1. *motivation* that is an important ingredient of academic intelligence, with such attributes as: dedications, persistence, hard work are considered as distinctive for intelligent persons.

2. *replacing the social component* with specific attributes of *practical intelligence* with attributes such as sensitivity, honesty, frankness.

Success is implanted on intelligence, whose variables are: linguistic, biologic variable, mathematic logic, spacely, musicality, kinesthetics, interpersonal and intrapersonal relationships that vary not only from individual to individual but also from culture to culture.

Gardner talks about “*personal intelligences*” meaning interpersonal abilities and an intra physical capacity. Thus, interpersonal intelligence is split in:

- leadership abilities, meaning the ability to maintain an interpersonal relationship;
- ability to keep friends;
- ability to solve conflicts;
- ability to do analysis.

This vision of intelligence offers a richer view the ability of a person and his potential for success than the standard intelligence coefficient can offer.

The interpersonal intelligence is the ability to understand others: what motivates them, how they act and how can one cooperate with them. Intrapersonal intelligence is the key of self knowledge, which includes access to own feelings and ability to discriminate and to draw based on a behavior guide and in the same time ensured the success in daily life is, on one side, distinct from the academic (theoretical) intelligence but, on the other side, constitutes a kind of specific sensitivity towards practice and inter human relationships.

In the current conditions it can be remarked that the emotional intelligence is an ability which implies a creative relation with the states of fear, pain and wish. It can be remarked that the IQ and the emotional intelligence are not opposite components but rather complementary ones.

Forming the emotional intelligence is made through

- perceptive evaluation and expression of emotion;
- emotional facilitation of thinking;
- understanding and analysis of emotion and using the knowledge of emotion;
- emotional adaptation in order to provoke emotional and intellectual growth.

The components of emotional intelligence are:

- the intrapersonal aspect (acknowledging ones own emotions) that is self awareness, represented by self knowledge, the capacity of knowing who you are and what you want from life. The management of one’s own emotions represents the capacity of managing one’s own states, impulses and resources in different situations. The emotional management includes understanding the implications of the social actions on emotions and controlling one’s emotions and those of the surrounding people. It is also appreciated the development of such skills in others – coaching;
- motivation represents the emotional tendencies that guide and facilitates attaining goals;
- optimism (asertivity), respect for oneself, auto achievement, independence;
- interpersonal aspect (empathy, interpersonal relationships, public responsibility, social openness that supposes social adaptability and persuasive and influencing capacity);
- team work and collaboration in creating a group synergy in following the goals of the group;
- catalist of change (initiating and managing change);
- adaptability (solving problems, testing reality, flexibility);
- stress control (tolerance to stress, impulse control);
- general mood (happiness, optimism).

For a manager knowledge and cultivation of positive emotional moods as: optimism, hope, abnegation contributes to individual performance, to group and leadership performance, to social interpersonal changes and adaptation to changes. The management of emotions plays an important role in preventing

wearing out and for keeping a high motivation and for preventing emotional crises. Emotions, when correctly managed and controlled, lead to loyalty and engagement, bringing increases in productivity, originality, team and organizational achievements.

Managers that have emotional intelligence have been seen as inspiring employees, giving them enthusiasm to perform in their activities and when they are involved and motivated, emotional intelligence can be more important than cognitive intelligence and combined technical talents.

3. Management – marketing- neuro marketing in business

The current business environment imposes to the management of any company to develop the best marketing activities. Marketing is considered by some specialists as a function of management, representing a concept as well as a planning and execution process of the activities of maintaining a relationship that would satisfy the individual and organizational objectives. That's why the management of the marketing plays an essential role in obtaining the competitive advantage by any company.

Business success of any enterprise is given by its capacity to identify the consumer needs and to offer products and services to satisfy them. From a marketing perspective the result of an enterprise is a satisfied client.

When a new generation appears, the needs of the consumers change. Thus, a product often seen today, such as the mobile phone, was unknown to the generation of 1960. The *king client* has become a reality, and the competition between enterprises for serving at high performance standards has become tougher. Indeed, the client is the one who chooses, the one who gives the verdict in the keen confrontation between companies. He is the one who decides the winners from the losers.

For a couple of decades, client satisfaction does not represent an aspect related only to the sales and marketing activities of an enterprise, but also influences all its activities. That's why numerous enterprises and organizations have adopted a policy that is directed towards the client.

The concept of marketing is based on the following fundamental principles:

- 1) the enterprise/company exists in order to identify and satisfy the needs of its customers (orientation towards customer)
- 2) satisfying the needs of the consumers supposes an integrated effort made by all the compartments/departments of the enterprise/company.
- 3) the company has to focus its efforts towards obtaining a long term success.

The marketing function of a company has the role to prospect the market and to project the efforts of the company in such a way that would ensure maximum profit, while satisfying an as complete as possible request. Unlike the commercial function that has a tactic value, the marketing function of a company has a strategic value and is always referring to the future. The marketing function is composed by a multitude of activities such as:

- elaborating market studies
- animating the sales force
- achieving product promotion
- determining an optimum distribution system
- identifying competitive ways of payment
- consequent and systematic realization of direct contacts with different categories of the public.

The analysis of the environment has to be the starting point of the management of any marketing activity because the changed of environment (internal, as well as external) can affect the capacity of the company to create and maintain profitable clients

The external environment of a company has the following forms of manifestation:

- stable environment;
- unstable environment;
- turbulent environment.

No	Forms of manifestation of the external environment	Essential characteristics
1.	Stable environment	-slow and easily predictable changes of the components of the environment -the management of the company has few adaptation problems
2.	Unstable environment	-frequent changes of the majority of components of the environment (micro and macro economic); -the management of the company adopts a prospective attitude.
3.	Turbulent environment	-sudden and unpredictable changes of the components of the environment; -the management of the company faces difficult adaptation problems and even the uncertainty of the company's survival.

Table 1 Forms of manifestation of the external environment

A good managerial process in a company supposes identification and a good knowledge of the components of the marketing environment of the company. Companies try to find out the answers to questions like:

- who buys?
- what buys?
- why he buys?
- how he buys?
- when he buys?
- from where he buys?
- how often he buys?

In the attempt to find answers to these questions we'll use neurosciences (neurology, psychology, psychiatry) and other disciplines (sociology, literary analysis, symbolically, cognitive science). Thus the neuromarketing is a combination between two sciences, the neurology and the marketing. The set of scientific disciplines considered "hard", from which neurosciences is a part, and more recently the biotechnologies, are offered to collaboration with the market logic of televisions, given that they are the extremely active supporters of a *scientism* that reintroduces the dualism mental-body.

The neuromarketing uses the technology of transmitting images through magnetic resonance – MRI (technology used in medicine for detecting cerebral tumors) which permits reading the way in which the brain receives, processes and interprets various images that are presented to it. Neuromarketing uses psychiatric tools to grant that the advertising message remains permanently and efficiently in the brain of the audience.

People who work in this branch can find out how the human brain answers to the advertising message and they can perfect their options of promoting a brand, by using a sample of consumers to which are presented images while they are introduced in a machine and are subject to some radio-magnetic waves.

The fragmentation of mass communication has determined an equally strong fragmenting of the way in which the consumers react. It is well known that Internet allows, click after click, following the behavior of the consumer. Implicitly, the big corporations search for as exact as possible means for targeting the advertising message.

4. The support offered by the new IT technologies for excellence in business

Knowledge has always been the real vector of any transformation and economic progress. Intimate knowledge of the brain of the consumer can only incite enterprises and their advertising representatives, to evade from the spaces which are normally allocated to them for communication. The conditions of receiving a brand are judged more favorable if the „target” is not really conscious that it is targeted. That's how the rapid development of advertisement can be explained, this hybrid mix of advertising and entertainment.

Nowadays, especially (but not only) in the postmodern, postcapitalist and postindustrial economies, developed and educated, there is a need for knowing the way in which knowledge takes place. Information is a very important resource for the society. The XXIst century is marked by an abundance of information on one side and on the other side by perfecting technologies of transmitting, treating and selecting information.

The practical problems that the management has to solve are:

1. The access of the employees to the up to date and pertinent information they need in order to accomplish their tasks (for example those who have an office activity have to be connected to Internet). It is also a good idea that the employees have at hand any other written materials they might need in order to work well and quickly.
2. Equipping offices with the required technology for receiving and transmitting information (for example, enough computers, so there will be no 2 employees competing for a computer, telephone, fax, printer etc.).
3. Designing communication channels inside the organization so that the time lost for establishing connection between employees to be as short as possible (for example, the offices of those who collaborate constantly should be next to each other). For medium and big size organizations establishing an Intranet network solves many communication problems. IT is a good idea that each employee should know precisely what his colleagues responsible are with (to know with whom he'll work and what will be the collective tasks) and whom he can ask questions (usually, his direct boss).
4. The access of employees to information in a more profound sense. It is well known that in all professions there are alert changes, so there is a need for a continuous professional learning. The manager has to understand and to create conditions (for example a modified or flexible working program) to allow the employees to go to trainings (for example courses for taking the European Computer Driving License ECDL). Such an attitude will contribute to increasing efficiency through the fact that the employees will be better trained and they will also be more motivated to work well.

The problems that appear in the access to information are inevitable, no matter how well designed are the communication channels and the performance of the technologies. There will sometimes be blockages. Their resolution is a task of the general manager and of the medium level managers.

The prompt and correct information of the employees on the decisions taken and the way of fulfilling them through meetings, circulation (spreading written materials to inform about the decisions that have been taken) or the existence of advanced informing technologies (computers connected to Internet or Intranet, when the communication between employees is mainly written – information will not be lost)

There is a risk that some of the employees with office tasks to be tempted to use Internet to look for information of personal interest. As a consequence the work tasks will be done superficially and in a hurry. For such cases there should be found efficient motivating strategies

The main methods for obtaining information are

- studying the sources of statistical data: data can originate from inside the company or from outside (i.e. INS)
- Media channels and Internet
- Books, manuals
- The marketing experiment supposes testing in lab conditions for an advertising campaign (rarely used in Romania)
- Marketing simulation: creating an artificial system, necessary for testing a natural system and also for testing, to prepared and training personnel
- direct research of an information source (individual/family/household).

Depending on the way of obtaining information there are two methods of direct research:

1. *Observation*: obtaining information from the direct source without involving him in a discussion (without him knowing)
2. *An inquiring* to obtain information from the researched subject with him knowing it and with his consent. This method reveals the declared behavior, not the real one (sometimes there can be differences of 10-15%)

Inquirings are of two categories

- *totals*: obtaining information from all its sources (i.e. census, governmental health screening programs).
- *selective*: taking information from a sample.

Conclusions

1. The real substance of a prosperous society is represented by the quality of knowledge and creativity. Thus, some economic structures can be defined as post epistemic economies and the globalization of world economy goes hand in hand with the process of unifying knowledge, knowledge having no physical boundaries.
2. The components of a business are the material and technologic resources, the employees (the workgroup), the international resourced, the time. A special component of a business in the interaction with the outside is the image, whose quality can influence efficiency and productivity.
3. The manager is the connection bond between the organization and the outer world and has a symbolic role especially in the case of the relationship of similar organizations that can promote values of excellence, but he has to communicate efficiently and to find a common ground using his intelligence.

ONLINE DECISIONAL SUPPORT FOR SELECTION OF THE BUSINESS PARTNERS IN THE CASE OF SMALL AND MIDDLE-SIZED ENTERPRISE

Mărginean Nicolae

Universitatea Bogdan-Vodă Cluj-Napoca, Facultatea de Științe Economice, Str. Spinoasa 14 Cluj-Napoca, e-mail:nicolae1976@yahoo.com, telef:0745/318321

***Abstract:** From the great amount of problems the organization management is confronted to, our interest field aims at one of the current problems met by a decision factor of a small and middle-sized enterprise, namely selection of business partners. The present study has established as main objective the accomplishment of an architecture of a decisional support regarding the selection of potential business partners. From the various number of decision support systems, we will focus on those where the management sub-system of certain large data volumes constitute the dominant technological component. Data will be stored as a data warehouse so that we will can analyse it from many point of view, including economical and financial analysis, using data mining. The result of these analysis will be interpreted by a special expert system and then the final results will be display using an internet interface.*

***Keywords:** data warehouse, expert system, DSS, data mining, decision*

Introduction

The increase of current business environment complexity, business globalization, digital economics, having a direct impact upon the management of an organization, lead to the enhancement of studies regarding the development of certain methodologies, techniques, instruments, with the purpose of granting a considerable support for all the aspects of the decisional process.

From the great amount of problems the organization management is confronted to, our interest field aims at one of the current problems met by a decision factor of a small and middle-sized enterprise, namely selection of business partners. Taking into account that the entire economic activity carried out by an organization is highly connected to the business partners, including both entrances and exists, the proper functioning of the organization is directly proportional to the amount of trust invested in them, from all points of view. As insignificant as it seems at a first glance, the decision of selecting a business partner is of high complexity due to its strong and unstructured character, lacking a faultless modality that should guarantee completely the success of the selection made. Nevertheless, due to their memorizing and processing capacities, the informatic systems are able to offer a substantial support within decision making process. The present project has established as main objective the accomplishment of such an computerized decisional support, as a working instrument of a financial counseling agency regarding the selection of potential business partners.

Used methodology

The process of selection from a multitude of decisional options, according to certain decisional criteria, the one deemed the most appropriate or satisfying, has as final stage the enforcement of a decision. In order to make the best decision possible, the thorough knowledge of the decisional process is necessary. We took into discussion the pattern of decisional process as seen by Simon. Briefly, it consists of four major stages:

- problem identification and definition;
- problem shaping or projection;
- choosing the solution;
- solution implementation and assessment of the effects obtained as a result of solution application.

We consider the Simon pattern one of the most general ones and our statement is supported by the patterns subsequently occurred and that concern the decisional process. The mentioning of Mintzberg's pattern from 1976, Holsapple's and Whinston's patterns from 1996 or Dumarest's pattern from 2001 are sufficient enough to realize the impact and generality of this pattern. Moreover, on Simon's pattern of decision

making relied the well-known conceptual architecture of a decision support system proposed by Sprague and Carlson.

Among others, IT field had, has and will have a considerable influence in granting a substantial support for the accomplishment of decisional process. According to our opinion, in the current economy, the computer systems are playing a critical role in the carrying out of the organization activity. Moreover, the computer systems, if designed and enforced in an appropriate manner, may become a decisive factor in the enhancement of an organization competitiveness and efficiency. The computer system, having as a prevalent function the support of all the stages of decisional process, with the purpose of finding solutions to certain complex problems, with a high degree of unstructuring, using a natural and familiar manner to decision factors bears the name of decision support system.

The capacity of expert systems to capture the auditing kept by one or several human experts in a computerized form, under the shape of a data base, the possibility of enforcing certain judgments, as in the case of human experts, the capacity of explaining their reasoning and the conclusions drawn following the judgment enforcement may extend in a benefic manner the capacity of a computer system to assist a decision.

From the various number of decision support systems, we will focus on those where the management sub-system of certain large data volumes constitute the dominant technological component. According to Power's classification from 2001, they are named data-oriented decision support systems.

The process of extracting new information from existing data collections within an organization bears the title of data mining. The extension of data mining techniques lies, among other, in the extremely comprehensive data volumes purchased by companies, related to different types of transactions, carried out throughout several years. For a long period, these were stored by virtue of a need for filing. The continuous growth of competition, the increasing market requirements made companies be aware of the potential inherent to those data files. The information obtained through data mining are of predictive and descriptive nature and are useful during actions like classifications, group analysis, optimizations.

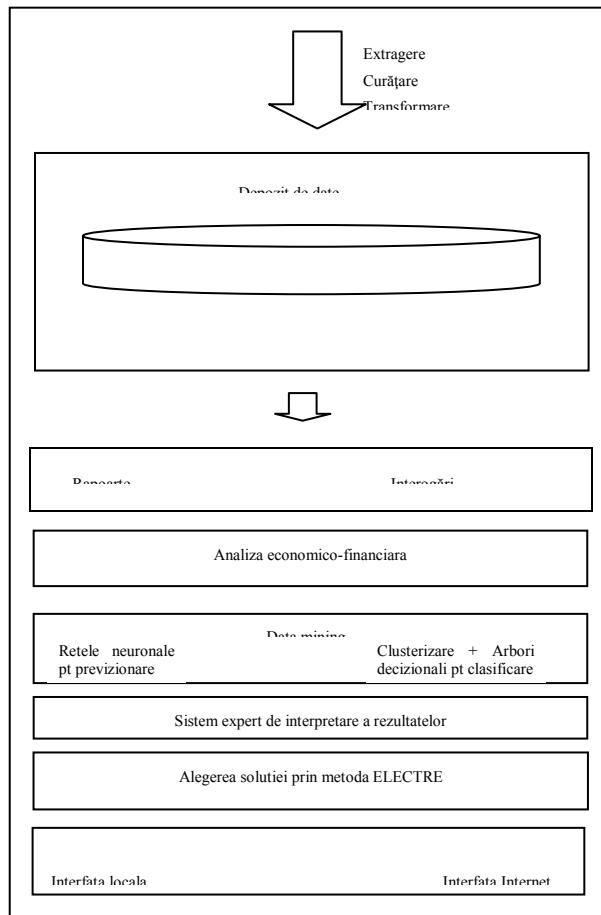

Taking into account that we are placed in a strongly unstructured decisional environment, classical mathematical patterns fail to grasp different unforeseen situations of reality, where interdependences within a pattern are described by procedures that may be solved solely by means of computer, the simulation instruments are resorted to. The simulation instruments have the capacity of performing experiments, describing the behavior of each business partner over a longer period of time. The economical and mathematical pattern, to which such procedures are joined, results in a simulation pattern. One of the most frequent simulation method encountered in the economical practice is the so called "Monte Carlo" method. It is an excellent approximation method and may be easily adapted to the analyzed problem.

There is no doubt that the Internet has the main value of an environment for communication, collaboration and knowledge sharing in a decision support system. Moreover, by means of certain special instruments for information extraction according to certain requirements, the huge data volume may be converted in any moment in consistent data and knowledge storage. The Internet portals will meet an unparalleled development and the Internet agents will constitute indispensable information intermediaries for each person in particular.

Architecture of the DSS

As we mentioned before, our global objective is the accomplishment of a computerized decisional support, as a work instrument of a financial counseling agency regarding the selection of certain potential business partners.

The below chart illustrates in a relevant manner the working frame associated to the accomplishment of the desired decision support system.

The working frame associated to the DSS

The building process of the decision support system will comply in all aspects with the classical strategy of life cycle, development of a computer system, according to which we distinguish stages like project preparation, system analysis, design, implementation and operation.

During the building process, we will take into consideration the following aspects. Firstly, the decision-assisting computer system must offer support to all stages of the decisional process, as they are highlighted in the Simon's decisional pattern. Furthermore, our conviction is that human decision factor is essential for finding solutions to some intricate problems, due to his creativity. That is why, within the framework of the decision-assisting computer system, both the existence of a manual decision making approach, as well as an automatic one are imperious, where the intervention of the decision factor is consultative, reduced to minimum, but still existing. In order to prove its complete usefulness, in our opinion, a decision support system must be an excellent collaborator of the decision factor, relieving him from certain routine tasks, signaling him the occurrence of certain dangerous or benefic situations, suggesting opinions related to the subject under analysis at a certain moment. Last, but not least, one must take into account the inconsistency of the business environment, requiring a perpetual adaptation to the new conditions, a flexible behavior, non-rigid, which imposes a permanent collaboration with the beneficiary, requesting the final decision.

Data source of the decision-assisting computer system will be essentially represented by the existing data in different reporting situations of a small and middle-sized enterprise to the state competitive bodies. In order to facilitate analysis from multiple perspectives, we are of the opinion that data organization in a multidimensional structure of a data storage is of much relevance. Consequently, analysis may be performed by 2 means: through classical instruments of interrogation and reporting, as well as the OLAP multidimensional analyses and data mining algorithms. To fulfill this purpose, we will use as technical support the facilities offered by SQL SERVER 2005.

The entire economic and financial analysis of the organizations included in data storage will be assigned to a group of agents having the responsibility of this task, each one of them being incorporated with knowledge and specific algorithms on the most important economical and financial analyses performed within the present economic environment, at the small and middle-sized enterprise level.

In order to supervise the key indicators with the purpose of forecasting their behavior depending on the dependent factors (established in the correlation matrix), we consider that the most adequate machine learning technology is the one belonging to neuronal networks. We resorted to this technology, as the relations that could be grasped by a neuronal network are higher in complexity than those caught by the mentioned statistic method. The neuronal network foresees the future evolution of a phenomenon on the basis of main factors involved in the performance of the shaped pattern.

For each key indicator a previously learned neuronal network will be launched, so that subsequently, by means of certain time releases, procedures for learning neuronal networks should be periodically launched, meaning procedures for adjusting their share, thus adapting to the new environmental tendencies.

To the values foreseen through neuronal networks will be added those resulting from Monte Carlo simulation method, reducing or enhancing trust in the obtained values.

By clustering process (K-means method), we will attempt a segmentation of business partners according to several pre-established criteria. After having identified these groups, through decisional trees method (ID3 and C45), we will proceed to their structural configurations, so that in the end we should be able to establish several classifications of business partners, according to different criteria.

All the analyses previously mentioned will be interpreted by an expert system especially designed for this purpose. Through the audit captured from different field experts under the shape of a knowledge base (in the production rules format), this system will operate the inferences necessary for the identification of the most plausible interpretation.

We are aware of the fact that deciding means choosing from a multitude of decisional options, depending on certain decisional criteria, the one deemed the most profitable for reaching the proposed objectives. Following the classification of the results related to each analysis type, the best decisional alternatives adequate to different analyzed angles may be identified. Those might be taken over and analyzed through the well-consolidated method for assessing decisional options - ELECTRE, resulting the most propitious option, compliant with the decision factor's preference.

The interface between system and user will happen by means of an interface module. Communication between module and user will take place naturally and what can be easier than communicating in a natural language, using DCG grammars. An interface agent must be endowed with a fundamental quality – adaptability to user's behavior. This requires mainly the existence of different modalities of data logging and posting, in compliance with user's profile. As a common fact, the decisive factors may be relieved from fulfilling some routine assignments, by transferring this task to the system, in a much more efficient manner. According to our opinion, the best modality to state a routine task is registering at the beginning all the user's steps taken for the fulfillment of the task under the shape of a mackerel, so that subsequently this task might be automatically called and executed by use of a key of key combination, click or double click.

We are foreseeing the execution of an Internet interface with the designed system, to such extent that its results could be also accessed on-line, from a remote distance. The Internet interface will take the shape of a site on the Internet, conceived as a small virtual store, trading a set of data access packages and economical and financial analysis packages placed at the client's disposal against an established and posted fee.

Conclusions and perspectives

As concerns the impact registered by introducing the mentioned decision-assisting computer system, we mention:

- the enhancement of decisional capacity by:
 - use of actual methods and concepts;
 - thorough analysis of phenomena;
- the substantial reduction of decision making period;

- increase of objectivity and impartiality degree as far as decision making is concerned;
- a better quality of the taken decision;
- a lower degree of dependence to experts in different fields due to the captured audit.

The decision support systems represent one of the most adequate instruments for assisting decision making process at an organizational level, in the contemporary society, characterized by a high degree of complexity of the business environment, global competition, informational bursting, uncertainty, marked versatile character. Without replacing the decision authority, the decision support system, due to its components placed at our disposal for granting assistance in each stage of the decisional process, may facilitate the work of the person incumbent with decision making by offering some useful clues necessary for problem solving or opportunity grasping. But taking into account that the final users of these systems are mainly average and top managers of an organization, with reduced time availability due to their busy schedules, with different decisional trends, there occurred the strong need for computer systems as friendly, natural and easy to handle as possible, that could offer a rapid and relevant answer. This assertion entitles us to consider that in the near future, the decision-assisting information systems and executive information systems will merge.

The capacity to learn, understand, know from experience and cope with old and new circumstances, this intelligence accompanied by information collection, processing, preparation of decisional alternatives and finally decision making propelled the artificial intelligence among the main technologies used in building decision-assisting informatic systems.

LES PROJETS INFORMATIQUES ET LES RISQUES DE LEUR REALISATION ET IMPLEMENTATION

Melnic Andreia-Simona

Universitatea "George Bacovia", Bacău, Facultatea de Economia Afacerilor, Strada Pictor Aman, nr. 96, Bacău, andramelnic@yahoo.com, tel/ fax 0234 516448

Because informatics projects are filled with risk, effective project management demands that solid risk management perspectives be factored into the overall management effort. For the most part, the best way to handle risks on projects is to carry out the project effort in accordance with good general management practice. Thus, you should plan well, monitor the team's performance carefully, communicate clearly, treat your employes with respect, and so forth.

Keywords: informatic project, risk, management risk

Les risques apparaissent dans le cadre de toutes les activités socio-économiques, pour chaque d'entre eux ayant des formes particulières, en fonction de leur type, mode de manifestation et intensité. Le risque représente l'incertitude de l'apparition d'un phénomène qui, dans les conditions qu'il se produit, a un effet positif ou négatif sur les objectifs d'un projet. Le risque exprime l'impact direct d'un événement dans le futur sur les projets actuels et il exprime le degré d'écartement des objectifs proposés, des standards proposés. Toutes les activités supposent connaître les risques et les assumer. Pour avoir du succès il est nécessaire d'identifier tous les risques possibles, leur quantification, assumer les responsabilités tout au long du déroulement de l'activité.

Le projet informatique représente un cas particulier du concept du projet. Pour tout projet il doit exister un support financier propre pour permettre la mobilisation des ressources nécessaires à aboutir les buts (ressources humaines, matérielles, informationnelles, informatiques). Pour chaque projet il doit exister une équipe de gestion du projet, avec un gestionnaire du projet qui soit capable d'orienter ses actions selon les fonctions de la gestion traditionnelle (planifier, organiser, diriger/coordonner, contrôler). Dans la mesure dans laquelle il s'agit des actions spécifiques au domaine informatique d'une organisation, c'est à dire: l'informatisation d'une fonction à l'intérieur, la modernisation d'un investissement informatique plus vieux ou des activités qui ont comme but la réorganisation des procès du domaine informatique, nous pouvons dire que le projet qui les réunit est un projet informatique.

Ce qui sépare le risque de projet d'autres types de risques est le fait que nous avons déjà une idée sur les types des problèmes que les équipes engagées dans le projet puissent les rencontrer. Nous savons qu'il y aura des sources prévisibles des problèmes organisationnels, des efforts inévitables pour gérer les besoins et les demandes et des problèmes liés à la planification et le contrôle inadéquat. Nous savons aussi qu'une source importante des problèmes peut être une estimation inadéquate. Ces problèmes sont universels et ils tiennent de la nature des projets et leur gestion. Si on comprend les sources des risques du projet, la possibilité que des événements défavorables pourraient apparaître, peut être réduite, et d'ici même leurs effets. Parce que une grande partie des risques sont liés des problèmes organisationnels, l'attention devrait être concertée sur l'identification de ces problèmes et sur le développement d'une stratégie pour leur gestion. Par exemple, l'expérience nous montre qu'au moment où des ressources empruntées sont utilisées, les gestionnaires rencontrent des difficultés dans leurs propres convictions de s'engager dans des efforts, d'être plus responsables envers leur mission, envers le projet. Ainsi, ils rencontrent un risque prévisible - celui dans lequel les membres de l'équipe du projet ne donnent pas toute leur attention au projet. C'est une réalité inévitable et ils devraient développer plus d'acharnement par rapport au projet. Certaines techniques de former une équipe, employées par les administrateurs s'appuient sur les systèmes de récompense et l'utilisation d'une puissante note personnelle dans le travail avec les membres de l'équipe. Alors quand on travaille avec des ressources empruntées on rencontre les risques d'un engagement réduit des efforts de l'équipe. Pour tenir tête à ce risque, on doit s'impliquer pour parcourir certaines étapes explicites pour développer l'engagement de l'équipe. La même logique s'applique / est valable pour deux domaines de problèmes prévisibles du projet: la gestion des besoins et des demandes et la planification et le contrôle adéquat. Par exemple, un problème besoins - demandes qui peut affecter tout le projet est celui de l'ajustement, cet état où les nécessités se change pour se plier avec les échanges dans la demande qui vient

de la part des clients, des managers et des membres de l'équipe du projet. Le résultat cumulatif de ces petits changements peut être destructif. Cependant il est possible d'apparaître des dépassements des coûts et des dérèglements dans le programme établi parce que le projet abandonne ses coûts et son plan initial. La prédilection pour ajuster ou changer est universelle. La meilleure méthode pour tenir tête aux risques est d'établir des puissants processus de contrôle du changement et de les appliquer dans le projet.

Le risque de rencontrer des problèmes à cause de la mauvaise planification ou contrôle peut être administré par s'assurant que tous les projets suivent des principes efficaces en ce qui concerne la planification et le contrôle doit utiliser des instruments adéquats. En dehors de ça, les membres de l'équipe doivent connaître ces principes et instruments et doivent les utiliser constamment. Si les principes concernant le contrôle et la planification sont bien utilisés, alors les problèmes produits par une mauvaise planification se réduisent beaucoup.

La meilleure méthode pour administrer le risque du projet est de suivre les procédures standardisées de la gestion des risques. Il faut planifier les efforts de la gestion des risques, identifier les risques, faire des analyses qualitatives et quantitatives sur l'impact du risque, établir des stratégies de la gestion des risques et surveiller et en même temps contrôler les risques dès le début du projet.

La gestion des risques comprend les méthodes et les moyens par lesquels l'incertitude peut être contrôlée comme important support des facteurs du risque, ayant comme but l'acquisition des objectifs exprimés dans le cadre du projet. La gestion du risque ne doit pas être regardé d'une seule perspective dans le chapitre composant la gestion globale d'un projet, à cause de sa complexité, elle étant située dans la catégorie des sciences de frontière qui nécessitent généralement la corroboration des informations des plusieurs domaines: économiques, techniques, juridiques, statistiques et psychologiques. La gestion des risques dans le projet informatique est un processus cyclique ayant plusieurs étapes distinctes:

- a) *L'identification du risque*, c'est-à-dire chercher et localiser les risques avant qu'ils se manifestent. Pour chaque risque identifié on rédige un plan de risque.

L'identification des risques associés à un projet informatique se réalise en utilisant plusieurs techniques: la réalisation d'une liste avec des risques possibles, la réalisation d'un profil de risque, établir des risques selon des expériences précédentes, comparer les risques avec ceux survenus dans le cadre des projets similaires, établir les risques qui puissent se manifester au cours du déroulement de l'activité et établir le budget.

La réalisation d'une liste avec des risques possibles est nécessaire pour consulter toutes les personnes impliquées dans le déroulement du projet sur les facteurs qui puissent contribuer directement ou indirectement à influencer d'une manière négative les activités ou les résultats des propos pour le financement, les modalités principales de leur constitution étant les réunions de brainstorming, les interviews et les questionnaires.

L'utilisation du profil de risque est utile en général dans le cas où les gestionnaires peuvent utiliser leur expérience accumulée dans le cadre des projets précédents, pour identifier les facteurs de risque spécifiques qui se retrouvent dans la nouvelle structure du projet, en réalisant une questionnaire qui s'adresse aux principales zones d'incertitude existantes dans le cadre du projet: l'équipe du projet, les clients et la technologie utilisée.

L'un des plus importants facteurs de prédiction pour les activités futures est d'employer l'expérience acquise dans le déroulement des projets antérieures, un bon gestionnaire de risque ayant la possibilité de s'en tirer des conclusions après avoir analysé les facteurs de risque qui ont été rencontrés avant.

La gestion de risque contribue à illustrer les activités planifiées ayant une opportunité d'identifier les risques. Pour réaliser cette analyse en détail pour chaque activité composante, il est nécessaire de réaliser une planification et une estimation du budget qui dans la plupart des situations est difficile à rédiger à cause des facteurs d'incertitude.

Dans l'étape de l'identification du risque on mesure les potentiels dangers, les effets et les probabilités de leur apparition pour décider quel risque doit être prévenu. Le processus d'identification des risques est régulier et il doit tenir compte aussi des risques internes, que de ceux qui viennent de l'extérieur.

Les risques internes sont ceux qui apparaissent à la suite de l'activité organisationnelle et ils peuvent être contrôlés par les gestionnaires par un règlement des activités. Les risques externes sont ceux qui ne tiennent pas de l'activité de l'organisation, mais ils peuvent l'influencer. Ces risques ne peuvent pas être

contrôlés par l'équipe de gestion, mais ils peuvent être connus, analysés et on peut prendre une décision pour minimaliser leurs effets ou même les éliminer.

Les risques internes d'une organisation peuvent être :

- Des risques dans le processus de la production (accident de travail, arrêt de la production etc.);
- Des risques dans le processus de gestion (implémentation d'une décision, l'utilisation des certains sources de financement);
- Des risques informationnels (inefficacité du système informationnel, l'utilisation des informations incorrectes etc.).

Dans la catégorie des risques extérieurs on peut distinguer:

- Des risques législatifs (l'apparition d'une législation défavorable à l'organisation);
- Des risques survenus à la suite des modifications de milieu économique (modifications des intérêts, inflation, monnaies d'échange etc.);
- Des risques technologiques à cause de l'apparition d'une technologie qui peut avoir des erreurs de projection (l'apparition d'un virus);
- Des risques causés par la relation avec les syndicats (le risque de grève).

L'identification des risques de l'extérieur de l'organisation peut se réaliser par désigner une personne capable de participer à des réunions des associations professionnelles, à des conférences et qui puissent suivre les publications dans le domaine, personne qui doit être continuellement informer sur les modifications de milieu et des éventuelles apparitions des risques nouveaux.

b) *L'analyse du risque* signifie la transformation des données qui font référence au risque dans des informations pour pouvoir prendre une décision. Cette étape comprend :

- Des analyses préliminaires: identifient les risques qui puissent intervenir dans le déroulement d'un projet ou d'une activité;
- Estimations du risque: calculent la probabilité de l'apparition d'un risque;
- Evaluation du risque: établie l'impact qu'un phénomène de risque peut l'avoir sur le projet ou sur une autre activité;
- Le contrôle du risque: assure la correction des écarts de la planification du risque.

c) *La réaction au risque et sa surveillance* a comme but les stratégies suivantes:

- L'acceptation du risque regarde la modalité dans laquelle le gestionnaire d'un projet comprend le risque, sa probabilité de se réaliser, les conséquences estimées qui en apparaissent et la décision de ne pas actionner pour son écartement. Une telle stratégie est utilisée d'habitude, alors quand la probabilité d'apparition d'une catégorie des risques est très petite et /ou les conséquences sur le projet ne sont pas significantes.
- Eviter les risques représente une stratégie utilisé dans des certains conditions pour minimiser les risques. La réduction des risques ne signifie pas éviter s'assumer des décisions de gestion ou l'exclusion du risque dans le cadre du projet. Cette stratégie est utilisée en général dans la situation du changement du but ou quand on annule une partie du projet;
- La diminution du risque représente un assemble des actions qui essaient de minimiser les effets produits par l'apparition du risque jusqu'à son encadrement dans des limites acceptables pour les gestionnaires du projet: la planification des activités, apprendre le personnel, réprojeter les activités;
- La répartition des risques est un instrument pour que les parties acceptent soit une part ou la responsabilité entière en ce qui concerne les conséquences du risque. Ce processus est un transfert du risque à une autre institution spécialisé pour assurer des compétences supérieures pour gérer et contrôler le risque. Il y a des modalités de transfert indirect des risques, comme par exemple l'embauchage d'un expert dans le cadre du projet pour évaluer ou surveiller le développement des certaines activités, représentant aussi une forme de transfert du risque vers une autre personne que le responsable du projet. On peut aussi utiliser dans le cadre du projet le contrat de service comme un autre forme de transfert du risque. Ainsi, le risque technologique est transféré à la compagnie qui assure contre remboursement des services pour le bon fonctionnement du système tout entier. Un chapitre important dans la gestion du risque est constitué par les coûts remboursables. Ceux-ci se

réfèrent aux paiements de quelques travaux sous - contractés par d'autres sociétés commerciales ou des matériaux utilisés dans le cadre du projet;

- La surveillance assure le renseignement continu sur les facteurs de risque;
- La feedback assure le transfert des informations dans le cas où le risque apparaît pour diminuer ses effets.

Les questions auxquelles un gestionnaire doit répondre sont les suivantes:

- Quels sont les risques pour le projet;
- Quelles sont les pertes dans le projet rapportées au total des coûts;
- Quelles sont les pertes assumées du projet;
- Quelle est la gravité des pertes dans la situation où les prévisions les plus pessimistes pourraient devenir réalité;
- Quelles sont les alternatives pour dépasser la situation de crise;
- Comment peut on éliminer ou réduire les pertes;
- Les alternatives décisionnelles acceptées conduiront-elles vers la supposition des risques plus grands ?

A la suite des réponses enregistrées aux toutes ces questions, on peut identifier dans une première forme les principaux risques qui puissent conduire vers un échec ou vers des situations critiques. En réalisant une analyse globale, les gestionnaires peuvent définir dans une forme primaire leur stratégie d'actionner dans le cadre du projet. Le gestionnaire du projet va s'assumer seulement la partie des risques majeures, capable de conduire à ne pas réaliser l'objectif du projet.

Le manager du projet, même s'il possède des qualités spéciales, il ne sera capable d'identifier tous les facteurs de risque existants dans un projet et d'ici résultera son impossibilité de le gérer. Il est nécessaire d'apercevoir et d'administrer les principaux facteurs de risque capables de conduire à la perturbation de la finalisation des objectifs du projet, ou même à son échec. Pour pouvoir décider quels sont les facteurs du risque majeur acceptables dans la sphère du normal, il faudra une connaissance a priori de ces facteurs et de la gravité des conséquences.

Une source majeure du risque des projets informatique est liée des difficultés de pouvoir gérer les besoins et les demandes. Si les besoins n'ont pas été identifiés correctement et si les demandes ne captent pas les nécessités réelles, alors le projet est destiné à l'échec parce que ses résultats ne vont pas correspondre aux besoins et aux désirs des consommateurs. Une gestion adéquate des besoins et des demandes est une condition nécessaire pour le succès d'un projet.

Les problèmes commencent avec les essais d'identifier les besoins. Une difficulté assez souvent rencontrée est l'identification des consommateurs. Les utilisateurs sont les consommateurs, ils sont ceux qui travailleront avec les résultats, les biens fournis par l'équipe du projet et leur satisfaction est importante. Mais l'identification des besoins des consommateurs peut être difficile parce que les utilisateurs n'ont pas une vision monolithique sur leurs besoins.

Un autre problème est la création d'une liaison entre les affaires et les solutions techniques nécessaires pour s'adresser aux besoins. Le problème surgit au moment où les membres de l'équipe technique ont des faibles connaissances sur l'affaire, et cependant les personnes impliquées dans le projet ne comprennent pas la technologie nécessaire pour l'implémentation de leurs produits.

Si de point de vue formel il est important d'identifier les éléments de risque majeur, au niveau pratique, une importance similaire doit être accordée à l'identification des solutions concrètes pour réduire et effacer ces facteurs. De telles mesures peuvent être:

- L'identification des zones de risque et de leurs composants pour chaque zone;
- La structuration des facteurs de risque impliqués;
- La gestion optimale des ressources propres;
- L'identification et l'analyse des alternatives possibles pour réduire les facteurs de risque;
- La sélection des meilleures alternatives pour chaque facteur de risque;
- Obtenir un feed-back pour identifier les actions de succès.

L'un des plus importants aspects pour le manager du projet est la délimitation exacte des zones de risque. Les principales zones de risque, liés aux projets informatiques concernent la projection, les données, les coûts et le domaine d'opération des systèmes.

Le projet informatique peut être incompatible avec la structure, la culture et les objectifs organisationnels. Les risques existent si le projet n'ait pas en vue que les besoins courants, sans être flexible aux besoins futures de l'organisation.

Les données utilisées peuvent avoir un haut niveau d'imprécision ou inconsistance. Les informations peuvent être erronées, équivoques ou présentées aux utilisateurs dans une manière inadéquate.

Les coûts du projet informatique peuvent, dans certains cas, dépasser les budgets établis initiaux; les frais afférents ne peuvent pas être justifiés par la valeur que le projet l'apporte à l'entreprise.

Les informations ne sont pas fournies très vite pour être utiles, peuvent être dans un format impossible à comprendre ou à utiliser ou contiennent des données incorrectes.

On a identifié trois dimensions qui peuvent influencer le niveau du risque: la grandeur du projet, sa structure et son niveau technologique.

Les projets grands sont plus instables que les projets petits.

Les projets ayant des structures plus compliquées sont plus risquant que ceux pour des petites unités. Les projets moins structurés s'appuient sur une implication significative des utilisateurs dans toutes les étapes de leur réalisation.

Dans le cas des projets informatiques avec un haut degré de risque technologique, les membres de l'équipe doivent avoir une expérience technologique plus solide et participer à l'établissement des objectifs et des termes pour les réaliser. Le risque du projet va croître si l'équipe qui établit le projet et les spécialistes ont une manque d'expérience technique. Si l'équipe n'est pas familiarisée avec les équipements, le soft de système, le soft d'applications ou le système de gérer les dates pour le projet, alors le risque peut croître considérablement. Dans la sélection du personnel engagé au projet il est nécessaire d'appliquer le principe d'utiliser les personnes compétentes et non pas ceux disponibles. Les risques peuvent apparaître dans toutes les phases de réalisation du projet informatique.

Les risques peuvent se manifester dans toutes les phases d'un projet informatique.

Dans la phase d'analyse du projet peut apparaître une série de risques déterminés par les aspects suivants:

- On n'a pas accordé des suffisants ressources, temps et argent pour étudier le problème; les objectifs sont vagues;
- On n'a pas réservé le temps nécessaire pour une planification préliminaire; les standards n'existent pas;
- Les demandes informationnelles sont obtenues à la suite d'une documentation faible, les utilisateurs refusent s'impliquer à côté de l'équipe du projet, pour établir les demandes informationnelles;
- Le personnel du projet n'est pas bien sélectionné;
- Les spécialistes en informatique promettent des résultats impossibles à atteindre;
- Les analystes du projet ne peuvent pas interviewer les utilisateurs dans une manière adéquate.

Des risques peuvent apparaître dans l'étape de projection aussi: les spécifications fonctionnelles ont une documentation inadéquate ou le projet n'est pas flexible aux besoins futures de l'organisation. Si les utilisateurs finals ne sont pas impliqués dans l'équipe de réalisation du projet, il est possible que le projet ne corresponde pas à la structure, aux activités, à la culture de l'organisation et aux priorités du management.

Si le projet informatique concerne la réalisation d'un logiciel, les risques peuvent sortir dans l'étape de programmation, c'est-à-dire le temps et l'argent nécessaires pour la réalisation du projet sont insuffisants, les programmeurs ne reçoivent pas des spécifications complètes ou ne bénéficient pas de l'avantage des technologies orientées objet ou de celles de planification structurée.

Dans l'étape des tests pour le produit obtenu, les risques peuvent surgir parce que l'équipe n'a pas réalisé un plan des tests correspondant, le temps et l'argent nécessaires pour la réalisation des tests sont sous-estimés, le management ne fait pas la révision et n'accepte pas les résultats des tests ou les utilisateurs ne sont pas assez impliqués dans les opérations des tests.

Au cas où il s'agit de la réorganisation ou la modernisation d'une fonction informatique; il peut se dégager des activités de conversion même, des conversions de données spécialement. En ce cas on peut surgir des risques au sujet de l'allocation des fonds, ou sommes d'argent insuffisantes pour soutenir ces opérations. De même, si la maintenance est inadéquate, il y a moins de personnes instruites pour assurer la maintenance du produit obtenu ou pour tenir tête aux changements nécessaires.

En présent l'accent ne se met plus sur l'écriture du code, mais sur les étapes qui précèdent ou qui suivent l'écriture de code. La qualité d'une application réside dans la qualité de la technologie des spécifications, de l'analyse du projet et de son projection, de contrôle, documentation et de la manière de le diriger. L'habilité de collecter des spécifications de plus en plus complètes des clients, et en même temps de déterminer le client voir la fonctionnalité du futur produit, va se refléter dans la satisfaction ultérieure du client envers le produit. L'analyse et la projection sont considérées aujourd'hui les étapes clés d'un projet et elles devraient couvrir 40% de la durée totale du projet. Pour cela on a développé des méthodologies d'analyse RAD (Rapid Application Development) ou OO (Object-Oriented) et des instruments CASE (Computer Aided Software Development).

Les risques pour réaliser des projets informatiques sont liés aussi de la partie financière. Pour calculer correctement le budget d'un projet, il est important que chaque partenaire connaisse la somme qui doit être investie pour le financement correct du projet. Le principe fondamental qui se trouve à la base d'une décision de financement est de trouver les heureuses combinaisons entre la source de financement et la modalité d'utiliser l'argent.

Degré de risque	Le type de projet	
Bas	Une expansion d'échelle Des produits fortement associés La même clientèle Des connaissances en ce qui concerne la technologie existante	Le même produit et le même marché
Moyen	Expansion d'échelle Canal de distribution différent Clientèle différente Technologie vérifiée, mais pas aucune expérience ou connaissance dans la technologie respective	Produit nouveau ou marché nouveau
Grand	Projet de recherche-développement Dépendance de la technologie non vérifiée dans la pratique	Produit nouveau ou marché nouveau

Table no.1. Classification des projets en fonction du degré de risque financière

Le succès d'un projet dépend dans une grande mesure des options qu'un manager les fait au moment où il adopte des décisions qui concernent les risques que celui-ci soit disposé d'accepter.

