external causes is to be found in the age group 80 – 85 years (patients aged at least 80 and less than 85 years). The percentage of the patients suffering from diseases of the circulatory system is in all 7 age subgroups 65+ (at least 65 years old) the highest among analyzed diagnosis categories, followed by the neoplasms in 3 age subgroups (65-70, 70-75, 75-80) and disease of the musculoskeletal system and connective tissue in 2 age subgroups (65-70, 70-75). For the last 4 age subgroups 65+ (80-85, 85-90, 90-95 and 95+) the next 2 highest percentages after the diseases of the circulatory system are registered by the categories injury, poisoning and certain other consequences of external causes and diseases of the digestive system. The data from table 1 shows that 6 of the 10 top primary diagnoses of the discharged patients aged 70 years and over in 2008 were diseases of the circulatory system.

Top 10 Primary Diagnoses for the age group 70+	Percentage of the 70+ hospitalized patients in all hospitalized patients by primary diagnosis (%)	Percentage of the sum of the hospital days of the patients 70+ in all hospital days by primary diagnosis (%)
Heart failure (I50)	79.4	80.2
Cerebral infarction (I63)	67.8	69.6
Angina pectoris (I20)	46.8	54.2
Femur fracture (S72)	77.7	82.3
Atrial flutter and atrial fibrillation (I48)	53.3	63.4
Acute myocardial infarction (I21)	55.0	60.6
Pneumonia, organism unspecified (J18)	54.6	62.8
Non-insulin-dependent diabetes mellitus (type-2-diabetes) (E11)	57.6	58.6
Essential (primary) hypertension (I10)	51.0	58.1
Knee osteoarthritis (M17)	49.2	55.0

Table 1: Top 10 primary diagnoses for the age group 70+.

Source: authors' own calculations based on statistical data from Statistisches Bundesamt (2009c).⁵⁰³

Table 2 indicates the gender differences with regard to the top 10 primary diagnoses (for example: angina pectoris, knee and hip osteoarthritis, arteriosclerosis, malignant neoplasms of bronchus and lung etc.) for the patients aged 70 and over discharged in 2008 from German hospitals. Analyzing the data with regard to surgical operations and procedures one can observe that the age group 65+ accounted for almost 42% of the inpatient surgical operations performed in German DRG-hospitals in 2008 (when not considering additional information on operations).⁵⁰⁴

Top 10 Primary Diagnoses: age group 70+, female	Top 10 Primary Diagnosis: age group 70+, male
Heart Failure	Heart Failure
Femur fracture	Angina pectoris
Cerebral infarction	Cerebral infarction
Essential (primary) hypertension	Chronic ischemic heart disease

Knee osteoarthritis	Acute myocardial infarction
Atrial flutter and atrial fibrillation	Pneumonia, organism unspecified
Non-insulin-dependent Diabetes mellitus (type-2-diabetes)	Other chronic obstructive pulmonary disease
Acute myocardial infarction	Malignant neoplasms of bronchus and lung

Angina pectoris	Arteriosclerosis
Hip osteoarthritis	Atrial flutter and atrial fibrillation

Table 2: Top 10 primary diagnoses for the age group 70+ by gender.

Source: authors' own calculations based on statistical data from Statistisches Bundesamt (2009c).⁵⁰⁵

Table 3 shows the percentage of the operation categories within all 7 subgroups 65+: the operations of the musculoskeletal system and of the digestive tract accounted for high percentages in all selected age groups (correlating with the information provided by the analysis of primary diagnoses by age groups) in the year 2008. Whereas the percentage of the operations on the nervous system, on the lung and bronchus, on the heart, on the blood vessels, on the male and female genital organs decreased in the higher age groups, the percentage of the operations on the skin and subcutaneous tissue and on the musculoskeletal system (partially) increased in the higher age groups.

Percentage of the number of performed inpatient operations within the selected age groups (%)							
Operations: categories	65 - 70	70 - 75	75 - 80	80 - 85	85 - 90	90 - 95	95+
Operations on the nervous system	5.0	5.0	4.5	3.7	2.6	1.6	1.2
Operations on the endocrine glands	1.5	1.1	0.7	0.4	0.2	0.1	0.1
Operations on the eye	4.6	5.7	6.8	8.1	8.1	6.6	5.1
Operations on the ear	0.6	0.5	0.4	0.4	0.4	0.4	0.5
Operations on the nose and paranasal sinuses	1.5	1.0	0.8	0.6	0.6	0.6	0.6
Operations on the oral cavity and face	1.1	0.9	0.9	0.9	0.9	0.9	1.0
Operations on the pharynx, larynx and trachea	1.1	1.0	1.0	0.8	0.5	0.3	0.2
Operations on the lung and bronchus	1.5	1.4	1.2	0.8	0.5	0.3	0.2
Operations on the heart	3.6	4.6	5.4	5.1	4.3	3.7	2.8
Operations on the blood vessels	7.3	7.1	6.8	6.3	5.6	4.7	4.4
Operations on the hematopoietic and lymph vessel system	1.9	1.4	1.1	1.0	0.7	0.5	0.3
Operations on the digestive tract	18.2	19.0	20.4	22.5	24.3	23.6	22.1
Operations on the urinary organs	5.6	6.0	6.4	6.4	5.9	5.3	4.2
Operations on the male genital organs	2.6	2.5	2.2	1.8	1.3	1.0	0.8
Operations on the female genital organs	3.3	3.1	2.6	2.1	1.7	1.1	0.6
Operations on the jaw and craniofacial bones	0.3	0.2	0.2	0.2	0.2	0.3	0.4
Operations on the musculoskeletal system	30.8	29.9	28.3	26.5	27.1	30.4	34.8
Operations on the breast	2.0	1.2	0.9	0.9	0.8	0.7	0.5
Operations on the skin and subcutaneous tissue	7.8	8.4	9.4	11.5	14.3	18.1	20.4

Table 3: Performed inpatient operations by age groups in 2008 in German DRG-hospitals.

Source: authors' own calculations based on statistical data from Statistisches Bundesamt (2009b).⁵⁰⁶

⁵⁰⁵ Statistisches Bundesamt, *Tiefgegliederte Diagnosedaten der Krankenhauspatientinnen und -patienten (Datensatzstruktur) 2008*, Wiesbaden, 2009c, table: Geschlecht_Anzahl_08.

⁵⁰⁶ Statistisches Bundesamt, *Fallpauschalenbezogene Krankenhausstatistik (DRG-Statistik) - Operationen und Prozeduren der vollstationären Patientinnen und Patienten der Krankenhäuser – Ausführliche Darstellung - 2008*, Wiesbaden, 2009, table 1.1.1.

The data presented above shows that even at present the elderly patients register a high percentage in the number of inpatient hospital cases, of hospital days and absorb a high degree of the operation resources in German hospitals.

3. Implications of an ageing population for the German hospitals

The data presented above together with the values of the hospitalized patients per 1 000 inhabitants by age groups indicate that the number of inpatient hospital cases increases considerably at a high age.⁵⁰⁷ Under the premises of the representativeness of the statistical data for the year 2008, one could expect a considerable increase of the age-related diagnoses as result of the demographic changes. Using the age and gender specific diagnoses probabilities of the years 2004/2005 and the results of population projections in order to quantify the impact of population ageing on the number of hospital cases and beds, one of the analyzed studies presented a projection scenario indicating an increase of about 12% in the hospitalized cases in 2030 compared to 2005; according to this projection scenario, high growth rates are expected in the age-related diagnoses categories, for e.g. diseases of the circulatory system (34.2%), neoplasms (20.9%), diseases of the digestive system (13.7%), injury and poisoning (10%), diseases of the musculoskeletal system and connective tissue (9.9%) and diseases of the respiratory system (11.5%). In the case of decreasing hospitalization rates (in accordance with the hypothesis of compression of morbidity⁵⁰⁸), the results of this projection scenario indicated an increase of 5.3% in the hospitalized cases in 2030 compared to 2005. With regard to the percentages of the hospital inpatient cases by age groups, both scenarios showed similar results: the percentage of the age groups 60 - 80 and 80+ are predicted to increase from 35.5%, respectively 12.5% in 2005 to 39.5%/42.1%, respectively 20.2%/20.4% in 2030.⁵⁰⁹ On the basis of the analyzed data, one can say that the implications of an ageing population for the German hospitals will be multiple and complex, ranging from changes in the diagnosis spectrum, allocated resources (number of beds, operation resources and capacities, qualifications of the hospital personnel, care effort etc.) to changes in the hospital organizational structure and processes (for e.g. case management, coordination activities and discharge management). The characteristics and often complex needs of the elderly patients require more than ever the implementation of multi- and interdisciplinary care concepts in hospitals. Due to the expected increase of the percentage and number of the patients aged 70/80 and over, German hospitals should consider the necessity of ensuring geriatric medicine knowledge in the hospital setting.

4. Conclusions

Many data illustrate implications of the demographic evolution for European health care systems. The hospital sector, as integrative part of each health care system, will be also facing challenges and changes. The precise analysis of the patient hospital structure and their characteristics can provide hospitals with important information and enable them to react in time by adopting necessary structural and organizational measures in order to be well prepared for the multiple facets of the demographic evolution.

THE INVESTMENT CLIMATE AND THE DECISION TO UNDERTAKE FDI

Macelaru Patricia-Sabina

Academy of Economic Studies, Bucharest

FDI is well acknowledged as an important factor stimulating growth at the level of national economies. Therefore, governments are interested in attracting FDI by adopting various policies and implementing focused strategies. However, the decision to undertake FDI is taken on a case-by-case basis by each foreign investor. Nevertheless, certain patterns can be observed which reveal the investor's objectives.

The article presents a specific analysis performed based on the latest statistical data available on FDI in order to evaluate which are the most appealing economies to foreign investors and argues on the potential criteria considered in the process of FDI.

Keywords: foreign direct investment, multinational enterprises, investment climate

JEL classification: F21, F47

Introduction

The multinational enterprises ('MNE' hereinafter) are continuously seeking to increase their profitability, when possible by extensive means, including under the form of increase of production capacities. When the domestic market is saturated, MNE eventually decide to focus on overseas expansion by carefully choosing where the planned investment is to be situated. The decision of undertaking a foreign direct investment ('FDI' hereinafter) is not less objective than the choice of the country where the new investment should be located, as feasibility studies and profitability forecasts usually fundament such decisions.

From another perspective, a set of priorities acknowledged by MNE transform the statistics of FDI in something else than a simple computation of assets held by MNE in foreign countries. From a broader point of view, FDI is characterised by heterogeneity which comes from the diversity of the factors considered by MNE when choosing the location of the future investment. In the context of the benefits brought by FDI to the stability and development of worldwide economies, countries attempt to become more attractive to MNE.

In the following pages, this article is trying to evaluate which are the criteria that determine foreign investors to choose a certain country as location for their foreign investment as well as on the tactics that governments often undertake in order to become more appealing to foreign potential investors. Finally, a specific analysis of statistical data regarding FDI inflows was performed in order to outline FDI trends and forecasts.

Key drivers for MNE to select a certain foreign location for their direct investment

From a general perspective, MNE are usually considering individually or as a group the following criteria in their assessment of undertaking FDI: natural resources availability, the potential of maintaining or increasing of sales in certain markets, acquiring strategic assets or low production costs in the light of subsequent exports. As such, countries with significant natural resources, large consuming markets, attractive corporate assets or low wages labour markets would become attractive for MNE searching to meet one or several of the above objectives. In principle, we could argue that the geographical distribution of FDI around the world reflects the capacity of countries to satisfy the above-mentioned objectives assumed by MNE.

In addition, we could note, especially in the past two years, most probably as a consequence of the global financial crisis, an increased interest of MNE in restructuring their business, by taking

into account specific tax aspects and more precisely by performing extensive tax planning (which hopefully generates low effective tax rates at group level and increases consolidated profitability).

On a related note, the distribution of FDI on the worldwide map during the 20th century and beginning of the 21st century proves a change of interest at the level of foreign investors. If during the 20th century (and particularly before the World War II) large investments in countries having available well-known raw material resources – the current poor countries of the world – were performed, nowadays the market-seeking investments in wealthy industrialised countries are the most frequently FDI undertaken.

Apparently, MNE are seeking for low waged and non-regulated labour protection countries where labour costs reach the lowest levels and at least theoretically the best profit level indicators should be achieved. However, FDI distribution statistics prove the contrary, meaning that, except for China, there is no positive relationship between the level of a country's wages and its capacity of attracting FDI. Moreover, statistics show that FDI usually moves from one wealthy developed country to another. One perfectly consistent explanation would be that MNE are looking for high productivities (computed as output per unit of input) which are quite difficult to achieve if only low instructed workers with bad working behaviour are available, which is frequently the case of less developed countries. In addition, other costs such as raw materials, equipment, transportation, tax burden should be also considered as components of the production cost endured by MNE. Therefore, we could argue that the high wages of the industrialised countries would reflect the level of their productivity.

In addition, statistics show that FDI is moving towards countries with potentially high foreign consumers' buying power and not towards weakened economies. The latter, although frequently capital-scarce economies with low developed labour markets, are not characterised, statistically speaking, by a high FDI inflow.

The investment climate

The investment climate is one of the main elements considered by MNE when selecting a location for establishing an investment. Although not quantifiable and resulting from a mix of factors, the investment climate represents mainly the foreign investor's perception on how business friendly is a potential host country. From a more pragmatic perspective, the foreign investors make a judgement on the risk involved by FDI and whether the expected returns are satisfactory in comparison to the level of uncertainties.

There is a list of most important factors which would determine the foreign investor to establish the nature of the investment climate, as follows: political and country stability, quality of governance, stable system of law, macroeconomic policies with direct influence on the entire economy, etc. Lately, the fiscal policy is also increasingly important for the investors, either envisaging FDI or simply business restructuring. Tax planning has become a major interest for MNE which envisage diminishing the tax burden (by applying efficient tax planning strategies, MNE actually manage to reduce their effective tax rate at group level and thus realise a significant reduction of costs). Corporate tax rates, as well as the monetary policies setting the cost of borrowing in the host country are the main features of the fiscal policy.

In addition, there are also meso-economic factors such as industry policies (providing for e.g. tax exemptions, protection from import competition), regulatory environment of business, quality of human and physical infrastructure, regulation of capital outflows, import barriers, etc. that cannot be ignored by MNE.

The strategies adopted at the governmental level are very important in attracting or, conversely, discouraging FDI. As such, as a first possible attitude, governments might decide to focus on attracting FDI by adopting policies and implementing strategies and measures (either applicable to all industries or customised for certain specific industries) in order to become more appealing

to foreign investors. Moreover, very aggressive governments might also target certain MNE or sectors and court them in order to offer different incentives which would hopefully determine the foreign capital inflow. Currently, from a worldwide perspective, this is the attitude the most frequently adopted by governments, interested in attracting FDI.

Nevertheless, a second possible attitude of governments is the “laissez-faire” one adopted, for example, in the US at federal level. Such attitude implies no effort of what so ever from the part of governments which have few or no policies implemented. The purpose of such position is to let the market mechanism completely free in attracting or, by opposite, discouraging FDI at different industries level. However, the above-mentioned example is one of the rarest ones.

Thirdly, governments may also adopt certain specific policies which provide for disincentives for the MNE. Such countries, under the intention of protecting the national interest (irrespective of what it consists of) may actually risk fully discouraging FDI and finding themselves destitute of the FDI benefits. This would be the case of certain very nationalists Asian countries.

A fourth situation, i.e. the one of a government which manages very poorly its national economic policies or handles very aggressively its political objectives so that is discouraging FDI, could also be considered, although such a situation would be mostly unintentional and could not be viewed as a strategy.

However, irrespective of the governments’ strategies with regard to FDI, there are also other factors which cannot be controlled, such as the level of the instruction of the labour force, the potential aggressiveness of union trades, the quality of the raw materials available, etc.

Despite all, it should be stated that investment climate improvement, which would normally lead to attracting FDI is a process which requires efforts and implication from the part of governments. Most likely, such improvement requires a period of time so that the transmission mechanism (from governments adopting official FDI supporting position to reception by the foreign investors of such message) to take place.

The decision to undertake FDI

The decision to undertake FDI is, from the foreign investor’s perspective, a case-by-case decision which ultimately takes into consideration the objectives of the investor, on one hand, and the strengths and weaknesses of specific countries/regions contemplated, on the other hand. In addition, the corporate culture has an increased significance in the decisional process, as it would attribute certain levels of importance to each of the countries’ attributes and finally it would determine the acceptance and the rejection factors.

Despite the above, in case of resource-seeking investments (e.g. oil drilling activities), we can argue that there are mainly three basic criteria influencing the investment decision making, i.e. easy access to important quantities of focused raw materials, costless transportation by means of satisfactory infrastructure and an acceptable level of corruption and environmental legislation.

On another side, there are market-seeking foreign investors (mainly all players in the consumer products industry) which are primarily looking for large economies, having constant economic growth, with a strong consumer purchasing power, goods infrastructure and human capital endowment. Most of the countries which could qualify for the above desiderates are located in the EU, US or Japan / Eastern Asia.

The efficiency-seeking foreign investors are attracted by economies with relatively low wage scale (e.g. less developed countries). However, such countries should be carefully analysed in order to avoid the ones with low labour productivity or possible sources of high production costs (e.g. increased corruption, less developed law systems, inadequate infrastructure).

Finally, in respect of foreign investors seeking for acquiring strategic assets or entering into a merger with a foreign company, specific factors are taken into consideration in relation to the objectives of the foreign investor. Therefore, it is difficult to enumerate a list of factors which

could be considered, as most of the times the decision is not related to the attractiveness of the respective foreign economy, but to intrinsic factors.

The bias of assessing positive factors characterising a potential host country also applies when it comes to negative factors. It is quite less probable for foreign investors to be able to find a host country for their investment having all or either part of the required strong points without having at least one weak point. Therefore, the foreign investors should determine very well which are the weak points that are acceptable and which are not from the perspective of their envisaged objectives.

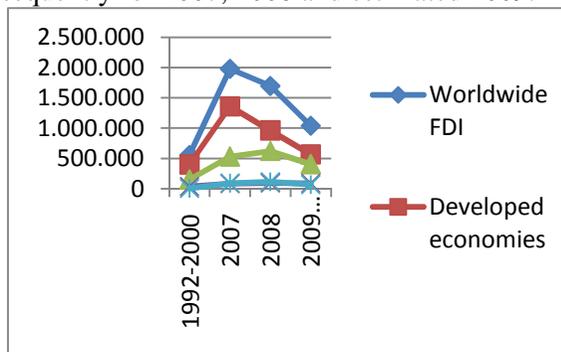

Specific statistical analysis on the development of FDI

We aim in the following analysis to determine which were the FDI trends in 2007, 2008 and partially in 2009 and based on such an analysis to forecast on the future potential actions to be undertaken by foreign investors with regard to the most likely location for their FDI (we note in this respect that we do not have yet official statistical data available for 2009 FDI flows, however, a specific analysis has already performed based on estimated figures).

Further to the review of the statistical data available on the online FDI statistical database of UNCTAD⁵¹⁰, we note that in 2008, the total FDI flow was evaluated at 1,697,353 MEAS⁵¹¹ in comparison to 1,978,838 MEAS in 2007.

With regard to 2009, the estimated FDI inflows are of 1,040,300 MEAS. This deep decrease (i.e. approximately 15% in 2008 and estimated 38.7% in 2009) of the level of the worldwide FDI comes after a long period of constant growth and is undoubtedly caused by the global financial crisis. As such, the companies have seen their capacity of investment significantly being weakened by the lack of financial resources (both internal and external) and their propensity to invest diminished by collapsed growth prospects and heightened risks.

In the following chart we have included the relevant information regarding the amounts of FDI inflows recorded by each category of country for the period 1992 – 2000 (considered as an annual average) and subsequently for 2007, 2008 and estimated 2009.

Please note that we have chosen the period 1992-2000 for our analysis as considered a period of relative economic stability. It is also a period of increase of FDI inflows at the worldwide level which proves the increased interest of foreign investors towards FDI (which is also due to the globalisation phenomenon becoming more obvious worldwide).

When analysing the data included in the above chart, we note that a constant increase in the level of FDI flows was registered since 1990. Also, we note that FDI inflows recorded a sinusoidal evolution as of 1990, with periods of constant growth during 1992-2000 and 2003-2007. The peculiar evolution of FDI in 2008 can be argued by the financial crisis which determined a significant decrease of FDI worldwide. In addition, we note a slightly increased interest of

⁵¹⁰ FDIStat, the official site of UNCTAD presenting extensive statistical information regarding FDI (<http://stats.unctad.org>)

⁵¹¹ US dollars at current prices and current foreign exchange rates in millions

investors towards developing countries and transition countries in 2008. With regard to the 2009 evolution of FDI inflows, we note a significant decrease affecting all categories of countries.

In addition, we note that a significant increase of the level of FDI inflows was recorded in 2007 and 2008 in comparison to the annual averages of the period 1992-2000 for each category of countries (i.e. the growth was up to 3.5 times). In addition, we note quite a small interest shown by foreign investors in the transition countries in the period 1992-2000 (i.e. only 1% of the worldwide attracted FDI), however such interest increased in the late 2000s, the share of attracted FDI being of approximately 6.74% in 2008.

We also note that the developing countries continue being very attractive to foreign investors, gaining advantage in comparison to developed countries (we note an important increase of the FDI inflows share in 2008 and 2009 compared to the annual average of 1992-2000). In addition, it seems that the global financial crises affected, at least based on the estimated figures, in a more profound way the developed countries rather than e.g. the developing countries (the latter having attracted an increased percentage of worldwide FDI inflows in 2009).

China appears to be a very important player in the category of developing countries, having by itself in 2008 a share of 6.38% of the total FDI inflows and of between 15% - 20% (decreasing from the period 1992-2000, when it was of approximately 37%) of the FDI inflows for developing countries, which shows an increased interest of foreign investors in other developing economies than China. In 2009, the interest of foreign investors in China seemed to have slightly decreased. However, its level of FDI attractiveness in the developing countries zone has increased (up to 8.65% of the worldwide FDI flow).

As per the above analysis, we note that the interest of foreign investors in developed countries started to slightly decrease over the past years in the benefit of developing countries (out of which China is a major player). Also, the transitional countries become more attractive from a FDI perspective.

Forecasts on FDI evolution in the years to come

In order to understand the way in which foreign investors think when analysing their possible destinations for FDI, UNCTAD took a survey at the level of the executives of 241 of the most important non-financial MNE. The aim of such a survey is to provide insights into FDI patterns over the following three years.

According to the 2009-2011 World Investment Prospects Survey undertaken by UNCTAD in 2009 ('WIPS' hereinafter), the most attractive countries from a FDI perspective are Brazil, the Russian Federation, India and China (BRIC countries). The respective rank was established by MNE after considering criteria such as market growth, followed by the availability of cheap labour, and, in some cases, access to natural resources, location of major assets, etc. They mentioned the quality of the business environment and market size as the main strengths of the most developed economies.

In addition, the WIPS reflects a high concentration of answers. As such, the top 15 countries in the list account for 74% of the total number of responses, while at the level of developing and transition economies the respective percentage is even higher, i.e. 76%. Thus, the interest of the MNE in developing and transition economies, although increasing, is still limited to a small number of countries.

From another perspective, as a slight increase of 3.1% of the worldwide GDP is expected for 2010 (as per the estimation of the IMF, included in the latest World Economic Outlook), against a decrease of 1.1% in 2009, we could argue that a modest recovery could be expected in 2010 mainly due to the stabilisation of the worldwide economies. However, FDI flows figures are most likely to be still significantly inferior to those recorded in e.g. 2007.

Conclusions

The interest of national economies towards FDI is increasing, especially under the conditions of the actual global financial crisis when the appetite of foreign investors for FDI is very low. Studies performed show quite pessimistic views of foreign direct investors with regard to 2010 and 2011; however it is envisaged an upward trend for FDI inflows for the years to come.

Foreign direct investors in developing and transitional countries are more optimistic about future FDI inflows in the years to come, probably also because their countries were less affected by the financial crisis from an FDI perspective.

The results of the above analysis show an important interest in performing FDI in wealthy countries. Apparently, there is not a migration of foreign capital from North to South (a vertical movement), but a horizontal one. However, percentages held by developing countries and transnational countries in global FDI inflows are slightly increasing.

In addition, it should be stated that the 2008 and 2009 data should not be considered as reference years for the purpose of this analysis due to the effects of the global financial crisis affecting with a different intensity the various categories of countries (e.g. developed countries versus e.g. transition countries). The most severely affected by the global financial crisis in 2008 and 2009 were the developed countries, while developing and transition countries have experienced low growth rates of inflows of FDI. However, it is quite probable that the worst is yet to come for the developing and transitional countries and they are expected to record decreases of FDI inflows in 2010 and possibly 2011.

The energy crises of the 70s led to the vigorous interventions of the industrialized states in the energy sector. On the European political agenda a new problem appeared, namely the one regarding the security of the energy supply. Romania is the third geothermal power in Europe, after Italy and Greece. The energy potential produced by means of geothermal resources of the West and North - West regions is approximately of 144 MWt. The production of a MWt of electricity through conventional sources (in our case study we chose diesel) emits into the atmosphere about 21,673 tons of CO₂. If it's used the entire installed capacity in these areas Romania reduces pollution by approximately 6,935,552 TCO₂.

Keywords: durability, externalities, renewable, geothermal, energy independence, pollution.

Jel classification: H23 - Externalities; Redistributive Effects; Environmental Taxes and Subsidies

For a long time it has been considered that the production and selling of energy is an area regulated by national policies and direct involvement of the governments. The natural monopole of production and distribution of energy activities and transport activities represents one of the reasons that determined the strengthening of the initial ideas of the governments.

The energy crises of 70s led to the vigorous intervention of the industrialized states in the energy sector. On the European political agenda a new problem appeared, namely the one regarding the security of the energy supply. Costly programs were initiated for the construction of nuclear plants and were allocated grant – in – aids for alternative energy. International Energy Agency was created in order to supervise the allocation of the financial resources and to encourage the diversification of alternative forms of energy. Meanwhile, in a modest way, began to emerge national energy policies and the implementation of agencies. However, some traditionally planned interventions proved to be hasty or even useless, so the capacity of the governments alone to intervene in energy policy began to be questioned.⁵¹²

In the history of the European Communities, the energy policy has been rather insignificant, although, paradoxically, two of the basic treaties, *the Treaty establishing the European Coal and Steel Community (ECSC) and the Treaty establishing the European Atomic Energy Community (EAEC or Euratom)* refers to energy. ECSC established through the Treaty of Paris of 1951, created a common cola market. Then was the Euratom Treaty that was signed in Rome in 1957, which originated in the Suez oil crisis of 1956. 1956. It aims to reduce the dependence on imports from the Middle East. Also, *the Maastricht Treaty* signed in 1992 and known as the EU Treaty, has brought some additions to the definition of the internal energy market (PIE).

⁵¹² http://www.renerg.eu/Document_Files//Evenimente/00000058/9dn9j.

The European Commission plays a central role in the debate between different actors on the energy market, some of them wanting decentralization, while others, on the contrary, as it had been seen previously. The first statement of the European Commission that approaches the issue regarding a common energy policy dates from 1995 and was called the Green Paper "For a European Union Energy Policy." In the same year came out, the White Paper "An Energy Policy for the European Union, then a new sequence of communications in 1996 and 1997, called "Green Paper for a Community Strategy - Energy for the Future: Renewable Sources of Energy" and "White Paper: Energy for the Future - Renewable sources of Energy.

These documents underpin the current common energy policy and the European legislation designed to implement it. The complexity of the problems regarding the production of energy, the transport and the energy consumption has much increased in the last decades, together with the ingravescence of the global environmental problems, climate changes and depletion of natural resources. In addition, the EU confronts itself with some specific problems among which the most serious being the one linked to the increased dependence on imported energy resources.⁵¹³

The efficient conservation, valorization and in an ecologic manner of the energetic resources and also the sustainable use of these resources, represent in recent decades is a major worldwide concern. Finding viable solutions for the problems with which man confronts today in the energy domain, is imperative because of:

- the gradual depletion of oil resources;
- the increased rhythm of growth of the greenhouse gases' emissions;
- the expansion of the nuclear power plants, having as consequence the volume of radioactive wastes;

In order to avoid these unwanted phenomena, over time it has been tried the adoption and implementation of measures designed to prevent the occurrence of this phenomenon. In this category belong the eco-taxes or environmental taxes that represent "extraordinary constraints" introduced by governments as to counterbalance the social costs resulting from damages to the surrounding environment due to externalities generated by people. This notion was introduced by the economist Alfred Pigou in 1920 which stated that for an economy it would be useful to correlate the price of goods with that of the common consumption goods by using property taxes. Another implication in this sense has the British economist Ronald Coase, Nobel Prize winner in Economics in 1991 who contributed to the development of the economic Theory of Externalities. Marketable pollution licenses - LPT (Tradable Permits)⁵¹⁴ are based on the principle of the right to emit pollutants within the limits stipulated by laws and regulations concerning environmental protection. This system is the most often used in the U.S.A. (regulated by the *U.S. Clean Air Act*). Through the system of tradable pollution licenses a company or a country has the permission to sell to a third party the right to issue the amount of pollutants due to the difference between the level of pollution permissible by law, considered as the maximum allowable level of pollution and achieved by adopting new ecologic technologies or ecologising the existing ones.

Reducing the environmental impact of the energy sector involves the use of regenerable energies including biomass, geothermal energy, solar energy, aeolian and hydropower that should play a key role in the future. On the other hand, it is necessary to strive for a more efficient energy use, as a relatively easy means to reduce the environmental impacts of energy. Thus, the geothermal potential of Romania and especially of the west and north - west region shows a great energy importance and implicitly an economical and environmental one for the country.

The population of the West and Northwest area

⁵¹³ Idem.

⁵¹⁴ <http://www.bibliotecadigitala.ase.ro/biblioteca/pagina2.asp?id=cap4>.

The northwest Region is one of the eight development regions of Romania and includes six counties: Bihor, Bistrița-Năsăud, Cluj, Maramureș, Satu Mare, Sălaj. The surface area is of 34,159 square kilometres, representing 14.32% of the country's surface, with a total population of 2,744,914 inhabitants.

The West Region of development of Romania is located at the border with Hungary and Serbia, and is organized from administrative and territorial point of view in four counties: Arad, Caras-Severin, Hunedoara and Timis. The West Region's population is of 1,924,442 inhabitants, representing 8.93% of Romania's population. The West Region covers up an area of 32,034 km², representing 13.4% of the country.

The table below presents a synthesis of the main parameters of the important geothermal perimeters from Romania, including theoretical power potential. Using the extracted geothermal energy is used for heating in a proportion of 37%, 30% for agriculture (greenhouses), 23% in industrial processes and 7% for other purposes. From a total number of 14 geothermal wells dug from 1995 to 2000 at depths of 1500-3000 m, only two wells were unproductive, registering an 86% rate of success.⁵¹⁵

Table 1. The Geothermal System Today

No. Unit	The geothermal system	Estimated area	No. of wells	Drilling Depth	Exploitable flow	Resource's temperature	Theoretical energy potential
		km ²		m	$\frac{l * s^{-1}}{m^3 * h^{-1}}$	°C	MW _t
1.	Crișul Negru – Someș Săcuieni, Margita, Ciumeș, Salonta – the counties of Bihor and Satu Mare	3570	18	1500	$\frac{148}{533}$	77	29,14
2.	Borș Borș City – Bihor County	13	4	2800	$\frac{148}{533}$	100	8,79
3.	Oradea Oradea City – Bihor County	77	12	2800	$\frac{151,5}{545,4}$	83,8	34,1
4.	Mures – Crișul Negru Curtici, Macea, City of Arad - Arad County	1060	113	1500	$\frac{79}{285}$	58	9,3
5.	Western Banat Nădlac, Sămnicolau Mare, Săravale, Tomnatic, Lovrin, Jimbolia, Periam, Teremia Mare, Comloșu Mare, Grabat, Beregsăul Mic – the counties Arad and Timiș	2790	20	2000	$\frac{318}{1144,8}$	77	62,75

Source: http://www.minind.ro/domenii_sectoare/energie/studii/potential_energetic.pdf

National exploitable reserve of geothermal water is of approximately 167,000 tep / year of low enthalpy resources, which currently capitalizes about 30 000 tep/ year. The total installed capacity in Romania in the west and northwest part is of 320 MWh (for a reference temperature of 300 °C).

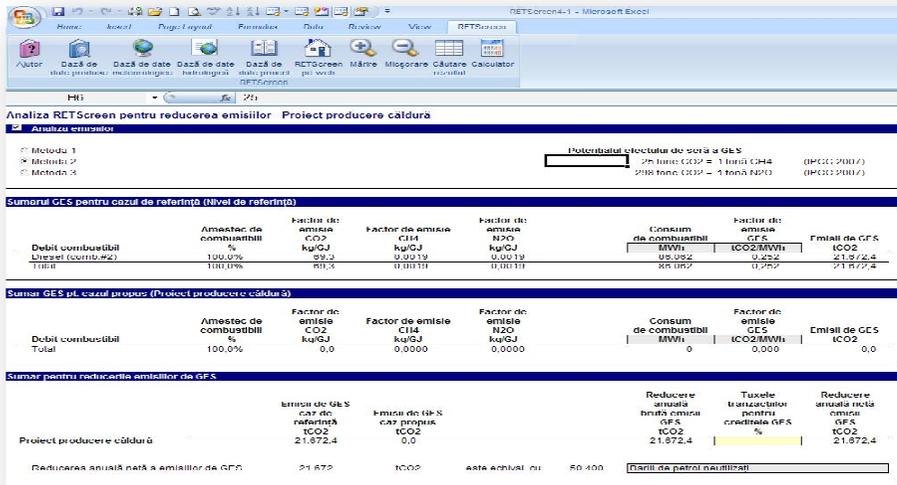

Western and North – Western Regions have an electric potential of approximately 144 MWt of the current well installed. The production a ton MW_t of electricity through conventional sources (in our case study we chose diesel) produces and emits into the atmosphere about 21,673 tons of CO₂.

From a simple calculation we observe that if we use the entire installed capacity in these areas of Romania reduces the pollution by about 6,935,552 TCO₂. By the end of 2009 the price of pollution certificate was of 15 Euros (a pollution certificate equals a ton of CO₂ emanated in the atmosphere). So, we can observe the economic benefits that Romania would obtain in the case of using at maximum the installed capacity of electricity generation that is of 104,033,280 Euros.

⁵¹⁵ http://www.minind.ro/domenii_sectoare/energie/studii/potential_energetic.pdf

In the White Paper it is proposed that by the end of 2010 to be produced using geothermal resources 1GW_t of electricity and 5 GW of thermal heat. The production of 6 GW_t by burning liquid combustibles can generate and emanate approximately 21,672,499 TCO₂. Or, it can reduce pollution in the case of using available geothermal potential or other renewable resource.

In Romania, the capitalizing degree of renewable geothermal energy resources is low, the main cause being determined by the lack of proper financial support, which doesn't favour the development of the energy sector with superior financial and economic effects. Using geothermal water constitutes a viable option when the extracted agent at surface insures a supply system at a constant flow, and the variation of the energy demand at the consumer in different periods of the year is not great. The recommended system is the one with several active wells, of which some will be for re-pumping. The advantages of this system, besides the provided energy, are the conservation of the water reserve and that of the water's layer pressure. In the U.S.A., the energies obtained from renewable sources, 5% came from geothermal sources and 1% of solar power.⁵¹⁶

At the present time, studies reveal that the Earth's geothermal potential is about 13,000 per year ZJ, of which approximately 2000 ZJ could be used to produce electricity, with the geothermal plants. If we could get to use only 0.25% of this potential, we won't need coal, plutonium, oil and gas for the production of electricity. Currently, we use only 1% of the world's electricity need which is covered by geothermal sources, so use 0.0025% of the full potential.⁵¹⁷

We consider being worth mentioning and underlined the positive effects of using this resource:⁵¹⁸

- Reducing the imported primary energy resources dependence (primarily fossil fuels)
- The diversification of the available energy resources.
- The production capacities considered for different parts of the country will simultaneously lead to employment's increase and the labour market will diversify its offer.
- The business environment will be diversified by attracting private companies (domestic and foreign) as well as local and central public authorities, in the process of exploiting regenerable energy resources.
- Investments in the domain of renewable energy resources will enable the manufacture, transfer and sale of products and modern technologies in this field.

⁵¹⁷ <http://www.energeia.ro/energie-geotermala/potentialul-geotermal-al-terrei-de-4000-de-ori-necesarul-energetic-global-549/>.

⁵¹⁸ <http://www.fonduri-structurale-europene.ro/poscce/valorificarea-resurselor-regenerabile-energie.html>.

- The valorisation of renewable energy resources will lead to a greater emissions' reduction possibly resulting from the fossil fuel combustion process and to the preservation of the environment.

STANDARD MONEY IN VICTOR JINGA'S OPINION

Olah Gheorghe
University of Oradea
Faculty of Economics

The author of this article has aimed to analyse Victor Jinga's opinion on currency or on standard money, with respect to the importance he gave to the stability of the buying power of the currency and especially to the source of this stability.

Keywords: standard money, buying power, paper money, stability

JEL code: A10

Victor Jinga's fundamental work about money entitled **Moneda și problemele ei contemporane (Currency and its current problems)** was published in Cluj-Napoca in two volumes at Dacia Publishing House in 1981. The following ideas spring, generally, from this work. Jinga also has other works about money but I considered that, in its size and content, and considering the author's age at the time of publishing, this work practically reflects his overall view upon money, a view established after a long and mature experience. Thus, as the title of this article states, what we assume to find out and present in this article is Jinga's view upon money, as it transpires from this fundamental work and, of course, the way we managed to grasp it. The task has not been an easy one because Jinga's book is quite big; it is also particularly complex, maybe even slightly complicated and highly illustrated with quotations and references; some several times (e.g. paragraph one page 114 and paragraph two page 147; or, Nogaro's quote page 188 and the same idea presented without reference on pages 76-77) and others contradictory indeed; without any comment, any argument or any evaluation from Jinga; he plainly exposes them and the readers can help themselves with whatever they like. Indeed, the literature consulted by Jinga for elaborating this work is really impressive.

Before moving forward we need to state that Victor Jinga prefers the word currency instead of the word money and we believe him to be right in doing so because in this work he is primarily preoccupied by the state and the evolution of the buying power of the currency. Indeed, understanding the essence of money boils down to understanding the essence of the currency, respectively of the monetary unit or the standard money. Thus, what does money or the currency look like in Victor Jinga's view?

The first thing that drives our attention is Jinga's insistence on the stability of the buying power of the monetary unit, an idea presented along the entire work "an essential quality of the currency –Jinga states on page 108, volume I – is the stability of the of its buying power; having this quality – he continues – a currency is considered 'healthy'. Its stable buying power – Jinga says – means stable prices." Hence, it is only by prices, by their static or dynamic nature that we realize what happens to the buying power of the monetary unit. On the other hand Jinga claims that "stability does not mean immobility ... the ocean does not rest at all – he argues – but in the vastness of its bed it is stable" (page 182 volume I). Finally, to close one idea, let's give another quotation: "any attempt to 'stabilize' the buying power of the currency is useless. As long as the economic organism is alive – Jinga goes on –, nothing stays the same; obviously, the succession of instabilities should not exceed a certain average line" (page 148 volume I). As we can note, it takes a lot of attention to interpret Jinga's thoughts as his statements are sometimes contradictory; at least apparently because the last part of the quotation, the part with "average line" shows though that Jinga is consistent. At the same time, regarding his ideas about inflation as well –

which we widely dealt with in another work (2) – we reach the conclusion that the stability of the buying power of the currency remains a constant of his thinking.

Another idea, as important as the former one and closely connected to it, is represented by the **source** of the stability of the buying power of the monetary unit. Where does this stability derive from and what does it assure or what **can** it assure? The problem is the more important as in real life we can notice that the stability of the buying power of money is more of an illusion, a fiction. On the other hand, the lack of stability most commonly manifesting in the form of inflation, sometimes raging, has disastrous consequences on the economic activity, being able to trigger even crises – as Rothbard states (3) – and a strong redistribution of the population's buying power against those with relatively constant incomes like budgeteers and especially retired people (4); as Jinga claims also. Consequently, lack of stability (of course relative stability, as professor Jinga accurately saw it) can generate great social inequities (in fact, that's what it does), with extremely serious consequences on people's participation to the economic life and so on the results obtained. Given these reasons, especially in the pages covering inflation, Jinga vehemently argues it and with scientific and convincing arguments. Thus, which is the source of the stability of the buying power of the monetary unit in Victor Jinga's opinion?

While going through the pages of Jinga's book I got increasingly curious even more as Murray N. Rothbard, the author of a recent work on money work of money to which I have referred to, relates this stability to the material the money is or, more precisely was, made of (gold or silver) and to the taking of the monopoly of coin manufacturing or monetary issue from the state and giving this activity to the private sector (3). At contrast, Jinga claims from the very beginning of his work and all along it that the link between money and precious metals has broken, has deteriorated and, at any rate, it does no longer present any importance currently, except perhaps in foreign trade for a given time. Why is that? Because, Jinga says, "Gold is – even when monetized – a merchandise as well, whose price fluctuates and thus cannot be a stable reference element, an essential feature for the currency in order to fulfil its role of general equivalent" (page 86, volume I). A few pages on, Jinga states again: "Previous standards have been and are based, more or less, on gold. So, monetary stability, the stability of the standards are dependent on the stability of the value of gold. We are aware how fluctuant this value has been for the last 150 years. A healthy currency, though, – Jinga goes on – doesn't have to be necessarily a golden coin but a coin with a constant buying power" (page 180 volume I); "a perfect standard – Jinga had written a bit earlier – supposes theoretically a stabile price of gold, stability practically unattainable" (page 83, volume I).

Constantly rising, along the book, against the gold standard, Jinga states at a point the following: "this standard claims a large quantity of gold whilst gold is so little, which triggers price reduction and bad trade (page 187, volume I). Incidentally – Jinga says – "Gold is not only little (...) but also wrongly distributed among the various nations" (page 87-88, volume I). Seeing these statements of Jinga's thinking, a few questions occurred to me. I wonder if the instability of gold value on the world market has been and is greater than instability of the buying power of the banknotes of the various countries from the moment of their complete abandon of the standard. The information we have about the price of gold on the world market, at least for the past 50 years, makes us believe it hasn't and it isn't. In this respect, let us consider what had happened to the Romanian currency since 1990 and by the time of its replacement with the current money; or to the US dollars after 1965 or, finally, to the German mark before Hitler's coming to power. Since 1991, since I observe even more carefully the evolution of the price of gold on the world market, this price has slightly and almost constantly increased, even more pronounced since the crisis began; perhaps because, as mass-media state, the demand for it has increased steeply in the time of crisis. This means that, in fact, the dollar devalued and not necessarily, as Jinga believed that the gold increased in value. As a matter of fact, at a point, Jinga stated in his usual note

quoting an indirect source without commenting it: "It is not that gold increased in price, but the dollar that depreciated as compared to gold" (page 109, volume 1).

I also wondered if the stability of the buying power of the banknotes is bigger from the moment of the abandoning of the gold standard, than it was before, when currencies were defined by reference to gold and were, at the same time, convertible into gold. Without deep search into the matter I would, however, think not. This opinion is based both on information rather inconstant, as those which we mentioned above were, and on logic; but especially on certain works of speciality as the book of the American economist we talked about.

As for the other reasons that Jinga considered to be at the basis of renunciation to gold as a base for stability of the buying power of the currency, such as 'littleness' and the gold's "inequitable distribution among nations", we have to say for very beginning that these are not sufficiently serious grounds to support this. First of all, because as the 'littleness of the gold' is concerned there is this principle of the Romanian peasant or, at any rate, of the Transylvanian one, that works properly, principle stating "if there is a lot, it will be used, if there is little, it will do"; be gold as little as it may, it is always enough as means of exchange, because the buying power of monetary unit grows proportionally to the decrease of the quantity of gold. In what its distribution among various nations is concerned, this depends on the competitiveness of the products of different countries and the customs duties system which both are at each country's determination. On the other hand, the dollars or euros, as paper money are particularly concentrated in a few countries, even though, at a world level, they are plenty (perhaps too many). Otherwise, Romania wouldn't have recently had to borrow almost 20 billion dollars or euros from the international institutions, while the USA didn't borrow any, though facing difficulties derived from the crisis, difficulties maybe even bigger than in Romania.

Thus, Jinga does not regret the abandon of the relation between paper money and gold, but on the contrary. But then, however, what is the source of the stability of the buying power of the monetary unit that Jinga, perfectly correctly, considers a sine qua non condition of the monetary health? However strange it may seem, this source is, in Jinga's opinion, the state: "Currency is currency - Victor Jinga writes - because this is what the state decides, and those that use it ratify this decision; can they do differently?" Jinga asks rhetorically (page 28).

A few pages further, Jinga argues again: "The socialist economy has vast and varied opportunities to socially plan and manage; it assures as many premises that favour a firm control of the monetary phenomenon and of the monetary stability" (page 32). Drawing a comparison between money and ordinary goods, especially as some economists argue that money itself is originally a merchandise like all the others, Victor Jinga argues: "The goods bear nothing more than the mark of their quality, it is not conditioned by laws and rules, it is not charged with certain forms and contents, while the currency has an established figure, is manufactured according to strict legal advice, it has the approval and guarantee of the state or of an issuing institute." (page 35, volume 1). All these statements of Jinga and, of course, many others in his work on money, which underlie our views, demonstrate that, from his point of view, the state's institutions are, or should be, the source of monetary stability.

We should not be misled into thinking that for Jinga the state's institutions have already solved the problem of the stability of the buying power of the monetary unit; not even in the former socialist countries at that time. Still, we must admit, the stability of the buying power of money in these countries was, however, much bigger than it was in the Western capitalist countries, as professor Jinga very properly appreciated, or bigger than it is nowadays in Romania or in other countries. Jinga thinks the state can and must assure the stability of paper money and, for that, it is not necessary that paper money are related to gold and defined by reference to the yellow metal. He even expresses his hope that sooner or later the world states will agree even on global paper money which would be stable and would allow international exchange without any disturbances or, at any rate, without the disturbances common to the previous decades. "We could

also note - Victor Jinga writes - that only an entirely superior organization of the human society could at a point establish and accept a non-metallic universal currency, bearing the approval and under the authority of a great monetary board unanimously acknowledged. (page 141, volume 1)

Unlike Jinga, Murray N. Rothbard, we previously referred to, does not trust at all the state's institutions, which historically have proved incapable or, better said, subjective and unfair in intentions, using the money to redistribute incomes in favour of their interests groups and, consequently, he hopes in a stable currency, as aforementioned, by readopting gold and silver coins, or gold only, manufactured by the private sector with no interference from the state. As we know, in the period 1990-1993, the American economist of Romanian origin Anghel Rugină came to Romania with high hopes and a proposition to put into circulation silver money instead of paper money. Vain hopes, because Romanian politicians did not pay much attention, but out of conventional courtesy. As well known, Rugină published a book in Romania in which he supports his ideas (5). He there pleads for returning to precious metals money or, at least, to compulsorily cover paper money, a 100 percent, in precious metals or, otherwise, completing with stocks of certain goods which can be stored for a long period of time. The reason - a bigger financial discipline of the state institutions. As we know, there isn't currently anywhere in the civilized world and, of course, neither in Romania, sufficient financial discipline or gold coverage of paper money.

Victor Jinga knew, of course, Rugină's ideas, but would not agree with them: "A. N. Rugină firmly assimilated the idea of monetary gold standard - Jinga writes - considering it the only one capable of bringing a sense of order in the difficulties created by the contradictory and controversial monetary experiments in the recent decades (...) And this option can be considered a prejudice as well, in favour of gold this time." (page 63, volume 1)

As we can note, in literature of specialty there appeared finally two directions concerning the monetary phenomenon: one, being led by prestigious names as Anghel Rugină, Murray N. Rothbard, J. G. Hulsmann, Ludwig von Mises etc., who relate the stability of the buying power of the monetary unit either to the manufacturing of money from precious metals in the private sector or, at least, to the obligativity for the state to entirely cover the paper money in precious metals or, in other words, to the limitation of paper money issuance to silver and gold stocks or to gold stocks only compulsorily constituted at the state's disposal; the other, supported by prestigious economists again, such as J. M. Keynes, for instance, Roy Harrod, Milton Friedman, Paul A. Samuelson or Victor Jinga who hope the states institutions shall stabilize the buying power of the monetary unit. The latter consider it may be obsolete to maintain a connection between paper money and the yellow metal, in modern times; let alone their manufacturing of gold and silver. Which of the two groups is right?

With no presumption to have thoroughly established a position towards this dispute, we can notice that, if we follow the evolution of the stability of the buying power of money, as it develops or, more precisely, as paper money move away from the metals it was initially manufactured of, we tend to be in favour of first group. Indeed, instability of paper money has increased over time, as the link between it and the yellow metal has been broken. As Jinga says: "In the past, inflation was a singular phenomenon, even accidental, while today, in the capitalist world, it has become an ordinary and almost generalized fact." (page 199, volume 1). A return to the precious metal seems, therefore, a return to peace and more monetary stability. But if we think that in order to return to the gold and silver money or to the free manufacturing in the private sector of gold and silver coin or, at least, to the obligation of the state to cover the paper money in these precious metals, we must somehow grab these rights from the hands of the state, which, as we can realize, will not willingly agree to it, then it seems quite as easy to force the state's institutions into being more careful and more accurate, into taking care that the paper money should maintain its buying power as stable as possible. The former socialist countries have demonstrated that this is possible. It is true, though, that we cannot point out or evaluate, at

this moment, what economic and social consequences this could bring about. Therefore, Victor Jinga seems to be right.

On the other hand, while the return to the gold and silver coins and to freely manufacturing them in the private sector involves a single dispute with the state's institutions (if successful, of course), the pressure exerted by the civil society upon state's institutions, in order to force them to maintain the buying power of the monetary unit as stable as possible in the case of paper money, even with coverage, should be permanent and, therefore, much more difficult. Still, a return to the past seems almost impossible. Jinga claims, even from the first pages of his book, that money means power as well. He gives plenty of references regarding this idea, accepting them without any comment. Indeed, today money in the government's hands also means an instrument of economic policy, inclusively or especially at an international level. The devaluation or revaluation of one country's money in relation to other currencies represents a means of stimulating or inhibiting exports and imports (as appropriate) in order to equilibrate the balance of payments or to temporise its disequilibrium. To deprive state of this lever means, under current circumstances, to let economy function according to monetary decisions of other states, which cannot be an advantage for the country in question. Of course, if all countries in the world simultaneously embraced paper money instead of precious metals money or the obligation of entire coverage of paper money in these metals then we could talk about a triumphal return to the past. But who would do that? And how? A country nowadays embracing by itself gold and/or silver coins could well end up without them, overnight, unless having forbidden their taking out of the country. But in the latter case, the country would have big problems with international trade. Therefore, Rugină had no chance with his proposition back in the '90s. In fact, in old times, when money was made of gold and silver, kings and emperors often withdrew from circulation a part of the money (as much as they could) and remelted the coins, only to put them back into circulation with a lower precious metal content, though. In other words, with a lower buying power. This argument also supports Jinga's opinion. Nowadays, the world economies are so closely connected to one another that we can only proceed together; either towards better or to the final disaster.

The economic literature tends to bring together development theory and institutional economics by emphasizing the institutions role in explaining economic performance differences among different countries. New institutionalism could also be seen as a very useful exercise to link education sector and economic performance. As we will underline in this paper, more education does not mean necessarily economic performance. Education could positively influence economic growth only if it is correlated with the individuals' preferences and labor market requirements. We will emphasize some institutional changes in order to bring more flexibility and responsibility in education sector in accordance to labor market signals.

Keywords: institutional change, education, labor market, economic development

JEL Classification: B52- I22- J24

Especially in the last decade, the economic literature tends to bring together development theory and institutional economics by emphasizing the institutions role in explaining economic performance differences among different countries. Indeed, the specific approach of institutionalists could be seen as a very useful exercise to link education sector and economic performance, since it has the capacity to explain and assert education role in development process comparing to other quantitative or qualitative theoretical approaches. The main explanation is based ultimately on recognizing that the educational inputs, as well as the quality of educational human capital existing in an economy, have a different contribution to economic development in accordance to the institutional arrangement that prevails in education sector, labor market and business environment.