Conclusions

Dans le cas de chaque projet informatique il faut qu'on ait de l'intuition pour prévoir les hypothèses concernant le futur, tout en analysant le milieu interne et celui externe de l'implémentation. Après avoir identifié les hypothèses on va évaluer le risque associé à chaque activité. Le risque signifie la probabilité d'apparition d'un obstacle qui va bloquer le succès de l'activité. Une activité qui a une grande probabilité d'échouer est soumise à un grand risque. Les types de risque auxquels sont soumis les projets sont: les défections techniques, l'insuccès sur le marché, les difficultés de réalisation, l'impossibilité de les finaliser à temps, ne pas finaliser le plan de recherche, une évolution inattendue, des chutes dans la projection ou dans la fabrication, des obstacles techniques insurmontables, des résultats imprévisibles, des incertitudes normatives et législatives, des événements imprévisibles, un know-how inadéquat.

Un bon gestionnaire de projet doit connaître et gérer les facteurs critiques qui puissent transformer le projet dans un succès: relations de collaboration étroite entre les membres de l'équipe de projet, clients et gestion, plan du projet et la direction à suivre, des responsabilités claires et indicateurs spécifiques pour mesurer le progrès dans l'exécution du projet, communication constante et efficace entre tous ceux impliqués dans le projet, le contrôle des compétences.

The exponential increase in internet connectivity and in electronic commerce is likely to have a lasting effect on the conduct of business activities. Consequently, the already observable changes indicate only the beginning of a long-term phenomenon, which might be labeled with the term new economy. The rapid spread of the internet as a means for business transactions has not yet been accompanied by corresponding modifications of the international framework. The potential that e-commerce has in productivity and competitiveness terms is so significant that any delay in ensuring the technological and infrastructure premises necessary to its spreading on a larger scale attracts the risk of the deepening of the digital difference and implicit of remaining behind related to the aspect of integration in the global and European structures.

Keywords: new economy, ECommerce, framework

The rapid diffusion of the internet and electronic commerce changes the way business and international trade take place. The new economy poses new challenges to the international and European regulatory framework, since small distortions due to differing sets of regulations and taxation between countries might grow to non-negligible dimensions. The rapid spread of the internet as a means for business transactions has not yet been accompanied by corresponding modifications of the international framework. An interdependent transborder network of business activities requires international policy coordination in order to ensure clear, predictable and non-discriminatory rules. A failure to establish these kinds of rules will restrain investment and, consequently, growth. For the new economy, important standardization issues concern questions like who determines the network norms, who decides on domain names, how is the compatibility between software programs ensured or how can new improved technological advances substitute obsolete, but still widely spread practices. The overriding principle to answer these question should be the desire to guarantee open network access and open electronic commerce practices. This means, that the use of existing business approaches can yield the benefit of common standards while the possibility of introducing enhanced applications or processes limits the monopoly power of the established firms. The frequent interaction between market participants encourages the formation of uniform standards within networks and e-commerce in a gradual market oriented approach.

The question is, how to build trust of consumers to eCommerce and increase security of the Web? Building of trust in eCommerce is not only a technological or judicial problem. It is related to overall strategies of Internet shops, branch organisations, as well as state authorities.

In many countries, apart from branch organisations, that are like the Internet self-government, special state committees for building trust were established (e.g. USA, UE, Singapore), which should help in quick and sound development of eCommerce.

What the State should do for building trust and security?

Main tasks of state bodies are:

- law regulations, which create friendly environment, where minimum of consumers. laws, especially concerning privacy as well as security, is protected by state,
- promotion of proper behaviours, credibility of Web-Sites and culture of security within the Web, what is especially important for private users.

- big companies feel danger and spend millions dollars for IT security - expenses for IT security and business continuity grow at 35% yearly (Ernst Young). After 11th September, number of organisations having business continuity plans during the system outage strongly increased (Ernst&Young 2003). Bigger problem is security of private users. It is a problem of lack of money as well as knowledge of proper behaviour.

The electronic cash systems operating currently offer high level of security . making payment through the Web safer than in a restaurant, where data can be easily stolen. However, users must check who is their partner. If a shop does not use proper technology, data could really be easily stolen by the shop itself or by hackers. So, the important task for state organisations is increasing awareness of users. Internet, if properly used, is safe.

We can list the following law problems connected with creating trust in eCommerce:

- protection of consumer rights,
- protection of privacy,
- making transactions in the Web,
- law frames for Alternative Dispute Resolution (ADR),
- localisation of the responsibility for materials in the Web,
- regulations for international eCommerce.

Because of specific position of the consumers in the Web, law regulations should secure especially high protection of their rights. Law regulations in Poland and EU fulfil this condition, e.g. assure possibility to return goods in defined time after purchase. Law extortsthat offers published in the Web should include complete information concerning offered goods, conditions of contract and guaranty, payment process, and final price including especially taxes, and cost of delivery. In case of privacy protection, law should ensure the minimum level of security of personal data of the Web users. Rules of registration and transmission of files with personal data, scope of information which may be collected, where data may be transferred, as well as how they should be kept to ensure proper security, all of this should be especially regulated.

In making transactions, the most important thing is to define the moment when transaction is contracted, the elements necessary for validating transaction, as well as establishing frames for legal recognition of the electronic signature.

The consumer has right not to fear about security of his data and its availability to other organisations. Why should he trust the Internet company about which he knows almost nothing? There is necessity to help them. This can be done with the declaration of proper *Privacy Policy*. But it is only, also in the case of the most rigorous policy, the declaration of goodwill. Researches show that leaving this problem to shops only is not a good solution.

We can indicate two models of privacy protection: first, based mainly on law instruments or market instruments, and second, based on self-regulation of the market.

The need for uniform technical standards is especially pronounced for electronic commerce that is depending to a wide extent on functioning and compatible networks. The provider of standards is, however, able to achieve a kind of monopoly power, and there might be a danger of commercial policy abuse by establishing standards and norms that favor one specific company or the companies of a specific country. Of course, the preeminence of the US companies within most sectors of the new economy will cause certain dependencies of such policy authorities on the US government or large US

firms. Furthermore, examples like the persistence of the English "QWERTY" and the German "QWERTZ" typing keyboards show that ingrained standards are sometimes very hard to replace. Nevertheless, in order to maximize overall welfare, it will be decisive to approximate as closely as possibly an open access approach to networks and electronic commerce.

Electronic commerce has, in a broad sense, a much deeper impact upon the evolution of the business and encompasses, in fact, not only the new commercial acquisitions, but also the total amount of activities which support the marketing goals of a company and which can include, for example, advertizing, sales, payments post-sale activities, clients oriented services etc. As a result the range of services which supports and lends assistance to this new business field has been expanded. These services refer to the Internet suppliers, to the security systems and the electronic signatures, to the on-line transactions or the shop

networks, as well as to the services of a more general nature, such as consulting, web design, site creation etc. This evolution has a major impact upon economy as the creation of new companies, the diversification of the existing ones and, especially, the potential of the labour market and its future degree of employment are concerned.

However, what is unique about e-commerce over the Internet and the efficiency gains it promises is the premium placed on openness. To reap the potential cost savings fully, firms must be willing to open up their internal systems to suppliers and customers. This raises policy issues concerning security and potential anti-competitive effects as firms integrate their operations more

closely. Another source of efficiency associated with e-commerce is the opportunity for “boundary crossing” as new entrants, business models, and changes in technology erode barriers that used to separate one industry from another. More generally, e-commerce illuminates differences that may exist between products, industries and countries, thereby highlighting the need to reform inconsistent regulations. While e-commerce can dramatically reduce some production costs, it does not offer a “friction free” environment. Rather, owing to new costs associated with establishing trust and reducing the risks inherent in this type of activity, it requires new intermediaries. Widespread “disintermediation” (producers selling directly to consumers without aid of any intermediaries) is not likely, but the nature of intermediary functions is expected to change. The translation of cost reductions into price reductions is not automatic. It is contingent on sufficient competition. Currently, price reductions attributable to e-commerce have only been evident in a few sectors. However, the lower costs associated with e-commerce should lead to greater product, market and international competition, especially in services, and thus to greater price competition.

It is clear that electronic commerce will change the structure, if not the level, of pricing as more and more products are subject to the differential pricing associated with customised products, fine market segmentation and auctions, and as the ease of changing prices increases. While these changes will generally improve economic efficiency, they may raise some consumer concerns. While consumers are accustomed to paying different prices for products such as cars, they may be less comfortable with differentiated pricing for smaller, common purchases. In addition, the more widespread use of variable pricing, the advent of greater price competition, and the ability to change prices quickly may affect expectations about prices and therefore have some bearing on monetary policy. In any case, changes in the structure of price setting will affect the ability to measure changes in prices and inflation accurately. Electronic commerce is transforming the marketplace by changing firms’ business models, by shaping relations among market actors, and by contributing to changes in market structure. Given the dynamic nature of these processes, the impact of electronic commerce will be firm-, sector-, and time-specific. Even if cyber-traders do not present a new commercial paradigm today, they play a catalytic role for other, more traditional companies that are entering electronic markets. Key market actors can thus contribute to the evolution and diffusion of e-commerce by forcing e-commerce solutions in sectoral and national contexts and, particularly, on suppliers. Electronic commerce does not always lead to greater market competition, but it changes firms’ competitive advantages, the nature of firms’ competition, as well as the market on which firms compete. The open, and potentially global, nature of electronic commerce is likely to increase market size and change market structure, in terms of the number and size of players and the way in which players compete on international markets. But the extent to which firms can reorganise in the new electronic environment will crucially depend on the flexibility and adaptability of the work force. The impact of e-commerce on the marketplace will also depend on the existence of a critical mass of consumers. A novel aspect of e-commerce is the emergence of virtual communities in online networks. E-commerce favours the combination of streamlined business processes, flat organisational hierarchies, continuous training and skills acquisition, inter-firm collaboration, and networking. All these elements contribute to a favourable environment for innovation and improve performance.

The speed with which information technology is transforming the economy and society makes it difficult to determine with absolute confidence the full range of social impacts and the net balance of social benefits and costs. It is clear, however, that fundamental changes are taking place at virtually every level of society, prompted by the growth of the Internet, electronic commerce and other applications of information networks. One of the hallmarks of electronic commerce is that, by drastically reducing transaction and search costs, it reduces the distance between buyer and seller, enabling businesses to target very small niches, develop individual customer profiles, and essentially provide a means of marketing on a one-to-one basis. The ability to realize this goal will largely hinge on the climate of confidence businesses are able to

create in their relations with their business partners and customers. Assurances about protection of privacy and personal information play an important role in building that confidence.

Both the public and private sectors need a fuller understanding of the requirements for

fostering confidence in electronic markets, particularly among consumers. E-commerce and other information and communication technologies reduce the importance of time as a factor that dictates the structure of economic and social activity. It both raises the potential of saving time as consumers shop more efficiently, but also could reduce leisure as the technology provides a continuous electronic link to work.

Regardless, many find that the pressure to perform tasks quickly is increasing. Linked to this is the broader question of the ability of policy-making apparatuses to accommodate.

In spite of its complex and multidimensional nature the e-commerce should be approached with complete seriousness by the political decision factors as well as by the business community in Romania if there is wished the capitalization of the opportunities that it is opening in terms of economical growing, of competitiveness and integration. The gains related the productiveness and efficiency generated by the e-commerce on the economy ensemble are so promising so that practically any attempt to ignore this new channel of business life development would be against productiveness and the pressure exercised by the big companies do not let to the Romanian companies other option than the one of the fast integration in the new electronic environment, if they want to maintain their competitiveness. The Romanian companies that are involved or that are intending to involve in the international commerce and want to derive gains from globalization must accelerate the incorporation of the new technologies and e-commerce in their business strategies. As the result, by the adopting of the electronic commerce the Romanian companies have the possibility to be part to the global production and distributing systems. At present, this seems to be the most efficient solution for the integration in the world economy and for the rendering more valuable the advantages of the present globalization wave.

The easiness entering on the market in some fields, associated to the decrease of the transaction costs, to the diminishing of the vertical integration advantages and of the companies dimension are opening new opportunities for the producers and consumers in Romania. Facilitating the small and middle companies access to the markets, to the information and other resources, otherwise inaccessible, the Internet and the e-commerce may place our country into a very favorable position to use the international trade and other tools of the globalizations (labor force fluxes, technology transfer, etc.) as instruments of the development.

The computers nor the Internet themselves cannot make an economy more productive or more competitive as well as the e-commerce is not a substitute for the export strategies. The on-line access to the markets and information do not themselves solve the ensemble of the issues related to the companies' competitiveness. Radical productivity and competitiveness bonuses may be expected providing that Romania shall built its capacity to exploit in a real manner the potential of the new TIC and of the e-commerce to make more efficient the economical processes. Making valuable the new opportunities inherent to the e-commerce in terms of efficiency as well as the globalization advantages by a more intense involvement in this commerce is not an easy task, because it depends on a huge variety of factors and conditions and the expected positive changes shall appear in time. Romania should have to confront numerous challenges and to cross over the many obligations that need to be approached concomitantly on more domains: economical, social, judicial., etc.

Romania must develop and consolidate its technological and informational infrastructure (facilities of telecommunications, TIC equipments, computers, etc.) needed by the acceleration of the diffusion of the e-commerce at the level of the whole economy. This means, firstly, the extension of the access to the telecommunications and Internet services at the level of prices, quality and speed supposed by the e-commerce. Related to this, Romania should develop the last technological progresses as well as the positive international experience related the reforms in the field of the regulation the telecommunications and the other infrastructure services.

Strongly connected to the efforts of consolidating the physical infrastructure and to the promoting of business environment favorable to the expansion of the e-commerce, there is the need of development of an advanced structure of services meant to stimulate the diffusion of the electronic transactions in its double quality of support and of content of those transactions. This is the reason that among the prioritizing in terms of industrial policies should be registered the extension of the Romanian offer of services as well as volume and as diversification, quality and efficiency degrees – as a premise and platform for the “taking-

off” and the dynamic expansion of the e-commerce. The competition stimulation on the services market by the mediation of the privatization, non-regulating and liberalization is a major requirement for the productive capacities strengthens of the Romanian sector of services and implicit for the increase of the efficiency on the national economy ensemble.

The experience of the developed countries shows that the Internet development and diffusion claims the involvement of numerous actors – governmental authorities, research universities and institutions, private companies and business associations, international agencies and bodies, etc. – as well as strong cooperation among them. If the modernization of the Internet and telecommunication infrastructure must be let as much as possible on the private sector investors the government belongs a significant role in the facilitating and promoting the e-commerce by the creation of a stimulating economical environment.

If Romania succeeded to adopt in a relatively short time the fundamental acts and legal norms needed to the operation of the e-commerce in national level and respectively, European level (for ex. E-commerce law, electronic signature act, etc), this should prove the same preoccupation for the steps at the multilateral level too, for the agreeing the game rules meant to govern the global electronic market, steps that are under evolution being supervised by the competent international authorities. The potential that e-commerce has in productivity and competitiveness terms is so significant that any delay in ensuring the technological and infrastructure premises necessary to its spreading on a larger scale attracts the risk of the deepening of the digital difference and implicit of remaining behind related to the aspect of integration in the global and European structures.

Conclusions

The exponential increase in internet connectivity and in electronic commerce is likely to have a lasting effect on the conduct of business activities. Consequently, the already observable changes indicate only the beginning of a long-term phenomenon, which might be labeled with the term new economy. In short, the paper has argued that it is particularly important to eliminate existing distortions. affecting the spread of electronic commerce and has pointed out the crucial importance of a certain set of criteria for international rules and regulations. The rules that govern the new economy have to be transparent, non-discriminatory, simple, enforceable, and consistent.

The separate frameworks of the countries can differ and it is neither likely nor desirable that the regulatory treatment of electronic commerce will converge to a single and exclusive corpus of legislation. Rather the different regulatory frameworks of the countries have to be compatible to each other in order to ensure the participation of all countries in the worldwide (digital) exchange of goods, services and ideas. Such an approach will enable further investment and growth in the new economy and will help to spread the benefit of the new economy to all countries.

A FUNCTIONAL SKETCH FOR RESOURCES MANAGEMENT IN COLLABORATIVE SYSTEMS FOR BUSINESS

Moca Mircea

Silaghi Gheorghe Cosmin

Universitatea Babeş-Bolyai Cluj-Napoca, Facultatea de Ştiinţe Economice şi Gestiunea Afacerilor, Str. Theodor Mihali nr. 58-60, {mircea.moca, gheorghe.silaghi}@econ.ubbcluj.ro, 0264-412569

Abstract: This paper presents a functional design sketch for the resource management module of a highly scalable collaborative system. Small and medium enterprises require such tools in order to benefit from and develop innovative business ideas and technologies. As computing power is a modern increasing demand and no easy and cheap solutions are defined, especially small companies or emerging business projects abide a more accessible alternative. Our work targets to settle a model for how P2P architecture can be used as infrastructure for a collaborative system that delivers resource access services. We are focused on finding a workable collaborative strategy between peers so that the system offers a cheap, trustable and quality service. Thus, in this phase we are not concerned about solutions for a specific type of task to be executed by peers, but only considering CPU power as resource. This work concerns the resource management module as a part of a larger project in which we aim to build a collaborative system for businesses with important resource demands.

Keywords: resource management, p2p, open-systems, service oriented computing, collaborative systems

1. Introduction

Nowadays businesses are becoming more and more dependent on technology. Applying a technology in a business can often increase returns. For example, a company can use the Internet in order to widen its market segment, employ a collaborative system to increase control over the production activity or to make the management process more efficient. Any of these situations may require innovation as a premise for a particular business progress. A new product, service or business idea requires building lots of scenarios and running simulations to conclude over the feasibility of the idea, which is the main pall for any investment.

Small and medium companies generally don't afford to buy access to computing resources for running their simulations. Computing services access is then a backset for small and medium companies.

Our work is related to the resource management module for a collaborative system that aims to meet small and medium companies' needs for computing resources. The service of access to computing resources is based on aggregating resources from all participating units. These entities are thought as collaborating nodes overlaying Internet.

In sections 2 and 3 we investigate technologies for achieving an economically efficient resource management for the mentioned collaborative system. Section 4 presents our work on establishing a functional model for the resource management module. Therefore, we discuss the general aspects of the module and assess alternative paths for the module behavior. In section 5 we conclude over the resource management module and the overall collaborative system, also presenting our future intentions concerning this work.

2. Technologies

2.1. Grids

Grid systems try to solve the following problem: the coordinated resource sharing and problems solving in dynamic, multi-institutional virtual organizations [5]. The CoreGrid network of excellence defines the grid as being "a fully distributed, dynamically reconfigurable, scalable, autonomous infrastructure to provide location independent, pervasive, reliable, secure and efficient access to a coordinated set of services encapsulating and virtualizing resources in order to generate *knowledge* [4].

The nowadays classical grid systems poorly fulfill the autonomy, scalability and dynamicity attributes of the above/listed definition. There are systems performing resource aggregation in a centralized manner building computing structures like TeraGrid [16] in USA, National Grid Service [17] in UK, Grid5000 [18] in France or the EGEE Grid [23] the project of the European Commission toward a global grid in Europe and world wide. Therefore, universities, research institutes, other selected organizations contribute with resources in this grid systems. These systems are used for running various scientific experiments that require huge resources, in various domains (particle physics, chemistry, biochemistry, medicine, Earth sciences, Life sciences, astronomy etc.). For participating in such a grid, an institution should follow a long and difficult process to get on with the technologies required to deploy the grid. To run experiments on the grid, a user should obtain security certificates, proving that the user already belongs to an agreed organization and it has a motivated research program for using the computing resources. Private companies are only very few involved in these grid systems. They prefer to build in-house closed grids to aggregate resources. Classical grid systems are based on middleware software platforms like Globus [19], Unicore [20] or gLite [21]. All the above mentioned platforms have problems to realize the scalability, autonomy and dynamicity attributes of the grid, because they are designed on a centralized coordination.

Classical Grids are relative closed systems, regarding the possibility of someone to enter the grid and contribute with resources. To outrun the organizational borders of the classical grid, the “grid economics” proposes the usage of methods from Economics for assessing and pricing the resources, for obtaining economic efficiency out of resource management [2]. Therefore they create the premises that each resource would have an associated value, users are able to pay the resources in correspondence with the utility they perceive from consuming the grid service. Therefore, negotiation between producers and consumers holds when allocating resources or when creating the so-called virtual organizations. The efficient exploitation of the grid is due to be realized through the usage of economic models. Economic-based resource management will be performed in a standardized framework, where the negotiation results will be described in the Service Level Agreements (SLAs), resources will be virtualized as web services. OGF [22] intends to standardize the WS-Agreement [15] language for SLAs. Part of the CoreGrid network of excellence, there are activities in this direction.

These research results are very promising, but, the classical grid systems still move to slow in this direction, also due to their centralized structure. Classical grid systems are mainly used for other scientific research, the money to support the grid are provided mainly from research councils or from the government; therefore, they do not push toward making the grid economically-efficient.

Up-to-date, the trust assumption holds in classical grids: the grid partners are trusted for delivering the quality of services they conceded to. This assumption does not hold on open systems that collect resources from various unsafe environments, or for systems that allow logging-in anonymous users. To tackle this problem, reputation models such as [13] are required for the grid to minimize cheating-users effects. This reputation model is based on the satisfaction perceived by the user and also intensively uses the huge amount of data supplied by the existing monitoring infrastructure.

2.2. Peer-to-peer

At the opposite side exists the P2P systems, which are applications that benefit from the resources (computing power, storage, network bandwidth) collected from Internet users [9]. These systems proved to be scalable because of the lack of centralization, auto-adaptable – they succeed to solve the absence of structure using internal mechanisms, and they are also very dynamic. In a remarkable vision paper, Foster and Iamnitchi [6] argue for the unification of grid and P2P, considering that both of these perform resource aggregation and sharing and each one has to solve problems that are identified in its counterpart system.

P2P is very popular for data distribution and sharing (Gnutella, Kademia, BitTorrent), but are almost inexistent for sharing computing cycles. These systems are based on reciprocity. If one user wants to download a file, she would have to deliver other files to the system or to help the file distribution to other users. Technically, P2P systems are based on structured or un-structured networks of peers. Structured networks are organized on so-called DHT (dynamic hash tables), like Chord [14], CAN [10] or Pastry [11]. These systems provide with a structure and an algorithm for message routing and information retrieval. Unstructured P2P networks allow a free collaboration between peers. Usual, they have some fairness rules [3], which directs the collaboration to the general goal of the P2P network. An important advantage in P2P networks is that malicious behavior usually affects only small parts of them. There are developments

showing out possible attacks on the structure of a P2P network and possible solutions to fight against these attacks [12].

2.3 Desktop grids

After presenting in sections 2.1 and 2.2 grid and P2P networks, in what follows we will describe Desktop Grids (DG), which, in general, supplies with the same functionalities like a classical grid but, apart from classical grids, they collect the computing resources of the (desktop) PCs spread over the Internet or over some computer network. In particular, if the computing resources are collected from volunteer users in the Internet, we say that we built an Internet Desktop Grid (IDG) and we deal with volunteer computing. Considering that most of the DGs are also IDGs, in what follows, we will simply use the expression “Desktop Grids” for mentioning IDGs.

Actual DGs are technically built on a master-worker computational model [8]: the master delivers tasks to workers and collects and verifies the results. Although the resources are collected from distributed Internet users, a master exists – being a centralization issue. The master distributes tasks and data related with those tasks and coordinates the whole activity of a DG project. The success of DGs resides on the fact that is cheaper and more flexible to manage a “master” in a DG, rather than to manage a supercomputer. Therefore, the computing power becomes available “on demand”, any time the user request it and at a fair price.

However, there are papers that try to design a desktop grid as a P2P system. We can mention the system proposed by researchers from Maryland University USA [7]. They analyze the situation that each peer can inject tasks in the DG, rather than only to contribute with resources. For the people to trust and use such DGs, these must be “trustable” and secure. In a P2P system, a peer joins in if it finds a benefit from joining the network. A peer will not participate in the system if the system will not offer him enough security warranties. In [7] the authors do not mention the mechanism that would attract volunteers to join the system and how to protect the system against sabotage, as in classical DGs. They omit the problem of protecting the volunteers against the risk that a peer to inject malicious code (viruses) or corrupted data into the system.

3. Resource management module

3.1. Overall system

We will shortly present now the main issues that determine our collaborative system. As a consequence of the previously presented technologies, we chose to design our system by employing P2P architecture. This ensures scalability of our system and openness to the aggregated resources. As a general view, the system gathers (buys) resources and then distributes (sell) them to different types of customers considering a SOA (Service Oriented Architecture).

The behavior of the system is wanted to be fully generated by economic rules (such as offer and demand rules). An important target which is not discussed in this paper but proposed for future work is the government of economics over our collaborative system. We are focused on finding a workable collaborative strategy between peers so that the system offers a trustable and quality computing service. Thus, in this phase we are not concerned about solutions for a specific type of task to be executed by peers, but only considering the computing capacity as resource.

3.2. System infrastructure

As Internet overlays, P2P systems can globally access resources. This is a key-advantage since by rule any resource is wanted in greater and greater quantity. Another reason is that resources in these networks are fast and cheap available. We will employ structured P2P architectures, because of their advantages over the unstructured ones. Such strong points are scalability, fault-tolerance resistance and guaranteed resource location. The structured P2P architectures evolved since their start, still being improved and this highly supports our target for global resource aggregation. We are not focused yet on a particular architecture, so we will make this decision based on results from simulations of our aimed resource management module on several P2P systems such as: Chord, CAN, Pastry, Kademia, comparing the different specific results.

3.3. Resources aggregation

An overview on the resource management issue raises certain demands on how the system should act in terms of resource gathering and delivering. Therefore, each participating node holds a specific resource quantity available for the system. The way a peer announces its capacity could be made in a web-service manner by publishing this information (resource offer), this being a common habit in SOAs. In our system, the web interface will be replaced with other types of connection-based communication.

After the announcement of individual available computing capacity, there comes the aspect of aggregating these resources. In this context, we will establish a method for maintaining resource-offer aggregated information. This means a place or a method for accounting the aggregated resource. This could be done in two ways: either using leader-peers to centralize information about resources or defining an algorithm for searching through the network to satisfy ad-hoc resource demand. The algorithm searches and gathers computing capacity until the needed quantity is reached.

The approach of creating leader-peers brings into discussion hybrid-p2p scheme, which premises weaknesses points to the system. Therefore, certain nodes must be endowed with server capacities in order to centralize and deliver information about the aggregated resources. The challenge is, here, to determine which nodes and under what circumstances should become leaders (reputation criterion). The disadvantage of this presumed solution is that the centralized information must be updated as the network evolves and vulnerability of the system concerning the leader-peers. As P2P systems are highly dynamic networks we intuit an overcharge on the leader-nodes, but we are not sure about certain consequences unless testing the solution.

The second possible solution to gathering the resources employs pure-p2p architecture. In this situation, peers are functionally equivalent. When a service-customer wants to access the aggregated resource, it only contacts at random a node in the system. To ease the reference to this node, we will call it *initiator*. In response to the request, the initiator will run a *gather* procedure in order to build a list with those nodes in the system that will “work” for this same request. This hypothetical method has no threats about a single point of failure, since no information or functionality is centralized. However, an obvious disadvantage would be a certain delay from the moment the service-request was placed in the system until enough nodes are co-opted so that the requested capacity is reached. The question that arises here is about the size of the system segment from which the leader-node should centralize information. As presented in [14], managing information about all other nodes in the system is not scalable in P2P architecture, so an alternative such as keeping capacity and availability information about neighbors should be taken into consideration. Manifestly, the results of this approach will be highly influenced by the kind of P2P system architecture, since each scheme tackles the neighbors issue differently.

When the initiator searches for nodes, it traverses the network and asks nodes of their current available capacity. Based on this answer, the initiator infers whether a specific node is available at that moment at all. This aspect resembles with the behavior of nodes in BitTorrent network (reference), where a node can temporarily refuse under certain circumstances requests from other nodes. A key issue here is that the searching mechanism is very tight to the employed P2P architecture since routing mechanism and topology differs from one to another.

3.4. Resource owner

In this section we will discuss the aspect of resource ownership and how this influences the negotiation for resource. From a real situation depicture, as in figure 1, a resource can be available from an individual, or from a group of nodes. In this particular case, the group is controlled for example by a company that invested in computing resource for own use. Since there are moments when the resources are not used (or used at partial capacity) for own interest, the company is motivated for making them available to our system in turn for money. This trade can for example lead to a shorter amortization period. For a greater efficiency of our system, we are motivated to consider that a node from the group will represent the entire group when negotiating resources. This node will keep track of the availability and capacity of any other member in its group, being the negotiator of the company in our proposed system. The other possibility of resource existence is an individual computer at a certain physical location.

Figure 1: group-role node and individual-role nodes

From the discussed resource ownership aspects we draw the conclusion that a participating node can play one of the following two roles: individual-role, when the node acts for itself in the system and group-role for interfacing a group. The latter role makes the node to act in the system as if the resources of the whole group were its own. In figure 1 nodes with individual role are marked with “i” and the one with group-role with “g”. The g-tagged node represents resources for company “A” in the system.

3.5. System trust

Since our proposed system globally aggregates resources, their heterogeneity must carefully be taken into consideration. This aspect does not concern as much the capacity and type of the resource as its availability and correctness. By resource correctness we mean all implied characteristics of a resource and its delivery so it is according to the negotiated parameters values. Therefore, our system should be endowed with a reputation mechanism, to reflect the quality parameters of a resource identity. Such a mechanism would contain pointing rules that maximizes the total score if the resource is stable (stays up for long time) and correct (doesn’t cheat).

The cheating aspect has the most important influence on the system trust. If there are nodes that receive a resource request and they agree but finally deliver an intentionally wrong result the system will be suspected and abandoned by customers. Consequently, the system failed from its target.

3.6. Peer specialization

In P2P systems, nodes are free to come and go as they wish. Therefore, our system will consider a mechanism for avoiding possible losses determined by a sudden node failure. A suitable approach for our system would be replication, as a common technique presented in structured P2P papers (struct.P2Particles). In our system situation, replication would mean periodically copies of a “working” node state to one or several of its neighbors. Therefore, the node that holds the copy would periodically check the presence of the node from which it received the copy. The moment no answer is received from it, a recovery action would take place.

Based on the presented resource management functionality of our system, we intend to build an upper layer on it, in order to differentiate resource identities by functionality semantic. While the resource management discussed in previous sections only concerns raw resource availability and delivery (hardware resources), this layer groups nodes into service-type classes (software resources). That is, the resource at a node can be used to perform a specific action, such as: physics-specific computations, accounting operations, graphic analyses, and so on. This layer plays an obvious role, since computing resource can only be used by running specific algorithms on it.

Having the second layer in mind, one can imagine our system as a large group of nodes with available resources, each of them being capable of performing a strict set of operations. When a customer needs complex information processing, it places a request on the system, which is further analyzed, decomposed and processed by certain resource entities in the system.

The upper layer acts for the system just like division of labor in human society, where each individual is a potential resource, but which becomes a full-resource when acting in a specific way. The specific behavior of an individual means specialization which is a brick in a particular workflow wall. If we consider the workflow of a complex activity, each piece of it would be carried out by adequate specialized nodes in our system.

3.7. Resource atomicity

There are two reasons for which we consider that the system should comprise different levels of resource aggregation. The first is that an individual-role peer represents a too small resource unit as compared to the

total resource demand for a resource request placed by a customer. That is, when searching for peers, the initiator must negotiate with many nodes in order to reach the demanded resource quantity. This problem resembles with the need of measuring or representing a long distance with a very small length measure unit, which is an arduous task. The second aspect is when payment for the service is done. If the customer gets to the moment of payment, it is not concerned at all about how many resource units needed its request and what is their identity. Thus, the payment must be centralized, implied resource units being transparent for the user. These two reasons lead us to creating leader peers, which represent, thus negotiate and receive payment in the name of a certain number of individual peers.

Individuals from a group are considered to form an alliance, since by this way, they can obtain a better price for their individual resources compared to the situation of acting alone. This is because a customer with a large resource demand would deal with a group much easier than with many individuals.

Figure shows our system as groups of resource individuals, represented by leader peers. Leader peers are tagged with “g”, since they play a group-role and the individuals from a group with “i”.

Figure 2: System viewed as groups of resource individuals

Two of the challenges here are to settle a rule to maintain the leader peer as the network evolves and to establish the size of a group.

3.8. Resource brokerage

When a user places a resource request in the system, a certain peer should handle it. This node is the access point of the customer in the system. Consequently, all actions that lead to delivering satisfactory results to the customer start from here. Once the conditions for the resource request are established by the user, the system must gather resources in order to accomplish the request according to those conditions. An example of such restriction would be the price that the customer is willing to pay for the resource. The finding of the available resources corresponding to the user conditions could be made through a negotiating process. Thus, we propose the broker peer role, as functionality responsible with finding user-restrictions-compliant resources in the system. In an implementation, the broker role could overlay the leader role since they both represent centralized, apart functionality.

4. Conclusions and future work

As mentioned in section 3.1, we are not aware of system behavior when employing a particular P2P architecture, so a future target is to test several architectures, compare the results and choose the most appropriate solution according to our functional design.

An important issue that concerns our model is the service currency. We have discussed functionality of the resource management module but haven't specified the motivation of different entities for making available their resources. Thus, we are concerned to find a realistic, workable and economically-driven scheme for determining participants to share and access resources. This target will consist of studying the implications of economics in the resource management module behavior.

Abstract. The paper presents some aspects regarding the joint use of classification and recognition techniques for the activity evolution diagnostication and prediction by means of a set of indicators. Starting from the indicators set there is defined a measure on the patterns set, measure representing a scalar value that characterizes the activity analyzed at each time moment. A pattern is defined by the values of the indicators set at a given time. Over the classes set obtained by means of the classification and recognition techniques is defined a relation that allows the representation of the evolution from negative evolution towards positive evolution. For the diagnostication and prediction the following tools are used: pattern recognition and multilayer perceptron. The paper also presents the REFORME software written by the authors and the results of the experiment obtained with this software for diagnostication and prediction of the degrees of economical development during the years 2003-2010.

Keywords: time-series, pattern recognition, neural networks, multilayer perceptron, diagnostication, prediction

1. Introduction

The paper presents a method based on mixed combination of some tools specific for the artificial intelligence for diagnostication and prediction regarding the evolution of an activity. The following techniques are used:

- pattern recognition and classification;
- multilayer perceptron.

The assessments of the development level for a specific activity can be carried out by using the analysis of the evolution of the indicators describing both the quantitative level as well as the qualitative mutations in time.

The diagnostication related problems are solved using pattern recognition dedicated techniques, implemented in the REFORME software. The data corresponding to the evolution in time of the activity considered are processed using the methods already mentioned, methods assessing the overall evolution trend of the indicators. The output is a qualitative variable representing the result of the assessment.

The general architecture of the system is presented in Figure 1.

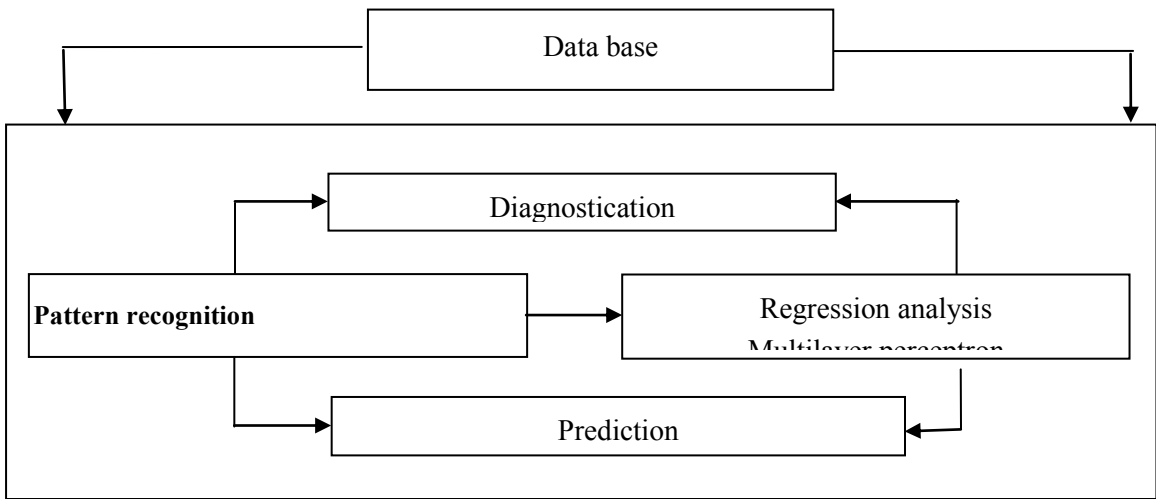

Figure. 1. The conceptual diagram of the intelligent system for diagnostics and prediction

The database includes the data referring to the specific indicators and the achievements per indicators organized as tables. A minimal database with a high degree of flexibility includes the tables INDICATORS and VALUES having the structure described below:

INDICATORS table

Codeind	indicator code
Nameind	indicator name
Umind	measurement unit used for the indicator

VALUES table

Codeind	indicator code
Date	report date
Value	indicator value

2. Pattern classification and recognition techniques

2.1. Pattern recognition

If we note x_1, x_2, \dots, x_n the characteristics set and x is a form defined by these characteristics, then the x form can be considered as a vector $x(x_1, x_2, \dots, x_n)$. The N parameters of the vector x are subjected to different processing methods: data normalizing, linear and nonlinear transformations, reducing and pattern selection, [3],[6],[7]. A supervised recognition problem can be formulated as follows:

Given a partition in classes of known forms, a new form must be included in one of these classes taking into account the existing classes.

The unsupervised recognition consists of dividing the space forms in classes using algorithms. The simplest grouping algorithm, named the threshold algorithm is based on the initial determination of a minimum distance between two forms, the threshold distance.

According to the algorithm mentioned above, two forms belong to the same class if the distance between them is smaller than the threshold distance. Using the threshold algorithm, the value of the threshold establishes the number of classes and the classification process can be reapplied for different values of the threshold until the best classification is obtained.

If the values of the parameters are of different magnitude, then the parameters with high absolute values will have a greater influence over the classification results and the values of the parameters must have the same order of magnitude. The method frequently used is the domain adjusting method, the following transformation of the parameters values being applied:

$$X_{i,new} = \frac{(X_{i,old} - X_{i,min})}{X_{i,max} - X_{i,min}} \quad (2.1)$$

If P_1, P_2, \dots, P_m are the reference patterns (the prototypes) and C_1, C_2, \dots, C_m are the corresponding classes, then the minimum distance classifier will assign the input pattern X to the class C_i if the distance $d = |X - P_i|$ is minimum. The most used distances are derived from the general Minkovski distance:

$$d_{Minkovski} = \left[\sum_1^n (x_i - p_i)^k \right]^{1/k} \quad (2.2)$$

For $k=2$, the Euclidean distance is obtained:

$$d_{Euclid} = \left[\sum_1^n (x_i - p_i)^2 \right]^{1/2} \quad (2.3)$$

For the determination of the class to which a pattern belongs, starting from a training set with known classification, one of the most frequently used method based on the minimum distance principle is the nearest neighbor method.

Let $F = \{f_1, f_2, \dots, f_n\}$ be a set of training patterns and C_1, C_2, \dots, C_p the classes in which the set F was divided using a classification algorithm. The rule of the nearest neighbor can be mathematically wrote as:

$$\text{if } d(f, f_a) \leq d(f, f_k), k = 1, 2, \dots, n \text{ and } f_a \in C_i \text{ then } f \in C_i$$

2.2. Neural networks

An artificial neural network with an input layer and an output layer divides the input vectors in two semi plans. Solving complex problems implies the need of complicated decision regions, problem that can be solved by using networks with one or many extra layers between the input and the output layer [1]. Such a network can be treated as a generalization of the perceptron, being known as the multilayer perceptron (MLP) presented in Figure 2.

Figure 2. the multilayer perceptron architecture

For such architecture, the input layer is made up from linear neurons whose goal is not to compute but to propagate the input signal to the corresponding neurons on the next layers.

Excepting the neurons on the input layer, for each neuron is computed the activation (the sum of products between the inputs and weights) and then the activation function is applied obtaining the output of the neuron. The output of the previous neuron becomes input for the neuron from the next layer.

When chaotic time series are involved, prediction is a difficult problem and can be viewed as temporal pattern recognition task, for wich purpose neural networks suit very well.

The predicted value $x(tk+1)$ of a variable x at a future time $tk+1$ is based on k previous values $x(t1), x(t2), \dots, x(tk)$. Figures 3, 4 shows neural network structures for univariate and multivariate prediction [2]:

Figure 3. Connectionist univariate time-series

Figure 4. Connectionist multivariate (two) time-series

The dependent variable subject to prediction can be different from the past data variables (independent variables), but both are on the time scale.

Backpropagation method

The backpropagation method is the most important and used method for multilayer feed forward neural networks training that minimizes the mean squared error using the gradient method. The method determines the minimum of a function of many variables or parameters through successive iterations.

We consider a network with I neurons of the input layer, H neurons of the hidden layer and O neurons for the output layer. Also, we consider a X(I) vector of inputs, Y(O) vector of outputs, W(H,I) the matrix of weights, connections between the input layer and the output layer and finally V(O,H) the matrix of weights, connections between hidden layer and the output layer.

For the f sigmoidal function of activation we have:

$$f(x) = \frac{1}{1 + e^{-x}} \quad (2.4)$$

With here derivation

$$f'(x) = f(x)[1 - f(x)] \quad (2.5)$$

The algorithm for the neural networks training with a single hidden layer through backpropagation method is presented bellow.

Read I, O, H

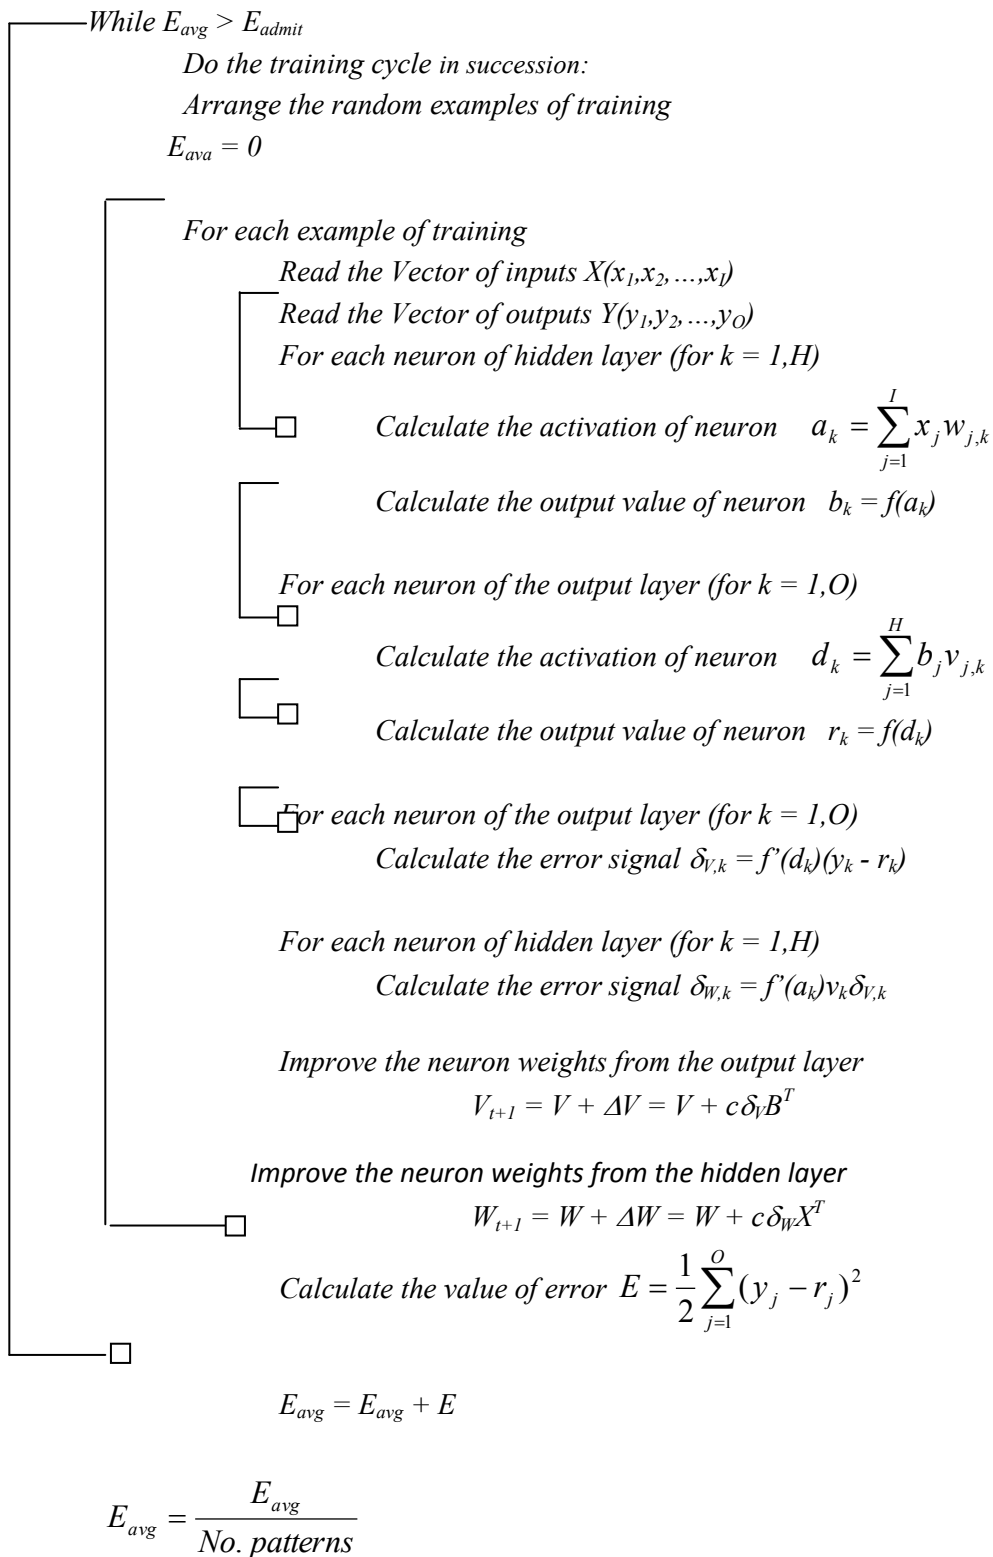

Initialization of the weights with random generating subunit values

Read the value (rate) of training $c \in (0,1)$

Read the admit error E_{admit}

$E_{avg} = \text{high value (99999999999)}$

Determining the numbers of patterns for training (No. patterns)

3. REFORME – A software PRODUCT for pattern recognition and classification

REFORME is a software designed for pattern classification and recognition using specific techniques [4]. The user interface of the program is presented in Figure 5.

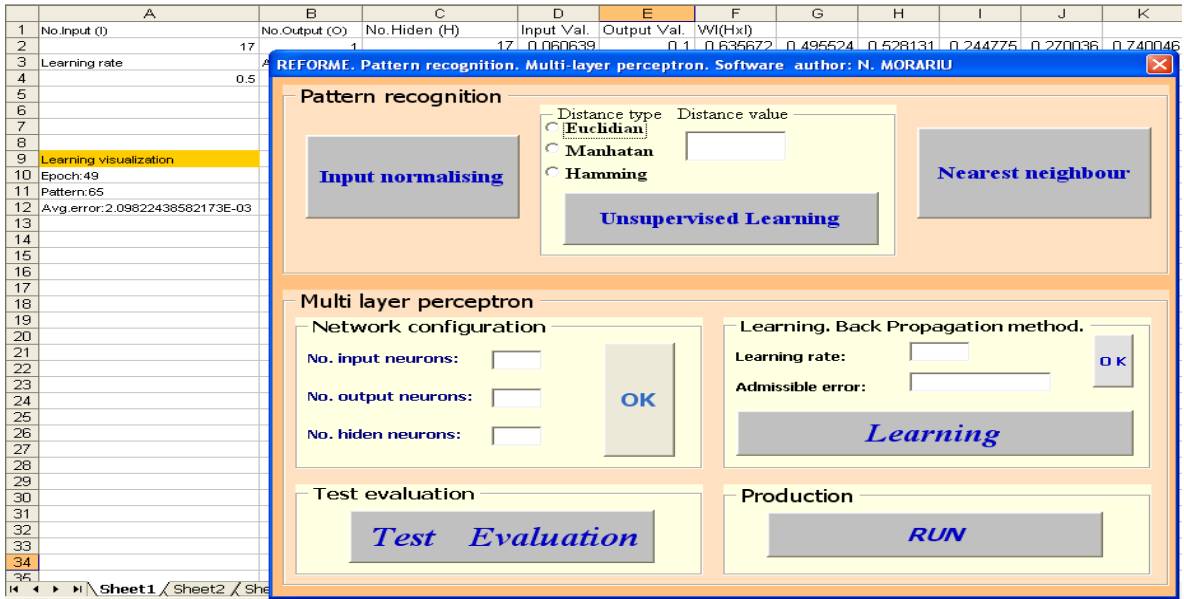

Figure 5. REFORME – Software for pattern recognition and

In this software we make use many of the pattern recognition and classification techniques referred to earlier in 2 sections. The program has two components:

- pattern recognition;
- multilayer perceptron

and allows the combined use of the two pattern and classification techniques for a common data set imported from Excel each of the imported pattern being one row in the spreadsheet.

The module “pattern recognition” has the following tasks:

- normalizes the inputs by means of the domain adjusting method;
- classifies unsupervised using the threshold algorithm with a classifier minimum distance based for the type of distance selected (Euclidean, Manhattan, Hamming) and specified threshold value. The classes resulted will be numbered from negative evolution toward positive evolution using an algorithm that induces the relation “<” over the classes set.
- determines to which class belong an unknown pattern and also determines the pattern at the minimum distance from the unknown pattern by means of the nearest neighbor rule.

The module “multilayer perceptron” accomplishes the following tasks:

- defines the network architecture
- learns supervised using the back propagation error algorithm
- test and assesses the network
- pattern recognition based on the results obtained in the training step.

The configuration of the network consists in:

- the specification of the number of neurons I on the input layer;
- the specification of the number of neurons H on the hidden layer;
- the specification of the number of neurons O on the output layer.

According to the values communicated for these data, that will be stored in Sheet1, the WI(HxI) and WO(OxH) random subunit weight matrix are generated corresponding to the connections between the input layer and the hidden layer, the hidden layer and the output layer respectively, also stored in Sheet1.

For the supervised learning phase there are specified the admissible error and the learning rate. A number of epochs are executed until the error condition is satisfied or until the specified number of specified epochs is completed. From one epoch to another the patterns are randomly sorted and the weight matrix will be replaced with the new weights calculated using the backpropagation method.

After the completion of a specified number of epochs, the training phase can be resumed with another number of epochs and another learning rate. The mean error at the end of each epoch is displayed on screen on a visible area of the Sheet1.

The assessment – test phase comprises the assessment of the result during the training process for a test data set.

The network previously trained for the unsupervised classification of a specified pattern set is used during the pattern recognition phase, with the weights resulted from the training phase.

4. Graphical representation of the evolution of analyzed activity

A graphical representation of the evolution of the activity in a coordinate system xOy can be obtained as follows: each pattern represents a point on a plane, the axis x being the time period corresponding to the pattern and y is the class that the pattern belongs to as shown in Figure 6. The accuracy of the representation depends on the number of classes. This representation implies first to sort and then renumber the classes taking into consideration the evolution direction (from negative evolution towards positive evolution).

To order the classes, for each class c is assigned a number M(c) that is calculated as presented below.

Let $x(x_1, x_2, \dots, x_n)$ be a pattern that belongs to the class c, with normalized parameters x_i . For each parameter x_i of the pattern x is assigned a weight p_i , representing the importance of the parameter x_i (the weights can be computed for instance as the partial correlation coefficients or can be set up by the expert).

For the pattern x, D(x) is calculated using the equation:

$$D(x) = \sum_{i=1}^n p_i x_i \quad (4.1)$$

D(x) represents a measure of the activity described by the pattern x.

For each form belonging to the class c the similar method is carried out, M(c) being defined as:

$$M(c) = \left(\sum_{x \in c} D(x) \right) / p \quad (4.2)$$

where p is the number of forms belonging to class c.

The class c1 is in relation “<” toward the class c2 if $M(c_1) < M(c_2)$.

An order relation over the class set has been defined. Renumbering the classes taking into account this order relation, a plot can be drawn representing the evolution of the activity analyzed as shown in Figure 7.1.

Given two time intervals t_1 and t_2 , $t_1 < t_2$ and $D_{t_1}(x)$, $D_{t_2}(x)$:

- If $D_{t_1}(x) < D_{t_2}(x)$ then the activity defined by the patterns x has a positive evolution at the moment t_2 toward t_1 ;
- If $D_{t_1}(x) = D_{t_2}(x)$ then the activity defined by the patterns x is stationary at the moment t_2 toward t_1 ;
- If $D_{t_1}(x) > D_{t_2}(x)$ then the activity defined by the patterns x has a negative evolution at the moment t_2 toward t_1

A similar interpretation can be done considering M(c).

A much accurate representation of the activity evolution in a coordinate system xOy can be obtained as follows: each form represents a point in plane, x being the time range that corresponds to the form and y is D(x) as shown in Figure 7.2.

5. Case study – Macroeconomical prognosis

We consider the next macroeconomic indicators. (Reference [8]):

modification toward previous year

COD	INDICATOR	U/M	2003	2004	2005	2006	2007	2008	2009	2010
I1	Gross Domestic Product	billion RON	197.6	246.4	287.2	330.3	372.3	414.2	453.3	492.1

I3	Goods import (CIF)	million EURO	21201	26281	32569	38620	44300	50450	56900	63500
I4	Goods import (FOB)	million EURO	19569	24258	30061	35650	40910	46600	52550	58650
I5	Occupational populations (average)	thousands pers.	8274.6	8087.7	8095	8105	8120	8135	8150	8165
I6	Average number of employees	thousands pers.	4590.9	4468.8	4575	4675	4760	4825	4895	4945
I7	Gross Income (average)	RON	664	818	958	1080	1200	1310	1430	1545
I8	Number of unemployment (the ending of the year)	thousands pers.	658.9	557.9	523	520	508	495	485	480

Taking into consideration the specific problems regarding macro economical prognosis, the indicators represents the parameters of the pattern and a pattern X_t is defined by the values of the parameters for an year.

For diagnostication is considered the interval between 2003 and 2006, and for prediction the interval between 2007 and 2010.

The input data are processed in Sheet3. Each row of the datasheet represents a pattern and characterizes the degree of economical development for the year considered.

After the data normalization, classification (unsupervised recognition using the threshold algorithm) with REFORME software, the distance used being the Euclidean distance and the threshold value =1., results the division of the patterns into 4 classes, the ordering and the renumbering of the classes as well as the representation of the plot for the evolution using the two solutions (classes, $D(x)$).

The results obtained are presented in Figure 6 and Figure 7.1., 7.2.

Figure 7.2. Graphical representation of analyzed activity by D(x)

For a better approximation one solution would be the design of specific models for nonlinear systems [2], [5].

For the prediction of the values corresponding to the next year the following neural architecture is defined: 8 neuron on the input layer, 8 neurons on the hidden layer and one neuron on the output layer. The network architecture is presented in Figure 8.

For training, the network uses the inputs for time t and the $t+1$ output is obtained.

Figure 8. The network architecture for the next year prediction

The results obtained with the software REFORME (using sigmoid activation function for the hidden layer and identity function for the output layer) are presented below.

The training process is made in three phases as well presented in figure 9.1, 9.2, 9.3. The training begins with the training for a number of years and then the prediction for the next years is carried out. The training is then restarted including in the training set the values predicted and the next prediction for the next interval is carried out.

Figure 9.3. The results of network training and prediction - phase 3.

6. CONCLUSIONS

The paper describes a method that quantifies and represents the evolution of an activity. Starting from a set of indicators that characterizes an activity, are defined a scalar $D(x)$ that allows to measure an activity described by the x patterns and an order relation “ $<$ ” over the set of classes resulted using unsupervised classification techniques for the graphical representation of the activity evolution using classes.

One of the methods used for solving diagnostication and prediction problems is the regression analysis. In the case of linear systems the regression approach has practical relevance. Because of their ability to detect nonlinear dependences in the input data set, neural networks represent an efficient alternative to the existing methods.

The prediction of the evolution of the nonlinear system is a difficult problem and sometimes impossible to solve. The obtained results confirm that prediction for a shorten period of time (1 year) is exactly, but for a long period of time (4 years) the results are approximately.

The researches in the field take into consideration other approaches that are using concepts specific to chaos theory such as: the phase space, attractors, fractals and Lyapunov coefficients measuring the sensitivity to the initial conditions, one of the main characteristics of the chaotic systems.

WEB APPLICATION FOR ON-LINE STATISTICS OVER A SQL SERVER RESPONDENTS TABLE

Năchilă Cătălin

Universitatea „Petrol – Gaze” Ploiești, Facultatea de Științe Economice, katonec@yahoo.com

The application presented in this article was developed under Microsoft Visual Studio 2005 (based on ASP.NET 2.0 platform) and Microsoft SQL Server 2005. It describes a way in which some statistic information about the data from the records of a SQL Server database can be acquired and how these data can be grouped by a continuous frequency distribution.

Keywords: on-line statistic, Sturges' rule, grouping of statistical data, continuous frequency distribution, SqlConnection, SqlCommand, Web application

Statistical data

General statistic information

The first type of statistic implemented in the application offers general statistic information about the records of the respondents table, such as:

- the percentage of respondents who has declared their email;
- the percentage of male, women or undeclared sex;
- the percentage of urban, rural population or undeclared type of residence;
- the percentage of respondents belonging to a category of job (budgetary, private, pupils, students, retired or undeclared type of job)
- the percentage of respondents which live in a specific country.

To obtain these percentages is used the well known formula:

$$\% \text{ of respondents} = \frac{\text{given amount} \cdot 100}{\text{total amount}} \quad (1)$$

Grouping of statistical data by a continuous frequency distribution

The second type of statistic made by this application is that of grouping statistical data by a continuous frequency distribution. A frequency distribution represents the division of a sample of observation into a number of classes (groups), together with the number of observations in each class. Each group is in order of magnitude in the data series. The results are presented in a table in which the data are grouped into classes (groups). For each class, is recorded the frequency of occurrence.

Based on data recorded, it is searched the minimum and the maximum value of data we want to group:

x_{\min} and x_{\max} .

Then, it is determined the amplitude of variation (**class range**): $A = x_{\max} - x_{\min}$ (2)

The number of classes is determined using the **Sturges Rule**: $r = 1 + 3,32 \cdot \log_{10} n$ (3)

where r = number of classes

n = number of data items to be classified

Size of the class interval is obtained by using Sturges rule: $k = \frac{A}{r}$ (4)

After the size of the class are obtained, there are computed the lower and the upper limits of each one. The method used in the application is that where the upper limit of the current interval is taken over as a lower limit of the next interval:

$$x_{i\min} \leq x_i \leq x_{i\max}, \quad i = \overline{1, r-1} \quad (5)$$

The Application Database

The SQL Server database, named *Sodaj (Pool)*, has two tables: *clienți (client)* and *respondenți (respondent)*. In the *clienți* table are stored the clients who command the pools and in the *respondenți* table the persons which are added to the database when they join an opinion pool. The structure of these tables is presented in figure 1. The *clienți* table has 10 records and the *respondenți* table has 1000 records. All the records are fictive.

Table - dbo.client		Summary
Column Name	Data Type	Allow Nulls
IDClient	int	<input type="checkbox"/>
ClientNume	nvarchar(100)	<input checked="" type="checkbox"/>
Clientemail	nvarchar(100)	<input checked="" type="checkbox"/>
ClientFirmaDen	nvarchar(100)	<input checked="" type="checkbox"/>
ClientFirmaAdr	nvarchar(255)	<input checked="" type="checkbox"/>
ClientNrSondajeComa...	int	<input checked="" type="checkbox"/>
ClientTipAbonam	nchar(10)	<input checked="" type="checkbox"/>

Table - dbo.articol_respondenti*		Summary
Column Name	Data Type	Allow Nulls
IDResp	float	<input type="checkbox"/>
RespLastName	nvarchar(255)	<input checked="" type="checkbox"/>
RespFirstName	nvarchar(255)	<input checked="" type="checkbox"/>
RespEmail	ntext	<input checked="" type="checkbox"/>
RespAge	float	<input checked="" type="checkbox"/>
RespSex	nvarchar(255)	<input checked="" type="checkbox"/>
RespBaseIncome	float	<input checked="" type="checkbox"/>
RespOverIncome	float	<input checked="" type="checkbox"/>

RespDataInput	datetime	<input checked="" type="checkbox"/>
		<input type="checkbox"/>

Figure 1. The tables of the database

The Application

For the design of the application it was used a *menu* control, dynamically created controls like *PlaceHolder*, *Label* and *TextBox* and a new ASP.NET characteristic: master pages. The application has five pages: *Home*, *Database tables*, *Respondents general statistic*, *Respondents age statistic*, and *Sturges rule for respondents' age*. The *Home* page is presented in figure 2.

Figure 2. Home page

3.1. Page “Database tables”

In this page the user can display the records of one of the two tables of the database. The tables are selected from a *DropDownList* control. After the *action click* event of the *OK* button, the records are displayed on a *GridView* control like in the figure 3.

IDResp	RespLastName	RespFirstName	RespEmail	RespAge	RespSex
1	a	a	a	12	F
2	Nume 2	Prenume 2	nume2@yahoo.com#http://nume2@yahoo.com#	16	F
3	Nume 3	Prenume 3	nume3@yahoo.com#http://nume3@yahoo.com#	17	M
4	Nume 4	Prenume 4	nume4@yahoo.com#http://nume4@yahoo.com#	18	F
5	Nume 5	Prenume 5	nume5@yahoo.com#http://nume5@yahoo.com#	19	M
6	Nume 6	Prenume 6	nume6@yahoo.com#http://nume6@yahoo.com#	20	F
7	Nume 7	Prenume 7	nume7@yahoo.com#http://nume7@yahoo.com#	21	M
8	Nume 8	Prenume 8	nume8@yahoo.com#http://nume8@yahoo.com#	22	F
9	Nume 9	Prenume 9	nume9@yahoo.com#http://nume9@yahoo.com#	23	M
10	Nume 10	Prenume 10	nume10@yahoo.com#http://nume10@yahoo.com#	24	F
11	Nume 11	Prenume 11	nume11@yahoo.com#http://nume11@yahoo.com#	25	M
12	Nume 12	Prenume 12	nume12@yahoo.com#http://nume12@yahoo.com#	26	F
13	Nume 13	Prenume 13	nume13@yahoo.com#http://nume13@yahoo.com#	27	M
14	Nume 14	Prenume 14	nume14@yahoo.com#http://nume14@yahoo.com#	28	F
15	Nume 15	Prenume 15	nume15@yahoo.com#http://nume15@yahoo.com#	29	M

Figure 3. Respondents table

The general syntax for displaying the record from a SQL Server table using a *SqlDataSource* is:

```
SqlDataSource user_name_of_data_source = new SqlDataSource  
(string data file, string select command)
```

In the application the following syntax is used for the *OK* action click event:

```
SqlDataSource SursaDeDateSQL1 = new SqlDataSource(@"Data Source=DELL;  
Initial Catalog=Sondaj; Integrated Security=True",  
"SELECT * FROM " + DropDownList1.SelectedValue + "");  
GridView1.DataSource = SursaDeDateSQL1;  
GridView1.DataBind();
```

3.2. Page “Respondents general statistic”

In this page, the general statistics for the respondents’ characteristics are displayed (email, sex, type of living residence, job and country). The results page is presented in the figure 4.

Because the way in which the information is obtained, calculated and displayed is similar for each statistic, it is presented only the one which regards the sex of the respondents. The number of the respondents for each category (men, women or unspecified) is obtain using a *SqlDataSource* which has a SQL aggregate function (*Count*) for the string select command. The number is placed in a *GridView* control and then memorized in a variable. After that, the number is transformed in a percentage and displayed using dynamically *Label* controls. The syntax is:

```
SqlDataSource SursaDeDateSQL4 = new SqlDataSource(@"Data Source=DELL;  
Initial Catalog=Sondaj; Integrated Security=True",  
"SELECT COUNT (*) AS numar4 FROM articol_respondenti WHERE  
(RespSex !='M' AND RespSex !='F');");  
GridView2.DataSource = SursaDeDateSQL4; GridView2.DataBind();  
numar_sex_Unspecified = Convert.ToInt32(GridView2.Rows[0].Cells[0].Text); ...
```

```

procent_sex_Unspecified = Math.Round((numar_sex_Unspecified * 100 /
number_of_respondents), 2); // ... similar syntax is used for the other categories
((Label) (Placeholder2.FindControl("Labelh2"))).Text = "" +
procent_sex_Unspecified + "%"; // ... similar syntax is used for the other categories

```

Figure 4. Respondents' general statistic

3.3. Page "Respondents age statistic"

This page is used to present the characteristics of the respondents' age. First are computed and displayed the minimum and maximum values of the respondents' age. Then, the respondents are numbered for each value of age (from the minimum to the maximum). The values are transformed in percentages. The results page is presented in the figure 5.

To obtain these values, there are used some classes derived from `DbProviderFactory`:

- **connection class** – used for the creation of a connection with the database (in our case: `SqlConnection`);
- **command class** – used to create and execute SQL commands or stored procedures over a SQL Server database (in our case: `SqlCommand`); the command classes have two properties: `CommandText` (contains the string of the command which will be executed over the data source) and `CommandType` (indicates whether the command is a SQL statement, the name of a stored procedure, or the name of a table);
- **data reader class** – the data reader objects provides fast, forward-only and read-only reading capability to quickly loop through the records; it can't navigate through it at random, and it can't use it to update the data source; a `DataReader` can only be returned from a call to the `ExecuteReader()` method of a command object; we can't instantiate it directly.

There are three distinct ways to execute a `SqlCommand`:

- `ExecuteReader` – returns a `DataReader`;
- `ExecuteScalar` – returns a single value;
- `ExecuteNonQuery` – to use when no data will be returned from the query (example: a SQL UPDATE statement).

The syntax for the minimum value of the age is:

```

string ConexiuneSQL1_interogare = "SELECT MIN (RespAge) AS minim FROM
    articol_respondenti WHERE (RespAge !='')";
string ConexiuneSQL1_String = "Data Source=DELL; Initial
    Catalog=Sondaj; Integrated Security=True;";
SqlConnection ConexiuneSQL1 = new SqlConnection(ConexiuneSQL1_String);
ConexiuneSQL1.Open();      SqlCommand ComandaSQL1 = new
SqlCommand(ConexiuneSQL1_interogare, ConexiuneSQL1);
SqlDataReader DataReaderSQL1 = ComandaSQL1.ExecuteReader();
while (DataReaderSQL1.Read())
    {   minimum_age = Convert.ToInt32(DataReaderSQL1["minim"]);   }

```

```
DataReaderSQL1.Close(); Label2.Text = "" + minimum_age;
ConexiuneSQL1.Close();
```

To obtain the number of respondents for each age it is used a for statement where the variable i represent the age of the respondent:

```
for (double i = minimum_age; i <= maximum_age; i++)
{ string ConexiuneSQLactual_interogare = "SELECT Count(RespAge) AS
numar1 FROM articol_respondenti WHERE (RespAge =' " + i + "')"; // ...
SqlDataReader DataReaderSQLactual = ComandaSQLactual.ExecuteReader();
while (DataReaderSQLactual.Read())
{ actual_age_number = Convert.ToDouble(DataReaderSQLactual["numar1"]);
```

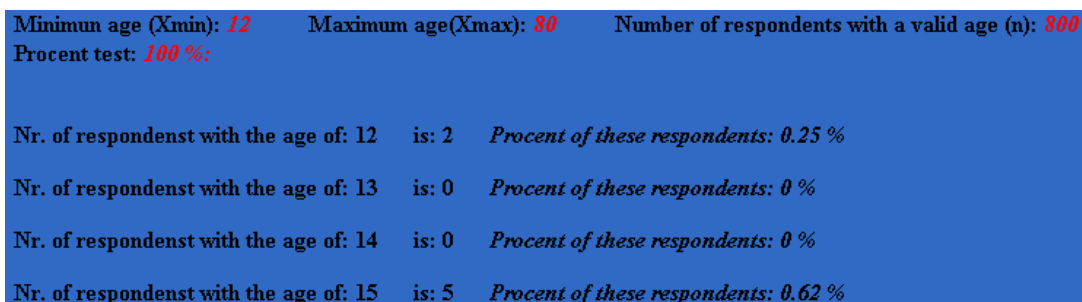

Figure 5. Respondents age structure

3.4. Page “Sturges rule for respondents' age”

In this page the number of classes and the size of the class interval are computed by using Sturges rule. Based on these values, the respondents' age can be grouped by a continuous frequency distribution. The results page is presented in the figure 6.

Figure 6. Respondents age structure

Based on the minimum and maximum age of the respondents, the formulas (3) and (4) are computed with the following code:

```
groups_number = Math.Round(1 + 3.32 * Math.Log(nr_resp, 10), 2);
groups_number_aproximated = Convert.ToInt16(nr_de_grupe + 0.5); // 0.5
is used because it must have an integer value for the number of groups
k = Math.Round((xmax - xmin) / groups_number, 2);
k_aproximated = Math.Round(k, 1);
```

The groups are created with the code (it is used a double number of `groups_number` because for each class we have two values: lower and upper limit according to the formula (5)):

```
interval_array[1] = xmin; for (int i = 2; i <= groups_number_x_2; i++)
    { interval_array[i] = interval_array[i - 1] + k_aproximated; }
```

The frequencies are computed by using a SQL aggregate function (*Count*) for the string select of a `SqlCommand` and a `DataReader` in a `while` statement:

```
string ConexiuneSQL1_interogare = "SELECT COUNT (RespAge) AS frequency
FROM articol_respondenti WHERE (RespAge >= '" + interval_array[i] +
'" AND RespAge<' + interval_array[i + 1] + "')"; // ...
SqlCommand ComandaSQL1 = new SqlCommand(ConexiuneSQL1_interogare,
ConexiuneSQL1); // ...
SqlDataReader DataReaderSQL1 = ComandaSQL1.ExecuteReader();
while (DataReaderSQL1.Read())
    {frequencies_array[i] = Convert.ToInt32(DataReaderSQL1["frequency"]);}
```

The results can be displayed in numeric or graphical way. The numeric results are displayed on dynamically created `TextBox` controls placed inside on `PlaceHolder` controls. The graphics are created using chart object from *Microsoft Office Web Component 11* (OWC11). Because the graphical data must not depend on specify values of frequencies and lower and upper limit of each class, the charts are created in a different page named *graphics.aspx*.

By using a `DropDownList1` control, the user can choose the type of the chart he wants. The available types are: *Bar*, *Bar3D*, *Line* and *Pie*. The type of the chart, the frequencies and the groups are transmitted to the *graphics.aspx* page using a `Response.Redirect()` command placed in the `SelectedIndexChanged` event of the `DropDownList1` control:

```
string DropDownList_selection = DropDownList1.SelectedItem.Text;
this.Image4.ImageUrl = "graphics.aspx?Value1=" + Categories
+ "&Value2=" + Values + "&Value3=" + DropDownList_selection;
```

These values and the options are taken over in the `Page_Load` function of *graphics.aspx* page. After the chart is created, it is converted to *gif* format and returned to the “Sturges rule for respondents' age” page for displaying in an `Image` control. The code for the pie chart is:

```
string Categories = Request.QueryString["Value1"], Values = Request.
QueryString["Value2"], chart_type = Request.QueryString["Value3"];
ChartSpace Chart_spatiu = new ChartSpaceClass();
ChChart Chart_obiect = Chart_spatiu.Charts.Add(0);
Chart_obiect.Type = ChartChartTypeEnum.chChartTypePie3D;
Categories = Categories.Remove(Categories.Length - 1, 1);
```

```
Values = Values.Remove(Values.Length - 1, 1);  
Chart_obiect.SeriesCollection.Add(0);  
Chart_obiect.SeriesCollection[0].SetData(ChartDimensionsEnum.chDimCategories, (int)ChartSpecialDataSourcesEnum.chDataLiteral, Categories);  
Chart_obiect.SeriesCollection[0].SetData(ChartDimensionsEnum.chDimValues, (int)ChartSpecialDataSourcesEnum.chDataLiteral, Values);  
Response.ContentType = "image/gif";  
Response.BinaryWrite((byte[])Chart_spatiu.GetPicture("gif", 500, 400));  
Response.End();
```

THE SIMULATION OF A PROJECT CONCERNING THE MENU ENGINEERING IN A FOODSERVICE ORGANIZATION

Negoita Nicolae

University “Dunarea de Jos” Galati, Faculty of Economic Sciences, 59-61, str. N. Balcescu, Galati, e-mail: nicu.negoita@gmail.com, Phone: 0722382758

The paper emphasizes the techniques referring to the strategic analysis of menu engineering with the support of specialized software – Menu Engineering. In the first part of the paper I presented a famous model in hospitality industry literature elaborated by Kasavana and Smith and the strategies applicable to each type of menu article (star, puzzle, plowhorse and dog). In the applicative, I realized the simulation of a sales project in a foodservice organization in order to manage efficiently a range of articles from a menu.

Keywords: menu engineering, foodservice, information technology

1. General considerations regarding menus' engineering

The menu represents a marketing support that helps the managers of the public alimentation units to promote their services and products. There are more instruments to measure the efficiency of the menus, to make the necessary adjustments in order to create a new menu meant to improve the profitability of the restaurant and the client's satisfaction, due to the improvement of the marketing mix.

The elements taken into consideration for the menu analysis are: the price of the products, the quantity of the sold products, the costs of the raw materials, the turnover, the profit contribution margin and the popularity index.

The menu engineering can be defined as the menu evaluation to establish its profitability. It is recommended that this menu evaluation process should be carried out at least once a month after the opening of the restaurant and at least once in three months after the first year of activity [1]. It is considered that the change of the menu once in three months can be tiresome for the client. At present, many restaurants develop, so that a 'fixed' menu will have less pleasant consequences and less visits from the loyal customers. In a unit of public food service, the concept must be coherent, which means that the personnel must be in harmony with the 'house' image, the dishes must be based on a specialty: either a patented method, or a type of product (grill products) or a regional gastronomic thematic. The framework must be in harmony with the concept, as well as the proposed serving manner (table serving, delivery in catering system).

A pattern of strategic analysis of the articles included in the menus of the public food service units, which is considered a reference point in specialty literature, was established by Michael Kasavana and Donald Smith [2], professors at Michigan Public University and famous counselors in this domain. The analysis they made resulted in a matrix that points out a classification of the menu articles in four categories, according to two dimensions: the products' popularity index and the profitability degree. (figure no 1.)

An article in the menu is very popular if the percentage of the menu mix or the popularity index is higher than the average and an article is very profitable if the profit contribution margin exceeds the average.

A strategy applied by most of the public food service companies consists in placing the most profitable articles in the superior side of the menus. For example, in the case of a restaurant which offers sandwiches, appetizers and snacks, most of the clients order sandwiches, characterized by a lower profitability; the restaurant's manager must place in the first pages, special offers with the appetizers and snacks that contribute in a large measure to the profit and the sandwiches in the central part of the last page in the menu; the client that really want them, will find them and those who haven't decided, will order an article with a higher profit.

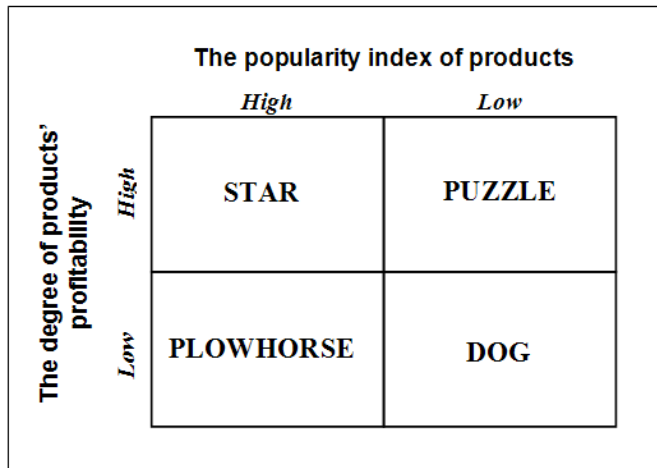

Figure no. 1 – The classification of a menu's products according to Kasavana&Smith model

The strategies available for the four categories of articles in the menu are the following [3]:

★ **STAR products:**

- the maintenance of the present standards (quality, quantity, training, presentation);
- the emphasis of these products by including them in promotional campaigns;
- the testing of the prices' increase on the clients' behaviour.

⊙ **PUZZLE products:**

- the drop in prices for the launch of the products' consumption;
- if it is an important products (at the profit margin level) – its promotion by means of aggressive marketing campaigns;
- if the product's popularity is diminished – its elimination;
- the restriction of the puzzle products number in the menu.

⊙ **PLOWHORSE products:**

- the testing of the prices' flexibility by means of their progressive increase;
- the decrease of costs diminishing the quantities;
- the restriction of the investments in the promotion of these products.

⊙ **DOGS products:**

- the increase of the distribution margin by diminishing the costs;
- the drop in sale prices for the launch of the consumption;
- the elimination of the product from the menu.

From the price strategies point of view of the four articles categories in a menu, the price for PLOWHORSE products can increase, but in a small measure so that it is accepted by the loyal clients; otherwise, drastic drops of orders may occur; the price increase strategy for STAR products is not recommended because these articles are part of the stars category (if we refer to BCG analysis) and attract a large number of clients by their high level of popularity; PUZZLE articles are often characterized by high prices due to their uniqueness in the restaurants' offers and the effect of some price reductions can be tested;

A price increase of the DCG products would inevitably lead to their elimination, the only reason they are kept in the menu is that they are preferred by some loyal clients or there are still some ingredients on the stock for their preparation. If, after a week from the launching of a new menu, a product is of the DOG

type, a change is imposed, which may be represented by a promotional activity in order to increase the product's popularity or even a change of the portion's size and its presentation on the plate.

2. The strategic analysis of menus by means of the MENU DESIGN MAKER information application

The menu management carried out with the Menu Design Maker information application presupposes an analysis of the sales, prices and costs' history, associated to each article from a menu of a public food service unit. The menu engineering presupposes the calculation based on the data stocked in a profit and distribution margin data warehouse of each article in the menu in close connection with the other articles in a certain period of time.

This software allows the implementation of two processes specific to the public food service domain: **the menu analysis**, which refers to the effects of the changes in the menu the manager of a restaurant could carry out and **the menus' management**, which consists in the determination of the maximum profitability for all the categories of articles contained in the menu, but it also involves the evaluation of the networks for an efficient administration of costs.

The manager of the Menu Design Maker software project, *Andreas Breidfuss*, presents the main **benefits** of the use of this information application [4]:

- it represents a support for the increase of the average net profit per customer;
- it offers replacement opportunities of the non-performing articles in a menu with profitable articles;
- it generates rapports in which there are presented the costs of all the ingredients used for preparing food and drinks;
- it identifies the most profitable articles in the menu which require a special attention from the managers of the public food service units;
- it provides up-to –date information, necessary for the determination of the price strategies for each category of products in the menu;
- it generates tendencies of the products' consumption within the menu;
- it evaluates each article in the menu and places it in one of the four categories of strategic analysis: star, puzzle, plowhorse or dog.

The **MENU ENGINEERING** software offers the managers of the public food service units the possibility to introduce all the articles in the menu, grouped on categories in the *Menu Items* tab and the profitability analysis of the products portfolio by means of the *Menu engineering* tab.

The main functions of the *Menu Items* tab, that illustrates the operational perspective of the software, consist in the insertion, edition or deletion of some articles in the menu, the introduction for each menu article of its cost as well as its sale price, guiding buttons to every article in the menu and the list of the data base that contains all the products introduced by the user of this software. (figure no. 2)

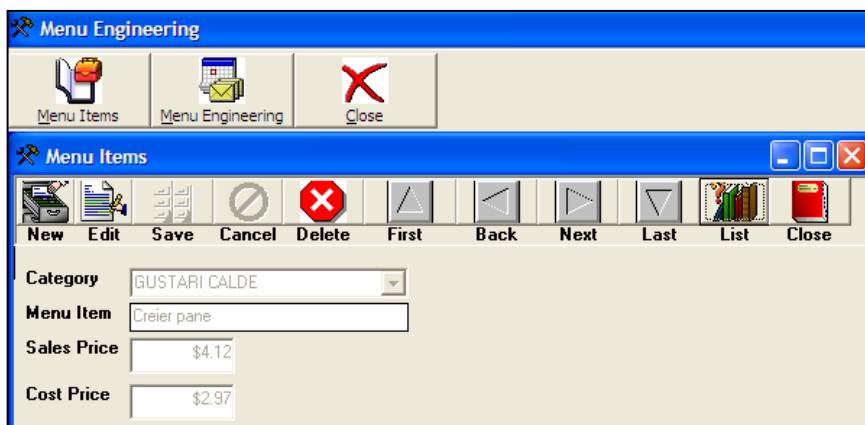

Figure no. 2 – The presentation of the Menu Items functions

To carry out the strategic analysis of the articles in a menu by means of the **Menu Engineering** information application, we selected a set of three categories of specific products in the menu of a public food service unit (warm snacks, cold snacks and basic products) and for each category we have inserted a representative sample of products, as well as the costs and sale prices presented in the menu. (figure no. 3) The data base can be accessed with the **Menu Items List** button and permanently updated by the manager of the public food service unit.

Menu Items List				
	Category	Menu Item	Sales Price	Cost Price
▶	GUSTARI CALDE	Creier pane	\$4.12	\$2.97
	GUSTARI CALDE	Crochete cascaval	\$3.10	\$1.68
	GUSTARI CALDE	Ochiuri cu sunca	\$3.32	\$1.67
	GUSTARI CALDE	Pui de balta meunier	\$3.86	\$2.87
	GUSTARI RECI	Biftec tartar	\$4.10	\$2.76
	GUSTARI RECI	Gustare Lloyd	\$3.45	\$2.14
	GUSTARI RECI	Gustare taraneasca	\$3.35	\$2.16
	GUSTARI RECI	Salata Caesar	\$3.67	\$2.11
	GUSTARI RECI	Salata de cruditati	\$2.95	\$1.78
	PREPARATE DE BAZA	Cotlet Palermo	\$6.10	\$4.24

	PREPARATE DE BAZA	Tochitura Haiduc	\$7.12	\$4.19

Menu Engineering
Engineering your menu for profit

Figure no. 3 – The listing of the menu articles from the Menu Engineering software database

The analytical perspective of the *Menu engineering* software emphasizes the criteria on which basis the articles in the menu will be classified (the profitability rate and the sales volume) in the four categories known in the specialty literature: STAR, PUZZLE, PLOWHORSE and DOG. (figure no. 4

The screenshot shows the 'Menu Engineering' software window. At the top, there is a toolbar with icons for New, Edit, Save, Cancel, Delete, First, Back, Next, Last, List, and Close. Below the toolbar, there are input fields for 'Period : Starting Date' (11/26/2007) and 'Ending Date' (12/5/2007). The main area is divided into tabs: 'Instructions', 'Units Sold', 'Statistics', 'Statistics', and 'Graph'. The 'Instructions' tab is active, displaying the following text:

Instructions
Set correct period starting date and ending date
Enter the quantity of units sold in the 'Units Sold' tab
Click on the statistic tabs to see and print the menu statistics

Key

- Star = High profit margin and high sales item
- Plowhorse = Low profit margin but high sales item
- Puzzle = High profit margin but low sales item
- Dog = Low profit margin but low sales item

What to do with this item

- Star: Keep this on your menu and possibly raise your price
- Plowhorse: Keep this on your menu and possibly raise your price
- Puzzle: Make this a house specialty or make an incentive up for the staff to sell this item
- Dog: Not much use in keeping this one

Menu Engineering
Engineering your menu for profit

Figure no. 4 – The determination of the classification criteria for menu's articles based on Menu Engineering analysis

The manager of the *Menu Engineering* software project offers a series of suggestions to the program's users in order to increase the efficiency of the marketing strategies; in this context, STAR products, characterized by high profitability and sales volume indicate the fact that they fully satisfy the expectations and demands of the customers and involve a high marketing budget and every price increase could generate the decrease of the sales volume; PUZZLE products, characterized by a high profitability and a low sales volume, must be included in the promotional campaigns launched by the marketing managers of the public food service units in order to increase their attractiveness and implicitly, their sales volume, which will determine their transformation in STAR articles; the recommendation of the *Menu Engineering* project manager for PLOWHORSE products is to increase the price slowly in order to enlarge the profit contribution margin, even if this thing will have negative consequences on the sales; in his opinion, this is the test PLOWHORSE products have to pass in order to be transformed in PUZZLE or STAR articles. Referring to DOG products, they have to be maintained at least for a short period of time until they are eliminated from the menu, because they can be launched by means of marketing campaigns towards certain segments of target customers.

The access of the **Units Sold** tab implies the determination of the carrying out period of the strategic analysis project of the articles in the menu and the connection of the software to the POS information system or to the sales manager's laptop, which will transfer the sales registered in the analysis period. The simulation we have carried out, emphasizes values of the sales deducted in four weeks, in the period 25.11.2007 – 23.12.2007 (figure no. 5).

Instructions	Units Sold	Statistics	Statistics	Graph	
Menu Item	Category	Qty Sold (Week 1)	Qty Sold (Week 2)	Qty Sold (Week 3)	Qty Sold (Week 4)
Crochete cascaval	GUSTARI CALDE	21	24	22	18
Escalop Zingarra	PREPARATE DE BAZA	38	31	29	40
File salau	PREPARATE DE BAZA	26	28	23	26
Friptura curcan	PREPARATE DE BAZA	23	19	25	27
Gustare Lloyd	GUSTARI RECI	31	29	20	19
Gustare taraneasca	GUSTARI RECI	26	30	32	31
Dechiuri cu sunca	GUSTARI CALDE	18	26	21	25
Papricas pui	PREPARATE DE BAZA	28	32	34	29
Pui de balta meunier	GUSTARI CALDE	13	17	16	16

Figure no. 5 – The sales simulation of a public food service unit on a determined period

The first version of the **Statistics** tab (figure no. 6) illustrates the total number of sales in each article from the menu (*total sales mix*), the sale price of each article (*Sales price*), the unitary cost of each product (cost price), the gross profit margin obtained for each article (*CM margin*), the incomes of each product (total revenues), the costs associated to the sales generated by each product (*Menu cost* – determined by multiplying the total sales with the unitary costs of each product), the profit margin of each product, as a result of the sales in the period submitted to the analysis (*Menu CM*) and the category associated to each product (star, puzzle, plowhouse and dog), which shows the contribution of each product to the profitability of the menu of the public food service unit.

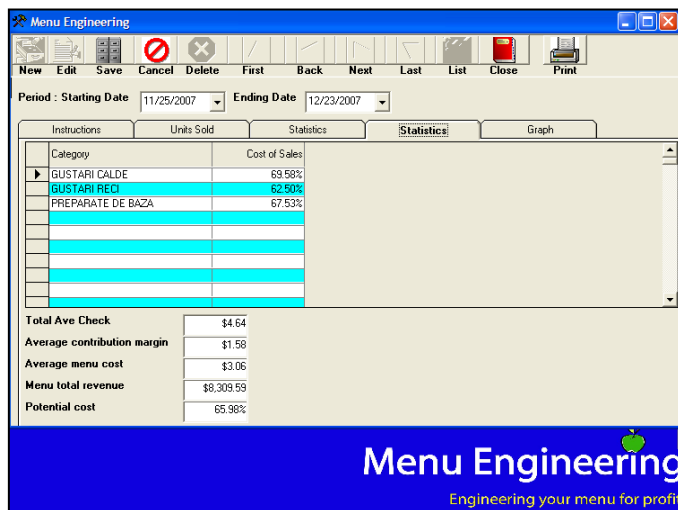

Figure no. 6 – The determination of the statistic indicators associated to the profitability analysis of the articles in the menu

The second version of the **Statistics** tab (figure no. 7) emphasizes the share of the costs in the sale price within each category of products (cold snacks, warm snacks and basic products), the sale price average of the articles in the menu, the average of the medium total cost and the profit margin on each article and the total incomes generated by the articles in the menu in the analysed period.

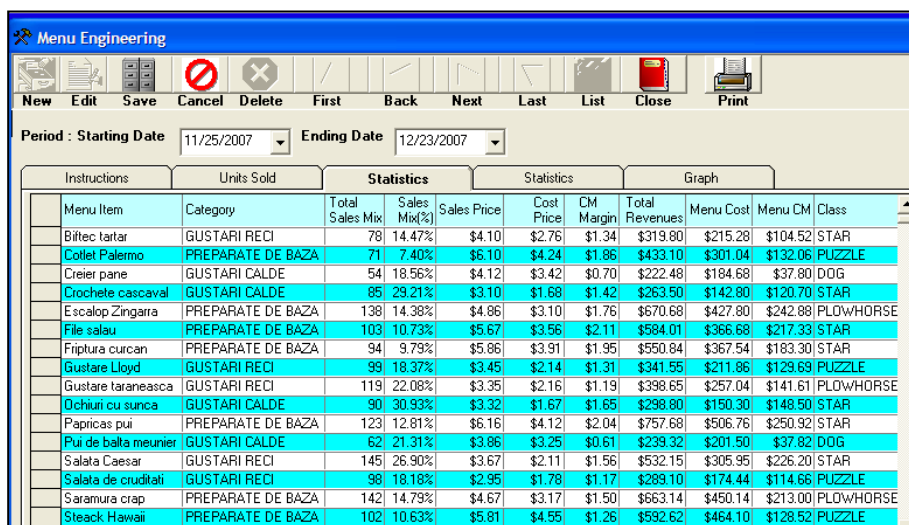

Figure no. 7 – The determination of the statistic indicators associated to the profitability analysis of the articles in the menu

3. Conclusions

The main advantage of the **Menu Engineering** information application consists, in our opinion, in the integrated vision on the set of indicators that ensure the performance of the sales of a public food service unit, thus, eliminating the sheets of chart calculation that are necessary for such operations; moreover, the software generates automatically the classification of the articles in the menu in the standard categories (star, puzzle, plowhouse and dog), offering the possibility for a quick adaptation of the marketing strategies to the customers' preferences.