This is the reason why we appreciate that simply emphasizing the impact of education on economic development based on vague and limited empirical correlations could lead to misleading results. Moreover, to understand the role of education on economic performance means taking into account an essential element: institutional structure e.g. the network of incentives and constraints existing in the economy. The specific institutional paradigm starts by considering two important economic sectors in the attempt to integrate education in the development function: education sector and labor market, as an anteroom for business environment.

As we will underline in this paper, more education does not mean necessarily economic performance. Education could positively influence economic growth only if it proves it's usefulness by increasing individual's income and economy's productivity and national output. Thus, the correlation between education and labor market in the first place necessary, but also inevitable as long as individuals view education the proper way to leave a relative poverty. From this perspective, the level of education is – or should be – the natural consequence of structure of incentives and constraints of the labor market. Moreover, educational services, as well as types of specific education, are subject to individual choice like any other good. The coordination of

individual preferences and labor market requirements lead us to the following conclusion: education sector should respond adequately to individuals' and labor market demand.

Further, we will emphasize some institutional changes in order to bring more flexibility and responsibility in education sector in accordance to labor market signals. In the economic literature there is a vast series of studies that explain the primordial role of institutions – seen as the existing set of incentives and constraints – in the education output. Thus, North (1990:72) emphasizes the double correlation between informal institutions and the level of social knowledge. Education undoubtedly influences the people's perception on the surrounding world but, at the same time, the way in which they judge, explain and justify their action in society. Similarly, their perceptions about the world tend to explain and influence their behavior in getting more knowledge⁵¹⁹.

The analysis of human behavior from the institutional perspective is able to explain, for example, the orientation of human capital (gained through education) to profitable activities such as piracy to the detriment of productive activities. Thus, if the opportunities favored by institutional existing frame make piracy a profitable work, then we could expect an increase of knowledge and abilities oriented to exploit such opportunities. As North (1990:73) pointed out “the incentives included in the institutional structure play a decisive role in selecting the most profitable knowledge and skills”. To a similar conclusion has also reached Pritchett (2004). He emphasized, because of the deficiencies of institutional arrangements, cognitive abilities have been mostly directed to unproductive social activities in many transition countries. Easterly (2002) considers education plays a secondary role in development process comparative to structure of incentives that prevails in emerging economies. Moreover, Hanushek and Wössmann (2007:41-43) emphasized the positive role of the openness of the economy on the quality of educational output and, in extent, on economic growth process. In the same time, they insist on the greater impact that qualitative education has on economic development especially in those countries in which institutions favor productive entrepreneurial initiatives. According to their opinion, productive institutions and the quality of education may develop a symbiotic relationship in order to lead economic development. Therefore, like in the case of an economy, where its performances depend on the quality of economic institutions that governs social interactions on the labor and goods market, on free trade or foreign investments, the education system could not work properly in the absence of a favorable institutional arrangement. The performance of every organization is strongly influenced by the incentives and constraints structure that influence the behavior of its members. Therefore, if the members of educational organizations (schools, education departments or minister) receive earnings or penalties in accordance with their personal achievements, then it is naturally to expect an increase in the organizations' performance. But this to be true, we should understand and create the specific pro-market institutional arrangement in the education sector⁵²⁰.

From this perspective, the reform directions should to aim three important areas: the introduction of a real competition among educational organizations, decentralization of education sector, and bringing more responsibility in educational organizations. We consider the first direction to be the most important one, as long as the other two directions appear as potential consequences of implementing an institutional arrangement aimed to increase competition among schools. Thus, furthermore we will focus on some different solutions destined to achieve this goal.

⁵¹⁹ For example, North explains that, in medieval period, the western societies have been dominated by church as regard education. This is probably the reason why the knowledge and discovery process has been stimulated in some areas, while in other countries social ideologies are intolerant to theoretical knowledge development.

⁵²⁰ Obviously, by market relations in education sector we do not understand only the existence of education demand and supply. The simply fact that students could choose a specific university or parents could choose the primary school for their children does not necessary mean there is a market. The absence of free entry and competition among schools, as well as the costumers' capability to penalize some education providers reveal there is no market at all.

The arguments in favor of competition are based on the natural right of parents to choose their children's education. The possibility to choose your own education or to your own children means necessarily competition among education schools, private or public, and stimulate them to diversify the educational services and to increase quality of education. In the past years, many education studies around the world reveal a negative correlation between public financing and the quality of education provided. Having no way to control public education has determined the individuals to spend less and less to influence government policies in this matter. This probably explains why public education is presently the subject of negotiations between school unions and minister, none of them paying attention to parent's and children's preferences. By promoting competition among education providers means the proper path in which the present educational controversies leave the struggle between unions and minister and become voluntary interactions between education providers and consumers. Instruments like voucher, fiscal credit or human capital contract could prove their usefulness in attaining this goal, even if the state will still play an important role in education matters, especially regarding the financing issue.

The specific voucher educational program

It is addressed especially to the pupils educated in public schools with low performances to turn to private schools which have well-known standards of education. Using the voucher system those children can be able to finance their studies. If this program is applied, it is expected that inefficient public schools become more motivated to improve their educational process, teaching methods, curricula and so on. It is also stimulated the emergence of new private schools focused on offering new innovative ways to serve education demand. The mentioned program is based on the experience of the state of Florida, combined with financing elements from Europe or Asia (e.g. Hong Kong); it is supposed to be flexible enough to ensure substantial growth of private education. For example, the model applied in Florida is based on two directions. On one hand it allows parents whose children attend low quality public schools to transfer them to private schools according to their preferences. On the other side, as a consequence to the possibility of choice, strong stimulants for public schools emerge in order to change their self-sufficient attitude towards the educational process.

An efficient way to test the viability of this model could be experimental schools. The Ministry of Education could implement this program in selected schools considered to have poor results obtained at national tests. It is obvious that the Ministry can use other performance indicators such as results to national exams, admission to college grades and so on. Although the Florida experiment has as purpose obtaining in two years out of four the F degree, it is possible to build another arrangement, for example three years out of four, or two out of three, according to the estimated representative time frame. We also suggest that the one year option could be efficient, the main reason being that public schools will be alert for new ways to improve the educational process even from the current year, motivated by their interest to keep the pupils for the next year, or even to bring in new ones. Regarding the value of the educational voucher, we can consider that public resources per student are a good start in financing matter. Concerning the ability to finance a new school, the Dutch model is the best example.

Therefore, following Holland's example, groups of parents (minimum 20) interested in founding a new school must be granted funds and investment grants for modernizing schools with technical equipment.

The universal educational voucher program

The second proposal for reform is more radical, trying to implement a universal voucher program based on Sweden's experience. Among the main features of this model we can identify: the educational voucher can be used for both private and public schools, depending on the parents choice; any school is free to participate at this program, including private schools profit-

motivated; the amount of governmental financing must not cover the entire school taxes (for example it could be about 75-80% of the sum, as in the Danish model); schools must be able to cover the rest of the costs for the educational process by imposing schooling taxes, such as in Germany or Hong Kong; similar to the model of Hong Kong, there must be a special system of scholarships meant to facilitate the access to education in private schools of children coming from low income family.

If this program would be applied in Romania, we foresee a very good perspective, for two reasons. Firstly, as mentioned above, it increases parent's influence in choosing schools (they become more responsible), assures opportunities for everyone and also stimulates competition between schools. Secondly, the development of the private schools is paradoxically meant to stimulate the government to implement this program. Most primary and secondary schools are public and by introducing the universal voucher there will be no extra pressure over budgetary resources. This program will only redistribute the public funds according to the demands and preferences of parents and not according to the bureaucratic decisions based almost exclusively on quantitative evaluations. We can also think of reducing public expense, for two reasons: Firstly, voucher covers only 75-80% of the educational cost in the public system and secondly, because increasing the education services competition, will lead to a cost-cutting management. Although such a measure can be blamed to put aside the quality standards, we remind that private schools (and even the public ones) depend on offering high quality education, because this is the criteria for receiving the voucher.

Fiscal credits for education

The third proposal is the result of a success of USA and Canada's models. It basically involves offering a fiscal credit to parents whose children go to private schools. The procedure is relatively simple: from the total amount of the taxes paid by one family, expenses for education are deducted. If the family has low incomes and the taxes paid are less than the schooling taxes we recommend creating a legislative context to allow additional funds to facilitate the access to private schools.

The advantage of this proposal is encouraging parents to send their children to private schools, and therefore stimulating competition among education services suppliers. Some parents, whose children used to attend public schools, will choose private schools. Therefore, the fiscal credit will bring into force the ethical criteria. The only losers in this model would be the inefficient schools, practically, that ones that don't fulfill the quality standards according to the customers' expectations.

In conclusion, we strongly believe that such proposals are aimed at achieving common goals like increasing quality in education process, bringing more ethics in this field and, furthermore, stimulating competition among schools.

Human capital contract

Human capital contract has a novelty nature comparing to voucher, the other instrument analyzed above. Comparing to voucher, it requires a minimal interference of the state, the essential role being that of building legal framework. "Human capital contract promote equal chance for everybody, and it is directed to the source of income disparities, without impending competition, without destroying incentives and without redistributing incomes in society. The foreseen results are an enhancing competition, a proper orientation of incentives and constraints, an elimination of causes that lead to (state created) arbitrarily inequalities" (Palacios, 2002:2).

Human capital contract is a specific contract through an individual could finance its higher education in exchange to a percentage of his future annual income paid for a specific period of time. The decision to finance the education of potential beneficiary (e.g. student), the (private) human-capital investment fund might be based on different criteria, like the evolution of the

economic sector, the reputation of university, his previous school results etc. Further, since repayment depends on earnings and thus adjusts to the student's capacity to pay, human capital contracts should be more attractive to students than traditional student loans. If, for example, the student is unemployed for a while, he should not pay anything to its investor until he enters again in the work field⁵²¹.

What are the main advantages of this instrument? In the first place, this institutional arrangement is less risky for the student, because it is not obliged to pay a fixed amount as long as repayment depends on the existence of earnings. Therefore, this instrument protects students from an eventually default in unemployment period. Moreover, due to its flexibility, it makes his life easier if his carrier is less profitable than he expect. This advantage can be seen as a powerful constraint for the investment fund to finance human capital, since it confronts with an increased entrepreneurial risk. Nevertheless, it might be surprisingly but the investor is in a better position than student regarding the risk. The first could reduce significantly the risk by diversification, exactly in the same way as insurance companies do. Student has not this opportunity at all. His future specialization cannot be changed costly and infinitely as response to economy trends. The investment funds could extend the number of contracts, and the loss from some contracts is compensated by the returns of other, or to extend the spectrum of skills and competencies financed according to labor market signals. Another advantage of this kind of contract, compare to other existing financing instruments such as traditional student loans, is that it requires no other guarantee mechanism. Another way to put this is: human capital contract is influenced by the type of education, the dynamics of a specific sector, not by the financial situation of his family.

The introduction and development of this instrument requires three steps: establishing the contractual clauses, finding the financial resources, and, very important, policymakers should assure investors that such contracts are fully enforceable and afford them the same legal protection that student loans receive today. Human capital contracts should be acknowledged as securities so that investment funds will be allowed to hold them. The effects of these arrangements are, among others, less risk for the student, transfer of risk to a party that can manage it better, increased information regarding the economic value of education, and increased competition in the higher education market.

In conclusion, these alternative institutional arrangements in the sphere of management and financing education could bring more liberalization of educational services, an important social field which has been wrongly treated as a traditional state monopoly.

FEMININE ENTREPRENEURSHIP AS A RESEARCH THEME. SOME CONSIDERATIONS REGARDING THE WAY OF INITIATING A BUSINESS BY THE ENTREPRENEUR WOMEN IN THE WEST OF ROMANIA⁵²²

Pop Coșuț Ioana

University of Oradea, Faculty of Economics

The present paper aims an incursion in the concern for researches in the field of feminine entrepreneurship – as a research theme, the study directions of the feminine entrepreneurship, on the basis of the special literature in the field. The applicative part of the paper refers to the research taken in the field of feminine entrepreneurship in Romania, through the project AntrES, in the area of the initiation way of business by entrepreneur women investigated and aligns aspects regarding the research methodology, the study of the way of initiating a business, the length with the age of manager women, the occupational situation at the moment of business initiation and their previous experience.

Key words: Entrepreneurship, feminine entrepreneurship, women entrepreneur, business start up, occupational situation

JEL code: E24, R11, J24,

Feminine entrepreneurship – research theme

Entrepreneurship is defined, from historic point of view, as a area with predilection masculine. The first characteristics of the entrepreneur included the notion of „*the leader of industry*”⁵²³ („Captain Man”), „*man with initiative*”⁵²⁴ (enterprising man), „*basis man*” „Key man”⁵²⁵ or „*the man who organizes the firm and/or increases its productive capacity*”⁵²⁶. Also, the literature in the field, describes the entrepreneurial theories as being „created by men, for men and applicable to men”⁵²⁷. These definitions centered mainly on the entrepreneur, are not surprisingly because,

Routledge Taylor & Francis Group, London and New York, Routledge Advances in Management and Business Studies collection, New York, 2007; p. 11;

from historical point of view, for many decades, they have been the most active in initiation, ownership and developing businesses.

More recent definitions of the entrepreneurship are less gender centered, suggesting that entrepreneurs that make activities that bring an added value depending on certain conditions⁵²⁸. Like this, entrepreneurs are definite as being all who⁵²⁹:

- try to find opportunities without considering the resources they control;
- create economic innovative organizations to obtain advantages and grow under risk and incertitude conditions;
- discovers, evaluates and exploits the opportunities to introduce new goods and services.

Even though the feminine entrepreneurship is defined in terms of creative activity, owner of the business of self-employed, a very big percentage of men and women are implied in entrepreneurship in all developed countries, even though there is a tendency of growing the feminine entrepreneurship in many of these countries.⁵³⁰ In the period 1975-1995, the percentage of women entrepreneur has raised with more than 60%, comparatively to the 20% growth of men entrepreneur⁵³¹. This growth has been registered until 1955, when, the percentage of those remained 12%, percentage who registered a tendency to increase only after the '90's.⁵³² In Europe, women entrepreneur are a minority, even so the proportion of those varies considerable from over 20% in England, Ireland, Sweden to 40% in Belgium and Portugal⁵³³.

Into the first notable article dedicated to the feminine entrepreneurship published at the middle of '70's, published by Eleanor Brantley Schwartz's (1976), the article „Entrepreneurship – a new feminine border”⁵³⁴, the writer appreciated that, the same like men, women are motivated by the wish of accomplishment, work satisfaction and independence. Also, other authors, Schwartz (1976)⁵³⁵, followed by Hisrich and Brush (1983, 1984, 1985, 1986, 1987)⁵³⁶ who have described the abilities of women entrepreneur and their business, reached to the conclusion that women's motivations are similar with men's motivations, but they are less qualified, less capable, less trained in the field of business, have a smaller inclination to entrepreneurship and manage to settle a business in a slower rhythm than men. Even though the preoccupations in the field of studying feminine entrepreneurship are growing, authors who have hold on inspection the profession bibliography⁵³⁷ show that approximately 7% of the articles published between 1969 and 1994 have included and have centered on business women. In 2000, the percentage of the

⁵³⁶ Hisrich și Brush (1983, 1984, 1985, 1986, 1987), quoted after Casson Mark; Yeung Bernard; Basu Anuradha, Wadson Nigel, op.cit., p. 612;

⁵³⁷ Brush, C. G., “*Research on women Business Owners: Past trends, a new perspective and future directions*”, *Entrepreneurship Theory and Practice*, 16 (4): 5-30 (1992); Baker, (1997), quoted after Casson Mark; Yeung Bernard; Basu Anuradha, Wadson Nigel, op. cit. p. 611;

articles on this topics reached 6%⁵³⁸. Also, other authors who have reviewed the articles written in the field of feminine entrepreneurship, counting over 400 scientific papers and several articles, published in professional magazines in the last years, have reached the same conclusion, which is that women entrepreneur represent, for sure, a field very little researched. This thing is surprisingly considering the fact that they register the most significant growth in line of entrepreneurs, the contributions of women entrepreneur being significant in innovation, creating workplaces and developing the business environment. Even though there is in the last decades an obvious concern for the domain, the specialty papers highlight that they have not managed to build adequate theories, particularly over the gender concept and the way in which entrepreneur's women experience are reflected in the socio-economic context⁵³⁹. Though, the research directions synthesize by the specialty papers in the field of feminine entrepreneurship are centered on the following directions⁵⁴⁰:

- characteristics and motivations of women entrepreneurs, with subthemes: differences in psychological characteristics between men and women, social background and business differences between women and men, the effect of labour market in the women's decision to start in business;
- the start-up patterns, resources and constrains, with subthemes: motivations, processes and structures used at start-up businesses, resource acquisition and mobilization including finance, social and human capital; the business start-up pattern and long-term performances of the business; Programs and development politics of women entrepreneurs;
- management of female-owned firms, with the following sub-themes: women's management style and approach to leadership; the family business and the wish of accomplishment; gender effects over the performance of the business;
- finance issues of female start-up businesses, with the subthemes: access to financing resources, guarantees on loans and relationship with external lenders and women's credibility;
- business relationships built by the female entrepreneurs, with the subthemes: gender differences in building business relationship; gender differences in the contain and the different approach to forming relationships;
- business performances and their growth, with subthemes: gender differences and criterions used in obtaining business performance; business performance in nowadays business performances.

Synthesizing these research directions, we observe that referring to Romania, the interests for studying female entrepreneurship are modest. A review of the publications in this field shows a lack of preoccupation of the researches for this field, even though it is registered a similar trend to the European one, of growing the number of female entrepreneurs in the last ten years.

Even so, the research directions emphasized in the specialty literature, have raised interest in the research activity realized during the project AnrES, who through the research made until this moment and the one that is prefigured to be outlined at the end of the project (January 2011), aligns in the study interests of the Romanian female entrepreneurship, especially on the North-West of Romania.

Aspects regarding the research methodology

The data base that stays at the basis of the present paper is constituted from the answers registered at the Questionnaires of research-monitoring⁵⁴¹ applied on a total number of 153 respondents – manager women⁵⁴², from the territorial centers created in the AntrES project, distributed as it follows: Baia Mare - 24, Satu Mare - 24, Oradea - 30, Arad - 27, Timișoara - 24, Reșița - 24.

The questionnaires applied to this target group I –manager women, have been constituted in a number of 52 questions, grouped as it follows: 39 questions in section A – Questions about entrepreneur/manager women and their businesses; 13 questions in section B – Aspects regarding the psychological profile of women entrepreneur/manager.

The present paper proposes to analyze answers given by women manager at section A – questions that have outlined at female entrepreneurs the following characteristics: the way of acquiring the business, the length with the age of business women, their previous experience.

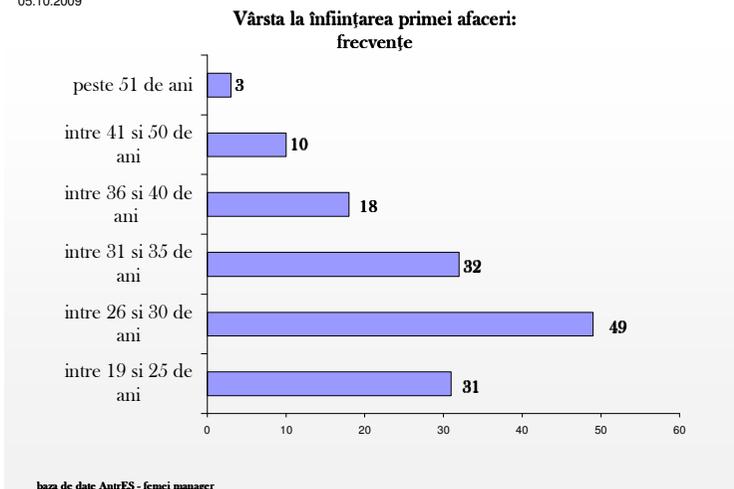

The study of the way of acquiring the business and the lengths validated

The majority of the persons from the data base of the manager women from AntrES, respective 85%, are at their first business developed, so the valid affirmations for the actual business are valid for the first business as well as a result. In the case of the first business, the age of respondents at its start-up is, for most of them, in the group 26-30 years, followed, with frequencies approximately equal, by the groups of 19-25 years, respective 31-35 years. This means that 78% of the persons who answered were, at the moment of starting-up their own business, aged under 35 years, *thing that confirms the appetite for entrepreneurship and for risks higher in younger ages* (Graphic nr.1 – *The age of manager women from AntrES research at the start-up of their first business*).

Graphic nr. 1. The age of manager women from AntrES research at the star-up of their first business

⁵⁴¹ These questionnaires have been applied, in the period 07.17.2009-07.31.2009, according to the Methodology of developing the research-monitoring activity using questionnaires, with the Instructions of application of the questionnaires and with the Instructions of filling in the data base, documents realized in AntrES project.

⁵⁴² Target group I in the project AntrES – business women – *who which to develop their business, form the counties situated along the West border (Maramureș, Satu-Mare, Bihor, Arad, Timiș, Caraș-Severin)*. For this target group, the projects wants to develop the managerial abilities, intra and entrepreneurial, in order to develop the existing business, for the optimum utilization of the opportunities existing on the market, of the success factors that raise competitiveness, of the management and marketing strategies etc. and promoting the adaptability, with effects upon performance, the SME's stability and the occupation level.

An Inter-regional Model of Women School of Entrepreneurship*”. Project financed through the European Social Fund - “Invest in people!” Contract nr. POSDRU/9/3.1/S/5. **Project manager:** prof.univ.dr. Anca Dodescu, www.antres.ro;

Though, the entrepreneurs have not been out of any professional experience at the beginning of their business, 78% of them declare that they have not worked forever in their own business, so they had previous workplaces, before their started their own business (**Graphic nr. 2. Previous experience of entrepreneur of the manager women form AntrES data base**). In average, manager women who have worked in other places than their own business, had two previous workplaces, the highest number of previous workplaces being 6.

Afacerea actuală este prima afacere

Source: ****Progress report nr. 2 –Research-monitoring study - aggregate and comparative – at inter-regional level*, realized in the project “*Entrepreneurship and the Equality of Chances. An Inter-regional Model of Women School of Entrepreneurship*”.

Regarding the present businesses of the respondents, as it can be noticed in the first table, The way of acquiring the business, 51% have been conceived personally by the entrepreneur women, 37.2% have been initiated together with other persons, 5.4% have inherited the family business, 1.4% have bought the business. Only 4.8% have acquired the business in other ways, either joined an existing firm or got a franchise.

Table nr.1. The way of acquiring the business

Your business was:	Frequency	Valid percentage
Started by you personally	76	51,0
Started by you together with someone	55	37,2
An inherited family business	8	5,4
You bought the business	2	1,4
I joined an existing firm	6	4,1
Franchise	1	0,7
Total	148	100,0

Source: ****Progress report nr. 2 –Research-monitoring study - aggregate and comparative – at inter-regional level*, realized in the project *AntrES*.

As the majority of the entrepreneurs begun their business alone, it is interesting to emphasize the main reasons, as well as the context in which they decided to start-up their own business. So, referring to the occupational situation in the moment of business start-up, 35.3% of the respondents have declared that they had a workplace but the salary was unsatisfying, 16.7 % did not have a workplace, 15.7% were happy with their workplace, 8.7% had a workplace but were going to lose it, 5.3% had a workplace but the conditions were difficult, 4% declared that they had a workplace but the relationships at the workplace were unsatisfying. Quantifying, over two thirds of them either did not have a workplace or were going to lose it, or they were unhappy with their workplace that they had because of their salary, work conditions, climate etc.

Though, it is to be remarked that the unhappiness towards the occupational statute from the respective moment has been associated with the apparition of a special business, with a favorable conjuncture 29.45% or with a special business opportunity (28.77%).

These conditions – unhappiness towards *status quo*, but the favorable moment for expressing the business idea – describe the context in which the nowadays entrepreneurs have assumed the risks of starting-up a business.

Regarding the business start-up determined by the motivation of self-determination, participants have been asked in to what extent they agree the affirmation „I started the business to demonstrate myself and those around me that I can succeed”; only 7.8% declared that they have not been determined at all by such motivations, while 41.8% have declared that they largely agree with this affirmation (24.8% have declared that totally they agree with the affirmation, and the same percentage has been registered for those who have declared their agreement in a small percentage with the affirmation).

Conclusions

As a result of our study, we conclude with emphasizing on the following correlations: there is a significant negative correlation between the age and the year of the business start-up, in other words as much as the age of the respondents grows as much the year of starting up the business decreases; the average age of women who have always worked in their own business is significantly smaller than the average age of the women who had other work places as well, on the extent to which the age increases at the moment of the business initiation, increases the number of workplaces that they had previous. The analyses did not emphasize a significant relationship between the age of the entrepreneurs at the moment of present business settlement and the number of businesses started up until present. In other words, we cannot state that older

women have a bigger experience in entrepreneurship comparatively with the younger ones. The factors considered more important in the decision to initiate a business look to be those bounded to the opportunity and not to need, even though enumerating the problems from the occupational situation from the start up moment, the problem of the unsatisfying salary appears as prevailing, followed by the lack of a work place (more than 53% of the respondent persons have stated that at the moment of the business settlement they had a workplace but were not happy with the salary). It is, like this, possible that the answers related to the entrepreneurial mobile to be rather desirable and not to present correctly the accent on opportunity towards the need. On this conclusion join, besides, the results obtained as a result of a study taken on the theme of entrepreneurship, made by 162 Romanian firms initiated after 1990⁵⁴³, study that revealed that the main reason for which the Romanian entrepreneurs have started their businesses has been the “opportunity”, followed by “the wish to use their experience”. This result coincides with the entrepreneurial theories accepted all around the world, according to which “the opportunity” is the main reason for starting-up a business⁵⁴⁴.

LA NATURE DE L'INCERTITUDE ET LA RELEVANCE DES PREVISIONS FINANCIÈRES

Prunea Petru
University of Oradea

Abstract

In the actual train of events, it would be a utopia for the economical agent to avoid the uncertainty. It had been argued that the dimension of this phenomenon knows two extremes: once it is a generator of anxiety but then also a strong motivator regarding the knowledge, innovation and production. The cause of this hazard are numerous, two of them are here reflected.

Key words: uncertainty, financial prevision, risk,

Jel: G38, M20, F30

Dans la mesure où l'essence de l'incertitude se réduit à un sentiment acquis à la suite d'une expérience personnelle ou d'une expérience du groupe auquel on appartient, la connaissance de l'évolution de sa dimension exerce une influence directe et indirecte sur les performances obtenues par une entreprise. Il a été démontré que la dimension de l'incertitude affecte différemment l'efficacité du travail des employés d'un agent économique car elle peut évoluer du niveau le plus haut, où elle génère une anxiété insupportable, excessivement dommageable, à l'autre extrême, où elle motive fortement en vue de la connaissance, de l'innovation et de la production. Dans le contexte actuel il serait une utopie qu'un agent économique se propose d'éviter l'incertitude. Les causes d'un tel hasard sont multiples, j'en retiendrai ici deux seulement. L'une résulte de la possibilité toujours plus grande de choisir, ce qui fait que l'avenir devient incertain pour toute société commerciale. Et la deuxième : la croissance exponentielle des influences externes sur n'importe quelle entreprise, beaucoup étant en dehors du set d'informations que l'on pourrait obtenir. C'est pourquoi ceux qui pensent pouvoir obtenir des habiletés d'action supplémentaires en respectant les opinions des experts qui promettent au moins d'appivoiser l'incertitude, entrent dans un jeu du hasard totalement injustifié.

Étant donné la nature imprédictible de l'activité économique, je crois qu'il faut mettre en doute l'ampleur de l'erreur qui résulte ou peut résulter des procédures de ces experts. Je ne veux pas dire par là que leurs méthodes sont incorrectes, mais que la confiance dans les résultats de leur travail est réduite, voire très diminuée dans certains cas. Le scepticisme est ici justifié par les permisses axiologiques et épistémologiques que les analystes financiers mettent à la base de leur démarche.

J'ai pu constater, grâce à la fréquentation quotidienne de ces experts s'étendant sur plus d'une décennie, que leur arrogance épistémologique trouve son explication dans les nombreuses prognoses correctes qu'ils font. Celles-ci sont facilitées par la longue phase de croissance du cycle économique et ne relève pas premièrement d'une capacité hors du commun de prévoir l'action ou la possibilité d'apparition de certains événements en mesure de justifier cette croissance. Leurs prognoses étaient en fait des constructions naïves et rappelaient des extrapolations des chiffres déjà réalisés pour la période suivante. Or, le regard rétrospectif, même si nécessaire lors de la prise de décision, sous-estime le degré de risque de la situation future. L'avenir doit être compris pour être prédit. C'est pourquoi il est nécessaire de recourir à certains éléments propres à cet avenir, et non seulement à des éléments qui ont prouvé leur validité par le passé ou dans le présent. Un tel procédé reconnaît implicitement le caractère aléatoire des variables utilisées dans la prévision financière, fait qui justifie l'élaboration et le suivi de plusieurs scénarios de l'évolution future d'une entité ou d'une activité économique.

La confiance dans sa propre capacité dont font preuve les experts financiers n'est pas d'abord fondée sur leur habilité exceptionnelle d'avoir l'intuition ou d'identifier la possibilité d'apparition des phénomènes surprenants. Nombreux sont ceux qui ont une conviction spontanée que leurs prédictions individuelles se superposent sur l'évolution du segment de la réalité de référence grâce à l'infailibilité de la méthode employée, à savoir la considération des données spécifiques à la période antérieure comme repère absolu pour la prédiction à propos de la période à venir. Les différences entre les prédictions individuelles ne sont pas considérées comme erreurs du moment où la prévision faisait preuve d'une même tendance, d'une même direction. Les distinctions concernaient le rythme, tandis que les différences d'amplitude étaient insignifiantes. C'est pourquoi l'on pourrait même parler d'un instinct de groupe dans cette catégorie socioprofessionnelle.

La justesse de la prédiction est influencée encore aujourd'hui, quand le point maximum de la crise a été dépassé, plutôt par la réputation de la personne qui l'énonce, que par l'adéquation finale des résultats à la supposition initiale. Forcément, une question surgit : les erreurs des conseillers financiers sont-elles inévitables, et relèvent de la nature humaine en général, ou bien dépendent-elles uniquement des particularités de ceux qui élaborent la prognose sur l'évolution d'un indicateur ou de plusieurs ? J'ai constaté que les deux niveaux de cette détermination agissent simultanément, dans des proportions variables. C'est la raison pour laquelle je fais mien l'avis que l'espèce humaine a une vision trop restreinte pour être capable de considérer la possibilité que les événements puissent dévier des projections initiales.

Les hommes et les experts regardent le monde dans et à partir du modèle qui leur est spécifique, à eux ou au groupe auquel ils appartiennent. Dans ce modèle, la possibilité de l'apparition des risques inconnus a été éliminée, ou l'on a exprimé la conviction qu'ils peuvent apparaître à tout moment et qu'ils peuvent, par conséquent, menacer les coordonnées financières du projet conçu pour des tiers. Faiblesse épistémologique qui fait que les scénarios élaborés soient ou bien trop optimistes ou bien trop pessimistes par rapport au résultat final. Or, cette déficience procédurale entache l'exactitude de la prévision car l'on ne calcule pas une échelle des résultats susceptibles d'être obtenus, l'on n'offre pas une marge d'erreur provenant de la manière de concevoir les projections respectives en fonction de la considération de la probabilité d'apparition des différents événements. Or, par exemple, le fait que le temps contribue à la dégradation des prognoses, même de celles fondées scientifiquement, est devenu un lieu commun.

La validité des prévisions diminue au fur et à mesure que s'agrandit la période temporelle pour laquelle elles ont été élaborées, justement à cause de la possibilité de l'apparition d'événements inattendus. Ce qui fait que la tendance d'établir des directions d'action à partir de ces prévisions revient à accepter un hasard non justifié. C'est pourquoi, ce qui gagnent leur vie en proposant à d'autres des prévisions, doivent s'abstenir d'énoncer des verdicts au-delà de la limite temporelle justifiée. Sinon, ils vont rendre dérisoire cet outil de travail indispensable - la prévision - par les explications permanentes qu'ils seront obligés de fournir.

Puisque la plupart des prévisions sont inefficaces, l'emploi de la règle de la flèche est souvent recommandé. Ou bien l'on peut se poser la question si ceux qui les conçoivent peuvent être considérés comme des gens moraux. Une réponse située à une extrême énonce que la prognose, fut-elle inexacte, est plus souhaitable que l'absence de prognose. Une autre réponse, propre à l'autre extrême, affirme que ceux qui élaborent les prévisions font plus de mal à la société que les criminels. Je pense que les limites de l'activité de prévision découlent, dans des propositions différentes, d'abord des caractéristiques des informations utilisées, et seulement dans un deuxième temps, de la nature humaine de leurs auteurs.

Quant à l'information, j'ai constaté que ceux qui décident réagissent à une certaine information non pas en fonction de ses qualités logiques, mais en fonction du cadre institutionnel qui la reçoit et l'apprécie. Ce cadre conduit aussi ensuite à l'évaluation inexacte de l'incertitude qui découle de l'information reçue, car il encourage la tendance de dénaturation de son interprétation. La

faute méthodologique qui consiste à isoler une régularité uniquement à partir de certains faits, conduit, inconsciemment, à l'erreur épistémologique qui surestime la valeur des faits en les présentant comme des preuves incontestables d'une vérité suprême.

On peut aussi tromper les bénéficiaires d'une prévision par une autre voie : on peut placer les souvenirs dans un cadre causal qui contient aussi le phénomène invoqué et situe ce dernier dans une histoire qui véhicule le message nécessaire à l'acceptation de la prognose proposée. J'ai également rencontré la catégorie d'experts qui créent de l'inquiétude par rapport à certaines sources d'incertitude, mais ne mentionnent que les sources qui ont peu de chance d'apparaître. Ainsi, l'auteur de la prognose jouissait seul des conséquences positives, palpables, tandis que le destinataire de la prognose avait affaire à ses effets négatifs.

Si le domaine où agit l'agent économique qui utilise la prévision est caractérisé par un degré élevé d'aléatoire, tel le marché du capital, il peut souffrir davantage des effets nocifs entraînés par des prévisions élaborées superficiellement. Ces agents arrivent à se considérer comme coupables, dans une mesure qui diffère dans chaque cas, d'avoir réalisé ou de ne pas avoir réalisé des opérations quand les prix leur étaient plus favorables qu'actuellement et quand ils auraient pu éviter, selon eux, les désagréments financiers qui maintenant les accablent. Contestant même le fait qu'ils sont victimes d'une chance non linéaire, ces agents économiques demandeurs de prognoses, arrivent littéralement non seulement à rejeter toute prévision, mais aussi à éviter les investissements et les opérations spécifiques à des domaines avec un degré peu élevé d'incertitude.

À propos du degré de culpabilité qui relève de la nature humaine dans l'élaboration des prognoses inefficaces, on peut parler de plusieurs de ses hypostases, toutes situées dans les limites de la moralité. Si l'on néglige la différence entre ce que savent véritablement les spécialistes du domaine financier et ce qu'ils pensent savoir, on ne saurait se contenter de mentionner qu'ils défient d'une manière esthétique la réalité en exagérant les regrets pour ce qui s'est passé et en ignorant ce qui aurait pu se passer. Ou de mentionner que, même s'ils travaillent avec l'aléatoire, ils acceptent la prédictibilité de la succession des phénomènes et des processus économiques. Plus faciles à percevoir sont en revanche les faiblesses de ceux qui, tout en sachant qu'ils ne sont pas en mesure de prédire l'évolution ultérieure de certains processus économiques, affirment qu'ils élaborent des prognoses afin de justifier le salaire perçu. Ou de ceux qui justifient leurs erreurs sur le plan de l'anticipation grâce à l'action imprévue d'un élément situé en dehors du système pris auparavant en compte.

Je suis convaincu que même si les prévisions sont d'une manière prépondérante inefficaces - car, je souligne, aujourd'hui plus que jamais, le déroulement des événements et des processus économiques est imprédictible, certains connaisseurs de ce domaine vont continuer à faire des prognoses si la demande est élevée et si, par conséquent, elles sont bien rémunérées. Les recherches ultérieures devront mettre en lumière si la fraude qui en résulte est individuelle ou institutionnelle.

A NEW PARADIGMA OF THE ECONOMICAL AGENT. FROM ADAM SMITH'S HOMO ECONOMICUS TO HOMO GENEROSUS BASED ON SOCIAL RESPONSIBILITY

Pup Anca

University of Oradea

Analyzed from outside, many actions of the economical agent seem to be impulse by the self interest. As a prototype of this kind of person we have the Homo economicus as Adam Smith described it. In a blitz portrait we identify some characteristics: he is perfect rational, perfect egoist, perfect free, perfect competitive and perfect social. The aim of this research is to permute the barycentre from Homo economicus based on self interest, to Homo generosus, based on social responsibility. As a support we have used the prison dilemma to illustrate the roll of cooperation instead self interest. This new coordination will be analyzed to the level of ethical system. Homo economicus is identified in ethics of consequences and the homo generosus in ethics of duty. In my vision, the prototype of homo generosus, is delineated under Kant's categorical imperative: respectful, based on principles as subject and sovereign.

Key words: ethical system, self interest, cooperation, Homo economicus, Homo genorosus

Jel: A13,N00, P12, P13,

Homo economicus based on self interest

Homo economicus based on own interest can be enclosed to the ethical system called ethical egoism. Egoism is the theory that people act out of their self-interest. When we describe an egoist person, we have the next portrait: a person devoted for his own interest and advantages, looking forward to accomplish his needs, without evidencing interest for people around. One occasional altruistic act dissembles a hidden further interest.

There are two versions of egoism. One is known as *psychological or descriptive egoism*; this view holds that people do, in fact, act in their own self interest. The second version of egoism is known as *ethical egoism or normative egoism*; it holds that people should act in their own self-interest. The distinction between these two type of ethical system is represented at the level "is" and "should be". When we are speaking of self-interest, there are some questions to be clarified, for example:

- Do people always act only for self interest?
- What is the meaning of the definition "self-interest"?

The two version of the egoistic ethical system mentioned above holds that whatever people do, they do in fact always act only out of their own self interest. A work hard to be promoted, I donate some many or I help a person to increase a reputation, to be considered a good man, or I love my children or my family to be also loved by them to be respect. In this situation can we identify Mother Theresa's action under the impulse of self interest? It is obvious that people seem to act for various other motivations other than just self-interest. But The egoist has to claim that these other motivations are only a mask for self interest, that the person who is doing something altruistic (i.e. action done for the sake of another) is really being altruistic for his own self interest -- he is doing this, the egoist claims, because he has a self interest in being seen by others as being altruistic or because he gets pleasure (thus satisfying his self interest) in being altruistic. To argue this affirmation Lloyd Eby, illustrate us the case of the red light of the fire engine. "Suppose someone claims that all fire engines are red. I reply that this is not true because I've seen green and yellow ones. The first person then responds, "But those are not true fire engines because all fire engines are, by definition, red." The first person may thus win the argument, but

does so only by introducing a highly tendentious - and false - definition of "fire engine." I think that, in a similar way, strict egoists likewise set up tendentious - and false - accounts of human motivation and altruistic behavior."⁵⁴⁵ The answer to the first question and its particularly arguments illustrate some actions which are not only motivated by self interest.

The second question proponents of egoism must distinguish between people's genuine self interest and their apparent self interest. Thus most of us would hold that a person who smokes a lot of cigarettes or who takes heroin is not in fact acting out of his self interest because those practices are highly self destructive. The proponent of egoism says that such people are acting not out of their true self interest but only their apparent self interest; such addicts, the egoist claims, believe that their actions are in their self interest, even though they are not in their actual self interest, and thus they do what they do out of their self interest after all. That answer, however, flies in the face of the fact that many addicts will say explicitly that they are not acting in their self interest when they continue to smoke or take drugs. This suggests that people are aware of the difference between true and false self interest and are well aware that they sometimes act out of motives other than self interest, either true or false self interest.⁵⁴⁶

Until now we have created a background to illustrate the coordination of the self interest. This type of system was claimed by Hobbles offering a psychological argument; Adam Smith illustrates an economical argument and Ayn Rand statues selfishness as a virtue quality.

In this paper work our interest is focus upon Smith's economic argument. Smith argument for a self interest which conducts to public benefits is exemplified by the well known quotation: "*It is not from the benevolence of the butcher, the brewer, or the baker, that we expect our dinner, but from their regard to their own interest. We address ourselves, not to their humanity but to their self-love, and never talk to them of our own necessities but of their advantages.*"⁵⁴⁷

The eighteenth century economist Adam Smith defended an egoistic approach toward morality based on the economic benefits that this would bring to society. Based on the theory of "**invisible hand**", in a competitive market, the homo economicus produce a state of optimal goodness for the society. Smith argues how competition determines the economical agents to produce a better product ant to sell it to a lower price compared to the other.

His self interest – to sell his products and to obtain profit – guides his actions, related with his competitors. This kind of attitude, in Smith's opinion, concurs to a public benefit not only for the one's sake.

The laws of the market formed by Adam Smith are quite simple. These can be reduced to a picture which illustrates two important things: **self interest**, and on the yonder side the **competition**. For example, if I am a gloves manufacturer my interest is to sell my merchandise and to obtain a substantial profit. To achieve my aim I would like to sell my products to a high price. But the high competition will not admit this situation, because the consumer would like to buy the gloves from my competitor, if they are to a lower price. I need to find ways in producing gloves to a reduced cost ant to sell it at a cheaper price in an effort to get more costumers. Adam Smith considers that in this situation the manufacturer gain, but so too does the costumer. Thus, my self interest leads to a best overall situation for society.⁵⁴⁸

For Smith, these two: self interest and competition can not be separated. It is both natural and an advantage to cooperate in economic affairs. Making reference to the quotation above, we understand that the butcher, brewer or the baker, do not give away meat, beer or bread, but they depend on mutual respect, fair play in business, the honoring of contracts, and indeed, even

cooperation to stay in business together in the same town.⁵⁴⁹ Adam Smith's economical argument directs to a two tier system:⁵⁵⁰

- individual motivation – egoistic;
- general goal – social utility;

Both levels are based on the ethical system based on consequences. On the first level the consequences are redound upon one person, the one involved in the action. This level is known under the terminology of ethical egoism. When it is looked for the social utility, there is involved a great number of people and it is intend to offer the greatest happiness, or good to a great number of people. This way of acting is known as utilitarianism. In Smith economical argument, we met on the highest level, the utilitarianism, which makes use of self interest to attain the good for a great number of people, a social benefit based on free-enterprise system that guides enlightened self interest to reach that goal. Conform to his theory the economical agent is not worry for the social good, but only for his own good and in this way he will attain the highest social good possible.

The problem with that argument is that not everyone has equal power and ability -- Adam Smith's argument depended on a more-or-less equal distribution of power, information, and ability among the actors in his economic drama -- and thus in pursuing their self interest the strong will prey on the weak, and the less powerful or wealthy or knowledgeable will be abused (and thus unable to achieve their self interest) by the actions of the powerful, the wealthy, and those with greater knowledge.⁵⁵¹

An example of self interest in business world was offer by Nestle Company which infant formula. During the 1970s and 1980s, Nestle launched a marketing strategy in developing countries that lured countless poor mothers into infant formula dependency. Wearing uniforms that resembled those of the legitimate nurses, Nestle's sales force infiltrated hospitals, accentuated the health benefits of their infant formula. The penetration of this product forced and made dependent the mother of this infant formula. However, proper use of it required up to 70 percent of a family income, an unable to pay, mother diluted the formula, often with contaminated local water. The result was the death of millions of infants from disease and malnutrition. After a decade-long worldwide boycott against Nestle, in 1984 the company changed their practices. The train of events illustrates how the follow of self interest does not conduct to a social benefit, as Smith argue.

Homo generosus based on social responsibility

Nowadays, many practices invoke the way self interest did not conduct to public good, different crisis exemplify the deficiency of classical *laissez-faire*. As a new paradigm for economical development we identify a *permutation from Homo economicus based on self interest to Homo generosus based on social responsibility*.

Under the terminology social responsibility, has been developed a new concept *corporate social responsibility*. Corporate social responsibility (CSR) is a form of [corporate self-regulation](#) integrated into a [business model](#). Ideally, CSR policy would function as a built-in, self-regulating mechanism whereby business would monitor and ensure its adherence to law, ethical standards, and international [norms](#). Consequently, business would embrace responsibility for the impact of its activities on the environment, consumers, employees, communities, [stakeholders](#) and all other members of the [public sphere](#). Furthermore, CSR-focused businesses would [proactively](#) promote the [public interest](#) by encouraging community growth and development, and voluntarily eliminating practices that harm the public sphere,

⁵⁴⁹ Robert Frederick, *A companion to business ethics*, Blackwell Publishing, 2009, p.336.

⁵⁵⁰ Louis Pojman, James Fieser, *Ethics: discovering right and wrong*, Wadsworth, Cengage Learnig, 2009, p.89.

regardless of legality. Essentially, CSR is the deliberate inclusion of [public interest](#) into corporate [decision-making](#), and the honoring of a [triple bottom line](#): People, Planet and Profit.⁵⁵²

This concept has developed from the classical form exposed by Milton Friedman: “*the social responsibility of business is to increase its profits*” - when corporate are responsible only to their shareholders - to the responsibility for the society seen as a whole.

Nowadays the impact of corporate social responsibility is measure on the level of reporting or standards. One of these is the Global Reporting Initiatives. The table below illustrates the number of the company who adopt this way of reporting. The evolution on 10 years is relevant to conclude the great impact assumed by the economical agent seen at the level of corporation.

Table nr. 2 – The numeric evolution of CSR-GRI reporting on period 1999 – 2009

Period of reporting	Number of company which have reported a CSR-GRI Report
1999	20
2000	50
2001	80
2002	150
2003	166
2004	272
2005	370
2006	507
2007	684
2008	1068
2009	1368

Conclusion

Adam Smith’s homo economicus relieved the portrait of an economical agent who action in the economical field based on self-interest. He is based on the premise that the economical agent does not have to worry about the social benefit or good but only about his own good or benefit and in this way he will attain the highest social benefit possible. The homo economicus can indoor his individualism under the theory of “invisible hand”, considering that the interactions between the egoistical impulses will lead to an unanticipated result: social harmony.

As a support, for cooperation instead self interest we intent to use the Prisoner’s Dilemma. It points to another possible logical error in egoism by offering an example in which the pursuit of self-interest results in both agents being made worse off.

Tabel nr.1 Prisoner’s Dilemma

	Prisoner B	
	Confess	Don’t confess

⁵⁵² Wood, D. (1991) *Corporate Social Performance Revisited*. The Academy of Management Review, Vol. 16, No. 4 (Oct., 1991) <http://www.jstor.org/stable/258977>, http://en.wikipedia.org/wiki/Corporate_social_responsibility

Prisoner A	Confess	5,5	½,10
	Don't	10,½	2,2

Source: Internet Encyclopedia of Philosophy <http://www.iep.utm.edu/egoism/>

From the table, two suspects in a crime are individually offered different sentences by their captors. A, for example, is offered 5 years in prison if he confesses, and he is told that if his partner doesn't confess he will be given 6 months in jail and his partner 10 years. If he refuses to confess, then A faces 10 years in prison if his partner does confess; however, both would only serve two years in prison if they both do not confess. A prior agreement between A and B *not to confess* would result in the best solution for the two of them, but that is not allowed by the game because they must make their decision by themselves without communicating with the other person. The incentive that each personally faces to avoid spending time in prison is to squeal in the hope that the other does not confess. If each does this, then both will end up serving the non-optimal solution of 5 years each.⁵⁵³

As an argument for the sunset period of homo economicus based on self interest are different depression and crises which could not illustrate how the classical laissez-faire works.

Included in an ethical system, Adam Smith's homo economicus, has a good responding to the consequences ethics, based on ethical egoism and utilitarianism. The consequences system sustains the moral of an action based on its consequences. If an action ends with good benefit for me and for the others, then we identify a moral action. If a fact produces bad consequences upon me, then it is immoral. Specified to Adam Smith theory, the ethical egoism is released under the concept of self interest and the utilitarianism – which sustain the spread of happiness or in this case benefit around as much as possible – is identified at the level of social benefit, which is accomplished if everyone is looking forward for own benefit.

I identify the economical agent based on social responsibility, homo generosus, having as coordinates the ethics of duty, substantiated by Kant. Specific to Kant's categorical imperative, the economical agent will “act only on that maxim which can be considered in the same time a universal law”, this means that his action are based on principles, compared to homo economicus, which based his action on consequences. Second, the prototype of homo generosus, according to the second Kant's imperative, will respect the human being, treating the stakeholders as persons: “always treat the humanity in a person as an end and never as a means merely.” And the third imperative analyses the business firm as a moral community.⁵⁵⁴

This is a way to understand the balance from the economical agent based on self interest to the economical agent active involved in social responsibility through ethical system.

UNEMPLOYMENT IN THE TIME OF ECONOMICAL CRISES

Roșca Mihaela Gabriela
University of Oradea
Faculty of Economic Sciences

Gal Anișoara
University of Oradea
Faculty of Economic Sciences

This article is a brief presentation of the periods of economical crises that occurred along history as well as a presentation of the effects that these crises had on the evolution of unemployment among the working population. The total effort the population, economy, and society in general can undertake subsequently to economical crises is immeasurable, and one can prefigure the adaptation of economic theories to the conditions and demands of the actual epoch to be a lasting and laborious process.

Key words: unemployment, unemployment rate, economical crisis, economic theory
JEL Code: J60

1. Great economical crises and the appearance of unemployment

World economy has been hallmarked by periods of upsurge and recession. Economical crises, irrespective of the period they occurred in, had the same negative phenomenon – the emergence and increase of unemployment within the working population.

The Great Depression between 1929-1933 had severely shaken the edifice of world economy. The great economical crisis or the Great Depression was a period characterised by the sudden, dramatic plunge of world economical activity. The first signs of the crisis were manifest from 1928. The extent of this world-scale event had catastrophic consequences: downsizing national income to half, drastic reduction of employed persons and the sudden increase of unemployment, the disequilibrium between merchandise demand and offer. All these revealed the fact that it was not the disequilibrium between merchandise demand and offer, as the word among economists at that time went, but due to more complex and serious causes in the market economy.

Of all contemporary western economists, J. M. Keynes was the one who adapted most efficiently and rapidly to the new situation. The serious and urgent problems he witnessed actually marked a double crisis: the economical crisis itself that encompassed the entire economical system, as well as an ideological crisis in the third and fourth decades of the past century that manifested through the above-mentioned crisis taking by surprise most economists: “evidence indicates that full, or even approximately full, employment is of rare and short-lived occurrence. Fluctuations may start briskly but seem to wear themselves out before they have proceeded to great extremes, and an intermediate situation which is neither desperate nor satisfactory is our normal lot. It is upon the fact that fluctuations tend to wear themselves out before proceeding to extremes and eventually to reverse themselves, that the theory of business cycles having a regular phase has been founded.”⁵⁵⁵

Unlike neoclassical economists who, usually supposed full utilization of production capacities and workforce, thus denying unemployment, J. M. Keynes acknowledges and recognizes the existence and emergence of involuntary unemployment, chronic mass unemployment as he would refer to it every time.

⁵⁵⁵ Keynes J.M., *Teoria generală a folosirii mâinii de lucru, a dobânzii și a banilor*, Editura Științifică, București, 1970, p. 261.

The crisis of the 1970s, the second economical crisis, is important in its depth, encompassing sphere, duration, and its consequences. For two decades after the war, developed countries experienced a growth based on the driving policy without relevant recessions managing to reduce considerably unemployment. But the experience of these years showed it is not enough for unemployment to decrease for economical instability to be attenuated, but one has to take account of the activities the former unemployed are doing at the moment. At the middle of the seventh decade and beginning of the eighth a series of data and facts considerably accentuated economical instability. Among these we can speak of the emergence of *stagflation* and *slumflation* i.e. the simultaneous presence of inflation, unemployment, and economical stagnation, that of inflation and recession which became ever more worrying. Trying to mend unemployment and economical blockages, monetary and budgetary policies became the source of other evils – inflation and the currency-financial crisis with a prolongation of negative effects on a global scale.