The information technologies and programs dedicated to the marketing management in the public food service domain offer a real support for the elaboration of the marketing strategies, the possibility to connect the front – office and back – office functions of the profile units in an information solution oriented towards the quick satisfaction of the customers’ needs and demands, the capacity to collect and analyze information in order to anticipate the customers’ needs and to build a profitable relation on a long term, as well as the collaboration along the processes with added value by the access to personalized information derived from the data bases in which the information referring to the clients is gathered.

THE LINE UP OF ROMANIA TO THE EUROPEAN GEOSPATIAL INFORMATIC SYSTEM GEO-SPATIAL DATA PROCESS AND ACQUISITION

Nidelea Marinela

Universitatea Titu Maiorescu, Facultatea de Stiinta si Tehnologie Informatiei, Str. Aurel Vlaicu, nr. 110, et. 1, ap. 5, sector 2, Bucuresti, matemaia@yahoo.com, Tel : 0722759923

Over the past few years, within the European Community for Geographic Information a large data base has been set up in order to create the European Infrastructure for Geographic Information. The main objective is the contribution to the foundation of the Romanian Informational Society in a specific area, that of GIS, through a national spatial data infrastructure (INDS). To this end, the most recent acquisition and processing techniques for geospatial data were borrowed and implemented. In what follows we will speak about some of these techniques and about the integration of Romania in the European geospatial Infrastructure.

Key words: geo-spatial, geodatabase design, the process and acquisition method, geographic information.

Geographic information in the European Union

Over the past few years, within the European Community for Geographic Information a comprehensive data base has been set up aiming to create the European Infrastructure for Geographic Information (EGII). Geographic information represents a complex part in the European Politics given the importance and continuous development of the information society. Geographic information applies to governments, business and national and international affairs and research. IG is important because of the content and value of spatial electronic information for planning, marketing, environment, recuperable energetic resources, emergency services, healthcare, political analyses and many other fields. Although newer IG technologies have already appeared and applications develop rapidly, further development in Europe is difficult because there are discrepancies in the way IG are collected, stored and distributed across countries and commercial and governmental sectors.

European infrastructure for geographic information

The main obstacles in the way of spreading and of successful use of IG across Europe are not technical but rather political and organisational. The lack of a European warrant in IG delays the development of common IG strategies, produces useless costs, blocks new goods and services and reduces competitiveness.

The difficulty in national/federal IG approaches both in Western and Central Europe interferes with information exchange and it harms both businesses abroad and the market within the UE which is no longer free. This situation can be improved through a European Infrastructure for Geographic Information which should be realized at European level and operated by and for the IG community. As for the countries of the central and eastern Europe, during the second forum CEEC/EU regarding Global Information Society, GIS was included as one of the main problems for the set up of the Information Society for the Eastern and Central Europe.

Generally speaking, an IG infrastructure presupposes a system for data exchange/transfer. This requires a few components:

The technical infrastructure through which data can be transferred (for instance : WAN, access to WWW or something similar):

- A set of standards for data transfer (sometimes called IT standards or operationals)
- Standards for the interpretation of specific thematic and geographic data aspects (semantic or thematic standards)
- Organizational agreements including economic agreements between the participants.

Technical infrastructure is a sine qua non condition for an IG structure and for many similar IT applications. Most of the CEE countries understand the importance of this technical infrastructure and make pressure for the set up of a largely distributed network. Together with this network there comes a set of low level standards for data transfer (IT standards, for instance the set of standards used on the internet and WWW).

The thematic standards which make possible the effective use of IT infrastructure for the set up of the IG network are being pushed to different levels. Efforts are made to standardise ISO and CEN (for instance CEN WG 278, CEN WG 287, ISO WG 211) and the correspondent groups for national standardisation. Under many circumstances national groups work for particular national standards and for the adjustment to international standards. The most important thing is the ensurance of an approach for Open System Architecture for GIS) and this concept is vital to the setting of a IG work infrastructure because it goes beyond the standardisation of data transfer folder by folder but it allows the intelligent access to a program which operates/runs (ruleaza) in a computer when data are provided on the central server.

The construction of IG infrastructure requires the sistematic pick up of spatial data and the description of quality and the content of the data set. A systematic method should be used to distribute this metainformation. This is currently the subject of intense research at international level.

The national spatial data infrastructure

The main objective is the contribution to the foundation of the Romanian Information Society in a particular area which is GIS, through the set up of spatial data national infrastructure (INDS)

In this case INDS is mainly a “coverage” of for politics, standards, partnerships between various sectors and subject matters which will promote the effective production and the use of high quality geospatial data.

INDS consists mainly of :

- - Organizations and individuals generating or using spatial data;
- - Technologies that facilitate the use and transfer of spatial data;
- - Actual spatial data;
- - Relationships and interactions between these entities.

And it has the following components:

- Data sources;
- Spatial data bases, spatial meta-data, data banks;
- Politics and standards for data generation and use;
- Data network and media for data transfer;
- Technologies affecting data bases, politics, standards and computer networks;
- Institutional agreements affecting data bases, data standards and networks;
- Spatial data users.

Naturally these components are parts of a system which function in a place very much influenced by culture, legislation, finance and education.

The word infrastructure is used to denote “ structures and services for accessing and for the use of geographic information as effective as possible” (in Groot, IL, "From geodesy to geometrics: A challenge of Information Society", in Proc. Of Int. Symp. Operationalization of Remote Sensing, 1990). It can encompass communication channels, transfer standards, educational support, maintenance facilities, legislative agreements to control the access the use and payment of taxes.

The infrastructure also includes:

- A register of the general survey;
- Standards for the classification of information and for digital qualification and communication;
- Thematic data bases which are spatially defined;
- Technical and legal bases for world connectivity to the world data base and legal interconnectivity rights;

Meta bases describing the content and components of data bases.

Geo-spatial Data Process and Acquisition

Acquisition procedures of graphic data

The photogrammetrical method

It represents the most well-known process of data collecting. The development period brought changes regarding the data process (digital sensory process) as well as regarding the new exploitation technique of the stereo-pattern, through digital working establishments. The digital image can be acquired by aero-photographing with ADS40 digital cameras. Thus, we get a 7908/15468 pixels digital image composed from four image segments. We can also get a digital image by scanning the photograms on the shadowgraph / film. By groups images shaping process or by aero-triangulation we obtain the stereo pattern, a 3D image, real tract correlated. The image can be exploited to draw out 3D vector information, ortho-images, digital patterns and 3D objects.

The cartographic method

The most usable sources for obtaining a geo-spatial database are represented by the cartographic background. This is a content of Stereo 70 or Gauss-Kruger plans and maps projections. The plans have representative scales between 1:500 up to 1:25 000 and the maps have scales between 1:25 000 up to 1:1 000 000. A plan or map content is built up from: the number of conventional marks, the authenticity and real degree of the representation. In the topographical plan, the elements are represented by their horizontally projection. The position of a certain shape in space is determined by its coordinates.

The cartographic projection is a mathematical proceeding of the Earth curved surface representation, correlated with its particularization and importance.

The regulated and defined projection for our country is Stereo70, a stereo-graphical projection characterized by the following elements:

- the view shape is situated on the sphere, exactly contrary to the central projection juncture,
- in this case the projection plan may be considered tangent or secant,
- keeps the angles unmodified,
- modifies the lengths,
- they are concordant projections.

Acquisition methods of descriptive data

An important component of GIS databases are the descriptive data. In many cases, the descriptive information regarding the cartographic objects are of big dimensions and represent a higher complexity. That is the reason why a new abstracted data apply is needed, using correlated database systems: client-server, or mono-user database systems. In order to people the correlated databases users, interfaces are developed and the clients have access to the correlated database resources server, introducing specific information for which it has been developed.

At the end of the people process, many interrogations are defined and affect the result of dynamic sets of descriptive data that contain specific information about the certain cartographic object.

The logical timing along the graphic elements and the information resulted from the dynamic set of the correlated data is made based on some exclusive indicators. These indicators have the same value in both data sets. In this way descriptive information regarding cartographic elements can be collected and can be easily attached to the end of database dissemination with specific information.

The Process and Acquisition Method of Airy and Satellite Images

The Primary Image Process

Digital Images

Any image is a bidimensional set of data. The images have in their constitution, certain elements called "pixels", equivalent to the picture form data. Their values can be represented by a natural, real or complex number, correlated binary as a volume of bytes. The images are divided into two main categories, depending the data type from the dimensional structure:

SCALAR IMAGES

In every content there is a certain unique number (scalar). In this category, the binary images (monochrome) and the grey level images are also included.

VECTORIAL IMAGES

Any content represents a vector of numbers. In this category stand the colour images with the three basic colour elements:

Several elements constitution images – in this category are also included the stereoscopic images, formed by images of the same stage taken from different pictures. The element from one picture may represent the radiant intensity source (particular cases).

Images used for GIS and teledetected systems may be classified into two main categories:

- *Non- visible images* (several spectrum images) - acquisitions of certain bidimensional fields of physical parameters (temperature, density etc.) – in this category are included pictures taken with airy difgital cameras (e.g.. ADS 40 - Leica) or teledetected satellite systems.
- *Visible images* (of lightening) are primary images (photos, maps, plans etc) obtained from operations as:
 - airphotography – using airy-digital or analogous cameras systems (the conversion between analogous and digital was further accomplished),
 - analogous - digital conversion of the cartographic existing documents (plans, maps).

There are two types of scalar images:

- **Strength images** – the value of each pixel represents a direct measure of the lightening intensity (e.g. grey level), expressed in real or natural values.

- **Index images** - the value of each pixel represents a natural index which helps finding information on the associated colour of the certain pixel. The information is stocked in a colouring table (LUT), specific for the indexed image, the table has a structure matrix and contains registrations. Each registration contains an order number of the LUT line and relative red, green and blue strengths that compose the certain colour through an additive mixture. LUT – requires a searching and finding method (indetification – extraction) of the associated information of an unique identification key.

Conclusions

In the nowadays context, using a large number of information requires an administration method as accurate as possible, completely adapted to the data. Thus, the information may be grouped into two categories: spatial information and qualitative information. These kinds of data may be incorporated in the same administrative system of information by creating a Geographical Information System (GIS).

A DOCUMENT MANAGEMENT SYSTEM MODELING

Pătrașcu Aurelia

Petroleum and Gas University of Ploiești, Economics Sciences Faculty, patrascaura@yahoo.com

Tănăsescu Ana

Petroleum and Gas University of Ploiești, Economics Sciences Faculty, atanasescuro@yahoo.com

The authors propose in this paper a model for a document management system, describing, briefly, the document management system and the model concepts, as well as, the Unified Modeling Language characteristics. Finally, they are presented some more important diagrams of this language.

Key words: Model, Document Management System, UML, Class Diagram, Use Case Diagram

Introduction

Business processes streamlining and productivity increasing are fundamental concerns for any organization (private, public or non-profit) [10]. In an increasingly strict regulatory environment, the document and records management is one of the major objectives of any organization.

The electronic document management has represented a continuous concern for computer scientists from all over the world and has developed as an important activity in the document archiving and retrieving field in the documentation centres. Although, almost all the documents from an organization are electronic documents, they can not be effectively used if they are not integrated into a management system. The present technologies, both hardware and software technologies, allow the presentation of the electronic document management concept in a new context, the collaboration and cooperation context in a knowledge based economy. The document management term is a part of a wider concept that covers the communication and knowledge management aspect of an organization [6].

The *document management* is an information system that allows the transfer, the storage and the retrieving of any electronic documents with connecting facilities with other information systems or electronic devices [1]. In the figure 1 it is presented the document management life cycle.

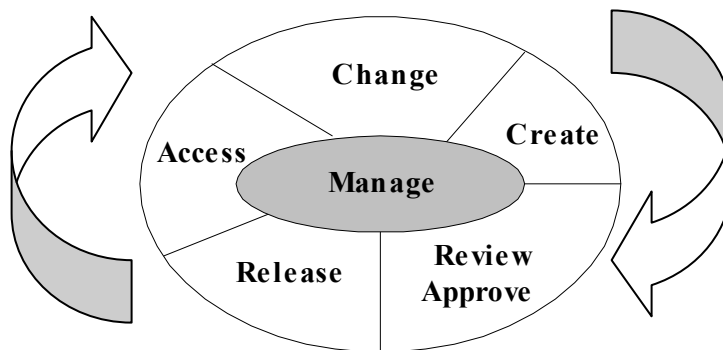

Fig. 1. Document management life cycle [9].

The *electronic document and records management* contains the capture, storage and retrieval of documents and records, potentially both paper and electronic, including workflow, content and knowledge management. The reality has proven that electronic documents and records are here to stay, at least for the foreseeable future. Every email is a record and every file is a source of information that carries a cost. Organizations avoid the challenge but they must accept the need to effectively manage their electronic documents [11].

The authors propose in this paper a model for a document management system (DMS). For that purpose, they are defined, briefly, the DMS and the model concepts, they are described the UML language characteristics and, finally, they are presented some more important diagrams of this language.

UML characteristics

The model is an abstract representation of a system that allows system performances planning, study, analysis, conception and control before its proper achievement, as well as, the design documentation creation, facilitating at the same time the communication between the design teams [3]. This model construction implies using of a modeling language, i.e. a communication mean for all the persons involved (designers and users) to understand the same thing.

Currently, the object modeling industrial standard is UML (Unified Modeling Language). UML is a fundamental graphic language that is defined round three diagrams categories, each of them being used in representation of some information system particular concepts. The first category describes the functional services, the second one represents the system static structure and the third one refers to the dynamics of the system running [4].

UML is the standard language for specifying, visualizing, constructing and documenting the artefacts of a software system [8].

UML – a specifying language

In the software engineering, the *specification* means to elaborate precise, complete and without ambiguities models. A visual specification, such as UML specification, is exposed to the risk of generating ambiguities in the communication process in a higher degree than the formal specification. However, a visual specification of the solution in all the software system development stages is preferred due to the importance of better communication between the software engineering specialists (users and beneficiaries) as partners in the same project [2].

UML – a visualizing language

UML emphasizes the *visualizing* of a software solution to remove the biggest part of the communication problems that can arise between different participants' categories at a software development [2].

UML – a constructing language

The models elaborated in UML can be easily translated in numerous programming languages. This state of things suggests the natural mapping possibility of a model in languages like Java, C++, Visual Basic etc. [2].

UML – a documenting language

A real software company produces all kind of components additional to executable code obtaining of a software system like [2]:

- requirements regarding software system;
- system architecture describing;
- design specifications;
- source code;
- development plans etc.

The UML language version 1.0 uses ten types of diagrams (fig. 2) that can be, thus, classified [5].

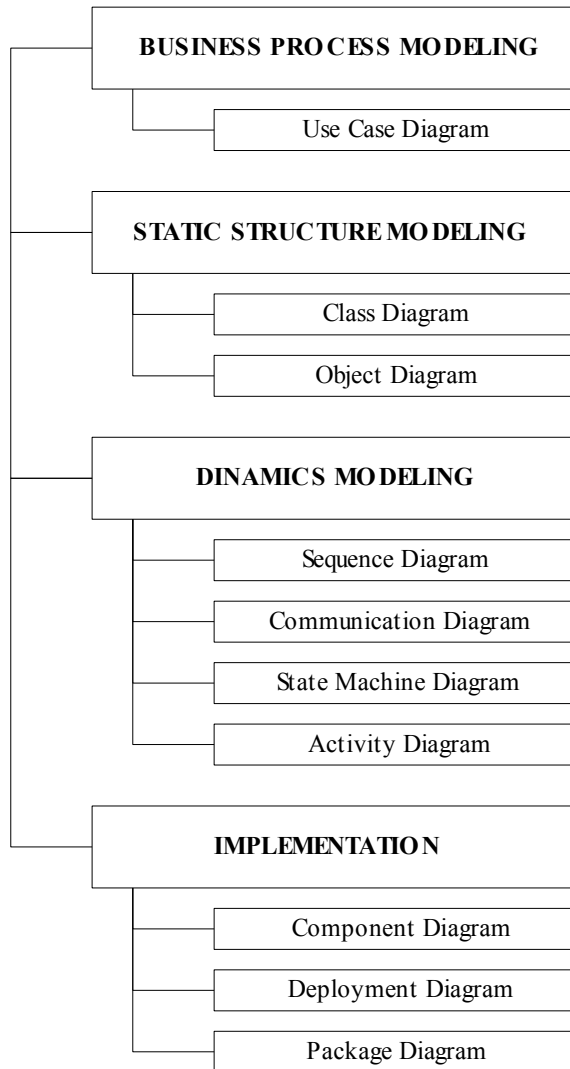

Fig. 2 UML Diagrams.

The current version (UML 2.0) adds three more diagrams: composite structure diagram, interaction overview diagram and timing diagram.

The functional model is represented in UML by the use case diagrams that describe the system from the user point of view [7].

The object model is represented in UML by the class diagrams and object diagrams that describe the structure system in terms of classes, objects, attributes, associations and operations [7].

The dynamic model is represented in UML by the sequence diagrams, communication diagrams, state machine diagrams and activity diagrams that describe the system intern behaviour [7].

System analysis and modeling

For system modeling the authors have used the Visual Paradigm for Unified Modeling Language development environment. This environment was created by the Visual Paradigm Company for designing of some information system object-oriented models and for generating, finally, the adequate code in Java Language [3, 12]. In Visual Paradigm are available all the diagrams, both static diagrams and functional and dynamics diagrams, the development environment allowing their creation and maintenance in the smallest details.

The authors presents, further, the Use Case Diagram and the Class Diagram regarding the DMS.

The Use Case Diagram produces a first view upon the system structure, a design point of departure, an identification of the objects and sequence diagrams [3]. This diagram's elements are: the actors (interns, externs, subsystems), the use cases and the relations between use cases.

The Use Case Diagram proposed by the authors is presented in figure 3.

Fig.3 The Use Case Diagram.

In the case of DMS, *the actors*, i.e. the roles which the users are playing with the respect to the system, are: the system administrator, the database operator, the database and the document.

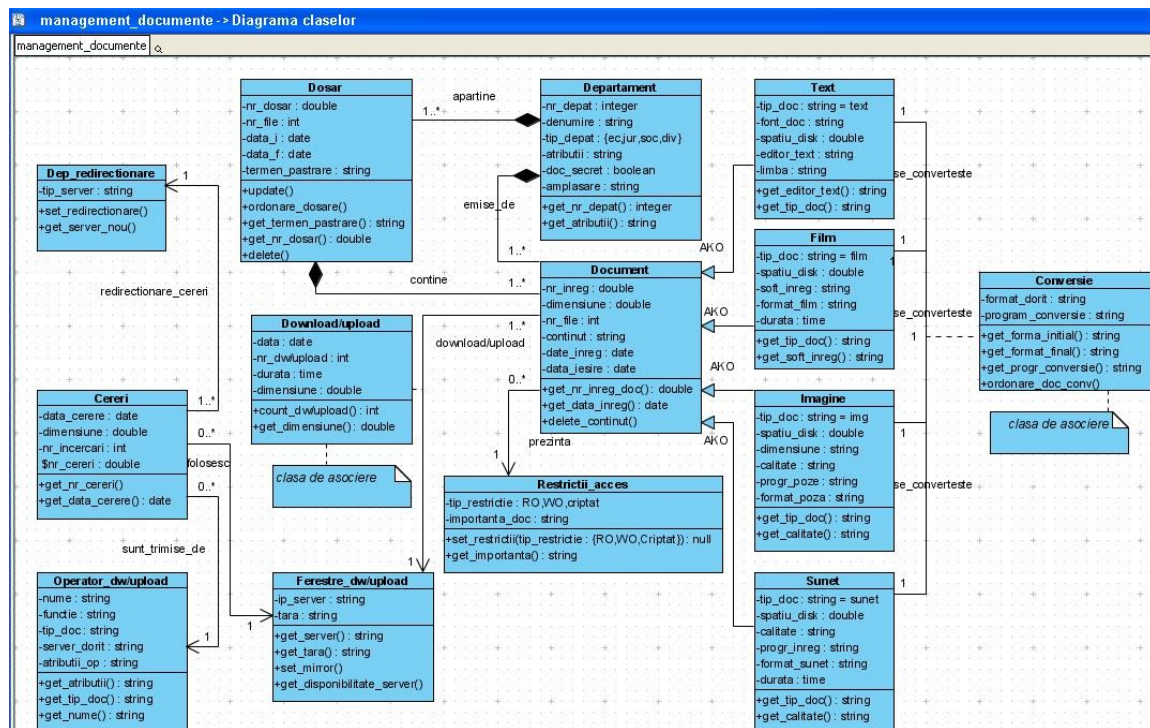

The use cases contains a set of actions sequences indicating what must be designed (conversion, document saving, deny saving).

The Class Diagram is the most important diagram in the object-oriented analysis and design. The diagram's purpose is to *structure the static nature of the classes* in terms of *attributes, operations and relationships* [5].

This contains classes and relationships between classes. A *class* is a model for objects with similar structure, behaviour and relationships. Each class has a name, attributes and operations.

Analysing the activity regarding the document management, the authors have identified and defined 8 object classes : the existing documents (Document), the departments that issued the documents (Departament), the files in which are the documents are included (Dosar), the access restrictions (Restrictii_acces), the downloading or uploading mirrors (Ferestre_dw/upload), the access requests (Cereri), the redirecting departments (Dep_redirectionare), the operators (Operator_dw/upload) and 4 subclasses regarding the document type (Text, Film, Imagine, Sunet). There are, also, 2 special classes Conversie and Download/upload that are *association classes* (figure 4).

Fig. 4 The Class Diagram.

A Class Diagram can contain both relationships between classes and relationships between classes' instances.

Relationships between classes are represented by generalization, dependency and realization. The diagram from this paper includes only *generalization relationships*. Generalization is a subclass-class relationship. According with the figure, in the diagram there are 4 generalization relationships between Document superclass and Text, Film, Imagine and Sunet subclasses (any instance of the Text, Film, Imagine and Sunet subclasses is, also, an instance of the Document class, inheriting the attributes and operations of this class).

Relationships between classes' instances are represented by association, aggregation and composition. In the application are traced:

- 3 compositions between Document and Dosar, Dosar and Departament and Document and Departament classes (e.g., an object of the Document class is a part of an instance belonging to the Dosar class and it can't be a part of other instance);
- 3 "one to one" bidirectional associations between Text, Film, Imagine and Sunet classes (e.g. a film document can be converted in one and only one text document and vice versa);
- 5 "one to many" unidirectional associations between Cereri and Dep_redirectionare, Cereri and Operator_dw/upload, Cereri and Ferestre_dw/upload, Document and Ferestre_dw/upload and Document and Restrictii_acces classes (e.g., a mirror can dispose of all of its requests while a request can't know what mirror have used).

Conclusions

The authors have realized a model for DMS using UML language. The UML language has the following advantages:

- is easy to use by the users;
- ensures extensibility;
- formulates specifications independent of a certain programming language and system working processes.

THE XML TECHNOLOGY IMPLEMENTED IN MICROSOFT SQL SERVER

Pirnau Mironela

Universitatea Titu Maiorescu, Facultatea de Stiinta si Tehnologia Informatiei, Str. Horia Mecelariu nr 8-10, bl 21/1 sector 1, Bucuresti , mironelapirnau@yahoo.com, Tel : 0723210205

The scripting languages from the Server (ASP and ASP.Net then PHP or JSP) are nowadays advanced and mature technologies that offer the possibility of developing new and complex applications on the Web.

Despite the existence of these technologies, basic changes took place lately regarding informational needs or equipments used by a large variety of users. Therefore, today not only the computers are connected to Internet but also hand- held devices. . Taking into account these necessities it is strongly required an universal language that can be understood by all these different devices XML proved to be the answer to this need, representing a new superior stage from all points of view. In the evolution of the information age data exchange is enabled among various equipments.

Key words: HTML, XML, IP, database, query language, web services

Definitions regarding XML

XML (Extended Markup Language) represents the center of a great number of technologies, presently forming the most used language. XML is the simplest and most efficient way of sending data through Internet.

The latest version of database administration systems of client-server type (Oracle, MS SQL Server or IBM DB2) generated a support for the XML technology. The users have the possibility, through extra parameters of SQL instructions, to realize all the operations they desire in a very simple manner.

We will show some facilities offered by Microsoft SQL Server 2000 for the XML technology. The theoretical elements on this subject will be followed by practical examples. We will present the integration manner of SQL Server along with the Web Internet Information Server (IIS), explaining at the same time new options specific to the SQL language, capable of offering support for XML.

XML or “Extended Markup Language” constitutes the base of all the elements that form the Web Services technology. Regarding the platform independence, XML represents the search engine that makes possible the data transfer through Internet, and it also constitutes the WEB services basis.

XML is related to the HTML HyperText Markup Language) language. Between the two types of languages there are some similarities but also a few differences that under no circumstance may be neglected. First of all we have to mention that both of them have the same origin, represented by SGML (Standard Generalized Markup Language). This is a general language that offers the users the possibility to structure their documents and data in an electronic format, through similar mechanisms of classical grammar.

HTML uses the same set of tags which help define the manner that the information will be displayed in the used Web browser.

The HTML private tag set is limited and unspecialized, being generated through SGML technology. In these conditions there is no possibility to particularize your available tag sets according to your desires and needs. The mentioned lack of flexibility could represent, in some cases, an important obstacle. Thereby, in applications for database exploitation, the usage of HTML language is improper for delivering data, which does not represent a major impediment.

Unlike HTML, the XML language offers the user the possibility to build up his own tag set that will be used for a certain document setup. In this manner there is a special flexibility because this element is needed to define electronic specialized documents.

Chart 1 XML and Web services form a basic solid hardware equipment variety

Structure of XML folders

Like HTML folders, for XML structures text format for stocking the information is used. In this manner the transferability of data on any platform or device is assured. Essentially, all the elements evolved in XML technology are as follows:

- The proper XML folder that contains a set of tags and the proper information, delivered through it.
- The validation regulated and all types of data declaration, included in the document, realized by DTD (Data Type Declaration) language. Using DTD language the set of tags used to mark up the document will be defined. DTD has the function to validate the content and the structure of XML folders. In the present time there is a series of DTDs dedicated to certain domains from which we mention: HL7 – element particular for human health domain or MathML – particular element for mathematical equations. Using DTD elements the information can be organized on specific domains much easier. In the latest years, XML Schemas was recommended for describing data included in XML folders. This kind of technology constitutes an evolution in time from the classical DTD data descriptive language.
- Sheets of XSL type will be used to particularize the XML browser folder information display manner. The type sheets have a similar function to CSS (Cascading Style Sheet) formatted folders. In this manner, we may establish a table structure, containing display data, colors and formatted fonts of the information, as well as other formatted data included in the XML folder.

XML and database connections

XML represents the simplest and the most efficient manner to transfer the information on the Internet. In the past every time a data transfer was needed on different platforms, the text folders were used. The data were separated through commas or other specific marks. Once XML language was born, this transfer manner was forgotten. Reported to other types of data information transfer, XML has the advantage of being very simple, having efficient structures of the information, as well as information transfer on any platform or device.

For operating and transfer the database information through XML language, several operations must be followed successively:

- The user sends a demand to the Web server, asking for example the stock exchange rates for the shares he wants to buy or sell.
- The Web server send the demand to the database server under a SQL interrogation, the former sending back the demanded set of registrations.
- The sent data to the database server are covered by specialized solutions and delivered through the Web server.
- On the personal computer of the user that made the request, the data are assumed and transferred in the local data base.

These steps make a great example of interrelation and inter-operations of the XML technology and Internet. It is mandatory to mention that the second and third steps will form a single step; therefore most of the administration database systems have incorporated direct export facilities of data in XML format, without using additional applications or accessories. SQL Server 200 and Access 2003 include a complex support for XML.

XML support used for SQL Server

In order to use XML support it is mandatory to install the SQL Server 2000 version. For installing the database server it is necessary to select the IIS component of SQL XML Support . This element offers the possibility to inter-operate with the Web Internet Information Services (IIS) server database. The Web IIS server offers the possibility to realize interrogations upon the database and to obtain results through a simple Web browser.

The XML support configuration for SQL Server requires the following operations:

- a) By applying the SQL XML Support in IIS the New – Virtual Directory option is selected. After that the interaction between the database server and the Web server will be established.
- b) Creating a virtual named directory and a physical directory where Web pages or specific elements will be stocked. Supposing that the virtual directory was called “XML”, through the browser, Web pages or SQL interrogations based on XML technology may be accessed, using the following address: “http://server name web/XML”. Instead of the name of Web server, it may also be used the IP address, according to it. In those situations when these interrogations are locally tested, on the personal computer, it is necessary to introduce the following URL addresses: http://localhost/XML and “http”//127.0.0.1/XML”.
- c) Through the “Security” section, it is possible to introduce a valid username and a password for accessing a SQL Server database we want to export through XML technology. Furthermore, if we established a mixed identification manner, we may access the database through a SQL Server account and also using a standard user account of the Windows operational system.
- d) “Data Source” section allows the SQL server to be accessed in the database we use. When you will access the server on the local network, it will be mandatory to mention the IP address. If you intend to test the local settings, you must mention the (local) SQL Server identification.
- e) “Settings” -sets the manner the interaction between the database server and the Web server will be realized through XML technology. Regarding these, two important options may be established:
 - “Allow ULR Queries”- option realizes SQL-XML interrogations, directly through SQL interrogations as supplementary parameter at the ULR address.
 - “Allow Template Query” – option realizes interrogations using a series of pre-defined patterns.

There are also other configuration options that allow the directory settings and the XSL folders configuration schemes to be stocked.

SQL and XML interaction

The interrogation allowance through old SQL instructions was realized by adding additional sets of supplementary parameters that allow establishing ways of database registrations in XML format. Therefore, at the SQL standard registration a FOR XML AUTO provision was added. Supposing that we want to interrogate the data in an “Employees” chart, we will realize the following interrogation: “SELECT*FROM<CHART NAME>FOR XML AUTO”.

Instead of the AUTO parameter, there is also the possibility of using the “Raw” option, offering the option of using the “row” tag for identification each database registration exported in XML format. Additionally, the SQL Server facilitates the possibility to import registrations-available on XML folder, into the database. Therefore, in order to accomplish this operation the “OpenXML” function is needed, being used as a parameter of the SQL Insert command.

SQL-XML interrogation manner

Implementing all the options of the IIS and MS Sql server, an efficient interrogation of the SQL interrogations are available. These return the database registrations from a database format into a XML one.

There are two fundamental manners of implementing these operations:

- a) a) Directly addressed interrogations- If the “Allow URL” option was activated, there is the possibility to realize the interrogation by introducing the SQL instruction, directly as a parameter of the accessing address of the Web server. Accomplishing this operation opening the Web browser and introducing the following address it is necessary:
- b) “**http://localhost/XML?sql=SELECT+*+FROM+name_table>+FOR+XML+auto&root=roo t**”.
- c) The first part of the address identifies the Web server and the XML virtual directory. The SQL instruction it is present by using the “?sql” parameter and the keywords of the interrogation have been separated using “+”.
- d) At the interrogation the “&root=root” section has been added stressing the presence of the root element of the XML document. Therefore, the root tag ”root” has a similar function as the “HTML” tag, specific for HTML language. Also, in a similar manner, the XML folder will be closed using the “/root” tag.
- e) b) The usage of interrogation patterns – Interrogations realized by introducing SQL instructions as a ULR parameter address it is harder to realize because it is needed a direct SQL instruction through the browser. For eliminating this disadvantage there is the possibility to use interrogation patterns. Introducing a SQL instruction in a XML folder a predefined tag may be used “sql:query”. Here is an example of a XML folder where a SQL instruction from a database chart was introduced: <ROOT xmlns:sql=”urn:schemas-microsoft-com:xml-sql”>

```
<sql:query>
  SELECT
  FROM <name_chart>
  FOR XML AUTO
</sql:query>
</ROOT>
```

For using the SQL interrogation on the Web browser, we used the following URL address:

<http://localhost/XML/interrogation.xml>.

When these interrogations are changed in the browser, as a result we will have a unformatted XML folder. When we want to individualize the manner the information are presented from the XML folder into the browser, it is necessary to use the XSL style sheets. These style sheets have a similar function with the CSS (Cascading Style Sheet) folders. In this way will a chart structure of presenting the data be established, the colors and the formatted fonts of the information, as well as other formatting elements included in the XML folders.

Stocking procedures

The stocking procedures represent a pre-collected set of SQL instructions, saved on the database server under a name and after that unitary processed. They enable the user to realize complex operations on the database through a single signal sent by the source application. The user may also use declared variables, conditioned instructions and other strong programming elements. The stocking procedures are always present in the relational database systems, based on the client/server (MS SQL Server or Oracle) technology. In the stocking procedures case, for MS Sql Server database, the Transact-SQL language it is used.

This language constitutes the standard manner to communicate among the resulted applications and the database server. Transact-SQL it is a language based on Structured Query language (SQL), the ANSI standard for interrogation database languages. They enable the chart creation, establish access rights for various elements and insert, modify or delete registrations from the database. In the stocking procedures

cases, Transact-SQL presents a supplementary set of instructions, reason that transform it from an interrogation database language into a genuine programming language.

Conclusions

By using the XML technology, one may easily change the stocking procedures on the server through a simple Web browser. For completing this procedure is mandatory the use of the “Execute” command, as a changing parameter to the URL address that accesses the Web server.

The interrogation of XML support into SQL Server 2000, allows an efficient data transfer among the various information systems.

Regarding economical applications, the XML technology offers an overflow inter-operational level, as well as many integration possibilities with different practical solutions.

The aim of this paper is to present the potential which could be offered by managing databases in direct marketing through gathering the information that could offer the shortest and efficient way to the clients needs. The paper includes the necessary steps to make this activity a real success.

Keywords: databases, marketing direct, customer database, information, databases update

The direct communication with the customer – The essence of a successful direct marketing activity

The process of defining and establishing direct *communication objectives* is a very important element of communication with the customer. Without clearly specified objectives, the target of direct marketing communication program can easily fail. Also, the objectives serve as reminders of what the economic organization is attempting to do with its communications to various customers.

The objectives of the communication with the customer are derived from promotion marketing objectives, which tend to be general because they relate to entire marketing plan and they also can be measurable. Communication goals are depending on the stage in the buying process that is addressing to. According to Kenneth E. Clow and Donald Baack, the *major direct communication objectives* address to both compartmental and psychological issues and regard the following issues:

- Build customer traffic
- Change customer beliefs of attitudes
- Develop brand awareness
- Encourage repeat purchases
- Enhance firm image
- Enhance purchase actions
- Increase category demand
- Increase market share
- Increase sales
- Reinforce purchase decisions²⁶⁰

Database marketing objectives

The *objective and role of the database in the direct marketing and communication* determine the structure and the content of the database. The typical questions posed concerning data collection include:

- What kinds of data are currently available?
- When and how often will information be collected?

²⁶⁰ Clow, Kenneth E., Baack, Donald – Integrated Advertising, Promotion and Marketing Communications, Prentice Hall, New Jersey, 2007, page 101

- When and how often will information be updated?
- What additional data are needed?
- Why certain data are needed and not other types?
- How will the data be used and who will use it?
- Where will the data be located?

Answers to these questions allow the marketing and information system departments to design the specific database. It is important to make sure the information helps the company maintain a successful communication program.

The objective related below may be changed or be modified as time passes depending the company's actualized needs but the essential information remains relatively consistent. Regarding these, the objectives *for direct marketing database communication with customer* can include the following issues:

- Provide useful information about company's customers
- Create information about why customers purchase the products they do
- Share information about customers as companies prepare advertisements and promotional materials
- Reveal contact points to be used in direct marketing programs
- Generate information about members of various buying centers in business to business operations
- Track changes in purchasing behaviors criteria used by customers²⁶¹

The steps to a successful direct marketing communication

In order to create a complete communications and promotion program, 8 steps are necessary according to Philip Kotler²⁶²:

- The first step is to **identify the market target**. The company must identify the target market from the beginning if it wants to know who it is addressing to. The target can be formed by: potential customers for the company's products, current users of company's products, decision factors and influence factors.
- The second step consists in **determining the communication objectives**. Once the market target is identified, and also its characteristics, the company that releases the message must decide what kind of answer wants to get.
- It follows the **creation of the message**. Knowing what kind of answer the company wants to get, the message must be created in that manner to achieve that objective.
- **Choosing communication channels** is the next appropriate step. The company must choose efficient communication channels to distribute its message. Many times these channels must be different and more than one.
- Next step is – **setting the promotion budget**. To set the promotion budget is one of the most difficult marketing decisions which companies are confronting with. Mostly there are 4 major ways to establish the promotion budget: the method based on the company's possibilities, sales percentage method, the method based on competitive priorities, objective and task method of budgeting
- It follows the step of **establishing the promotional mix** – the elements that compose the promotional mix are: advertising, personal selling, sales promotion, public relations, and direct marketing.
- **Determining the results of the promotional activities**. After the implementation of the promotional plan, the company must evaluate the impact produced on the market target.
- The final step is **the organization and the coordination of marketing communications**. To reach the communicating objectives, the companies must use more than one communication tools referring the promotional mix.

²⁶¹ Clow, Kenneth E., Baack, Donald – Integrated Advertising, Promotion and Marketing Communications, Prentice Hall, New Jersey, 2007, page 350

Customer Database – the tool which can bring the real advantage in knowing customers' needs

The first thing that must be presented in this section is the database definition. A database is a collection of data/information that is organized so that it can be easily accessed, managed, and updated in order to select desired pieces of data depending on combined selection criteria.

Referring to marketing, a definition of marketing database according to TechTarget (www.techtarget.com) is “Database marketing is a systematic approach to the gathering, consolidation, and processing of consumer data (both for customers and potential customers) that is maintained in a company's databases. Although databases have been used for customer data in traditional marketing for a long time, the database marketing approach is differentiated by the fact that much more consumer data is maintained, and that the data is processed and used in new and more sophisticated ways. Among other things, marketers use the data to learn more about customers, select target markets for specific campaigns (through customer segmentation), compare customers' value to the company, and provide more specialized offerings for customers.²⁶³” (TechTarget provides enterprise IT professionals with the information they need to perform their jobs - from developing strategy, to making cost-effective IT purchase decisions and managing their organizations' IT projects - with its network of technology-specific Web sites, events and magazines.)

So, a customer database is a structured collection of records including information about customers or potential customers. A good customer database is the key for developing efficient customer relationships. But what does it mean “a good customer database”? What kind of information must it contain? Is it enough to know information like: name, address, age, marital status, etc.? The idea of using databases is to manage customer relationships to increase both sales and also the customer satisfaction. In order to get customers satisfaction, next to information like:

- demographics: address, telephone, age, birthday, marital status, occupation, etc.,
- information like:
- psychographics: activities, interests, opinions, buying patterns, etc. – are also needed.
- An appropriate database can offer important information about the customers needs, wants and buying patterns, and also information such as the most and the least profitable customers. This process containing methodologies, software, and usually Internet capabilities that help a company to manage the relationships with its customers in an organized way, is called Customer Relationship Management (CRM), and it plays an important role in many small business' sales and marketing strategies. The role of the Customer Relationship Management – CRM – consists in helping companies to understand, so that to anticipate, the needs of current and potential customers. One of the most important information the CRM system may offer is to determine the most profitable customers and also, what common characteristics do they share. But, first of all, in order to offer appropriate and essential information about the customers, a CRM is based on an effective marketing database.

Customer database development

- The first step in building a customer database, management must first determine the **company's primary objectives**. Some of these objectives may be:
 - future promotional activities;
 - introducing a new product and service;
 - to sell different products/services;
 - distributing information about an event;
 - thanking them;
 - creating customer loyalty programs;
 - determine the most profitable customers;
 - and many others.
 -

²⁶³ http://searchcrm.techtarget.com/sDefinition/0,,sid11_gci939072,00.html

The second step is to determine what kind of data a company needs about its customers, in order to achieve the objectives. In order to developing a good marketing database, the management must know that it also must include details of **prospective**, as well as existing customers. Not only existing clients must be targeted, but also the potential clients. This is one important principal a customer database must refer.

Source Data for Customer Databases

- The information kept in a customer database comes from different data sources. These sources can be internal or external.
- **The internal data** are the data that refers to the existing customers and comes from the inside of the company. The internal data may refer to: client files, orders recordings, information selected from customer reclamations, data referring to customers' satisfaction, reactions to promotions actions, market research, questionnaires, etc.
- **The external data** is the data which comes from outside, for instance by renting a list of names and addresses or by changing data with another company.
- Each marketing department must determine the particular source data which is needed in order to get all necessary information for their customer database. This depends on specific products or services, the domain of activity or even the competitive situation of the company.

Customer Database Accuracy

Database accuracy is essential for an effective Customer Relationship Management system.

First of all, the quality of data and the quality of the customer database maintenance are very important. They must be updated frequently because some data are changing often. Problems may appear when data from different sources are mixed, for instance data from internal sources with data from external studies.

Wrong data as: duplicates, wrong addresses, personalization errors, etc., may drive not only to losses in the company's budget, but also can affect the marketing strategy by giving wrong information.

Customer Database Using

The using of customer databases in marketing is a very powerful and competitive weapon for companies because it helps them to stay close to the customers, to understand their needs, to treat them well after the sale, and this way to develop a fidelity program. Using the information kept in the customer databases, advertising campaigns' messages may be tailored to specific segments of the market or even to the individual customer. In conclusion, there are many ways a customer database can help companies to improve their activity by: profiling existing customers (looking at customers to identify common characteristics between them), keeping in touch with the customers, customer segmentation (people with similar attributes tend to have similar tendencies in purchasing patterns), customer scoring, customer retention (to identify groups that are likely to leave (potentially to rival providers)), cross-selling (in order to sell other products to existing customers), up-selling (in order to sell more expensive products or services to existing users of the same type items).

THE ROLE IN ENABLING GOVERNMENT TO ORGANIZE AND OPERATE ITSELF IN A MORE EFFICIENT AND COST-EFFECTIVE MANNER BY USING THE INFORMATION TECHNOLOGY

Popeanga Vasile

Vatuiu Teodora

Universitatea "Constantin Brancusi" Facultatea de Stiinte Economice, Str.Stefan cel Mare, nr 1, Targu-Jiu, Gorj, Romania e-mail:vatuiu_teodora@yahoo.com

This paper illustrates the value of interoperability in the delivery of Government e-services: Government-to-Government, business-to-Government and citizen-to-Government. It describes the many issues involved in achieving successful interoperability programs—together with the tools, technologies and standards that help make this possible.

The information technology, the delivery of Government e-services, successful interoperability programs

1. Generals considerations

Government systems are generally purchased on a solution-by-solution basis, and driven by the need to acquire the best solution for a specific purpose. The result of this is the creation of a wide range of separate information and data islands across Government—with no easy way of unlocking the valuable information assets they collectively contain to support more useful and productive processes.

Interoperability programs can help resolve these problems. A well-structured approach to interoperability helps open up data and information silos and enable information to be exchanged more easily and usefully between systems. Business applications can then take advantage of that integrated information to provide greater insight, better control and improved operational efficiency in information handling. The net outcome can be better-informed and more time decision-making and related cost efficacy.

E-Government interoperability programs need to be based on a clear set of publicly accessible technical standards and policies that act as a foundation for the overall e-Government strategy. Such technical standards range from those defined by the numerous open standards bodies (like ISO, ECMA, ETSI, ITU and ANSI-accredited developers), to those proprietary standards adopted by companies across the marketplace. For example, HTML and TCP/IP are widely recognized open standards, while Adobe's PDF format, the Microsoft[®] Office XML file formats and the Java and Win32[®] APIs are widely accepted proprietary standards. Yet each of these standards provides proven interoperability between different systems and applications.

Successful interoperability programs exploit existing Government investments—and provide a means of enabling those existing systems to participate in a wider ecosystem of information systems. By exploiting best interoperability practice, Government systems are able to achieve improved data exchange and more integrated systems and application access. The result is more effective use of information not only within the public sector, but also between the public sector and citizens and businesses.

Establishing an agreed approach to interoperability can help lead to a step-change improvement in Government services through, for example, internal efficiencies and the provision of better online access. The adoption of interoperability initiatives by various Governments around the world has already provided a powerful means of ensuring true interoperability across public sector systems and between the public, private and voluntary/not-for-profit sectors.

2. Microsoft and Interoperability

As a well-established and recognized industry leader, Microsoft has long embraced the importance of interoperability. It has been one of the leading players in designing interoperable products, licensing its

intellectual property to enable interoperability, developing interoperability standards such as C#/CLI, IPv6, USB, XML and Web services, and collaborating with partners and competitors to provide interoperable solutions (such as the Nokia-Microsoft mobile music solution, the Cisco-Microsoft security initiative, the Sun-Microsoft interoperability Agreement, the palmOne-Microsoft e-mail interoperability effort, and Siebel-Microsoft effort to enhance interoperability)

The European Union's IDA (Interchange of Data between Administrations) program has also acknowledged Microsoft's practical commitment—both now, and in the future—to meet interoperability requirements.

Microsoft has consistently invested in helping customers integrate our platform and applications with a broad array of popular (and even not so popular) hardware, software and networks ... As a result of these efforts, Microsoft offers a comprehensive portfolio of interoperability software capabilities, from the operating system to individual applications. Our software works with a vast array of technologies in the marketplace, whether they shipped last week or decades ago. Microsoft software can talk to mainframes and minicomputers from IBM and other manufacturers; other operating systems such as the Mac OS and various UNIXes including Linux; NetWare or AppleTalk networks and native Internet protocols; dozens of programming languages, ranging from COBOL and RPG, through C++ and Java, to the latest experimental languages; hundreds of databases including Oracle, Sybase and DB2; popular business applications like SAP or Siebel; vertical industry standards like SWIFT or HL7; email systems; and infrastructure products providing message queues, directory, management and security.

Microsoft's practical delivery of interoperability reflects a long-standing drive for continuous improvement in software quality to support better and more predictable software experiences, even in a highly interconnected environment. Microsoft is committed to enabling interoperability between Microsoft products and other companies' technologies to meet customers' present and future needs.

Microsoft Office, for example, is not only a familiar desktop office suite but also provides strong support for interacting with existing information systems, enabling the smart use of data drawn from multiple underlying information systems. Using Office in this way minimizes training (since users are already familiar with Office) and enables more efficient interactions with new and existing data, regardless of the underlying systems in which such data resides.

Beyond the significant development time Microsoft spends to ensure interoperability between old and new generations of software, it incorporates hundreds of industry standards into its products to enhance their interoperability with third-party products and services. Microsoft also participates in many formal and informal industry standards organizations to help define the specifications that are a prerequisite for interoperability.

We publish APIs, protocols and software development kits, and we also license our underlying intellectual property associated with this and other technology, to help others deliver interoperable software. And we work with a wide array of partners, some of them direct competitors, to deliver interoperability solutions that work well with our products. In the last year alone, Microsoft entered into interoperability agreements with AOL and Yahoo! (instant messaging interoperability); Cisco (interoperable security solutions), Oracle (database interoperability), palmOne (e-mail interoperability), Sun Microsystems (Windows Client and Server and Java/.NET interoperability); and Vodaphone (PC-mobile interoperability).

The design and development of the Microsoft platform creates compelling opportunities for third-party software and hardware—something that is only achievable if the platform provides interoperable mechanisms. This is further underpinned by the increasing transparency provided to the industry (for example, documented Windows interfaces and access to the Windows source code for Governments under the Government Security Program).

In addition to the extensive support for open standards across its product range (such as, for example, the features in Microsoft Office System that enable it to use open standards such as XML and Web services), Microsoft provides other products specifically focused on helping ensure interoperability between systems (linking for example the world of XML data interoperability with those of proprietary applications and technologies). These help to ensure the kind of cross-system integration necessary to underpin online service delivery and e-Government programs.

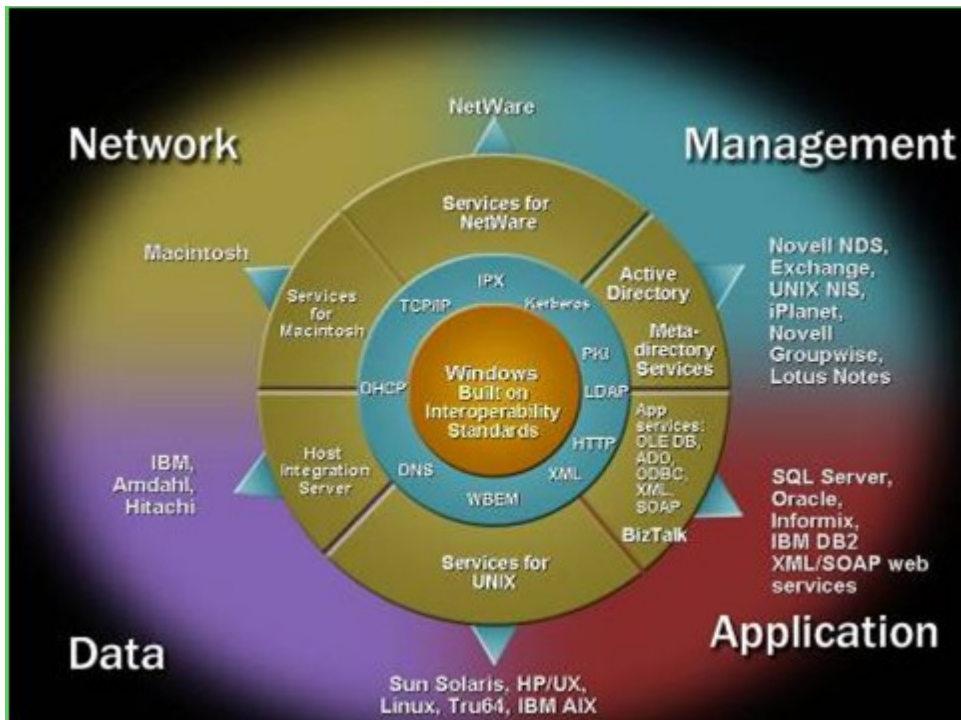

Figure 1-: Microsoft Interoperability

As illustrated in the preceding graphic, the result of Microsoft’s commitment is that we offer a comprehensive portfolio of interoperability software capabilities, from the operating system to individual applications. Specifically, Microsoft software can talk to mainframes and minicomputers from IBM and other manufacturers; other operating systems such as the Mac OS and various UNIX derivatives including Linux; NetWare or AppleTalk networks and native Internet protocols; dozens of programming languages, ranging from COBOL and RPG, through C++ and Java, to the latest experimental languages; hundreds of databases including Oracle, Sybase and DB2; popular business applications like SAP or Siebel; vertical industry standards like SWIFT or HL7; email systems; and infrastructure products providing message queues, directory, management and security.

An important feature of Government interoperability programs is that they interact successfully with systems in use in the wider IT marketplace—notably the private and voluntary/not-for-profit sectors. Government systems do not exist in isolation and need to interact with external systems, taking advantage of the same industry standard applications and technologies that the competitive world of private business enjoys. For this reason, successful Government interoperability frameworks are built on adoption of the systems, specifications and standards in widespread use—including open and proprietary standards—together with published interfaces, file formats and protocols.

3. The New Applications to Portal with E-Government Interoperability Engine

The government of Romania has added new interoperability capacity to its e-government portal and National Electronic System (NES) to support a large range of applications. The NES was built by the General Inspectorate for Communications and Information Technology in 2003 in partnership with Microsoft. The solution employs the Microsoft® .NET Framework development system and Microsoft BizTalk® Server 2004 at its orchestration layer, along with Web services for the delivery of new electronic services. The solution has become an integral part of the government’s administration reform programmer and been the impetus for the full realization of e-government in Romania.

The NES works as a data interchange hub that ensures interoperability with back-end systems across government.

Romania has hundreds of public-sector agencies—from ministries to regional and local government. Each organization has its own procedures, information systems, and Web sites. Traditionally, there was little or

no interoperability among these different parts of government. Processes were usually paper-based, and with the lack of integration, citizens and businesses often had to go from office to office, filling out a number of different forms, to obtain a service.

Romania's transition to the information society started in 2001 with its first 30 e-government pilot projects. Led by the General Inspectorate for Communications and Information Technology (IGCTI) on the basis of the European Commission's eEurope framework, the pilots provided basic online services to citizens and businesses.

One of the key goals of the e-government initiative was to ensure the "back-end" of the public sector—each of the existing systems and processes involved in service delivery—could feed into new "front-end" entry points such as Web sites and mobile devices. This is where citizens and businesses can access and use electronic services.

The difficulty for government deploying online services is to ensure its back end and front end work together in a secure and coherent manner. We needed to resolve this technological issue to create the right environment for e-government and develop one-stop, citizen-centric services. But we also needed to go a step further and ensure that we added new interoperability capacity to the National Electronic System (NES). This would make it easier for third parties to add new applications to enrich the service and make it more flexible for users.

The IGCTI—together with Microsoft and Softwin, a leading provider of computer software and services in Romania—developed an e-government portal (<http://www.e-guvernare.ro/>) and the NES as a pilot in 2003. The IGCTI and Microsoft worked together to roll out the solution nationally in 2005 with modifications to accommodate specific requirements for local government services. All Romanian public institutions are now legally required to provide access to their online services through the portal and NES.

Built using the Microsoft® .NET Framework development system, the portal runs Windows Server® 2003 and Microsoft Internet Information Services to provide a single point of contact for accessing public services from different government departments. The NES serves as the portal infrastructure, routing service requests to a back-end system using XML-based Web services.

Microsoft BizTalk® Server 2004 is used to call on Web services for interactions between the NES and disparate operating systems and databases from IBM, Oracle, and other vendors used within different government ministries.

In this way, the NES works as a data interchange hub that ensures interoperability with back-end systems across government. A citizen or business accesses the portal, signs on, and fills in and submits a form directed through the NES to the relevant government agency.

With the help of Microsoft Services, the IGCTI is now planning to build a delivery engine for new services to be added to the NES. The new functionality, which is still a work in progress, will support third parties that want to offer new applications through the NES system, giving them the benefit of code and templates. We want to get as many Microsoft partners as possible to back the project to provide an even richer environment than at present.

4. The NES marks the beginning of a general digital reform in Romanian society

The Romanian government is enriching its e-government service by making its award-winning portal fully interoperable for new applications. Its best-value solution, developed in partnership with Microsoft, is breaking down a legacy of silo working.

With interoperability between the NES and new applications, the Romanian government can provide even better one-stop, citizen-centric services. The NES provides a central authentication service so people can access all services using a single password and digital certificate issued by the IGCTI. The portal helps citizens and businesses access public services anytime, anywhere, in a fast, simple, and secure manner.

The first services to go online were primarily aimed at the business community, including the filing of tax and VAT returns and declarations for unemployment, healthcare, pensions, and other social insurance payments. Further services are being extended as more agencies automate their back-office processes and connect their systems to the NES.

The NES makes facilitate the conditions for others to provide electronic services and it possible for all public service providers to interconnect through electronic means. This does not imply the elimination of

over-the-counter service delivery, but it is a necessity for creating an alternative that did not exist before and offering citizens a choice.

Conducting transactions electronically and ensuring the governments front-end and back-end systems work together coherently is also essential for rationalizing costs and improving administrative efficiency.

The portal and the NES are an integral part of Romania's programmed for administration reform and it changes the way in which each and every citizen or company interacts with government. The technological capabilities for integration can help break down the silo approach of service delivery, citing as an example the creation of a single set of accurate data that can now replace costly, overlapping, and redundant data collected manually by different agencies. Together with the migration from paper to electronic workflow, this will result in substantial cost savings and faster and more efficient processes both within and between administrations.

The ability to interact with government electronically further provides a stimulus to Romanian companies to invest in IT and modernize their own business systems, contributing to the long-term competitiveness of the country's economy. Digital certificates have been issued to about 1,400 primarily large businesses so they can use online services, and efforts are being made to register small and medium-sized companies as well.

It is still a young project, but the benefits for the businesses using the NES are already there and they can submit documents from anywhere and receive instant feedback rather than have to come into Bucharest every month to hand in hard copies of their statements.

The NES and the E-Government Portal have been the impetus for the full realization of e-government in Romania. With a common environment for integration and service delivery, the IGCTI has encouraged government agencies to work with the same protocols and concepts for whole-of-government goals.

Conclusions

The NES marks the beginning of a general digital reform in Romanian society and demonstrating that e-government is the best way of organizing public management to increase efficiency, transparency, accessibility, and responsiveness. It also helps to reduce bureaucracy and corruption in the inner management of the public sector and in its daily relations with citizens and business users of public services. The Romanian government's strategic partnership with Microsoft has been a key factor in the success of the NES and portal. Microsoft technologies have proved scalable and flexible for future expansion because of their use of open standards such as XML. Large technology companies usually have their own way of working with the public sector, but with Microsoft, the IGCTI built the system in partnership and could deploy a best-value solution that met its specific needs and requirements.

The development of the informational and communicational technology makes possible the use of a diversity of systems, instruments and technologies that offer to the decisional factors sharp and safe informations and also proper ways to process and analyse those informations in order to achieve an efficient development of their activities. We chose the internet - for theoretic and also for practical reasons - as informational technology because it stays at the base of other informational, decisional and communicational technologies - the intranet, the extranet, the web, the e-commerce, the groupware etc. Among the practical reasons we mention: low costs, fast communications and the performances inside the office and in relation with other people, especially with the clients; the market's development and the easier acquisition and fusion processes.

Key words : the management's data base, the federative data base systems, the client/server architecture, the internet/intranet technology, the distributive application.

The perfection of the informational system of an organization is placed within a strategy of global improvement and durable of the organization's performances. In approaching the general aspects of perfection of the informational system we start from two premises. On the one hand, **the development according the levels**, in order to formalize the new system in different hypostasis: contributions to the strategy of the company, the usage of administration rules, organizational states and technique, for which it is appealed to modern techniques of formalization, such as the conceptual models and logical models. On the other hand, **the development according the phases**, which allows a hierarchy of the decisions that are to be taken during the period of projection and operations of the new informational system. Thus there can be better dominated the **risks** (costs, terms of realization, influences over the employees implicated in this process) and **effects induced by the new informational system** over the company's activities, among which: the efficacy of administering the problems that appear, the improvement of the registered performances, the amplification of the commercial impact and others. At the same time the double approach favors the assimilation of the new technological concepts (data basis oriented on the object, technology Internet), but also the evolution of the informational system, according the changes that intervene in the activity of the organization or in the environment in which it is integrated.

At present many organizations and professionals who realized the informational systems rethink the traditional way taking into account the new technologies, creating a diverse literature of specialty and sometimes controversial for the computer users and, starting from the requests of the organizations for more cheap practices of realization, more productive and faster. In the practice of elaborating the complex systems, among which those distributed, there are distinguished more methods of projection that make the object of referential classifications from the literature of specialty. Thus there can be distinguished methods

of the functional decomposition; methods of the data fluxes; methods oriented towards information or popularized data from the informational engineering of James Martin but also by the approach of the diagrams entity-relation of Chen; methods oriented on the object.

Since it appeared the necessity to write programs for the computer it was also felt the need for instruments of work that could automate and ease the work of programmers. Between these there are found also the CASE instruments that are capable to ensure the necessary support for one or more specific activities of the engineering of programming. Their usage shapes a methodology of later-day that combine the elements of success from the traditional methodologies with the requests of the informational society due to the possibilities of realizing an equilibrium between the organization's requests, the technological opportunities and the risk associated with the inevitable substantial changes that appear frequently.

The interdependence of the data from the data base imposes a federative approach of the data base of the organization. The data base of the organization is conceived as a federation of data basis connected functionally (according the organization's functions) or by process (according the processes of leading on hierarchical levels). The main component of these federations is constituted by the operational data basis, because it represents the main source of data for the other data basis that, in fact, contain data resulted by the aggregation of the data from the operational data basis.

In the case of organizations dispersed on the territory the data basis work in federative systems open towards Intranet/Internet (fig. 1).

The informational base contains the informational nucleus formed by the totality of attributions necessary for the processing of the informational system and the informational structure represented by entities between which there are established correspondences and connections.

The content of the informational base is determined according the variants of approach of the chosen general projection.

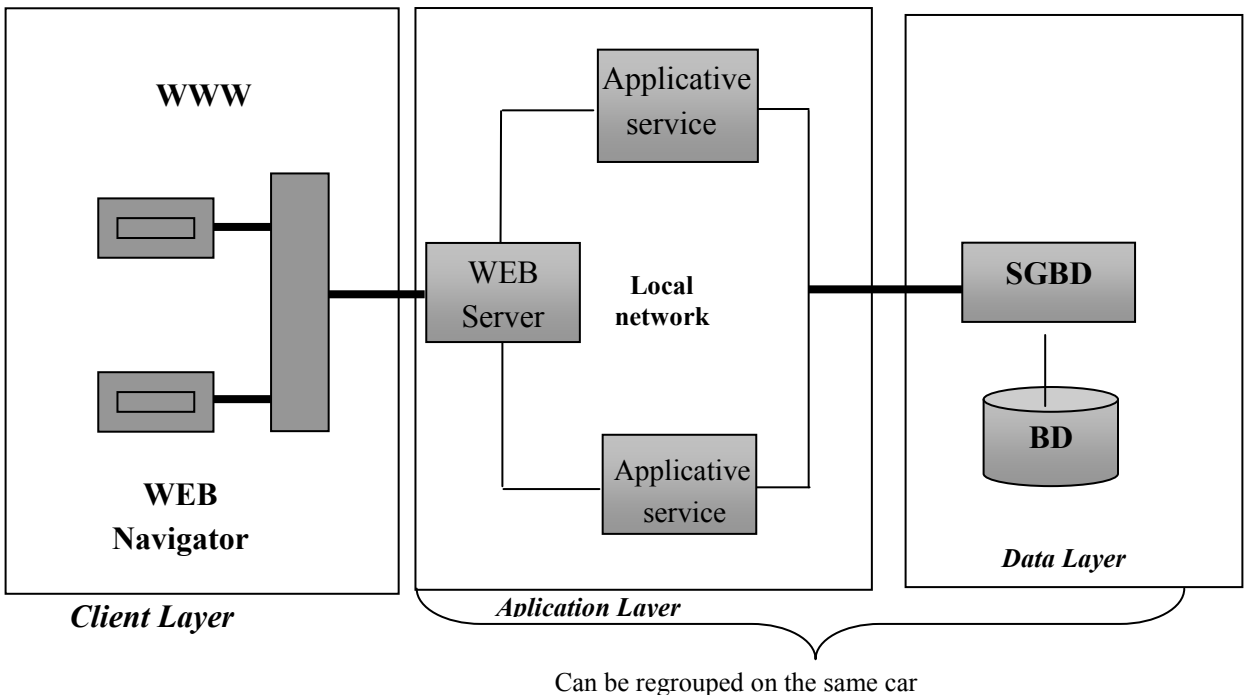

Fig. 1 Federative systems open towards Intranet/Internet

In the variant exits-entrance the content of the informational base is determined according the proposed objectives concretized in the situations of exit. The informational base will be constituted on the solicited exits and will be modified during the whole time of exploitation of the system in accordance with the dynamic of the phenomenon and the processes from the benefiting unit.

Data base for technological analysis is formed by the extraction from the primary data base of those files that contain the evolution in real time of the parameters and files which reproduce different phenomenon and incidents (signals, preventive and of alarm).

Data storehouse for management

From the primary data base, operative reports and the results of the technical analysis it will be built a storehouse of data designated for the level of technical and economic manager. The information extracted from this storehouse is presented in adequate forms (graphics, tables, diagrams) to the factors of decision and constitute a support for decisions and corrections.

Within the technological framework of the last years, which led the power of calculation to prices wide accessible, and the evolutions to open systems allow an almost total connectivity to any type of data sources and interoperability between the different platforms, it is questioned: the existent operational systems, the data can be accessed anywhere, the need for information is acute, and the power of calculation and storage is cheap. It is felt the need of a new paradigm: data storehouses.

The data storehouses represent an acute request of modern organizations (enterprises, banks or administration) and at the same time a technological relationship frequently put into practice. The current vision over the data storehouses is concentrated upon their role of informational base for the managerial decision, thus keeping a high level of generality and allowing to the multiple implementations to enter into the sphere of this notion.

So, the role of storehouses is that of offering an informational base for the foundation of managerial decisions. Likewise, the definition given by Bill Inmon is extremely concise: a data storehouse is a collection of data for the foundation of the process of making managerial decisions, oriented on the subject, integrated, variable in time and non-volatile.

From the point of view of the operational system, the analysis of incidents is qualitative and exhaustive, being realized individually, pursuing the registration realized during the incident and correlating the behavior of different elements. But managers are interested by a qualitative analysis, complex of the incidents, correlating their frequency and intensity in time with the variation of the rivers' flow, the meteorological conditions, the hours of changing the shifts etc., in search of schemes of production of the incidents.

Within the data storehouses, the data is naturally set on hierarchies and sediments, according their semantic, on levels. Thus, for production there will be gathered all the data of process that will allow detailed analysis for each incident or phenomenon appeared during the period of detail pre-established. They are extremely useful for the discovering of defections before accidents are produced or for the deduction of the probabilities of some immediate defections, by the technical personnel especially trained.

Because the informational system of a company is in continuous interaction with the informational system of other companies or of other governmental institutions, it is imposed the necessity for correlating the own informational system with the informational systems of the others. Within this context the exits of an own informational system can constitute entrances in other informational systems, while the exits of other informational systems can be exits into the projected informational system.

These inter-conditions can be realized through the computers that will ensure the connection between associated data basis, between which it is realized the exchange of data.

The architecture client /server is constituted as a versatile infrastructure, based on messages and modular, that was born from the intention of improving the use, flexibility, interoperability and scaling of the software applications. The client is defined as a solicitor of services, and the server is defined as the supplier of services taking into account that one and the same station can be the client and also the server, according the software configuration. The client and the server communicate through message exchange.

Any client / server system is composed of minimum three main components:

- the interface with the user (operation system environment / graphic)
- the application (the processing or the processes)
- the system of administration of data basis

In practice, there are more modalities of distributing the functions between the client and the server

- *The model distributed interface.* The code afferent to the user interface is divided between the client platforms and the server, and the application and the SGBD are, both, resident on the server. It is the model of a classic architecture with a central host computer to which are coupled the passive terminals (the Romanian mini-computer systems INDEPENDENT, CORAL, the mini-systems PDP of the company DEC).
- *The model deported application.* The code afferent to the interface is placed on the client platform, while the application and the SGBD are situated on the server (X Windows run under sub Unix).
- *The model distributed application.* Presupposes the localization of the interface on the client-computer, of the SGBD on the server-computer, while a part of the application is resident on the station and the other part on the server.
- *The model deported data base.* The interface and the application are resident on the client-platform, while the SGBD is placed on the server. It is the model of the architecture client / server 'classic', on whose logic are realized the majority of the systems commercialized under the title 'client / server'.
- *The model distributed data base.* The interface, the application and a first part of the SGBD are found on the client-system, while a second part of the SGBD is resident on the server.

Many organizations applied mixed solutions, on the basis of combining the facilities of two or more methods, according the specific of the unit, the stage of information (equipments, programs, specialists), resources and culture of the enterprise in the field of informational systems.

Toader Valentin

Babeş-Bolyai University, Faculty of Business, 7th Horea street, Cluj Napoca, E-mail: valentin@tbs.ubbcluj.ro

In this paper we will present an important category of Decision Support Systems (DSS), spreadsheet-based DSS. After a short review of literature, we will specify the main characteristics that make Microsoft Excel 2007 an appropriate environment for DSS building. Then, we will analyze the instruments throughout we can enhance the spreadsheet capabilities. We will conclude presenting our view about the use of spreadsheets as DSS generators.

Key words: decision support system, spreadsheet, models

1. Literature review

According to Peter Keen and Charles Stabell, the concept of decision support evolved from “the theoretical studies of organizational decisionmaking done at the Carnegie Institute of Technology during the late 1950s and early '60s and the technical work on interactive computer systems, mainly carried out at the Massachusetts Institute of Technology in the 1960s” [Power, D. J., (2003)]. An earliest definition of decision support systems appeared in an article written by G. A. Gorry și M. S. Scott-Morton in 1971. They defined these systems as “interactive computer-based systems which help decision makers utilize data and models to solve unstructured problems.” [Mora, Forgionne, Gupta, (2003), p. 102]. Another definition is the one given by G. M. Marakas: “a decision support system is a system under the control of one or more decision makers that assists in the activity of decision making by providing an organized set of tools intended to impose structure on portions of the decision making situations and to improve the ultimate effectiveness of the decision outcome.” [Marakas, (2003), p. 4].

In general, decision support systems applications are made up of three components: model management, data management and dialog management (user interface management). More and more DSS include also a knowledge management component which provides the necessary expertise and knowledge for resolving difficult and complex problems. We can classify DSS applications in many ways. One of the classifications is based on the dominant components of DSS application. D. J. Power identified five specialized types of DSS: data-driven DSS, model-driven DSS, knowledge-driven DSS, document-driven DSS and communications-driven DSS [Mora, Forgionne, Gupta, (2003), p. 24]. Holsapple and Whinston categorize DSS into six frameworks: text-oriented DSS, database-oriented DSS, spreadsheet-oriented DSS, solver-oriented DSS, rule-oriented DSS and compound DSS [Turban E., (2000), p. 113-114]. At the beginning, most of DSS applications were model oriented and were using accounting and financial models, optimization models, representational models, etc.

A paper spreadsheet is an accounting ledger page with columns and rows that organizes data about transactions and shows quantitative information useful for managing a business. Paper spreadsheets have been used in accounting for hundreds of years. A spreadsheet shows the expenses, revenue, taxes, etc. and the columns and rows represent either debit or credit sides. Professor Richard Mattessich had an important contribution in the development of computerized spreadsheets. Between 1960 and 1967 he wrote a number of papers and books on computer spreadsheets in which he developed the following subjects: the use of matrices or spread sheets, the simulation of financial events, financial spread sheets and the calculation that support each matrix cell. Later, in 1978, Daniel Bricklin, student at Harvard Business School, came up with the idea for an interactive visible calculator and, along with Bob Frankston invented and created the first spreadsheet software named *VisiCalc*. Electronic spreadsheets became popular only after the introduction of Personal Computers, in 1980s. In the early 80s, spreadsheets were also used for building model-driven DSS [Power, D. J., (2004)]. In an electronic spreadsheet information are organized into software defined

columns and rows. The data in the worksheet can be summarized using diverse functions. The most popular spreadsheet programs are *Microsoft Excel*, *Lotus* și *QuattroPro*.

A DSS can be built in two ways: using a DSS generator or using primary tools. Sprague and Carlson defined a *DSS Generator* as “a *package* of related hardware and software which provides a set of capabilities to quickly and easily build a Specific DSS” and *DSS Tools* as “hardware and software elements which facilitate the development of a specific DSS or a DSS Generator” [Sprague, H. R., Watson, J. H., (1993), p. 9]. A generator is software that provides a number of instruments for building a DSS, it does not automatically generate the system. Spreadsheet packages can be used as DSS generators because: they offer instruments for building a variety of models (statistical, financial, optimization, simulation, representational), they offer graphic capabilities for data representation, can perform what-if analysis and can be use to develop quickly and easy a specific DSS.

Decision support systems that are built using spreadsheet software can be called spreadsheet-based DSS. [Power, D. J., (2004)]. Spreadsheets can be used to build data-driven, model-driven DSS and solver-based DSS. Spreadsheet are appropriate for building a DSS with small models, for building a DSS prototype or for testing the DSS models, etc. The user interface can be build using buttons, lists and the operations can be automated using Macros or *Visual Basic*. For data-driven DSS data can be imported from a DBMS, a web site or a text file. If one wants to use a DSS generator for creating a specific DSS can choose between the well-known software products: Microsoft Excel, Lotus 1-2-3 (IBM Lotus Development Corporation’s product) or *Quattro Pro* (Corel’s product). These programs are included in Office Suites: *Microsoft Office*, *Lotus SmartSuite* and *Corel WordPerfect Office*. In our paper we choose Microsoft Excel in order to examine the capabilities of spreadsheet and their importance in DSS development.

2. Building DSS using Microsoft Excel 2007

A great number of customers are using *Microsoft Excel* in order to realize calculations, analyses and reports necessary for decision making process. Due to the fact that it is the most used software for spreadsheet, the DSS creation in Excel facilitates the accessibility and the easiness of use for customer. As a result of the new facilities included in *Microsoft Excel 2007*, we consider it as being an appropriate environment for DSS building. Our reasons are:

- contain instruments that can be used for developing the main DSS components: data management, model management, dialog management and knowledge management;
- for data management component the input data can be imported from external sources and can be updated using *Data Connections Library*. It is easiest to import data from external sources if the data connections libraries are customized. Microsoft Office contains drivers that facilitate the data import from the following data sources: *Microsoft SQL Server Analysis Services*, *Microsoft Access*, *dBASE*, *Microsoft FoxPro*, *Microsoft Office Excel*, *Oracle*, *Paradox*, *text files*, *OLAP databases*. Also, it can be used ODBC drivers. In order to use the latest data, *Microsoft Excel 2007* offers to the customers the possibility of data refresh from the external sources;
- using *Microsoft Query* component, the user has the opportunity to: connect to external source of data, create queries, import the selected data using queries and refresh the data in order to synchronize them with the data from the external sources. The *Web query* instrument can be used to import data from web sites, if the data are organized in a table;
- high performance: in *Excel 2007*, a worksheet contains 1.048.576 rows and 16.384 columns. This allows the import and the process of a great quantity of data and eases the calculation process. Using Excel we can solve linear programming exercises with tenth thousand variables and other kind of problems with a great number of variables;
- the new version has a friendly interface – using the *Office Fluent* interface - oriented to results - the new version is easiest to use due to the fact that the commands and the options are logically grouped;
- we can create the DSS interface using *Visual Basic for Applications*;
- has a diversified collection of charts that can be use for the data and results presentation. The charts are easy and rapidly to make;

- the cells and the tables can be simply formatted using the *Cell styles* and *Table styles*. The tables contains *Autofilters*, while the typing of formulas inside the table cells is easy to make using the conditional formatting option;
- allow the conditional formatting of cells data: this facility can be used to highlight some values, to give a graphical image to the numerical data from the spreadsheet. Using color gradients, data bars and illustrations we can discover and illustrate important trends or exceptions;
- for DSS building, Excel offer a great number of statistical, financial, math and other functions. *Excel 2007* has an resizable formula toolbar and permit the formula autofill;
- permit *PivotTable* creation – one-dimensional or two-dimensional reports that present data in synthetically manner, easy to understand by the customer. Using pivot tables the spreadsheet data can be grouped and summarized. To create a pivot table the data must be organized in a list. The Excel lists have the following characteristics:
 - each column contains only one type of information;
 - the first row contains the columns label;
 - the list does not contain blank fields;
 - the list is bounded by blank row and columns;
- allow to group, sort and filter the data: in Excel, data can be grouped, summarized (using different criteria) and sorted by diverse fields. The functions *Filter* and *AutoFilter* display only the information that verifies the imposed conditions (the other are temporary hidden). *Excel 2007* has new filter and sort options, like multiple selection in *AutoFilter*, filter or sorting by color or quick filters for some types of data;
- *Microsoft SQL Server 2005 Analysis Services* allow the business data query. With the *cube* function we can build a customized report from an OLAP database;
- due to *Excel Services* integration and to the new file format *XML Microsoft Office Excel* introduction, *Excel 2007* facilitates the share of spreadsheets. Using *Excel Services* a Excel worksheet can be dynamically displayed in HTML format and can be seen by other users through a web browser. With the help of a web browser, *Excel Services* can be used to browse, sort, filter, bring in parameters and interact with the data contained in the spreadsheet. The possibility to save the worksheets in XML, PDF or XPS formats eases the share of data in *Excel 2007*. XML (*Extensible Markup Language*) represents a standard code, universally for data schemes definition. XML simplify the data exchange, recognition and interpretation between different applications;
- using *Office SharePoint Server 2007* the reports and the charts can be shared with other persons from the enterprise;
- allow *What-If* analyses;
- facilitates the solve of some problems using *Solver* or *Goal-seek*;
- permits the realization of various scenarios.

Even if the final DSS will be realized with specialized software, *Microsoft Excel 2007* can be used to build the DSS prototype. In Excel the models are easiest to test and analyzed.

3. Add-ins for Microsoft Excel

The spreadsheet capabilities (functions) can be extended using add-ins products. The integrated set of products offered by Palisade (*Decision Tool Suite*, *Neural Tools*, *Palisade Developer Kits*, *@Risk*, etc.), Frontline Systems' *Solver*, Decision ToolPack (*Decision Tree Add-in*, *Sensitivity Analysis Add-in*, *Monte Carlo Simulation Add-in*) provided by Decision Toolworks or *Crystal Ball* offered by Decisioneering are examples of such add-ins tools. Next, we will present the main characteristics and functions of such products.

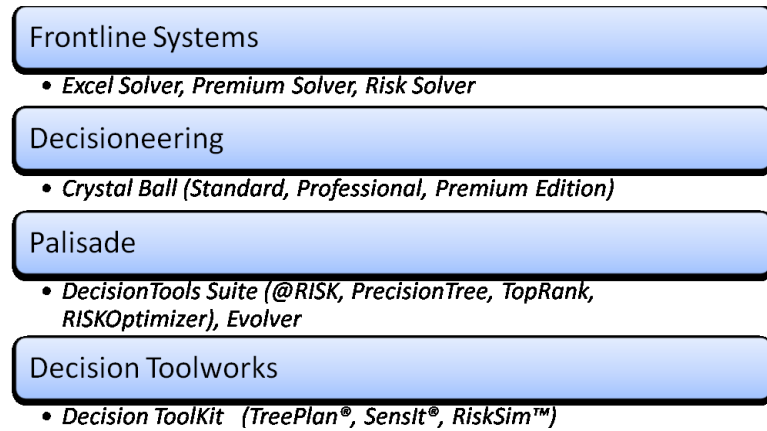

Figure 2. Excel Add-Ins

1. *DecisionTools Suite* include the following tools:
 - *@RISK* – is a risk analysis add-in for Excel that can be used to identify hidden opportunities and avoid pitfalls. This product uses Monte Carlo simulation and allows the replacement of uncertain values in a spreadsheet with *@RISK* distribution functions and simulate. Based on historical data the user can obtain a distribution of possible outcomes and the probabilities of those outcomes occurring. The obtained results can be presented using presentation-quality graphs and charts.
 - *PrecisionTree* – is a decision analysis add-in for Excel which is used to create decision trees and influence diagrams in spreadsheets. The main functions of decision tree are to facilitate the communication and to model the decision making process. The results are presented using statistical reports, sensitivity charts and risk profile graphs.
 - *TopRank* – determine the most critical factors in spreadsheets automatically. The use of *What-If* analysis narrows the user’s analytical focus in seconds. *TopRank* scans your entire spreadsheet and identifies which cells affect the bottom line the most, and then ranks them in easy-to-understand Tornado charts and statistical reports.
 - *RISKOptimizer* – this optimization add-in solve tough combinatorial problems in Excel. Use genetic algorithms to find the best possible combination of controllable factors to lead to a desired result. The user can run a Monte Carlo simulation on the scenario to see the effects of uncontrollable variables. This product is available in *DecisionTools Suite Industrial*.
 - *Evolver* - is an optimization add-in for Microsoft Excel. *Evolver* uses innovative genetic algorithm (GA) technology to quickly solve complex optimization problems in finance, distribution, scheduling, resource allocation, manufacturing, budgeting, engineering, and more. *Evolver* is available in three versions: Standard, Professional, and Industrial.
2. *Frontline Systems* developed the Solver in Excel for Microsoft and therefore all their products are upward compatible from the standard Excel Solver included in Microsoft Excel.
 - *Frontline Systems’ Solver Products (Excel Solver, Premium Solver)* improve the simulation capabilities of spreadsheet with solvers for a variety of optimization problems. With the solver offered by *Frontline Systems* the user can solve much larger problems, much faster than with the standard Solver, and also can solve entirely new types of problems.
 - *Risk Solver* is a powerful tool for risk analysis in Excel. It uses Monte Carlo simulation that is up to 100 times faster than simulation using Excel alone.
3. *Decision ToolPack* is produced by *Decision Toolworks* and contain the following analysis tools:
 - *TreePlan* is specialized in building a decision tree diagram in an Excel worksheet using dialog boxes. Decision trees are useful for analyzing sequential decision problems under uncertainty. *TreePlan* automatically includes formulas for summing cash flows to obtain outcome values and for calculating rollback values for determining optimal strategy.

- SensIt performs sensitivity analysis on Excel a worksheet what-if model. SensIt automates sensitivity analysis and creates simple plots, spider charts, and tornado charts. In a decision situation, sensitivity analysis helps you determine which of your input assumptions are critical so that you know where to focus your effort for gathering more information or reducing uncertainty.
 - RiskSim provides random number generator functions as inputs for user's Excel worksheet model, automates Monte Carlo simulation, and creates charts. RiskSim automates the simulation by trying thousands of what-ifs consistent with user's assessment of the uncertainties and displays the results in both histogram and cumulative distribution charts.
4. Crystal Ball automate "what if" analysis with Monte Carlo simulation. Quickly assign ranges of values to user inputs and automatically calculate thousands of different outputs and their probabilities. Record the results for in-depth analysis or summarized reporting with Crystal Ball's many reports, charts and tools. There are three versions of this product: Standard, Professional și Premium version.
- *Crystal Ball Professional*: include all the elements from Standard version plus some advanced features - OptQuest®, for finding the optimal solutions, CB Predictor™ for creating precise predictive models, Developer Kit to customize own models and Extreme Speed to run simulations up to 100 times faster.
 - *Crystal Ball Versiunea Premium*: include all the elements from Professional version plus Real Options Analysis Toolkit.

Crystal Ball has also a component available as an Application Programming Interface for the Microsoft .NET Framework. OCB provides a framework of classes that can be use to perform Monte Carlo simulations and optimizations.

There are also other tools that can be used in order to build a DSS. In our paper we mentioned only some of them. Due to the great number of DSS generators existing on the market it is practically impossible to know all the available products, to compare these products and to choose the most suitable for developing a certain DSS application.

Conclusions

The main purpose of DSS is to support managers in decision making process, to improve the quality of their decisions and to reduce the necessary time to make a decision. DSS improve managers' activities and the way the problems are solved. DSS support all phases of the decision-making process.

Spreadsheet programs are the most popular modeling tools because its incorporate financial, statistical, mathematical and other functions. The spreadsheet programs have evolved into an important tool for analysis, planning and modeling. Choosing Excel as a DSS generator has a number of advantages: is accessible, is known by a great number of business users, is easy to use, can perform a lot of analysis – optimization, simulation, sensitivity analysis, what-if analysis. We think that the development of spreadsheet programs had a great influence on the development of DSS, especially of the model-based DSS. The great number of Add-ins existing on the market proves that the decision analysis tools are considered as being important in companies' activities.

INFORMATIONAL TECHNOLOGIES IN LIFE INSURANCE

Stofor Ovidiu Ilie

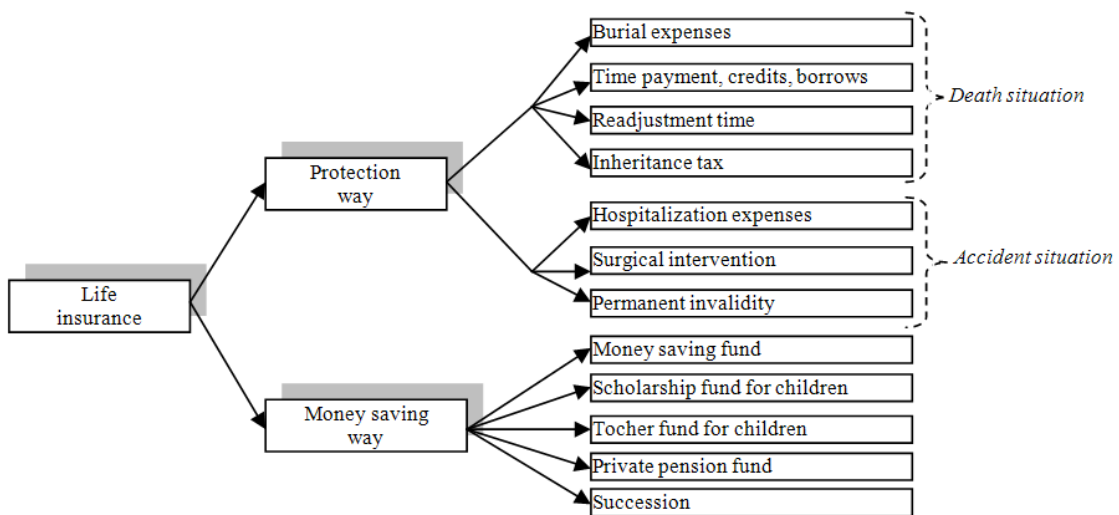

Universitatea „Al. I. Cuza” Iași, Facultatea de Economie și Administrarea Afacerilor ,
 ovidiu.stofor@feaa.uaic.ro, 0742/458.258

Informational technologies can increase the efficiency of the mediation in insurance by supporting the marketing activity, both through simple presentations which offer a high level of attractiveness, and by using database, simulations or graphic representations to define as well as possible the parameters existing in an insurance program.

Key words: insurance, informational technologies, insurance marketing

Life insurance – a real need

Life insurance is a way to make things easy on one's own account or his family at a difficult time. It can say a life insurance represents *white money for black days*. A premature death is always tragic but an undesired accident is hurtful. There is a scheme with life insurance's components.

The components of a life insurance

In the West insurance is part of the quotidian, people having any kind of insurance (for life, medical, for car or home insurance). Unfortunately, Romanian experience showed that, for a lot of people, the word “insurance” offers some meanings, away from the actual ones:

- activity that bothersome people develop by nagging and confusing people until they “swallow the bait” and become their clients;
- financial operation through which, when a person concludes a long-term credit, some money are being held from him for the safety...of the bank;
- investment program through which one invests money but does not receive anything in return;
- amount of money for which I, as a potential customer, can surely find a better use than placing it in a financial investment...

It can remark, by comparison between Romania and Germany, especially to the person insurance chapter, we have more needs.

Country \ Insurance type	Germany	Romania
Non-Life Insurance	39%	80%
Health Insurance	17%	0%
Life Insurance	44%	20%

Insurance situation in Romania and Germany, on segments of assurances

Informational technologies for life insurance marketing

An insurer must keep up with the market dynamics, and this is impossible without a modern IT system. Data which is inserted and processed can also be useful in the post-sale activity, since they offer helpful information in establishing long term relationships with the clients.

Only those who have comprehensive knowledge in this domain can create an informational technology which would correspond to the complex needs that life insurance companies have.

Introducing informational technologies in insurance is more than necessary both for accounting the activity, thus reducing the time needed to perform operations, decreasing costs and minimizing the risk of errors, and for the marketing in this area. Quantity, nature, the quality of the information gathered, processed and capitalized formed the elements of progress, in all the stages of the social development.

Informational technologies can increase the efficiency of the mediation in insurance by supporting the marketing activity, both through simple presentations which offer a high level of attractiveness, and by using database, simulations or graphic representations to define as well as possible the parameters existing in an insurance program.

Data which is inserted and processed can also be useful in the post-sale activity, since they offer helpful information in establishing long term relationships with the clients.

An insurer must keep up with the market dynamics, and this is impossible without a modern IT system.

Only those who have comprehensive knowledge in this domain can create an informational technology which would correspond to the complex needs that life insurance companies have.

The more and more frequent legislative modifications in insurance, the necessity of an efficient increase by reducing costs as well as the reports to CSA impose to the insurance companies the implementation of some highly complex computational systems.

Until not long ago, paper was the base of information and its accounts were held manually. The spectacular development of electronic technique opens to the informatization the path to the insurance system. Computers help insurers to calculate insurance prices rapidly, to fill in agreements and insurance policies, to highlight data, to confirm the insurance agreements' validity. Besides, computers hold book keeping and technical-operative accounts. The consequences can only be benefic:

- efficiency in data gathering,
- complex documentation database,
- on-line intercommunication system,
- web site insurance offers,
- the possibility of an on-line insurance and documentation via Internet

So, informational technologies can improve speed and consistence through integrated sales tools and advanced user interface.

Implementing a suitable informatics platform is the premises of the improvement of services offered to clients, of developing new insurance products, but also developing marketing and branding strategies; all this absolve companies' management of a series of additional tasks. An important element in influencing the purchasing behavior can be the presentation of some precise, calculated insurance offers. Obviously, it is more difficult to do, every time, the differentiated calculus of the different components of an insurance

system (insurance premium, insured sum, the supplementary reserve, the final sum, the duration of an insurance etc.), without using various computerized simulations.

More specifically the tasks that electronic insurance applications accomplish are:

- Provide the client with web forms of different insurance offers.
- Make an online validity of the data the user inserts in the form.
- Receive the electronic applications via web.
- Make the offer/application pricing and registration and return to the client official printings of the insurance offer.
- Offer the client the chance to check his financial status on-line.

According to a study of the BearingPoint Company, the share of insurance companies that own a business processes' technological automatization system is about 30%. This way, insurers who use computational systems in database administration and in the administration of services offered to the customers or of administrative processes registered a total cost reduction of 30% but also a significant increase of efficiency in the activity they develop.

According to a study of the public opinion poll agency, GLOBAL Switch, over 50% of Europe's insurance companies do not have the IT infrastructures needed to correctly establish the premiums.

According to a poll on a population of European profile companies with a number of at least 1000 employees, computational systems are not an essential element in the insurers' daily activity.

Thus, only 48% of the participants on the Great Britain profile market think that the calculating technique is an important element in establishing the premiums' dimensions, whilst France is the only country in Europe in which this share rises to 74%.

The share of actors on the profile market who think that computational technologies are necessary in establishing premiums' dimensions

Source: <http://www.lasig.ro/Sistemele-informatice-un-factor-cheie-pentru-asiguratorii-articol-2,3,117-19306.htm>

An insurance marketer can use a variety of tools depending on his purpose: Internet, database, multimedia, client-server technologies.