The catastrophic decrease of production was the major cause of the great depression from 1929-1933. The economical crisis in that period was characterized by underproduction resulting from poor crops as a consequence of natural factors (as drought, flooding) or due to wars. The crises occurring in modern times are due to overproduction. These crises do not merely refer to a certain branch or activity sector, but they encompass different branches and sectors of activity, economy as an ensemble, and, under certain conditions, the entire world economy. They have important economical and social consequences: between 1929-1933 the plummet of production in the USA was of 46%, while that of prices was of 30%, and the number of registered unemployed persons was of 13.5 million. In UK the unemployed were numbering 3 million, and in Germany the figure was of 5.5 million.

Comparing the two unsatisfactory state of economy during the two economical crises of the 1930s and of 1970s, Joan Robinson speaks of two distinct crises: “The first crisis surfaced out of a theory that could not explain the occupation level. The second crisis was born out of a theory that could not explain the content of occupation.”⁵⁵⁶

In other words the events of the 1930s proved the inability of neoclassical theory to explain involuntary unemployment and economical crisis, just as the events in the 1970s proves the new Keynesian and neokeynesian trend failed to explain how it reached the fantasy of “digging useless holes” mentioned by Keynes.

Greek academic Angelos Angelopoulos, in his work *A World Plan of Occupying Workforce. For an International-Scale Keynesianism*, published in France in 1984 and translated into Romanian in 1987, tackles by Keynesian means the issue of underdevelopment of countries in the third world and its causes. He forwards a series of measures to trigger their development at a fast pace and to achieve durable international cooperation among peoples. In the view of the Greek economist unemployment is a deeply negative phenomenon to be encountered not only in developed countries, but on a large scale and under different forms in under-developed countries. Causes of unemployment in developed and developing countries reside in the insufficient productive investments and modern technology. To avoid a future crisis Angelopoulos, adapting the Keynesian policy and theory, proposes a global plan to relaunch economic activity in all categories of countries by attracting and stimulating international cooperation of the countries in the North with those in the East and South “nowadays everybody wishes for a better, more righteous, and more humane world not only on a national scale, but on a global scale as well.”⁵⁵⁷

Thus, according to statistics presented by Angelopoulos in *A Global Plan of Occupying Workforce. For Keynesianism on an International Scale* “Between 1979-1981 in EU the unemployment rate increased by 55%, while between 1981-1983 by 32%. In the US the increase

⁵⁵⁶ Robinson J., *Contributions to Modern Economics*, Academic Press, New York, 1978, p. 9.

⁵⁵⁷ Angelopoulos A., *Un plan mondial de ocupare a forței de muncă. Pentru un keynesism la scară internațională*, Editura Politică, București, 1987, p. 28.

was devastating higher than 75%. The lowest unemployment rates were in Canada – of 12.3% and in Britain where unemployment rate reached 13.5% in 1983.”⁵⁵⁸

During the economical crisis absolute size and unemployment rate were not uniform. They varied from one country to another and within each country they also varied from one (activity) branch to another. Therefore, according to the information presented by the great Greek statistician during 1976-1981 the textile industry in the EU suffered 8.8 million workplaces loss, the shoemaking and clothes industries went through a 9.1 m workplaces loss, metallurgy – 8.3 m, the automotive and shipbuilding industries – 6.3 million workplaces.

The evolution of workforce occupation, under-occupation, and unemployment were directly influenced by the labour market dynamics, especially by its absorption capacity, that of creating new workplaces for the active under-occupied population. According to calculations referring to the 1970s out of 100 active persons on the labour market 89 in Japan, 85 in USA, and only 25 in four EU countries actually found a job. During this interval there were countries that registered rather low unemployment rates, such as Japan, Norway, Switzerland, and Sweden. Due to this fact there was a full occupation of the workforce.

According to these statistics one of the main structures of unemployment is that of the youth. Taking a look at its evolution in different countries and periods we reached the conclusion that at the beginning of the 1980s the number of young unemployed persons reached 6.5 million in Europe, compared to 1 million ten years before. In 1984 every fifth person apt for work was unemployed. In 1995 the percentage of young unemployed individuals aged 15-24 was as follows: 26.9 in Canada, 39.1 in Italy, 31.7 in Holland, 32.1 in Spain, 29.9 in Britain, 35.4 in USA, and 50.3 in Romania.

Women unemployment rate is another worrying figure. Therefore the rate of unemployed men represents 10.6%, while unemployment values referring to women indicate 18.4%. In some countries these indicators have the following values: 9.8 and 13.9% in France, 8.5 and 15.8% in Italy, 9.6 and 11.4% in Germany, 5.9 and 8.8% in Holland, and 5.4 and 7.3% in Romania.

Despite the fact that in the last two decades following the economical crisis of the 70s, other ideological currents made way in the history of economics (neoclassicism and neoliberalism), yet some major features of Keynesianism and driving policy continuing to raise interest: macroeconomic approach and state support for the private entrepreneurs by adopting new macroeconomic policies (budgetary, fiscal, monetary, and commercial policies). In this context positive results of these policies materialised in Austria – that ensured full workforce occupation up to 1981, while in all other OCDE member countries unemployment continued to increase. After 1981 unemployment surfaced in Austria as well, yet this country registered a high level of workforce occupation.

The economical crisis we are experiencing nowadays has as a starting point the year 2007 when on the mortgage market in the US the first transient financial signs manifested, consequently these would determine a very economical crisis that is fully manifesting. Therefore, according to the devastating implications this would have, one considers that the present economical crisis is the greatest after the one recorded 8 decades ago. The present economical crisis has repercussions on the global unemployment degree which is quickly bursting.

According to Eurostat statistics the number of unemployed persons in the EU is close to 22.9 million in November 2009, out of which more than 15.7 million coming from the Euro zone. Compared to the previous month the number of unemployed individuals increased by 185,000 in EU and by 102,000 in the Euro zone. Compared to November 2008 the number of jobless persons increased by 4.978 million in the EU and by 3.04 million in the Euro zone. At the end of last year (2009), lowest unemployment rates were recorded in Holland (3.9%) and Austria (5.5%), while the highest were reported in Latvia (22.3%) and Spain (19.4%). According to

⁵⁵⁸ Angelopoulos A., *Un plan mondial de ocupare a forței de muncă. Pentru un keynesism la scară internațională*, Editura Politică, București, 1987, p. 56-57.

studies carried out it was noted that the most affected by unemployment are persons with secondary education. Therefore, a continuous professional training determines the potential jobless person to cope better in case of a possible layoff. In fact “unemployment rate tend to be reversely correlated to the qualification degree.”⁵⁵⁹

Romania does not report data referring to the monthly evolution of unemployment rate according to the standards of the International Work Bureau (IWB), only to quarterly data – the latter being for the third quarter of 2009 when the unemployment rate was 7.2%, unlike the third quarter of the previous year (2008) when Romania had a 5.9% unemployment rate, as Eurostat shows.

The evolution of the unemployment rate in the previous period (November 2008) and the current period (November 2009) shows that among men this has gone from 7.2% to 9.7% in the EU, while the increase in the Euro zone was from 7.5% to 9.9%. for women unemployment rate went up from 7.8% to 9.2% in November 2009 in the EU, respectively from 8.6% to 10% in the Euro zone.

More recent data shows that in Romania unemployment rate reaches ever higher levels, fact which determines us to assert that Romania has not exited the economical crisis, but on the contrary it deepens ever more. So “in January this year unemployment rate continued to increase, reaching 8.1% compared to 7.8% in the last month of the past year, nad 4.9% in January 2009 according to the information of National Workforce Occupation Agency (ANOFM). In the first month of 2010 unemployment rate exceeded 8%, such a level in this period being unprecedented from 2003, when in January there were 781,388 jobless persons, the national level being of 8.6%. In January 2010 740,982 jobless persons were reported, 459,158 were on redundancy payment and 281,824 were not. According to ANOFM most jobless persons, respectively 605,371 (over 81%) come from the private sector.”⁵⁶⁰

An outline of the current crisis can not be made but approximately because this is fully in process, and the causes of its start off as well as its characteristics could only be exactly presented when the economical crisis is over.

We are nevertheless attempting to present some similarities and differences between the Great Depression of 1929-1933 and the current economical crisis.

2. Similarities between the present crisis and that of 1933

Even if the period between the two economical crises is considerable and the current economical crisis is still manifesting, there are some obvious similarities with the one from 1929-1933. Firstly both crises have as a starting point the US and the financial market of this country. These similarities must not be viewed as random, they should be analysed very minutely considering the fact that it is happening in the most developed country in the world where every wrong step has serious repercussions on global economy.

Secondly, the present economical crisis, like that from 1929-1933, has a global nature affecting most of the countries (including our country which admitted entering the crisis rather late).

The third existing similarity between the two crises is their global nature. Thus, just like the Great Depression “the crisis that recently began will involve, to a different degree, all sectors, respectively both those of real economy, and those of nominal economy.”⁵⁶¹

Fourthly, but more importantly than any other arguments presented above, the present economical crisis just as the Great Depression of the 1929-1933s anticipates to be a lasting one. It is very difficult to predict the length of the present crisis what is more because we are at its debut and we do not have enough data yet regarding the content, depth, and its encompassing sphere.

⁵⁶⁰ Bălan, Ionuț, *România în stagflație: recesiunea, inflația și șomajul se adâncesc concomitant*, Săptămâna Financiară, February 12, 2010, p.1.

⁷Adumitrăcesei, I.D., Niculescu N.G., *Criza economică globală (2009-20..?) cauze, implicații, soluții*, Editura Academiei, Iași, 2009, p. 25.

The history of economy and the aspects analysed from the perspective of economical crises emphasize the fact that in contemporary times there are a series of factors both in favour of renewing economic theory, and in favour of protecting and diffusing the old into the modern. In the confrontation to take place again between the new and the modern at the level of economic theory, one can foresee and claim the birth of a new theory that would lead us to a new economic science of the 21st century. To consent with the previously-stated, Nicoale N. Constantinescu noted: “Under the current conditions... we need, more than ever, an economic theory based in contemporary realities, ... a theory free of any prejudices and mastered only by the truth.”⁵⁶²

THE BERTRAND MODEL OF THE SINGLE MARKET

Sîrghi Nicoleta

Faculty of Economics and Business Administration, West University of Timisoara

Vădăsan Ioana

Faculty of Economics and Business Administration, West University of Timisoara

Starting with the signification of the rationality hypothesis when the agent's contentment is directly affected by the other agents' decisions, the theory of games defines solutions for solving different situations of conflict. The economic actors have different behaviours of the Single Market. Oligopoly strategic behaviours were analysed by the Bertrand model. The two types revealed in the work show that strategic interactions are sensitive to the companies' features, products and markets. Regarding the situation when we have an oligopoly competition, the companies make interdependent decisions in the environment affected by risk and uncertainty of the Single Market. For this reason it is an opportunity to study the structure of oligopoly type of of the Single Market with the aid of non – cooperative games.

Keywords: the Bertrand model, the Single Market, theory of games, Nash equilibrium.

JEL: D43

1. Introduction

The economic models and the practice of economical - mathematics constituted an excellent instrument for studying the economic games, stimulating the research in this field. In the last decade, a series of methods regarding the representation of the economic theory were used in order to study the evolution of state parameters of the social- economic field. The category of systems highly studied in the economic dynamism are those who pattern the business circle, patterns of economic increase and patterns which study the costs game in a dynamic perspective. In the last decade, from time to time, evolution and chaotic behaviour were noticed in the economic patterns. The main conception of the economic science was demonetized, which says that the economic balances are constant even with the lack of external shocks, the economy leaning towards a stationary state.

From this point of view, conducting a study in a dynamic environment, about costs mechanism seems to be a very important problem. Taking into account the cost which is an economic phenomenon, this work trying to approach it, using a modern instrument of work, belonging exclusively to mathematics, which is *the game theory*.

We are interested in the theoretical results which are revealed in literature regarding the theory of games starting with the key concepts of this one: games, strategies, balance, game value, etc. the research is focused on the main oligopoly market structures from the microeconomics point of view. The theory of games studies the human behaviour in situations of conflict, where the reason is contrary to the reason, each of the parties involved being able to analyse and to decide in order to reach their own targets. It emphasises the meaning of the rationality hypothesis when the contentment of a person is directly affected by the other agents' decisions and defines solutions for various situations of conflict. The theory of games is a method of research for strategic interaction situations, where the economic agents are aware of the interdependence which exists between them and each of them will make their own decisions taking into account the others' behaviour.

The theory of games was first mentioned and historically related to the year 1944 when the mathematician John von Neumann and the economist Oskar Morgenstern publish the famous work: Theory of Games and Economic Behaviour

Augustin Cournot studied in 1838 the operation of the oligopoly markets where each company takes action knowing that its volume of production affects the market cost. In 1833 J. Bertrand studied the operation of the oligopoly markets where the companies with constant efficiencies produce the same product settling the selling price. The result mentioned by Bertrand is known as Bertrand paradox⁵⁶³. In 1934 Stackelberg shows that some companies can be leader and that are able to impose the price to the others. The leader company, as a barometer company, knows best the market situation and has the means necessary in order to control the counter party. This doesn't mean that the company is the most powerful but well informed and organised.

The following question comes up: Which of the behaviours mentioned above should be followed of the Single Market? In order to answer this question, a theory was needed which could explain the interactions between companies. This is the great contribution of the game theory. It allows the elaboration of an analytical framework regarding the situations when an agent's decisions can affect the earnings of the other agents.

The theory of games studies the manner in which the rational decision are made by people in interactive situations when the results of their action depend directly on the others; actions. In this case, where the coordination of the individual actions is adjusted by competition, each economic agent (named player in the game theory) must forecast the future actions of the other agents and then optimise their own behaviour depending on the results. In the last two decades the rent-seeking type of dynamic games were analysed (to share the fortune). A systematic study of the balance point for this kind of games was made by Okuguchi K. and Szidarovsky F. who revealed that these games are equal to the Cournot type of oligopoly with price hyperbolic function.

The theory of games hypens the meaning of the rationality hypothesis when the contentment of the person is directly affected by the decisions of the other agents and defines solutions for different situations of conflict. Out of this reason knowing the analysis instruments of this theory is essential nowadays, the theory of games constituting a real matrix of the contemporary financial theory. Its postulates are based on the analysis of the people's interdependent relations.

The economic description and analysis must be oriented towards solving the conflicts caused by the problems of redistribution. The approach moves from solving problems related to assignment towards the analysis of the availability restrictions which influences the resources assignment and distribution. In conclusion, the economic reality can't be properly presented by a static approach, as the traditional microeconomics theory does it, but it must be seen as a process, with the help of a dynamic approach, from the new microeconomics perspective.

2. Competitive strategies of the Single Market.

Some of the economic agents have a different behaviour on the market affecting the other economic agents' behaviour. This type of reality resides in the "market structure" concept. The meaning of *market structure* represents the features of a market by the number and the relative power of the companies which operate on the market having the purpose of settling their behaviour and its consequences on the economic efficiency of the economic system. The contributions of the game theory to the study of the Single Market can solve some problems related to the costs system and to the intelligence exchange. Competition was and is related to the behaviour hypothesis of the economic agents and to the relative hypothesis of the market operation.

⁵⁶³ Binmore K., *Jeux et théorie des jeux* Ed. De Boeck Université, Bruxelles, 2001, p.23

The market structures vary depending on: the influence on the costs settlement; the companies' production of standardized or non - standardized products; the companies' possibility to enter on the market; the publicity, the products' features, etc. The oligopoly means a market structure controlled by a restricted number of producers, the actions of each producer affecting the others competitors' actions. If a producer cuts the price in order to increase the sales, then its competitors will react by cutting their price too, thing which will determine a profit decrease for the first company. Before making the decision regarding the price cut, the oligopoly company would have to analyse first the future reaction of its competitors and the consequences upon it. In the first works on oligopoly, Cournot (1838) and Bertrand (1883), write about the elements used by the theory of games for analyse of the imperfect competition. The theory of games uses a general method of analysing the strategic interaction situations. This theory applies on analysing the companies' strategic behaviour of the Single Market, starting with the general framework of a game situation.

The game situations are based on few important elements: game rules; strategies to follow; earnings and in oligopoly situations we have: rules of the oligopoly game; strategies of the oligopoly game; earnings of the oligopoly game. The rules of an oligopoly game are made starting with the features of the economic, social and politic environment of the oligopoly market, with the laws of the trade practices. One of these rules regards the number of players meaning the number of companies operating on the market. The rules of an oligopoly game represent all the possible actions of each player. This one makes a complete list of game strategies. The possible strategies in an oligopoly game can be: prices increase, cutting prices or keeping them at the same level; increase, decrease or keeping the production at the same level; more, less or the same advertising; improving, lowering or maintaining the quality, etc. The earnings of an oligopoly game may be represented by the economic profits or losses of each company⁵⁶⁴. The earnings of the companies depend on their strategies and on their constraints which they deal with.

Studying the situations of imperfect competition, especially the *Single Market* where the buyers' decisions are interdependent, can be achieved with the help of non – cooperative games. Important applications of the game theory reside in different aspects of the oligopoly competition, for example: secret agreements or price forming study in a closed economic system. The situation of oligopoly competition, the companies can't deal with an unreceptive environment. The interdependent situations between different centres of decision and their contribution to obtaining a credible solution can be done with the help of *non-cooperative games* which developed a lot over the last years.

For the duopoly games, the possible strategies the two companies can follow are: agreement for profit division; or breaking the first agreement, thing that would allow the cheating company to obtain greater profits than its partner. This kind of structure is similar to the one of the game named prisoner's dilemma⁵⁶⁵. In case of a balance situation the two companies break or follow the duopoly agreement, they will sell at the same price, producing the same volume and obtaining the profit of a monopolist.

The theoreticians of the game with practice in economy showed that price war can be considered to be the result of a repeated duopoly game. The producers follow the concluded agreements until the request variation determine the price cut under a certain limit. The companies' reaction to the price cut is like it would be the result of a problem the competitors deal with. They have to operate in order to make the competitors believe in the penalty in case of agreement breakage. Updating the credibility of the menaces is important in order to respect the agreement as longer as possible. On this kind of markets, from time to time, price war can occur, which can end with the exclusion from the market of the weaker competitors.

⁵⁶⁵ Jhele G. A., Reny P. J. – *Advanced Microeconomic Theory* - Ed. Addison Wesley, New-York, 2006,p.231

3. The Bertrand model

Bertrand (1883) suggested a solution which depended on price variation; he started with a rather simple case where two companies produce the same product, settling their selling price. The production costs for each product are constant (marked with letter „c”) and identical for both companies. In this case the consumers will buy from the company which has lower prices. We suppose that the two companies share the total request in two, if the prices are the same.

Bertrand’s paradoxical result is that at an equilibrium level the price is equal to the marginal cost and the profits are null. None of the companies can improve the profits because it would obtain a negative one cutting the price. If a company settles a price higher than the marginal cost, the other company will be interested in settling a lower price in order to cover the entire request. The question is if Nash equilibrium is present where the price is equal to the marginal cost. The Nash equilibrium, if present, is it unique?

In the Bertrand model, Nash equilibrium is a combination of strategies weakly controlled: some players are not interested in settling an equal or higher price than „c” (the cost), others set a price equal to „c”⁵⁶⁶. An irrational player who sets a price (P) higher than the cost (c) he obtains the same profit as the player who will obtain Nash equilibrium if the competitor always sets a price (P) equal to the cost (c). The player’s irrationally occurs when a competitor must explore such behaviour, choosing a price (P₁) higher to the cost but lower to P. This kind of argument shows that players can be interested in manipulating their competitors making them believe that they are irrational. If player 1 is an agent with “irrational” reputation, choosing a monopoly price, then player 2 sets a price P₂ lower to the monopoly one. But he is not sure that player 1, declared irrational but being rational benefits by his reputation, then he will chose a price lower to P₂.

Such reputation problems can be studied in a dynamic framework. We will consider the reputation game for two companies of the Single Market, marking with δ the discount factor and trying to settle the perfect Bayesian equilibrium. The game can run by converse induction taking into account the beliefs. If the cooperation was supported in the first period, then in the final period the players will have the same reputation. If the players broke the agreement then they would lose the initial reputation. But choosing a cooperative strategy the player maintains the reputation, without bringing any new information regarding his behaviour, meaning the cooperative one. If we assume that the players cooperated in the first period then in the last one, a player obtained $\alpha\delta\pi$ this one being a price lower than the monopoly one. The question which rises is: are the players interested in cooperating at the beginning? The company has an updated hope for earning equal to $\alpha(\pi/2 + \delta\pi)$ in case of cooperation. In case of non cooperation for the entire monopoly profit the company will obtain $\alpha\pi$, losing its reputation. The company is interested in cooperation when $\delta \geq 1/2$. This model shows that the companies can be interested in cooperating at the beginning when their option for the present is low enough. In this case, we can talk about cooperation at the beginning of the game which degenerates in a price war. The reputation phenomena can be very important if there is the slightest incertitude regarding the perfect rationality of the players. Such a feature can explain many behaviours assuming that the players believe there are other “irrational” players but with a lower probability.

The examples mentioned above express the result of the strategic interaction which is very sensitive to the companies’, products’ and markets’ features. There are many different situations by which the consequences of these features can be studied (for example: the problems related to noticing the products’ quality, the advertising, the strategies of research and development, the network of distribution, the possibilities of market input and output). If we start with a normal game $(x_1, \dots, x_n; u_1, \dots, u_n)$ we will assume that the players behaviour is decentralized, each of them having to chose alone a strategy, ignoring any decision of other players. The communication

⁵⁶⁶ Kreps D. M., *Théorie des jeux et modélisation économique*, Ed. Dunod, Paris, 2002,p.136.

possibility between players is excluded. There is no initial result or a game history which could emphasize the strategies used more frequently than the one of the others. We can take into account all the strategies as being a priori equally possible and also the choice of the best strategy.

In order to determine a *non-cooperative* behaviour the controlling strategies can be removed. Strategy Y_i of player “i” is controlled by strategy x_i (where the results $(x_1, \dots, x_{i-1}; y_i, x_{i+1}, \dots, x_n)$ represent a non – controlling assembly of strategies of player “i”) when whatever would be the strategic choice of other players, the use of x_i is at least as profitable for “i” than the use of “ y_i ”, meaning strategy “ x_i ” better than y_i . The games which have an equilibrium regarding the controlling strategies will be the decentralized solution of the non-cooperative game.

The strategy used by the company of the Single Market depends on the forecasts made on the reactions of the competitor companies, its analysis can be achieved with the help of the “game theory”. In this game each player must choose between a *pacifist strategy and an aggressive strategy*. The results of this game are described in picture nr.1.

		Y*	
		Pacifist	Aggressive
X*	Pacifist	(2, 2)	(0, 3)
	Aggressive	(3, 0)	(1, 1)

Fig. 1 — Game matrix of the Single Market.

In picture 1 each of the four boxes in the game matrix represent a result of the game with use of X^* in left and use of Y^* in right. We can verify if the pacifist strategy of a player is controlled by his aggressive strategy. In our situation the game has only an equilibrium in controlling strategies (aggressive, aggressive) which corresponds to an open price war of the Single Market. Such a result is not acceptable because the result “peace” meaning (pacifist, pacifist) is proffered by the two players in other words the war is not an optimal Pareto. The dilemma of the game shows that for a player which is not entirely sure on the pacifist intentions of its partner the use of the aggressive strategies is needed to follow the individual interests but the mutual interest recommends that everything has to be done in order to obtain a pacifist result.

The dynamic approach of the economic reality goes to the change of parameters of the variables which economic and social life. The key to survive in case of economic games is the capability of the companies to adjust their strategies to the environment which is in continuous change⁵⁶⁷. A correct forecast of the future events it is necessary. The cross - impact analysis, the request - hazard forecast as well as other numerous scenarios are just a few of the methodologies used in economic forecasts.

4. Conclusions

In the economy structural changes and oscillations are the rule and not the exception and the stationary states become instable when certain parameters vary. The economic actors have different behaviours on the Single Market which have different consequences depending on the number, relative size and strategies approached by the other economic actors. Starting with the rationality hypothesis when the agent’s contentment is affected by the others decisions the game theory defines solutions for solving the situations of conflict.

⁵⁶⁷ Sirghi Nicoleta, *Microeconomie Aprofundata. Teorie si aplicatii*, Editura Mirton, Timisoara, 2008, p.92.

The economic level of the competition can be considered as a mechanism of resources allocation which allows, in many cases, the promotion of the economical efficiency. The game theory contribution to the development of the competition politics can solve some problems related to the price system and to the intelligence exchange. For this reason the notion of competition was and is related first to the behaviour hypothesis of the economical agents and second to the relative hypothesis of the market operation. When the coordination of the individual actions is adjusted by competition, each economic agent must forecast the other agents' actions and then maximise depending on the results their own behaviour.

Conducting a study in a dynamic environment regarding the Single Market represents a very important problem of the contemporary economy. We are interested in the theoretical results which are revealed in literature regarding the theory of games starting with the key concepts of this one: games, strategies, balance, game value, etc. The research is focused on the main oligopoly market structures from the microeconomics point of view. For this reason it is an opportunity to study the structure of oligopoly type of markets with the aid of non – cooperative games.

The use of the game theory as reference framework regarding the representation of the economic agents' on different market structure opens the way for an expansive field of investigation. The problem of the economic agents is no longer. The problem of the economic agents is no longer conducting studies for the operation of the perfect competition markets but to analyse the means in which they can coordinate the decisions, in dynamic configurations in a competitive environment affected by risk and uncertainty.

GENDER DISPARITIES IN THE ENTREPRENEURIAL FIELD IN WESTERN ROMANIA

The entrepreneurial spirit may develop in any economic sector and any type of business, both in the case of men and women, it is applied to a wide range of organisations, from family businesses to large companies, irrespective of the structure of shareholders, from NGOs to companies gone public on the capital market, firms from all sectors of activity.

As regards the gender disparities in the entrepreneurial field, studies reveal the fact that although the two genders are similar, women entrepreneurs differ from men through motivations, their business ability and occupational past.

Although the gender differences are still important, the number of women entrepreneurs has significantly increased compared to the previous period.

Keywords: entrepreneurship, gender disparities, motivations

JEL classification: L26, M13, M21

1. Introduction

According to the definition of the MacMillan Dictionary of Modern Economics⁵⁶⁸ the entrepreneur is the factor who organises the manufacturing process, is in charge with the economic decisions regarding what is produced, in what quantities and through which manufacturing methods.

Entrepreneurship is first of all a state of mind referring to the motivation and capacity of an individual to identify opportunity and follow it with the purpose of producing value or economic success.

Entrepreneurship means people and refers to the decisions they make and to their actions in starting, taking over or managing a business.

Although the financial independence is very important, some people say they choose to become entrepreneurs motivated not only by potential earnings, but especially by the challenges the business world implies. For others, who do not feel fulfilled by the position of employees, the chance to become entrepreneurs present the opportunities they need in order to build a better position. It was found that the satisfaction provided by work is higher among entrepreneurs than among employees.

Some persons are involved in the entrepreneurial activity because they have identified certain attractive business opportunities, whereas others are involved in entrepreneurship because they do not see another way of earning their living. For those attracted to entrepreneurship one may identify two major reasons of opportunity, i.e. independence and increase of revenues. The other motives of involvement in entrepreneurial activities are the necessity and the maintenance of the present revenue level.

⁵⁶⁸ MacMillan Dictionary of Modern Economy, Codex Editions, 1999, p. 216.

Women are motivated, in general, by their need for independence and achievement, resulted from the frustrations related to the place of work. In contrast, men tend to be led by the desire to be in control, to try new things.

In terms of personality, women and men entrepreneurs match the classic success profile, proving courage, energy, discipline, orientation towards goals, enthusiasm, innovation, persistence, passion, vision, orientation towards the customer and desire of commitment to hard work. In comparison with men, women tend to be more flexible, balanced and tolerant, more realistic. Some researchers pointed out that women are more prudent, more confident, less aggressive and more easily persuaded, with more reduced abilities of leadership and problem-solving, when decision making implies certain risks.

Moreover, women have been described as being dependent of those around them, as caring more about the others; the tendency towards ethic behaviours is more powerful among women, being less likely that women grant incentives for closing a deal.

2. Dimensions of the entrepreneurial phenomenon in the west of the country

Actually, typical studies on women entrepreneurs are focused upon their distinct individual features (motivations, personality traits, experience) or upon the characteristic of the firms they have created (size, sector of activity, management style, strategies adopted by women, performance of the business led by women).

Similarly to the entire country, in the western Romania (Maramureş, Satu Mare, Timiș, Bihor, Arad or Caraș-Severin), although the increase of business owned by women is encouraging, their size is reduced in terms of earnings and number of employees, compared to men's businesses.

Moreover, if as regards the rate of the active population registered in Romania's western counties we find that the data, as they are presented by the National Institute of Statistics, do not reflect the existence of certain gender disparities (the average of these counties is of approximately 96% both for men and for women), in the case of business ownership the discrepancies are still very high between women and men.

By comparison, we may remark that men are more frequently found in the role of company managers, but also among the self-employed (natural authorised persons) in the year 2008.

As regards the number of natural authorised persons (self-employed persons) legally registered until 31 December 2008 (table no. 1), in Timiș county there are only 8348 such entities, less than in Maramureş, Satu Mare, Bihor, Arad; in Caraș-Severin, at the level of the year 2008 a number of 4940 self-employed people were registered. Moreover, we find that in Timiș the number of women registered as self-employed is not even half, compared with the number of men (43.39% of the number of men).

Table no. 1

Self-employed persons legally registered until 31 December 2008

	MM	SM	BH	AR	TM	CS
Women	5955	3528	4024	6277	2526	1896
Men	8848	5512	6528	10136	5822	3044

Source: *National Office of the Register of Commerce, 2009*

Although at a different level, discrepancies are found in all the other analysed counties, where the number of self-employed women is nevertheless above the half of the number of men, the less gender difference are registered in Maramureş county (but here also, the number of self-employed women is much more reduced than in the case of men, because their percentage is only 67.30% of the number of men registered as self-employed).

Table no. 2

Managers of companies registered in 2008

	MM	SM	BH	AR	TM	CS
Women	710	1455	1039	870	1569	399
Men	1985	1592	2754	1956	3792	772

Source: *National Office of the Register of Commerce, 2009*

As regards the management of a company (table no. 2), we remark that in the Timiș county we encounter the highest number of businesspeople, but the gender differences are found also in this case (1569 women and 3792 men).

In the Timiș County also, we register the highest number of women administrators of small and medium companies (table no. 3).

Table no. 3

Administrators of small and medium companies registered in 2008

	MM	SM	BH	AR	TM	CS
Women	4967	4006	8659	5455	9834	2186
Men	10444	7698	17012	10740	20957	4168

Source: *National Office of the Register of Commerce, 2009*

Although the figures in this field, as they appear at the county level, are higher than the national average, the gender disparities are evident, if we were to relate of the number of women and men who are managers of companies, administrators of SMEs, or self-employed persons.

According to the data supplied by the Office of the Register of Commerce, in the Maramureș county there are 4967 women managing SMEs and 10,444 men. Nevertheless, the density of companies in this county is much more reduced in comparison with the regional or national average, as there is a percentage of 16.96% companies per 1000 inhabitants (the regional average being of 26% companies per 1000 inhabitants). We refer mainly to SMEs preponderantly led by men.

One particular fact draws our attention by far, i.e. irrespective of the type of incorporation, the Caraș-Severin county ranges last, as the number of entrepreneurs is much more reduce compared to any of the other analysed counties.

The potential of creating small enterprises in Caraș-Severin county is limited, as there are few people who dispose of private capital, and the banking systems offer a very reduced access to capital. However, where experience was present, solid businesses were created, that efficiently used the valuable management resources and where access to western markets was, there also occurred remarkable results. In other cases, management was confronted with the issue of formulating and implementing a good strategy of survival and development.

As for the gender differences, we remark that in this county also the women managers are much fewer compared to men, but the latter are very few in their turn.

We may remark the fact that in all the analysed counties the number of men managers of SMEs is approximately double than that of women, the discrepancies being more obvious in the case of the managers of large companies (table no. 4), in the latter case the number of men being seven or eight times higher than that of women.

Table no. 4

Managers of large companies registered in 2008

	MM	SM	BH	AR	TM	CS
Women	33	13	38	83	67	11
Men	121	67	141	220	264	89

Source: *National Office of the Register of Commerce, 2009*

On the other hand, we must underline that along with the increase of the number of newly-founded companies, the number of companies created and/or managed by women has increased as well.

We also wish to highlight the concentration of the SMEs in the region dealing in the field of textile industry, a field toward which especially women tend to orient themselves.

The feminine entrepreneurial culture in Romania is closely connected with the attitude of society towards the status of women managers. In a traditionally patriarchal society that expects women to be first of all good administrators of their home (i.e. good mothers and skilled housewives) it is difficult to feel integrated into the men-dominated entrepreneurial world.

Moreover, the segregation on the labour market has major influences also upon the entrepreneurial tendencies of women. Similarly to the labour market, in the field of entrepreneurship the women's interest is also oriented toward traditionally feminised sectors.

It was found that the domains in which women work are preponderantly traditionally feminine, e.g.: public administration, commerce, education, housekeeping, and social work. Nevertheless, their interest for self-improvement are focused on exact domains and sciences such as: finances, management, environment protection, tourism, human resources or methodology.

And yet, women face a series of difficulties men do not normally encounter. The banks and other financial institutions are more conservative and reluctant to grant loans to women entrepreneurs. An explanation is the fact that some banks assign successful entrepreneurs' traits especially to men.

3. Conclusion

The decision to start a business in the case of women is more complex, as they are usually more connected than men to the obligations related to family.

On the other hand, the starting points and the motivation to start a private business are similar for men and women, although women tend to be more motivated by the need of achievement resulted from the frustrations at the place of work, provoked by the lack of opportunities of promotion and talent manifestation, both genders have a strong interest for the domain of the firm.

As regards the sources of financing, women generally rely on the personal assets and savings, as women get loans from banking institutions with more difficulty than men.

We also found that in general the personality traits are similar for men and women entrepreneurs. Both men and women are energetic, independent, sociable. However, men are often more self-confident and less flexible and tolerant than women, which may led to the existence of very different management styles.

The nature of businesses led by men and women are also different. Women tend to start a business especially in the field of services and retail. Consequently, the businesses owned by women are often smaller, and their revenues more reduced than those of men. However, the business opportunities for women have an unprecedented growth tendency, as the field of services exhibits an accented development trend.

As shown by one of the most complex studies in the field of feminine entrepreneurship in the year 2007⁵⁶⁹, we may underline the following:

- Potential women entrepreneurs are 35 years of age on the average and they have around 8 years of experience. Most of them (62%) have studies or training in management and business administration;
- While the new and potential women entrepreneurs declare that their main motivation to start a business is the opportunity to earn higher revenues, the

⁵⁶⁹ Driga Otilia, Lafuente Gonzales Esteban, *Feminine entrepreneurship in Romania – Personal traits and effects of socio-cultural variables*, CEBR, 2007, p. 9.

SMEs owners consider that their main motivation is the identification of a business opportunities they wanted to take advantage of;

- The social status associated to entrepreneurs and the feeling of respect towards them are perception factors positively influencing the decision to become an entrepreneur;
- The existence of positive entrepreneurial models stimulate the activity of women entrepreneurs in Romania. 38% of the women who have not started a business yet, but intend to do it in the future, declare to have acquaintances that are entrepreneurs within their social circle (family, friends). In comparison with men entrepreneurs, women however dispose of less entrepreneurial examples. This result confirms the results obtained in empirical studies at the international level and to support the idea that women, because of their exclusion along time from economic and social life, dispose of less entrepreneurial examples.
- Women tend to start smaller businesses than men entrepreneurs. Considering the initial number of employees as the size criterion for the business, this number is of 3 employees in the case of women and 4 in the case of men. Nevertheless, the businesses of Romania women entrepreneurs tend to develop more rapidly by a growth rate of approximately 39% compared to 31% in the case of men.
- Women entrepreneurs in Romania are involved in international business more than men entrepreneurs. 13.2% of the products or services provided by firms created by women are dedicated to export while this percentage is of 13.14% in the case of men.

Consequently, we may conclude that although the gender differences are still important, the number of women entrepreneurs has significantly increased compared to the previous period. The modification of family life and professional activity made more and more women get involved in business. Women entrepreneurs are different from the other women by the fact that they are more inclined to assume risks, they are more decided and firm and they exhibit a higher desire to control their own destiny.

DEVELOPMENT OF ENTREPRENEURIAL ACTIVITIES – PREMISE OF THE INCREASE OF ECONOMIC COMPETITIVENESS

Tănase Diana

University “Eftimie Murgu” of Reșița

Faculty of Economics and Administrative Sciences

Tănase Adrian

University “Eftimie Murgu” of Reșița

Faculty of Economics and Administrative Sciences

In the context of the integration into the European Union, the issue of the increase of firms' competitiveness has become essential for Romania's economy also, which requires as a mandatory condition the elaboration and application of certain clear strategies, both at the level of firms, and of the Government's, with specific goals and actions.

Although it has made certain progress, Romania has significant competitiveness delays compared to the EU member states.

In this context, development of entrepreneurial activities is a premise of the increase of economic competitiveness.

Entrepreneurship is first of all a state of mind referring to the motivation and capacity of an individual to identify opportunity and follow it with the purpose of producing value or economic success.

Keywords: entrepreneurship, competitiveness, development

JEL classification: L26, O10, R11

1. Entrepreneurship and competitiveness– overall perspective

After several years of rapid and almost unhindered growth, the global economic landscape has changed. The raise of energy and food prices, the international financial crisis and the slow-down caused by it confronts the managerial policies of the present economy with new challenges.

The present context has underlined the importance of competitiveness that can help national economies survive these types of shocks, with the purpose of assuring economic performance in the future.

Competitiveness is a complex concept, largely debated at present by economists and politicians throughout the world.

Representing the highest degree in which, under the conditions of a free market, a nation is capable to produce goods and services that can be successfully launched on the international market, contributing thus to the increase of the living standard of its citizens, competitiveness is a challenge, which applies not only in the case of nations, but also at the level of each of the actors of the national economy.

Competitiveness suggests security, efficiency, quality, high productiveness, adaptability, success, modern management, superior products, and low costs.

Creativity or innovation are needed in order to access and become competitive on a market, to change it or even to create a new market. Moreover, in order to turn a business idea into success one needs the ability to combine creativity or innovation with solid management principles.

In relation with the remarkable importance of *innovation*, P. Drucker⁵⁷⁰ underlined the following: *“innovation is the specific instrument of entrepreneurs, the means with which they exploit change as an opportunity for various businesses or services; it can be also represented as a subject and*

⁵⁷⁰ Drucker P., *Innovation and the entrepreneurial system*, Encyclopaedic Publishing House, Bucharest, 1993, p. 19.

thus it can be learned and practised. Entrepreneurs must seek with precise purpose the sources of innovation, its changes and symptoms, which indicates for them favourable opportunities for successful innovations. They need to know and apply the principles of successful innovation.”

Furthermore, entrepreneurship contributes more and more to the creation of new jobs. One remarked at the global level that small firms and not large firms created most jobs. Studies have shown that entrepreneurship can significantly contribute to the stimulation of economic activity, to the integration of the unemployed and social disadvantaged groups, contributing thus to the economic growth of a country.

2. Stimulating factors of entrepreneurship in our country

The new entrepreneurial initiative, the start of a business or the reorientation of an exiting one (after the transfer of a business to a new owner), the support for productiveness - all these raise the pressure of competitiveness, forcing other firms to react by enhancing efficiency.

The increase of efficiency and innovation within the firm, in products, services or markets, raise the force of the competitiveness of an economy as a whole. This process brings thus benefits to all participants in economic life, and thus not only to entrepreneurs, but also to consumers, who have the possibility to choose the best existing offers.

Although slight progress has been registered in our country lately, there is not yet an entrepreneurial culture and consequently the State institutions, the academic institutions and the SMEs recognise the necessity to act in this direction. The limited number of studies on entrepreneurship in Romania made entrepreneurship itself remain in a continuous state of inferiority (because of the absence of resources put at the disposal of universities and governmental agencies).

In spite of the improvement efforts under progress, entrepreneurs identify *bureaucracy* as being a major obstacle in the way of business operations, especially for those who desire to operate and develop within the European market. The legislation is not generally differentiated in accordance with the size of the firm and thus it disproportionately affects smaller companies. The local public authorities must be encouraged to think at the micro level at the beginning and keep the legislation as simple and appropriate as possible.

Adequate *fiscal measures* can contribute to the development, growth and longevity of companies. The structure of the fiscal system, including income tax, corporate tax, labour tax and VAT influence the capacity of firms to expand. The complexity of the fiscal systems is in itself an administrative burden for entrepreneurs.

As the rates of marginal tax raise, the entrepreneurs tend to expand their own business more slowly, to invest less and to employ less personnel. The level of the labour taxation can also be a decisive factor in the decision of the firms in our country to employ staff. The fiscal reform in the past year have not contributed to the creation of a clearer trend as regards the creation of small and medium enterprises, as the labour taxation is still high.

On the other hand, the strangulations on the labour market create barriers in the way of development and one must intensify the qualification efforts for workers.

Although unemployment still constitutes a major challenge for Romania, the recent years have exhibited higher difficulties in *recruiting labour force* in certain regions and counties. The firms already respond to the qualification voids, for instance, by providing formal or informal training for their own staff.

Consequently, we are currently witnessing the need to make sure that most qualifications of the local, regional and national labour force correspond to the economic and technological evolution. The permanent enhanced training represents an effective means of getting a qualification.

Moreover, *the access to financing* is indispensable for development, but most SMEs encounter difficulties such as: the risk capital market is underdeveloped and banks avoid more and more risky loans.

Furthermore, in order to deal with the challenge of a harsh competition, entrepreneurs must be encouraged to innovate and to tend towards the internationalisation of the business. For this reason, they must have *access to knowledge, relevant contacts, specialisation and support* for a first-rate business.

SMEs consider that the Single Market has led to a higher competition, but also to new opportunities of expansion. The competitive pressure makes firms continually exploit knowledge and innovation. Firms can modernise themselves in different ways, including by means of technologic development, quality management, new modalities of work organisation or distribution channels. The human capital is important for creating innovating ideas.

A stimulating factor for encouraging entrepreneurship is also the *business incubators*, a facility putting at the disposal of small entrepreneurs, besides working premises, centralised services of secretarial activities, guarding and cleaning, a package of consulting and business services. In the period of incubation, ranging from 1 to 3 years, the newly-established firms, those in their first years of operation or in their first years of crisis are assisted by the consulting team of the incubator to develop managerial and operation capacities in order to become viable partners of the local business community.

A study performed by GEM (Global Entrepreneurship Monitor) and forwarded in Romania's country report 2007 – Global monitoring of entrepreneurship – highlights the features of entrepreneurship in Romania in an international comparison:

- absence of entrepreneurial tradition, activity and education before the '90s during the socialist period;
- unfavourable entrepreneurial environment in the transition period of the '90s;
- in the period of economic growth, after 2000: acceptance by the population of jobs offered by the large companies, as they are perceived as having a lower risk.

The explanation for the rather low level of entrepreneurship development in Romania can be found in the restrictions faced by small companies as regards resources and their vulnerability related to the environmental changes and uncertainty, the enhanced comprehension of factors and mechanisms explaining the development of firms⁵⁷¹.

3. Conclusion

In the present context of economic crisis, both new SMEs and the existing ones are confronted with financial problems and especially with the absence of resources, limited access to loans and absence of customers, increase of the number of customers with due payments.

As for demand, entrepreneurs consider that their problems depend on the constraints of their competition on the sales markets and the lack of economic resources of their potential customers. Thus, in the context of the economic and social changes exhibited at the national level as a result of the global financial crisis, we find that the labour market is undergoing a continual change. The high rate of BIM unemployment or the absence of prospects of economic investments able to stimulate the development of local communities are factors generating stagnation or social crisis. This reality highlights the need for the intervention of public institutions or other non-governmental organisations for the support of entrepreneurship development. The need for information, counselling, professional training or creating a support network for entrepreneurs or for those who desire to become entrepreneurs can be palliated by certain legislative regulations, efficient programmes and projects able to respond to the specific needs of this category.

Under these circumstances, entrepreneurship can contribute to the economic and social growth in the area whose development is delayed as it is, by stimulating economic activity and creating new

⁵⁷¹ Lafuente Esteban, Rabetino Rodrigo, *Human capital as a determinant of small firms growth in Romania a quantile approach*, CEBR, Working Paper Series 03 – 2007, p. 10.

jobs, **all the above contributing to the regional development and implicitly to the increase of economic competitiveness.**

Entrepreneurship is crucial for competitiveness, as the raise of efficiency and the introduction of innovation in companies, either related to management, processes, products, services or markets increase competitiveness among competitors, and leads to the obtaining of new products and to the reduction of prices.

Entrepreneurship offers the possibility of exploiting the creative potential of the person, as owning a business is not only a way to earn money, but also a modality to earn independence, to deal with a variety of challenges and thus to reach a higher level of satisfaction.

THE COORDINATES OF THE INTERNATIONAL ECONOMIC CIRCUITS – REFERENCE POINT FOR THE SCIENTIFIC DEFINITION OF SMALL AND MEDIUM SIZED BUSINESSES AND THEIR INTEGRATION IN NATIONAL, EU AND WOLRD WIDE DISTRIBUTION SYSTEMS

Tănăsescu Virgil Romeo

The Bucharest Academy of Economic Studies

The new framework for the development of contemporary society will have in the future, through the generated results, a powerful impact on the overall integration coordinates of small and medium size businesses within the economic network, a shift from seeing them as a means of escaping poverty to perceiving them as important entities orientated towards the satisfaction of both client and market from the point of view of product demand – entities with a high flexibility ratio capable of a better reaction time to change and a faster sell of their products. The conducted analysis in this present study mainly concern two aspects: the figures concerning homogeneity and eclecticism within the greater international economic system and the place of business in the new century – with an impact upon the fruitful integration of the above mentioned businesses within different structures from the international economical system.

Keywords: homogeneity, heterogeneity, businesses

JEL codes: M16, M21

The impact of the major challenges of the current century and early twentieth century upon our contemporary society trigger a positive outlining for the future, making it seem more attractive, inspiring and compelling, so people should be able to gradually change their current mentality that focuses on immediate effects of the economic crises and consider a lot more an economic-social development, in which the well-being of the population can be achieved in full while preserving the planet's health. In terms of development specialists, this new visionary environment means a move towards a new era of business, on one hand business will remain society's most powerful institution and the power behind any change, and on the other hand business will bring its contribution on the outlook of managerial-corporate direction, in the future, the firms - regardless of their nature and size will be able to survive only if fundamental change will occur in the way they address individual and social needs, thus becoming more democratic from both the social-structurally aspect and in terms of targeted objectives.

Such a potential framework of development represents in regards to the issue addressed by us, a special importance because insofar provides the details of the overall integration of small and medium size businesses in the economic system, and a new vision of the role and place of these entities in society, and could thus move from thinking of them as a means of escaping poverty, to conceiving them as important entities in a customer-oriented design characterized by high flexibility, enabling them to respond more quickly to market changes and to market faster their novelties.

This prompted us to perform some analysis on the new data concerning the international economic system and on some aspects of the visionary thinking of specialists in respect to the future framework and role of business in a changing society, concentrating our efforts on two major issues: the coordinates of homogeneity and heterogeneity in the current international economic system and the role of business in the new century.

The first issue under review relates to how the details of homogeneity and heterogeneity of the current international economic system need to be considered as reference points for activities designed for small business firms. In this regard, we have assumed that the current global

economy is characterized by particularly complex features, in which the continuous interference affects two important processes. All of this is about, on one hand the process of consolidating globalization with the inclinations of his followers for even a relative specialization of production profiles of States to be able to remove mimicry production structures, such as competition and the struggle for outlets and, on the other hand, the regionalization process that has seen a strong impetus in recent years, promoting the concept of "open regionalism" as the most appropriate way to bring together the augmentation of preferential trade commitments which runs over 60% of global trade, and the rules of conduct of the trading system, managed by the World Trade Center. Among the effect of these two processes, which give the shape of the evolution of our contemporary society, we must notice further phenomenon that generate the further complication of the processes mentioned before, among them economic autonomy, inter-independence, economic integration, modernisation and underdevelopment. All seven of the phenomena mentioned put their mark on the orientation system of state trade policies and strategies on the foundation underlying the development policies of different grounding of distribution systems or of large multinational companies or the small and medium entrepreneurs.

In terms of the power of impact of different factors upon the localization of small and medium-sized commercial businesses within the economic circuit, in the foreground, it is believed to be located globalization, which takes place concurrently with the regional integration processes in the greater context of a general tendency to assert the identity of national economies and the peoples' aspirations to use resources to increase wealth, making the role of organizer of the market contrary to the already established national and economical arrangements, thereby emerging the problem of mutual and sustainable relationships between firms, areas and departments specialized in regional and global integration. In such a sense, with globalization seen as a central aspect of the system, the priority of the process is the need to ensure appropriate joints between local and global, through the help of a new relationship between the two which should be based on a new type of the division of labor, based on the coordination, while respecting the spirit of the market, of small and medium business either in the same territory, or working in the same field of activity, each having the duty to specialize in one segment of the marketing process.

In its turn, Regionalism, through its judgments on trade liberalization in the area profile and the segregated attraction in the economic system of sources and values specific to different areas, is also focused on small commercial companies which through their flexibility in adapting to the customer's needs in a regional profile and, in particular, through their creativity and continuous innovation, can contribute to the efficient realization of various facets of the process envisaged by the concept of open regionalism. In addition, such commercial entities, through their unique flexibility, creativity and innovation, may form links between sustainable global development and activities that constitute an integral part of the open regionalism idea, especially the so called "Seven Sunrise" actions which involve pollution reduction, the recycling and substitution of resources, environmental services and information technology, all of these activities having a clear potential to create wealth, long term viability and are considered to be business that will prosper once the ecological rehabilitation will become an imperative of the era of serious ecology.

Regarding autonomy, interdependence and economic integration as concepts that seeks to functionally combine on one hand nationalist, maybe even chauvinist trends, with rational thinking on the other hand, which consists in the acceptance of interdependence and wish for the achievement of effective economic integration, outline a large playing field for small and medium businesses, including the commercial type. It has been acknowledged since the 80's and - 90's that the world economical evolution has shifted from autonomy to a complex economic interdependence, economic process that takes place between a variety of businesses, through a variety of shapes, circuits and systems or channels and without the existence of structures of

authority and hierarchy. The experts added that the same developments shaped and developed a strong integrationist process, which is a positive phenomenon in the implementation under different types of distribution area -community and regional - of small commercial businesses, either through collaborations with large multi-business firms or by cooperation in specific systems such as organized independent trade – within the national borders or outside borders.

Small and medium commercial enterprises can have an important role in the international economic flow through their involvement in actions meant to counter or mitigate the tensions arising from modernization processes, as oppose to underdevelopment. It is a well known fact that economic growth is linked with the modernization of production and marketing structures. However, it is recognized that in the same time this process can generate inequalities in development, in the distribution of the income, in the welfare of the population and in some cases even underdevelopment, leading to the emergence of disadvantaged areas, which will be isolated and ignored by potential investors. In such cases it is recommended that entrepreneurship should be encouraged – through the cooperation between market and theories that encourage the involvement of the state in private business principles, the encouragement of partnerships between public and private sectors, the direct stimulation using different forms and funds to improve cohesion among small businesses – which will lead to a more dynamic role in both economic and social field. In such a context entrepreneurs may turn out to be the dominant factor in the entire process, the power of their influence surpassing the value of their size as expressed in numbers, leading to the realization of their place in the system, as the growth and technological progress engine, becoming the promoters of the new economy, they can – in a business environment under the influence of competition – to introduce new innovative products and services, pushing forward the boundaries of technology, creating new jobs and making it possible for them to emerge in other markets. Moreover, in such situations, small business entrepreneurs – supported by the previously mentioned reforms – can access to modern and sophisticated commercial technologies – for example those common for electronic commerce – and thus easily navigate in a fluid business environment – taking advantage of the available opportunities, which tend to have a shorter life span as time passes.