Maybe the most important technological (and social) event of the 20th century has been discovery of *Internet*. Societies which wish to launch their activity on the Internet have to radically change their strategy of development. Entry costs on the virtual market are minimized because the cost of developing the classic distribution network from man to man disappears.

It can be stated that the Internet itself can be considered a good intermediary in the insurance activity; using it in insurance brokerage can be an advantage when realizing an efficient marketing. The accessibility that the Internet offers to potential clients requires a well thought out advertising to make an insurance program as attractive as possible. The Internet have developed in different proportions like in this figure.

Internet users/buyers

Source: Dobrin, M., Tănăsescu, P., *Teoria și practica asigurărilor*, Ed. Economică, București, 2003, p. 261

Not all insurance products can be sold via Internet. Generally, introducing a certain product to be commercialized on the Internet depends on how much assistance is needed to complete a contract. The more complex product is and the more it supposes the transaction of bigger values, the more the client is willing to pay for specialized consulting. The connection between the complexity of the product and the possibility of introducing it on the Internet is shown in the following figure.

The percentage of insurance products that can be distributed on the Internet

Source: Dobrin, M., Tănăsescu, P., *Teoria și practica asigurărilor*, Ed. Economică, București, 2003, p. 262

To insurance, introducing the concept of *database* means that data is registered once and can be linked to other information inside the database. For example, an account name can be linked to multiple policies, or a certain policy can be linked to multiple damage records. From the broker's point of view, database can be a good background for advertising campaigns, and on the grounds of these databases useful analysis can be made and thus influencing future strategies.

Multimedia means using the computer to present and mix texts, graphics, sounds and video images; the instruments employed in these processes allow the user to navigate, to interact, to create and to communicate. This definition contains the four essential components of multimedia:

- the computer which coordinates the user's actions;
- links that facilitate access to information;
- navigation tools;
- methods of collecting, processing and transmitting information and ideas.

These multimedia tools can increase the force of conviction of potential clients, by realizing presentations as attractive as possible (e.g. PowerPoint slides, Macromedia files etc.).

Client-Server architecture ensures the full control of connections and transactions as well as data safety. In this kind of architecture there is a server that is usually the database, and a client which inquires the database and executes applications.

On the client-computer small software applications (such as Java applets) can be embedded in html pages. These applications implement the e-forms and handle the connection and data interchange with the server.

For any connection received from a client the application initializes a respective server-thread that undertakes the service of the particular client. For any separate action the server-thread needs (as the pricing or the editing process) a new respective thread is initialized. When the action is completed then the respective thread is stopped and closed. Finally when the connection purpose is completed then the server-thread is stopped and closed.

Actually, any economic domain is practically dependent on the client-server technologies; these realize a real-time and efficient interaction between seller and buyer.

Besides the preponderant marketing aspect, by using computational technologies one can hold strict accounts, other than book keeping, regarding as many details as possible on the customer, on the consultants with whom one collaborates and eventually, on the relationship with the superiors.

BUSINESS INTELLIGENT INSTRUMENTS FOR SALES MONITORING

Serbănescu Luminița

University of Pitești, Faculty of Economics Sciences, Pitești, str. Negru-Vodă, bl. D3, sc. a, sp. 1, Argeș, luminitaserb@yahoo.com, 0745030906

Abstract. The managerial structures need a powerful instrument for measuring, monitoring and tracking down the key business processes. Under harsh competitive conditions, managers are now forced to solve complex problems, often not sufficiently clearly- defined, which have multiple-planned implications. Their reactions to the business demand must be not only quick, but also the right ones. They must achieve short-term results, but also have long-term orientation. The BI solutions have appeared as a response to managers' demands to obtain quickly matched synthesis information, with explanatory details, associated with the displayed synthesis. In this article, I will present a BI solution, implemented through QlikView Application, thanks to which it is possible to monitor the company sales, (by establishing the performance pointers).

Keywords: sales, business intelligence, QlikView, monitoring, evolutions

The IT revolution which invaded all the domains of human development could not ignore the world of sales. The reasons why Business Intelligence needed to be introduced, at a certain moment, in the activity of a company or institution in our country are not only due to the need to face the competition imposed by the European market, to the standards and the legislation that have to be observed, but also to the acute need to save time and to enhance performance.

An efficient solution for Business Intelligence must not be limited to a single department of the company. Its beneficiaries must be from all the hierarchical organizational levels so as maximum of profit can be taken from this application. Business Intelligence is also needed because all the companies need information in order to make decisions.

The Organizational Management considers Business Intelligence to be a vital means of activity improvement, gaining of competitive advantage and meeting the strategic goals.

In Romania, the market of Business Intelligence solutions, together with that of ERP solutions (Enterprise Resource Planning), experienced an impressive evolution due both to the national economical development and to meet the need of companies to remain competitive on the market.

The work instruments which Business Intelligence applications offer give the managerial department of the company the possibility to get involved and to begin analyzing data, without having to wait for the IT departments to hand in complex reports.

To be more precise, such applications can do many operations and, what is more, they can be done in various departments of the company. One of the activities performed by this application is marketing analysis.

In this way, demographic analysis are done by using the information about clients and the data of sales, the response to price, the preferences regarding products. By using this information, the marketing campaigns can be better planned and their effect can be measured. As for the analysis of sales, the system identifies the tendencies, analyzes the seasonableness and establishes matches between products. By using this information you can set sales aims and you can measure the progress with regard to these aims.

In order to build the monitor of sales application we made use of the QlikView application, a strong and complete pack of Business Intelligence software and of data analysis which offers a better means of handling the data of a business.

The strong engine Business Intelligence of QlikView analysis uses the revolutionary technology AQL (Associative Query Logic), which accesses structured information from various sources in an interactive and dynamical way, propelling the selections of analysis throughout the entire available data basis in order to build an associative, non-relational and extremely efficient data basis.

AQL offers QlikView the possibility to work with millions of data cells and yet to answer the questions within less than a second. By replacing the classic relational technology with AQL, QlikView replaces the need of pre-aggregation of data.

Furthermore it gives the possibility of connecting to any source of data (ERP, CRM, Microsoft Excel, logs, Access data bases), thus achieving the gathering of the pieces of information generated by the multitude of independent applications used within a company.

Any objective in QlikView – from lists to graphics and tables – is accessible through a “click”. QlikView enables the users to find their own way towards the analysis and understanding of things.

To give an example we considered a company that deals with product distribution. The company has got several warehouses situated at different addresses and furnishes products to several clients from all over the country. The used information refers to:

- Articles characterized through: Product Code, Product Name, Weight, Product Group, Group Type;
- Customers defined through: Customer Code, Customer Name, Location Code, Customer Location Name, Customer Group, Customer Group Type, Department, Town, Invoicing Code;
- Invoice heading which comprises: ID, Invoicing Code, Date, Warehouse Location, Warehouse and Bill
- Invoice lines consisting of: ID, Product Code, Quantity and Price.

The most important operation that can be done very easily with QlikView is the “Filter” spreadsheet. This allows visualizing several pieces of information at the same time. The operations that can be made on this page are:

- The simple or multiple selection: for example if we select a certain product we can visualize information about the name, the customer’s type and location to whom the product was distributed, about the group of product to which the particular product belongs, the warehouse, the delivered quantity and the price of the product, about the bills released for the sell of the product.
- The search: for example, if we want to find a bill number in order to see the information comprised in this particular bill (sold product, date of release, quantity, price), we have to select the thing corresponding to the bill and introduce the number of the bill. As the numbers are being introduced, all the bills that have the specified values comprised in their number are selected (see fig. 1).

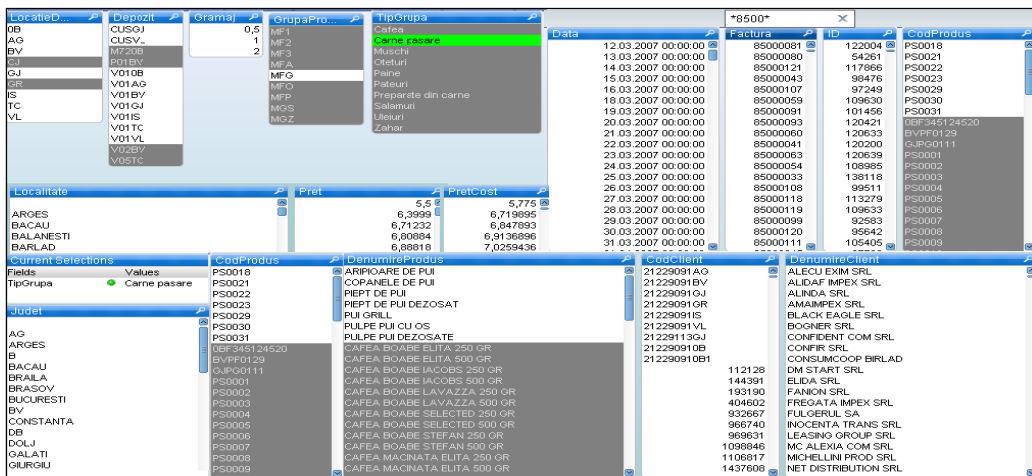

Figure 1 - Filter Page

A very important thing for the drawing of all the spreadsheets is the dimension established as representative for them. Thus we used as dimensions: time, location of warehouses, customers, products, etc. These can be selected and altered on each sheet and we can use combinations of these dimensions in order to define groups. Using the information taken from the database information above we made the following spreadsheets:

1. **Sales map:** where the sales in each warehouse are graphically represented for the selected period. We can get a clear picture of the sales from each day, week or month, for a certain group of products, or for a certain group of customers. (see fig.2)

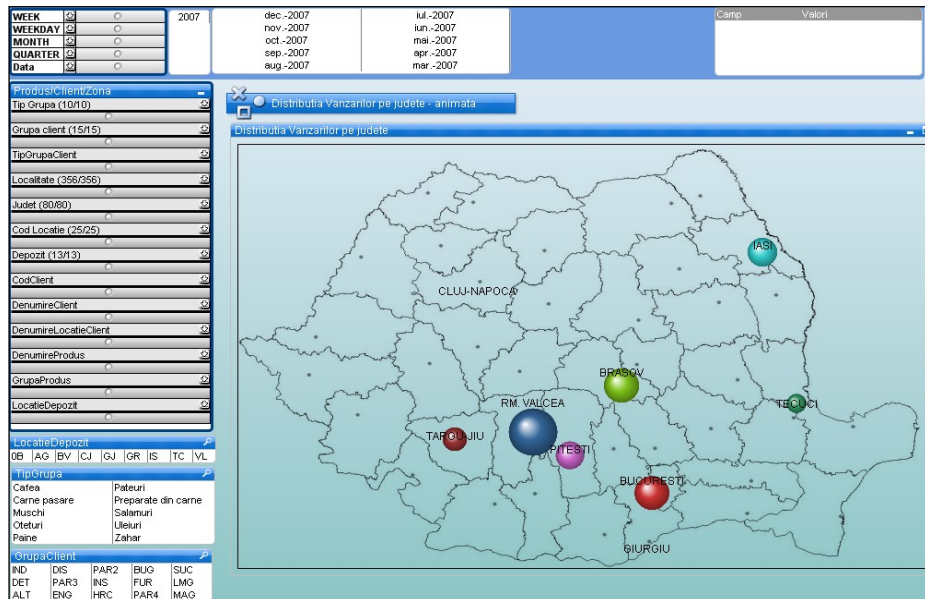

Figure 2 - The Sales Map

2. **Q, RON, PM** which contains the following graphics:

- Periodical evolutions. It is a graphic representation of the sales from each month following several dimensions, such as: value, pieces, average price.
- The number of clients, products and sales volume. Here we analyze the sales from the monthly point of view.
- Top 10 customers. It displays the first ten clients in the order of the sold values.
- Comparisons. Here we draw graphics in which we can change axes depending on the values used(see fig. 3)
-

Figure 3 - Comparisons

Region sales. We build the annual or monthly evolution of sales for each warehouse.

Figure 4 - Region Sales

3. **Comparative evolution** where we make a detailed analysis of the sales following several dimensions graphically represented on one axis or two. Here we can establish if there is or not logical correlation between the chosen dimensions, on certain periods of time, for example between the average price and quantity (we can study what happens to the quantity if the average price rises, or the other way) (see fig. 5)

Figure 5 - Comparative evolution

4. **Comparisons on certain periods** such as:

- Comparisons between the days of the week. We build the evolution on a certain day of the week of the value, average price and sold quantity. For example, establishing the date of 01.08.2007 we get specific data for the three dimensions only for the day of Wednesday from the current or previous

month (we take in account the last 4 weeks) and we compare these days to one another in order to establish if there was or not an evolution of the sales.

Figure 6 - Days of the week comparisons

-
- Period comparisons era done using the same dimensions, but we establish a certain period for which we want to visualize sales evolution. For example, if we use a 7 days period, this does not mean that we built the evolution for that week, but for a 7 days period previous to the analysis date.
- Monthly comparisons – we draw the sales evolution following the three dimensions for each of the 12 months previous to the analysis date.

Conclusions

The need of Business Intelligence solutions is obvious, especially in those companies where the top-management realizes they cannot make tactic decisions in due time based on the existent information under certain forms inside the company, they cannot harmonize the strategies in order to reach the aims and the are dangerously heading towards a competitively risky situation on the market. Taking the current dynamics into account, the data a company holds must be used 100%. They must be translated into information which can answer the critical questions of the management. In the cases where the reports still represent the main support for decision making, presenting all the necessary data but not an analysis or interpretation of these, the need for a Business Intelligence software will, sooner or later, impose itself in a clear way. That is because the current business environment does not accept anything else but well-founded, fast and based on reliable information decisions which, once taken, gain credibility and extra value for the company.

Evidently, when we take into account the implementation of such a solution, one of the questions that arise concern the possibility of customizing of the application taking into account the needs and aim of the company. Not only is the answer a positive one, but it also constitutes one of the main advantages such an application offers.

The benefits of implementation of a Business Intelligence system are:

- It simplifies the analysis for each person in the company;
- It is easy to use – the ultimate users do not need training;
- It is flexible – unlimited dimensions that can be changed within seconds;
- It is integrated – solution of business analysis integrated with the ERP system and other independent applications used within the company;
- It is strong – immediate response for huge bulks of data.

THE TRADITIONAL TEACHING-LEARNING METHOD VERSUS MULTIMEDIA TECHNOLOGY. USING THE WILCOXON TEST AND THE GAUSS REPARTITION

Șerbănescu Luminița

University of Pitești, Faculty of Economics Sciences, Pitești, str. Negru-Vodă, bl. D3, sc. a, sp. 1, Argeș, luminitaserb@yahoo.com, 0745030906

Abstract. This article highlights the ways of applying various statistic methods with the purpose of comparing modern teaching methods, which are based on the implementation of information technology, with the traditional teaching methods, tested, for a period of two years, in parallel groups: experimental and control groups.. Thus, the Wilcoxon (T) test is used for processing data in case of exams and a creativity task within the experimental and the control groups. This test applies in case of comparing ordinal dependent values and is used with the purpose of determining the correlation of indexes, within one and the same selection, measured in two distinct situations. Outlining the results is done with the help of Gaussian comparative curves for both groups (experimental and control).

Keywords: test, creativity task, experimental group, control group, Wilcoxon test, Gauss distribution

The Wilcoxon test

„The Wilcoxon test statistic is based on the study of differences which appear between a couple of observations, taking into consideration both the sign of the differences, and their absolute values” [0]. Let us consider two independent series of data:

$$\begin{aligned} X; &x_1, x_2, \dots, x_n \\ Y; &y_1, y_2, \dots, y_m \end{aligned} \quad (1)$$

which are extracted from two correlated samples, of size n, which characterize the stages of independent values, generated by the first (series X) and the second (series Y) measurement, within the experimental and control groups.

Considering : X- the test results from the experimental groups; Y – the test results in the control groups; D_i – the result of the subtraction ($D_i = X_i - Y_i$); R_i - the rank of the subtraction; $|R_i|$ - the absolute value of the rank of the subtraction.

The application of the Wilcoxon(T) test for the processing of data, regarding the completion of the test, is done as follows:

- a) The validation hypotheses are elaborated:
 - The Null Hypothesis H_0 : $D_i=0$, (the equality of the distributions) the repartition of the measured index for the experimental group and the repartition of the measured index for the control group in the case of both examinations is the same, which means that the changes by means of increases in grades are purely random;
 - The Alternative Hypothesis H_1 : $D_i \neq 0$ (distributions are distinct), which means that the distribution laws of the index are different and that the increase of the grades as a result of applying multimedia technology in the teaching-learning process are predictable.
- b) The test statistic is obtained by following these steps:
 1. The observed differences are calculated;

<i>Experimental Group</i>	<i>Control Group</i>	<i>Difference</i>
x_1	y_1	$x_1 - y_1$
x_2	y_2	$x_2 - y_2$
....
x_n	y_n	$x_n - y_n$

Table 1. Observed Differences

3. null results are eliminated and the following series is obtained: d_1, d_2, \dots, d_k , with $k \leq n$;
4. the series of non-null results in absolute value is sorted ascending: $|d_1| \leq |d_2| \leq \dots \leq |d_k|$;
5. ranks are attributed to the series obtained, following the procedure of the Mann-Whitney test;
6. the sum of ranks corresponding to the initial positive differences (T^+) and the sum of the ranks corresponding to negative differences (T^-) are calculated;
7. the T test statistic is the minimal value of the two sums calculated within step 5:

$$T = \min(T^+, T^-). \quad (2)$$

The decision in the test involves the following [0]:

- b) In the case of the bilateral test: the H_0 hypothesis is rejected in favor of H_1 , if the calculated value is smaller or equal to the critical value for the bilateral test;
- c) In case of applying the one-sided test: the H_0 hypothesis is rejected in favor of H_1 , if the calculated value is smaller or equal to the critical value for the one-sided test.

In case of smaller sizes of the samples ($n < 27$), the critical values for the Wilcoxon test are outlined in correspondent table [4]

The statistic data for testing the experimental and control groups, processed with the aid of the Wilcoxon criterion, are outlined in table 2

No.	Grade exper. group	Grade control group	Difference $D_i = X_i - Z_i$	Absolute value of difference	Rank of the absolute value of the difference

7	9.67	8.33	1.33	1.33	7.50
8	7.33	6.00	1.33	1.33	7.50
9	6.33	4.67	1.67	1.67	10.50
10	10.00	8.33	1.67	1.67	10.50
11	8.00	6.33	1.67	1.67	10.50
12	8.33	6.67	1.67	1.67	10.50
13	8.67	6.67	2.00	2.00	13.50
14	9.00	7.00	2.00	2.00	13.50

No.	Grade exper. group	Grade control group	Difference Di=Xi-Zi	Absolute value of difference	Rank of the absolute value of the difference
15	10.00	7.33	2.67	2.67	15.50
16	7.00	4.33	2.67	2.67	15.50
17	10.00	7.00	3.00	3.00	17.00
18	9.67	5.67	4.00	4.00	18.50
19	8.00	4.00	4.00	4.00	18.50
20	5.00	9.33	-4.33	4.33	20.00
21	10.00	5.00	5.00	5.00	21.00
Sum of ranks					231

Table 2. Statistic data for the experimental and control groups, in the case of the test, processed with the aid of the Wilcoxon criterion

Performing the calculations:

1. The sum of the ranks is calculated and must coincide with the one calculated according to formula:

$$\sum R_i = \frac{21 * 22}{2} = 231 \quad (3)$$

2. The T+ și T- statistics are calculated:

- Lista The T+ statistic (the sum of ranks corresponding to the positive differences) equals 204 (T+=204).
- The T- statistic (the sum of ranks corresponding to the negative differences) equals 27 (T-=27).

The T statistic is the minimal value of the two calculated sums:

$$T = \min(T+, T-) = 27 \quad (4)$$

The decision in the test:

The Wilcoxon statistic is T=27. The table of critical values shows for the bilateral test, for a sample size for n=21, the value of T*=58 for the significance level $\alpha=0.05$.

Because $T < T^*$ (the calculated value is smaller than the critical value), the null hypothesis regarding the equality of distributions is rejected. Therefore, the alternative hypothesis is valid, which means that the distributions of the index are distinct in the first and second measurement and that the increase of the grades as a result of applying multimedia technology in the teaching-learning process are predictable.

The statistic data for the creativity task for the experimental and control groups, processed with the aid of the Wilcoxon criterion, are outlined in table 3.

No.	Grade exper. group	Grade control group	Difference $D_i=X_i-Z_i$	Absolute value of difference	Rank of the Absolute value of the difference	Symbol (+ / -)
1	7	6	1	1	3	+
2	6	7	-1	1	3	-
3	8	7	1	1	3	+
4	6	7	-1	1	3	-
5	9	10	-1	1	3	-
6	8	6	2	2	7.5	+
7	8	6	2	2	7.5	+
8	8	6	2	2	7.5	+
9	10	8	2	2	7.5	+
10	10	7	3	3	12	+
11	8	5	3	3	12	+
12	9	6	3	3	12	+
13	7	4	3	3	12	+
14	10	7	3	3	12	+
15	9	5	4	4	16	+
16	8	4	4	4	16	+
17	9	5	4	4	16	+
18	10	5	5	5	19.5	+
19	10	5	5	5	19.5	+
20	10	5	5	5	19.5	+
21	9	4	5	5	19.5	+
Sum of ranks					231	

Table 3. The statistic data for the creativity task for the experimental and control groups, processed with the aid of the Wilcoxon criterion

Performing the calculations for the T criterion:

- The T+ statistic (the sum of ranks corresponding to the positive differences) equals 222 ($T^+ = 222$)
- The T- statistic (the sum of ranks corresponding to the negative differences) equals 9 ($T^- = 9$).

The decision for the test is similar to the one in item 2. and is performed similarly.

The Wilcoxon statistic is $T=9$. The table of critical values shows for the bilateral test, for a sample size of $n=21$, the value of $T^*=58$ for the significance level $\alpha=0.05$.

The test decision: Because $T < T^*$ (the calculated value is smaller than the critical value), the null hypothesis regarding the equality of distributions is rejected. Therefore, the alternative hypothesis is valid: the

distributions of the index measured for the first population is situated more to the right, which means that the proposed methodology is more efficient.

The Gauss repartition

The outline of the results is elaborated with the aid of histograms in which the horizontal axis represents the grading intervals and the vertical axis symbolizes the frequencies (the number of students within the respective grading interval) and the Gaussian comparative curves [5] for both groups (control and experimental).

We have defined the grading intervals as follows: exceptional – 10; very good – [9..10); good – [8..9); mediocre – [7..8); poor – [6..7); very poor – [5..6); – [4..5).

Fig. 1. Histogram of the test results obtained by the students in the experimental group and the control group

By transforming the histograms in Gaussian probability curves, we can compare the obtained results. The bigger the size of the sample, the more the curve will come closer to resembling the "ideal" form. In case of the experiment conducted for the two groups we obtain the following graphs (see fig. 2).

Fig. 2 Gaussian comparison curves obtained after testing

Within the experimental groups, in the case of the test, the average value is 8.14, and for the control groups, the value is 6.62. If the results obtained by the experimental groups are compared to those obtained

by the control groups, it is obvious that the maximal value of the experimental sample is placed between grades 8-9, and the maximal value for the control sample between grades 6-7.

By analyzing the Gaussian comparison curves we notice a movement of the maximal value towards the right, which corresponds to a real progress of the students resulting from the assimilation of information through multimedia courses.

Through numerous practical applications, the normal Gaussian distribution has a distinct importance in metrology. With its aid, the following can be analyzed:

- a series of measurements, strictly under the same experimental conditions, performed on the same X value;
- the results of some measurements on a collection of objects characterized by a certain trait, in order to determine a certain characteristic of the collection.

Conclusions

We have outlined data processing with the aid of statistic tests, applied in the evaluation of the results of the educational experiment. Based on the criteria used and the verified hypotheses, we can state the following, in conclusion:

- the overall analysis of the mathematical and statistical evaluations indicates a satisfactory progress for the students in all the groups involved in the research experiment;
- applying the elaborated methodology contributes to the amplification of the efficiency of the teaching-learning process and offers training possibilities that take into consideration the individual characteristics of every student;
- the implementation of multimedia courses contributes to information assimilation, by applying knowledge in the creative process
- computer assisted training has as a result an increase in the quality of data acquisition.
- by applying the multimedia courses in the process of teaching-learning all subject matters, we amplify the interest of the students towards the respective subject matters.

Artificial intelligence is the science and engineering of making intelligent machines, especially intelligent computer programs. It is related to the similar task of using computers to understand human intelligence, but artificial intelligence does not have to confine itself to methods that are biologically observable.

Intelligence is the computational part of the ability to achieve goals in the world. Varying kinds and degrees of intelligence occur in people, many animals and some machines.

The problem is that we cannot yet characterize in general what kinds of computational procedures we want to call intelligent. We understand some of the mechanisms of intelligence and not others.

Keywords : Intelligent machines, IQ, human intelligence

Intelligence involves mechanisms, and artificial intelligence research has discovered how to make computers carry out some of them and not others. If doing a task requires only mechanisms that are well understood today, computer programs can give very impressive performances on these tasks. Such programs should be considered "somewhat intelligent".

On the one hand, we can learn something about how to make machines solve problems by observing other people or just by observing our own methods. On the other hand, most work in AI involves studying the problems the world presents to intelligence rather than studying people or animals. Artificial intelligence researchers are free to use methods that are not observed in people or that involve much more computing than people can do.

IQ is based on the rates at which intelligence develops in children. It is the ratio of the age at which a child normally makes a certain score to the child's age. The scale is extended to adults in a suitable way. IQ correlates well with various measures of success or failure in life, but making computers that can score high on IQ tests would be weakly correlated with their usefulness. For example, the ability of a child to repeat back a long sequence of digits correlates well with other intellectual abilities, perhaps because it measures how much information the child can compute with at once. However, "digit span" is trivial for even extremely limited computers.

However, some of the problems on IQ tests are useful challenges for AI.

Computer programs have plenty of speed and memory but their abilities correspond to the intellectual mechanisms that program designers understand well enough to put in programs. Some abilities that children normally don't develop till they are teenagers may be in, and some abilities possessed by two year olds are still out. The matter is further complicated by the fact that the cognitive sciences still have not succeeded in determining exactly what the human abilities are. Very likely the organization of the intellectual mechanisms for AI can usefully be different from that in people.

Whenever people do better than computers on some task or computers use a lot of computation to do as well as people, this demonstrates that the program designers lack understanding of the intellectual mechanisms required to do the task efficiently.

After World War II, a number of people independently started to work on intelligent machines. The English mathematician Alan Turing may have been the first. He gave a lecture on it in 1947. He also may have been the first to decide that artificial intelligence was best researched by programming computers

rather than by building machines. By the late 1950s, there were many researchers on artificial intelligence, and most of them were basing their work on programming computers.

Some researchers say they have that objective, but maybe they are using the phrase metaphorically. The human mind has a lot of peculiarities, and I'm not sure anyone is serious about imitating all of them.

Alan Turing's 1950 article *Computing Machinery and Intelligence* discussed conditions for considering a machine to be intelligent. He argued that if the machine could successfully pretend to be human to a knowledgeable observer then you certainly should consider it intelligent. This test would satisfy most people but not all philosophers. The observer could interact with the machine and a human by teletype (to avoid requiring that the machine imitate the appearance or voice of the person), and the human would try to persuade the observer that it was human and the machine would try to fool the observer.

The Turing test is a one-sided test. A machine that passes the test should certainly be considered intelligent, but a machine could still be considered intelligent without knowing enough about humans to imitate a human.

Daniel Dennett's book *Brainchildren* has an excellent discussion of the Turing test and the various partial Turing tests that have been implemented, i.e. with restrictions on the observer's knowledge of artificial intelligence and the subject matter of questioning. It turns out that some people are easily led into believing that a rather dumb program is intelligent.

The ultimate effort is to make computer programs that can solve problems and achieve goals in the world as well as humans. However, many people involved in particular research areas are much less ambitious.

A few people think that human-level intelligence can be achieved by writing large numbers of programs of the kind people are now writing and assembling vast knowledge bases of facts in the languages now used for expressing knowledge.

However, most artificial intelligence researchers believe that new fundamental ideas are required, and therefore it cannot be predicted when human level intelligence will be achieved.

Computers can be programmed to simulate any kind of machine.

Many researchers invented non-computer machines, hoping that they would be intelligent in different ways than the computer programs could be. However, they usually simulate their invented machines on a computer and come to doubt that the new machine is worth building. Because many billions of dollars that have been spent in making computers faster and faster, another kind of machine would have to be very fast to perform better than a program on a computer simulating the machine.

Some people think much faster computers are required as well as new ideas. My own opinion is that the computers of 30 years ago were fast enough if only we knew how to program them. Of course, quite apart from the ambitions of artificial intelligence researchers, computers will keep getting faster.

Machines with many processors are much faster than single processors can be. Parallelism itself presents no advantages, and parallel machines are somewhat awkward to program. When extreme speed is required, it is necessary to face this awkwardness.

Idea about making a "child machine" that could improve by reading and by learning from experience has been proposed many times, starting in the 1940s. Eventually, it will be made to work. However, artificial intelligence programs haven't yet reached the level of being able to learn much of what a child learns from physical experience. Nor do present programs understand language well enough to learn much by reading.

Alexander Kronrod, a Russian artificial intelligence researcher, said "Chess is the *Drosophila* of artificial intelligence." He was making an analogy with geneticists' use of that fruit fly to study inheritance. Playing chess requires certain intellectual mechanisms and not others. Chess programs now play at grandmaster level, but they do it with limited intellectual mechanisms compared to those used by a human chess player, substituting large amounts of computation for understanding. Once we understand these mechanisms better, we can build human-level chess programs that do far less computation than do present programs.

Unfortunately, the competitive and commercial aspects of making computers play chess have taken precedence over using chess as a scientific domain. It is as if the geneticists after 1910 had organized fruit fly races and concentrated their efforts on breeding fruit flies that could win these races.

The Chinese and Japanese game of *Go* is also a board game in which the players take turns moving. *Go* exposes the weakness of our present understanding of the intellectual mechanisms involved in human game playing. *Go* programs are very bad players, in spite of considerable effort (not as much as for chess). The

problem seems to be that a position in *Go* has to be divided mentally into a collection of subpositions which are first analyzed separately followed by an analysis of their interaction. Humans use this in chess also, but chess programs consider the position as a whole. Chess programs compensate for the lack of this intellectual mechanism by doing thousands or, in the case of Deep Blue, many millions of times as much computation. Sooner or later, AI research will overcome this scandalous weakness.

The philosopher John Searle says that the idea of a non-biological machine being intelligent is incoherent. He proposes the Chinese room argument www-formal.stanford.edu/jmc/chinese.html. The philosopher Hubert Dreyfus says that artificial intelligence is impossible. The computer scientist Joseph Weizenbaum says the idea is obscene, anti-human and immoral. Various people have said that since artificial intelligence hasn't reached human level by now, it must be impossible. Still other people are disappointed that companies they invested in went bankrupt.

Aren't computability theory and computational complexity the keys to artificial intelligence? These theories are relevant but don't address the fundamental problems of artificial intelligence.

In the 1930s mathematical logicians, especially Kurt Gödel and Alan Turing, established that there did not exist algorithms that were guaranteed to solve all problems in certain important mathematical domains. Whether a sentence of first order logic is a theorem is one example, and whether a polynomial equation in several variables has integer solutions is another. Humans solve problems in these domains all the time, and this has been offered as an argument that computers are intrinsically incapable of doing what people do. Roger Penrose claims this. However, people can't guarantee to solve *arbitrary* problems in these domains either.

In the 1960s computer scientists, especially Steve Cook and Richard Karp developed the theory of NP-complete problem domains. Problems in these domains are solvable, but seem to take time exponential in the size of the problem. Which sentences of propositional calculus are satisfiable is a basic example of an NP-complete problem domain. Humans often solve problems in NP-complete domains in times much shorter than is guaranteed by the general algorithms, but can't solve them quickly in general.

What is important for artificial intelligence is to have algorithms as capable as people at solving problems. The identification of subdomains for which good algorithms exist is important, but a lot of AI problem solvers are not associated with readily identified subdomains.

The theory of the difficulty of general classes of problems is called *computational complexity*. So far this theory hasn't interacted with artificial intelligence as much as might have been hoped. Success in problem solving by humans and by artificial intelligence programs seems to rely on properties of problems and problem solving methods that the neither the complexity researchers nor the artificial intelligence community have been able to identify precisely.

Algorithmic complexity theory as developed by Solomonoff, Kolmogorov and Chaitin (independently of one another) is also relevant. It defines the complexity of a symbolic object as the length of the shortest program that will generate it. Proving that a candidate program is the shortest or close to the shortest is an unsolvable problem, but representing objects by short programs that generate them should sometimes be illuminating even when you can't prove that the program is the shortest.

The branches of artificial intelligence :

- **logical** artificial intelligence

What a program knows about the world in general the facts of the specific situation in which it must act, and its goals are all represented by sentences of some mathematical logical language. The program decides what to do by inferring that certain actions are appropriate for achieving its goals.

- **search**

Artificial intelligence programs often examine large numbers of possibilities, moves in a chess game or inferences by a theorem proving program. Discoveries are continually made about how to do this more efficiently in various domains.

- **pattern recognition**

When a program makes observations of some kind, it is often programmed to compare what it sees with a pattern. For example, a vision program may try to match a pattern of eyes and a nose in a scene in order to find a face. More complex patterns, e.g. in a natural language text, in a chess position, or in the history of

some event are also studied. These more complex patterns require quite different methods than do the simple patterns that have been studied the most.

- **representation**

Facts about the world have to be represented in some way. Usually languages of mathematical logic are used.

- **inference**

From some facts, others can be inferred. Mathematical logical deduction is adequate for some purposes, but new methods of *non-monotonic* inference have been added to logic since the 1970s. The simplest kind of non-monotonic reasoning is default reasoning in which a conclusion is to be inferred by default, but the conclusion can be withdrawn if there is evidence to the contrary. For example, when we hear of a bird, we may infer that it can fly, but this conclusion can be reversed when we hear that it is a penguin. It is the possibility that a conclusion may have to be withdrawn that constitutes the non-monotonic character of the reasoning. Ordinary logical reasoning is monotonic in that the set of conclusions that can be drawn from a set of premises is a monotonic increasing function of the premises. Circumscription is another form of non-monotonic reasoning.

- **common sense knowledge and reasoning**

This is the area in which artificial intelligence is farthest from human-level, in spite of the fact that it has been an active research area since the 1950s. While there has been considerable progress, e.g. in developing systems of *non-monotonic reasoning* and theories of action, yet more new ideas are needed. The Cyc system contains a large but spotty collection of common sense facts.

- **learning from experience**

Programs do that. The approaches to artificial intelligence based on *connectionism* and *neural nets* specialize in that. There is also learning of laws expressed in logic.

- **planning**

Planning programs start with general facts about the world (especially facts about the effects of actions), facts about the particular situation and a statement of a goal. From these, they generate a strategy for achieving the goal. In the most common cases, the strategy is just a sequence of actions.

- **epistemology**

This is a study of the kinds of knowledge that are required for solving problems in the world.

- **ontology**

Ontology is the study of the kinds of things that exist. In artificial intelligence, the programs and sentences deal with various kinds of objects, and we study what these kinds are and what their basic properties are. Emphasis on ontology begins in the 1990s.

- **heuristics**

A heuristic is a way of trying to discover something or an idea imbedded in a program. The term is used variously in artificial intelligence. *Heuristic functions* are used in some approaches to search to measure how far a node in a search tree seems to be from a goal. *Heuristic predicates* that compare two nodes in a search tree to see if one is better than the other, i.e. constitutes an advance toward the goal, may be more useful.

- **genetic programming**

Genetic programming is a technique for getting programs to solve a task by mating random Lisp programs and selecting fittest in millions of generations.

The applications of artificial intelligence

- **game playing**

You can buy machines that can play master level chess for a few hundred dollars. There is some artificial intelligence in them, but they play well against people mainly through brute force computation--looking at hundreds of thousands of positions. To beat a world champion by brute force and known reliable heuristics requires being able to look at 200 million positions per second.

- **speech recognition**

In the 1990s, computer speech recognition reached a practical level for limited purposes. Thus United Airlines has replaced its keyboard tree for flight information by a system using speech recognition of flight numbers and city names. It is quite convenient. On the the other hand, while it is possible to instruct some computers using speech, most users have gone back to the keyboard and the mouse as still more convenient.

- **understanding natural language**

Just getting a sequence of words into a computer is not enough. Parsing sentences is not enough either. The computer has to be provided with an understanding of the domain the text is about, and this is presently possible only for very limited domains.

- **computer vision**

The world is composed of three-dimensional objects, but the inputs to the human eye and computers' TV cameras are two dimensional. Some useful programs can work solely in two dimensions, but full computer vision requires partial three-dimensional information that is not just a set of two-dimensional views. At present there are only limited ways of representing three-dimensional information directly, and they are not as good as what humans evidently use.

- **expert systems**

A "knowledge engineer" interviews experts in a certain domain and tries to embody their knowledge in a computer program for carrying out some task. How well this works depends on whether the intellectual mechanisms required for the task are within the present state of artificial intelligence. When this turned out not to be so, there were many disappointing results. One of the first expert systems was MYCIN in 1974, which diagnosed bacterial infections of the blood and suggested treatments. It did better than medical students or practicing doctors, provided its limitations were observed. Namely, its ontology included bacteria, symptoms, and treatments and did not include patients, doctors, hospitals, death, recovery, and events occurring in time. Its interactions depended on a single patient being considered. Since the experts consulted by the knowledge engineers knew about patients, doctors, death, recovery, etc., it is clear that the knowledge engineers forced what the experts told them into a predetermined framework. In the present state of AI, this has to be true. The usefulness of current expert systems depends on their users having common sense.

- **heuristic classification**

One of the most feasible kinds of expert system given the present knowledge of artificial intelligence is to put some information in one of a fixed set of categories using several sources of information. An example is advising whether to accept a proposed credit card purchase. Information is available about the owner of the credit card, his record of payment and also about the item he is buying and about the establishment from which he is buying it. Artificial intelligence research has both theoretical and experimental sides. The experimental side has both basic and applied aspects. There are two main lines of research. One is biological, based on the idea that since humans are intelligent, artificial intelligence should study humans and imitate their psychology or physiology. The other is phenomenal, based on studying and formalizing common sense facts about the world and the problems that the world presents to the achievement of goals. The two approaches interact to some extent, and both should eventually succeed. It is a race, but both racers seem to be walking.

What should I study before or while learning artificial intelligence. Study mathematics, especially mathematical logic. The more you learn about science in general the better. For the biological approaches to AI, study psychology and the physiology of the nervous system. Learn some programming languages--at least C, Lisp and Prolog. It is also a good idea to learn one basic machine language. Jobs are likely to depend on knowing the languages currently in fashion. In the late 1990s, these include C++ and Java.

E-BANKING – IMPACT, RISKS, SECURITY

The evolution of electronic banking (e-Banking) started with the use of automatic teller machines (ATMs) and has included telephone banking, direct bill payment, electronic fund transfer and online banking. According to some, the future direction of e-banking is the acceptance of mobile telephone (WAP-enabled) banking and interactive-TV banking. However, it has been forecast by many that online banking will continue to be the most popular method for future electronic financial transactions.

Electronic funds transfer (EFT), refers to the computer-based systems used to perform financial transaction electronically. The term is used for a number of different concepts including electronic payments and cardholder-initiated transactions, where a cardholder makes use of a payment card such as a credit card or debit card. Card-based EFT transactions are often covered by the ISO 8583 series of standards.

Keywords : e-banking, e-commerce, e-banks.

Introduction

In order for customers to use their banks online services they need to have a personal computer and Internet connection. Their personal computer becomes their virtual banker who will assist them in their banking errands. Examples of e-banking services that customers can get online are:

- Attaining information about accounts and loans,
- Conducting transfers amongst different accounts, even between external banks,
- Paying bills,
- Buying and selling stocks and bonds by depot,
- Buying and selling fund shares³⁹

These services that are offered by e-banking are changing and being improved because of the intense competition between the banks online. Banking industry must adapt to the electronics age, which in its turn is changing all the time.

EFT transactions require authorisation and a method to authenticate the card and the card holder. Whereas a merchant may manually verify the card holder's signature, EFT transactions require the card holder's PIN to be sent online in an encrypted form for validation by the card issuer. Other information may be included in the transaction, some of which is not visible to the card holder (for instance magnetic stripe data), and some of which may be requested from the card holder (for instance the card holder's address or the CVV2 security value printed on the card).

EFT transactions are activated during e-banking procedures. Various methods of e-banking include:

- Telephone banking
- Online banking
- Short Message Service (SMS) banking
- Mobile banking
- Interactive-TV banking .

Independent of location or time, you can execute your payments and stock market orders and you get detailed information on your accounts and custody accounts.

Impact of e-banking on traditional services

One of the issues currently being addressed is the impact of e-banking on traditional banking players. After all, if there are risks inherent in going into e-banking there are other risks in not doing so. It is too early to have a firm view on this yet. Even to practitioners the future of e-banking and its implications are unclear. It might be convenient nevertheless to outline briefly two views that are prevalent in the market.

The view that the Internet is a revolution that will sweep away the old order holds much sway. Arguments in favour are as follows:

- E-banking transactions are much cheaper than branch or even phone transactions. This could turn yesterday's competitive advantage - a large branch network, into a comparative disadvantage, allowing e-banks to undercut bricks-and-mortar banks. This is commonly known as the "beached dinosaur" theory.
- E-banks are easy to set up so lots of new entrants will arrive. 'Old-world' systems, cultures and structures will not encumber these new entrants. Instead, they will be adaptable and responsive. E-banking gives consumers much more choice. Consumers will be less inclined to remain loyal.
- E-banking will lead to an erosion of the 'endowment effect' currently enjoyed by the major UK banks. Deposits will go elsewhere with the consequence that these banks will have to fight to regain and retain their customer base. This will increase their cost of funds, possibly making their business less viable. Lost revenue may even result in these banks taking more risks to breach the gap.

Portal providers, are likely to attract the most significant share of banking profits. Indeed banks could become glorified marriage brokers. They would simply bring two parties together – eg buyer and seller, payer and payee.

The products will be provided by monolines, experts in their field. Traditional banks may simply be left with payment and settlement business – even this could be cast into doubt.

Traditional banks will find it difficult to evolve. Not only will they be unable to make acquisitions for cash as opposed to being able to offer shares, they will be unable to obtain additional capital from the stock market. This is in contrast to the situation for Internet firms for whom it seems relatively easy to attract investment.

There is of course another view which sees e-banking more as an evolution than a revolution.

E-banking is just banking offered via a new delivery channel. It simply gives consumers another service (just as ATMs did).

Like ATMs, e-banking will impact on the nature of branches but will not remove their value.

Traditional banks are starting to fight back.

The start-up costs of an e-bank are high. Establishing a trusted brand is very costly as it requires significant advertising expenditure in addition to the purchase of expensive technology (as security and privacy are key to gaining customer approval).

E-banks have already found that retail banking only becomes profitable once a large critical mass is achieved. Consequently many e-banks are limiting themselves to providing a tailored service to the better off.

Nobody really knows which of these versions will triumph. This is something that the market will determine. However, supervisors will need to pay close attention to the impact of e-banks on the traditional banks, for example by surveillance of:

- strategy
- customer levels
- earnings and costs
- advertising spending
- margins
- funding costs

- merger opportunities and threats.

Risks

Strategic Risk - A financial institution's board and management should understand the risks associated with e-banking services and evaluate the resulting risk management costs against the potential return on investment prior to offering e-banking services. Poor e-banking planning and investment decisions can increase a financial institution's strategic risk. On strategic risk E-banking is relatively new and, as a result, there can be a lack of understanding among senior management about its potential and implications. People with technological, but not banking, skills can end up driving the initiatives. E-initiatives can spring up in an incoherent and piecemeal manner in firms. They can be expensive and can fail to recoup their cost. Furthermore, they are often positioned as loss leaders (to capture market share), but may not attract the types of customers that banks want or expect and may have unexpected implications on existing business lines.

Banks should respond to these risks by having a clear strategy driven from the top and should ensure that this strategy takes account of the effects of e-banking, wherever relevant. Such a strategy should be clearly disseminated across the business, and supported by a clear business plan with an effective means of monitoring performance against it.

Business risks - Business risks are also significant. Given the newness of e-banking, nobody knows much about whether e-banking customers will have different characteristics from the traditional banking customers. They may well have different characteristics. This could render existing score card models inappropriate, this resulting in either higher rejection rates or inappropriate pricing to cover the risk. Banks may not be able to assess credit quality at a distance as effectively as they do in face to face circumstances. It could be more difficult to assess the nature and quality of collateral offered at a distance, especially if it is located in an area the bank is unfamiliar with (particularly if this is overseas). Furthermore as it is difficult to predict customer volumes and the stickiness of e-deposits (things which could lead either to rapid flows in or out of the bank) it could be very difficult to manage liquidity.

Of course, these are old risks with which banks and supervisors have considerable experience but they need to be watchful of old risks in new guises. In particular risk models and even processes designed for traditional banking may not be appropriate.