The second issue examined in the context of concerns about how to define the place occupied by small and medium business enterprises within the greater international economic flow, concerns the role of business in a changing society - a phenomenon which, according to experts, will characterize the new century – and how will small firms contribute in running these businesses.

It is estimated that the double transition towards a society founded on knowledge and sustainable development requires new paradigms of production and consumption - to this list we add the concept of new marketing - must move from the resource-based approach to one based on knowledge, to shift from quantity to quality, from mass products to new concepts of a higher added value, eco-efficiency and new durable products, processes and services. Linking such issues places the concept of the firm – regardless of size and nature – in the center of the discussion. Moreover, we have to highlight a phenomenon of great interest, especially for small and medium size businesses: the phenomenon refers to the fact that while concerned with the sustainable reconstruction of the company - the requirement of macro policy which envisages the creation of a free society, prosperous and just, based on democratic capitalism and on a market economy system - emphasis on the idea that "the greater the economy, the more power is available to the smaller players and the higher the system, the more effective its component parts must be".

Starting from such premises, in the context of trying to determine the best way in which we can address the scientific framework for defining small and medium business enterprises and their integration into the distribution system, we further tried to examine some of the main issues that can be taken as the axes of the development system such as: business goals, possible key business

structure and finally, the underlining of the place that will be occupied by small and medium businesses in the continuation of those specific business activities.

Regarding the potential axes for the development of the twenty-first century, focusing on the implications for small and medium business enterprises, we found it necessary to start from two major paradigms: new landmarks of a constantly changing world and the new role of business - serving the global needs. Regarding the first point of the discussion, I started from the new type of producer and consumer behavior outlined by the model proposed by BSFrey. That model brings up three institutional elements which, in our opinion, will make its mark on future changes. It is all about the systems of decision making in our society - the market and its pricing system, democracy, hierarchy or authority and negotiation procedures, rules, traditions and other rules of behavior - some set explicitly, others formally expressed, institutional organizations - the state, the groups of interest, businesses and governments, private clubs, families and informal associations. Under the impact of such concepts the proposed study case outlines five key assumptions - which in time will materialize in major changes: individuals continuously act, their behavior can be understood as the result of interactions with their environment, but also with different people and different institutions, incentives influence behavior, a phenomenon that makes people not act randomly, but systematically and forecast, forcing them to react when they consider that the possibility of action is more beneficial, incentives are produced by preferences and constraints which are strictly differentiated, which makes the concepts of price and cost to be understood not only in monetary terms but also in terms concerning the costs of an action or interaction, a good example for this type of situation is the opportunity costs, individuals pursue their interests and in general they display egocentric behavior, promoting a neutral behavior, constraints determine human opportunities and are produced mainly by institutions, the main restrictions being represented by income, relative prices of goods and services, the time required to obtain, consume or react.

Putting together the institutional elements with the economic assumptions of "Frey" model, scientists have outlined a model whose basic assumptions can help to generate changes that will characterize the evolution of society in the twenty-first century and is likely to make their mark on the revised entrepreneurial approach to business, regardless of the size and nature of investors. The result of the analysis conducted on the new model of behavior for producers and consumers that will constitute the backbone for the development of the twenty-first century society, and on that company's earlier developments, which had as a research basis the concept of the waves of change, identified seven trends that will gradually turn out to be paramount landmarks for future changes, in fact trends that will become reference points in the process of locating and determining the importance of small and medium business enterprises within the economic requirements of the system. As a consequence the focus is on a strong tendency to shape a fundamental shift of values, a trend that will shape the transition from competition to cooperation, from consumerism to the concern for economic and social justice, from materialism to intangible values, the support for a new systems that will promote social values based mainly on environmental and economic justice, which means new views on natural resource management, end economic imperialism and the need to reorganize the realities of global interdependence, the emergence of a new borderless society based on interdependence, composed of regional groups economically and technologically united, thus the emergence of the concept of bioregionalism, under which land is divided into uniform areas according to the principle of ecology, sharing the same habitats, soils, climates and similarities with the firm in question.

Our opinion is that all these milestones of change foreseen for the future evolution of society constitute on the one hand, in a thought concerning the possibilities of integrating all dimensions and responsibilities of life for all possible development and the recognition of the identity of all living systems, reflections that will give rise to new ways of networking and interaction for the benefit of all human factors and, on the other hand constitute into the reference points for all the

political, social and economical powers that can be convinced into joining this process, becoming responsible and effectively contributing to the process of achieving the aspirations outlined by the foreseen changes. This means identifying macro-social and political capabilities, and at the micro level, the types of companies, partnerships and systems that will be involved in entrepreneurial activities among those entities, specialists giving great credit to small and medium businesses.

As far as the second paradigm is concerned – the theory according to which global services will shape the new role of business in the twenty-first century – I considered, in our analysis, and as many other scientists considered, as a basic reference point in locating the place of small commercial businesses in the future economic, that a business will no longer be just a business made out of other businesses. The businesses field must take responsibility for the whole, the firms will have to be considered as being producers of moral effects, the producers of something a lot bigger than the sum of financial ratios and the strategic planning should be focused on the future needs that will exist independently from the firm, businesses will be considered as a means by which these companies will be able to grow and serve others, starting from the premise that as long as the company will serve customers, employees and community, in turn, all of them will serve it in turn. Within the new framework of business - whose role will be the overall global service - the company will have to create and assume, in addition to the role of providing goods and services to a basic consumer base, also the role of an integral part of the overall system, to which demands also to be served, thus shifting from a concern based on the priority for producing, to a concern on servicing individual needs, acting as a leader in addressing global issues raised by the community of which it is an integral part.

Obviously, in the context of such changes new perspectives appear in the overall orientation of the activities conducted by the company, and also new reference points for the business, both set of problems influencing the nature of the commercial activity which in turn will influence the objective of the firm, its strategies and its way of promoting itself, its size and especially its possibility of getting involved in different types of economic systems; competitions will take place that will involve more than just money, but also creativity, innovation and visions that will need substantial investments in the human part of the firm, in intelligence and skills, elements of which the entrepreneurial department has plenty of.

Starting from such issues, our research that set out to identify the place of small and medium size commercial firms within the economic system and the system formed by these companies, have identified a series of options that specialists have brought to focus. Taking this issues into consideration we consider the idea that the gigantism and automation type of economy is unable to resolve the small real problems of our time, making us realize that we require a system of thought that will place people before things, switching from mass production to production through the help of the people, only possible through small firms. Both ideas have begun to influence big companies which slowly start to realize that they need a reconfiguration in order to survive, starting to create new structures that have at their core small and flexible firms, autonomous and democratic, units that easily switch from competition to cooperation in order to achieve a rapid penetration of the market, markets which with time have gradually started to become smaller as they begin to be constructed on the idea of different styles of living, a standard that slowly replaces the standard of the economic power. This means that as the present day society moves forwards towards the embrace of knowledge and globalization – important reference points for the twenty-first century- small and medium size firms, also the commercial ones, will start finding a better economic and social place within the greater economic system, and the information models of our society, will encourage these types of firms in becoming real partners for cooperation and competition. Besides these ideas we have also identified ideas that promote the view that the economy of the twenty-first century will represent a perfect period for the small and medium sized companies. These theories, which do not exclude the existence of

large corporations, put forward the idea that these huge companies will have around them a lot of small and medium sized companies – sub-contractors, clients, supplies – either independent or part of chains more or less formal, different groups of small and medium sized companies, administrative branches, which seem to be the best fitted structures to survive in the future economy.

Putting forward the above mentioned ideas, regarding the reference points for the social development of the twenty-first century, raises new problems regarding the new orientation and structuring of the local, national, regional and world economic systems, but also put forward problems regarding the place of different types of firms – including small and medium businesses. We will witness a complex restructuring of the business framework on several vital fields of activity, which in turn will influence the nature of the future firms, their size, small and medium businesses being put in front of other types of businesses, in turn having to be more motivated, more creative, innovative and intelligently run in order to survive.

At the centre of the thoughts regarding the orientation of the business environment in the twenty-first century, with a powerful effect on the place firms will occupy in the future economic system, lies, according to specialists, the necessity to create in each area of the world adequate technologies, that can correctly react to the level of education and culture in that area, to the needs and customs with which the consumers in that area are used to. For all of these to take place, small and medium size businesses will have to be involved, not giant multinational corporations.

Taking into consideration that a lot of countries and areas have a lot of human resources but have a low buying power, some specialists, consider the necessity of the reorientation of an important part of the economic activity from a focus on materials to a focus on labor, information and intelligence. Even from this point of view, small and medium size businesses have an advantage, having a great potential.

The two reference points seized - the need to promote appropriate technology and the relationship between human resources and financial resources - can be real challenges for small and medium sized companies - whatever their nature - in their effort to mobilize in order to develop new technologies and marketable product, challenges arising as inevitable consequence of technological progress based on biology and high-tech discoveries – this way of thinking will make the boundary between living and non-living matter virtually disappear- and as a result of the single system of conditions facing the world today. Among the challenges that appear in the depicted context, for both businessmen and for small and medium sized businesses, as well as for the general public – as a reference point – also appear challenges that focus on the need of telling apart between the variants of a product – product or service- that will be manufactured in order to be sold and to clearly express the difference between what it is intended to be created and what we wish to be created followed by an action taken according to the conclusion of this way of thinking. Thus, at least in the business environment, we will have to get rid of the international way of looking at things and the future will bring a new reality, the economic entity will be found in business literature with also a learning component, which will have become an integral part of its definition. Thus, in future economic systems, new small firms or even individual willing to collaborate with big companies could be integrated within the economic system, becoming important sources for changes, investments and new production and commercialization technologies, phenomenon that will simultaneously establish the viability of the business environment on the long run.

SOME CONSIDERATIONS ON THE TERTIARY EDUCATION SECTOR IN ROMANIA AND ITS CONTRIBUTION TO ECONOMIC DEVELOPMENT

Tigănașu Radu

„Alexandru Ioan Cuza” University of Iași

Faculty of Economics and Business Administration

The performances achieved in economy depend in a good measure on the possibility of developing innovative projects. The development of this capacity at national level is a goal that a country should always pursue.

In the present paper we intend to realize an analysis of some of the problems in educational sector and some performances of the tertiary education in Romania in comparison with other central and eastern European countries, in terms of some specific indicators, relevant especially for innovative process and the economic progress.

Our statement is necessary for Romania as the indigenous human capital is clearly under-utilized by the neglect of public and private spending in education and research.

Keywords: education, innovation, employment

JEL Classification: I 21, J 21, J31

Introduction

The present stage of evolution at global level and the open competition have generated the need of special attention in investing, at national or even communitarian level, in the human resources which are supposed to be able to produce, adapt and implement innovations. This imperative is the main reason for which we tried to analyze in the present paper the situation of the Romanian tertiary education, which should be the first field to generate added value in what is concerning the preparation of the young specialists and their formation in a manner that will stimulate them to try to bring their own contribution in their domains, through innovative projects.

Romania has a good potential in what is concerning the innovation possibility, fact that is proved by the numerous prizes obtained by the Romanian inventors at international competition in field, but in our opinion this potential is not only far from being utilized at its maximum capacity but it has not, in some cases, the possibility to affirm and develop. This situation occurs in principal because of the lacks of the educational system, especially of the tertiary education, which are not able to encourage the creativity and to support the exceptional students with low financial possibility. This system is created to pursue some immediate interest and goals and have little performances in what is concerning the long time results of the instructed students and their added value in the field they work. The system based mainly on testing and individual study, the lack of interest of the teachers are only some aspects that require immediate measures. We do not intend to make here a qualitative analysis of the tertiary education, because of the lack of space, but we hope that the presented facts and data will be sufficient to get an appropriate image of the issues we proposed for analysis. In what is concerning the education and the tertiary education in general, other paths to change are possible. On a national level, we may consider Finland. As the unemployment rates were almost 19 percent in the early 1990s, Finland consciously coordinated economic and educational transformation. The nation's effort to develop a creative and flexible knowledge economy was accompanied by the development of a significantly more decentralized education system. Finland now has a largely local curriculum and virtually no standardized testing. Finns control teacher quality at the most important point, the point of entry. Applicants to teacher education programs have only a 1 in 10 chance of acceptance. Even though teacher pay is only average for industrialized nations, teacher retention is high because conditions are good. Within broad guidelines, highly qualified teachers create curriculum together in each

municipality for the students they know best. In classes rarely larger than 20, Finnish teachers know their students well. Teachers are free from excessive paperwork and endless external activities. They receive generous specialist support as needed. With these advantages, teachers strive for quality by quietly lifting all students up one at a time. Rectors share resources across schools and feel responsible for all the students in their town and city, not only for those in their own university. In each university, the rector is seen as part of a "society of equals", not as a line manager. The results: Finland boasts with one of the best tertiary education system in the world. It also ranks at or near the top in economic competitiveness⁵⁷².

General considerations on education sector in Romania

In what is concerning the situation in Romania, although the number of students increased approximately four times between 1999 – 2008, their percent per 1000 inhabitants in Romania is lower than in the other eastern European countries, and among the lowest in Europe. This is certainly a premise for some of the failures of this country, both economically and socially.

In the Table 1 are presented the number of graduates on different level of education in Romania, considering its population of 21.53 millions in December 2007.

Table 1. Number of graduates on level of education

Number of graduates on level of education	2005/2006	2006/2007
Secondary education	231800	219500
High school education	185300	187600
Vocational and apprenticeship education	150200	133800
Post high school and foremen education	15900	12700
Tertiary education	112200	125500

Through the Lisbon Agenda, EU established 5 indicators showing the extent to which a country and the Union, in its totality, are capable to face the challenges of knowledge economy. Five EU benchmarks for 2010 are⁵⁷³:

- No more than 10% early school leavers;
- Decrease of at least 20% in the percentage of low-achieving pupils in reading literacy;
- At least 85% of young people should have completed upper secondary education;
- Increase of at least 15% in the number of tertiary graduates in Mathematics, Science and Technology (MST), with a simultaneous decrease in the gender imbalance;
- 12.5% of the adult population should participate in lifelong learning.

Romania's positioning in relation with the third, fourth and the fifth knowledge economy indicators ("Lisbon indicators") is presented in the table bellow⁵⁷⁴.

Table 2. Positioning Romania in relation with the Lisbon indicators.

Lisbon indicators	Romania	EU	EU target (2010)
Percentage of 22 years old population who graduated at least from high-school (higher secondary education)	66.5%	77.3%	Min. 85%
Proportion of graduates in the mathematics, sciences and technologies fields	23%	24.1%	+10%
Participation of adults to permanent education	1.6%	10.8%	12.5%

⁵⁷² Hargreaves, A., Shirley, D., Evans, M., Johnson, C, & Riseman, D. *The long and short of school improvement: Final evaluation of the Raising Achievement*, Specialist Schools and Academies Trust London, 2007.

⁵⁷³ Commission of the European communities, Commission staff working document, *Progress towards the Lisbon objectives in education and training. Indicators and benchmarks 2008*: http://ec.europa.eu/education/policies/2010/doc/progress08/report_en.pdf.

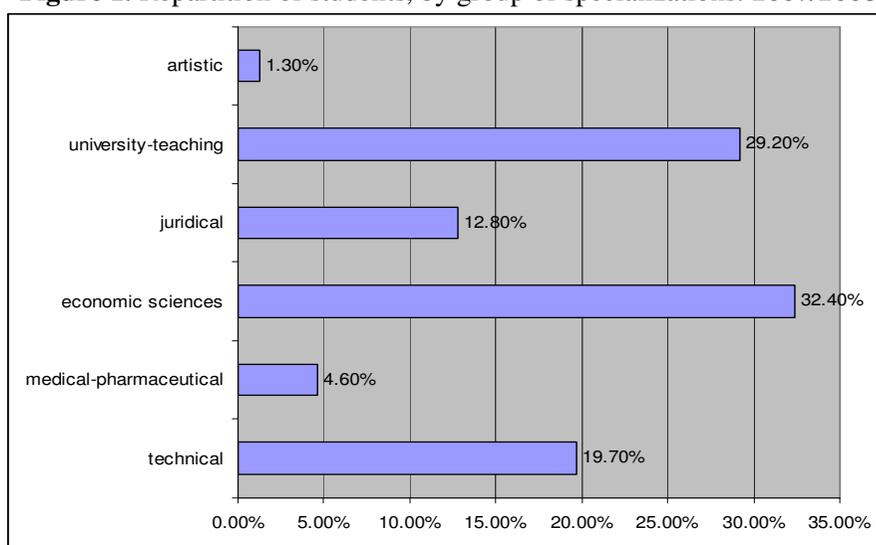

⁵⁷⁴ *Romania education, Romania of research*, Report of the Presidential Commission for analysis and policy making in education and research, Bucharest, July 6 2007.

From the analysis of these data, a clear conclusion results: the current educational system is not capable to ensure a competitive position in the knowledge economy. We can see that these proportions are worrisome. Although the targets were established for 2010, we observe that for Romania will be quite difficult, if not impossible, to achieve this value, the more so as today the rate of premature leaving school is 23.6%. Another quite sad obtained result refers to PISA tests, where the percentage of those who have not managed is 41% compared to the EU average of 19.4%. Also see that although the participation of parents in education is always vital, is only 1.6% the proportion of those who take part in this, there is therefore a great disparity between the EU average which is 10.8%.

Characteristics and performances of tertiary education in Romania

In order to get an as comprehensive image of the preferences of students for tertiary educations in Romania, we found appropriate to analyze the repartition, by group of specializations, in the academic year 2007/2008. A representation of this indicator can be seen in the Figure 1.

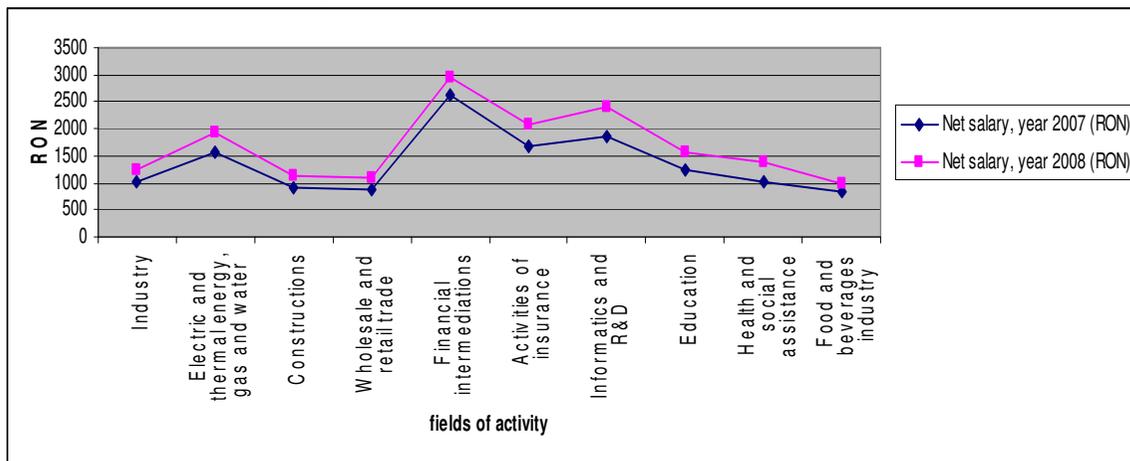

Figure 1. Repartition of students, by group of specializations: 2007/2008

Source: data offered by *National Institute of Statistics*, Bucharest, 2008

As it is easy to be observed, the percent of the students at economic sciences is the highest, fact that could be explained by the need of specialists in the field, educated in the capitalist spirit. Anyway, our opinion is that in the next interval, this percent should and will decrease, in favor of the other specialization, especially technical and medical sciences. We stated that the Romanian realities, especially now, in the context of economic crisis, affect in a very large measure all graduates. Jobs are less and demand is very high. Also, the wages in education and not only, are a problem in Romania. The motivation to learn for the young generation almost does not exist. In figure 2, we emphasize the net salary in different fields.

Figure 2. Net salary in different fields of activities in Romania (1 Euro=4,2 RON)

Source: data offered by *National Institute of Statistics*, Bucharest, 2008

The highest net wage gain is in financial intermediation (2622 RON=624.2 Euro in year 2007 and 2935 RON=698.8 Euro in year 2008). In education, the net wage gain is very low (1224 RON=291.4 Euro in year 2007 and 1557 RON=370.7 Euro in year 2008). These statistics put in evidence a sad reality. With such gains, far below the EU average, it is very hard to do performance.

In what is concerning the employment rate, by highest level of education attained - [tsdec430]; Tertiary education - levels 5-6 (ISCED 1997), we can see in the table below the percentage in some central and east European countries, including Romania. Employment rate, by highest level of education attained, Tertiary education - levels 5-6 (ISCED 1997), % of age group 25-64 years.

Table 3. Employment rate, by highest level of education attained; Tertiary education - levels 5-6 (ISCED 1997)

Year	2005	2006	2007	2008
Hungary	82.5	81.2	80.0	79.5
Latvia	84.6	86.9	86.9	86.9
Lithuania	86.3	87.8	88.1	87.7
Romania	84.0	86.1	85.8	85.7
Slovenia	86.6	87.8	87.5	87.5
Slovakia	83.2	83.9	83.1	83.8
Poland	81.1	81.7	82.8	83.7

Source: Eurostat

The obtained percent in Romania is not far from the average of the countries analyzed. But, if we have in consideration that the number of students per 1000 inhabitants is in Romania one of the lowest in Europe, the gap is still present. An eventual increase of the student number in the future, although welcomed, will face the limited possibility of absorption on the labor market, because of the low competitive economy (including the private sector), especially after the economic crisis. Only a very optimistic scenario could have in consideration that the employment rate, by highest level of education attained will remain the same or it will increase.

Comparison on innovation impact on productivity

The dates presented, sustain our appreciation that Romania could, with an appropriate strategy, to gain an important place and advantage between the countries with the highest rate in what is concerning the innovation possibility. In the table below are presented the proportion of the turnover from innovation in the total turnover in some countries in central and east Europe, including Romania.

Table 4. Turnover from innovation (% of total turnover)

Year	2004	2006
Hungary	7.0	10.5
Latvia	5.1	3.4
Lithuania	9.7	12.4
Romania	16.6	18.5
Slovenia	14.3	13.3
Slovakia	19.2	16.7
Poland	13.5	10.1

Source: Eurostat

The permanent need to adapt of our people, due the challenges faced in the last five centuries, have developed creative skills which should be used with no delay in producing prosperity. The fact that the innovations have an important role in economic growth, can be deduced from the following table, in which are presented the growth rate of labour productivity per hour worked in Romania and some central and east European countries.

Table 5. Growth rate of labour productivity per hour worked, % change over previous year

Year	2005	2006	2007	2008	2009
Hungary	3.8	3.5	1.5	1.9	-2.9
Latvia	7.1	8.0	7.5	-1.2	-2.3
Lithuania	1.7	6.8	5.7	1.6	-7.5
Romania	5.4	6.2	5.4	7.6	:
Slovenia	21.7	6.0	4.5	-1.2	:
Slovakia	3.2	6.8	8.4	2.3	2.0
Poland	1.5	2.9	2.3	1.6	:

Source: Eurostat

The positive trend of the labour productivity is an important gain for the Romanian economy, but it should be interpreted having in consideration the fact that Romania has one of the lowest levels in Europe in what is concerning this indicator.

Conclusions

We have highlighted in the present paper some characteristics of the Romanian tertiary education, and some indicators on its performance and we tried to highlight the fact that, although with an insufficient number of students and with many other unsolved problems (like the insufficient number of students in the mathematics, sciences and technologies fields), Romania prove its potential through positive results in what is concerning the employment rate, by highest level of education attained, turnover from innovation and growth rate of labour productivity per hour worked.

This situation makes us conclude that if Romania will increase the investment in human capital, we could hope for the future at economic growth and an increase of the standard of living. No matter how many funds the European Union or any other international financial institution allots us, without an understanding and a significant effort to increase the quality of educational system, and especially the tertiary one, Romania have no chances to improve its condition.

The example offered by Finland is relevant. There is no excuse for the lack of action in this field, as without it, the future is compromised. The benefits of investing in human capital are in the same time individual and general. This means that the governments should play without doubt the central role in the direction of forming and developing the human capital. A solid frame should be built in what is concerning the education, which should not limit the responsibility of us all in this direction.

Abstract: Considering the current particular economic situation but also the community regulations developed by the EU Commission to diminish the crisis effects, we believe that local institutions should still take into consideration measures to encourage investments and creating work places by supporting potential investors, which very often have to confront against difficulties in accessing funds. However, unlike large sized companies, small and medium sized ones are confronted to this issue of accessing funds. This global economic situation, not only affects severely the economic situation of most solid enterprises and their employees on short term, but it also has negative effects on long term. In this context we have to stress the fact that future investments from the common market of EU, especially those that concern the long term development and other strategic objectives from Lisboa, could be delayed or even cancelled.

Keywords: minimis aid, European Community, legislation, Council of Competition, fiscal benefit

JEL code: H71, O11, P25

I The content of de minimis aid for stimulating investments and creating workplaces in local economy

The minimis aid schemes for stimulating investments and creating new workplaces follow the criteria's and conditions provided by the EU Commission Regulation nr.1998/2006 regarding the minimis aid for the application of art.87-88 of the Treaty establishing the European Community, published in the OJ nr.379/5 since 28 oct 2006. These schemes are exempted from the prior notification of the EU Commission, according to art.3.E.C Regulation nr.800/6 aug 2008 that declares certain aid categories compatible to common market.

Through this scheme, the minimis aid is granted only if the criteria's of the EC Regulation nr.1998/2006 are respected and followed. This regulation mentions that a measure up to 200.000 Euros for a company over a period of 3 years does not represent a truly state aid. Therefore, the companies that invest more than 500.000 Euros (new buildings) and create workplaces in an area, can benefit of building tax reduction, accessing the minimis aid schemes for stimulating investments and creating new workplaces in that area. The scheme is approved by the Local Council in that area and it can be applied from that moment to a period of at least 5 years, and all the companies that invested and requested a tax exemption have to benefit of the scheme facilities. Such a minimis aid scheme has to provide the whole procedure of granting fiscal benefits in the form of building tax reduction.

The minimis aid scheme's objectives are:

- regional development;
- sustain the development of small/medium companies in that region;
- increase the rate of employment;
- stimulating enterprises which develop economic activities with profitable effects both economical and social.

The general objective should be the regional development in all the 3 main areas of local economy: industrial production, services, commercial activities and tourism.

That certain area can pursue, by applying this scheme, on the one hand a regional development attracted by fiscal facilities in the form of building tax reduction for the companies that invest more than 500.000 Euros, and on the other hand creates a certain number of workplaces. People who issue the scheme should estimate the budget on the whole period (ex.5 years), but also on each year, because granting fiscal benefits is based on 3 criteria's:

- the value of the investment;
- the number of employees;
- the profit of the enterprise.

As a consequence, according to the norms, the building tax reduction(fiscal benefit) varies based on the value of investment, the number of employees and the profit of the company. For example:

- Investments- for investments between 500.000-5.000.000 Euros the reduction is 15%, and for investments over 15.000.000 Euros the reduction can go up to 60%;
- Employees - for creating 20-80 workplaces the reduction is 5% and if more than 300 persons the reduction can go up to 20%;
- Production activity - 20% reduction in services, commercial activity - 5%.

For all the activities, the gathered minimum reduction percentages can go up to 25% and the maximum to 100% from the building tax for a period of at most 5 years.

Beside these 3 criteria's the investment has to be eligible, meaning it has to consist of building industrial hales or other buildings for placing the company's activity. The fiscal benefit solicitor has to invest over 500.000 Euros in building and create new workplaces as a consequence of the investment in a certain area, this being another eligibility condition .Worth mentioning is the fact that the whole value of the minimis aid granted to a company over a period of 3 successive years (2 past fiscal years and the current one),gathered with the value of financial allocation granted conform the respective scheme must not exceed the equivalent of 200.000 Euros, regardless the area of activity, and for the companies that activate in transport must not exceed 100.000 Euros. These limits apply to all minimis aid forms, regardless the objective pursued or the financing source (nation, communitary).The fiscal benefits provided by the minimis schemes are granted only for new buildings, regardless their economic purpose.

The aid provided by the scheme can be granted through the decision of the local council for each recipient, based on a request and a file completed with all the fulfilled eligibility criteria's/conditions.

II The minimis aid scheme's content for companies that place their activity inside industrial parks in an area

Through these schemes, minimis aid can be granted in the form of property tax exemptions provided in the art.250 line 1 point 9 and art.257 from Law nr.571/2003 regarding the Fiscal Code, upgraded, for the enterprises which place their activity inside industrial parks in an area. This aid is exempted from the prior notification of EU Commission, according to EC regulation nr.1998/2006 for the application of art.87-88 from the Treaty of establishing the European Community. The minimis aid is granted by such a scheme if the above mentioned minimis criteria are provided by the EU legislation are respected and followed.

According to OUG nr.117/2006 (Government decision) approved by Law 137/2007 regarding the state aid national procedures, the mayor of that area can issue a decision approving a regulation regarding state aid procedures, after receiving the prior notice from the Council of Competition. The above mentioned procedure is based on art.250 line1 point.9 and art.257, (1) Law 571/2003 regarding the upgraded Fiscal Code, where the buildings and lands subjected to tax exemption are established. In this sense, the real estates and sites part of industrial, scientific, technologic parks are mentioned.

This sort of fiscal benefits are state aid measures because they gather the necessary elements for state aid, transforming the economic and business environment because:

- they create an economic advantage;
- they are selective;
- they are granted by the state or administrative-territorial authorities from sources administrated by themselves;
- distort or threat to distort competition.

Therefore we can conclude that companies can benefit of fiscal facilities for the estates and terrains placed inside industrial parks, in the shape of state aid.

As a consequence, respecting the lines of art.1 (5) Law 571/2003 regarding Fiscal Code, “any fiscal measure that represents state aid is granted according to OUG (Gov. decision) nr.117/2006 regarding state aid national procedures, approved by Law 137/2006”. In this sense, art.3 line 3 from the above mentioned government decision says that “granting state aid measures involves the issue of state aid or individual state aid schemes.

1 Implementing the minimis scheme

The minimis scheme should contain the eligibility conditions but also the exact way of implementing the scheme. Therefore, according to chapter III from HG regarding minimis aid granting for the development and modernization on companies since 26 Nov 2007, only companies that fulfill all the eligibility criteria`s can benefit of special individual allocations, based on the minimis aid scheme. The eligibility criteria`s are:

- are registries according to Law nr. 31/1990 regarding small and medium companies (framed by Law nr. 346/2004);
- activate in the areas specified in the appendix nr.1 to HG regarding the grant of minimis aid in 26 Nov 2007;
- were granted minimis aid that doesn`t exceed the 200.000 Euros limit on a period of 3 consecutive years prior to the date of soliciting;
- have an investment plan which reflects the way the sums will be used
- are not in debts to the state (general budget);
- are not in the middle of bankruptcy, judicial reorganization, forced execution, operational closure
- do not find themselves in the “companies in difficulty” category, according to EC Communicaton - *lines on State aid for rescuing and restructuring firms in difficulty, published in OJ of EU - C244/2 since 1 oct 2004*
- no decision of recovering a state aid was issued or if it was, it has been executed;
- no illegal aid was received.

Therefore, the request of solicitor (company) for granting fiscal benefits completed by the justification documents is lodged at the Local Council of that area. In term of 10 working days all the requests go to Fiscal Direction from that area, to issue the file for each solicitor. After the evaluation of each case, a proposal is made, whether the solicitor should or not be granted this kind of facility. The facilities are actually being operated only based on the decisions of the leader of that Fiscal Direction.

To ensure a suitable transparency and an effective control of minimis aid, the local council, through the Fiscal Direction, communicates the scheme to the Council of Competition (applying this way the lines of O.U.G. nr. 117/2006 regarding the state aid national procedures) in term of 15 days since it was adopted.

The local council from that area, through the Fiscal Direction, as a state aid supplier, communicates each year the Council of Competition a report regarding the implementing of the granted minimis scheme. At the same time the allocated budget for that certain scheme is but also the content of “The minimis aid scheme” that all the companies that place the activity inside the industrial parks of that area can benefit of, compulsory published on the local council`s site.

As a consequence, the agents of the Inspectorate of Competition, together with the agents from the Fiscal Direction from that county can organize work sessions for ensuring professional assistance to find best ways of granting such fiscal facilities from local financial sources. For example, these would consist of building tax reduction over a period of 5 years, starting right from 1st January 2010, that would generate an intense economic growth and fulfill all the conditions and criteria's established by the approved minimis scheme. *We have to outline the fact that we, the people who started this project have to participate too, as well as the agents of the special direction of the Council of Competition, who can make observations about each structure of the scheme.*

In this context, the Council of Competition can mention its attitude and position if such a minimis aid scheme is the right option or not in the current economic context of granting fiscal benefits.

Moreover, for implementing a minimis aid scheme, the agents of the business environment should be taken into account. This way, through the minimis aid scheme which pursues to create workplaces in that county, the investors bond tight with the local administration, because the estate tax is very high, and the effective reduction of this tax gives the investors a positive signal, at the same time being found solutions for the economic and financial crisis. Nevertheless, this is not either the first or the last measure adopted by the local administration in order to attract investors.

This kind of initiatives should be intensely brought up in the local media, because minimis aid schemes for stimulating investments and creating new workplaces, should be known by those interested in order that all the economic activities influenced by the local administration, contributes to the diminishing of economic crisis effects and improve the standard of living of the population living in that county.

2 EU's economic straightening proposals

Beside the "traditional" state aid instruments, The European Commission decided, in the context of global economic crisis, to make the conditions for granting certain state aids more flexible. In this context, at the end of 2008 (26 nov), the EU Commission adopted the "*Temporary Framework for State aid measures*" (Communication from the Commission — Temporary Community framework for State aid measures to support access to finance in the current financial and economic crisis OJ – C.O.16 din 25 feb 2009). This legislation frame purses to allow state members to grant state aid to firms who are confronted with difficulties in accessing funds.

The state aid that can be granted based on this temporary framework are:

- a) state aid in the form of 500.000 Euros/firm;
- b) state aid in the form of guarantees;
- c) state aid in the form of interest rate subsidy;
- d) interest rate subsidies to loans for investing in ecological/green products.

1) State aid in the form of 500.000 euros/firm

This aid is considered compatible with the common market by the EC if the following conditions are cumulated:

- the aid is granted in the aid scheme form;
- the aid must not exceed 500.000 Euros/firm;
- the aid is not destined to export or privilege intern products over imported ones;
- the aid scheme does not apply to firms that activate in primary production of agricultural products and those from fishing;
- before granting the aid, the supplier asks for a declaration from the firm regarding any minimis aid and any aid granted according to this measure in the current financial year and checks if the aid will not lead to the raise of the total value of the aid received between 1st January 2008-31st December 2010 that can exceed the limit of 500.000 Euros;

-the aid can be gathered to other aids granted according other schemes .notified or exempted from notification, with the condition of respecting the intensities provided by this scheme.

II) State aid in the form of guarantees

This aid is compatible with the common market if the following conditions are cumulated:

-a small or medium enterprise can be granted an up to 25% annual prime reduction that has to be paid for the new guarantees according to the level of safe-harbor provided in the appendix to the temporary framework;

-large enterprises can be granted an annual prime reduction up to 15% calculated on base of the same prime;

-the maximum value of the loan must not exceed the salary annual cost (included the budget obligations) of the recipient for 2008. In case of firms established after 1st January 2008, the maximum value of the loan must not exceed the estimated annual cost with salaries for the first 2 years of activity;

-the guarantee must not exceed 90% of the loan, the whole period of the loan;

-the guarantee applies to investment loans but also for work capital loan;

-the guarantee prime reduction applies only on a perios of maximum 2 years since the guarantee grant.

d) interest rate subsidies to loans for investing in ecological/green products

Communitarian regulations provide that this type of state aid is compatible to common market if the following conditions are cumulated:

-interest reductions are granted only to loans for investments destined to financing projects that pursue the production of new products that improve significantly the environment protection

-this aid is granted not only for starting a new project but also for an existent one, if its progress is necessary, taking into account the special economic situation;

-the financed projects consist of fabricating products that imply the anticipated adjustment to future community standards and the investment should start before 31 dec 2010 and the new product should come out on the market at least 2 years before the standard;

-the loans can cover investments costs in tagible and intangible fixed assets;

-the loans should be granted until 31 dec 2010;

-the interest rate reductions can reach 25% for large firms and up to 50% for small/medium firms, being taken into consideration the risk factors of the company;

-the subsidies interest rate applies for a period at most 2 years since the grant of the loan

In the context of economical-financial crisis, the banking system plays an important part. Concerning the state aids that can be granted to banking sector, a high authority from the General Direction of Competition of EC, said that the “banking stability is the most important element to limit the extension of negative effects of financial crisis over real economy”. The banking system was in danger of crashing but EC activated the article that allows state aid grant in crisis situations and permits the regulation of problems in state members.

This context includes also capitalizing of CEC Bank with the sum of 900 million lei and Eximbank, with the sum of 170 million lei, taking part in the anticrisis measures program included in the Romanian budget in 2009. The CEC Bank and Eximbank funds will be used mainly to ensure co financing and granting projects accomplished from European funds and financing small and medium firms.

Moreover, “Prima Casa” (First House) and “Rabla” (Wrecked car) programs (the recipients are physical and legal persons) initiated by the Romania Government are a successful example according to official sources. The Council of Competition collaborated with the Government, Finance Ministry, banking sector so as to find the most acceptable solutions for these programs so that no more competition problems, and the program is as quick as possible operational.

Another example: EC authorized for Romania through Decision 467/2009, the state aid scheme for supporting investments in extending and modernizing the distribution lines of electric energy and natural gases notified by Romania authorities.

The total budget of the scheme is 28.400.000 Euros, and the state aids will be granted in form of non-reimbursable financial allocations from EU and national funds. This state aid scheme, initiated by the Economy Ministry, will be implemented in applying the proprietary Axe 4 "Raising the energetic efficiency and the security of supplying in the context of climate change" in the frame of Sectorial Operational Program "Raising the economic competitiveness".

As a *conclusion* to the above information, we can affirm the fact that granting fiscal benefits is, usually the creditor's attribute, but unfortunately, there are some exceptions provided in the Fiscal Code, that, in our opinion, are not necessary. For example, *it is not natural for a creditor (ministry) to grant fiscal benefits on behalf and on the account of other creditor (local public authority)*. In this case, fiscal benefits related to local budget obligations should be granted only by the administrator of the local budget (The Local Council) through its documents. Proceeding the modification of the norms of Fiscal Code, the local autonomy principle would be exactly respected, a main principle in the context of EU integration. Thanks to these legislative modifications, the local public administration is offered the possibility of guiding better the local economic life, including with this fiscal aid. The fact that the state is the only competence to promote fiscal policy is acknowledged but, at the same time, respecting all the constitutional principles is necessary.

THE FOREIGN INVESTMENTS IN THE ECONOMIES AFFECTED BY THE WORLDWIDE FINANCIAL CRISIS

Țirlea Mariana Rodica

“Dimitrie Cantemir” Christian University

Faculty Of Economic Sciences Of Cluj-Napoca

The direct foreign investments are related to the real investments and represent an investments undertaking in an economical object or in a services activity, which functions on the territory of another country. The resources for the direct investments can materialize in material or un-material assets, and offer the right or direct control over the economical agent where the investment was made.

Keywords: Direct foreign investments, portfolio investments, external financing, the capital offer and demand, portfolio investments oversea.

JEL Classification: G

Content

The modern economies, in the context of the worldwide financial crisis are more and more related of the international financial cash-flows which, in the context of global and economical integration actions, play at the same time the role of cause and of effect into these financial cash-flows.

In this situation, the foreign investments represent for suppliers and for paymasters, during this crisis period, an investment on long term oversea, and for users, these investments can be materialized in two ways: direct investments and/or portfolio investments.

The direct foreign investments are related to the real investments and represent an investments undertaking in an economical object or in a services activity, which functions on the territory of another country. The resources for the direct investments can materialize in material or un-material assets, and offer the right or direct control over the economical agent where the investment was made.

The foreign direct investments are considered a real industrially package, which contains: capital, technology, organization methods, managerially experience, marketing methods, modern financial instruments, etc, which allow to the paymaster to have the control over the funds users but, at the same time, creates premises for a sustained development, on performing coordinates for the direct investments users, even during this profound financial crisis.

The portfolio investments are related to the financial investments and represent found investments oversea, in securities (value papers, patent acts, programs, etc.)

They generally mean buying shares and bonds which are published by the public authorities (countries, local authorities), by economical agents with national or private capital.

In present, the financial market uses a lot of financial instruments related to the monetary market, but also to the capital market.

These foreign portfolio investments don't give to the funds suppliers the right to manage the activity of the value paper issuers, but they offer to the investors important incomes and/or financial wins specifically to the financial market.

Regarding the financing procedures, as forms of the most representative practices of international economical cooperation, the two big classes of foreign investments can be characterize:

- The direct investments, which can be realized by different ways:

co-production, under-production, mixed production or marketing capital companies, tripartite international cooperation, production on order, production licenses cession, common programs

and instruments of research, special technical assistance, international marketing specialization, common goods offer, mixed banks, international banking consortium, etc.

- The portfolio investments, financing by the capital quotation or extra-quotation market, futures contracts, options, international factoring (the financial technique), etc.

Despite the global present crisis, foreign investments can happen in all the economical domains: industry, exploration and natural resources exploration, infrastructure and telecommunications, civil, industrial and military building, scientific research and technological development, marketing, transport, tourism and banking and assurance services, as in many other activities.

But, in some domains are necessary prior advices (for example, for the foreign investments in telecommunications, is necessary the advice of the minister. For the military investments, is necessary the advice of the Defense Minister, etc), but there are also domains where is interdicted the creation of enterprises or companies with foreign or mixed capital, as for example the activities which represents country monopoly or in domains interdicted by the law, as the production and commercialization of drugs, occult activities etc.

By the aspect of the nature of resources in the external finance, there are the following classes of foreign investments:

- investments financed by the own available resources, mobilized by the foreign paymasters, which can be: big foreign economical agents, natural persons, entities or collectivities, foreign state;

- investments financed by the own available resources, mobilized by the foreign paymasters, which can be: big foreign companies, natural persons, entities or collectivities, foreign state;

- investments financed by the foreign banking and financial system from different countries, system which goes over an internationalization action;

- investments financed by financial international organisms;

Basically, the foreign investments are related to the capital offer and demand from the international financial market and it's possible to appreciate that, into the present international financial crisis, for any financial market it's impossible to ignore the international market, as well as, thanks to the present expansion of the financial transactions, a part of the financial assets available in a country are invested in an another country, and a lot of the funds needs of the economical agents of a country are covered by external resources.

The external capital offer is related to the strategy and to the international development strategy, to the external due problem, and, finally, to the global economical atmosphere. Hereby, the international development strategy from the 6-th development decade of the United States, which regarded the period 2000-2010, has established an economical growth with 7% on year, able to assure the employment, with acceptable salaries, at the same time with the creation of the necessary resources for the social protection and for the environmental protection. Particularly, the alimentary protection should have an annually growing rate of 4%, near the resolution of the demographical and environmental problems. In reality, these provisions could not have been accomplished in many countries because the external capital offer did not evolve to sustain the development, according to the ONU predictions. There is, in fact, a real vicious circle, because the under-developed countries need resources, but, because they are under-developed, they are avoided by the foreign capital.

Regarding the foreign capital demand, there are more ways to attract the capitals from the international market:

- the financing of direct investments;

- the contraction of external credits;

- financial assistance for development;

- investments of securities, offered by the economical agencies from a country, on the capital market of an another country, or on more markets;

- joining on other countries bourse with financial investments;

It's very important also the inverse economical action, the cash outflow, named "the running" of the financial funds from the countries considered politically and economically unstable, over international capital markets, so that sometimes, paradoxical, the "poor countries" offer more funds to the "rich countries".

In these economical-financial process are concerned at the same time the authorities of the poor countries, that don't assure the development of their own economies or can not control the illegal cash-outflows, and the rich countries which allow "the money wash" or accept illegal speculative operations.

The international cash-flows of the last years can be characterize by a lot of important divisions, regarding the geographical orientation, their volume and their destination in the developed economies, comparative with the under-developed economies or the economies which are in transition, namely:

- a) first, these cash-flows have place, usually, between the economical developed countries, resulting a marginalization of the countries or zones less developed;
- b) second, the volume of foreign investments had a permanent tendency to grow for the economies of developed countries, but a tendency to go down for the under-developed or transition countries;
- c) on the impact of the spectacular grow of the international financial markets, the destination of the international financial funds modified as rapport between the direct and the portfolio investments; hereby, in the developed economies occur every day huge capital transfers on the share markets and extra-share markets. On the other side, for the under-developed economies, the portfolio investments are insignificant. For example, Romania has a very small daily transaction volume.

Conclusions

The conclusions that result from these aspects show that:

- the international cash-flows and the creation of extern investments are an aspect of the modern economies which are open, dynamic and with a high organization and stability level;
- the growth of the international financial markets role in this period of serious economical crisis created an orientation overt portfolio investments, so that the financial market has a big influence over the amelioration of the economical activity in general, and also over the necessity of an investment activity specially on micro and macro economical level for the countries where this type of investment was made;
- the creation of economical marginalization for some countries, related to a specially orientation on the international flows, bring to the growth of the economical global differences and of the economical crisis of these countries;

The possibilities to stimulate a development of the foreign investments depend of international political factors, but also of the specific factors of every country, especially in the less developed countries.

The big transformations and political openings after 1989 confirmed the fact that the east-European countries have a lot of natural resources, a cheap and high qualified labor, enough elements to attract foreign paymasters.

But the reality shows that in the modern economies exists other condition to locate the available resources for investments.

The foreign paymasters run first over the strictly economical interests, so they prefer the economies which are already based on economical principles and are politically stable, proved by the level of efficiency of the investments.

Other said, the foreign paymasters don't agree the economies from countries with problems of political instability, because the solution of the intern problems of a country costs and has too big risks.

So, a country can not attire an investment as long as that country don't have political stability, an economy that can be modernized, which can assure important economical effects, and the efficiency of the investments can allow the recovery of the amounts allocated in a short time.

PRICE FOR PRODUCTION

Vaduva Maria

*Universitatea Constantin Brâncuși din Târgu-Jiu,
Facultatea de Științe Economice și Gestiunea Afacerilor*

Input markets is an important segment of the market. Inputs are purchased for the contribution they have to his business. Meet this market related inputs to entrepreneurs who need such items. The confrontation between supply and demand determines the price of each factor at a time on a certain market.

Keywords: input, buyer, market, marginal productivity.

Cod JEL lucrare : D2, D5

If this market is that demand specific inputs is a derived demand and also an independent application.

If the consumer buys the finished goods they produce them immediate satisfaction, the firm buys factors of production to achieve with their production and gain revenue. As the demand for finished goods products have greater success on the market, as demand curve for factors of production move to the right. For the analysis of demand for production factors to be fair, you must keep in mind that individual consumer demand determine demand for inputs. For this reason the application of factors of production is called derived demand. Production is the result of union and combination, factors of production. Factor productivity depends on the amount available from other factors that combine. Inputs interact. The input markets confirm buyers interests demand factors are the bearers of interests bidders.

Buyer base their request on the theory of marginal productivitatii input. Company acquires a factor of Proctor and increase their production to point of that last unit of variable factor used as much add revenue and costs. Adding to the total cost resulting from the employment of additional units is the cost factor again. The amount that a unit adds to the income factor is the amount that the unit adds to total production (marginal product) multiplied by income variation caused by the sale of additional units of production that is just the product price. Quantity result is the value of marginal product. As an expression of the law of non-proportional returns, marginal product value obtained by attracting additional amounts of a factor at first increases, reaches a maximum and then decreases. Is profitable for a company to buy quantities of an input to the point where the marginal product value curve ball crosses the right price. When the value of marginal product falls below the price is no longer profitable to increase the amount of input required.

In the field of equilibrium price of each factor is equal to the marginal product. A company to know how much a particular factor of production can be used to purchase the state in which pursues profit maximization must know the marginal cost is the cost factor of an additional unit of factor used. If perfect competition price, factor price equals marginal cost factor. Curve marginal cost factor is labor supply curve of work for that company and is perfectly elastic. It appears as a horizontal line at the market price. In determining the amount of work factor to be bought and used the company needed to know the effect of using it, that the marginal product based on which company should determine how these factors add the income is the marginal product value of the product. The use of increased quantities of factor marginal product value is obtained from increasingly lower. As long as the marginal product value is higher than marginal cost firm secures its profit growth by increasing the amount of factors used. When the price factor is greater than the value of marginal product is no longer profitable for the company to hire

and use a higher factor Cantiere. The firm level is obtained when the value of marginal product equals the marginal cost of the product.

Value of marginal product curve is the demand curve for that factor and its intersection with the price line is used in conditions of maximum profitability. Formation of price factors is a complex mechanism that occurs interdependent nature derived from the demand factor determining the demand for production is a more complicated process than for some items. In this case curve ultimo wax for a produys is given by the sum of individual demand curves for the product. If a branch in the factor of production is low wage work and effort as a result of increased supply and undertake a greater amount of work. The effect is to increase branch production and product price changes. Is a chain effect on firm demand and market demand for certain inputs.

Market demand for a simple multiplication factor is a firm demand and market demand curve is less elastic than the demand of each individual company. Elasticity of demand is influenced by several factors. First time. Elasticity is even greater as time is longer, which enables companies to adapt to changes in prices of production factors. Second, the weight factor in the total cost of production. If it is a factor with a low share price change influences its small size and the total cost is less elastic demand for it depending on price. If the factor has an important contribution in the production process and a greater share in the cost when a new purchase price adjustment has marked influence on the cost. Increase or decrease the price of a factor leading to increased or decreased demand for other factors when the possibility of their substitution. This is known as the substitution effect.

Changing factor prices may result in adjusting the production company that maximum profit is achieved. If the price increases the Q factor decreases and vice versa. They increase or decrease in production determine the effect on demand for production factors. If the effect on demand for production factors is greater than the substitution effect, then demand for a factor will decrease when the price increases of other fator. Similarly, lowering the price of a factor increases the demand for another factor, if actual production is greater than the substitution effect.

Determination of equilibrium price and quantity for a production factor does not pose special problem. Price factors of production are determined by market supply and demand interaction. Market demand is obtained by adding horizontally the individual demand curves for a given input. This procedure is valid for all inputs and is based on the value of marginal product to factor considered. The same operation is done for all job inputs. Accumulating cost factor gather all quantities offered on the market to gain market offer. Equilibrium price of an input form when offered and the required conditions are equal. If all units of an input should be identical and moves freely between all markets should be paid the same in terms of balance. Different units of any factor other remuneration obtained. Diferentede fiimpartite ready and can occur in two distinct types:

- the difference in situations of imbalance

-differences in conditions of equilibrium. Some differences in the factors reflecting a temporary state of imbalance in the market. They are determined by an industry growth and decline of another. Price differences lead to reallocation of factors. In turn reallocation of production factors resulting in the elimination of price differences.

COMPETITIVE MARKET STRUCTURE AND COMPETITIVE BEHAVIOR

Vaduva Cecilia Elena

Universitatea Constantin Brâncuși din Târgu-Jiu,

Facultatea de Științe Economice și Gestiunea Afacerilor

Mechanism of market economy is a competitive mechanism. This means that within his face and through producers and consumers, bidders and buyers, but producers among them, consumers between them.

Keywords: competition, market economy, manufacturers, competitive behavior, market

Cod JEL lucrare : D11, G10,A11,O12,O16

To see who is competing with whom and in what sense it is useful to distinguish the behavior of individual firms and type of market where they operate. Usual sense of the word "competition" refers to competitive behavior. Competition means a situation where there is a clash free, complete and truthfulness among businesses both in supply and demand of goods and capital. Seen as an open process of confrontation, in which individuals learn through a process of "exploratory and error" to improve the situation, competition is valued by some economists, among them G. von Hayek as "the best way of meet the interests of everyone concerned to maximize profits for entrepreneurs and to maximize consumer needs are met. Effective competition, where it can be created, is a superior means of guiding individual efforts to achieve beneficial effect. " Competition is the battle between manufacturers for as large segments of the market to increase sales and achieve higher earnings and single. It expresses the specific behavior of economic agents in market conditions, fighting against some others, each against all. In the battle of competition, a number of entrepreneurs are continuously removed and others also appear. Through a filter of all severe individual activities, social competition that devote only those that respond to market demands. For the operation of competition, market economy dominated area must include the social organism. Competition is possible in the first place, when market prices are formed freely, making any buyer to be able to choose the vendor with the best prices. Secondly, competition is related to the existence of private property that ensure freedom of action of economic agents. Determine if private property and emphasized the autonomy of the producer, deepening division of labor specialization and development put businesses in a growing interdependence. To the extent that is open, loyal, regulation and surveillance, competition has several functions: a) the overall progress that stimulates innovation and creativity incite or b) differentiate businesses: favors the skilled, creative and others are eliminated c) lead to diversification, to reduce costs and possibly even reduce prices; d) allows the customer to find the best supplier interests, e) if not properly regulated and supervised as it can be a disadvantage on evolution consumer. Economic analysis refers to both the behavior of individual firms and the competitive market structure. The concept of market structure refers to all characteristics that can affect behavior and performance of firms in a market. Competitive market structure refers to the extent that individual firms have the power to influence price or terms on which the product is sold on the market. The more an individual form has less power to influence the market, the more competitive market. Extreme form of competitiveness occurs when the firm has no market power. This means that there is a market large number of companies and each must accept the price imposed by the forces of supply and demand. Firms may wish to sell as the market price which can not influence it. If the company ask for a higher price does not sell anything, there are enough firms that sell at market price. This extreme situation is called perfectly competitive market structure. According to this market structure, individual firms should not enter actively

competing with each other, because no company has no power over the market. Ability of firms to sell their product does not depend on the behavior of other firms. Traders operating on a market with perfect competition may not change the price by its own conduct. Competitive behavior is a concept that expresses the fact that companies are in active competition with each other. Companies that are actively competing each other is a market that is not perfectly competitive structure. Being small in number, they have some real power over their market. Each company should be able to raise prices and continue to attract consumers. Such companies have the power to decide, within limits imposed by customer preferences and prices of competing products, the price buyers will pay it. Unlike firms that are in active competition, the competitive behavior not believe the only way they can change prices is to adjust the quantity or cost. Companies that operate on competitive markets is not actively competing each other, while competing firms do not operate on an active market with perfect competition. In everyday language "industry" and "market" are familiar, but they have precise definitions. "Market" means a system or network of sales relationships, a "space" in which buyers and sellers can negotiate a good exchange. An industry consists of all firms that produce a well defined product or a range of related products. Distinction between market and industry is important to clarify the issues demand. Market demand curve for any product demand curve facing the industry that produces the good. When a firm decision to adopt production and sale should be aware that a good amount it can sell it, the different prices. Company's main concern is not market demand curve for product industry, but rather the firm demand curve for its product. If the company knows the demand curve that it faces, means that its sales have information about every price that might require and can calculate potential income. And cost if known, can calculate the profits associated with each level of production. With this information, the firm can determine the output that maximizes profits. Affecting behavior and performance characteristics of firms that sell in a market and define the market structure that determine the relationship between market demand curve for product and industry demand curve for a firm acting in a certain industry. The main theoretical structure of the market that are widely considered are perfect competition, monopolistic competition and oligopoly. In addition, space is given a bilateral monopoly and monopsony.

Markets, Competition, Prices

In the economy and the future market and will remain is the central institution around which revolves the economic life. Market appeared many centuries ago, when the economy instead frigid as a communication channel between production and consumption, between producers of specialized, autonomous and independent consumers. It has evolved over time, becoming a reality becoming more complex. Development process and increasing market complexity can be seen on several levels: - the operator of any activity through the market mechanism, (the share of input and output total) has increased enormously, while the depletion of self-production. Any institutional trader activity is dependent on increasing size of the other market mechanism, at the microeconomic level, the market mechanisms involved in GDP exceeds 80% in developed countries - in time, expanded into "width" by attracting the mechanisms them - supply, demand, competition, price-new and new territories, fields, etc.. If she initially realize the connection between production and consumption for a relatively small part of satisfactory and prodfactori (usually the material, substantial), now any form of human activity is involved in different proportion in market mechanisms. It has become a universal institution, embracing the global scale and within each country. This will be illustrated in the paragraph devoted to diversity and competition markets. But the reader can anticipate and submits some hostile reaction exaggerated expansion of the market appreciation synthesized as "we are for a market economy, so reject the idea and practice of a market society" - markets that have diversified due division of labor, sortotipo-dimensional range of economic assets has increased enormously, especially in the last half

century, we believe that in the microeconomic sense, there are so many types of goods and services that there are individual markets: The consumption and capital, financial assets, monetary and foreign exchange, trade and professional or occupational specialties. Markets and diversity can be seen in terms of a transaction forms: from the fairs and markets "classic" in modern supermarkets, to transactions by mail, by exchange, fax, internet (virtual market), etc.; - Linkages and interdependencies between different types of markets are more obvious today than ever, favorable situations or disturbances by generating one or more reactions on other markets. Defining a synthetic concise market is difficult due to its great complexity, diversity and elements. Because of this, there are many angles as can be seen, each being a partial definition, "all" offering a more contemporary meaning of the market close. In this sense it may be that the market is: a) the economic space they meet more or less direct and act in the interest buyers (as agents of demand) and sellers (as agents of supply), and in some cases various categories of intermediaries, b) the meeting place at a time (not meeting neat physics, but also indirectly through symbols: written orders, telephone, fax, booklets, books, etc. carini.) buyers desires and interests with those of producers, c) a set of communication means by which buyers and sellers to inform each other of what have, what they need and the prices required and proposed before the end and make transactions, d) all about relationship selling economic space in which they occur and what processes are related characteristics (demand, supply, competition, advertising, price, legal regulations, customary, moral, etc.).. Market and face meet buyers and sellers, supply and demand, each with specific interests, but which can only be made by "legarrea" and "coleziumea" partner interests, e) instead of showing the competition, the competition between agents with identical or similar interests. Competition, competition is present in all pores of a free economy, but it stands out, becomes perceptible "naked eye" in the market. In a capitalist market economy, regardless of type and degree of maturity and modernity, the market has several functions. Along with supply, demand and price competition is one of the variables defining the market, an essential feature of the market. Competition is particularly interested behavior of the subjects of property, to sell its objectives, enter into relations of cooperation and confrontation with others. It is a manifestation of free enterprise. From this definition follows several defining elements to understand the content of the competition. It is a race, meaning a confrontation, but cooperation between economic agents in order to obtain better conditions of production, sale, purchase of consumer goods, by making cash transactions, foreign exchange, financial and so it is a competition obtain benefits (or at least reduce the likelihood of risk). In this competition, each participant works of interest. For example, the buyer "run" to find vendors with lowest price, best quality, most favorable delivery terms etc.. Sellers compete among themselves for "client money" to attract as many buyers, with high economic force, established in acquisitions, responsive to price and other favorability. From this competition, and that usually the best rule out winners. As market competition had a different magnitude in time and space. Extent of competition is influenced by many circumstances, that:

- the number of agents and economic power and supply and demand;
- degree of differentiation of supply and preferences (needs)
- degree of market transparency; -
- the extent to which society, economy, social, political, cultural, are able to stimulate initiative, creativity, risk, competitive spirit, but also cooperation;
- degree of substitutability and complementarity of economic assets; -
- revenue size and the mechanisms by which they are obtained;
- level of economic development, cultural, spiritual and moral members of society;
- any competition, and competition takes place based on certain rules.

In all countries the legal regulations are in effect doing the competition rules, the penalties applicable to those who inalcabodies empowered to supervise and to apply punitive measures. To the extent that is open, loyal, regulated, regulation, surveillance and prices based on free

competition has several functions: a) Stimulates overall progress: it incites innovation and creativity, which favors increasing efficiency, saving resources, satisfacerea needs better. b) Differentiate traders: favors the creative, skilled, entrepreneurs, remove them or shifting them to other areas on the real estate agencies, conservative, salubritatea economic life. c) sometimes leads to differentiation and diversification, to reduce costs and even the sale price. d) Allows the customer to find the best supplier with goods and more eficienta and stimulates or compel the producers to find solutions to broaden their market. e) When it is inappropriate regulated and supervised, it can become competitive or otherwise: generates waste of resources, lead to excessive concentration of economic forces, can weaken the quality of goods freight, it unfavorable to the consumer lead to monopoly, which is essentially a denial of competition. During the competition using various means that have evolved along with the market and competition. They are presented in various forms of market and competition. As general and synthetic, they can be presented as tools (means) economic and extraeconomic. Stands of economic means to reduce costs, increase quality, diversification and renewal of assortment, advertising, granting benefits to buyers, and in some cases even reducing prices below those of competitors. The key factor is innovation. Among the instruments used in the competition extraeconomice are common: getting information on competitors activities, sponsorship of social-cultural, economic espionage, and in limiting cases, corruption, blackmail, boycott or open violence

SUB-SECTION: BUSINESS ADMINISTRATION

SOME ASPECTS REGARDING THE PERFORMANCE INDICATORS USED IN THE MANAGEMENT OF A COMPANY

Popa-Lala Ion

West University, Faculty of Economics and Business Administration

Aniș Cecilia – Nicoleta

West University, Faculty of Economics and Business Administration

To assess the economic performance of an enterprise four indicators are commonly used: return on investment, residual income, economic value added and profitability of sales.

The performance analysis is a constituent of any managerial control system. Strategic planning and control decisions require information on how different subunits of the enterprise worked. To be efficient, performance indicators and remuneration have to motivate the managers and the employees from all enterprise levels and to make sustained efforts to implement strategies and to attain business objectives.

Key words: performance, profitability, economic value added, investments

JEL classification: M, M2, M21.

1. Introduction

Although it is a frequently used term, the concept of performance is seldom defined clearly, its meaning being considered as implicitly known .

A definition, translated from English, explains the term "performance" as, among other things, "the proportion/extent to which an investment is profitable⁵⁷⁵."

Extending this definition, one can consider that firm management is efficient if it is able to generate profits or it is advantageous, useful, noting that profit does not necessarily mean a financial plus, but meaning a gain, a benefit, or the converted form of capital gains, that is to say that it can be of various kinds: financial, social, human, environmental, etc. Therefore, performance can be interpreted as the gained profit, namely the result of the action and performance evaluation as the realized gain assessment.

The information about the performance of an institution is needed in order to assess potential changes of the economic resources which the entity will be able to control in the future, to anticipate the ability to generate cash flows with the present resources, to formulate judgments about how efficiently it can engage and use new resources.

In practice, financial performance information is provided primarily by "the profit and loss account", respectively by the budget execution account, but things are not as simple as to reduce them to the synthetic data in a particular periodic reporting form because it would be a pity to ignore the information in real time the account book provides. Performance is more important than money. Money reflects a possession, performance expresses the ability to capitalize the possession.

2. Performance measurement from financial perspective

Performance measurement is part of any managerial control system. Strategic planning and control decisions require information on how different subunits of the company worked. To be efficient, performance indicators and remunerations should motivate the managers and the

⁵⁷⁵ Judy Pearsall, *The Concise Oxford Dictionary*, Tenth Edition, Oxford University Press, New York, 1999, p.1060.

employees at all business levels and make a sustained effort to implement the strategies and to achieve the business objectives.

A variety of performance indicators are based on internal financial information. Businesses supplement more and more the internal financial indicators with indicators based on:

- external financial information (eg. the stock);
- internal non-financial information (eg. Product fabrication time, the number of new patents, the rate of flaws);
- external non-financial information (market share, customer satisfaction).

These indicators are often compared to those registered in other subunits of the same companies or other businesses.

In some companies financial and non-financial performance indicators registered by their subunits are presented in a single report called balanced scorecard. In the balanced scorecard⁵⁷⁶ the enterprises record various elements, but most scorecards include:

- indicators of profitability;
- customer satisfaction indicators,
- internal indicators of efficiency, quality and time;
- innovative indicators.

Some performance indicators, such as the number of patents, have a long-term time horizon. Others, such as efficiency deviations of direct raw material, have a reduced time horizon. In this article we will refer to the most commonly used performance indicators, covering a medium to long-term time horizon. They are internal financial indicators based on accounting data of an enterprise.

To assess the economic performances of an enterprise four indicators are commonly used.

Some companies record high levels of the profit made from operating, but the question is whether they are the most advanced.

The main weakness of making comparisons on the sole basis of profits from operating is that this way one ignores the differences between the volumes of investment in each firm. Investments refer to resources or assets deployed to achieve profits. There is no question of how much is the profit made from operating, but how much is the operating profit compared to investments made to obtain it.

Three of approaches regarding performance measurement include also an indicator of investment: return on investment, residual income and economic value added.

The fourth approach, the profitability of sales, does not include an investments measure indicator.

2.1. Return on investment

Return on investment (ROI) is a book value of profit divided by a book value of investments:

Return on investment (ROI) = Profit/ Investments

Return on investment is one of the most common ways to measure performance, and this for two reasons:

- combines all the elements of profitability - revenue, costs and investment - into a single indicator;
- can be compared with the rate of return opportunities from other parts.

ROI is also called accounting rate of return or cumulative accounting rate of return. Managers usually use the term "ROI" when assessing the performance of a subunit and the term "cumulative accounting rate of return" when an ROI indicator is used to evaluate a project.

⁵⁷⁶ C.T. Horngren, S.M. Datar, G. Foster, *Contabilitatea costurilor, o abordare managerială*, Ediția a 11-a, Ed. Arc, 2006, p.858.

Some companies prefer to use operating profit in the denominator, others prefer to focus only on assets financed by a long-term debt, using total assets minus current liabilities.

Businesses may increase ROI through increasing revenue or through lowering costs, through reducing investments. ROI can clearly define the performance issues when it is determined by its components:

$\text{Profit/investments} = \text{Profit/income} * \text{Income/investments}$

or

$\text{ROI} = \text{Return on investment} \times \text{number of investment rotation}$

This approach is known as DuPont method of profitability analysis. This method identifies the two basic ingredients in making a profit: increasing the proportion of profit from each leu income and mobilizing assets to generate higher revenues. Improvements in a component without changing the other component will generate an increase in ROI.

ROI sets out clearly the benefits the managers can obtain by reducing assets investment or fixed assets investments. Some entrepreneurs are aware of the need to increase revenue or reduce costs, but pay little attention to reduce the investment base. Reduction of the investment base means good credit management, reducing the amount of idle cash, setting appropriate levels for stocks and the mobilization with high attention to the long-term assets.

2.2. Residual income

Residual profit (RP) is an accounting measure of profit minus a value expressed in lei of the required return on investment.

$\text{Residual profit (RP)} = \text{Profit} - (\text{Required rate of investment} \times \text{Investment})$

By multiplying the required rate of return on investment to investment value is obtained imputed cost of investment. The imputed costs are costs identified in certain situations which usually are not reflected in financial accounting systems.

Some companies prefer RP, because managers will focus on maximizing the absolute value, such as RP expressed in RON and not on a percentage, as the ROI. The objective of maximizing the RP means that, while a subunit records a return that exceeds the required rate of return on investment, that subunit activity should be extended.

The objective of maximizing the ROI might determine the very profitable subunit managers to reject the projects which, in company's view as a whole, should be accepted.

Matching goals (ensuring that division managers are working towards achieving company goals) is more easily achieved using PR and not ROI as an indicator of the division manager performance.

2.3. Economic value added

Attaining the major objective of the company, maximizing the overall value can not be achieved, but by creating value within firms. The overall performance is defined according to the company's ability to create value to its holders of interests, eg. shareholders, creditors, employees, suppliers, local community etc. Of course, company shareholders prevail, who are in fact the owners. Managers appointed by these must constantly seek to achieve this objective by permanently creating value.

Performance indicator most commonly used for assessing the growth in value of the enterprise is the economic value added.

Normally, a company should not reinvest the net profit, but if its future investment projects are capable of generating a higher return rate than the rate of fructification of capital market for comparable risk projects.

Otherwise, the net profit should be distributed as dividends to shareholders or redemption of own shares. Investors will be able to capitalize the amounts received at the obtained market return from the financial assets of similar risk.

As the main problem of any performance indicator of a title based on the issuer profit, beyond a possible "creative" handling, is not taking into account the cost of capital used by the firm in the analyzed period, a more accurate measure could - be considered to take account of this element, comparing it with the return obtained.

The concept in this way is called Value Based Management (VBM). Accepting the assumption that business value is directly dependent on the future financial flows generated by the firm, conceptual VBM, becoming in time a real philosophy of doing business, acknowledges that a company generates value in excess in time only if its capital investments will have a higher return than the cost of capital.

VBM is used by many leaders of companies as a way of managing them and through which to generate an additional value for shareholders

VBM appeared initially and experienced a tremendous development in the United States, giving rise to a managerial philosophy which enforces the managers for un the companies so that the shareholder wealth (whose first constituent is the amount of shares) to increase over time. So it is put emphasis on the interests of business owners unlike some earlier approaches, common in many European countries, according to which the interests of employees, customers, suppliers and the public ones were considered at least as important. The harsh reality of capital markets globalization, evidenced by international corporations access to formerly protected markets, the more increasing competition in high technology and resource control, the major acquisitions, takeovers and mergers between leaders of economic sectors have led to rapid spread of this philosophy in Europe too, it being understood, accepted and required in Western Europe economies. Based on this philosophy running a company it have been developed various concepts and methods to allow detection of capital gains made in past times and to provide valid criteria for selecting investment projects for horizontal or vertical development.

The best known alternative concept, based on the central idea that there is no real income if one does not exceed the cost of capital used, is that one launched by U.S. firm Stern Stewart: Economic Value Added, in short EVA.

“EVA” - *Economic Value Added* or economic value added is the most famous and one time, the most publicized performance indicator in the speciality press.

The economic value added has become in the decade 1990 - 2000 a quality standard of company's total, a performance indicator of the management team, a reference in foundation and assessing the efficiency of decisions.

The reasoning underlying this indicator is simple and logical: equity, like borrowed capital, has a specific cost. Unlike the cost of borrowed capital, which appears explicitly in the profit and loss account, the cost of capital, expressed by compensation set to investors, has a different accounting treatment.

To create value, the company must earn enough to cover both the cost of financial debt and the opportunity cost of capital. Also, bear in mind that pay equity must be at attractive rates, in any case higher than that the investor could obtain in case of a risk-free investment. Economic value created by an enterprise during a period should take into account not only the amount recorded in the accounts, but also the opportunity cost of capital.

Cost of capital is a concept useful for management company helping it in the selection of alternative investment projects and allowing the development of strategies to optimize the financial structure of the company, respectively the optimal proportion between the medium and long-term, the capital consisting of preference shares and ordinary share capital formed. Optimization goal is to minimize the cost of capital of the business used on the market and to perceive profitability of the capital providers and company specific risk and, ultimately, the firm's accessibility to different forms of financing. Minimizing the cost of capital used by the firm has a direct impact on maximizing business value through minimizing input regarding the financing operations carried out.

Economic value added is a specific model calculation of residual profits which lately gained considerable importance. Economic value added (EVA) is equal to operating profit after tax minus the weighted average cost(after tax) of capital multiplied by total assets minus current liabilities.

Economic value added = Operating Profit after tax - [weighted average cost of capital x (Total Assets - Current Liabilities)]

Economic value added substitute the following figures in residual income calculations:

- profit is equal to operating profit after tax;
- required rate of return equals the weighted average cost of capital after tax;
- investment equals total assets minus current liabilities.

Total assets less current liabilities may also be calculated as:

Total Assets - Current Liabilities = Fixed assets + Current assets - Current liabilities = Current assets + Working capital

Where:

Working Capital = Current Assets - Current Liabilities

Economic value added, and residual profit, are costs associated with investments in long-term assets and working capital. The value is created only if the operating profit after tax exceeds the cost of capital investments. To improve the EVA, managers should:

- record operating profit after tax higher with the same capital;
- to raise less capital to achieve the same operating profit after tax;
- the capital to be invested in projects with high profitability.

Managers of firms use the estimated impact on EVA to take certain decisions. The division managers consider EVA useful because it allows them to use the cost of capital to take decisions at the division. The comparison between the actual and estimated EVA is useful for performance evaluation and for obtaining feedback on performance managers.

2.4. Return on sales

The relationship between profit and income (or sales), also called return on sales (RS) is a financial indicator of performance. RS is a component of the ROI in DuPont profitability analysis method.

Some companies record high levels of RS, but their performances are considered to be lower than other companies performances using indicators such as return on investment, residual income and economic added value.

3. Conclusions

The role of financial management consists in the task it has to use various instruments which ensure an adequate protection against risks At the same time, financial management aims at maximising the company value, not only with reference to its own capitals, but also to the future investment and projects which the company's equity will be engaged in.

The wealth accumulated by a company at a given moment is only one of the elements that allow for the appreciation of its value. We must also take into account the results expected in the future, as a result of using the accumulated equity.

Consequently, the company value is a value anticipated in that it takes into account the current value, which is correlated with the forecast future revenues obtained from the company's activities. For this reason, the company value cannot be separated from the quality of the projects its equity is engaged in.

Mastering all the means and tools in achieving the major objective of financial management, namely to maximise the company value, based on its performance, emphasises the important role played by financial management at company level.

To assess the overall performance, return on investment indicators, residual income and economic value added are more suitable than the profitability of sales because these take into account both the profits made and the investments.

ROI identifies the investment with the highest profitability. The EVA and RP indicators help solve problems of matching the goals generated by the ROI. Some managers prefer EVA, because it takes into account tax issues, while RP before tax does not include these considerations.

Other managers prefer RP before tax, because it is easier to calculate and because, in most cases, leads to the same conclusions as EVA.

Taking into account the practices of companies, it is noted that companies use multiple financial indicators to evaluate performances.

CRIMINAL LIABILITY FOR CERTAIN ECONOMIC ACTIVITIES-TAX EVASIOAN

Fodor Alexandrina

Universitatea din Oradea, Facultatea de Stiinte Economice

Evasion is equivalent to the offense or crime, and what is civil or criminal depending on the seriousness and rufnesse. Reasons for this phenomenon in Romania is difficult to quantify and are prevented complex and numerous, among them may be mentioned: many imperfections and speculiarities in the tax laws, the business tax accounting method, not using the national macroeconomic record, massive tax evasion carried out by various interest groups and economic agents only appear to take advantage of loopholes laws lack of a tax code, the principle of confidentiality.

Key Words: taxes, evasion, economical, illicit, budget, law, taxpayer, strategies

As the development of capitalism the technique of settlement and collecting taxes has also continuously improved, but was not able to ensure the universality of imposition because it remained in practice in one form or another to circumvent the imposition of the taxpayer.

Evasion is a form of circumvention of the tax effects together with the repercussion.

Tax evasion is at present an economical and complex social phenomenon. It is imperative for all the world, that the result of this phenomenon have to be limited, reduced, to lose the scale, where it became clear to everyone that they can not be eradicated. Tax evasion has a direct and instant effect on the levels of tax collections, which leads directly to imbalances in market mechanisms and the enrichment, in illicit ways, of the practitioners of this method of deception affecting the state and ultimately each of us , honest taxpayers. There are many interpretations and names of this phenomenon, so it is normal for it to be hard to define. There are used phrases like "fraud, illegal fraud, international evasion, legal fraud, fraud by law, the underground economy". Terminology is not the only element of confusion, but also the ambiguous law, the boundary between licit and illicit being very fragile.

The Law no. 87 of 18 October 1994, published in the Official Gazette nr.299 of 24.10.1994, in its first article, considers tax evasion as "circumvent by any means, in whole or in part, from taxes, fees and other amounts due to state social insurance budget and special extra-budgetary funds by individuals and legal persons of Romanian or foreign ...".

Evasion is the flight from taxation, which means that trough the tax evasion the state loses, the amount that should get in its cashiers. Depending on the relationship with the phenomenon regulations, tax evasion is of two kinds: non-fraudulent and fraudulent.

In Romania you can not say that tax evasion was imported, but this phenomenon is a result of the economic situation, the passiveness of the authorities, interest groups that pursue their own affairs under the endorsement of past or present governance, the living standards of most citizens, the degree of civilization, culture and civic consciousness, and especially the aggressive fiscal policies, and even exaggerated sometimes taken by the authorities. Not for nothing was found, over time, through experience, that a tax system is not effective or appropriate in light of the big revenue, but the extent to which it is accepted by the taxpayer, whether natural person or legal entity. In time there have been developed numerous ways to circumvent the payment of tax liability, but those who use them can be divided into two categories: those who exploit the shortcomings of the normative acts in the field and those who use illegal methods. Legal tax evasion is an action by the taxpayer to circumvent the law, recourse to an unforeseen combination of law and therefore "tolerated" by the slip of memory. The legal support that is given to the principle is that what the law does not forbid is allowed. Art.983 of the Civil Code

Romanian example states: "Conventions should be interpreted in the sense most favorable to the debtor."

Non-fraudulent evasion occurs in two situations, when there is such an organization of tax collection and settlement that allows certain categories of taxpayers to not pay or pay less tax. Carefully studying the law, some taxpayers may find the shortcomings and use them to remove the subject of a tax matter fully or partially. By non-fraudulent evasion, the law is not violated. Non-fraudulent evasion, involves interpretation of the favorable tax laws, so cases of legal tax avoidance, for example:

1. The formation of the depreciation funds or reserves in an amount greater than what is justified from an economic point of view, lowering the taxable income.
2. Family associations and societies of his wife and children and the entrepreneur. The result of such maneuvers is imposing separate their income distribution associated with each leading to lowering the tax burden. By such solutions there are speculated the legal provisions governing the tax rate or lower set of reductions or exemptions for income tax up to a particular ceiling.
3. The use within certain limits of legal proceedings on philanthropic donations, whether they occurred or not, lead to the unlawful removal of part of the revenue realized from taxation.
4. A taxpayer has the option to opt either for income tax of individuals, either for the applicable income taxes of legal persons (system comprising numerous tax incentives).
5. The decrease in taxable income of the protocol costs, and advertising services, whether made or not.

If the second form of tax evasion - fraudulent evasion - taxpayers violate legal provisions on taxation or falsely stating not certain amount of income which means that the wrong therefore rule against them take very serious. Some of the forms of tax fraud, like the preparation of false statements, preparation of documents for fictitious payments, setting up accounting books unreal, non-tax matter, the declaration of taxable income below the actual register double record, a real copy another fictional, made without a sales invoice, falsifying balance sheets.

Evasion is equivalent to the offense or crime, and what is civil or criminal depending on the seriousness and rufeness.

Reasons for this phenomenon in Romania is difficult to quantify and are prevented complex and numerous, among them may be mentioned: many imperfections and peculiarities in the tax laws, the business tax accounting method, not using the national macroeconomic record, massive tax evasion carried out by various interest groups and economic agents only appear to take advantage of loopholes laws lack of a tax code, the principle of confidentiality, etc.

Forms banks to eliminate tax evasion:

- Among the measures that may be taken or items that might be contained in future acts in the field can apply: The correlation of the fiscal system with socio-economic realities and appropriate tax strategies for at least 4 years, the period for which the word order to be stability.
- The application of a differential tax, adapted to each sector of economic activity, also under the strategy, this measure is very useful in terms of lack of initial capital.
- Following these strategies under the principle of publicity, to be followed the development of each area of social interest, by application of low levels of taxation for that area.
- Decrease the number of non-deductible expenses when calculating taxable profit, gradually.
- Resizing tax base in terms of contributions to special funds that currently creates difficulties in targeting tax reform, because they are numerous and do not take into account the economic situation of the payer.

- The use of more efficient modalities for the reimbursement of VAT for sales of goods and services for non-individuals.
- Elimination of preferential treatment regarding payment obligations to the state budget and any other tax liability.
- Distribution of the payment of excise duty between producers and retailers of alcoholic beverages and cigarettes, so that final traders are more responsible when it comes both on the origin of products sold and the payment of contributions to the state.
- Organizing an integrated information system on taxpayers of any kind and their history (including previous employment, wages, taxes paid, the tax staff).
- Introducing the same information system able to link the activities of fundraising by the treasuries, the preparation required to implement file tax for individuals, all these measures will lead to discourage undeclared work.
- Cancellation facilities for real or so-called revolutionaries.
- Providing a system of punishment/reward for all those working in state tax and a payroll system and sufficient enough to remove the temptations.
- Establishment of an administrative body, under the supervision of Parliament, who has sufficient powers and logistics so that it can detect and send directly prosecute anyone has done a fraud.

As a measure to eliminate tax evasion, since 1 January 2005, was introduced single tax rate, tax on such companies' profits will be reduced from 25% to 16%, and the system overall, the income tax individuals will be replaced with a quota of 16%. People have more jobs they will hold a tax of 16% of income (after less social contributions), without the need to complete statements of income in 2006 for income earned in 2005. To not be registered losses by employees as a consequence of flat, a deduction system, whose value depends on the number of persons in the maintenance and salary. Deduction amount will increase if the number of dependents within is greater, and will decrease as salary increases. Personal deductions will be granted once only for income derived from salaries to workplace rules.

In conclusion, adoption and implementation of a modern legal framework and transparent, with enhanced motivation of personnel in these institutions would lessen the harmful effects of the true economic scourge of the contemporary world and to create preconditions for better cooperation with the taxpayer but also for the development of civic consciousness in the obligations to which the State must charge him as a protector and not as a despoiler.

Criminal liability is one of the fundamental institutions of the criminal law. It's a form of legal liability, along with civil, administrative, and disciplinary patrimony. Criminal liability is the most serious form of legal liability. It consists in the obligation of people who break the rules to bear the criminal legal consequences of criminal deed sale. Criminal liability as long time as she could for effective recovery and referral of offenders.

The activity of criminal liability is not carried out at random, but is organized by specialized organs. These bodies act according to rules established in advance, called rules of procedure. Based on these rules to the discovery of acts of crime, identifying perpetrators, to determine culpability and criminal liability for them. Activity is integrated in what is called a criminal process.

In order to analyze the criminal liability of legal person, believe it is necessary first to give it a notion.

Legal person is a matter of law, is subject to collective right, meaning a group of people, meeting the conditions required by law, is the proprietor of subjective rights and civil obligations. By a legal person means being an abstract, intellectual fiction created by law in a social and in a purpose of public utility, having a great heritage, capable of rights and duties. Only the legislature has the right to create such persons for any fiction can not exist without law, because only by will

power, which only by laws, institutions and establishes rules to prescribe public order, morality and defend the general interests society.

Criminal liability of legal persons is not a new problem, it goes back to their origins in ancient right, then returns to the end of the XIX century the attention of European criminal doctrine, that today reach one of the central themes of scientific and legal approaches .

The question whether a legal person may see their criminal responsibility engaged in the consideration of its actions or inaction of the subject of a dispute that has marked criminal doctrine throughout the last century. Criminal liability of legal person constituted in the framework of international studies, articles, notes and monographs, devoted to this problem, over time, doctrinal confrontations between partizanii and opponents of this idea.

Legal persons shall enjoy legal recognition capacity in most branches of law, as a patrimony own separate assets which comprise members have rights and obligations distinct from those of members, so their existence is a reality both in the social , and plan juridic118.

Also, people enjoy legal recognition capacity liabilities, including in the sphere of criminal law. When a crime is directed against a legal person, is widely accepted that it is subject to liabilities of the crime, and can act as a party in criminal proceedings by means of its organs. It would be bizarre to at least consider that the person is a legal reality when he was prejudiced in his rights as a result of a crime, but that same person is an imaginary entity, fictional, when it violates the very rights to others.

Taking into account the provisions of international conventions in criminal matters to which Romania became a part, which establishes criminal penalties apply in case of legal persons, as well as commitments made by our country in the negotiations for accession to the European Union has drafted the Law no. 278/2006 - on criminal liability of legal person. Juridical person, except state, public authorities and public institutions to criminal liability in cases stipulated by law for offenses committed in the name or legal interest. The criminal liability of legal person does not exclude criminal liability of the person who participated in committing the same acts.

For crimes and offenses committed, the legal person and may apply penalties and punishments main components.

System of legal punishments include, besides the main penalty fine and penalty complements. Additional penalties are:

- Dissolving the legal person - can be pronounced when the legal person was constituted for the purpose of crime was committed or when the object or activity was diverted for the purpose of crime was committed and has the effect of the opening of winding-up proceedings.

- Suspension of activity or activities of a legal person for a period from one year to three years - is to ban the activity or activities of the same legal person in the exercise of which the crime was committed and can be applied over a period of one year three years.

- Dissolution and suspension can not be applied to political parties, trade unions, employers, religious denominations or organizations of citizens belonging to national minorities, established by law, can not be applied to legal persons who exercise their activity in the press or broadcasting, and also work in press or broadcasting can not be suspended.

- Prohibition to participate in public procurement for a period from one year to 5 years - consists in the prohibition of participating, directly or indirectly, to the procedures for awarding public contracts, provided by law for a period of from one year to five years.

- Prohibiting access to some funds for a period from one year to five years - is to ban to get funds from credit institutions or financial institutions for a duration from one year to five years.

Additional penalties may be applied in a cumulative manner, wholly or partially. Displaying the decision of conviction or disseminate them in the Official Gazette of Romania, through the press or by means of audio-visual communication is achieved at the expense of the legal person

convicted, these charges can not exceed the amount of fine imposed punishment legal. Court may order the display or distribution, in whole or extract a decision of conviction and establishes where and when, can not exceed a period of two months. The identity of the victim or his legal representative shall not be disclosed without their consent.

ENTREPRENEURIAL MOTIVATIONS: ARE WOMEN DRIVEN BY DIFFERENT MOTIVATORS THAN MEN? (I – THE LITERATURE)

Bădulescu Alina

University of Oradea

Faculty of Economic Sciences

The present article has the goal to reveal the (eventually) differences between entrepreneurial motivations between men and women, in the case of EU and Romania. In the first part, we make a brief research into the literature related to this subject, and in the second part we shall reveal the facts and figures in the EU and Romania.

Key words: entrepreneurship, women entrepreneurship, motivation for business start-up

JEL code : M13, G32

1.Introduction

The present article has the goal to reveal the (eventually) differences between entrepreneurial motivations between men and women, in the case of EU and Romania. In the first part, we make a brief research into the literature related to this subject, and in the second part we shall reveal the facts and figures in the EU and Romania.

2.Motivations for entering into the entrepreneurship

Analysing the literature on factors determining people to start a business and become an entrepreneur we find a variety of reasons for this issue.

An empirical research carried by Shane, Kolvereid, and Westhead (1991) on the basis of a questionnaire

identified four factors: labeled recognition, independence, learning, and roles. Birley and Westhead (1994) instead identify seven factors: need for approval, need for independence, need for personal

development, welfare considerations, perceived instrumentality of wealth, tax reduction, and following role models. On the basis of these findings, Carter, Gartner, Shaver and Gatewood (2003) have developed five categories of entrepreneurship reasons: innovation, independence, recognition, roles, and financial success, adding self-realization as a sixth factor.

A very useful taxonomy is achieved by The Global Entrepreneurship Monitor, an international research consortium covering survey type research in 43 countries (2008) on three directions: entrepreneurial attitudes and perceptions, entrepreneurial activity and entrepreneurial aspirations. The GEM proposes two categories of entrepreneurs according to their motivations:

- the “opportunity entrepreneurs”, who start a business based on finding a good opportunity on the market⁵⁷⁷, and
- the “necessity entrepreneurs”, who start a business rather because they have no better choice or to avoid unemployment.

The GEM taxonomy is related to the “pull-push” factors approach. The “opportunity entrepreneurs” are driven by classical pull motivations, such as: the perception and exploitation of a market opportunity, of a better solution than the existing ones, the emergence of a new or

⁵⁷⁷ Entrepreneurial opportunities are “situations in which new goods, services, raw materials, and organizing methods can be introduced and sold at greater than the cost of their production” (Shane, S., & Venkataraman, S. (2000). The promise of entrepreneurship as a field of research. *Academy of Management Review*, 25(1), p. 220)

innovative idea, the recognition of an existing network he or she could try to exploit etc. (see McClelland, 1961; Shane et al., 1991; Birley and Westhead, 1994, cited by Caliendo and Kritikos, 2009a⁵⁷⁸). The usually enjoy a better development According to the taxonomy suggested by Carter et al. (2003), other pull motivations relate to motivations such as:

- independence and willingness to be free of any control or to become one's own boss;
- recognition and gain of acceptance and appreciation by other people (Nelson, 1968);
- self-realization, achievement of the entrepreneurial goals (Fischer, Reuber, and Dyke, 1993);
- financial incentives, the desire to gain more and achieve financial success (Birley and Westhead, 1994).

On the other hand, people's willingness to pursue entrepreneurial opportunities depends on factors such as: their opportunity cost (Amit, Mueller & Cockburn, 1995), their stocks of financial capital (Evans & Leighton, 1989), their social ties to investors (Aldrich & Zimmer, 1986), and their career experience (Carroll & Mosakowski, 1987; Cooper, Woo, & Dunkleberg, 1989)⁵⁷⁹.

The "necessity entrepreneurs" are driven by push factors and their main motivations are:

- lack of other or better alternatives to unemployment (Evans and Leighton, 1990, Storey, 1991, Clark and Drinkwater, 2000, Masuda, 2006);
- lack of other income option in the case of unemployed persons facing the end of their unemployment benefits;
- advisement from other parties of the unemployed people to try self-employment as an alternative option to wage-employment and unemployment (see Caliendo and Kritikos, 2009b⁵⁸⁰).

Unlike "opportunity entrepreneurs", whose businesses enjoy better development, "necessity entrepreneurs" may suffer a high risk of failure (see Carrasco, 1999, Pfeiffer and Reize, 2000, or Andersson and Wadensjo, 2007), or, if they survive, they may produce only marginal businesses (Vivarelli and Audretsch, 1998), invest insignificant amounts of capital (Santarelli and Vivarelli, 2007), fail to create further jobs (Shane, 2009), and earn minimal incomes (Hamilton, 2000, and Andersson and Wadensjo, 2007)⁵⁸¹.

A model of the factors motivating the entrepreneurial process was achieved by Shane et al. (2003):

⁵⁷⁸ Marco Caliendo, Alexander S. Kritikos (2009). "I Want to, But I Also Need to": Start-Ups Resulting from Opportunity and Necessity, Discussion Paper No. 4661, December 2009, IZA

3. Are there gender differences about motivators?

Since the pioneering article on women's entrepreneurship of Eleanor Brantley Schwartz⁵⁸², the literature on entrepreneurs' motivations enriched considerably. There were plenty of researches studying the main motivators for women versus men entrepreneurs and trying to identify classes of homogenous factors and their effects on the survival and the performance of the entrepreneurial firms.

Eleanor Schwartz founded in her above mentioned article that the main motivators of female entrepreneurs are the same as previously identified in the case of male entrepreneurs (Collins & Moore, 1964)⁵⁸³, namely: the need for achievement, job satisfaction, economic payoffs and independence. She found differences in the operated sectors (the predominance of service based businesses in the case of women) and discrimination regarding the access to financing.

Goffee and Scase (1985), analysing the women entrepreneurs' motivations in UK, proposed a typology of female entrepreneurs based on their relative attachment to conventional entrepreneurial ideals and their willingness to accept conventional gender roles, often subordinate to men. Four types of female entrepreneurs emerged in this taxonomy:

- 'conventional' entrepreneurs who were highly committed to both entrepreneurial ideals and conventional gender roles;
- 'innovative' entrepreneurs who held a strong belief in entrepreneurial ideals but had a relatively low attachment to conventional gender roles;
- 'domestic' entrepreneurs who organise their business life around the family situation and believed very strongly in conventional female roles and held low attachment to entrepreneurial ideals;

⁵⁸² Schwartz, E. (1976). "Entrepreneurship: A new female frontier". *Journal of Contemporary Business*, 5 (1), 47-76

⁵⁸³ Collins, O. F. & Moore, D. G. (1964). *The Enterprising Man*. East Lansing: Bureau of Business and Economic Research, Graduate School of Business Administration, Michigan State University

- 'radicals' who held low attachment to both, often organising their businesses on a political, collectivist basis.

Hisrich and Brush (1986) continued these research trends, describing the 'typical' female entrepreneur as: the "first born child of middle-class parents ... After obtaining a liberal arts degree, she marries, has children, and works as a teacher, administrator or secretary. Her first business venture in a service area begins after she is thirty-five" (Hisrich and Brush, 1986, p. 14). The main factors motivating women to start-up a business were reported to be the desire for job satisfaction, independence and achievement.

However, some other researchers studying the women's motivations for starting-up new businesses founded gender differences between men and women. Scott (1986)⁵⁸⁴ founded that men were concerned by the issue of independence and the desire to be their own boss, while women were concerned by personal challenge and satisfaction.

Empiric research carried on a national basis reported gender difference in the start-up motivations (Ljunggren & Kolvereid, 1996, Shabbir & D'Gregorio, 1996) and also the similarity across countries of women's motivations⁵⁸⁵.

We can conclude that, overall, most studies consider that the motivations for start-up there are similar in the case of women and men entrepreneurs. People – male and female – enter into entrepreneurship and start-up businesses motivated by the desire to achieve job satisfaction, independence and financial payoff. The literature reported however differences in terms of growth motivation, women having lower growth ambitions than men (Carter, 1997, Wiklund, Davidsson & Delmar, 2003). The results are stable across industries and over time.

„Women tend to self-select from self-employment because they do not perceive that they have the competence needed to start and manage firms, that entrepreneurship is often perceived and portrayed as a male occupation. The lack of perceived competence will also diminish the motivation of women as the perception of competence and motivation are closely related to each other. If they decide to start firms they will to a higher degree choose to start more part-time and home-based firms in order to balance professional responsibilities with family responsibilities. Saying this, it is also necessary to remember that individual women may well act differently, that is some women will always behave in a non-typical way, resembling men in their pattern of behaviour" (OECD 2004)⁵⁸⁶.

Karen Hughes⁵⁸⁷ uses a taxonomy grouping the motivations into three classes:

- Classic entrepreneurs – motivated, as men, by: desire for greater independence, challenge and self-fulfillment, „own boss" desire, financial independence;
- Forced entrepreneurs ('necessity based') – driven by unemployment, job loss, lack of work opportunities;
- Work-Family entrepreneurs – motivated by: work-family balance, flexibility. These factors are especially important for women (see Brush 1992; Stevenson 1986, 1990). Lee-Gosselin and Grise (1990) underline the role of family-based motivations, noting that for some women "starting a business may be an adaptive

response to the demands of the parent and spouse/partner roles, which are very important to them”⁵⁸⁸.

D. P. Moore and E. H. Buttner (1997)⁵⁸⁹ suggested that women started their own businesses from a desire for self-determination and for career challenge, and that they expect the corresponding respect, recognition, and self-esteem that both self-determination and challenge provide. For some women, high unemployment rates, and divorce force them into entrepreneurial activities⁵⁹⁰.

ENTREPRENEURIAL MOTIVATIONS: ARE WOMEN DRIVEN BY DIFFERENT MOTIVATORS THAN MEN? (II – SOME EVIDENCE FOR EU AND ROMANIA)

Bădulescu Alina
University of Oradea
Faculty of Economic Sciences

The present article has the goal to reveal the (eventually) differences between entrepreneurial motivations between men and women, in the case of EU and Romania. In the first part, we make a brief research into the literature related to this subject, and in the second part we shall reveal the facts and figures in the EU and Romania.

Key words: entrepreneurship, women entrepreneurship, motivation for business start-up

JEL code : M13, G32

1.Methodology

In order to reach both the primary objective of finding the motivation driving women to enter the entrepreneurship, and the second one, of identifying similarities or differences between female and male motivators, in Romania and in the EU, we used the dataset “Enterprises managed by the founder - broken down by gender of the entrepreneur”, available in Eurostat database. We select from this database the data regarding the start-up motivation available for Romania and European Union (aggregate changing according to countries available), NACE: Industry and services excluding public administration and management activities of holding companies. Available data are for the year 2005.

First, we select the data for the EU, broken by the gender of the founder and manager of the firm and search to arrange the motivation starting with the most important, e.g. more nominated by the respondents. Second, we did the same thing for the data available for Romania, sorting them by relevance. Third, we tried to make some comparison between:

- Male versus female entrepreneurs in EU
- Male versus female entrepreneurs in Romania
- EU women entrepreneurs versus Romanian women entrepreneurs.

Finally, we will conclude and emphasize some implications of the findings.

2.Discussion

The main driving forces motivating women to enter into entrepreneurship is the desire for independence, with the answer “desire to be one’s own boss” indicated among main motivators by 73.7% of the female entrepreneurs. The second motivation, indicated by 70.6% of the respondents, is the prospect of making more money, which expresses the desire for financial independence and payoff. The third motivation is the desire for new challenges.

It is remarkable the pre-eminence of full factors, generating the classical, opportunity entrepreneurship, and also motivation directly related to the Schumpeterian-innovative approach: realizing an idea for a new product or service. Besides the classical factors, it is to note the relatively great importance of the push factor “avoiding unemployment”, indicated by 54.8% of the female entrepreneurs. Another push factors, indicating the extension of the necessity entrepreneurship, are: getting away from unsatisfactory work situation; only possibility to carry out profession.

As expected, motivations related to work-family balance are present: “combining work and private life” indicated by 49.5% and „children are big enough” indicated by 22.6%. The last motivation indicates the women previously forced to be involved in family and child care activities, activities which had not left them enough time for work (self-employment or wage-employment).

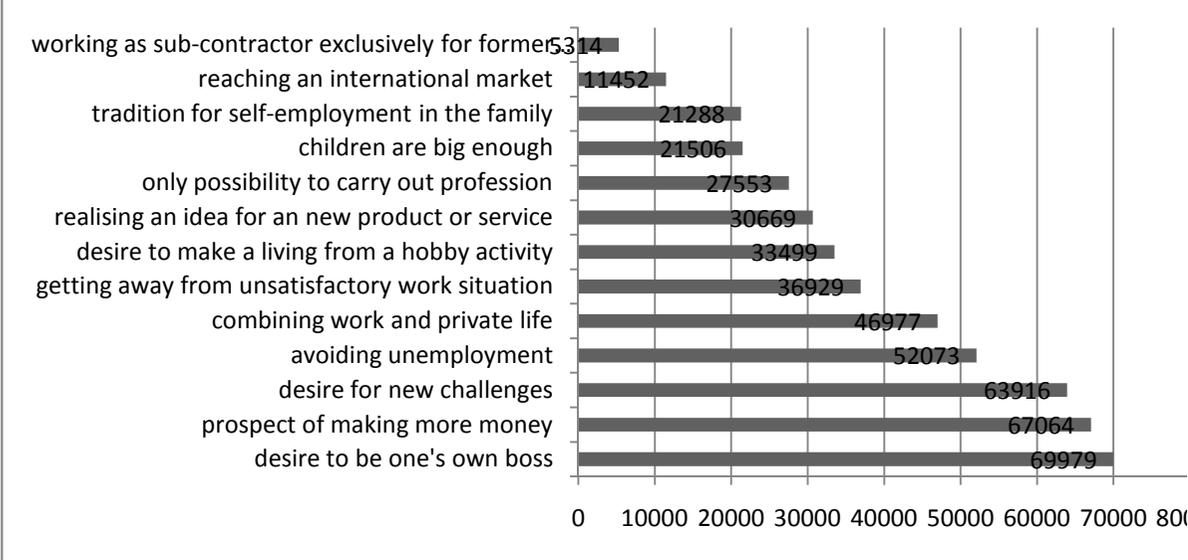

Chart 1. The motivation for start-up of the enterprises founded by the manager – EU 2005, women

Source: own calculation based on Eurostat database

Male entrepreneurs bring out mainly the same motivations, the top 3 indicated motivators being the same. The desire for independence, more money and new challenges motivate men to start up a business. The pull factors are the most important drivers, but there are also present the push factors, such as: avoiding unemployment, getting away from unsatisfactory work situation.

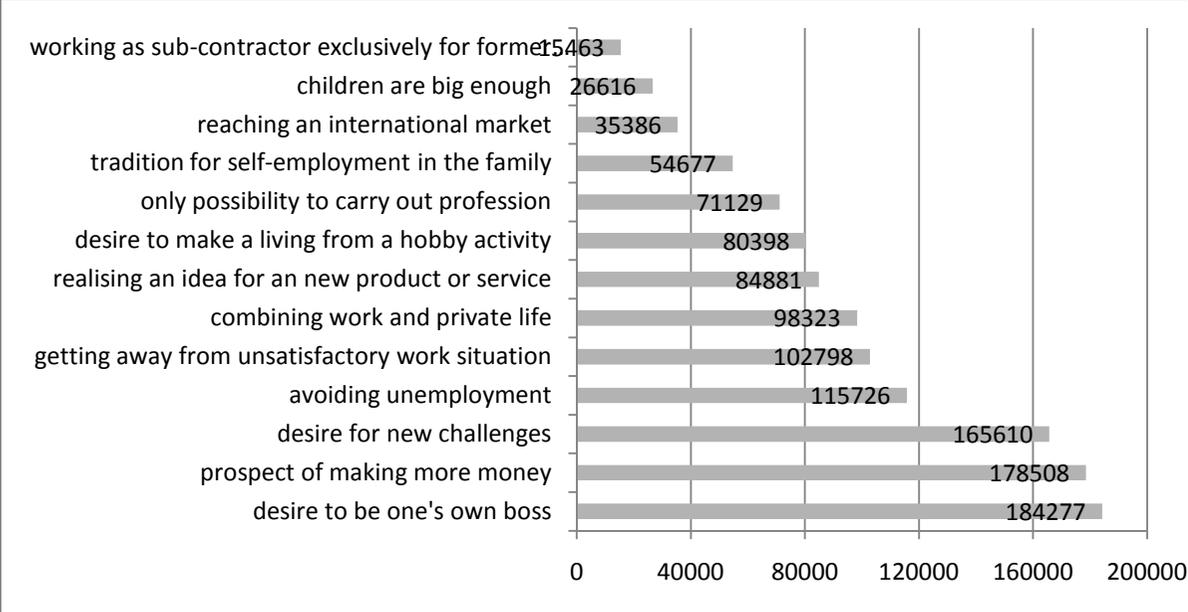

Chart 2. The motivation for start-up of the enterprises founded by the manager – EU 2005, men

Source: own calculation based on Eurostat database

A brief comparison between females and males reveal that the motivations are basically the same. Nevertheless, some differences can be drawn:

- The “children are big enough” motivator was indicated by 22.6% of the women, twice the proportion of 11% of the males; this fact is a major difference, indicating that child carrying is still a women activity, and gender matters a lot when it is about to factors inhibiting the economic participation of females;
- The “combining work and private life” motivator was nominated by 49.5% of the females but only 40.5% of the males; the work-family balance (including the children carrying issue) is a more concerning problem for women than for men;
- “avoiding unemployment”, motivator indicated by 54.8% of the women versus only 47.6% of the men, testify that unemployment is usually a problem affecting women more than men, and thus the concern has a gender dimension;
- The last motivation indicated in a greater measure by women than by men (but with not a big gap) is “desire to make a living from a hobby activity”; this can be related with the fields of services, arts etc., field and profession more associated with women than with men, and where female entrepreneurs tend to operate rather than males.

The other motivations were rather indicated by men than women, but the differences are far not to be as important:

- desire to be one's own boss (75.8% males versus 73.7% females)⁵⁹¹;
- prospect of making more money (73.5% males versus 70.6% females)⁵⁹²;
- desire for new challenges (68.2% males versus 67.3% females)⁵⁹³;
- getting away from unsatisfactory work situation (42.3% males versus 38.9% females)⁵⁹⁴;
- realising an idea for an new product or service (34.9% males versus 32.3% females)⁵⁹⁵;
- reaching an international market (14.6% males versus 12.1% females)⁵⁹⁶;
- working as sub-contractor exclusively for former employer (6.4% males versus 5.6% females).