Transaction/operations risk - Transaction/Operations risk arises from fraud, processing errors, system disruptions, or other unanticipated events resulting in the institution's inability to deliver products or services. This risk exists in each product and service offered. The level of transaction risk is affected by the structure of the institution's processing environment, including the types of services offered and the complexity of the processes and supporting technology.

In most instances, e-banking activities will increase the complexity of the institution's activities and the quantity of its transaction/operations risk, especially if the institution is offering innovative services that have not been standardized. Since customers expect e-banking services to be available 24 hours a day, 7 days a week, financial institutions should ensure their e-banking infrastructures contain sufficient capacity and redundancy to ensure reliable service availability. Even institutions that do not consider e-banking a critical financial service due to the availability of alternate processing channels, should carefully consider customer expectations and the potential impact of service disruptions on customer satisfaction and loyalty.

The key to controlling transaction risk lies in adapting effective policies, procedures, and controls to meet the new risk exposures introduced by e-banking. Basic internal controls including segregation of duties, dual controls, and reconciliations remain important. Information security controls, in particular, become more significant requiring additional processes, tools, expertise, and testing. Institutions should determine the appropriate level of security controls based on their assessment of the sensitivity of the information to the customer and to the institution and on the institution's established risk tolerance level.

Credit risk - Generally, a financial institution's credit risk is not increased by the mere fact that a loan is originated through an e-banking channel. However, management should consider additional precautions when originating and approving loans electronically, including assuring management information systems effectively track the performance of portfolios originated through e-banking channels. The following aspects of on-line loan origination and approval tend to make risk management of the lending process more challenging. If not properly managed, these aspects can significantly increase credit risk.

- Verifying the customer's identity for on-line credit applications and executing an enforceable contract;
- Monitoring and controlling the growth, pricing, underwriting standards, and ongoing credit quality of loans originated through e-banking channels;
- Monitoring and oversight of third-parties doing business as agents or on behalf of the financial institution (for example, an Internet loan origination site or electronic payments processor);
- Valuing collateral and perfecting liens over a potentially wider geographic area;
- Collecting loans from individuals over a potentially wider geographic area;
- Monitoring any increased volume of, and possible concentration in, out-of-area lending.

Liquidity, interest rate, price/market risks - Funding and investment-related risks could increase with an institution's e-banking initiatives depending on the volatility and pricing of the acquired deposits. The Internet provides institutions with the ability to market their products and services globally. Internet-based advertising programs can effectively match yield-focused investors with potentially high-yielding deposits. But Internet-originated deposits have the potential to attract customers who focus exclusively on rates and may provide a funding source with risk characteristics similar to brokered deposits. An institution can control this potential volatility and expanded geographic reach through its deposit contract and account opening practices, which might involve face-to-face meetings or the exchange of paper correspondence. The institution should modify its policies as necessary to address the following e-banking funding issues:

- Potential increase in dependence on brokered funds or other highly rate-sensitive deposits;
- Potential acquisition of funds from markets where the institution is not licensed to engage in banking, particularly if the institution does not establish, disclose, and enforce geographic restrictions;
- Potential impact of loan or deposit growth from an expanded Internet market, including the impact of such growth on capital ratios;
- Potential increase in volatility of funds should e-banking security problems negatively impact customer confidence or the market's perception of the institution.

Reputational risks - This is considerably heightened for banks using the Internet. For example the Internet allows for the rapid dissemination of information which means that any incident, either good or bad, is common knowledge within a short space of time. The speed of the Internet considerably cuts the optimal response times for both banks and regulators to any incident.

Any problems encountered by one firm in this new environment may affect the business of another, as it may affect confidence in the Internet as a whole. There is therefore a risk that one rogue e-bank could cause significant problems for all banks providing services via the Internet. This is a new type of systemic risk and is causing concern to e-banking providers. Overall, the Internet puts an emphasis on reputational risks. Banks need to be sure that customers' rights and information needs are adequately safeguarded and provided for.

Security

Security is one of the most discussed issues around e-banking.

E-banking increases security risks, potentially exposing hitherto isolated systems to open and risky environments.

Security breaches essentially fall into three categories; breaches with serious criminal intent (fraud, theft of commercially sensitive or financial information), breaches by 'casual hackers' (defacement of web sites or 'denial of service' - causing web sites to crash), and flaws in systems design and/or set up leading to security breaches (genuine users seeing / being able to transact on other users' accounts). All of these threats have potentially serious financial, legal and reputational implications.

Many banks are finding that their systems are being probed for weaknesses hundreds of times a day but damage/losses arising from security breaches have so far tended to be minor. However some banks could develop more sensitive "burglar alarms", so that they are better aware of the nature and frequency of unsuccessful attempts to break into their system.

The most sensitive computer systems, such as those used for high value payments or those storing highly confidential information, tend to be the most comprehensively secured. One could therefore imply that the

greater the potential loss to a bank the less likely it is to occur, and in general this is the case. However, while banks tend to have reasonable perimeter security, there is sometimes insufficient segregation between internal systems and poor internal security. It may be that someone could breach the lighter security around a low value system.

It is easy to overemphasise the security risks in e-banking. It must be remembered that the Internet could remove some errors introduced by manual processing (by increasing the degree of straight through processing from the customer through banks' systems). This reduces risks to the integrity of transaction data (although the risk of customers incorrectly inputting data remains). As e-banking advances, focusing general attention on security risks, there could be large security gains.

Financial institutions need as a minimum to have:

- a strategic approach to information security, building best practice security controls into systems and networks as they are developed
- a proactive approach to information security, involving active testing of system security controls (e.g. penetration testing), rapid response to new threats and vulnerabilities and regular review of market place developments
- sufficient staff with information security expertise
- active use of system based security management and monitoring tools
- strong business information security controls.

These are the issues line supervisors will be raising with their banks as part of their on-going supervision.

Conclusion

In conclusion e-banking creates issues for banks and regulators alike. For their part, banks should:

- Have a clear and widely disseminated strategy that is driven from the top and takes into account the effects of e-banking, together with an effective process for measuring performance against it.
- Take into account the effect that e-provision will have upon their business risk exposures and manage these accordingly.
- Undertake market research, adopt systems with adequate capacity and scalability, undertake proportional advertising campaigns and ensure that they have adequate staff coverage and a suitable business continuity plan.
- Ensure they have adequate management information in a clear and comprehensible format.
- Take a strategic and proactive approach to information security, maintaining adequate staff expertise, building in best practice controls and testing and updating these as the market develops. Make active use of system based security management and monitoring tools.
- Ensure that crisis management processes are able to cope with Internet related incidents.

One of the benefits that banks experience when using e-banking is increased customer satisfaction. This due to that customers may access their accounts whenever, from anywhere, and they get involved more, this creating relationships with banks.

Banks should provide their customers with convenience, meaning offering service through several distribution channels (ATM, Internet, physical branches) and have more functions available online. Other benefits are expanded product offerings and extended geographic reach. This means that banks can offer a wider range and newer services online to even more customers than possible before.

The benefit which is driving most of the banks toward e-banking is the reduction of overall costs. With e-banking banks can reduce their overall costs in two ways: cost of processing transactions is minimized and the numbers of branches that are required to service an equivalent number of customers are reduced.

With all these benefits banks can obtain success on the financial market. But e-banking is a difficult business and banks face a lot of challenges.

Abstract: The internet became an important part of the company's informational system. In order to take advantage on the Internet's interactive nature, a lot of companies have created their own websites. Companies use the website for numerous applications: to promote themselves, online shopping, and communication with targeted clients. This study reveals the fact that the company's size and field of activity have influence on website's functionality and interactivity. Small companies use the website to successfully compete corporations which do not have yet necessary stimulants to fully exploit the internet capacities.

Keywords: websites, informational system, company's promotion, market studies, on line selling, targeted audience communication

1. The Web's role in companies' activity

From the moment of its penetration in Europe, the Internet knew an extremely high extension. Businessmen don't hold loose to this phenomenon. They started utilize the Internet not only as an extremely effective communication mean but also as a distribution channel for more diversified goods and services.

Electronic means are used wider for advertising, and selling products and services all over the world.

Using the Internet, companies offer their products together with information regarding utility, quality, advantages, content or components, prices, terms and conditions regarding delivery and payment conditions. Buyers can order the desired products to the most competitive companies.

Internet technologies and applications have developed faster than anyone could imagine opening new ways for communication, cooperation and coordination between producers, consumers and suppliers.

The Internet has created new business opportunities, facilitating the access at the consumers' level, thus contributing to the increase of the competition. In the new competitive climate businessmen took interest in using the Internet for a better market approach and an increased marketing efficiency. And this is due to the fact that the Internet represents not only a new technology but offers marketing new ways for products and services offered by the companies. The Internet modifies not only the business market and its nature, but also the relationship between them.

A lot of companies have created web pages to present their services and products offer both on local and national or international level.

1.1 The Internet in Romania

The Internet entered Europe in 1993. But its adoption was made in time differently across the continent. The first countries interested on the Internet were the northern countries, the southern part being interested later.

According to the European Bureau of Statistics[1] in Romania the weight factor of the companies having Internet access is 58%, which positions our country on the last place in the European Union, at a significant distance behind others.

Firs places are occupied By Finland (99%), Slovakia (98%), Austria, Belgium, Denmark(97%) and Holland(96%).

On the last places are situated Romania (58%), Bulgaria (75%), Latvia and Hungaria (86%), Cyprus (88%), and Lithuania (89%).

The weight factor of the companies having Internet access

2. The integration of the Internet in the company's informational system

The Internet becomes an important element of the enterprise informational system. A company's Internet connection offers the possibility of relevant information acquiring about the environment in which the company activates, about the market and the competitors. Collected information are stored in company's databases, processed, analyzed and used for efficient decision making processes, allowing thus quick and correct matching to the environment conditions which permanently changes.

The Internet has changed the functionality and the orientation of the companies' information system. Whereas the traditional informational system was mainly focused on the information internal storage and flow, the Internet had the effect of dynamically connecting the company with the external world. The functionality emphasis of information system has changed from providing the managers with relevant and timely information for decision-making, to integrating the company into the external information environment.

A lot of companies have created their own web site to exploit the interactive facilities of the Internet. Web sites are used mainly:

1. For company promotion:
 - Presents general information of the company. Under competitors' pressure, companies rush to create their own web sites.
 - Offers a large variety of information about company, gathered in an online brochure in which information considered useful for clients are presented. Therefore informational value of the site for its visitor isn't that great.
 - Visitors' center – contains relevant information for the visitors having grater informational value for them. These kind of sites are the most expensive regarding the maintenance but significantly contributes to the brand's top position.
 - Brand consolidation
2. For online selling:

- Contains the products and technical descriptions catalogue for each catalogue's position. Data Base Management System (DBMS) is used to manage the information. DBMS's role is to store and manipulate data, offering data access facilities.
 - Contains, along with the product catalogue, facilities for the clients' online orders, through e-mail or interactive forms
 - Contains facilities for the online orders and payments.
3. For market studies
 4. For communication with target consumers.

A company which has the aim to fully exploits its web site functionality has to integrate it in its informational system. Thus, the web site will represent:

- An interface between the corporate information system and online customers
- A promotional tool
- A communication channel between online customers and the company
- A market studying tool.

Web site integration in the company's informational system causes complex reorganization of the informational system, on both operational and structural level. Also, the company's marketing and communication strategies must be integrated with the online marketing strategy.

2.1 Web sites in Romania

According to the European Bureau of Statistics[1] in Romania the weight factor of the companies having their own web site is 24%, which positions our country on the last place in the European Union.

On the first places are situated Sweden, Denmark and Finland. At the end one can find Romania, Bulgaria and Latvia.

The weight factor of the companies possessing their own web site

3. Data analysis and interpretation

The research lays on two hypotheses:

- Web site functionality is influenced by the company dimension
- Web site functionality is influenced by the company's field of activity

In order to collect primary data related with the mentioned research hypothesis, 600 questionnaires have been sent by e-mail to randomly selected Romanian companies. 283 of these questionnaires were returned, but only 279 of them were properly completed, and could be used for data analysis, thus resulting a response rate of 46,5%.

The questions were grouped as follows:

1. Questions related to the company's size.
 6. The companies were structured as follows:
 - Small companies – up to 50 employees
 - Medium-sized companies – between 51 and 500 employees
 - Large companies – with more than 500 employees.
2. Questions related to the company's field of activity
 7. The companies were structured in three fields of activity as follows:
 - Manufacturing
 - Services
 - Other activities
3. Questions related to the interactive features of the web site.
4. Questions related to the aim of the web site use, thus identifying the following four directions:
 - Company's promotion
 - Market studies
 - On line selling
 - targeted audience communication

Among responding companies 111 are small companies, 92 are medium-sized companies and 72 are large companies.

Collected data showed that:

- Large companies uses web sites for self promotion and communication with targeted audience
- Middle and small-sized companies uses web sites for market studies and online sells.

Results are synthesized in the table below:

The aim of web site use / Company's size	N	Company's promotion	Market studies	On line sell	Targeted audience communication
small companies		83	92	97	49
	%	72,17	80	84,34	42,6
medium-sized companies		65	73	75	44
	%	70,65	79,34	81,52	47,82
large companies		72	26	16	67
	%	100	36,11	22,22	93,05

It can be noticed that company's size has an important influence on company's capacity on targeted audience communication (the greater the company, the better on line communication strategy). This result can be interpreted in the way that although the Internet provides a level plain field for companies of different sizes and organizational structures, in the case of marketing communication, additional resources and expertise can determine a difference in selecting and targeting the high priority audiences.

Among the companies that have returned the questionnaires 87 have manufacturing as the field of activity, 157 are service-oriented companies (many of them have an Internet related field of activity) and 35 activate in other fields.

Collected data showed that:

- Companies having manufacturing as the field of activity use web sites for self promoting and communication with targeted audience
- Companies providing services use web sites for promotion, market studies an online selling.

Results are synthesized in the table below:

The aim of web site use / Company's field of activity	N	Company's promotion	Market studies	On line sell	Targeted audience communication
manufacturing	%	87 100	45 51,72	43 49,42	86 98,85
services	%	120 76,43	117 74,52	118 75,15	69 43,94
other activities	%	13 37,14	19 54,28	27 77,14	5 14,28

Regarding the web sites interactivity collected data showed that:

1. the corporate web site of the small companies has more interactive features than the web site of medium-sized or large companies. The Internet can be used creatively by these companies to reach and communicate with their targeted audiences, with low costs and effort.
2. the service-providing companies implement web sites with higher levels of interactivity (e-mail, discussion forums, online membership form) in comparison with manufacturing companies. However, in terms of their relationship with the IT technology the differences are small, although the Internet-related companies have, overall, a more interactive web site.
3. the IT-related companies do have the necessary expertise and motivation to intensively use the corporate web site. They often provide specialized services over the Internet, which requires a fully functional and highly interactive web site

4. Conclusions

Current research accentuates the fact that the company's dimension and field of activity influences some aspects regarding the web sites functionality and interactivity

Small business companies use the web sites to successfully compete large companies which have not yet the necessary stimulants for a fully functional exploit of the Internet's facilities

Despite the slow development of the online market in our country in comparison with other UE countries, the Internet system is already integrated with the informational system of some companies, allowing a cost-effective collection of market information, and communication with target audiences.

The corporate web site is successfully used by the majority of respondent companies to promote the company and its activity, and, in a smaller measure, to sell online products and/or services.

Abstract: During research project activities, an important role is played by an effective communication between research team members. A communication web site was realized in order to allow an operational and effective communication of the intermediary results between the members of the research team. Meantime, the site keeps a record of the team members' activity from the communication point of view. The web site allows an efficiency increasing for the project's activities in order to achieve the research objectives rezumat.

Keywords: web site, database, communication monitoring

1. Communication process

To communicate in an effective mode, a cybernetic system has to gather the following elements: the source (emitter), the message, the receiver, and the communication channel (media), through which the message reaches the receiver. The message is coded by the emitter in a structured assembly of elements known by the mean of a convention, and is decoded by the receiver.

The “feedback” allows the source to verify – and modify if necessary – if the message was correctly received and understood and consists in the “receiver’s” response. Thus, the feedback closes the system, making it dynamic and somehow interactive.

In the communication process, distortions or perturbations may occur, as unplanned elements of the message’s emitter.

The communication process with its components and relationships can be represented as figure 1.

Started from the concise presentation above the main problems of the communication process may be identified and presented as questions, as follows:

1. Who communicates?
2. To whom the communication is addressed?
3. What is communicating?
4. How is communicate?
5. What are the communication’s results?

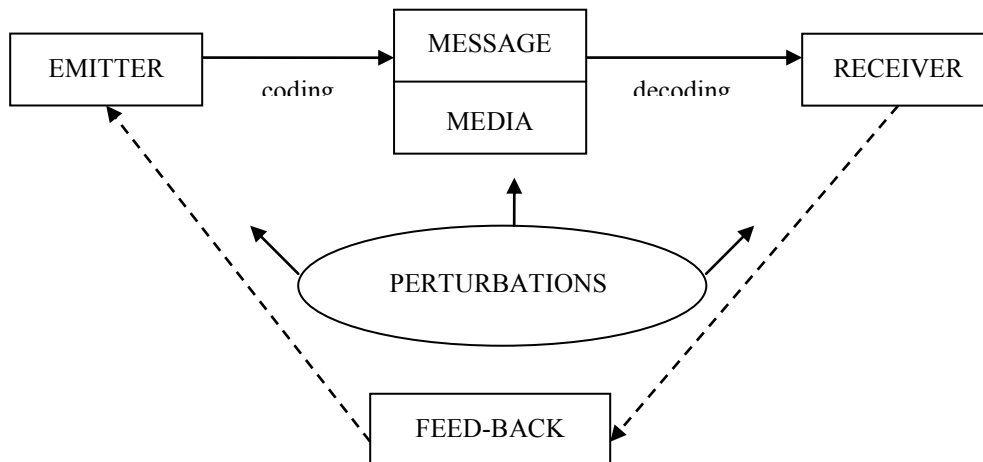

Figure 1 – Communication process

These representations describes the main factors which are specific to each communication process and permit the identification of the conditions that are to be accomplished by an efficient communication process:

1. The emitter needs strictly evaluate both the targets on which is interested and the type of answer it is looking for.
2. The messages has to be made considering on one hand the receiver's experience and on the other the way in which the target audience tends to decode the message. In other words, for the message to be efficient or significant, the coding process needs to be correlated with the decoding process adopted by the receiver.
3. The emitter has to transmit its' messages through the proper media, dedicated to the considered target.
4. The emitter has to develop feedback channels to receive and know the receivers' reactions and answers; this is necessary for the communication self-evaluation.

2. Communication between research team members

Two communication aspects were taken into account:

1. Operational communication between the team's members
2. The communication of the research results.

Regarding the operational communication, the necessity of solving problems in real time was the main issue to be solved. From the start, all time consuming media were eliminated. Also, important communication aspects was the elimination of the disturbing factors and information security together with a monitoring system regarding the members' participation to the project's activities. Media channels considered were personal communication, phone, mail and the Internet, each one with its advantages and disadvantages. Only the Internet can correlate the real time communication with a message monitoring system and a broad dissemination of the information, through its instruments: e-mail and instant messenger. However, these tools need to assure the information's security.

This problem was solved through an operational communication web page with secure access based on account and password. In the meantime the problem of the monitoring system of the members' participation to the project was solved, through a database table which records both the problems that needs responses and the members which posted the problem, and the members who answer the problems and give solutions, in a blog-type web page.

3. The database for the communication monitoring

The database has to accomplish the following conditions:

1. To assure data a high degree of independence in respect to the programs and vice versa

2. Database structure has to be conceived in such a manner that it can assure necessary and sufficient information for decision and informational demands
3. To assure minimum and controlled data redundancy
4. To permit quick access to the data

Database used to create the website named “blog” is a relational database, implemented under MySQL database management system.

MySQL is a multi-user multi-threaded database server, which uses SQL (Structured Query Language), the standard database query language throughout the world.

Entity-relationship modeling process was used to design the physical and logical structure of the “blog’s” database (E-R modeling), considering the great quantity of heterogeneous information stored in the database.

In the E-R modeling context, the entity is similar to a relational table (containing data describing a set of correlated activities). The main tables of the database are: *Users*, *Topics*, *Replies*, *Files* and *SM (Smileys)*.

For the creation of the *blog’s* database, the phpMyAdmin software capable to manage the entire MySQL activity was used.

In the following, the blog database’s tables are presented through their schemas.

1. Users table contains the following fields related to the blog’s users information:

	Field	Type	Collation	Attributes	Null	Default	Extra
<input type="checkbox"/>	id	int(11)			No		auto_increment
<input type="checkbox"/>	user	varchar(30)	latin1_general_ci		No		
<input type="checkbox"/>	pass	varchar(30)	latin1_general_ci		No		
<input type="checkbox"/>	nume	varchar(40)	latin1_general_ci		No		
<input type="checkbox"/>	prenume	varchar(40)	latin1_general_ci		No		
<input type="checkbox"/>	email	varchar(40)	latin1_general_ci		No		
<input type="checkbox"/>	telefon	varchar(20)	latin1_general_ci		No		
<input type="checkbox"/>	judet	varchar(15)	latin1_general_ci		No		
<input type="checkbox"/>	oras	varchar(20)	latin1_general_ci		No		
<input type="checkbox"/>	unitate	varchar(70)	latin1_general_ci		No		
<input type="checkbox"/>	arii_experienta	mediumtext	latin1_general_ci		No		
<input type="checkbox"/>	descriere	mediumtext	latin1_general_ci		No		

Explains:

1. Id – unique identifying field for users
2. User – user’s account
3. Pass – user’s password
4. Nume – user’s last name
5. Prenume –user’s first name
6. Email – user’s email address
7. Telefon – user’s phone number
8. Judet – user’s address county
9. Oras – user’s city
10. Unitate – user’s workplace
11. Aarii_experienta – user’s area of competence
12. Descriere – explanations about user’s professional experience

Id is the primary key of the table, defined as an Auto_increment type. User field does not allow duplicate values and is used as an external key (owner) in the rest of the database’s tables to associate information with the user’s account.

2. Topics table is used to manage information about user’s themes and contains the following fields:

	Field	Type	Collation	Attributes	Null	Default	Extra
<input type="checkbox"/>	id	int(11)			No		auto_increment
<input type="checkbox"/>	title	varchar(50)	latin1_general_ci		No		
<input type="checkbox"/>	contents	longtext	latin1_general_ci		No		
<input type="checkbox"/>	owner	varchar(30)	latin1_general_ci		No		
<input type="checkbox"/>	date_time	varchar(30)	latin1_general_ci		No		

Explains:

1. Id – unique identification field
2. Title – theme’s title (description)
3. Contents – theme’s content
4. Owner – the user’s account that initiated the topic
5. Date_time – date and time of the topic’s post

ID is the primary key, defined as an Auto_increment type. ID field is used as an external key (topicid) in the Replies table, to associate users’ answers to the topic.

3. Replies table contains the following fields:

	Field	Type	Collation	Attributes	Null	Default	Extra
<input type="checkbox"/>	id	bigint(20)			No		auto_increment
<input type="checkbox"/>	topicid	int(11)			No	0	
<input type="checkbox"/>	owner	varchar(40)	latin1_general_ci		No		
<input type="checkbox"/>	contents	mediumtext	latin1_general_ci		No		
<input type="checkbox"/>	data	varchar(20)	latin1_general_ci		No		

Explains:

1. Id – unique identification field
2. Topicid – the id of the theme for which the answer is posted
3. Owner – the topic’s responding user’s account
4. Contents – the content of the response
5. Data – the response post data

Primary key is the Id field, defined as Auto_increment type.

4. Files table contains the following fields that permit data identification of the users’ uploaded files. These files are available for all interested member of the research team:

	Field	Type	Collation	Attributes	Null	Default	Extra
<input type="checkbox"/>	id	int(10)		UNSIGNED	No		auto_increment
<input type="checkbox"/>	cat	varchar(20)	latin1_general_ci		No		
<input type="checkbox"/>	owner	varchar(40)	latin1_general_ci		No		
<input type="checkbox"/>	title	varchar(50)	latin1_general_ci		No		
<input type="checkbox"/>	desc	mediumtext	latin1_general_ci		No		
<input type="checkbox"/>	date_time	varchar(30)	latin1_general_ci		No		

Explains:

1. Id – unique identifying field
2. Cat – category to which it belongs
3. Owner – user’s account of the user which uploaded the file
4. Title – file’s title
5. Desc – file’s description
6. Date_time – uploaded file’s date and time

Id is the primary key defined as Auto_increment

1. SM table. The table contains the identification code of the communication’s page available emoticons. Its structure is:

	Field	Type	Collation	Attributes	Null	Default	Extra
<input type="checkbox"/>	nume	varchar(20)	latin1_swedish_ci		No		
<input type="checkbox"/>	cod	varchar(20)	latin1_swedish_ci		No		

Explanations:

1. Nume – emoticon’s name
2. Cod – emoticon’s code

The following connectivity relationships are defined inside the “blog” database:

1. one to many relationship between Users and Topic tables
2. one to many relationship between Users and Files tables
3. one to many relationship between Topics and Replies tables

In order to model the use of the information scenarios, derived descriptions from the E-R model can be used. The database E-R diagram is presented in figure 2.

Figure 2 Database’s relationships diagram

4. Web site’s structure

The web site’s structure is presented in figure 3.

The start page is “Home Page” and all users, regardless of their membership to the research team, have full access to it. From this page, there are links to the project’s description page (History, Contact and all the public information pages).

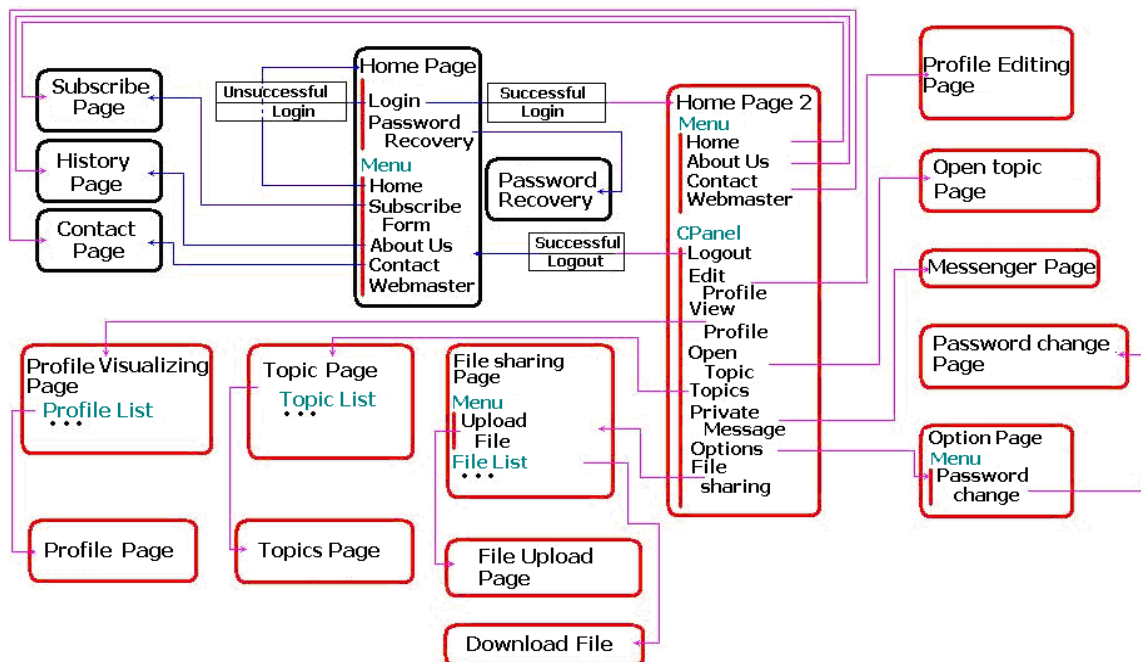

Figure 3 Operational communication web site's structure

Successful login offers a new home page with extended functions (Home Page 2), granting thus, in respect to the member's interest zone, access to specific information of the project. Accessible pages are: topic initialization page (Topic Open Page), specific topic responses (Topic Page). The person that starts a topic is the manager of the topic, granting specific access rights to the user for that topic. In addition, pages for files sharing were provided, which are useful in the project's documentation elaboration activity. To prevent switching between programs, a mailing page was created. Once the user account created there is the possibility of configuring it with identification elements (in the Profile Editing page), or of the password change (Option Page and Password Change Page). The system allows the password recovery with the site's administration assistance.

5. Conclusions

The designed web site ensures an operational communication between the members of a research team and an evidence of their activity regarding communication. This way the efficiency of the activities developed to reach the objectives, increases.

TECHNOLOGIES SOLUTIONS AND ORACLE INSTRUMENTS USED IN THE ACCOMPLISHMENT OF EXECUTIVE INFORMATICS SYSTEMS

Vatuiu Teodora

Universitatea "Constantin Brancusi" Facultatea de Stiinte Economice, Str.Stefan cel Mare, nr 1, Targu-Jiu, Gorj, Romania e-mail:vatuiu_teodora@yahoo.com

The role of a system for the control of the data bases and the facilities offered by it is highly important in the success and performance of an executive informatics system. From this point of view, the analyze will take into account the facilities of working with evolved data bases and storages of data, the implementation of some OLAP functionalities an data mining but also the integration of data and applications coming from different sources, the way in which the process of extraction, transformation and loading of this data in the final storages takes place, the easiness in administration and the instruments offered for the developing of interfaces.

One important point of this analyze refers to the performance in interrogation, both on operational data bases and the extraction of data from data storages.

The executive Informatics System, OLAP, Data Mining

1. Comparative analyze of the performances and facilities obtained by the available SGBD

Taking into account that the majority of organisations have already implemented applications of different generations on two big platforms of data bases, namely Oracle and Microsoft SQL Server, the comparison will be resumed to these two types of SGBD, and the current versions brought forward for analyze are Oracle Database 10g and Microsoft SQL Server 2005. Each of these two is available in different editions or variants in order to satisfy all the requests of the market.

Oracle Database 10g is available in five editions, each having implemented specific characteristics for each segment of the market:

- Oracle Database 10g Standard Edition One (SE1) is intended for business mediums with quite a low request of adaptation, departmental levels, being limited to maximum two processors;
- Oracle Database 10g Standard Edition (SE) is the superior variant of SE1, having also facilities of clustering with Real Application Cluster, still it is limited to a server with maximum four processors;
- Oracle Database 10g Enterprise Edition (EE) represents the most complex version, with control programs for big volumes of data in transactional mediums and critical applications. Optimizations in the extraction of data from storages, high security and administration;
- Oracle Database 10g Personal Edition (PE) is the edition designated for individual development of applications, being compatible with the other products, such as SE1, SE and EE. The advantage lies in the fact that it circulates on variant stations, with more processors, but it is limited to a single user.
- Oracle Database 10g Express Edition (Oracle Database XE) is a recently launched edition, free of charge, designated for business mediums with small and medium adaptation request, it can be installed on any station, but being a free edition, the data base dimension is limited to maximum 4 GB.

The majority of available editions contain advanced facilities of administration and security, such as clustering, partitioning, ciphering algorithms, control programs for users, control of resources, and optimization of data request. Both adaptation transactional methods and Business Intelligence options are implemented with the OLAP functionalities, data mining and the support for the construction of data storages. From the data integration point of view, services for the interconnection of data from external sources and systems and present.

2. Analyze of the Business Intelligence facilities and instruments offered by Oracle Database 10g vs. Microsoft SQL Server 2005

About the performance in the accomplishments of requests on relational data bases in a study carried out in June 2006 by *Transaction Processing Performance Council (TPC)*, at the performance test TPC-C V5 which evaluates the processing of transactions performances in the OLTP systems (on-line transaction processing) on the variant without clustering, Oracle Database 10g occupies positions 3 and 4, after IBM DB2 and ahead of MSSQL Sever 2005, and in the clustering variant Oracle Database 10g is the only possible variant with a score of 1,184,893 tpcm.

At the *TPC Benchmark H (TPC-H)* test, for the processing performances in the ad-hoc reporting, in decisional mediums *Oracle Database 10g* with Real Application Clusters obtained a new record of performance in what concerns data processing for a dimension of the data base of 3000 GB. This is a test of evaluating analytic processing characteristics, of extracting data through requests and concurrent modifications.

The performance unity of measurement is called *TPC-H Composite Query-per-Hour Performance Metric* and it reflects many characteristics of data processing. These include the data base dimension, the processing and modification of data speed. As a result, on a 64-Node HP ProLiant server, with dual-core AMD processor Opteron 2.4 GHz and Red Hat Enterprise Linux 4, Oracle Database 10g with Oracle Real Application Clusters established a new record of performance, with 110,576.5 QphH@3000GB, having a cost/performance rate of \$37.80/QphH@3000GB.

The Oracle Database 10 g performances are obvious also at a data base dimension of 300, 1000 and even 10000 GB, while MSSQL Server 2005 occupies positions 5 to 10. At a data base dimension of 100 GB, the roles are reversed, MSSQL 2005 being on the first positions.

Figure 1 -The score of performance tests

3. Instruments and technologies for the development of applications and business intelligence systems

The Oracle platform offers a series of instruments and technologies for the development of applications and business intelligence systems which can be used in the accomplishment of EIS.

These are grouped in a special class - *Oracle Business Intelligence* and have the following components:

1) Components for data storage and preparation for analyze:

- Oracle Business Intelligence Warehouse Builder (OracleBI Warehouse Builder) for the projection, implementation and maintenance of data storages;
- Oracle Business Intelligence Discoverer Administrator (OracleBI Discoverer Administrator) for the accomplishment and administration of a vision oriented on business of relational data;
- Analytic Workspace Manager for the structuring of data in the scope of an advanced analyzes.

2) Components for data analyze and reports accomplishment:

- Oracle Business Intelligence Discoverer Plus (OracleBI Discoverer Plus) for the accomplishment of ad-hoc reports;
- Oracle Reports for the accomplishment of detailed reports at the entire company level;

- Oracle Business Intelligence Spreadsheet Add-In (OracleBI Spreadsheet Add-In) for the analyze of data directly into a calculus Excel paper;
- Oracle Data Miner for the accomplishment of data mining process;
- Oracle Spreadsheet Add-In for Predictive Analytics for the accomplishment data mining process directly into Excel.

3) Components for publication and interaction with the created reports:

- Oracle Business Intelligence Discoverer Portlet Provider (OracleBI Discoverer Portlet Provider) for publication of reports in OracleAS Portal;
- Oracle Reports for the distribution and publication of reports in the organization's medium, on the Internet through the integration with E-Business Suite or OracleAS Portal;
- Oracle Business Intelligence Discoverer Viewer (OracleBI Discoverer Viewer) which bares the visualization of reports on the Internet.

4) Components for the applications' development:

- Oracle Business Intelligence Beans (OracleBI Beans) is a component integrated in Jdeveloper and it permits the development of JSP applications;
- Oracle OLAP allows the creation and application of analytical functions which can be used in the applications made with OracleBI Beans.

The architecture of Oracle Business Intelligence offered by the Oracle Corporation is presented in the following figure:

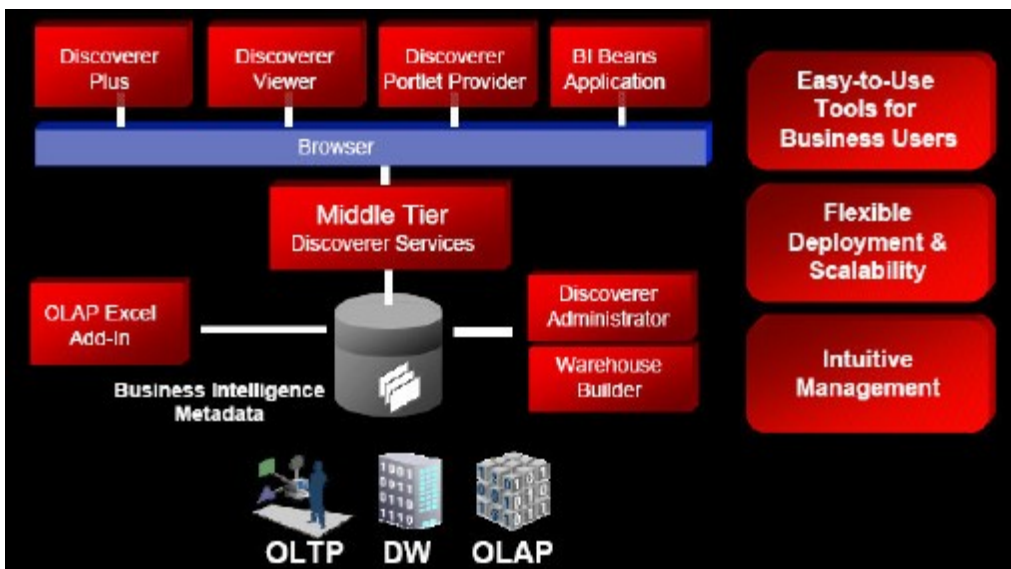

Figure 2 –Architecture of Oracle Business Intelligence [ORACLE Corporation]

Oracle Data Miner offers the possibility of accomplishing flexible applications with an intuitive graphic interface which can be easily modified by final users through the application of data mining algorithms and construction of predictable models of analyze.

As a result of the application of these models, a Java or PL/SQL code is generated. A series of applications can be built in order to apply the data mining process automatically.

In the following figures is presented the accomplishment of this kind of application (figure 3) and the obtained results (figure 4).

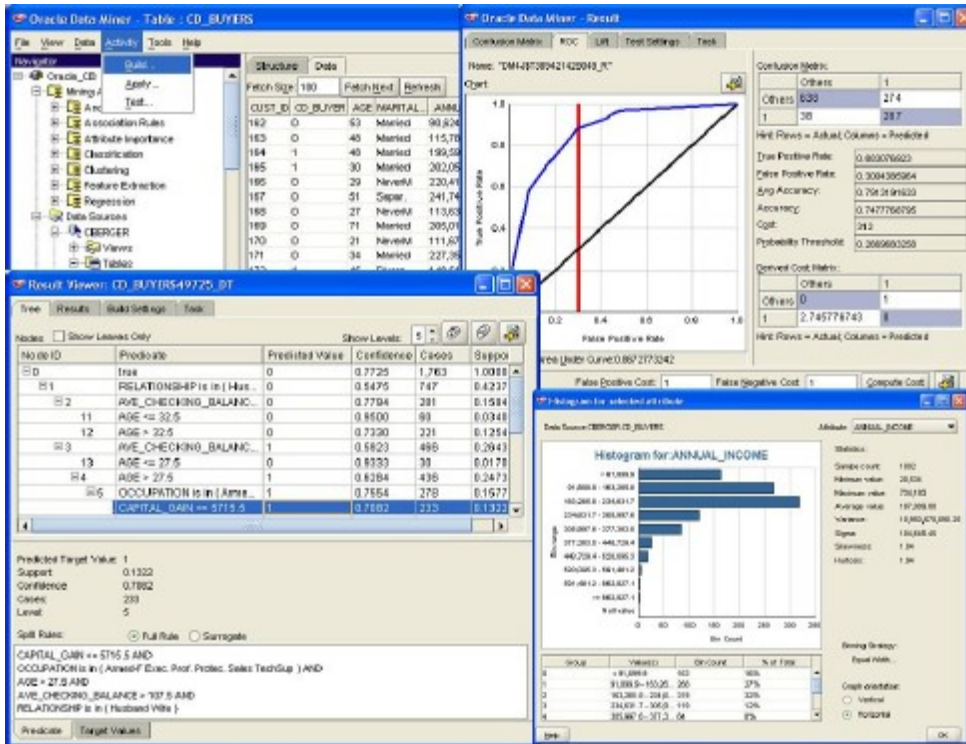

Figure 3: The construction of an application in Oracle Data Miner

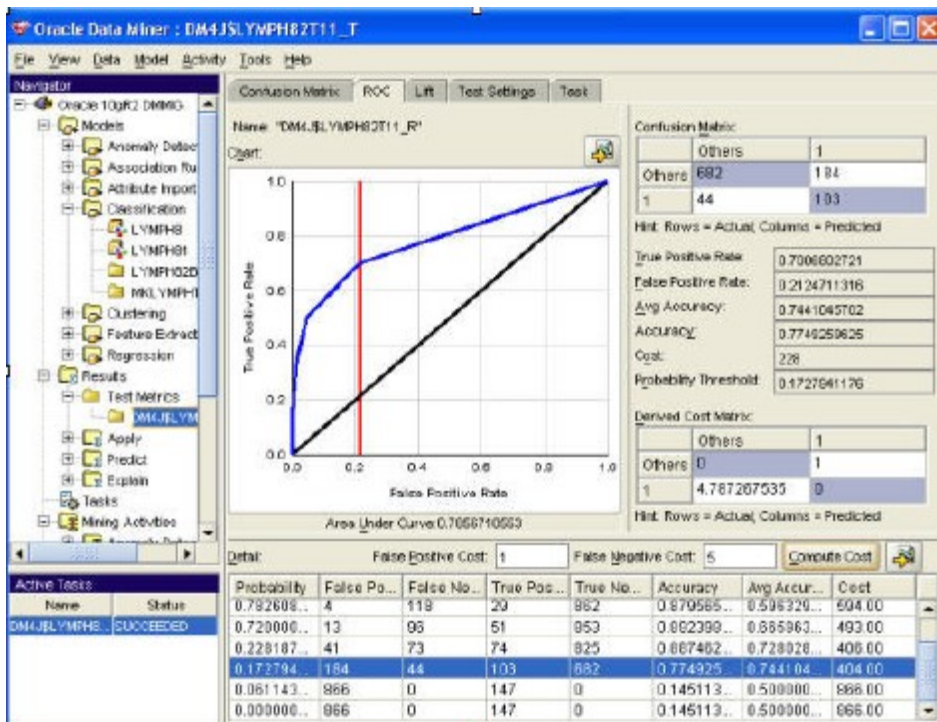

Figure 4: Results obtained after the application of data mining process

Oracle Data Mining permits the application of the following types of algorithms:
 Predictable models or supervised instruction:

- Algorithms of classification which suppose data grouping in different classes and then auto-classification of the new introduced values;
- Algorithms of regression – functions of approximation and of predicting the continuous values;
- Selection of the important attributes – the most relevant attributes of data is selected for the predictable results;

Descriptive models or unsupervised instruction:

- Clustering – discovery of grouping in data;
- Association rules based on the analyze of the “shopping cart”;
- Algorithms of extraction for the accomplishment of new attributes based on the existing ones;

-Models for multimedia (TEXT) and bioinformatics (BLAST)

Data necessary for the process are extracted directly from the Oracle data base, without being necessary their storage.

The Oracle components necessary for the accomplishment of a system for business intelligence bears the entire cycle of the system’s development which supposes the following steps according to ORACLE Corporation:

- Identification of the business requests coming from final users;
- Identification of data sources;
- Design of the data model;
- Accomplishment of the data storage;
- Generation of data;
- Preparation of data for the access of extraction and analyze instruments;
- Rendering of access rights;
- Distribution of reports and applications and catering of documentation.

Business requests can appear at all levels and departments of a company and the Oracle components allow the accomplishment of applications for the satisfaction of these requests:

- Board of administration: analyze of the key indicators for performance, analyze of the tendency of the organization’s development, exceptional reports;
- Planning and administrative analyze: investments, reorganization, allocation of resources, politics concerning human resources;
- The financial development: budgeting, consolidation, variance analyze, financial modelling, cash management, financial indicators;
- The commercial department: profitability, buyer’s profile, commercial profitableness indicators, sales analyze.

In order to ensure success in the competitive world of business, companies must accommodate the needs of their clients, partners, employees and capital owner. Companies that pay attention to the way their documents and information are administrated are more prepared to face cost reduction and can respond much faster to the changes occurred on Basically, it is all about information and controlling it and thus the response time is minimum to any inquiries or demands that come from inside the informational system of the company. So, you need an efficient document management. Software solutions that come to your aid, in order to optimize this process are Electronic Document Management System.

Key words: Management, document, efficient, efficiency, opportunity, safety, IT.

Introduction

In the modern economy the rate of changes occurred in this environment is becoming more rapid.

Organizations are being bombarded with more and more information, which they must manage accordingly so they can benefit from opportunities and avoid possible threats. More and more management specialists agree on the idea that information represents one of the most important resources of a company, that is why it must gathered, analyzed transmitted, stored in an efficient, opportune, clear and safe way. This is why companies give great importance towards developing IT systems capable of:

- manage information with low costs;
- allows receptors in real time to receive information needed in the decision making process;
- contributes to the fulfillment of the objectives of the organization;
- eliminates or reduces to a minimum a series of specific deficiencies of an IT infrastructure such as: filtering, distorting, short-circuiting informational circuits, overcongestioning this circuits or even their redundancy;
- ensure increase security for information.

A solution for developing IT system with the above mentioned characteristics is the IT systems for managing documents

Actual problems in managing documents

According to an IDC¹ study, done in the USA on 550 companies (small, medium and corporation) the following conclusions arose:

- a) a 68% percentage of the participants at this study have expressed their belief that efficient initiatives in the management of documents generates competitive advantage, profit and higher income;
- b) efficient management of documents influences client services;

- c) approximately two thirds of the participants at this study estimated that they will obtain cost reduction with almost 20%.