Virtually with the same frequency among men and women there are: “only possibility to carry out profession” and „tradition for self-employment in the family”. The complete picture is shown in Table 1.

Table 1. Start-up motivations: females versus males, EU versus Romania (2005)

Start-up motivation	Nominated by ... % of the females (EU)	Nominated by ... % of the females (RO)	Nominated by ... % of the males (EU)	Nominated by ... % of the males (RO)
prospect of making more money	70.6	81.6	73.5	86.5
desire for new challenges	67.3	76.3	68.2	79.1
desire to be one's own boss	73.7	62.5	75.8	68.7

⁵⁹¹ Are men willing and loving freedom and independence more than women?

⁵⁹² Are men more money-oriented?

⁵⁹³ Are men more adventure and change oriented?

⁵⁹⁴ Are men suffering more in the case of unsatisfactory work? Are women more resigned?

⁵⁹⁵ Are men more innovative or more self-confident? Do the prevalence of their technical education play a role?

⁵⁹⁶ Are men more desiring of adventure, more open to unknown, or simply more self-confident?

Start-up motivation	Nominated by ... % of the females (EU)	Nominated by ... % of the females (RO)	Nominated by ... % of the males (EU)	Nominated by ... % of the males (RO)
combining work and private life	49.5	56.7	40.5	55.7
avoiding unemployment	54.8	54.1	47.6	54.1
desire to make a living from a hobby activity	35.3	35.7	33.1	37.8
getting away from unsatisfactory work situation	38.9	30.7	42.3	28.5
children are big enough	22.6	24.8	11.0	20.4
only possibility to carry out profession	29.0	22.5	29.3	22.6
tradition for self-employment in the family	22.4	21.0	22.5	24.0
realising an idea for an new product or service	32.3	18.0	34.9	21.9
reaching an international market	12.1	13.2	14.6	19.6
working as sub-contractor exclusively for former employer	5.6	6.3	6.4	6.9

Source: own calculation based on Eurostat database

The second problem we try to answer holds of a eventually national determination, e.g. are there or not noticeable differences in the motivations of female versus males entrepreneurs in Romania. In order to draw the picture, we use the same database, available for the year 2005, for Industry and services excluding public administration and management activities of holding companies. Mostly, females are driven into entrepreneurial activities by the need for money. It is hard to say if this motivator is a pull or a push factor, given the low income level of the majority of the households. Other motivations indicated were the desire for new challenges, the desire for independence, the work-private life balance and the avoidance of unemployment. The other factors are mentioned at a considerable distance (see Chart 3).

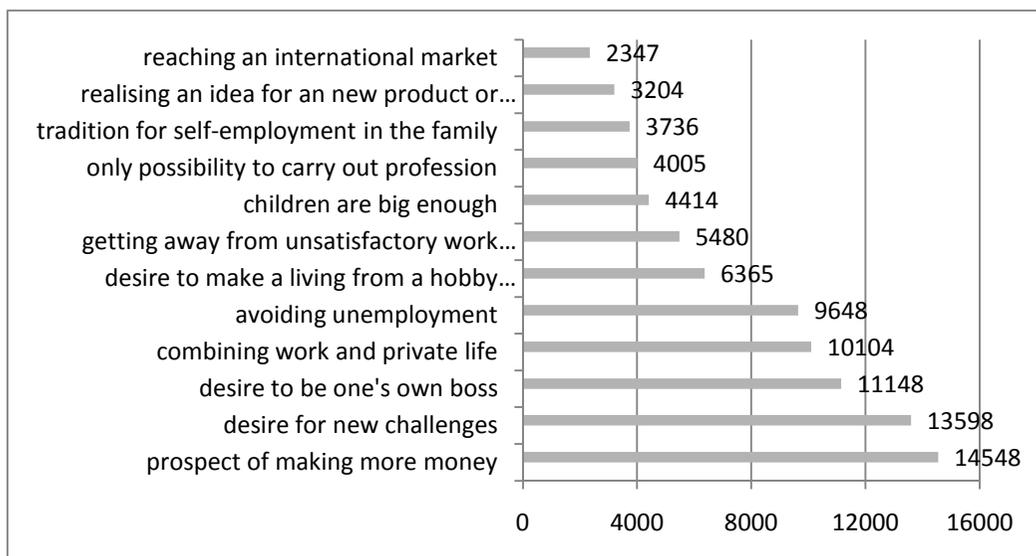

Chart 3. The motivation for start-up of the enterprises founded by the manager – Romania 2005, women

Source: own calculation based on Eurostat database

About the Romanian male entrepreneurs, the first 7 out of 12 indicated motivators are the same. The need and desire for independence, financial payoff, new challenges, but also the necessity factors related to family-work like, unemployment, and also the desire to change either activity or unsatisfactory work are mentioned (see Chart 4).

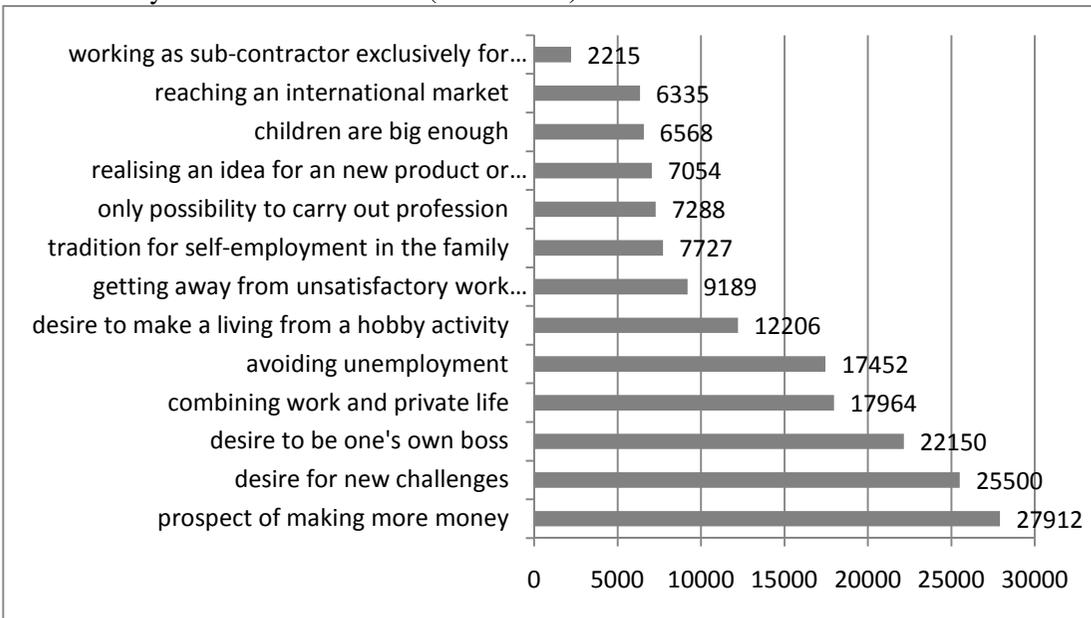

Chart 4. The motivation for start-up of the enterprises founded by the manager – Romania 2005, men

Source: own calculation based on Eurostat database

As was the case with the EU dataset, the only relevant difference is related to the family issues. The more “feminine” motivations (see Table 1) are:

- children are big enough: 24.8% of the females indicated this motivation, against 20.4% of the males;
- getting away from unsatisfactory work situation (30.7% of the females versus 28.5% of the males);
- combining work and private life (56.7% of the females versus 55.7% of the males);

Women appear to be less money oriented, less willing for independence and new challenges, the prospect of making more money motivating –motivated, less motivated by tradition factors, innovative ideas or international dimensions. Briefly, Romanian women entrepreneurs appear to be more conservative than man, more oriented to family and children carrying issues, an less motivated by money making than men. Virtually the same role irrespective to gender have the push factors: avoidance of unemployment, the entrepreneurship as the sole possibility to carry out profession etc.

3.Concluding remarks

Finally, putting together all motivations indicated by females and males in EU and Romania, we conclude (see Table 1) that:

- the prospect of making more money is a greater motivator for males than for females, both in Romania and EU, but the strength of the motivator appears to be

more obvious in Romania compared to the EU average; this fact can be related with the reality of more opportunities to make profit on the Romanian market, full of shortages and thus with better prospects for rapid gains, but it also can be related with the lower level of well-being and the higher level of poverty in Romania, factors that strongly motivate people, and also create great expectations regarding the entrepreneurial profits;

- The desire for new challenges is considerably a stronger motivator for the Romanians entrepreneurs; however, surprisingly, “getting away from unsatisfactory work situation” motivated considerably less Romanian as other EU citizens;
- The desire for independence is also not as strong for the Romanian entrepreneurs, largely habituated with the employee role;
- “Combining work and private life” and “children are big enough” are stronger motivators for the Romanian entrepreneurs; this fact can be related with the traditional cultural models, but also with the insufficient child care services and facilities etc.
- The motivation of realising an idea for an new product or service is considerably less motivating for Romanian entrepreneurs; its nomination is nearly half in the case of women;
- The motivation of avoiding unemployment is mentioned in the same measure by Romanian women and men and EU women entrepreneurs; only EU male entrepreneurs appear to be less concerned about that possibility
- It is interesting that tradition for self-employment in the family is nominated in very similar measures by male and female in Romania and Europe; that means that there are already functioning the entrepreneurial family models, but it could also mean that the presence of entrepreneurial models in the family acts not so strong as motivator.

The final conclusion is that there are no outstanding differences between entrepreneurial motivations between men and women, with the exception of those related to the family-work balance. This conclusion holds also for the analysis in terms of EU male entrepreneurs versus female entrepreneurs, but also in the case of Romanian male versus female entrepreneurs. It appears also that there are several difference on a international basis comparison, revealing enhanced motivators for Romanian entrepreneurs than in case of other countries: the prospect of making more money, the desire for new challenges, combining work and private life. In the same time, Romanian are considerably less motivated as entrepreneurs by the desire to be one's own boss, by getting away from unsatisfactory work situation, and especially by realising an idea for an new product or service. More necessity and less opportunity and innovation entrepreneurship appear to characterise Romanian entrepreneurs' motivations.

TOTAL REWARD CHALLENGES IN THE ROMANIAN EMPLOYMENT MARKET

Andrei Monica

Doctoral School at Academy of Economic Studies, Bucharest, Romania

Oprea Margareta

Doctoral School at Academy of Economic Studies, Bucharest, Romania

Joining the European Union meant that the employment market had to align to EU requirements. Recovering after the financial crisis will keep on putting financial constrain on many organizations in the next 2 years. This alone demonstrates that the reward strategy will be of high importance in the years to come in Romania.

This paper aims to analyze the concept of total reward, financial and non-financial remuneration with estimated trends on the employment market in Romania.

Keywords: Financial remuneration, Non-Financial Remuneration, EU Integration, Employment Market

JEL Classification: J30, J31, J33

Introduction

Starting with the 1980 there was a general understanding that financial reward is a big motivational factor. Most of the human needs can be satisfied by buying and in order to be able to buy, people need money. Therefore, money can be a huge motivational factor but not the only one.

Wallace and Szliagy (1982) concluded that money can support several reward function such as:

- Acting as commun purpose for people who work with different levels of involvement;
- Can ofer valuable results;
- Can be a symbol which indicates the value of an organization;
- Can act as reward and therefore can directly motivate.

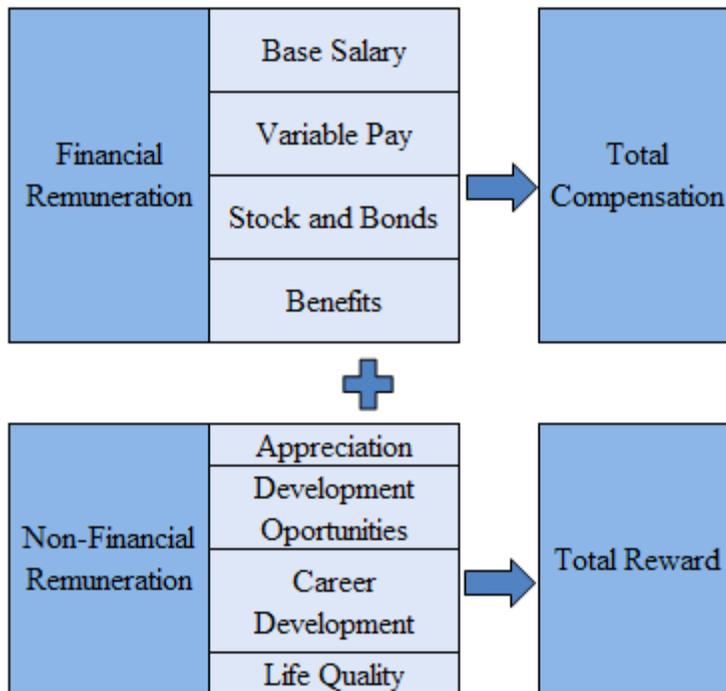

In contrast, the economist Kohn (1993) believes a financial motivation of employees is doomed to failure. He believes that the more you use reward in order to motivate people, the more these looses their interest in what they have to do in order to obtain their financial remuneration.

Five years later, Gupta and Shaw (1998) reinforce the symbolic power of money as a motivational factor. The financial remuneration concept is analyzed through his direct utility: buy a bigger house, a more powerful and modern car, trendy cloths, healthy food, more exotic holidays, etc.

In 2010, after two years of turmoil generated by the financial crisis, the financial recompensation is more important than ever. Many organisation were unable to provide pay rises in the last 2 years, redundancies reached high levels, bonuses were frozen and contribution to private pension schemes were reduced.

What does Employee Reward mean?

Armstrong and Brown (2001) define Employee Reward as a balanced combination of Financial Remuneration and Non-Financial Remuneration.

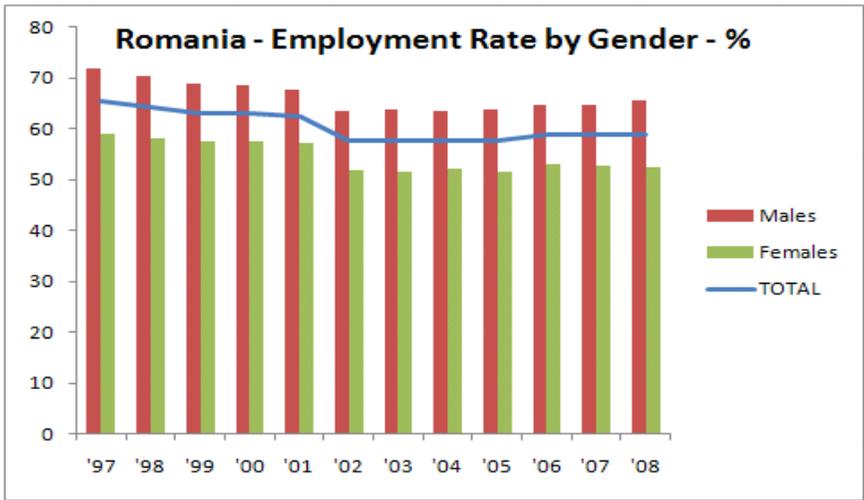

Picture 1. New Dimensions of Reward Management

The above figure indicate that **financial remuneration** is defined by base salary, variable pay (bonuses and incentive payments), long term payments (stock and bonds) and employee benefits. The **non-financial** compensation is harder to quantify and it introduces elements such as appreciation and recognition at work, development opportunities, lateral career movements and promotions as well as life quality by achieving a work – social life – family balance.

Since 2001 to present the value of non-financial compensation has grown, even in Romania. In the light of joining the European Commission where the work culture focuses just as much on the non-financial compensation Romania had to adapt. Organizations, especially international ones started to offer new packages with more career development opportunities.

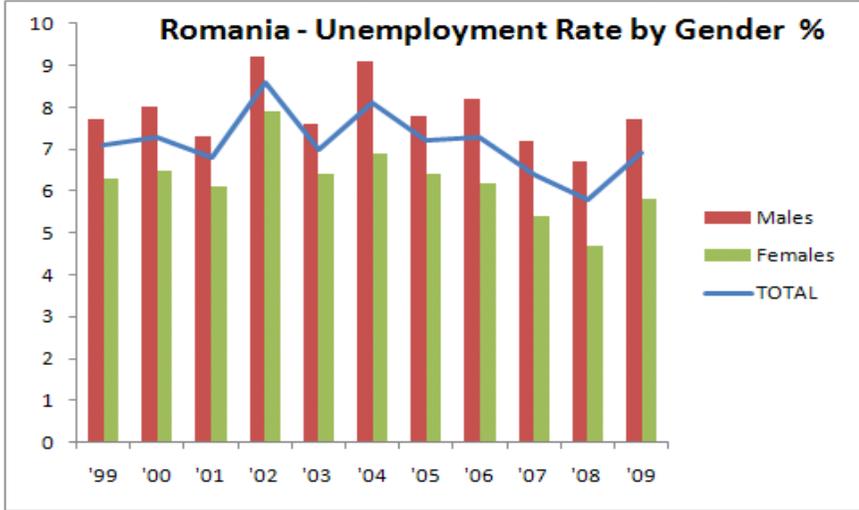

Employment market in Romania

In the last few years the Romanian employment market was affected by the recent changes: firstly joining EU and aligning to the EU requirements and the financial crisis. However, the employment rate was rather constant since 2002, reaching its peak 59% in 2008. The below chart also indicates that there is a higher rate of employment in Romania among the male population – a difference of 13.2% in 2008.

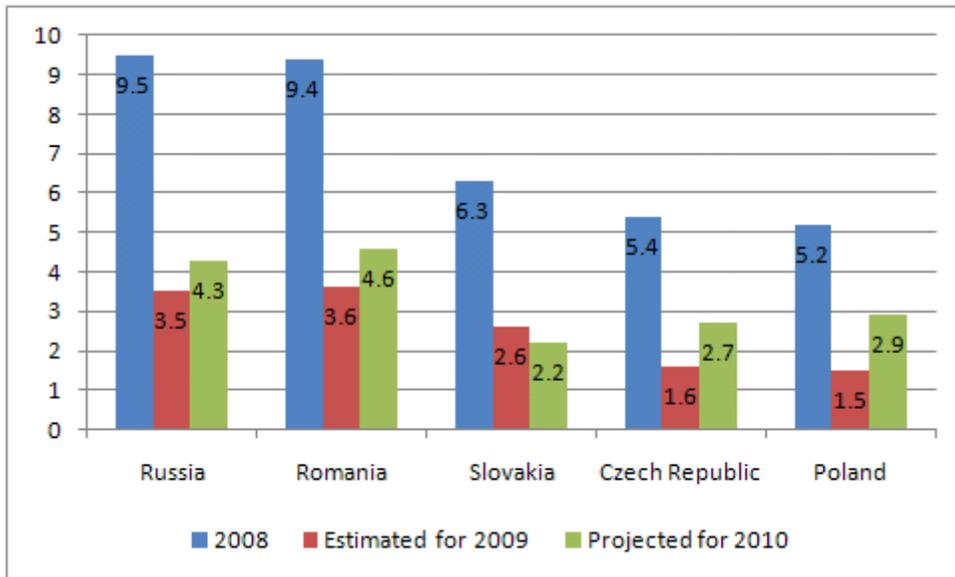

Picture 2. 1997 – 2008 Employment Rates in Romania
 Source: <http://epp.eurostat.ec.europa.eu>

The unemployment rate started to increase again in 2008 with almost 1.1% increase.

Picture 3. 1999 – 2009 Unemployment Rates in Romania
 Source: <http://epp.eurostat.ec.europa.eu>

According to the Radford consultancy firm, Romania is doing much better in terms pay increases as percentage of salary in comparison with its Eastern European neighbours.

Picture 4. Pay rises as percentage of salary

Source: Radford ISSIT – September 2008 and September 2009 – General pay rises

In 2008, Romania had some of the highest increases reported almost as high as Russia (9.4% increase in Romania, 0.1% less than Russia). Despite the financial crisis, Romania had the highest estimated increase at 3.6% for 2009 and should still lead the market with 4.6% increase projected for 2010 while most of the Eastern European countries are considering an increase of 2%-3%.

Trends and conclusions

It is a known fact that Europe's largest economies have emerged from recession already: France and Germany where the first ones followed by United Kingdom. Other countries are also showing a frail recovery.

The reward strategy will be of high importance in the years to come in order to adapt the employment market to the new rules designed post recession, tax changes introduced and the ongoing redundancies.

Romania will have to adapt as well. The inflation rate will continue to grow in 2010, discretely affecting salary budgets and employee benefits. Most of the companies will still have their salaries frozen as in 2009 (two thirds of salaries frozen salaries in 2009 according to Radford consultants) and there will be new challenges: the ongoing uncertain economical environment, low and reduced budgets to manage, high expectations of employees, management and clients and developing alternatives ways of employee recognition.

ROMANIA'S TRANSITION IN THE CENTRAL EUROPEAN CONTEXT

Bâc Dorin Paul
University of Oradea
Faculty of Economics

The Eastern bloc countries have been under communist leadership for almost fifty years. After the 1989 collapse of communist leadership, new regimes have been installed. The roads from socialism to capitalism, from totalitarianism to democracy have been extremely difficult and tested both the people and the leaders. The present paper takes a look at the first years of Romania's democracy and its economic reforms. Although democratic elections have been organized and some reforms have been undertaken, compared to other states Romania might not have done enough.

Keywords: socialism, capitalism, democracy, Eastern Europe,

JEL code: P21, P51

Introduction

1989 was a year of revolt in Eastern Europe. Poland, Hungary, Czechoslovakia and Romania won back their freedom by eliminating their leaders peacefully, in the case of the first three or violently in the case of Romania, as "Nicolae Ceausescu, was the one Communist despot who was determined to shed blood rather than relinquish power"⁵⁹⁷. The most representative moment of the year was the dismantling of the Berlin Wall which started in November.

All the above mentioned countries had to go through massive and painful reforms to change their economies, political and social life from socialism to capitalism and democracy. But the process was different from country to country. White⁵⁹⁸ considers two main types of change: transition from below (the case of Poland, Romania and Czechoslovakia) and transition from above (Hungary, Bulgaria and USSR)

In the case of Poland, the Solidarity was considered the most powerful symbol of liberty in the communist world⁵⁹⁹. Its leader, Lech Walesa had a major role in 1989 and became the first elected president in 1990. The change of power was peaceful and based mainly on round-table negotiations between the leaders of the Communist Party and the leaders of Solidarity.

In Hungary, the democratic breakthrough between March and June 1989 consisted in a considerable shift from a dichotomy between officialdom and the opposition towards a growing self-inclusion of party hardliners into the opposition. It continued in October, when the Communist Party Congress decided to form a European-style Hungarian Socialist Party, committed to democratic socialism and mixed economy. The elections in the spring of 1990 were won by the Democratic Forum, and together with their allies they formed the new government, thus eliminating the old communist leadership of the country.

The change of regimes in Czechoslovakia was known as the "Velvet Revolution", which stands for the peaceful mass gatherings that toppled the Czechoslovak government in November 1989. While the notions "velvet revolution" or "soft revolution" referred only to the mass protests in November, they soon came to signify the whole process of the demise of communism⁶⁰⁰. The process of change ended in June 1990, when Vaclav Havel was elected president.

The political perspective

Romania became a republic again after the communists won the 1946 elections and forced King Mihai I to flee the country the next year. In the case of all the Eastern Europe the original transition to socialism did not arise by organic development: “the socialist system does not originate spontaneously from the intrinsic, internal forces of the economy. Instead, the socialist system is imposed on society by the communist party with brutal force, when it gains power. It liquidates its political opponents and breaks up any opposition. The communist party that comes to power has a vision of what society, economy and culture it wishes to create: a system that eliminates private property and the market, replacing them with state ownership and planning”⁶⁰¹. All the above mentioned characteristics could be observed in Romania’s evolution during 1946 and 1989.

More than forty years later, in December 1989, Romanians fought and won back their freedom. The repression of demonstrations for democracy in Timisoara, when the security forces, the hated Securitate⁶⁰², shot dead 71 on the weekend of 16–17 December⁶⁰³, sparked off mass protests in Bucharest. Ceausescu, and his wife Elena, refused to budge and ordered the mobilization of the Securitate, and the army, to put down the demonstrators by whatever means necessary.

The army hesitated, as did a section of the Securitate. In face of continuing intransigence, and growing popular opposition (Ceausescu was heckled by the protesters in Bucharest when he appealed to them to go home on 21 December), long hidden opponents within the Party, headed by Ion Iliescu, army officers and even some Securitate leaders, organized to overthrow him. Arrested as they tried to flee the country, Ceausescu and his wife were executed on Christmas Day, an execution seen on television by a global audience

The exact nature of the events of December 1989 in Romania has long been the subject of intense speculation, it is still unclear whether the events constituted a revolution or some other form of irregular political challenge such as a coup d’état or popular uprising. The overall conclusion is that although a revolutionary situation arose in the country in 1989, a revolutionary outcome is not yet assured⁶⁰⁴. There are critics that argue that Ion Iliescu and NSF took advantage of the chaos in order to stage a coup. It is still not clear if it was thought in advance or whether it was a pragmatic action of an elite group who took advantage of the situation. What is without doubt is that because of his ruthless politics, Ceausescu was abandoned by numerous officials of the Government, the Party, the Army and his secret police⁶⁰⁵.

After the events on December 1989, Romania became a democracy again and it organized its first free elections in May 1990. The big winners of the elections were, as expected the National Salvation Front and its leader Ion Iliescu. The National Salvation Front was a coalition of former communists which took over the functions of the government after the overthrow of Ceausescu in December. It later split into the Social Democrat Party, led by Iliescu and the Democratic Party, led by Petre Roman, and later by Traian Basescu.

Ion Iliescu was a former member of the Politburo – considered by many the future leader of Romania, after the death of Ceausescu. Iliescu did not have the “revolutionary’s aura” of Havel or Walesa, but he still won the 1990, 1992 and 2000 elections.

Unfortunately, 1990 was a year marked by violence as coal miners “visited” Bucharest to stop anti-communist demonstrations organized by the political and social opposition of NSF. One of

the greatest discontents of the demonstrators was the implication of the second level activists of the Communist Party in the new structures of Power⁶⁰⁶.

The new Government, led by Petre Roman wanted fast reforms and established new relations with the EU and USA. Roman's failure to explain adequately both the purposes and the consequences of genuine liberalization and stabilization fueled the resentment of precisely those constituencies to whom the NSF owed its May 1990 electoral victory. So, in 1991 Petre Roman was replaced with Stolojan, the finance minister.

The 1992 elections were won again by Iliescu who made an alliance with the nationalist parties and the party of the former communists. Although the composition of the Parliament and government changed, the domination of Iliescu and the presidency continued⁶⁰⁷. Vacaroiu was named prime-minister and the goal of the new Government was to "slow down market reforms that might favor foreign business interests"⁶⁰⁸. The 1992-1996 period was marked by privatization scandals and frauds made by the people in power, determining the halting of progress and reforms needed at that time.

Economic perspective

There is a debate regarding Romania's economic situation. Some argue that as Romania entered the 90s, the country was in many ways in a better position to pursue economic restructuring than other East European countries. In December 1989, Romania had almost no foreign debt and maintained a current account surplus of \$2.8 billion and foreign exchange reserves of \$ 1.7 billion. Other economic indicators (current account balance, debt-to-GDP ratio and hard currency holdings) were better than any other East European country⁶⁰⁹. Others consider that Romania started its transition to a market economy at a serious disadvantage, with significantly worse initial conditions than those prevailing in the leading reform countries. Romanian policy makers have had less room to maneuver in taking the painful political steps necessary to liberalize Romania's formerly Stalinist economic system. Apart from the reduced level of investment, growth possibilities were also impaired by a sharp reduction in imports of machinery and equipment from the West. The heavy overtaxation of domestic consumption, which took place during this period in order to meet external debt obligations, resulted in lower growth rates of production, reduced welfare (consumption), and bigger domestic imbalances, both visible and hidden⁶¹⁰.

Privatization moved slowly in the first years although the legal framework was set up to sell of 55% of state equity. The state maintained its control in strategic areas as energy, transport and telecommunications. In selling equity 30% was to be allocated to Romanian citizens, leaving the rest for foreign and domestic investors. The allocation to the citizens was done through vouchers, but the system proved its limitations because of inflation, speculation and public apathy.

In 1992, industry was still 90% controlled by the state and registered a continuous fall to score a cumulative decline of 54% over 1989⁶¹¹.

The macroeconomic data for 1993 and 1994 would seem to suggest an unanticipated level of success for Vacaroiu's policies. The decline in GDP was reversed (with 1.5 and 3.9 percent gains, respectively), and industrial production increased (with increases of 1.3 and 3.3 percent, and with overall industrial productivity jumping to 9 and 14.7 percent, respectively)⁶¹². However,

due to high inflation and further price liberalizations, real wages fell by 16.7 percent in 1993 (with a marginal 0.4 percent recovery in 1994).

Table 1.

Selected economic indicators of Romania's economy (1990 - 1997)

Indicator	90	91	92	93	94	95	96	97	98

Source: http://www.indexmundi.com/romania/gdp_real_growth_rate.html, <https://statistici.insse.ro/ipc/>, <http://www.insse.ro/cms/files/pdf/ro/cap3.pdf>

Moreover, the Vacaroiu government's decision to continue subsidies to state enterprises increased the budget deficit to 4.4 percent of GDP in 1994; and despite the National Bank's reluctance, the money supply was increased by 500 percent during these two years, resulting in inflation of 256 and 136 percent respectively, for 1993 and 1994 (Table 1.).

Critics asserted that while temporary improvement in some areas had been reported, it was largely at the expense of, rather than due to, genuine economic reforms. The World Bank's comparative analyses of transitional economies (1995) found Romanian liberalization and private sector development near the bottom of Group 2 (which, in addition to Romania, included Bulgaria, Albania, the Baltic countries, and Mongolia).

Bacon is trying to find out why did the macroeconomic data reflect so dramatic a recovery? He considers the data on the state budget's deficit as a proportion of GDP are enlightening. While the deficit was 2.6 percent of GDP in 1993, the transitional year, it had risen to 4.2 percent in 1994. Despite the attempts by the National Bank to institute a tight monetary policy, the government, out of the political need of their voters, continued to pursue a policy of "soft credit"—heavily subsidizing indebted and inefficient state economic units, directing the state's fledgling commercial banks to provide negative (1993) and low-interest (1994) loans to loss-making enterprises and state farms⁶¹³.

In 1994, the private sector accounted for only 35 per cent of the economy, a low figure when compared with 55 per cent in Hungary and Poland and 65 per cent in the Czech Republic.

1995 was an even more favorable year. GDP grew 7.1 percent, and industrial output grew by 9.4 percent, while inflation fell to 27.8 percent⁶¹⁴. Real income, "electorally the most fungible indicator, rose 12.5 percent"⁶¹⁵. However, the budget deficit remained at an unacceptably high 4.1 percent of GDP. The expansion of the GDP, which should have enabled the economy to "grow" out of indebtedness, had been realized. However, genuine reform within the framework of the "Washington consensus" remained inconsistent⁶¹⁶.

An unexpected energy crisis began in 1996, a year of discontent for Romania. After some delays, the government was obliged in May 1996 to raise prices for basic consumer goods, including energy, after a sharp devaluation of the forced its hand. The annual inflation rate, projected by the government to be 20 percent for the year 1996, soared to nearly 60 percent by year's end (Table 1.). To add to the uncertainty, two Romanian banks, Credit Bank and Dacia Felix, became illiquid due to massively nonperforming loan portfolios, incompetent management, endemic cronyism, and corruption. The National Bank, already overextended by a looming increase in

foreign and domestic debt, had to bail out the banks, all the while trying to counter the government's spendthrift ways.

Conclusions

Romania's transition has been a long and strenuous road. According to Crowther, there have been two significant turning points in Romania's transition: 1) the events in December 1989 which displaced the Ceausescu dictatorship and 2) the 1996 transfer of power to the liberal opposition parties which initiated a second phase of reform.⁶¹⁷ Although the 1989 events brought change and democracy, the elites of the old Romanian Communist Party, or at least a sizable number of them, were actually the beneficiaries of the revolution. In fact, one could easily argue that they have taken full advantage of the transition to the "free market," using their inside knowledge, political power, and control of state resources to *privatize* their power over the Romanian economy, transforming, quite legally, the political domination of the old nomenklatura into the economic domination of a new oligarchy⁶¹⁸.

Figure 1.

Economic growth of Romania, Hungary and Poland 1990-1998 (%)

Source: http://www.indexmundi.com/romania/gdp_real_growth_rate.html, http://www.indexmundi.com/poland/gdp_real_growth_rate.html, http://www.indexmundi.com/hungary/gdp_real_growth_rate.html

Compared to the progress of Poland, Hungary and Czechoslovakia, Romania has and is still lagging behind. A proof of this lag is the date of joining the EU, which the first three countries have achieved three years faster than Romania.

Turnock considers that in Hungary privatization moved also slowly, but the Government was able to privatize faster than Romania its main industries and services and also established numerous joint ventures with Austrian, German and Swiss companies⁶¹⁹.

In Poland's case, we have to take into consideration the unions. After 1989, the reform program adopted by the new government sought to stabilize the macroeconomic environment and to begin moving the country toward a market economy. Although initially the economy went into a deep

⁶¹⁷ Crowther, W. (2010) *Contemporary Romanian politics*, Communist and Post-Communist Studies No.43, p.1 .

⁶¹⁸ Gabanyi p.353

⁶¹⁹ Turnock, D. (2005) *The East European Economy in Context*, Routledge, London, p.194

recession, by 1992 growth resumed. “By the end of the decade the Polish economy was one of the fastest growing in Europe, with an average rate of growth of 6.5 percent between 1995 and 1997 and 4.5 percent between 1998 and 1999, and Poland was seen as the most successful of Central European countries that had embarked on similar political and economic transitions in 1989”⁶²⁰.

From a political perspective, one notable difference when compared to other former communist states is the background of the post-revolutionary leaders. In Poland, Czechoslovakia and Hungary the number of former communist leaders in the new governmental apparatus was rather low. Two decades after the December Revolution, it is still unclear if it had been a transition to democracy: communist party figures are still influential⁶²¹, property has been privatized but allowed to accumulate in the hands of a small group of oligarchs, and although there were free elections, there had been “only a partial move to a form of limited and accountable government that was based on the rule of law”⁶²².

We can conclude that the political will for real reforms did not exist. Most of the decisions were populist, and in spite of this regimes changed every four years. One excuse could be the avoidance of popular unrest which could have led to civil war.

Faculty of Economics and Business Administration

Automatically when we talk about tourism, tourism industry and hospitality industry we refer to the term also increasingly mentioned. Through this work we describe the hotel, restaurant business and other travel related activity services, which since 2008 have been continuously developed and represent a source of benefit to the economy of any country. The paper aims to assess the perception of tourists based on a questionnaire about the quality of hospitality services in Romania compared to European Union countries.

Keywords: hospitality, hotel industry, restoration, perception

Cod JEL lucrare: L, L8, L83

Concept Clarification

Oxford English Dictionary defines hospitality as "receipt and maintenance of guests, visitors and foreigners with generosity and kindness". Hospitality includes all services which provide accommodation and/ or food and beverages to persons who are not resident in the area, regardless of how long they will spend away from it, including a wide range of business such as small guest houses, fast food, pizza house and related services. Public accommodation and catering are different due to service quality, to the people who receive them and due to the targeting customer segments, and they are different by the comfort and quality offered as part of a wider group of activities grouped under the name of tourism.

Hospitality Industry in Romania and the European Union

Hospitality Industry

Systematic analysis of tourism service quality and taking the necessary measures are top priorities in the current period to transform the hospitality industry in a cost-effective resource with high share in GDP, as there are countries with a tourism well developed, such as Spain, Italy, Greece, Switzerland. The creation of a culture of quality in this area, where they have established for decades some inappropriate practices takes time in order to professionally and ethically train all staff and change its mentality.

Tourism professionals say that it should be smiles, courtesy and decency to be part of a quality system. Such a system was launched in Spain, where the number of stars appears with a Q, symbolizing of a system showing the highest degree of service quality Star alleged.

In the Romanian hotel sector, although we can still find obstacles, however, we see significant changes in legal law, in the state economy which shows a financial jam and also the leadership characters involved in tourism that began to change their mentality and understand the need for quality tourism.

The first major trend is the increase in service quality and enhance the facilities offered to tourists, so often met in hotel units integrated into large hotel chains (e.g. Hotel "Mara", Sinaia), in hotels under joint ownership with foreign investors (e.g. hotel SOFITEL-Bucharest) and in other hotels that have passed from public ownership to private ownership (e.g. most of the hotels in Mamaia). The second trend is the realization of investments aimed at building new hotel units. Another trend, but a negative one for Romanian tourism is due to increasing prices charged for hotel services which was not always consistent with the quality of the offered services, which resulted in loss of both foreign and Romanian tourists to other holiday destinations such as Turkey Greece, Croatia, Spain, etc.

Restoration Industry

In collective and commercial consumption the major trade groups increasingly make their presence felt. Comparable levels of collecting revenue for food and trade leads to the assumption of equal relative intensity of expression of horizontal concentration. Moreover, we see the same group both carrying out the activities of collective food and catering business activities (e.g. ACCOR group).

In France, Sodexho Group has 1714 restaurants, serving over 145 million customers annually. From the total number of restaurants, 30% work in education institutions, 43% in enterprises, 27% in health institutions and in asylums.

Across Europe, the rule is held by Mc'Donalds' Corporation. In the context of commercial food, chain fast-food restaurants have the most spectacular results and it's expected that in the future development potential of the fast-food formula will be considerable. Thus, an American spends on fast food restaurants over 10 times more than in a French one and 100 times more than in an Italian one.

Restoration or catering and housing activity are an extremely complex component. Restoration must be distinguished from so-called "commercial" and "collective", which concerns mainly: restaurants, hospitals restoration, restoration of prisons, restoration of the military, school canteens, university restaurants, holiday villages, settlements, social restoration. The first restaurant franchise type McDrive opened in Romania in Braşov in 1998, and the only KFC restaurants opened in Bucharest in 1997. Since 1994 works in Bucharest first Pizza Hut unit, other units operating in Constanta and Cluj-Napoca, Timisoara.⁶²³

Research method and interpretation of data related questionnaire

An inquiry based on a survey questionnaire it was conducted on the situation of the hospitality industry covering tourism accommodation services in Romania in comparison with services in EU countries. It was chosen in random a sample of 30 respondents of different ages.

Following analysis of survey data on tourists who have traveled to Romania, highlights the following:

- All respondents have traveled to other cities in Romania than the residence one until that moment and only 27 of 30 respondents traveled in Europe.
- Highest weight is for visiting relatives or friends 38%, sightseeing (24%), recreation and spending a holiday both with a share of 14% and with 5% are business an treatments.
- On average tourists spent more than 10 days (47%).

Following analysis of survey data on tourists, who have traveled to countries in the European Union, highlights the following:

- A 10% have traveled outside the border, and on the other hand a 90% crossed the borders of Romania in a certain period of time.
- At the question that refers to the highest weight for travel, it is visiting friends or relatives 30%.

⁶²³Băbăiță Carmen – *Cateringul ca afacere*, Editura Mirton, Timișoara, 2010

- Tourist attractions in European countries accounted 23% to 24% for sightseeing in Romania. This means that Romanians still expect changes in tourism, with further opportunities for Romanian tourism. Spending a holiday in European countries has a 20% share compared with 14% against Romania. Consequently, the Romanians still choose to spend their holiday abroad than at home, for various reasons. Other purposes for travel abroad are conferences, school projects or Work and Travel Program with a rate of 17% and business at a rate of 10%.

- Average foreign tourists spent over 10 days.

Agreement/disagreement with several statements about the services in the hotel units in Romania. Note that at the professional competence the highest score was obtained in Agreement - 8 points, followed by neutral category where the score was 6 points. The difference between the two is rather low, which means that respondents are not fully convinced of the competence of workers in tourism and from the hotel units in our country. Employee courtesy is rated equally between agree and neutral with 10 points each. The tourism industry needs people with knowledge in tourism and which are passionate about working with people in this area. They need to have the desire to satisfy all customers requests with courtesy and kindness.

The agreement/disagreement with several statements about the services of the hotel units in Romania. Note that if professional competence achieved the highest score at the Acord Hotel - 8 points, followed by neutral, category which obtained 6 points. The difference between the two is rather low, which means that respondents are not fully convinced by the competence of workers in tourism and hotel units in our country. Employee courtesy is rated equally between agreement and neutral with 10 points each. The tourism industry needs people with background knowledge in tourism and be passionate about working with people in this area. They also need to have the desire to satisfy all customers with courtesy and kindness.

In respect to the employees' seriousness, respondents gave a score of 9 to neutral and 7 points to disagree. This should give thought to those who have major influence on tourism, which should take into account customer feedback in order to avoid losing them. The high standard of services received the highest score in neutral-10, followed by totally disagree with 9 points. Services clearly need improvements and also need valuable people who have certain essential qualities for those in hospitality, in order to have credibility with customers.

The agreement/disagreement in respect to the hotel units in Europe. Professional competence in Europe received 18 points from respondents, meaning that tourists appreciate the professional competence of workers in European housing units, implicitly the managers who deal with their management. In respect to the courtesy most employees received 20 points, as all respondents agree that foreign employees are very friendly and respect the rules of conduct imposed by the hospitality industry, having a professional conduct. The seriousness of employees was awarded 17 points and 10 points in total agreement. The seriousness of the staff is very important for the guests, who spend a holiday in the tourist accommodation units and who need to feel confidence and reliability from those who attend them. Standard services received a score of 19 points in total agreement and 5 points in the agreement, and only 3 of the respondents gave 3 points to neutral.

Data analysis indicates that respondents had to assess service hotel units in Romania and Europe. Thus, solving the problems arising and professional competence was quoted by the mark 3, although it would be situated in the middle of the chart, compared with hotel services in Europe. Almost the same situation applies to the quality of service and culinary products which have all received a 3, as a mark. In respect to the cleanliness of the room, the mark received was 4, close to maximum, which means that those who take care of cleanliness of the rooms are doing their job thoroughly and seriously. Respondents marked with 3 the technical state of the facilities offered by the rooms and the hotel. Hotel managers should pay more attention to the equipment used in hotel, in order to be able to provide the best conditions to those who cross the threshold and have the confidence to spend a holiday there. The courtesy of the staff was noted with almost

the maximum score, i.e. 4, which is very beneficial for those working in the reception area, in contrast with waiters, who received a score of 3. Managers of hotel units should have some criterion by which staff is elected, in order to avoid certain future issues.

Advantages of hotel services in Romania, as listed by the interviewed people:

- diverse landscape, attractive and different services;
- some hotels offer low-cost accommodation and food packages, meeting a good quality-price ratio;
- other people consider that Romanian hotels have good managers, that show respect for both their business and visitors;
- good food and special dishes, also trying to provide international menus;

Listed disadvantages:

- complaints are perceived as insults, showing lack of professionalism;
- some hotels charge more than they offer for their services, thus the visitors are dissatisfied;
- some hotels are careless in terms of room and hotel cleanliness, there are still issues regarding the staff and their daily duties;

Profile of the interviewed people: 57% women, 43% men. Age: the largest percent is made up of people under 30 years old, then people aged between 30-40, 40-50 and only 3% over 50 years old.

Recommendations: Romanian hotels and their managers should take more advantage of our diverse landscape in order to offer flawless services and attract more visitors, offering a proper quality-price ratio. The hotel staff should be trained accordingly and speak at least one foreign language. Room cleanliness should be done in accordance with the star classification. Hotel owners should be more polite and provide more facilities and information regarding their services. Most of the answers refer to the professional behaviour of the staff and their availability, the fact that they should have the necessary education in order to do this job, the cleanliness in the rooms. More quality services should be provided, according to European standards, at a fair quality-price ratio, as well as more free time activities.

Conclusion

As a consequence of all the facts presented above, one can strongly claim that the hospitality industry, tourism in general, is an important factor in a country's development, from economic, social and cultural standpoint. Tourism can turn an unknown country into a popular, thriving one. In Romania, the hospitality industry is still developing, especially if we consider the fact that Romania has to comply with the EU regulations.

According to our questionnaire, Romanians think that there are differences between the services provided in Romania and Europe, especially regarding the professional skills, availability and professionalism of the employees. In order to reach European level, we have to pay more attention to the staff, because it is the image of a particular hotel and represents indirectly the quality of the services offered.

A person working in the tourist industry should have communicative skills, be able to interact immediately with people, being trustworthy from the first minutes of the conversation. He/she should be able to solve any problem properly and in a nice manner and at the same time be an expert in the services provided.

The quality of the offered services must also be improved, at an excellent quality-price ratio and, as far as entertainment goes, more free time activities should be developed.

In the specific literature, success may be achieved by two important attributes: competitiveness and sustainability. Competitive advantage represents an essential criterion for surviving on the tourist market and defines the ability of one destination to use these resources effectively and in the long term. The paper work continue a study begun last year by the same authors about tourist perception of attractiveness of the two tourist SPA destinations (Buziaș and Băile Felix) on a different market segment (18-35 years old people). This time, we undertake an analysis on SC Turism Felix SA in order to determine and underline the tourist competitiveness through sustainability and financial efficiency (tourism performance indicators evolution, market share, turnover, investment volume, financial returns and costs).

Keywords: Competitive advantage, financial efficiency, sustainability, SPA

Cod JEL: L, L8, L83

A certain destination may be considered successful if it offers its visitors a similar or better experience compared to other destinations. Therefore, all that a destination offer to a potential visitor in terms of information, images, impressions, must be appealing and interesting. Thus, the destination may be competitive on the market.

Competitiveness in tourism defined as “the level a nation, under the circumstances of a free and honest market, can provide competitive goods and services increasing its citizens’ real income”⁶²⁴, competitiveness is therefore a challenge available not only to nations but also to worldwide regions and cities/ resorts.

Tourism companies should be aware of the fact that, nowadays, they operate on powerful competitive markets, and they have to come up with those specific elements in order to obtain profits considering their consumers’ needs, thus distinguishing themselves from the other companies. Hence, one can define tourism competitiveness as” *the ability to cope with competition efficiently and productively*”.

Although the issue of competitiveness of tourist destination has been approached by many researchers, such as M. Porter, who put into practice the diamond pattern for tourism, Crouch and Ritchie have designed a pattern being named after them a.s.o., at the moment there is no singular pattern. However, the existing patterns have many common elements, which have different names.

⁶²⁴Kotler Philip - *Marketingul locurilor*, Teora, București, 2001, p. 232

The concept of sustainable development has been set during years, within scientific debates worldwide and has been awarded specific political connotations within the globalization process. Sustainable tourism is a new approach for tourism and entertainment development in a country, region or tourist destination. This approach considers the main principles of sustainable tourism and embraces concerns for social equity and quality of life, environmental protection, cultural diversity and local economy of the host region. The relationship among these three pillars is represented by a concept called “*sustainability triangle.*” According to this pattern, a society is divided into three main groups called “dimensions”:

- *Social dimension*: elements concerning health, education, training, culture etc.;
- *Environmental dimension*: natural resources, quality of environment, biodiversity, etc.;
- *Economic dimension*: technology, fixed assets, financial means etc.;

The purpose of sustainable development is to maintain a balance among these three dimensions, both locally, nationally and internationally. Lately, there has been added a fourth dimension, concerning the preservation of cultural heritage and traditions.

Purpose of the paper and research directions:

This paper undertakes a study to determine and underline the tourist competitiveness of a major tourist destinations, spa resorts S.C.Turism Felix S.A.

We have taken into account *three research directions*:

- tourist competitiveness through activity’s financial performance: 2005-2009
- evolution of tourism performance indicators (average level (days) and number of tourists, turnover)
- an analysis based on quality services and corelation between staff competency (according to their training in tourism) and tourist satisfaction.

Research methods and results

The resort’s competitiveness based on the growth of the activity’s financial performance

The financial performance of the activity intends to highlight the efficiency ratio between the profit effects and the efforts needed to obtain them.

$$r = \text{Effect/Effort} * 100$$

The measurement of the financial performance is made taking into consideration the size used to create it and is made throughout a number of rate.

- Profitability rates; they are build as a ratio between profit and income results and expenses.
- Rentability rates: they are build as a ratio between the profit results and the actives or capital.
- Stock return rates: they track the stock investment efficiency.

The building of the financial performance rates, generally reports a profit result, either to a workflow or to a stock, intending to best characterise the economic performance of the company. The different rates used have different information power, reflecting the efficiency of different sides of the whole activity.

The rates that are build taking into consideration the advanced capital express the investors interests, while the rates build on the consumed resources express the managers interests.

In this article we will analyze the comercial pofitability rate and the consumed resources profitability rates, by using the available information.

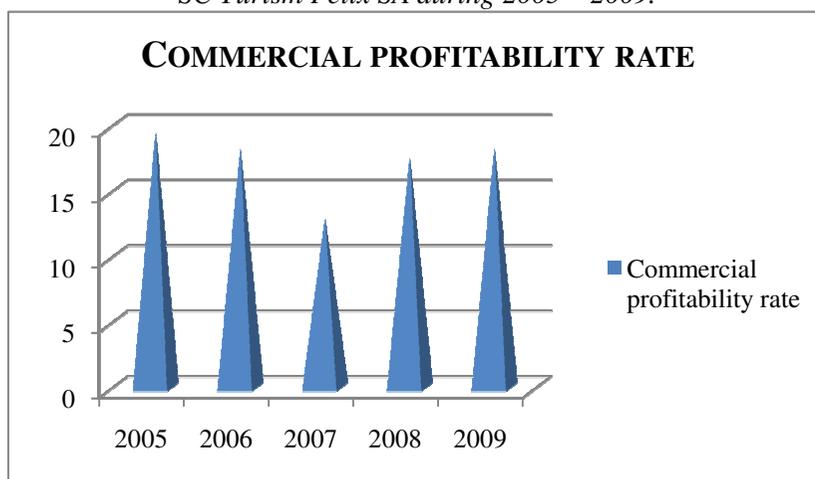

Tabel no.1 Profitability rates analysis for SC Turism Felix SA

Specificati on	Period of time					U M lei
	2005	2006	2007	2008	2009	
Gross result form exploitatio	6.891.218	6.838.223	5.650.000	8.460.000	9.755.000	

n						
Business revenue	35.374.369	37.494.458	43.918.000	48.300.000	53.300.000	lei
Exploitation expenses	29.121.774	32.829.832	39.760.000	41.250.000	44.945.000	lei
Commercial profitability rate	19,48	18,24	12,86	17,52	18,30	%
Consumed resources profitability rate	23,66	20,83	14,21	20,51	21,70	%

The commercial profitability rate characterise the commercial policy efficiency (supply, store and sell) and te competition between the company’s products reflecting especially their price policy. The commercial profitability rate is determined by reporting the result of exploiting to the result of the business revenue . Thus we evaluate the company possibility to generate a certain level of profit for a given size of the business revenue. In the economic practice it is considered that a commercial profitability rate of 5 to 20% is acceptable. If the company achieves a great sales volume, this rate will decrease without threatening their market position.

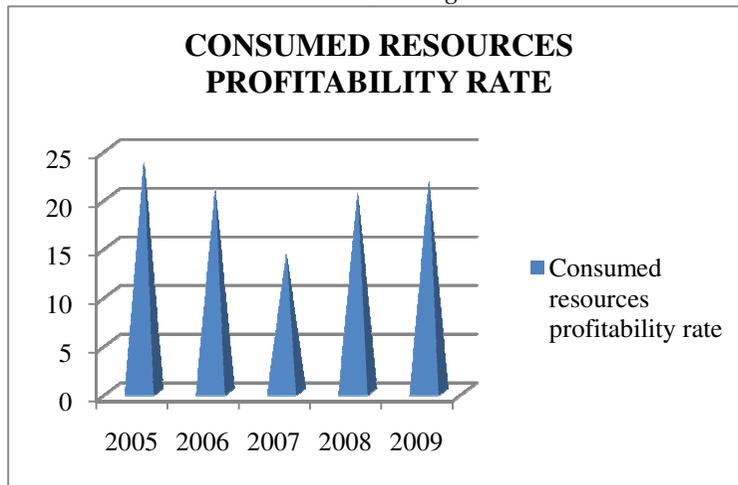

Figure no 1. The commercial profitability rate evolution at SC Turism Felix SA during 2005 – 2009.