An electronic document management system offers organizations the necessary tools to create, manage, distribute and control efficiency electronic documents. Thus it is possible to solve complex problems generated by:

- a) a large quantity of documents found in the IT system;
- b) directing these documents towards the persons responsible with analyzing the information, the decision makers;
- c) the informational content of these documents and the way it is transmitted;
- d) searching for documents, respectively the information contained on them;
- e) archiving documents;
- f) bringing them up to date and analyzing the documents (working with different versions or copies;
- g) documents security.

In the following we will present a series of solutions offered by an electronic document management system:

a) Large amount of documents

Problems	Solutions	Advantages
Registering documents	Capturing all entrance sources: - Registration; - Fax; - E-mail; - Electronic files of any type.	Easy management of documents.
Marking up documents	Indexing documents: - manually; - automatic.	Eliminating the risk of losing any documents.
Slow and hard evidence	Creating document packages on the basis of just one common information.	Reducing the time for gathering and analyzing information.
	Associated documents: Each document will be linked to another.	Creating the premises for a fast search and found operation for the documents.
		Diminishing or eliminating major deficiencies of the IT system linked with over crowding of its circuits.
		A unitary procedure for classifying documents in the company.

b) Directing documents towards the receptors who analyze the information needed in the decision making process

Problems	Solutions	Advantages
Loosing documents	Finding in real time the place where the document is.	Decreasing the time for the decision making process.
		It reduces or even eliminates the probability of short circuiting voluntary or involuntary the IT circuits (through wrong sending of documents).
Over passing the deadlines of the documents because of: <ul style="list-style-type: none"> - issuing the, by the decision makers; - absence from the organization of the in charge person; - the jamming in an information point of the IT circuit. 	Launching in an automatic or manual mode, on pre-establish work flows or ad-hoc.	Eliminating the blocking in document handling.
Modifying IT circuits in the company on short term due to sharing responsibilities, occurred due to the changes in the organizational chart. Launching documents on other informational documents the right ones.	A rapid programming of the IT circuit in concordance with the management request. Delegating responsibilities from a managing point of view.	A flexibility of the IT system, rapid adaptive to the changes occurred in the environment, allows the sustainability of management delegation process, and offers more flexibility to management.
A delay in transmitting documents, respectively information to some receivers.	Announcing the management factors of the premises for not meeting the deadlines.	A real and permanent evidence of the delegated tasks.
		The possibility for a direct intervention in order to meet the approved deadlines.

c) The informational content of these documents and the way it is transmitted

Problems	Solutions	Advantages
Omitting unintentionally or intentionally of information.	Documents become typed.	A better fundament of decisions and/or increasing operating efficiency.
	Correlating the informational content from more documents.	
	Automatic generation of documents that present dynamically information (charts, tables) that realize correlation between other documents.	Allows the applicability of a management system through exceptions, a faster way to interpret information/

The receptor does not understand the information in the message.	Adopting a same format for documents, based on the receptor.	Increases the efficiency and the effectiveness of operations and decision making process.
A long time for gathering analyzing and transmitting information.	Automating and comprising operations.	The information opportunity increases and operating costs of the IT system are reduced. The premises for implementing and developing a management based on knowledge are instituted ² .

d) Searching for documents, respectively the information contained on them

Problems	Solutions	Advantages
Loosing an important amount of time for finding the desired documents.	Searching after certain criteria for documents.	Decreasing the duration of the informational-decision making process.
A wrong identification of documents and of their locations in which they are located.	Searching for documents according to the information existent on them	Finding very fast the desired information.
The found documents do not contain the desired information.	Placing documents into folders according to the contained information or their responsibility.	Eliminates the times allocated to classifying documents.
	An automatic classifications of documents based on their contained information	Putting into use the entire content of the documents.

e) Archiving documents

Problems	Solutions	Advantages
Insufficient space for storing documents	An automatic classifications of documents based on their contained information or any other criteria	Decreasing the duration of the informational-decision making process
High financial resources allocated to this activity.	Electronic saving of this documents	Reducing the expenses allocated for his activity.
Allocated time for this activity	An automatic classifications and storage of documents based on their contained information.	The impossibility of misplacing or loosing any documents.

f) Bringing them up to date and analyzing the documents (working with different versions or copies

Problems	Solutions	Advantages
An almost impossible evidence of revisions made to multiple versions of the document.	An automatic evidence for versions as well as operations (who, when and what was done).	Reducing the expenses for document multiplying.
High consumption of resources:	The circulation of an electronic	A clear evidence of the

<ul style="list-style-type: none"> • paper; • consumers for printers and copying machines. 	copy of the document inside the company, ensuring the integrity of the original document.	operations done on any document.
A high probability that instead of the current version of the document, on the workflow there is another version.		The possibility to keep or to delete the desired versions of the document.
Allocating manpower, time and resources for this activity.	Electronic archiving of this documents.	The existence of an exact replica of the original documents.
The danger of destroying and/or deteriorating over time or due to wrongful usage the documents.	The existence of an exact replica of the original documents.	The quick find of the archived documents.
The hard and slow process of finding existing documents in the archive.	Storing the electronic archive in different locations.	A strict control over the persons who have access to the archive.
High costs for reconstructing an original document lost or partially destroyed.	Automating archiving of documents due to the desired usage/conditions.	

g) Document security

Problems	Solutions	Advantages
The existence of risk that confidential information can be divulged.	Keeping documents safe.	Minimal cost allocated to documents security.
	Automatically settling some priorities for access to different level information based on structure and decision competencies.	Reducing the risk of divulging any information. The possibility to efficiently apply a management though exceptions with its specific advantages.
The possibility of loosing documents or them being stolen.	Ensuring the conditions imposed by the companies security policy.	Eliminating the ways though which the information can leak.
The possibility to forge documents.	A strict control of the exit ways of documents from the company : <ul style="list-style-type: none"> - Fax; - E-mail; - Printing. 	Eliminating the premises for altering the content of the documents.

UNE APPROCHE BASÉE SUR LA MÉMOIRE ORGANISATIONNELLE POUR LES SYSTÈMES INFORMATIONNELS

Vrîncianu Marinela

Académie d'Études Économiques de Bucarest, Roumanie, Faculté de Comptabilité et Informatique de Gestion, Adresse postale: Rue Saradei, no. 110, Bucarest-1, Roumanie, marinelavrincianu@yahoo.com, Téléphone :40216685895

Le concept de "mémoire organisationnelle" n'est pas nouveau mais, dans son acception courante, il répond à une problématique ancienne et récurrente, celle de la gestion des connaissances. Les défis d'une organisation qui entend mettre en place une mémoire organisationnelle sont difficiles à transcender, à cause d'un manque d'approche prescriptive sur ce sujet. Les systèmes informationnels de mémoire organisationnelle concernent le développement actuel d'outils de travail collaboratif permettant le transfert massif d'information au sein d'une organisation. Cette étude(1) présente ce que recouvre la notion de mémoire organisationnelle et (2) fait l'analyse des formes de représentation et des outils informatiques de développement d'une mémoire organisationnelle.

MOTS CLÉS: *Mémoire organisationnelle, base de connaissances, base de cas, Web sémantique*

1. INTRODUCTION

Capital immatériel (social, technique et culturel), la mémoire organisationnelle cartographie l'architecture cognitive d'une organisation, pour identifier, analyser, valoriser et préserver des connaissances (explications, prévisions, technologies), des informations (représentation des connaissances, idées, événements), des normes et des valeurs de groupe. Les motivations qui justifient la construction d'une mémoire organisationnelle peuvent être diverses (Barthès, 1999 ; Benayache,2005 ; Dieng, 2002):

- exploiter les acquis cognitifs des employés qui émergent au fil de la vie (valoriser l'expérience);
- éviter la perte de savoir-faire des spécialistes après leur retraite ou mutation;
- conserver les leçons du passé, afin d'éviter de reproduire certaines erreurs;
- exploiter la cartographie des connaissances d'une organisation à des fins stratégiques;
- améliorer la gestion des flux informationnels et la communication organisationnelle (susciter des connaissances utiles à l'action) et intégrer les différents savoir-faire d'une organisation;
- diffuser les meilleurs pratiques efficaces et conforter l'intuition et la créativité;
- améliorer l'apprentissage et l'intégration des nouveaux dans l'organisation.

Concept sociologique, la mémoire organisationnelle est intégrée par la communauté informatique dans le cadre théorique des systèmes de type OMIS (en anglais, Organizational Memory Information Systems). Une analyse des recherches dédiées aux systèmes de type OMIS relève la difficulté à solutionner les problèmes qui visent: la complexité de la modélisation d'un contenu diversifié ; la capitalisation des connaissances formelles et informelles, explicites et tacites ; le caractère hétérogène des sources de la mémoire organisationnelle ; l'existence d'un spectre large des définitions et des concepts associées à la mémoire organisationnelle et la nécessité d'articuler plusieurs points de vue: socio-organisationnel, économique, financier, technique, humain et légal dans la modélisation d'une mémoire organisationnelle. Cette étude réalise une analyse de la recherche empirique sur la mémoire organisationnelle des cinquante dernières années afin de mettre en évidence les principales tendances des choix théoriques et méthodologiques effectuées et l'impact de ces choix quant à la genèse et l'évolution de la connaissance dans le domaine. De façon plus spécifique, notre recherche apporte des réponses aux questions suivantes : « Quels sont les approches théoriques de base de la mémoire organisationnelle ? », « Quels sont les outils informatiques disponibles pour matérialiser cette mémoire ? », « Quelles implications pouvons-nous en tirer de cette analyse pour le développement des systèmes informationnels? ». En ce qui concerne la démarche méthodologique, nous avons utilisé : a) le recensement des ouvrages à analyser : consultation

systématique des bases de données bibliographiques en ligne; consultation progressive des ouvrages riches en références bibliographiques; consultation systématique des collections de revues spécialisées sur ce sujet ; b) l'élaboration d'un cadre d'analyse des travaux à analyser: prise en compte des critères d'analyse élaborés antérieurement dans d'autres recherches ; c) l'analyse des données, c'est-à-dire l'analyse de contenu et l'analyse descriptive.

2. Mémoire organisationnelle : une approche classique pour un concept encore émergent

Dans son acception courante, la notion de "mémoire organisationnelle" couvre l'ensemble des savoir et savoir-faire en action (Barthes, 1999) mobilisés par les membres d'une organisation pour lui permettre d'atteindre ses objectifs. L'actualité de ce concept résulte d'une prise de conscience d'un nombre important d'organisations que les acquis cognitifs détenus par leurs membres constituent un capital immatériel qui offre un immense avantage concurrentiel. Les approches existantes dans la littérature (El Louadi&Fourati, 2005) offrent une notion de mémoire organisationnelle qui varie en termes de contenu : informations pour (Walsh&Ungson, 1991), connaissances pour (Stein, 1995), paradigmes pour (Wijnhoven, 1999), compétences pour (Nonaka&Takeuchi, 1995). L'organisation considérée (Dieng et al., 2002) peut être une entreprise ou un organisme public, mais elle peut également se restreindre à un département ou à un service donné ; elle peut également consister en un groupe, une communauté, ou une entreprise virtuelle constituée de membres provenant éventuellement de différentes entreprises, rassemblés pour un objectif commun (par exemple, la réalisation d'un projet). (Ackerman&Halverson,2000) ont avancé l'idée de l'existence d'une mémoire supra-individuelle, peut-être même de plusieurs mémoires, totalement distribuées entre plusieurs individus et technologies.

La mémoire organisationnelle a été conceptualisée de différentes manières (Seville-Girod, 1996). C'est pourquoi nous considérons qu'il est nécessaire de revenir aux définitions de la mémoire données dans les premiers travaux sur la cognition organisationnelle. Selon (Cyert&March, 1967), la mémoire organisationnelle est l'ensemble des procédures standards opérationnelles. D'après (Argyris&Schön, 1978), (Weick, 1979), elle est un ensemble de cartes cognitives collectives. Pour (Van Heijst et al., 1996) elle est une représentation explicite, persistante, et désincarnée des connaissances et des informations dans une organisation. Selon (Muller, 1997) elle représente un ensemble de données collectives et des ressources de connaissances d'une organisation. Pour (Polanyi, 1967 ;Dieng, 2002), la mémoire organisationnelle est un ensemble de connaissances explicites (connaissances transmissibles dans un langage, qui peuvent être énoncées, communiquées et capturées dans un écrit ou exposé, dans des documents, bases de données, etc.) et tacites (connaissances connues sans en avoir conscience, difficiles à énoncer, formaliser et communiquer par le langage).

Le développement d'une mémoire organisationnelle repose sur la volonté de préserver, afin de réutiliser les raisonnements, les comportements, les connaissances, même en leur contradiction et dans toute leur variété (Pomian, 1996). (Walsh&Ungson, 1991) considèrent que la mémoire organisationnelle ne se limite pas aux mémoires humaines puisqu'elle s'étend aux archives, aux procédures de travail, à la structure organisationnelle et à la culture de l'organisation. Dans leur modèle, (Walsh&Ungson, 1991) considèrent que la mémoire organisationnelle vise six éléments: les individus, la culture, les transformations organisationnelles, les structures, l'écologie organisationnelle et les archives externes (El Louadi, 2004 ;2008). (Ackerman, 1996) souligne le fait que les dépôts d'information tels que les manuels d'utilisation, les bases de données, les systèmes d'archivage manuels et même les anecdotes devraient également être inclus dans le construit d'une mémoire organisationnelle. Selon El Bortef, cité par (Dieng, 2002), on peut distinguer dans la structure d'une mémoire organisationnelle cette typologie des connaissances: compétence (*savoir-agir responsable et valide*) ; savoirs théoriques (concepts, schémas, connaissances disciplinaires, connaissances sur les processus, connaissances sociales, connaissances organisationnelles, connaissances sur les produits/matériels) ; savoirs procéduraux (« *comment-faire* » pour une action) ; savoir-faire procéduraux (permettant, après l'entraînement d'appliquer lors de l'action les méthodes, procédures connues grâce aux savoirs procéduraux); savoir-faire empiriques (comprenant les leçons tirées de l'expérience pratique) et savoir-faire sociaux.

D'une façon presque générale, les concepts énumérés ci-dessus ont été proposés et utilisés dans d'autres disciplines (sociologie, management et psychologie cognitive). L'utilisation d'outils informatiques pour matérialiser une mémoire organisationnelle modifie intrinsèquement les approches et les structures

traditionnelles. D'une part, ils facilitent l'existence des communautés cognitives (Crepet, 2004) et leurs interactions réciproques et d'autre part, ils favorisent la perméabilité des frontières cognitives internes et externes.

3. Mémoire organisationnelle : formes de matérialisation et outils de développement

Depuis le début des années 90, plusieurs techniques ont été adoptées pour la construction d'une mémoire organisationnelle. Elle peut être non informatisée (une publication sous forme de document de travail, un livre, une exposition de photographies, un film, une cassette audio) ou être matérialisée sous forme logicielle (Dieng et al., 2002). Le choix d'une solution technique dépend du type d'organisation, de sa taille, de ses besoins, de la culture organisationnelle, de l'environnement de travail des acteurs concernés par la mémoire. Les technologies d'information et de communication (TIC) assurent l'infrastructure et les outils pour matérialiser cette mémoire dans une diversité de formes qui sera analysée dans la suite:

a) Mémoire documentaire

Une mémoire documentaire se matérialise par un système documentaire exploitant les documents existants de l'organisation (Bahoul, 2006 ; Dieng et al., 2000). Les approches de la mémoire documentaire existantes dans la littérature présentent des systèmes de consultation de documents techniques ou exploitent des techniques d'ingénierie documentaire (catalogage, analyse et indexation) et hypertexte (Dieng et al., 2002).

La construction d'une mémoire documentaire implique les étapes suivantes (Dieng et al., 2002) :

- Le choix des fonds documentaires qui seront intégrés dans la mémoire (pour déterminer les documents qui devront faire partie de la mémoire) ;
- La numérisation des documents qui consiste en la transformation des documents papier en documents électroniques (à l'aide des systèmes de type OCR ou des scanners) ;
- L'homogénéisation éventuelle du format des documents suivant leur nature (selon le cas, on peut adopter des formats bureautiques classiques (Excel, Word, Lotus), des formats structurés (SGML, XML) ou des formats pour le WEB (HTML) ;
- L'élaboration éventuelle de nouveaux documents (dans le but d'intégrer des documents décrivant les savoir-faire d'experts) ;
- L'indexation des documents (pour faciliter la recherche d'information) qui consiste en la utilisation des différents types d'index : index intégral, index relatif au domaine des connaissances capitalisées, index relatif aux activités de l'organisation ou un thésaurus spécialisé.
- Le choix de l'organisation de la mémoire documentaire (la mémoire documentaire doit être organisée, mise en forme et structurée pour être accessible aux utilisateurs) ;
- L'utilisation d'un système de gestion électronique de documents pour permettre la préparation des documents, la recherche documentaire, l'ajout ou la retraite d'un document. Ce type de système couvre, en général, tout le cycle de vie de certains documents de l'organisation ;
- La mise à disposition des documents dans l'intranet de l'organisation (utilisant un moteur de recherche avec des facilités de traitement linguistique).
- L'évolution de la mémoire vise le mode de collecte de nouveaux documents qui seront intégrés dans la base documentaire. Cette collecte peut être active ou passive du point de vue de l'organisation, centralisée dans un service ou répartie entre les membres de l'organisation.

b) Mémoire à base de cas

Le raisonnement à partir de cas est un paradigme de résolution de problèmes qui vise à trouver, pour un problème présent une solution construite en réutilisant une solution mémorisée d'un problème similaire au problème actuel. Chaque organisation dispose d'un ensemble d'expériences antérieures (succès ou échecs) qui peuvent être représentées et enregistrées dans une base de cas (chaque expérience pourra alors être décrite dans un cas). Toute nouvelle expérience peut être mémorisée dans la base de cas la rendant immédiatement disponible pour les problèmes futurs. Ce type de système a la capacité d'établir une relation entre le passé et le présent dans une perspective de valorisation de l'expérience. D'une façon générale, un cas contient au moins deux parties : une description représentant "un problème" et "une solution" utilisée pour remédier à cette situation. Ce type de système offre la possibilité de capitaliser

l'expertise d'une organisation. Le raisonnement à partir de cas est particulièrement bien adapté pour les applications ayant les caractéristiques suivantes (Oumar, 2005) :

- les situations qui seront formalisées sont répétitives et les solutions sont réutilisables ;
- le domaine est mal formalisé (peu de documentation, expert non disponible) et un modèle du domaine ne peut pas être élaboré ;
- les expériences sont disponibles dans une base de données, dans des documents ou chez un expert humain ;
- une analyse détaillée du domaine n'est pas nécessaire pour obtenir des solutions satisfaisantes et la tâche n'exige pas une solution optimale;

c) Collecticiels

Le concept de Travail Coopératif Assisté par Ordinateur (en anglais, *Computer Supported Cooperative Work -CSCW*) recouvre les systèmes interactifs multiutilisateurs permettant à plusieurs utilisateurs de travailler ensemble. Les termes *collecticiel* (en anglais, *groupware*) et *synergiciel* désignent ce type de système interactif.

Les principales fonctionnalités des collecticiels (Dewan, 2001; Parrend, 2005) qui peuvent favoriser la construction d'une mémoire organisationnelle sont : l'interaction individuelle ; le couplage (effet d'action d'un utilisateur sur la présentation des autres); faire-défaire (undo) ; trouver des différences dans les versions indépendantes d'un objet (en anglais, *diffing*) ; combiner des version indépendantes d'un objet unique (*merging*) ; contrôle d'accès (gestion des droits des auteurs, autorisation d'action); contrôle de concurrence (prévenir l'inconsistance d'actions effectuées simultanément); gestion du processus du déroulement d'interventions et d'actions (en anglais, *workflow*) ; conscience de l'autre (en anglais, *awareness*; rendre compte des activités des autres afin de partager une perception rendant compte de l'évolution globale du travail collectif); gestion de session : gestion des arrivées et des sorties des différents acteurs dans une session de travail collaboratif.

(Nigay, 2008) groupe les collecticiels en quatre catégories qui sont : (1) les applications dédiées à la communication homme-homme médiatisée (en anglais, *Computer-Mediated Communication*) qui visent les messageries électroniques, les forums de discussion, les systèmes de vidéoconférence et les *mediaspace* ; (2) les applications d'édition qui regroupent les éditeurs de texte et les tableaux blancs partagés ; (3) les applications pour la coordination qui rassemblent des systèmes *workflow*, les systèmes d'aide à la décision et les calendriers partagés, (4) les applications de jeux en réseau.

Selon (Nigay, 2008) il y a des différents types de collecticiels qui favorisent la communication et le travail coopératif assurant la création et la diffusion d'une mémoire organisationnelle:

- *Les messageries électroniques (e-mail)* : qui sont actuellement les collecticiels les plus répandus et les plus utilisés, la grande tendance dans ce domaine étant celle de la messagerie instantanée.
- *Les forums de discussion (chat et newsgroup)* diffèrent par leur mode d'utilisation, synchrone ou asynchrone. La première classe regroupe les forums en ligne du type IRC (*Internet Relay Chat*), des applications très répandues qui reposent sur le concept de canal de discussion. La seconde classe rassemble des listes de diffusion (*mailing list*) et des *newsgroups* pour des discussions asynchrones sur un thème donné.
- *Les systèmes de vidéoconférence* permettent à des personnes physiquement distantes de se réunir et communiquer par l'intermédiaire d'un support audio et vidéo. Il s'agit d'un forum de discussion offrant une communication reposant sur des données audio et vidéo à l'opposé des forums de discussion du point précédent qui se basent sur des échanges textuels.
- *Les mediaspace* sont des collecticiels mettant en œuvre une liaison vidéo au sein d'une équipe dans le but de favoriser la communication informelle et d'entretenir une conscience de groupe forte entre membres distants. Ce système immerge des utilisateurs dans un espace en trois dimensions. Les utilisateurs sont observables à travers une vignette vidéo collée à l'extrémité d'une forme géométrique longiligne.
- *L'édition conjointe (en anglais, shared editing)* est assurée par les éditeurs partagés qui sont des systèmes dédiés à l'édition collaborative de documents avec gestion des différentes versions. Les éditeurs de texte partagés ou les éditeurs de dessins partagés comme les tableaux blancs partagés (*shared whiteboard*) sont des exemples de collecticiels permettant l'édition conjointe.

- *Les systèmes workflow* sont des systèmes dédiés à la gestion de processus industriels et à la coordination des différents intervenants au cours d'un processus. Le logiciel de workflow doit permettre de répondre aux questions "qui fait quoi, quand et dans quel but", la logique pour déterminer dynamiquement les itinéraires au moment de l'exécution d'une tâche et des exceptions aux règles.
- *Les calendriers partagés (en anglais, group calendars)* sont des systèmes qui offrent des services de planification de tâches, de gestion de projets et de coordination de membres d'une équipe de travail. Les fonctionnalités usuelles incluent la détection d'incompatibilités dans la planification d'une tâche ou la détermination de plages horaires communes aux membres d'un groupe (ex : Lotus/Organizer est un outil de planification collaborative).
- *Les systèmes d'aide à la décision (en anglais, GDSS-Group Decision Support Systems)* fournissent un soutien aux décideurs durant le processus décisionnel. Ces systèmes utilisent des modèles analytiques, des bases de données spécialisées, des idées et des jugements du décideur, et un processus informatisé de modélisation interactive en vue de soutenir chaque décideur lors de la prise de décisions semi-structurées et non structurées (Nigay, 2008). Ils sont donc conçus pour fournir des réponses rapides et ad-hoc et pour faciliter la prise de décisions grâce à l'apport de nombreux outils : brainstorming, votes, pondération des décisions, génération et annotation des idées, etc. Les bases de données multidimensionnelles (hyper cubes) généralement utilisées de manière décisionnelle, peuvent constituer une forme de matérialisation de la mémoire organisationnelle exploitable par l'approche OLAP. Un entrepôt de données c'est un outil décisionnel caractérisé par des données orientées métier (qui peuvent constituer un support pour la matérialisation de la "mémoire métier") ou business (une autre forme de matérialisation de la "mémoire société") en accord avec la typologie de la mémoire organisationnelle proposée par Tourtier (Tourtier, 1995)

d) Mémoire à base de connaissances

L'ingénierie des connaissances permet la construction d'une mémoire organisationnelle basée sur l'acquisition et la modélisation explicite des connaissances de certains experts de l'organisation. Au lieu de viser une résolution automatique pour une tâche (élément spécifique aux systèmes experts qui possèdent capacités automatiques de raisonnement), une mémoire organisationnelle doit plutôt aider l'utilisateur, en lui fournissant des informations appropriées de l'organisation mais en lui laissant la responsabilité d'une interprétation et d'une évaluation contextuelles de ces informations (Dieng et al, 2002 ; Benayache, 2005 ; Kühn et Abecker, 1997). La mémoire organisationnelle peut intégrer une base de connaissances formelle représentée dans un formalisme de représentation des connaissances tel que les formalismes objets, les réseaux sémantiques ou les graphes conceptuels, etc. Le niveau de détail visé par la modélisation des connaissances est variable. Selon le cas, il pourra s'agir de (Dieng *et al*, 1998 ; Benayache, 2005) :

- *Un annuaire des compétences*-qui permet de construire une cartographie des compétences de l'organisation pour identifier les types d'activités, le contexte dans lequel un expert est consulté, les compétences individuelles, la localisation de ces compétences, etc.
- *Une base des meilleures pratiques*-qui est représentée par une base de connaissances sur les "meilleures pratiques" pour certains métiers d'entreprise (Dieng et al., 2002). Une telle base vise des connaissances en provenance de multiples sources à la fois internes et externes.
- *Un livre de connaissances* : celui-ci consiste en un document contenant les descriptions textuelles et graphiques des modèles de connaissances obtenus après la modélisation des connaissances de certains experts de l'organisation (Ermine, 1996 ; Benayache, 2005). Le livre de connaissances peut être organisé sous forme d'un hyper-document, avec des liens vers d'autres sources d'information de l'organisation. Les techniques de gestion d'une mémoire documentaire peuvent alors s'appliquer au livre de connaissances, une fois celui-ci mis sous forme de documents. Les méthodes d'ingénierie des connaissances peuvent être adaptées pour construire une mémoire à base de connaissances: a) une méthodologie descendante (ex : CommonKADS) proposant des modèles génériques à partir desquels on peut interpréter les données recueillies des experts ; b) une méthodologie ascendante (ex : KOD) où, partant des données du recueil, on les abstrait de façon à construire des modèles ; c) une méthodologie mixte, combinant les approches ascendante et descendante.

e) *Mémoire hybride*. Dans le cadre d'une mémoire organisationnelle matérialisée dans des documents, on peut associer à de tels documents une connaissance formelle sur laquelle pourra être effectué un raisonnement afin de rechercher les documents adéquats ou les parties adéquates du document (Dieng et

al., 2002). Il s'agit d'un Web sémantique, qui désigne un ensemble de technologies visant à rendre le contenu des ressources du World Wide Web, grâce à un système des métadonnées formelles, utilisant notamment les protocoles et les langages standards du Web : le protocole HTTP, les URI (Uniform Resource Identifiers), le standard XML. À ces standards s'ajoutent ceux qui sont propres au Web sémantique : RDF, RDF Schema, OWL, SPARQL. La connaissance formelle peut représenter une partie du document ou peut consister en des méta-informations sémantiques sur le document qui contiennent des informations supplémentaires non explicites. La recherche documentaire des documents accessibles par le Web, annotés sémantiquement, peut être guidée par une ontologie.

4.CONCLUSION

Les organisations vivent dans un environnement hétérogène, dynamique et en cours d'évolution qui mène souvent à des changements externes et internes requérant l'évolution de leur mémoire organisationnelle. Peu de recherches actuelles font face aux changements et fournissent des facilités de maintenance pour les systèmes de mémoire organisationnelle. Du point de vue opérationnel, il est nécessaire d'exploiter les avantages des technologies de l'information et des communication dans le but de développer les échanges de savoir-faire, de créer des communautés de pratiques en utilisant les potentiels apportés par les nouvelles technologies et d'inventer de nouvelles formes de travail coopératif au travers des réseaux électroniques. Pour assurer l'apprentissage organisationnel, la mémoire organisationnelle (1) doit être étendue et mise à jour pour soutenir les pratiques de travail ; (2) doit être continuellement réorganisée pour intégrer les nouvelles informations et les nouvelles préoccupations, et (3) doit stocker des informations pertinentes pour une nouvelle tâche à accomplir.

THE AFFORDABILITY AND THE FISCAL PRESSURE – MAIN INDICATORS IN CAPITALISING THE DECISIONS OF THE PUBLIC MANAGER

Petru Filip

University of Oradea, Faculty of Economics

Abstract: The paper's objective is to present the affordability and the fiscal pressure, essential indicators, in our opinion, in capitalising every local community's fiscal policies, specific to the natural person and legal person tax payers. Therefore, these indicators must be considered when arguing the public manager's decisions in order to follow the pressure that the local taxes and fees owed by the natural person tax payers are exercising on the family budgets.

Key words: affordability, fiscal pressure, public management, public services

JEL code: M1, H3, H4,

General considerations

The importance of the income and expenditure budget for the financial management of a local community is such an obvious reality that it is not necessary to be underlined.

Generally, a public budget is conceived as “architecture of values” and it is the place where the collections confront the payments, budgetary surpluses or deficits might result.

Therefore, the problem a public manager might encounter is to maximize the incomes of the local budget, to streamline the costs of the public services that he/she must ensure to the citizens of the community and to make the most realistic decisions for the capacity of own citizens to cover their fiscal obligations to the incomes of that particular community's budget.

The budget's classical structure gives the possibility to make the calculation for a series of indicators regarding the incomes and expenditures, the most important being the scissors effect according to which the local communities' own incomes with an increasing tendency, in a certain period of time T_n , intersect with the levies from the state budget with a decreasing tendency.

The significance of the T_n moment is important for the financial management from several perspectives.

-it indicates the existence of possible treasury gaps due to the decrease of the sums received from the state budget but also to some possible syncope in the process of fee and tax payment by the tax payers of that particular community

- T_n is the moment when the public manager must decide whether the local fiscality can be borne by the tax payer or it is inhibiting

The scissors effect is very important for the financial management for in the moment T_n the local budget's availabilities are affected, occurring the tendency of own incomes increasing in the same time with a strong diminishing of the levies from the state budget. Without detailing too much, we will mention that the T_n moment has **multiple meanings** for the public manager:

- a) it indicates consolidation of the **financial independence** up against the central budget, which must be compulsorily followed by a transfer of fees, taxes and shared taxes portfolio;
- b) it indicates an increase of **own incomes** either as a result of a fiscal policy based on an increase of the taxation rate or, on the contrary, as a result of the support of local economic development we are witnessing a fiscal policy based on an extension of then taxation basis;
- c) the T_n moment can be accompanied by a significant increase of the **capital incomes** as a compensation measure of the policies based on the continuous increase of the taxation rates.

Together with the scissors effect and the indicators determined based on the income and expenditure budget, we consider the two indicators mentioned above: the affordability and the fiscal pressure to be useful for the “dashboard” of the financial management.

The affordability and the fiscal pressure

A recently introduced concept in the Romanian specialty literature²⁶⁴, affordability means the pressure that the local fees and taxes owed by the natural person tax payers exercise on the family budgets. Thus defining affordability, it results that its defining elements contain:

- the local fees and taxes owed by the natural person tax payers from the estate duty (building tax, land tax, car tax etc.);
- the family budget resulted from the statistic surveys, a indicator usually communicated by the County Statistic Boards;

For the financial management it is important to know the calculation “technique” of this indicator starting from the following model:

$$Af = \frac{It, l / inh}{Bft}$$

Where:

Af – affordability

It,l / inh – local taxes and fees /inhabitant

Bft – family budget during the t period

$$It, l / inh = \sum_{i=1}^n \frac{It, li}{Np}$$

Where:

It,li – local taxes and fees resulted from the budget execution

Np – number of population

Relatively simple to determine, the traceability of evolution and of the weighting that the fiscal incomes have in the family budgets is important in order to establish the type of fiscal policy to apply to the natural person estate duty.

The graph below is representative in this view:

Figure 1 – The Af and Paf/Bf evolution during the t period

²⁶⁴ USAID – Studiu privind credibilitatea financiară și descentralizarea administrațiilor publice locale, 1997, București

The following situations occur:

I) A tendency to increase the affordability value during a t period of time, followed also by an increase of the weighting of the affordability value in the family budget indicates the existence of a fiscal policy on the rise and may be the result of:

- a) the increase of the taxation rate (ri), a negatively appreciated thing by the tax payers, the yield of the collections from taxes and fees being also endangered;
- b) the increase of the taxation basis (Bi), as a result of the support of a sustainable economic development;

II) A tendency to diminish the affordability value and its weighting in the family budget is the result of a relaxing fiscal policy having as potential causes:

- a) a decrease of the taxation rate (ri) followed, up to a certain level, by an increase of the yield of collections and it is based on a fiscal policy considered to be favourable by the tax payers;
- b) a diminishing of the taxation basis, considered unfavourable, with a negative impact on the local economic development.

No matter the evolution of the indicator – affordability – I consider that, when establishing the fiscal policies for the natural person tax payers, it must have a deciding role in capitalising the type of fiscal policy to be implemented during a financial year.

The fiscal pressure – the second spectator in capitalising the fiscal policy decisions

The affordability and the fiscal pressure are main indicators in arguing the fiscal policies of every local community, specific to natural person and legal person tax payers. The fiscal pressure, determined as a ratio between local taxes and fees, owed by the legal person tax payers as estate duty, land tax or the car tax and the added value has a relatively simple mathematical expression, yet the calculation technique is relatively complicated, being an expression like:

$$Pf = \frac{\bar{It}, l / \text{contr}}{\bar{V}_{At} / \text{contr}}$$

Where:

Pf – fiscal pressure

$\bar{It}, l / \text{contr}$ - local taxes and fees per legal person tax payers during the t period of time

$\bar{V}_{At} / \text{contr}$ - average added value per tax payer

Establishing the average taxes and fees per legal person tax payer is a mathematical attribute, being used a relation like:

$$\bar{It}, l / \text{contr} = \sum_{i=1}^n \frac{It, li}{Nci}$$

The added value, in turn, belonging to the category of intermediary balances of administration²⁶⁵, is known in the specialty literature as remuneration source, including of the local budget, in the forms of the priority tax, being established according to a relation like:

$$\bar{V}_{At} / \text{contr} = \frac{\sum_{i=1}^n (Q \text{ ex } i - C \text{ tertii})}{Nci}$$

Replacing the relations from above in the fiscal pressure formula, it is obtained:

²⁶⁵ *Georgeta Vintilă – Gestiunea financiară a întreprinderii, Ed. Economică, București, 2003, p. 152*

$$Pf = \frac{\sum_{i=1}^n I_{t,li}}{\sum_{i=1}^n (Q_{ex\ i} - C_{terti\ i})} \times 100$$

It is important, in my opinion, to establish the manner to interpret the fiscal pressure in comparison with the fiscal policies, two situations, as in the case of affordability, being encountered:

I) The value of the fiscal pressure follows an upward trend and the weighting of the fiscality in the added value is increasing and it has as causes the following:

- a) an increase of the taxation rate (r_i), a situation usually appreciated as being unfavourable by the tax payers, even though it can be the consequence of an underestimation of the value of the taxable basis;
- b) an increase of the taxation basis (B_i) reflects a favourable situation, determined by the support of a sustainable economic development, through implication modalities presented in the previous paragraph.

II) The value of the fiscal pressure has a descending evolution and a weighting of the fiscality in the added value which also follows a descending evolution, has as causes:

- a) a diminishing of the taxation rate (r_i), a result of relaxing fiscal policies, favourably appreciated by the tax payers;
- b) a diminishing of the taxation rate (B_i) with most unfavourable consequences on the local economic development.

I am convinced that the two indicators, beyond the hardships encountered by the mathematic calculus or the interpretation of the values, will represent an orientation guide for the manager interested in obtaining the best performance for the fiscal policies, so that the ration between the values of the budget debts and collections register as low as possible values.

Conclusions

In the analysis of the financial management assumed at a certain interval of time by a public administrator (public manager) it must be considered the degree of affordability of the fiscal “burden” by the citizens of the local community, either it is about natural persons or legal entities (economic entities). If this reality does not represent a major benchmark in the field of public incomes, it is certain that the capitalization of own incomes achievement is wrong from the point of view of the tax payer’s financial capacity to pay off his/her legal obligations to the local budget, with repercussions on the chapter of public expenses fulfilment engaged at the beginning of the budget period.

DIAGNOSIS ANALYSIS –THE FIRST STAGE IN DRAWING UP LOCAL STRATEGIES

Petru Filip

University of Oradea, Faculty of Economics

Abstract: The paper intends to present the manner in which the public services diagnosis is made, taking into consideration the complexity of its making. The making of the public services' diagnosis is determined on one hand by the number and diversity of public services ensured by the local authorities, and on the other hand, by the extremely high number of service operators and also by the different forms of organization that these have. We consider that the best way to achieve the public service diagnosis is yet the consultation with the public opinion as a beneficiary of these services. We appreciate that the diagnosis analysis would not be finished if a general conclusion regarding the activity performed by the local communities were not made, a reason for which we recommend that each type of diagnosis made should be appreciated with ratings.

Key words: diagnosis analysis, juridical diagnosis, economic-financial diagnosis, public service diagnosis, management diagnosis, human resources diagnosis.

JEL Code: M1, H3, H4,

General considerations

As a specific management technique, the **diagnosis analysis** consists in investigating the organization²⁶⁶ and its competences, in order to emphasise its strengths and weaknesses, to evaluate the potential and to word out recommendations, based on causes generating dysfunctionalities and positive aspects.

In other words, the **diagnosis analysis** means setting up the strengths, the weaknesses, the advantages and the opportunities for the Romanian local communities, following that later, based on the established objectives, all the resources necessary to achieve them are used, in due time and according to the measure plans approved.

The SWOT analysis is a good opportunity to reflect on the opportunities that they have, the local communities (for example a certain utility network endowment, the disposal of certain natural resources inexistent in other areas) to make them attractive from the perspective of the investors. We must not forget also the advantages that may wear different forms, from the attractive cost of the labour force to a certain degree of the latter's specialization or the production of material resources in a certain place, all are examples of advantages representing a **potential of benefits** for the local communities.

Opportunities-advantages

The **opportunities-advantages** relation must be quantified together with the emphasis of the dysfunctionalities and the wording out of recommendations at the level of collectivities, for only in this way, I consider, that the chances of the strategy to be implemented in the interest of the community, are maximal.

Beyond the diagnosis typology consecrated in the speciality literature, I appreciate that for the local communities the following categories of diagnoses are very useful:

- **the juridical diagnosis** has as main purpose to appreciate the capacity of the local communities to implement the legal norms no matter their form: laws, decrees or decisions, for their mission is to ensure public services based on the resources collected, cannot be fulfilled if the compliance with the general interest norms is not ensured.

Yet, which are the criteria that can be used to make the **juridical diagnosis**?

Among the criteria I recommend to be used, I mention:

²⁶⁶ Ovidiu Nicolescu (coordinator) – *Strategii manageriale de firmă, Ed. Economică, București, p. 186;*

- the volume of regulations that the local authorities have to implement (the emphasis of the degree of bureaucracy);
- flexibility in implementing legal regulations;
- promptness, expressed in terms of answer to the citizens' claims;
- the volume of actions, determined by the implementation of legal norms.

It is obvious that the experts will be able to identify other criteria, too, but, in my opinion, those mentioned above are relevant when wording out an authorised diagnosis on the feasibility of the juridical system that the local authorities have at a certain moment.

- **the economic-financial diagnosis**, an important component of the general diagnosis and it has in view the appreciation of the **state of performance and of the financial position of each community**, and considering the reform of the public accounting system, through the transition from the cash accounting to the engagement accounting, it is possible to calculate and use some indicators reminding of:
 - the economic-financial potential of the local community (expressed in liquidity and solvency indicators);
 - the capacity to invest in the investments;
 - the capacity to contract the debts (borrowed sources);
 - the size of the result of the financial year and the budget execution;
 - the ratio between own incomes, borrowed or pulled out, but also the ratio between the operational expenditure and capital, to be able to characterise the financial policies and those regarding the use of the resources at the level of local communities.

For this type of diagnosis, too, other criteria and indicators can be conceived. It is essential in my opinion the need to detect the best those indicators characterising the financial position and performance of that community and also in comparison to other communities.

- **the public service diagnosis**, the most important aspect of the general diagnosis of a group, for, as we have underlined several times, the mission of the local authorities is to ensure public services in the interest of the inhabitants. The public services must be appreciated both from the perspective of their quality and from the perspective of endowment with the necessary equipment in order to be provided.

Certainly, there are criteria that can be used to make the diagnosis of the public services, but, I consider that in the category of the most important services the following can be included:

- the volume of the public services provided by the local authorities;
- the number of complaints **recorded** for the quality of the public services provided;
- the number of the complaints **solved** during a period of time;
- the frequency of the disconnections in providing public services and the evaluation of the causes determining them;
- promptness in the service operators' intervention in solving the complaints;
- the size of the financial performance and the economic-financial potential recorded by the service operators;
- the frequency of equipment endowment of the service operators;
- capital expenses allotted to renew the material base that the service operators have.

The complexity in making the public service diagnosis is determined on one hand by the number and diversity of the public services ensured by the local authorities and, on the other hand, by the extremely high number of service operators and the different ways of organization that these have.

I consider that the best way to make the public service diagnosis is to consult the public opinion, as a beneficiary of these services.

- ✓ **the human resources diagnosis** has in view the appreciation of the performance obtained by the public servants in providing public services, knowing the fact that their status, the remuneration and promotion policy are regulated by law ²⁶⁷.

Therefore, I recommend as criteria for this type of diagnosis:

- the quality of the public servants considering the ratings obtained regarding their professional performance (evaluation usually annually);
- the servants' promotion policy, in compliance with the seniority and education requirements regulated by law;
- the motivation policy, based on the bonuses and incentives, can be given according to the performance obtained by the public servants in the activity performed.

Lastly, the last type of diagnosis recommended for the general diagnosis is the **management diagnosis**, usually appreciated based on their own unit that the local authorities, service operators or the officers providing public services have.

The quality of the public services provided depends on making this diagnosis, in the category of appreciation criteria being:

- the capacity of the local authorities to draw up and implement appropriate strategies and policies;
- organizational flexibility;
- decisional rationality;
- the quality of the informational system;
- the availability to use and implement evolved managerial instruments;
- informational and managerial innovative capacity.

Conclusions

The diagnosis analysis requires the covering of the stages we have mentioned at the juridical diagnosis, economic-financial diagnosis, public service diagnosis, human resources diagnosis up to the management diagnosis, which confer certainty to the analysis of each type of activity performed by the local communities, for the recommendations and the dysfunctionalities signalled be as rigorously as possible capitalised.

I appreciate that the diagnosis analysis could not be finished if a general conclusion referring to the activity performed by the local communities were not made, a reason for which I appreciate that each type of diagnosis made is appreciated with ratings, according to the table below:

Table 1. – Ratings given to diagnoses

Type of diagnosis	Rating			
Juridical diagnosis	Very good	Good	Satisfactory	Unsatisfactory
Economic-financial diagnosis	Very good	Good	Satisfactory	Unsatisfactory
Public service diagnosis	Very good	Good	Satisfactory	Unsatisfactory
Human resources diagnosis	Very good	Good	Satisfactory	Unsatisfactory
Management diagnosis	Very good	Good	Satisfactory	Unsatisfactory

It is obvious that the use of the ratings can lead to a certain subjectivism, but I am convinced that the group of experts to make the general evaluation will be interested in wording out the most realistic recommendations for the objectives established within the strategy have chances to be implemented.

²⁶⁷ Law 188/1999 regarding the status of public servants, published in the Romanian Official Gazette. no 600 of 8 December 1999;

Yet each category of diagnosis has a certain importance in making the general diagnosis and which can be ranked as follows:

- the juridical diagnosis has, in my opinion, the importance coefficient $C_1 = 0,10$;
- the economic-financial diagnosis, more important than the juridical one, can have the coefficient $C_2=0,20$;
- the public service diagnosis, the leader in the top of importance, has the coefficient $C_3 = 0,40$;
- the human resources diagnosis, important for the quality of the public services, can have the coefficient $C_4 = 0,20$;
- the management diagnosis, as a final aspect of the general diagnosis, can also have a coefficient of importance $C_5 = 0,10$;

The relation **coefficient of diagnosis ranking – rating given** remains at the experts' appreciation, the sum obtained from the points given cannot be higher than one.

$$Dg = \sum_{i=1}^n Di \leq 1$$

It is recommended that the grid points were conceived so that the unsatisfactory rating corresponds to a minimum score and for the very good rating the score is maximal. In my opinion, there will be two distinct situations:

- a) $\underline{Dg \rightarrow 0}$, corresponds to an intensely unfavourable situation which can endanger the activity of public service providing, so that recommendations will be **urgently worded out** for the situation to be improved;
- b) $\underline{Dg \rightarrow 1}$ is a situation which is overall appreciated as being favourable, the strategic objectives worded drawn up having maximal chances to be implemented.

No matter the method adopted to finally appreciate the activity of a local collectivity, as a result of the general diagnosis, I consider that in this stage it is very useful to word out the recommendations but also to notice the dysfunctionalities, for the overall strategy to be implanted.