In the case of SC Turism Felix SA we observe the fact that the commercial profitability rate register an ascending trend, reaching a minimum value for those 5 years of 12,86%, in 2007 reaching then the value of 18,30% in 2009.

The consumed resources profitability is established by reporting the business revenue result to the entire cost of the sold production. This rate is also known as the standard model for the profitability rate and it measures the capacity of the activity to generate profit through costs. The recommended level of the consumed resources profitability rate is between 5% and 20%.

Figure no 2. The consumed resources profitability rate at SC Turism Felix SA during 2005 – 2009

The case of SC Turism Felix SA, the consumed resources profitability rate, as the commercial profitability rate registers a minimum value of 14, 21 % in 2007, with an ascending tendency in 2009, to the level of 21, 70%. The growth reserves of the commercial profitability rate as of the consumed resources profitability rate refers to: improving the structure of services, in the way of growing the shares of those with high commercial profitability rate. Also rising prices; increasing the power to negotiate with the suppliers and obtaining good prices; sales increase (high occupancy of the hotel's rooms)

The evolution of performance tourism indicators: 2006 - 2008

We took into account for this study performance indicators as average level (days) and number of tourists, turnover (See table no 2)

As you can see from the table below the average level of accommodation inregistered a continuously growth from 6,77 days in 2006 to 7,16 in 2008 although the number of tourists during the analyzed period has decreased (66.136 tourists to 60.644 tourists). The continuously growth of the average level of accommodation determined an increase of the turnover from 37.494.458 RON in 2006, to 55.448.042 RON in 2008.

Table no 2. General Tourism Indicators SC Turism Felix SA

Year	Average level of accommodation (days)	Turnover (RON)	Number of tourists(persons)
2006	6,77	37.494.458	66.136
2007	7,05	43.341.563	62.569
2008	7,16	55.448.042	60.644

Source: data where processed by the authors.

Data where collected from SC Tourism Felix SA

Analysis based on employee competency and tourist satisfaction.

From the table (Table no 3) below you can see the level of qualification of employees to SC Tourism Felix SA. Tourism professionals say that the staff must have a training or faculty tourism background, qualification but it also must have a smile on their face, courtesy and decency in order to be part of a quality services system.

Table no 3. Staff Skills and qualification SC Turism Felix SA

Year	Highly qualified staff with a BA in Tourism	People attending training courses	Total	Staff skills and qualifications (%)
2006	9	19	794	3,53
2007	7	49	845	6,63
2008	10	30	844	4,74

Source: data where processed by the authors.

Data where collected from SC Tourism Felix SA

Tourist perception about staff competency in Felix is (Staff is highly qualified – 45%, Employees display a professional behaviour-51%).The recommended measures would be: to select qualified people or business graduates (for management positions) and employees who followed professional training courses. We can say that overall the tourists are pleased of services and staff behaviour.

In a previous study accomplished in April - May 2009, we point out that Buziaş SPA recorded a higher degree of staff qualification than in Felix SPA (Staff is highly qualified 67%, Employees display a professional behaviour - 69%). We also developed a *competitiveness polygon* of the two touristic enterprises for 2006, 2007 and 2008.

Another tourist perception regards reasons why Felix SPA is avoided: no programs and special offers for students, lack of information, advertising concerning the offered services, lack of attractiveness, high tariffs, poor services, poor infrastructure, and bad condition of buildings. Thus, it may be useful designing some tourist packages for young people (students) and using aggressive advertising to promote them, embracing new price policies suitable both for older and younger segment.

The advantage of Băile Felix is the fact that, it has European acknowledgement, being visited by Hungarian and German tourists. 45% have admitted its regional competitiveness and 25% admitted its international competitiveness.

Conclusions

For higher level of services, managers must hire persons who graduated a faculty of tourism or persons which have a qualification diploma (waitresses, chambermaids, etc). Also, managers must take care of soft skills (how to act in a urgent or critical situation, how to make a good day for your client etc) and abilities, and must offer to their employees trainings on this kind of needs. According to the Development Strategies of SC Tourism Felix SA 2007-2011, since 2006 it has begun the modernization of many pleasure, entertainment activities (for eg: swimming place Apollo and Felix). It also is under construction an AquaParc valued at 12 millions euro in Felix. Total value of investments program is about at 285 millions RON.

Overall we can say that a tourism enterprise performance do not depend only of its higher financial results. It also dependes on importance given to employee involvement in professional development programs. They are those who are in direct contact with tourists and they know that a satisfied customer is a reliable source of positive publicity. The employers are those who bring added value services.

GUEST SERVICES QUALITY ASSESMENT IN TOURISM, USING AN ATTRIBUTES SCALE

Ban Olimpia

Universitatea din Oradea

Facultatea de Științe Economice

Popa Luminița

Universitatea din Oradea

Facultatea de Științe Economice

It is considered that a weakness of the Romanian tourism offer is the quality of guest services. In this paper we established as an objective to examine in detail the importance given by the consumers to the components of guest service quality and their perceived performance, based on the three pillars of service quality: the material base (equipments), staff training and staff behavior. The emphasis is on the investigation regarding staff training and behaviour, taking into account the multiple attributes SERVQUAL scale. On the basis of this work lies a survey done in March-April 2010 on the population of Oradea, on a sample of 1060 people. Results confirm the importance granted to staff in ensuring quality of tourism services and their perceived relatively weak performance.

Key words: service, quality, tourism, evaluation, Romania

JEL Classification: M21, M31

1. Introduction

Human resources in tourism has a key role in ensuring the quality of tourism services. Interaction between employees and consumers of services is recognized as a critical factor in determining consumer satisfaction⁶²⁵. Interaction time is the moment of truth. Of meeting the consumer's expectations depends its retention and loyalty, reason why this is one of the important sources of competitive advantage of a destination.⁶²⁶ The pleasure to be served completes and sometimes overcomes the pleasure of the actual products consumption³.

2. Challenges of guest services work

Service staff has a major role in ensuring service quality.

- The most important difference from the productive sphere is that among the duties of service workers is the interaction with customers⁶²⁷.

The contact between employees and customers is a co-participation in the service experience. The employee must not only be task oriented but also able to interact, to oversee the customer while he is consuming the services. Thus, the employee must be able to motivate the client to assume the role of co-producer of the service, to instruct and to correct, to monitor and help the consumer to assess their own performances⁶²⁸.

Employee relationship with customers is an interpersonal experience⁶²⁹, with everything it implies: communication, knowledge, relationship.

⁶²⁸ Idem.

⁶²⁹ Idem.

- A specific aspect of the service employees is that in the definition of the ideal employee, positive personality has a dominant role. A category of service positions requires specialized training and high-class preparation, but for the majority emphasis is on personality, energy and employee attitude. Selecting a suitable employee for customer interaction is „like a casting for a movie”⁶³⁰, because it means hiring for various roles.
- Service employees may be harder to follow when interacting with customers. Intervention in the interaction between employee and customer would disrupt the service process on one hand, and on the other hand, the employees have freedom to find specific solutions for specific problems.
- Working in the first line of service involves a certain emotions management. Emotions management means the effort of controlling the body language, to build a side that conveys the desired message. An employee in guest services should be a perfect actor (no matter how cynical this sounds). If he is not a good actor he is not a good professional. The way in which a doctor delivers a diagnosis is more important than the healing prognosis. A teacher must show interest in a student, in his needs for knowledge.
- The employee in guest services, who is in direct contact with consumers is called front-line staff because he is in the conflict zone. The employee is the interface between the company and the client and any complaint, any unsatisfied expectation is transmitted to this staff, although it usually has little power of decision. This employee receives all complaints though is often not empowered to resolve them. Depending on consumers' exaggerated claims, the causes of conflict are: unreasonable customer requests, claims against company policy, unacceptable treatment of employees, violation of social norms, particular needs of clients and drunk clients⁶³¹.
- Front-line employees can reinforce and promote the company offers and the company itself or - on the contrary - they can undermine it, there is no middle option.
- The perception of service employees on the organization working climate influences consumers' perception of service in regards to the services they received⁶³². By this we understand that the working environment/climate is leaving a mark on the employees, which is reflected in their work.

3. THE SERVQUAL INSTRUMENT- research and applications

Quality in guest services is evaluated from two perspectives, namely the quality standards of the service provider and the consumer's quality standards. The quality of service will be given by the extent to which service providers offer meets consumers' expectations. Lewis and Booms say that: "service quality is a measure of how well the service level delivered matches customers' expectations".⁶³³

Researches on service quality have been focused initially on the way of offering high quality services.

The studies conducted by Parasuraman et.al in 1985, 1986 and 1988 resulted in a quality assessment tool. This instrument called SERVQUAL is a scale with multiple attributes that allows measuring expectations and perceptions of service quality⁶³⁴.

SERVQUAL was initially applied in banking and later on it was applied in tourism services⁶³⁵.

⁶³⁰ Idem, p.52.

⁶³¹ Fitzsimmons, J.A., Fitzsimmons, M., J. (1994), *Service Management for Competitive Advantage*, McGraw-Hill, Inc., pp.168-169.

⁶³³ Lewis, R. , Booms, B. (1983) , *The marketing aspects of service quality*, in Berry, L., Shostack, G., and Upah (eds), *Emerging Perspectives of Services Marketing*. Chicago: American Marketing, pp.99-107.

⁶³⁴ Parasuraman, A., Zeithaml, V.A. and Berry 1988, L.L., *SERVQUAL: A Multiple-Item Scale for Measuring Consumer Perceptions of Service Quality*, *Journal of Retailing* , 64, Spring, 12-37.

⁶³⁵ Fick, G.R., Ritchie, B.J.R. 1991, *Measuring Service Quality in the Travel and Tourism Industry*, *Journal*

The assessment of service quality is made by comparing the expectations regarding the service quality and the perceptions regarding the performance of received services (importance-performance analysis). When expectations exceed perceived performance, services are assessed as having low quality and performance, but when expectations are exceeded by the perceived performance, the level of service is considered high. A critical point of service consumer satisfaction represents the construction of expectations that through reality-check do not subclass the reality. Initially, in 1985, SERVQUAL had 10 categories of attributes, which were then reduced to five categories with 22 items.

The five dimensions of service quality, SERVQUAL scale components are⁶³⁶:

Tangibles: Physical facilities, equipment, and appearance of personnel;

Reliability: Ability to perform the promised service dependably and accurately;

Responsiveness: Willingness to help customers and provide prompt service;

Assurance: Knowledge and courtesy of employees and their ability to convey trust and confidence;

Empathy: Caring, individualized attention the firm provides its customers.

SERVQUAL experienced improvements in several directions made by the creators themselves⁶³⁷. Thus they attempted to clarify further their conceptualization regarding satisfaction as a component of quality service.

Carman was among the first researchers who gave a reply to SERVQUAL and proposed improvements and adjustments in order for the instrument to be applied in retail.⁶³⁸

Fick and Ritchie⁶³⁹ extend the use of SERVQUAL instrument in tourism services, for four categories of services. It regards services provided by: airlines, hotels, restaurants and ski slopes.

4. Empirical research study for quality tourist services

During March-April 2010 a survey was conducted among the population of Oradea, Romania. The sample was composed of a total of 1060 people, sampling method chosen was the stratification method⁶⁴⁰ (margin of error of 3%). The criterion used was age. Distribution criterion was chosen as follows: 150 people aged 18-24 years, 234 people aged 25-34 years, 208 people aged 35-44 years, 192 people aged 45-54 years, 152 people aged 55-64 years, 124 people aged 65-80 years. The respondents were persons who received accommodation services at least once since 2007 till presently.

Research goal was to investigate the level of Oradea inhabitants satisfaction, with the quality of tourism services and the performance of service personnel.

The research instrument was a questionnaire with 21 questions, plus some questions related to socio-demographic aspects.

The respondents were investigated on three dimension of tourist services quality, respectively: the material base (equipments), staff training and staff behavior. It was investigated the importance given to these dimensions and their perceived performance for tourist services in Romania.

⁶³⁹ Fick, G.R., Ritchie, B.J.R., op.cit.

⁶⁴⁰ Studiu realizat în colaborare cu ActiveJob Consulting

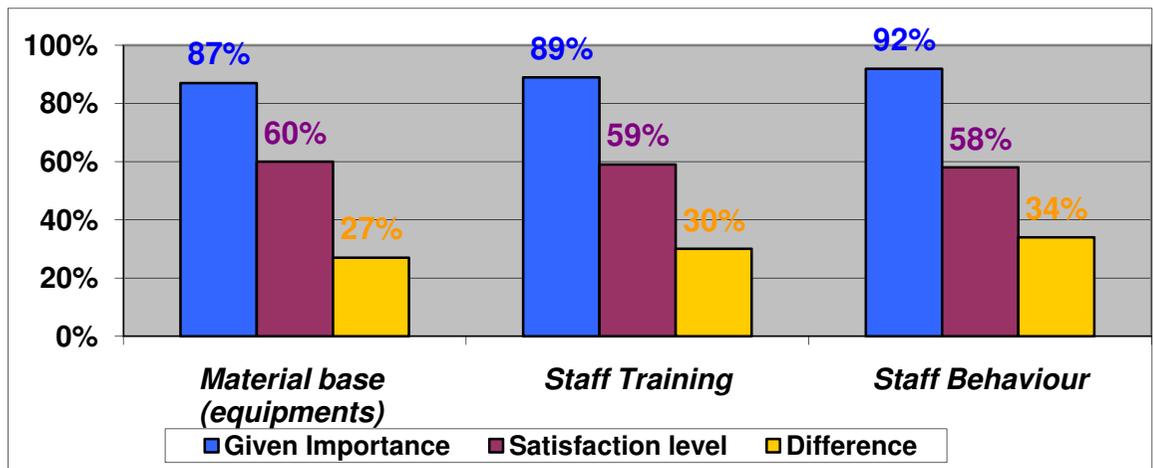

Figure no.1 Importance / performance dimensions of tourist services quality and their relationship

The results reflect that out of the three dimensions of service quality the utmost importance is given to staff conduct, which is also evaluated at the lowest level in terms of performance. A discussion should be the extent to which high expectations lead to a more severe performance evaluation. Zeithaml, Berry and Parasuraman argue that expectations are dependent on the consumer's background experiences⁶⁴¹, therefore a richer experience leads to more realistic expectations. Next place as level of importance is the *Staff training*, also on second place as perceived level of performance.

Guest services staff in general, but tourism staff in particular has a crucial role in ensuring quality of provided services.

There were 19 attributes chosen for tourism staff, in correspondence with SERVQUAL, for which it was done the analysis of the importance given by respondents and the analysis of the perceived performance of the staff from Romania (Table no.1). A scale with five steps was used in this research, from "unimportant" to "very important".

The results show that a great importance is given to all attributes. Situated on the first places, with values over 4.5 are attributes of Staff Kindness (Courtesy) and Responsibility, Communication and Timeliness. Also, from another study by Ban⁶⁴² among customers of six hotels situated on the Black Sea seaside, it resulted that the characteristic Politeness of staff is the most important from clients' perspective. The lowest values were obtained by the attributes Anticipation and Enthusiasm of staff, the reason being maybe the insufficient definition of these attributes or misinterpretation. (Figure no.2)

In assessing the performance it was observed a decrease for all attributes. The best values, although all were average level, were obtained for *Physical Appearance* and *Staff Communication*.

Interesting correlations were highlighted by identifying the links between the education of the respondents and the importance given to *Staff Kindness (Courtesy)*, the education of the respondents and the importance given to *Professional Knowledge* of staff and education of the respondents and the importance given to *Communication*.

⁶⁴¹ Parasuraman, A., Zeithamal, Berry, L. (1993), *The nature and determinants of customer expectations of service*, Journal of the Academy of Marketing Science, 1-12.

⁶⁴² Ban Olimpia, *Synthetic measure of the quality of service taking into account the client s perspective in the hotel industry*, Economia Aziendale Online-International Business Review, N. 1/2008, Special Issue ISSN 1826-4719 Reg. Trib.Pavia-n.685/2007 R.S.P., pp.1-7, www.ea2000.it.

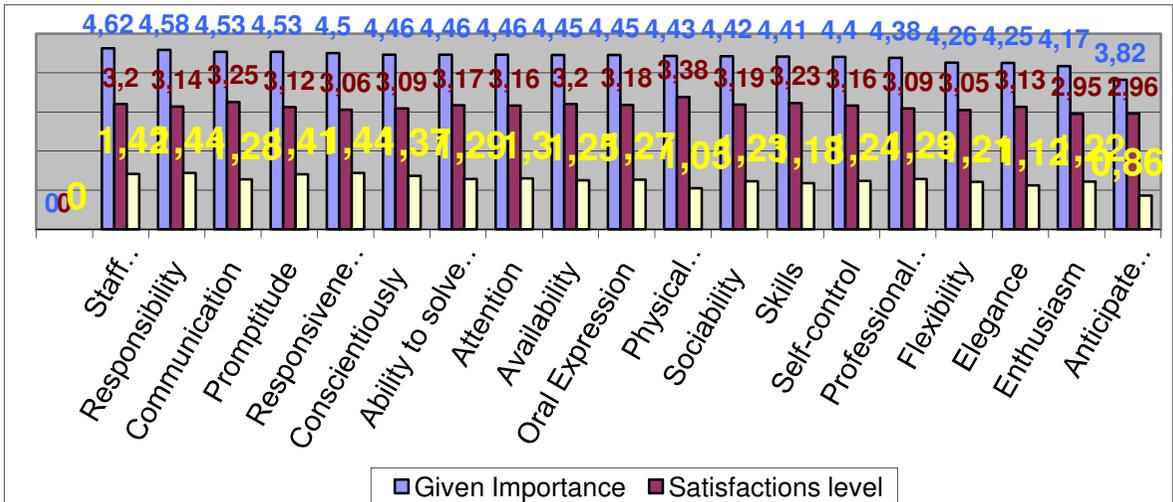

Figure no.2 Importance / performance of the attributes of tourism personnel and their relationship

An analysis of the investigated attributes, divided into groups, as proposed by SERVQUAL, shows that Oradea inhabitants are giving the highest importance to *Trust* and *Responsiveness* categories. Highest level of satisfaction was expressed for the *Tangibles* category. (Table no.1) In research done by Fick and for all four categories of services provided by: airlines, hotels, restaurants and ski slopes, resulted that it is given utmost importance to *Confidence* and *Assurance*.⁶⁴³

Table no.1 Correlation between service quality dimensions (SERVQUAL) and the studied aspects

Nr.crt.	Service quality dimensions (SERVQUAL)	Studied service quality dimensions	Given Importance
1.	Tangibles	Appearance and hygiene of personnel Elegance	87%
2.	Reliability	Conscientiousness Skills Responsibility	90%
3.	Responsiveness	Attention Promptitude Availability Responsiveness to problems Staff Kindness / Courtesy	90%
4.	Assurance	Professional knowledge of staff Ability to solve problems Self-control Communication Oral expression	89%
5.	Empathy	Anticipate desires	83%

⁶⁴³ Fick, G.R., Ritchie, B.J.R., op.cit.

		Flexibility Sociability Enthusiasm	
--	--	--	--

If we analyze the histogram for the importance given to *Confidence* and the histogram for the importance given to *Elegance* of staff, we observe a relatively large dispersion, suggesting a relatively broad range of responses.

5. Conclusions

Tourism service staff has an essential role in ensuring quality of tourism services. Research done on Oradea population showed that between the three components of quality of service, the utmost importance is given to staff conduct, and then staff training and material base (equipments). This view is reinforced by the important attribute of tourism staff located on 1st place: *Staff Kindness/Courtesy*. Staff Kindness is an attribute which is difficult to define and standardize, however service quality is often measured by Staff Kindness by the Romanian customers. After Staff Kindness, *Responsibility* is much appreciated by the Romanian tourism consumers. We can see there is need of (re)gaining trust in the tourism services employees in România.

In regards to the perceived performance, evaluations reflect an average level of consumer satisfaction, the most appreciated attributes being *Appearance*, *Communication* and *Staff Skills*. Divided into the five dimensions of service quality, according to SERVQUAL, we see that Romanian consumers give the utmost importance to *Confidence*, followed by *Receptivity*.

We observe a sensitivity of the Romanian tourism consumer towards service staff behaviour, also because of some negative past experiences.

DERAPAGES DE L'ECOTOURISME DANS LA CONCEPTION D'ANNE VIGNA

Borma Afrodita

Universitatea din Oradea, Facultatea de Științe Economice

The paper has three parts:

Introduction wich has the following sub chapters: 1.1. Tourism a double faceted activity and 1.2 OMT and ecotourism. The second part, Ecotourism failures, structured on the following sub chapters: 2.1.A list of disgrace, 2.2. The archaeological site of Mirador, 2.3. Paraiso del Mar, 2.4. Micos Beach, and the last part Conclusions and Bibliography. The paper is meant to define ecotourism, especially its failures in Central and South America, famous tourist destinations, natural sites and lanscapes, spectacular and vergin teritories. These future destinations are becoming an easy prey for „human sharks“, careless of natural and social environment. They hide themselves under the magic word „ecotourism“

Keywords: ecotourism, OMT, El Mirador, Paraiso del Mar, Micos Beach

Cod JEL: O13

1. Introduction:

1.1. Le tourisme: activite a double visage

À partir surtout du XX ème siècle, le tourisme est devenu un secteur majeur de l'économie mondiale et un phénomène social incontournable. Souvent présenté comme un flux de personnes et de capital, le tourisme est, avant tout, un vecteur d'interaction entre les visiteurs et les composantes sociales, économiques et d'environnement des espaces visités. Vu de cet angle, le tourisme se présente comme un secteur qui façonne les territoires, crée des dynamiques d'acteurs du secteur, confère un nouveau sens a des facettes oubliées de notre milieu naturel et humain, ou meme il en modifie les caractéristiques.

Le tourisme constitue donc un élément dynamique du développement, mais egalement une raison du renforcement de la dépendance des pays. Et comme il modifie profondément la société dans laquelle il s'exprime, **le tourisme est une activité à double visage, en meme temps structurante et destructurante, productive et dégradante, facteur de liberte et instrument de dépendance.**

Il y a 20-30 ans on tirait le signal d'alarme sur la massification du tourisme, qui a toutefois permis d'initier un nombre croissant de personnes dans la pratique récréative et des voyages, massification qui crée des dégats à la nature et à l'environnement, facteurs majeurs de l'attrait des sites, et qui n'est pas toujours positivement accepté par la population concernée. On parle de plus en plus de biopiraterie, d'incidences négatives du tourisme, de requins du tourisme, comme les appelle Anne Vigna⁶⁴⁴ dans un article du Monde diplomatique.

Liliane Bensahel et Myriam Donsimoni⁶⁴⁵, soulignent elles aussi le fait que l'image de marque du tourisme n'est pas toujours flatteuse ou bien fort positive. Les deux auteurs dénoncent, et pour de bonnes raisons, le tourisme sexuel, la dégradation des cohérences familiales, sociales, écologiques, patrimoniales et culturelles, des couts du tourisme qu'il ne faut pas ignorer lorsqu'on parle du role du tourisme dans le développement d'une société. Ce sont toujours elles

qui soutiennent l'idée de l'information et de la protection contre les excès et les dérapages du tourisme.

1.2. L'OMT et l'idée de l'écotourisme

L'Organisation Mondiale du Tourisme⁶⁴⁶ a promu, il est vrai, l'idée de l'écotourisme⁶⁴⁷, en a donné la définition, ou plutôt les définitions, mais dans certains cas et certains pays il s'avère être un simple mot, très alléchant pour les touristes conscients de la nécessité de protéger le milieu naturel et social. Malgré les signaux d'alarme tirés par des ONG (comme le Tourism Concern britannique), ayant pour objet l'étude de l'impact du tourisme sur les gens et leurs milieux, la promotion d'une activité propre et honnête dans le tourisme, malgré les discussions sur une éthique du développement, terme développé par Amartya Sen⁶⁴⁸ (prix Nobel d'économie), on maintient dans le tourisme, surtout dans les pays en cours de développement, d'importantes et visibles disparités entre un secteur riche et bien fourni et le maintien d'une zone de pauvreté importante et pratiquement irréversible.

Tout le monde a adopté l'idée d'un tourisme sain, propre, vert, tourisme-nature, d'un écotourisme respectueux des sites et des gens, mais dans certains coins de la terre, comme par exemple en Amérique centrale, du sud, en Afrique, en Asie, les objectifs financiers des requins du tourisme ne tiennent pas compte du patrimoine, des réserves protégées, du sort des populations, certaines obligées de délocaliser ou de s'enfoncer dans une plus grande pauvreté.

Et tout cela malgré l'intensification des lois de préservation de la nature, de l'environnement, tout un arsenal législatif que les faux promoteurs de certaines zones à potentiel touristique réussissent à éluder, avec l'aide, certes, des gouvernements des pays concernés, des conseils locaux, des présidents mêmes.

2. DERAPAGES DE L'ECOTOURISME

2.1. Liste de la honte.

De tels exemples on peut avoir en Europe aussi, mais là, quand même, les lois s'appliquent et des sites menacés par la massification ou la voracité des promoteurs se voient aujourd'hui protégés par la loi et la conscience des touristes. Et pourtant...

Le magazine britannique Wanderlust publie chaque année une liste de la honte, **Threatened Wonders List**⁶⁴⁹, une liste des merveilles en danger. On y a mis huit destinations les plus menacées: en Jordanie, Wadi Rum⁶⁵⁰; Yangshuo⁶⁵¹, un village de Chine qui attire plus de trois millions de visiteurs par an, par-dessus la capacité d'accueil; viennent ensuite: Tulum⁶⁵², au Mexique, le site néolithique Stonehenge⁶⁵³, en Grande Bretagne, Machu Picchu⁶⁵⁴, sites incas piétinés chaque jour par 2500 touristes! N'oublions pas Jaisalmer⁶⁵⁵, Timbuktu⁶⁵⁶, les 30 km de plage de Bay of Fires... Les causes? trop de touristes, mauvaise organisation et faible surveillance.

On s'est arrêté sur trois pays de l'Amérique centrale (Le Guatemala, le Mexique, le Honduras) parce que là des choses touristiques assez louches se font sous le couvert du mot écotourisme ou bien tourisme vert. Et parce que, 60% des touristes actuels recherchent à tout prix des zones de nature vierge, des endroits pas encore vus ni visités. Et des fois, la voracité et l'inconscience des promoteurs sont à même de détruire l'équilibre écologique pour toujours car très fragile dans ces

⁶⁵⁶ <http://en.wikipedia.org/wiki/Timbuktu>

coins-la. On a d'ailleurs l'exemple du Galapagos⁶⁵⁷, dont le système écologique, fragile par lui-même, se voit dangereusement bouleversé par les activités touristiques. C'est pourquoi, on a mis cette zone sous protection par l'UNESCO, elle fait partie du Patrimoine mondial de l'humanité. Les décideurs de la zone n'y ont même pas participé.

2.2. Le site archéologique du Mirador⁶⁵⁸

Bien que l'OMT ait promu l'idée d'un tourisme écologique, bien que ce soit un mot qui sonne bien aux oreilles de certains touristes consciencieux, dans l'absence d'une définition précise, des gouvernements et des groupes privés mettent ce label au front de leurs projets très peu écologiques et même antisociaux. Anne Vigna⁶⁵⁹, dans l'article "*L'écotourisme frelate*", présente le site du Mirador, situé au nord du Guatemala, comme la plus importante aire protégée de l'Amérique Centrale. Le site était un vrai bijou gardé par les forêts l'entourant. Il n'y avait que les archéologues et les gens du site qui étaient au courant de l'existence des 26 cités maya, de la période préclassique et antérieures à d'autres sites comme Palenque, Copan et Tikal. Il y a là les pyramides les plus hautes de l'Amérique (147m). Jusqu'au jour où un archéologue américain, Richard Hansen⁶⁶⁰, a vu dans ce patrimoine une mine d'or, un potentiel touristique de premier choix pour le Guatemala, combinaison unique de forêt tropicale et des sites archéologiques uniques. Le projet El Mirador prend contour avec l'appui du président du pays, Oscar Berger, et d'une longue liste d'institutions qui ne jurent que sur la conservation et la protection du milieu naturel et social, mais en réalité l'impact de ce projet aura un effet tout à fait contraire.

2.3. Paraiso del Mar⁶⁶¹

Au Mexique, l'offre des plages croît, il y a 142 projets en cours visant l'enlèvement des plages dans du béton. Les décideurs de ces pays (un peu moins le Costa Rica) se rendent compte que la nature se vend bien. Mais le plus souvent, les projets qu'ils qualifient d'écotourisme n'impliquent pas la participation des habitants à la définition et à la gestion du projet, pas d'aménagements écologiques qui puissent réduire la dureté de l'impact. Le président mexicain, Vicente Fox, a soutenu dès le début un projet catastrophique pour l'environnement: **l'exploitation du dernier aquarium mondial**, dans la Basse Californie, zone d'une biodiversité marine unique au monde et lieu de reproduction de la baleine grise et du requin-baleine. Transformer donc 244 îles, très sensibles à la pollution sonore et chimique, en zones touristiques pour les bateaux de plaisance américaines (il y a de la place pour 50 000 embarcations privées), voilà ce que le projet Mar de Cortes (dont fait partie Paraiso del Mar) pense faire car ils attendent cinq millions de touristes jusqu'en 2014! Ils n'ont pas encore obtenu les autorisations nécessaires mais ils prévoient la construction de 1500 villas, 2000 chambres d'hôtel, terrains de golf, parc de distractions, deux hôpitaux... UNESCO⁶⁶², pour essayer de sauver ce coin paradisiaque a classé les îles dans le Patrimoine de l'humanité, en 1978. Malgré cette classification, l'UNESCO a les mains liées car elle ne peut intervenir que si le gouvernement du pays l'exige! (Gonzalo Halffter)⁶⁶³.

2.4. Micos Beach⁶⁶⁴

⁶⁵⁷ <http://ecoturism-ro.blogspot.com/2009/03/turismul-distruge-insulele-galapagos.html>

⁶⁶⁴ Anne, Vigna, juillet 2006. L'écotourisme frelate. *Le monde diplomatique*.

<http://www.monde-diplomatique.fr/2006/07/VIGNA/13608>

Micos Beach représente un projet écotouristique du Honduras sur la plus belle partie de la cote des Caraïbes. Le pays avait déjà vendu aux nord-américains ses îles pour la pratique de la plongée sous-marine, et des terres agricoles pour l'ananas à une compagnie américaine. Pour le projet *Micos Beach*, le Ministère du tourisme du pays a exproprié 300 hectares et en 2004, il a vendu cette partie du littoral (19 millions de dollars) à une société privée qui s'était constituée en vue du projet. un terrain de golf de 25 hectares, 2000 chambres d'hôtel, 170 villas...L'attraction principale étant le Parc national ou devraient avoir lieu de nombreuses activités, un terrain de golf de 25 hectares, 2000 chambres d'hôtel, 170 villas...

3. Conclusions:

Tous ces projets dont on a parlé ignorent ce qui est le plus important: l'environnement, le milieu naturel et social, la nature est vendue et exploitée, ce n'est que le profit qui compte. Ils vont faire de ces coins de paradis ce qu'ils avaient fait, il y a quelques dizaines d'années, avec la superbe baie d'Acapulco. Les méthodes sont restées les mêmes: corruption des autorités, informations floues, indemnités ridicules ou même inexistantes pour s'approprier les terres des gens, et, qui plus est, faire tout sous le si joli label écotourisme! À l'origine de ces projets, les mêmes requins du tourisme, les mêmes investisseurs à la recherche des derniers coins vierges, intacts de la terre. Il y a, certes, un code mondial de l'éthique du tourisme et des tas de déclarations sur l'écotourisme, mais nulle part une stricte définition de l'écotourisme ni des lois qui puissent forcer les gouvernements à s'engager sur la voie honnête d'un tourisme sain et respectueux de la nature et des gens. Il faut, certes, continuer à mettre en valeur et à valoriser le patrimoine de chaque pays mais également, et surtout, faire en sorte d'assurer aussi, en même temps, sa conservation.

THE BUSINESS PLAN – A PREREQUISITE OF FEMALE ENTREPRENEURIAL SUCCESS IN THE WESTERN PART OF ROMANIA

Botezat Elena

University of Oradea, Faculty of Economics

It is more and more obvious that a proper planning of various activities/actions is a key of long-term success of a business organization. Writing a well grounded business plan is not easy, but nobody says that. What we can state is the fact that is worth it! Certainly no business plan guarantees success, but at least reduces the risk. And so the vulnerability can and should be reduced and kept under control. My research topic is integrated within the framework of the project called "The Entrepreneurship and the Equality of Opportunities. An Inter-Regional Model of Entrepreneurial School for Women (AntrES)", implemented in 6 counties situated on the Western border of Romania. The main objectives of my paper were to explore the chances for success of the futures business delineated in the business plans and to prove that these business plans represent a resource of the female entrepreneurship in the Western part of Romania.

Keywords: *business plan, correlation coefficients, female entrepreneurial success*

JEL Code: M13

Introduction

Today, the topic on the agenda is the crisis! More or less knowledgeable, but more numerous are those who complain of excessive consumption, lack of entrepreneurial spirit and culture of winning. Romania's entrance in the second project of modernity, the European integration process involves: 1. To break the blockage on periphery condition; Romanians to be otherwise and Romanians to be someone else, to internalize the culture of democracy and entrepreneurship 2. To leave the logic of loss, represented by the fact that modernity has not been treated first organically, the formula for importing institutional recipes was preferred, of change from top to bottom, in the absence of standards regarding consistency and time horizon of transformation⁶⁶⁵. Paradoxically, as the world is economically integrating and as the global economy becomes more and more open, more important are small businesses⁶⁶⁶. Spirit of democratic capitalism, which has led to development was to encourage individuals, based on the understanding that it represents the main source of economic and social power⁶⁶⁷. Learning a new culture of the area located far enough from habitat of forms without substance, focusing on proactive attitude and the direction change from the bottom up, is conditioned in our opinion by the definitely desertion of what the team of researchers led by Polish sociologist Piotr Szompka called the "culture block". It is a cultural background acquired over four decades of socialist regime characterized by: the predominant orientation towards the sphere of private life against the public one, to the detriment of future past, to a rather fatalistic attitude to the detriment of the individual acting power, by utility at the expense of truth⁶⁶⁸. If traditionally men were those in the leadership of a company and dealt with assertiveness, often exclusive, their professional career, in the present context the chances of women to develop a successful career substantially increased, to occupy leadership positions, to set up their own businesses. Of vital importance for a successful business is apart from confidence in your own strengths, a more careful planning and more realistic. An

indispensable tool designed to increase chances of success of any entrepreneur is the business plan. Writing a well grounded business plan is not easy, but nobody says that. What we can sustain is the fact that is worth it! Besides rationality, intuition plays an important role for an entrepreneur. Businesses are not built with dreams. But neither without them! It is estimated that women are inclined to a more careful and prudent analysis regarding business risks, which emphasizes the role of the business plan by the effects of an increased clarity and a greater realism. Certainly no business plan guarantees success, but at least reduces the risk. And so the vulnerability can and should be reduced and kept under control. It is crucial to become able to identify and recognize the challenges imposed by new risks for what they really are: opportunities for defining new directions to stimulate renewed activity in the context of our aspirations for growth and social reality⁶⁶⁹.

My research topic is integrated in the framework of the project called “The Entrepreneurship and the Equality of Opportunities. An Inter-regional Model of Entrepreneurial School for Women (AntrES)”, implemented in the Western border of Romania in the follows counties: Bihor, Timiș, Arad, Maramureș, Caraș-Severin, and Satu-Mare.

My main objectives were to explore the chances for success of the futures business delineated in the business plans and to prove that these Business Plans represent a resource of the female entrepreneurship in the Western part of Romania.

Materials Studied and Methodology Approach

The study was conducted based on two questions: “Why do most business plans developed by students concern the services sector?”, “What is the value of their business plans for female entrepreneurship in western Romania?” So have emerged two working hypotheses:

- First case: the services sector is generally dominated economy, the economy in western Romania in particular, as demonstrated by the number of viable SMEs in this sector which is “a guarantee” for female entrepreneurs in western Romania;
- Second case: a lot of business value lies in its founder's mind, and because business plans are drawn up in a very special asset, although you will need to study and learn more about the importance of intellectual capital and on unaudited values.

The Business Plans - 360 were issued during July 1 to December 31, 2009, of the 360 graduates of the Entrepreneurial School organized at the level of 6 Territorial Centers: Bihor, Timis, Arad, Maramures, Caras-Severin, and Satu-Mare (144 female managers, ages 20-66, monthly income – 2611 lei; 144 women wishing to start a business, ages 19-58, monthly income – 1197 lei; 72 women-formators who recently graduated Economics). In the 6 months that were conducted business school courses, the 360 students developed, based on identified business idea and developed gradually over the 6 issues: a business plan for starting a business or for business growth which they already have. Developed business plans include information on: business, products and services, marketing, sales strategy, customers, competitors, location, management, personnel, financial issues.

AntrES general objectives aim on one hand side, the development of entrepreneurial and managerial skills of women in counties located along the western border of Romania (Maramures, Satu Mare, Bihor, Arad, Timis, and Caras-Severin), the improvement of the current performance and their training, the development of the entrepreneurial spirit and the generation of an increasing number of businesses, both rural and urban; on the other hand, the promotion of equal opportunities in entrepreneurship by encouraging women's involvement generally, rural women in particular, the initiation and development of their own businesses in the context of sustainable development of communities in the counties located along the western border of Romania.

⁶⁶⁹ Giarini Orio, Stahel Walter, *Limitele certitudinii. Înfruntând riscurile în noua economie a serviciilor*, ediția a II-a revizuită, Editura Edimpress-Camro, București, 1996, pp.110-111

The research based on theoretical documentation, analysis of documents prepared in the Territorial Centre 6: Bihor, Timis, Arad, Maramures, Caras-Severin, and Satu Mare and on collecting data from the participants, allowed the analysis of business plans and testing the two working hypotheses.

Results and discussion

Out of the 360 business plans developed by women in the 6 counties located on the western border of Romania, 314 business plans, or 87.23% have a business idea based on the services sector. By counties, the order is: Arad (95%), Caras-Severin (91.66%), Satu Mare (90%), Bihor (86.66%), Timis (83.33%), and Maramures (76.66%).

In developing the 360 Business Plans, 60 for each territorial center, the Entrepreneurial School graduates had in mind the opportunities of the area: the favorable geographical location, close to the borders of western markets, economic development top the national average, business friendly environment, skilled labor and business opportunities in areas as services, tourism, trade, agriculture.

Several SMEs are operating in the 6 counties, whose number and distribution sectors are presented below:

Number of active SMEs as the sector in western Romania, 2007

Research links (interdependence) between business plans developed by industry sector (y) and the number of active SMEs by sector (x₁) that the number of employed population by sector (x₂) was performed using the Simple correlation coefficient (or statistics), denoted by “r”⁶⁷⁰:

$$r = \frac{n \sum xy - \sum x \sum y}{\sqrt{[n \sum x^2 - (\sum x)^2][n \sum y^2 - (\sum y)^2]}}$$

Where:

x_{1,2} - independent factor, x₁ - the number of active SMEs by sector, x₂ - the number of employed population by sector
y - dependent factor;

The Simple correlation coefficient “r” can take values belonging to the interval (-1,1). The symbol “r” shows us the meaning of relationship and the value of “r” shows the intensity of the link.

⁶⁷⁰ Ionciță Maria (coord.), Probleme-Proiecte-Teste, Editura Uranus, București, 1997

When “r” is positive, between x and y factors, there is a direct link, and when “r” is negative, the link between the two factors is indirect. If:

$r \in (0-0,2)$ there is no connection between the two factors;

$r \in (0,2-0,5)$ between the two factors exists a weak link;

$r \in (0,5-0,75)$ between the two factors exists a link of medium intensity;

$r \in (0,75-0,95)$ between the two factors exists a strong link;

$r \in (0,95-1)$ between the two factors exists a very strong link (deterministic relationship between the two factors).

Correlation Coefficients for the six counties analysed, separate and cumulated – Western part of Romania, 2007

Correlation Coefficient Value (r)	BIHOR	TIMIȘ	ARAD	MARAMUREȘ	CARAȘ-SEVERIN	SATU-MARE	Cumulated (from the 6 counties)
Correlation between y and x_1	0.98	0.99	0.98	0.98	0.98	0.97	0.98
Correlation between y and x_2	0.75	0.85	0.74	0.76	0.70	0.60	0.73

Source: author’s calculations based on data provided by partners: Bihor, Timiș, Arad, Maramureș, Caraș-Severin, Satu-Mare

Interpretation of results:

- The positive signs of the two coefficients indicate a direct link between the indicators measured;
- The values of two coefficients shows that there is a strong link between the business plans by sector and the number of active SMEs by sector and a moderate link between the business plans and the number of employed population by branch.

In our opinion, the results show that:

1. in developing business plans for expansion / development of business owned, for starting a business, respectively, the female managers, respectively women who want to start a business have taken into account general trends and examples of success. We can assume that they have been strongly influenced by the specific examples that they saw nearby: functional service companies, business owners in this domain, “entrepreneurial success stories” etc. There were no differences by county. At this point we can launch the assumption that the 360 graduates of the Entrepreneurial School at local level in western Romania have “carefully weighed their chances of success and have opted for services because it is a sector with potential and can provide some security”;
2. the factor, the existence of a skilled workforce was considered to a lesser extent in developing business plans for expansion / development of business owned, respectively for those starting a business by the 360 graduates of the Entrepreneurial School at local level in western Romania. The results are more different by counties, the intensity of the relationship between the two indicators in a decreasing order are as follows: Timis (0.85), Maramures (0.76), Bihor (0.75), Arad (0.74), Cara- Severin (0.70), Satu-Mare (0.60). We state that the majority of the employed population is working in trade, industry dominated by the big players with a large number of workers per commercial unit.

Conclusions

Therefore, the first working hypothesis is verified: the services sector generally dominates the economy, the economy in western Romania in particular, as demonstrated by the number of viable SMEs in the sector and the share of employed population in services, which represents “a guarantee” for the 360 women-manager, respectively women who want to start a business, and have pursued rationally and intuitively to reduce the risk of failure.

Long-term success of a business organization considers Harrington & Harrington⁶⁷¹, is determined by three main categories of factors: 1. proper planning of various activities / actions: 2. proper implementation of various plans / strategies, 3. luck/chance or non-chance in a given context (but the chance never comes to an unprepared mind). Results to confirm this second hypothesis, namely: “a lot of business value lies in its founder's mind, and therefore developed business plans are drawn up in a very special asset although we will need to study and learn more about the importance of intellectual capital and monetary values / unaudited”. What entitles us to say this?

First of all, the fact that developing a business plan is a first step towards success in business because in its development, the female-entrepreneur will have to find answers to many different questions that will allow better knowledge of the business. This will receive a shape/form and *anything with shape can be defined and everything that can be defined can be defeated*⁶⁷². Work remains unrewarded because it changes the entrepreneur who: is able to avoid some mistakes because she has already overcome the mind, gains the skills to plan a business and thinks on a long-term, gains confidence in her managerial capacity to initiate and conduct business effectively, develops her skills to be persuasive in presenting ideas on which the business is based. And *running a business is not just something in terms of improved production, improved quality control, improved labor relations, (and) improved management of creative personnel, but it is management that improves the person involved and improves the world*⁶⁷³.

Second of all, the business plan becomes a resource. Resources are everything (good, service, idea etc) that can be used in a business. Currently, traditional resources are added to others. The Business Plan presents the characteristics of resources: by its appropriate use we may gain profit, it appears as an expense and therefore has value and price, it can be replaced and supplemented with other resources, and in some ways it can be mobilized (put on moving). The great advantage of this resource, other, is the fact that it depends almost exclusively on the female-entrepreneur and can be “certified” in accordance with her own objectives and abilities.

MEASURES AND INITIATIVES ADOPTED TO MANAGE AND DEVELOP TOURISM ACTIVITY IN THE UE MEMBER STATES

Cojocariu Steliana

Ministry of Regional Development and Tourism

Molnar Elisabeth

Remtours

Abstract

The paper presents measures adopted to manage and develop tourism activity by the UE member states as: Croatia, Germany, Greece, Hungary, Denmark, Italy, Ireland, Malta, Spain and Romania.

Key words: measures, seasonality, demand, tourism activity

JEL Classification: M29

Current position of tourism in the World and Europe

Latest data from UNWTO was presented; in 2009 to July, we have seen a 7% decline on 2008 in worldwide tourism, whereas Europe has seen a 9% decline.

The UNWTO Resilience Committee is focusing on three main areas: market intelligence, stimulus measures and the green economy. It was noted that the downturn has identified the underlying weaknesses and threats which should be tackled if we are to ensure the long term competitiveness of tourism in Europe. In particular, we need to undertake work on product development, sustainability and to increase the marketing of tourism towards Europe⁶⁷⁴.

Measures taken in tourism to reduce the seasonality of demand

Croatia

One of the key problems of Croatian tourism is seasonality. In the period from June to September 86% of total overnight stays are realised and 62% in the two peak summer months. The reasons for outstanding seasonality are focusing to the one main product 'sea and sun', adverse structure and quality of tourism offer and its concentration in the coastal region of the country. Steps to ease seasonality are mainly connected to raising the quality of tourism supply and thus higher usage of accommodation, focusing on diverse segment of tourist's demand as well as to diversification of tourist products that are not closely related to the summer period such as spa and wellness tourism, urban tourism, wine roads and traditional dishes, excursion routes and national parks etc. Relevant documents are: The Development Strategy of Croatian Tourism by 2010 and Ordinance on Classification and Hospitality Facilities Categorization.

Germany

The Federal Government's Commissioner for Tourism advocates staggering the school summer holidays in the Länder, in order to bring about a broader utilisation of available capacity in the hotel and restaurant sector.

Greece

An important purpose of the Ministry of Tourism is to mitigate seasonality in tourist demand. In order to succeed, it seeks to enrich and diversify the tourism product through special forms of

⁶⁷⁴ UNWTO, Eu Tourism and the Economic Downturn: new Opportunities for a Sustainable Prosperous Future?, 8 th European Tourism Forum, Brussels / Belgium 9 th October 2009.

tourism. The Ministry aims in particular at nine sectors of specialised tourism products (Seaside, Sea, Cultural, MICE, Rural, Health and Wellness, Luxury and “City Break” Tourism). The overall aim is to offer a variety of options concerning the Greek tourism product, penetrate into as many and different markets as possible as well as set an influential tourism pattern, confirming the country’s capability to meet the expectations of visitors with varied motives and multiple demands.

This differentiation of the tourism product aims at the sustainability of enterprises which have completed 12 months of operation. The main objective is to improve quality in all domains (services, tourist infrastructure, visitors) which will help upgrade the international presence of Greece (new markets, enhancement of traditional markets) and will guarantee the conditions for bigger investments.

Hungary

In the National Development Plan until 2013 1.197 billion EUR can be spent for tourism development as indicated in point 2.5, mainly for tourism attraction development, accommodation development and for the establishment of destination management system. The developments contribute to the establishment of high quality tourism services and widening the tourism offer throughout the whole year.

In the priority tourism product development areas detailed substrategies are established outlining the major aims and development measures. A substrategy has been already elaborated in health and spa tourism, ecotourism and equestrian tourism development. A cultural and a youth tourism one is under development. These strategies serve partly quality development of the main tourism products, partly to decreasing the seasonality through widening the product offers throughout the whole year. It gives guidelines to the evaluation of applications for funding of developments and supports co-operation between the governmental bodies and industry organisations.

One of the main objectives of the Hungarian National Tourist Office is to reduce the seasonality of inbound and domestic demand in order to help the sustainability of the sector. Some major marketing actions in co-operation with the service providers also contribute to decreasing the seasonality. In the field of inbound tourism, the most successful measure has been the Budapest Winter Invitation campaign that aims at inviting tourists to Budapest off the high season: between the 1st of November and the 31st of March. This is the third year of this campaign that attracts more and more visitors to the Hungarian capital while more and more hotels and other service providers join the campaign. What refers to domestic tourism, the Hungarian National Tourist Office has several initiatives with the regions and service providers (for example 2=3 or 3=4 nights in hotels) to help reducing seasonality in the framework of the so called thematic years (2006: the Year of Gastronomy, 2007: the Year of Ecotourism, 2008 the Year of Water tourism, 2009: the Year of Cultural Tourism, 2010: the Year of Festivals). Through thematic year promotions the HNTO promotes a specific product through the whole year by this generating demand towards certain tourism products all over the year.

The promotion of off-season mega events like Budapest Spring Festival also contribute to decreasing seasonality. The HNTO also stimulates the utilization of the holiday cheques for domestic travelling which also contributes to decreasing seasonality. The HNTO has developed the national tourism database as a united source of tourism information to public and professionals which makes the all year round events available.

The first results of developments can be measured as regards the seasonality. Even though the average stay of tourists did not change in 2007, the share of the first 4 months in the total demand increased by 5 %.

Denmark

In 2006 VisitDenmark initiated the project “All-year tourism” with the aim of developing strong tourist destinations and attracting more tourists off-season. The project is supposed to support innovation, co-operation and growth in Danish tourism and focuses on product development (accommodation facilities, attractions, general tourism offers and experiences, tourism service infrastructure etc.) and branding. Seven destinations through-out the country have been chosen as “all-year destinations” and a few might be added. VisitDenmark is responsible for the project management, including the planning of workshops and seminars, study tours etc. In January 2009 the seven destinations have finished their implementation plans for their development 2009-2015. The project will continue throughout 2009 with a focus on strategic organisational development (DMOs), target group oriented product and experience development and strategic marketing.

Italy

Face to the current economic downturn, the Secretary of State for tourism signed in January 2009 a decree on “holidays vouchers” to benefit low income families. Vouchers can be used from the 6th of January until the first week of July, and from the first week of September until the 20th of December. The amount granted covers between 20% and 45% of the average family expense for holidays, calculated according to several criteria, such as annual income and number of persons in the family.

Ireland

The tourism agencies have been working with industry for a number of years to encourage tourism in the non-peak season, in particular by offering good value packages at these times. A National Conference Centre is due to open in 2010. A number of conferences have already been secured in the off-peak season and strategies are being implemented to grow this business. A new Cultural Tourism Initiative should encourage visitors outside of the peak season.

Malta

One of the main objectives of the National Tourism Policy is to reduce seasonality, though it is acknowledged that tourism activity is by its own nature seasonal.

Product improvement projects are being developed aimed at encouraging tourists to visit and experience the different localities during their stay on our islands. This will help to achieve a fairer distribution of income and increase employment throughout the islands whilst alleviating some of the pressure off the more visited sites and locations.

Cruising – Government will continue its efforts at promoting Malta as a ‘cruise and fly’ destination. Cruise passenger visitors are potential tourists. Investment in artistic projects will be undertaken to ensure the possibility of providing a local art experience to the tourist. The sister island of Gozo may be promoted with operators of clippers (small cruise ships carrying less than 1000 visitors). These will visit Gozo and Malta. Travelling in smaller numbers but providing a higher yield, these tourists are more attractive for Gozo. Government will make the necessary investments in order to have offshore berthing facilities.

Strengthening short breaks – Government will continue to maintain and promote a national calendar of events. Various measures are being taken aimed at attracting low cost airlines to operate to and from Malta thereby increasing the number of short-stay holidays in Malta. Government will continue supporting events that add value to the visitor’s stay in Malta.

Relaxation – In the last couple of years a number of hotels have invested in health and spa facilities in order to market Malta for this emerging market. These facilities provide an added-value for short break holidays.

Medical Holidays – Government will continue supporting private institutions interested in developing this niche. Private hospitals are working with international organizations in order to

obtain permits to be able to carry out medical procedures on their behalf. Marketing efforts are underway to support these initiatives.

Wedding Holidays – The related product and services are continuously being refined to offer a memorable experience to the growing number of foreign spouses who are deciding to get married in Malta.

Our policy is to ensure that marketing, product development, human resource development and quality assured initiatives are well co-ordinated and integrated to ensure that the identified segments continue to develop and result in a positive economic and social contribution to Malta and Gozo.

Spain

The model of action used in most tourist destinations has hitherto been marked by a two-pronged approach of standardisation and diversification. These concepts must be replaced by specialisation and differentiation in response to the new challenges facing the sector. This will inevitably have an impact not only on the setting of priorities for action but also on the content of the actions to be implemented.

Actions to support the design and planning of tourism products

The aim of developing the reference methods for designing and planning tourism products is to provide support to the tourist destinations that need it, so that actions can be appropriately defined and implemented in order for these destinations to be able to achieve the required level of specialisation and differentiation.

The most important actions that will be carried out or promoted relate to the following areas:

- The planning, organisation and management of the specialist product.
- A manual for the specialist tourism product.
- The creation of a specialist product club and/or specialist tourism association at national level.
- A tourism product observatory - scorecard.
- Comparative analysis with the leading international specialist destinations.
- Fostering innovation with regard to tourism products.
- Destination specialisation
- A model signposting system – homogenisation.
- Marketing and commercialisation of the specialist tourism product.
- Marketing and commercialisation model for the specialist tourism product.
- Guidelines on the image and positioning of the specialist tourism product.
- Customer service and information model for dealing with tourists in the destination.
- Internet presence and online marketing.
- Loyalty to the specialist demand.

Romania

There are 3 programmes developed for extending the season by offering low price tourist packages for holidays taken in spring and autumn: “The Sea Coast for Everybody”, elaborated by ANAT - the National Association of Travel Agencies and Tour Operators, “A Holiday in the Countryside” elaborated by ANTREC - the National Association for Rural, Ecologic and Cultural Tourism, and a “A Week of Recovery in Spas” and the “Spa Decade”, elaborated by OPTBR -the National Association for Spa Tourism.

Conclusions

This meseures provides Member States with an opportunity to outline specific initiatives and policies that are or are going to be adopted to manage and develop tourism activity in ways which respond to the key challenges of the Agenda and which fall within the six main aims of the Agenda itself.

1 Economic prosperity

To ensure the long term competitiveness, viability and prosperity of tourism enterprises and destinations.

To provide quality employment opportunities, offering fair pay and conditions for all employees and avoiding all forms of discrimination.

2 Social equity and cohesion

To enhance the quality of life of local communities through tourism, and engage them in its planning and management

To provide a safe, satisfying and fulfilling experience for visitors, available to all without discrimination by gender, race, religion, disability or in other ways.

3 Environmental and cultural protection

To minimise pollution and degradation of the global and local environment and the use of scarce resources by tourism activities.

To maintain and strengthen cultural richness and biodiversity and contribute to their appreciation and conservation.

Due to the crisis, competitiveness of the industry has come more into the picture. Different elements such as sustainability, branding or diversification strategies receive more attention than before the crisis.

Improving competitiveness has to be achieved, firstly, by improving price/quality standards and, in a second stage, by implementing sustainable development process.

Emerging markets (e.g. China, India) constitute new market opportunities for the european tourism and hospitality sector. However, the current visa policies should be facilitated. Training is being organised to facilitate the hosting of these new giests with different cultures.

SOFTWARE DEVELOPMENT BUSINESS MOVING TOWARDS A UNIFIED COLLABORATIVE SYSTEM IN IT. SAAS MAY BE THE NEW ORIENTATION.

Costin Aurelian-Răzvan

Universitatea Babeș-Bolyai, Cluj-Napoca

Facultatea de Studii Economice și Gestiunea Afacerilor.

Țolea Eniko Elisabeta

Universitatea Babeș-Bolyai, Cluj-Napoca

Facultatea de Studii Economice și Gestiunea Afacerilor.

In this paper we will present an alternative way of programming. Our opinion is that, in the next few years, software development business will suffer serious changes. Software vendors will adopt SaaS (Software as a Service) as the new way of selling their products. We will try to guide you through the basic concepts of this relatively new domain. The article also includes a brief description of an application, developed indoor but using SaaS applications for some of its modules. In the end we want to make an SWOT analysis of the opportunity of using SaaS.

Keywords: Software as a service (SaaS), informatics, business, vendors, new technology.

Introduction

Application to be described in this article is a dynamic site which aims to create a mode of communication between lawyers and those who need advice on legislation. Thus users are both those who need answers to various questions related to legislation and those that will provide answers and are able not only to advertise through this site but also to gain something from their involvement in this business.

The basic idea of the application is relatively simple and can be summarized as follows: A client, a user who needs legal advice in the legislative field, will post a question on this site and lawyers who are willing to provide information, will establish a supply response. The supply response means that they will set a price they are willing to answer the question posted. The customer will decide based on reputation and offer which lawyer will offer the answer that he needs. The application will download from the customer's account the amount of the transaction and will transfer it in to the lawyer account (90%) and the remaining 10% in to the webmaster account.

As will be seen in this paper we will debate whether the use of free tools that can be found on the Internet and integrate them into an application is or isn't a good idea. We will elaborate on this process in what follows.

Not everyone can post their questions on the site, only those customers who have made an account in advance, and more, have uploaded their budget with a certain amount of money. In a classical way, the work on this application begins by creating an account. To access all the features of the site, a visitor will need, whenever he visits the site, to login. This procedure is valid for lawyers as well. The procedure is a standard for most online applications. Using logging is clear an opportunity, whereas it provides some security in terms of users but, also to prevent overloading the application with non-human users, or so called robots.

Applications Description

For creating this application we have chosen to use PHP and MySQL. The system is built using our own set of code and, where needed, using outsource services. This paper goes on to explain how the site works and which the innovative elements of our application are.

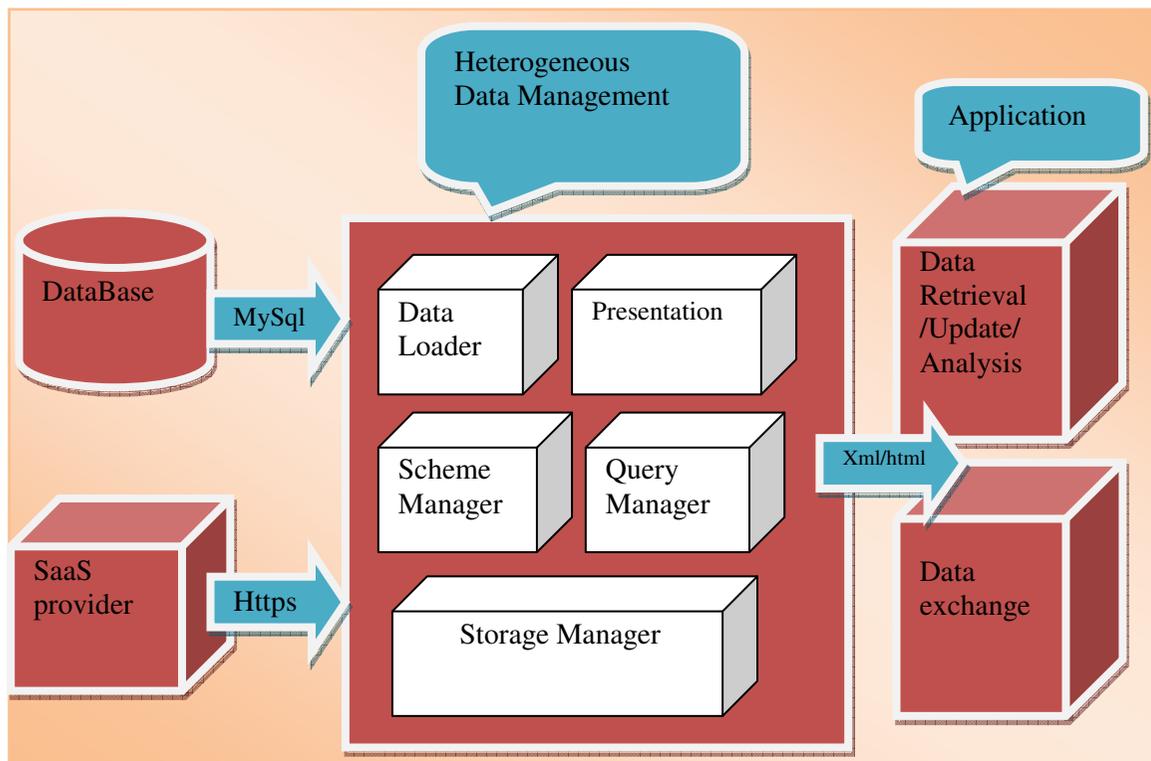

Fig.1. Applications Architecture

Virtual communities are one of the most important developments in Internet history. Due to rapid exchange of information, they have brought major benefits in almost all areas of everyday life. Legal advice is not an exception. Thus both lawyers and clients can meet and make exchanges of information using the digital advantages of having quick information, eliminating bureaucracy and endless queues.

We have inserted a virtual community in this site using a forum application, named Simple Machine Forum (<http://www.simpleremachines.org/>). This choice is understandable as it is easy to use, secure and relatively high positioned compared to the popular PHPBB. For more enjoyable browsing of the site we chose to integrate the forum using an iframe. This allowed us, as programmers to save a lot of time and hard work. This forum is the first free source that we used to sustain our idea that one does not have to reinvent fire when he develops an application.

So, the site has a forum that allows stakeholders to communicate. Access is allowed from the outset and does not require prior authentication. This is because we consider that a new visitor must be able to pursue such discussions and know how other users use the application, and thus be motivated to create their own account and to commence their activity. About the economic side will discuss later in this article.

What is SaaS?

“Quite simply, Software as a Service (SaaS) is a service that allows you to outsource the technical aspects of your business. By finding a good SaaS provider, you can eliminate the worry about purchasing, installing and maintaining software or hardware, and focus on managing and expanding your business. The SaaS model is expected to become an important alternative - especially during a financial crunch - not only for larger companies but also for small and medium businesses with low budgets for IT. Since a traditional IT budget is made up of an IT team, SW licenses, and equipment such as servers, SaaS offers a significantly reduced TCO (total

cost of ownership). This is due to low cost of deployment, no expensive equipment purchases, and the ease and speed of implementation. As SaaS is often put into service on a pay-per-use basis, or subscription based on usage, this further reduces corporate expenditures. The right SaaS provider offers a business approach to ease your decision-making regarding IT and will reduce your budget. Implementing SaaS also eliminates the time spent for upgrades and maintenance.” (Galor Systems & Software Development, March 2009, content cannot be changed).

Types of SaaS

SaaS must be defined depending on the type of its users. So software as a service can be considered an:

-On-demand software purchasing where clients purchase applications using the Internet. For software providers, this type of SaaS represents a cost-effective sales channel and software delivery mechanism. Another asset for vendors is the fact that they would no longer have to think about a licensing protocol. For users, it provides a fast and easy way to obtain software, information and all this at a very cheap price, comparing with buying software traditionally.

-On-demand IT service-oriented architecture (SOA) where an application or software is created using exchanged information between programmers. A SOA offers a flexible approach to application development that encourages service re-use and reduces the need to build point-to-point connections for data and application integration.

-On-demand application services where individual users or organizations pay external third-party providers for the use of their application services. The objective of this type of SaaS is to trim software and hardware costs, and to reduce IT staffing and skill requirements. This approach may also be used as an interim step before bringing application software in house.

Some industry analysts describe the on-demand application services model as SaaS 2.0, because it extends the capabilities of earlier SaaS initiatives. An on-demand application services vendor may, for example, support a SOA for providing easier access to the services it offers. (Colin White, 2010)

SaaS- the end of classical IT business

Software as a service could turn out to be the end of classical business in software providing world. Customers would have a lot of benefits from using these alternatives: They can have access to sophisticated technology without up-front expenses or the hassles associated with the installation and maintenance of traditional software. For providers, SaaS could mean the opportunity to challenge new markets, to break down classical frontiers and no more headaches concerning software licensing.

So a great thing concerning SaaS providers is that they offer their application with their obligation to maintain it and to host it on their servers. As it can be seen this alternative could turn out to be very cheap for a user as his costs with maintenance and hardware requirements would be minimal.

Like any new concept, SaaS has its own shortcomings. The fact is that not even today theoreticians agree on a definition, as SaaS still experience a perpetual process of evolution. At a global level, people are still reluctant to use such services as there is a lack of trust to save data bases outside an organization’s firewall. We couldn’t help but wonder: Could you run a business entirely on hosted offerings? The answer is not clear but even so IDC said that in 2009 people all over the world spent \$10.7 billion on SaaS.

In my opinion healthy enterprises need to develop their own unique applications, and any modern IT infrastructure needs to be fully integrated in a manner that cannot be achieved with SaaS solutions today. But an urgent need to stop piling cost and complexity on IT is sowing the seeds of change. Although enterprises may not be replacing effective, large-scale systems with SaaS alternatives, the SaaS option suddenly becomes perfectly viable when it comes to adding new

functionality. And, as Salesforce.com discovered, SaaS can be particularly successful at replacing in-house or off-the-shelf software that has failed miserably.

As I have mentioned SaaS has some deficiency. One of them is the lack of trust providing, so that an organization to use only outsource software. Indoor software still seems more reliable and efficient in a manager's eye. In my opinion this happens, not because SaaS is not the best alternative, but because the infrastructure all over the world is not allowing an exclusive usage of this kind of services.

SWOT analysis for SaaS

<ul style="list-style-type: none"> -Domain knowledge -Low cost -Infusion of investors -Customer relationship -Web API scanning -Pay per use model 	<ul style="list-style-type: none"> -Customer understanding -Quick deployment -Uses existing solutions -High growth -DB scanning -VMware capability 	<ul style="list-style-type: none"> -Server level management -Low transparency -Small research team -Operations cost -Infrastructure -Low access -Lower security -Small support team -Web-centric sales -User experience
<ul style="list-style-type: none"> -New markets -New distribution channel -technological development -Integration with 3rd party blocking technology -Higher profit opportunity 	<ul style="list-style-type: none"> -Greater market share -3rd party experience 	<ul style="list-style-type: none"> -Lot of competitors -Address weaknesses -Big players already on the market -Company acquisition -Lack of trust -Alternative technologies -Malicious impostors

What to look for in a SaaS provider?

There are a number of elements to consider when evaluating a SaaS provider:

1. Industry expert – When deciding on a software provider it is logical to try to find the one that is most familiar with your industry. Familiarity with your specific vertical market ensures the solution that is tailored to your needs.
2. Experience – it is one of the most important criteria as an experienced provider could offer you a plus of value and security.
3. Team – ensure the team who will be servicing your business knows the ins and outs of your industry.
4. Support – make sure your SaaS provider includes implementation support, help desk, and training in your agreement.
5. Security – always check security services are included. This includes backup, recovery, encrypted data, firewalls, and unique ID and password access

Electronic payment

PayPal is an online electronic payment system recognized worldwide for its benefits to the electronic trading methods. Recently this system has entered the Romanian market with a fairly high success, given that Internet commerce status in Romania is at a relatively low level, compared with other EU countries. It is a safe (secure) application for e-payment, bringing many benefits to the protection of user data.

PayPal provides a powerful tool for automatic creation of HTML code for its integration in virtual shops. HTML code is defined by a series of specific parameters. Beside this, in the website we had to integrate and sequence PHP code to manage the database.

Thus each client after authentication will be given the possibility of loading the budget account. This will be possible by accessing the load account page. Once the page is activated, it will generate a payment process through PayPal. Through a secure connection, the client is returned to that page Avocat.NET and the amount of money enters in the sites circuit. This will refresh the account values.

The database contains the client identification code, time and date of loading account. Note that the load transaction does not charge commission. All administrators can withdraw the amount available under its credit card account registered at any time.

A counsel may request a withdrawal. Its request is processed by an administrator who will send the Advocate a transaction confirmation message. Money circuit in Avocat.NET system is described in the following scheme:

Step1: The client account on Avocat.NET loads using PayPal.

Step2: Following the transactions between clients and lawyers a fee of 10% of transaction value is passed into administrators account and the rest of 90% is transferred into the lawyers account. The total amount is deducted from customer's account. It represents the questions price. This operation takes place within the site.

Step3: Attorney may request the withdrawal amount from his account. The request is being processed by the administrator manually. Once satisfied the transaction, the administrator will notify the lawyer by a confirmation email.

Why PayPal

We have chosen PayPal for our payment facilities as we consider that it is very easy to use by the applications clients, the provider is accomplishing the criteria mentioned above, and last but not least is very easy to integrate in our web-site. More than that PayPal has a pay per use type of pricing, consisting on a \$0.30+ 1.9-2.9% of the transaction value. It's by far the cheapest solution on the net.

Conclusion

One of the biggest problems in informatics is the tendency of the designers to reinvent fire. When developing an application, most programmers don't pay attention to the solutions that already exist on the market. They just start creating. If we analyze all e-commerce applications we would observe that most of them have a similar structure. A lot of their modules have same functionality, but each one of them was created by different people. Isn't that a waste of time?

Unfortunately, comparative with other industries, in informatics, there is still a lack of standardization and work efficiency. In the Microsoft Visual Studio 2010 Conference that took place on 15 February 2010 in Cluj-Napoca, Ciprian Jighici said that an IT project has no more than 20% chance to succeed. Another 60% of the projects are starting for a reason but turn out to be something completely different. The last 20% are totally failed. If we compare informatics with the airline transportation industry, for example, the statistics are really frightening. Lets imagine what would be if we would have to leave from an airport and the chances to arrive to our destination to be only 20%; in 60% to go elsewhere; and in 20% of the departures to be sure we won't land at all.

This issue is debated by theoreticians since the explosion of Dot Net technologies. The question everybody asks is how could we make programming process more efficient? How could we share our work to help others and gain something of it? The first intention to respond to this question was represented by ASPs (application service providers) and now the domain concerned to give answers to these questions is SaaS (software as a service). The promoters of this type of services thought to give designers an alternative to programming. A designer can decide to implement a service for a module that has a common functionality. Having this into consideration, we have implemented in our application the PayPal service for the online payment. We consider that

developing an on-line payment mechanism is time consuming, very expensive and the final result isn't at all secure. PayPal, on the other hand, is a service that is cheap and easy to use. One needs only 6-7 hours to transform his marketing site into a veritable e-commerce application only by using the PayPal's service.

EIGENSTÄNDIGE PRÄ- UND NOTFALLKLINIK ALS ZENTRALES RETTUNGSZENTRUM FÜR DIE REGION 10

Heribert Fastenmeier
Klinikum Ingolstadt GmbH

Mirela Leuca
Wirtschaftswissenschaftliche Fakultät
Universität Oradea

The German health care system has been undergoing many reforms. The introduction of the DRG-financing system, as one of the major changes for the German hospital setting in the last decades, had huge impact on the evolution of the hospital resources and capacities, economic situation, organization, structure, processes and average length of stay. In this context, the optimal organization and structure of emergency departments is becoming a strategic factor of success for hospitals. This paper presents briefly the present situation with regard to the organization and structure of emergency care in Germany and describes the strategy, goals and expectations when establishing a new interdisciplinary emergency department for Region 10 in Germany.

Keywords: Notfallversorgung, eigenständige Notfallklinik, Rettungszentrum.

JEL Classification Code: I10 M10 L20

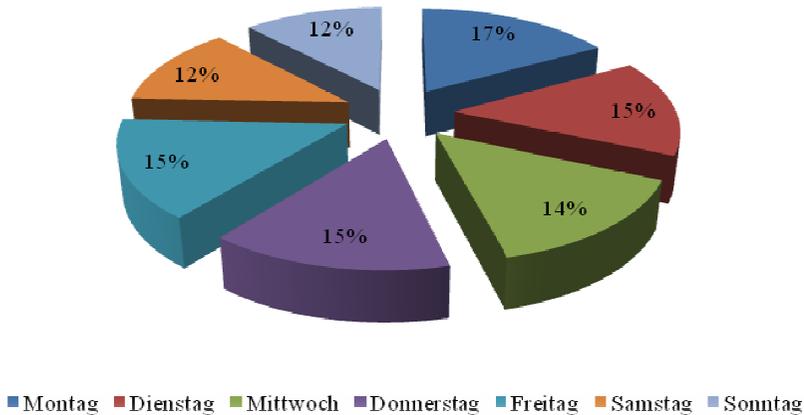

1.Einführung

Die ambulante und stationäre Notfallversorgung im Klinikum Ingolstadt war seit den achtziger Jahren so organisiert wie in allen deutschen oder europäischen Kliniken. Ärzte der verschiedenen Fachabteilungen wurden entweder bei eintreffenden Notfällen alarmiert und aus den Fachkliniken tagsüber abgezogen und zu den Notfällen entsandt oder nachts wurden die im Hause tätigen Bereitschaftsdienste der Fachabteilungen informiert einen aufgenommenen Notfall zu behandeln. Das System zeigt schon ganz zu Beginn seine Schwäche! Die Leitstellenkraft oder die Pflegekraft taxiert und bewertet den Notfall nach Schwierigkeit, Komplexität und Dringlichkeit und alarmiert die Hausdienste der Fachabteilungen? Diesem Alarmierungsruf geht somit eine „erst Diagnose“ durch genannte Personen voraus, die eigentlich dazu weder ausgebildet noch in der Lage sind. Die Dringlichkeit des Falles konnte überdies durch den reinen „Piepser ruf oder das Telefonat „ nicht vermittelt werden. Oft waren die Diensthabenden auch durch und an ihre geplanten Routinen der Fachabteilungen gebunden und nur mit zeitlicher Verzögerung abkömmlich. Zeit ist Qualität zumindest in der Notfallversorgung, dies erkannte man zunehmend oft. Ein weiteres Problem das offensichtlich wurde war die Qualität der entsandten Mediziner die sich mit den Notfällen beschäftigen sollten – Ärzte in Weiterbildung, oft am Anfang ihrer Medizinerlaufbahn mussten sie sich mit den schwierigsten und kompliziertesten Fällen im ersten Zug beschäftigen. Manchmal dauerte es sehr lange bis sie sich fachärztliche Kompetenz der eigenen und oder anderer Abteilungen zu Rate zogen oder gar den Fall an diese abgaben. In einem ersten Schritt hat man vor Jahren teilweise eigene Schichtbesetzungen und vor Ortbesetzungen in den Notfallzentren etabliert ohne dabei auf die Struktur oder Qualität zu achten und man sich nicht wirklich mit dem Fallaufkommen und den Strukturen beschäftigt - die medizinische Versorgung blieb auch in der Notfallaufnahme ein Teil der Fachklinik und war zu sehr „spezialisiert“ und am üblichen Aufnahmeverfahren orientiert.⁶⁷⁵

⁶⁷⁵ Für ergänzende Literatur siehe auch: Hogan, Barbara, *Veränderung in der Versorgung von Notfallpatienten in den Notaufnahmen deutscher Krankenhäuser – ein Paradigmenwechsel?*, in: das Krankenhaus, 2010, Nr. 4, S. 304- 312.

Erst als sich die Notnahmefrequenz erkennbar änderte und die Häufigkeit der Aufnahmen stieg und die Bevölkerung sich mit den tradierten Klinikstrukturen zunehmend wenig identifizieren konnte war man in der Ärzteschaft und im Pflegedienst bereit neue Strukturen an zu denken und um zu setzen. Nachfolgende Graphiken verdeutlichen das Aufnahmespektrum, die Aufnahmestruktur und die fachliche Diversifikation für das Jahr 2009.

Notfallzentrum - Fallzahl je Wochentag

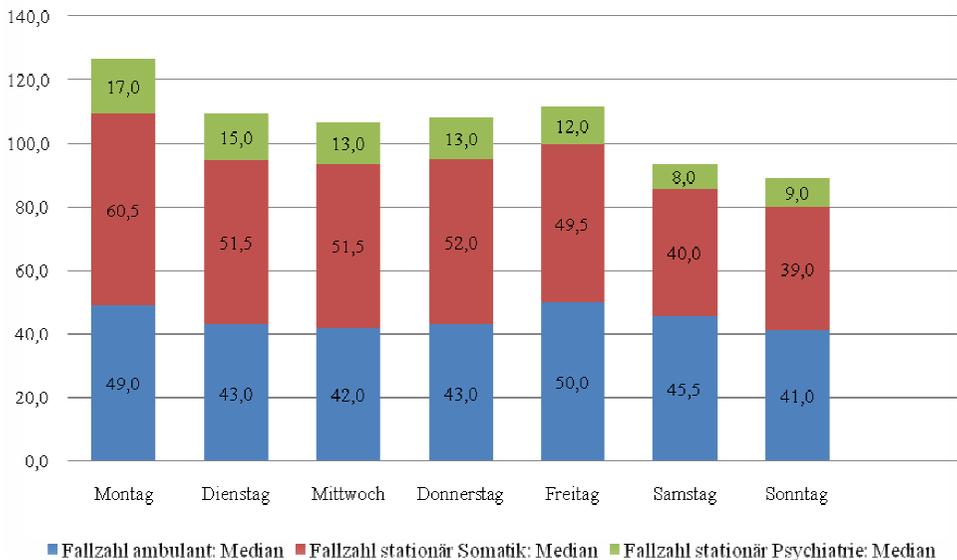

Graphik 1: Notfallzentrum- Fallzahl je Wochentag in 2009

Quelle: eigene Berechnungen auf Basis der Daten des Klinikums Ingolstadt.

Das Klinikum Ingolstadt hat sich fortan mit diesem Thema beschäftigt und die unternehmerische Leitentscheidung getroffen eine eigenständige Prä- und Notfallklinik als Rettungszentrum für die Region mit eigenständigem Personalkörper und verantwortlichen ärztlichen Leiter(Chefarzt) ein zu richten.

Notfallaufkommen: Median

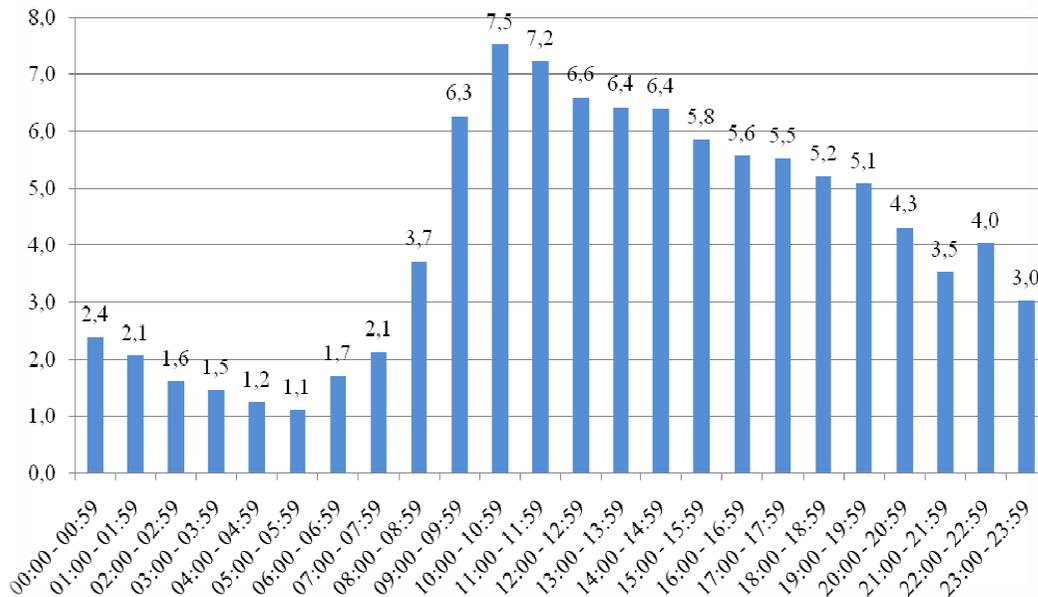

Graphik 2: Notfallaufkommen: Median (2009)

Quelle: eigene Berechnungen auf Basis der Daten des Klinikums Ingolstadt.

Dieses Thema wurde auch in der deutschen Fachliteratur analysiert und beschrieben.⁶⁷⁶

Notfallaufkommen je Zeitintervall (%)

Graphik 3: Notfallaufkommen je Zeitintervall (%) in 2009

Quelle: eigene Berechnungen auf Basis der Daten des Klinikums Ingolstadt.

2.Strategie und Organisation

Im Klinikum Ingolstadt soll eine Klinik bautechnisch eingerichtet werden, die in der Lage ist alle Notfälle aufzunehmen und kompetent und zuverlässig die Erstversorgung garantiert. An einer Stelle soll die ambulante und stationäre Versorgung gewährleistet und abgebildet werden. In einem Triage-System soll dabei ohne großen Zeitverlust (grün – gelb –rot) der Patient im Hause ohne es selbst zu merken von den noch rechtlich getrennten Systemen einheitlich und prozessual Zusammenhängend versorgt werden. Dabei muss das KI die baulichen Voraussetzungen schaffen und die Anfahrtswege zwischen und für leichte und schwerverletzte Patienten trennen und eigene zu diesem Zweck notwendige Behandlungseinheiten schaffen.

Das inhaltliche Ziel war dabei:

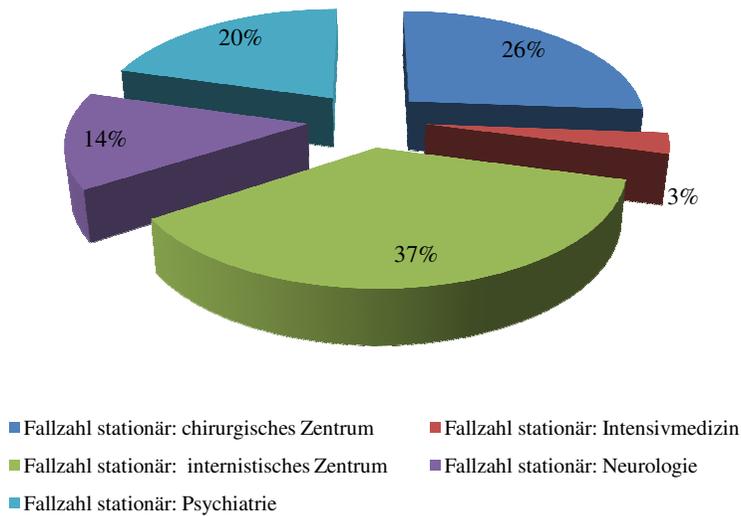

- Notfallpraxen für Erwachsene und Kinder ambulante Notfälle betrieben durch die Niedergelassenen im Klinikum Ingolstadt in einem abgestimmten Schichtsystem inhaltlich kommunikativ vernetzt;
- Notfallzentrum für stationäre Patienten;
- einheitlicher Gemeinsamer Aufnahmebereich technisch und logistisch vernetzt;
- Polytrauma- und Schockzentrum;
- Rettungszentrum;
- ambulante und stationäre Notfallversorgung psychisch Kranker (Erwachsene und Kinder);
- Stationierung sämtlicher Rettungsdienste incl. der Notärzte in dieser Klinik und in diesem Team

⁶⁷⁶ Siehe auch z.B.: Bey, T.A.; Hahn, S. A., Moecke, H., *The current state of hospital-based emergency medicine in germany*, in: Int J Emerg Med, 2008, Nr.1, S. 273-277 und Hogan, Barbara; Fleischmann, Thomas, *Interdisziplinäre Notaufnahme – Konzeption und personelle Besetzung*, in: Krankenhaus Umschau, 2008, Nr. 2, S. 30- 32.

- einheitliches und abgestimmtes Screeningverfahren;
- abgestimmte Prozessabläufe;
- eigener Personalkörper mit den relevanten Facharztgruppen und hochspezialisierten Pflegekräften.

Die eigenständige völlig selbstständige Klinik mit chefärztlicher und pflegerischer Leitung wird Schwerpunktmäßig die relevanten Fachärzte in einem 24-Stunden Schichtsystem beschäftigen. Überdies sollen ausgewählte Notärzte auch die Rettungsfahrzeuge besetzen und die Patienten vor Ort versorgen, in die Klinik transportieren und dort zunächst die Übergabe, Weiterversorgung und Sicherstellung der Datenübergabe gewährleisten. Flache hierarchische Organisationsstruktur mit Schicht-Blockmodellen und dem Auftrag der echten Notfallversorgung (Sicherung der Vitalfunktion, Prozess beschleunigend etc.) zur Weiterversorgung in den Fachkliniken.

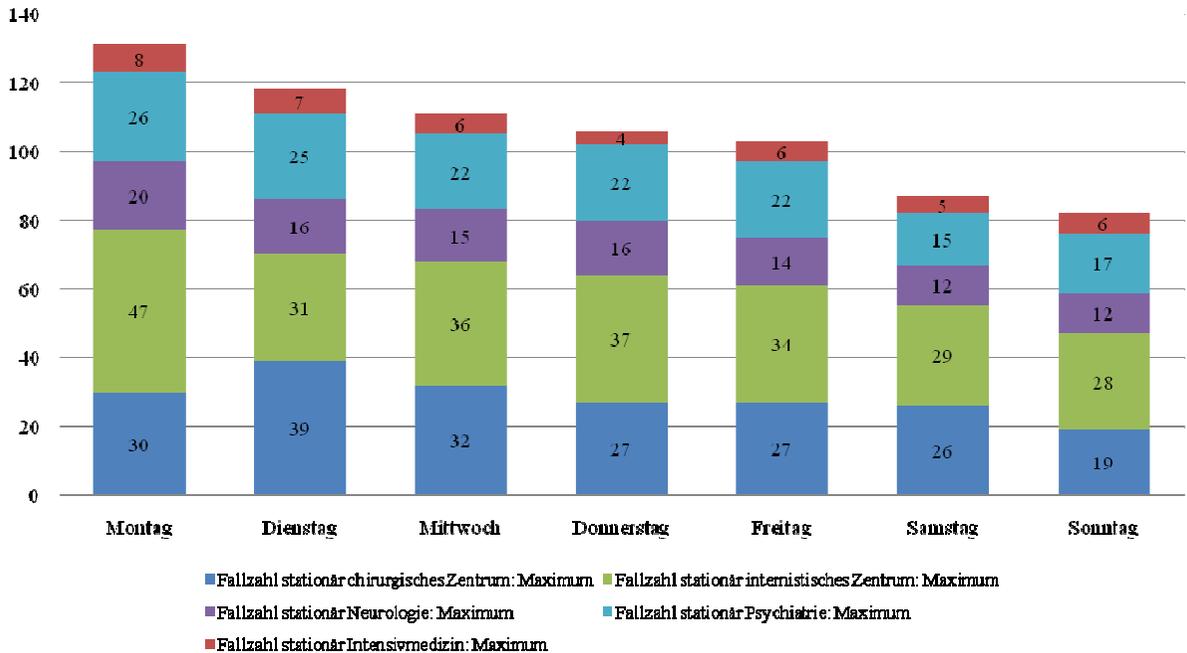

Notfallaufkommen je Schwerpunkt (%)

Graphik 4: Notfallaufkommen je Schwerpunkt (%) in 2009

Quelle: eigene Berechnungen auf Basis der Daten des Klinikums Ingolstadt.

Notfallaufkommen: Maximum

Graphik 5: Notfallaufkommen: Maximum (2009)

Quelle: eigene Berechnungen auf Basis der Daten des Klinikums Ingolstadt.

Dies führt zu einer besseren Versorgung der Patienten und mehr Zufriedenheit bei den Mitarbeitern da Sie inhaltlich, organisatorisch und prozessual in der Patientenkrise stark standardisiert arbeiten und handeln können.

3. Prozess- und Qualitätserwartung

Zeit ist Qualität - ist Leben und Gesundheit! In dieser Klinik muss im **Triagesystem** eine klare Vorgabe bestehen wie mit Patienten um zu gehen ist. Innerhalb klarer Vorgaben muss der Arzt Patientenkontakt in einem entsprechenden Zeitfenster stattfinden. Der Patient ist und wird im Prozess permanent begleitet und über den Sachstand seiner Behandlung informiert. Erhobene Daten dienen in einer Eskalationsstrategie zunächst der Erkennung der Krankheit (Screening) und dann der Vorbereitung der Weiterbehandlung in den Organzentren. Die Fallsteuerung erfolgt durch den Arzt und alle notwendigen diagnostischen Bereiche sind in dieses Verfahren integriert – Weisungsrechte in alle Bereiche macht der Weg schneller. Vorhandene Daten aus Vorbehandlungen (stationär, ambulant) stehen genauso zur Verfügung wie Daten aus der akuten Anlieferung im NAW. Der Patient einmal im System aufgenommen ist permanent in Begleitung und Betreuung bis er entweder an die Fachabteilung abgegeben wird oder wieder entlassen wird. Polytraumen, Infarkte und Geburten haben in diesem System nochmals eine andere und eigene Wertigkeit und werden verkürzt und direkt an die Fachabteilungen übergeben.

Die Etablierung einer eigenständigen Notfallklinik hat klare Qualitätsziele, die im Folgenden Bereichen liegen:

- Qualität der Berufsgruppen (Qualifikationsmix bedarfsadaptiert, z.B. Facharztstandard, Fachpfleger);
- Zeit, Inhalt und Ablauf der Behandlung;
- Team- und Arbeitsstrukturen, Teamstruktur Notfallversorgung;
- Arbeitszeitstrukturen;
- Professionalisierung des Screeningverfahrens (Notfälle, Alter, Infektionen u.a.);

- SOPs abgestimmt mit den nach- und weiterbehandelnden Organzentren.
- klare und abgesprochene Fallsteuerung zwischen dem ambulanten und stationären Bereich mit beschleunigter Übergabe aus den Sektoren und unter Nutzung der bereits erhobenen Daten.

In einem **eigenständigen Rettungszentrum** werden alle Notfälle Hand in Hand mit den ambulant tätigen niedergelassenen Ärzten, mit den Rettungsärzten aus den NAW und aus dem Rettungshubschraubern in einem Zentrum in örtlicher und räumlicher Nähe versorgt. Alle Datensysteme sind ebenfalls miteinander vernetzt und innerhalb dieses Notfallcampus ist der Patient in einer dauerhaften und organisatorisch abgestimmten Begleitung und Betreuung. In diesem Zentrum soll es ausschließlich um die Erstversorgung, um die Vitalfunktionen gehen und es soll jede Art von notwendiger Weiter- und Nachbehandlung vorbereitet werden auf der Grundlage zwischen allen Beteiligten abgestimmter SOP mit der notwendigen und richtigen Diagnostik. Der Erfolg der Behandlung ist zu evaluieren (Zeitliche Abläufe, Synchronisation, Arbeitsweise der Mitarbeiter nach SOPs). Ein weiteres Tätigkeitsfeld der Notfallklinik wird die sich aus der Behandlung heraus ergebende „**Kurzliegerstation**“ sein. Solange der Notfallpatient als solcher nicht abgeklärt ist und solange nicht klar ist ob er wirklich stationär aufgenommen werden muss, bleibt der Patient in der Notfallklinik, jedoch maximal bis zu 2 Tagen. Damit werden die Kernkliniken von häufigen, manchmal unnötigen Aufnahmen befreit und entlastet. Im Klinikum Ingolstadt sind dies jährlich rund 3000 Patienten. Dazu wird die Notfallklinik neben der Holdingarea eine über eine eigene Bettenstation mit 17 Betten verfügen, die in den Betriebsablauf und in die Routinen zu integrieren ist.

4. Schlussfolgerungen

Das Klinikum Ingolstadt versucht mit der Einrichtung und Etablierung einer eigenständigen, cheffärztlich geleiteten Prä- und Notfallklinik ein anerkanntes Rettungszentrum zu schaffen. Ziel dieser Klinik ist ausschließlich die Erstbehandlung und die Sicherung der Vitalfunktionen. Damit verlässt das Klinikum Ingolstadt den Weg den man in Deutschland über Jahrzehnte hinweg ging und selbst in der Notaufnahme mit der Spezialisierung der Medizin begann ohne zu wissen ob diese in dieser Art richtig und notwendig ist. Andere Länder gehen diesen Weg seit längerer Zeit und haben zwischenzeitlich im ärztlichen Bereich die Notfallmedizin zu einem ebenfalls eigenständigen „Facharztbereich“ gemacht. Diese Entwicklung wird sich wohl auch in naher Zukunft abbilden. Solange dies aber nicht der Fall ist, wird man in unserem Hause entsprechend der Falldichte und –schwere immer die Disziplinen vorhalten müssen die vermutlich am häufigsten oder am ehesten gebraucht werden. Die Vernetzung der Sektoren ambulant und stationär, die Vernetzung der Notfälle im Hause über die Fachabteilungen hinweg, das einheitliche und abgestimmte Triage-System wird in kürzester Zeit erfolgreich sein und auch ökonomisch wirken. Standards geben Sicherheit, helfen Prozesse zu beschleunigen und lassen sich gut planen. Standards in der Notfallversorgung und standardisierte Notversorgung geben den Akteuren vor Ort die Zeit die wirklich schwierigen und komplexen Fälle dann auch außerhalb der Standards mit der emotionalen Intelligenz anzugehen wie es im Bedarfsfalle auch erforderlich ist.

BUSINESS PLANNING IN THE CONTEXT OF THE ECONOMIC CRISIS

Gherman Liliana - Victoria

"Constantin Brancoveanu" University of Pitești,

Faculty of Management Marketing in Economic Affairs Braila

Abstract:

During the economic crisis, a successful business is the one which answers to the tangible needs and produces benefits. Any business must offer practical solutions for the society problems. In the context of the economic crisis, it is vital to pay a special attention to the planning stage in order to diminish the risk and to eliminate the fail.

Keywords: economic crisis, business planning and management

JEL Classification: M21 - Business Economics

Business is the organized effort of individuals to produce and sell, for a profit, the goods and services that satisfy society's needs. The term business refers to all such efforts within a society or within an industry.

A person who risks his or her time, effort and money to start and operate a business is called an entrepreneur. To organize a business, an entrepreneur must combine four kinds of resources: material, human, financial and informational. Material resources include the raw materials used in manufacturing process, as well as buildings and machinery. Human resources are the people who furnish their labor to the business in return for wages. The financial resource is the money required to pay employees, purchase materials and generally keep the business operating. Information is the resource that tells the managers of the business how effectively to the other resources are being combined and utilized.

The business efficiency consist in the using way of the resources, thus the business manager must obtain the most economical results using the engaged or available resources currently⁶⁷⁷.

Generally, the business can be of three types. Manufacturing business are organized to process various materials into tangible goods, such as delivery trucks or towels. Service business produce services, such as haircuts or legal advice. And some firms – called middleman – are organized to buy the goods produced by manufacturers and then resell them. For example, a company that produces some things, these products may be sold to a retailing middleman, who then resells them to consumers in its retail stores. Consumers are individuals who purchase goods or services for their own personal use rather than resell them.

All three types of business may sell either to other or to consumers. In both cases, the ultimate objective of each of them must be to satisfy the needs of its customers. People generally don't buy goods and services simply to own them; they buy products to satisfy particular needs. People rarely buy an automobile to store it in a garage; they do, however buy automobiles to satisfy their need related to transportation.

When firms lose sight of their customer's needs, they are likely to find the going rough. But when the business that produce and sell goods and services understand their customers' needs and work to satisfy those needs, they are usually successful.

Normally, a business receives money from its customers in exchange for goods or services. It must also pay out money to cover the various expenses involved in doing business. If firm's sales revenue is greater than its expenses, it has earned profit.

⁶⁷⁷ Peter Drucker – „Despre profesia de manager – A Harvard Business Review Book”, Meteor Press, 2006, p. 70.

The profit earned by a business becomes the property of its owners. So in one sense profit is the return, or reward, that business owners receive for producing goods and services that consumers want. A business that cannot earn a profit is very likely to fail, in which case the owners lose money, effort, and time they have invested. For business owners, the challenge of business is to earn a profit in spite of these risks.

When starting a business, a lack of planning can be as deadly as a lack of money to the new enterprise. Planning is important to any business, large or small, and it should never be overlooked or taken lightly. A business plan is a carefully constructed guide for the person starting one's own business. It also serves as a concise document that potential investors can examine to see if they should invest in or assist in financing a new venture.

The business person, who constructing a business plan, should strive to keep it easy to read, uncluttered, and complete. Officials of financial institutions just don't have the time to flip through pages of facts and figures.

A great amount of time and consideration should go into creating a business plan. The plan will probably end up saving time later.

Generally speaking, for initiating and developing a business, it is important to plan the business. Moreover, when we talk about a crisis period, it is vital to pay a special attention to the planning stage in order to diminish the risks and to eliminate the fail.

So, planning will help us to organize the ideas, to have an objective and critical analysis of the future business taking into consideration the ways of functioning and the estimated results.

After studying the market and identifying the opportunities, the most important problem for an entrepreneur to solve is to identify and mobilize the financial, human resources and also the intangible assets. For a person with entrepreneurial spirit, this issue doesn't represent an obstacle but a challenge.

During an economic crisis, the entrepreneur must have a strategically thinking studying the social and economical environment of which the business will be initiated, identifying the available assets and defining the ways to get in their possession, identifying the potential financiers and mobilizing the necessary human resources to start the business.

Moreover, if the business addresses to particular needs which were clearly defined, the access to the resources will be easier because all the involved people will be more trustful in their success and chances to obtain adequate benefits.

For planning and starting a business in a crisis period, it is important to have a strategic approach because this ensures not only the establishing of goals on long term but also defines the modalities to achieve these goals, how and when the resources will be allocated in order to effectively reach the estimated objectives.

No matter the business concerns, the strategic thinking can't be applied without planning the activities which must be correlated with the demand as the market economy requests. This is why, the researches on demand lead to a planning which has the aim to efficiency the production meaning to product or commercialize the requested products or services. For sure, this strategic thinking will ensure the estimated profit.

A strategic thinking can't be considered complete until the success or failure isn't measured and also the results compared with the expectations. If all or mostly part of these coincides, this means that the expected objectives were achieved.

The planning is the essence of a good management. It represents a process based on analysis which requests involvement and engagement towards the objectives determining results and communication at external and internal level⁶⁷⁸. Having in mind that the most efficient objectives suggest a competition, the plan – a instrument for the planning process, represents the description and rationalization of a vision and, also, a base for communication.

⁶⁷⁸ I. Ciochină, L. Gherman, S. Dugan – „Managementul proiectării și derulării afacerilor”, Ed. Independența Economică, Pitești, 2009, p. 55.

The plan, not only presents the future policy of the enterprise, but also has the aim to precisely quantify the predictable effects of the future decisions. It facilitates the description of the enterprise's future based on hypotheses regarding the patrimony analysis, the financial structure, the means that allow the strategies implementation. Forecasting the financial results including the earning capacity determine the base for the decision-making process regarding the investments volume, possible solutions that ensure the profit and the business success.

A role, not less important, of the business plan refers to communication at all levels: internal communication, the business plan having the advantage of overall image on goals, means, results; communication with business partners, associates, clients, suppliers - the business plan indicating the position of every single participant involved in business, their competences and responsibilities and also the organisation and management of the relations between them; the communication with the financial institutions, the business plan representing a way to justify the financial requests and their appropriate management. The setting-up of the business plan will determine positive effects if this instrument is based on reliability, competency and realism.

The business plan represents a complex system based on interaction and expresses in an easy manner the business idea and its evolution in time.

Its role is not only to demonstrate the fact that the business worth being financed, but also to guide the entrepreneur beginning with the first operational year of the business. Its implementation means control and adaptation depending on the actual evolution. This control carried out during the business implementation will point out all the important elements of the economic entity (stocks, production costs, quality control, the sales, the payments etc.)

Entrepreneurs need to have not only the capital to open a business but also the money to operate it in its possibly length start-up phase. One cash-flow obstacle often leads to others and a series of cash-flow predicaments usually leads to a business failure. An entrepreneur can have two separate sets of credit difficulties: he might be pressured into selling on credit, causing cash-flow troubles, or might rely too heavily on credit, these becoming overwhelmed by bill collectors.

The companies have difficulties due to decreasing sales intercompany debts and higher credit margins. Only companies with multiple profiles can survive, which are not fully dependent on large projects or state businesses, so they can manage their costs.

Many entrepreneurs lack the management skills required to run a business. The management is one of the most challenging and rewarding of professions. The persons who manage business firms play an important part in shaping the world we live in.

Money, time and personnel all need to be effectively managed if a business is to succeed. A frequently asked question in the business planning stage is: "firstly to find a business idea and then to set-up the company in order to implement the idea or firstly set-up the company and then to find out the business idea"?

Our opinion is that the idea is fundamental for setting-up a business. An idea might not be good from the start but there are cases when ideas can be developed, otherwise they remain only ideas. This is why, you can say that the idea must be correlated with a plan in order to facilitate its implementation. An idea is innovative when it is linked with an opportunity because setting-up of a business must answer to the economic needs, in efficiency conditions. The novelty and originality aren't mandatory in setting-up a business, but there are necessary for taking advantage of the existent opportunities and for having a profitable activity.

Frequently, entrepreneurs with initially successful business make the mistake of overexpansion without taking into consideration the crisis conditions, but fast growth often results in dramatic changes in a business.

To administer a crisis can be considered an "art" but also a "science" of management taking into account the unexpected situation and the unusual measures. The international economic business management represents the concepts, methods and instruments needed to identify the business

opportunities.⁶⁷⁹ The taken measures must comply with the Romania's actual needs such as: creation of the appropriate conditions for an extended social and geographical mobility in order to facilitate the employers' access to jobs unequally distributed from the point of view of professional structures and geographical areas. Some of the measures should be focused on the financial support of the disadvantaged categories or regions.

Every day, people plan or actually open new business. Many of these may not succeed. Others represent well-conceived ideas that are developed by entrepreneurs who have the expertise, resources and determination to make their business succeed. A real business is the only who solves the material or spiritual needs and that in this process it produces financial returns⁶⁸⁰. As these well-prepared entrepreneurs pursue their individual goals, our society benefits in many ways from their work and creativity.

The paper disseminates the results of National Research Project: STUDY REGARDING THE OPTIMIZATION OF THE NATIONAL TOURISTIC POTENTIAL DEVELOPMENT STRATEGY AND THE IMPROVEMENT OF ROMANIA'S IMAGE AS A TOURISTIC DESTINATION, PCE 375/2007 (CNCSIS), Research Manager - Assoc. Prof. Ph.D.Gruescu Ramona.

Tourism is a complex phenomenon on account of the wide variety of factors which determine its shape, organization and development. Some of the numerous factors interacting with tourism merit close attention: tourists, employment, businesses, social cohesion, stability, culture and heritage, accessibility to persons with disabilities, the environment, peace and solidarity, and the roles of the various players.

Although tourism is not directly part of common EU policy, a number of European institutions are engaged in measures and actions which affect tourism because of their horizontal nature, or which rely on tourism in order to achieve a range of major EU objectives, including sustainable development, employment, economic and social cohesion, etc.: in other words, a better quality of life for European citizens.

Keywords: tourism, policy, development, sustainable, employment

Cod JEL lucrare: L83, L11

1. Introduction

Developing tourism has a direct impact on economic, social and environmental conditions; consequently, it can and must be an important means of enhancing European citizens' quality of life and must be used as such. However, in order to ensure that this potential is effectively harnessed in the longer term, tourism must meet sustainability requirements which all the players involved - public and private bodies, businesses and users - must in turn observe.

Tourism is widely recognized around the world - and especially by the European Union and its institutions - as an area of economic activity of strategic importance in achieving a range of objectives which lie at the very heart of the EU's existence, its policies, and its desire to create a better Europe for present and future generations.

It is important to point out that the only reference to tourism in the EC Treaty, as consolidated at Nice, and following the revision and expansion of certain protocols, is in Part One: Principles, Article 3(u), which reads as follows: "For the purposes set out in Article 2, the activities of the Community shall include, as provided in this Treaty and in accordance with the timetable set out therein: (...) measures in the sphere of energy, civil protection and tourism."

Several Commission and Council documents have attached importance to tourism as an instrument for generating employment, but it may readily be agreed that tourism nevertheless has

a very low profile among European policies as a whole, and that it should perhaps be strengthened and expanded in line with the universally accepted strategic importance of tourism at present and, most probably, in the future. A higher profile for tourism in the activities of the EU and of its various institutions and, more clearly, the coordination of all Community policies affecting tourism have been both called for and predicted. For this to happen, more and better data on all aspects of tourism and the way it ties in with other sectors must be available in the future, so that tourism's contribution to the quality of life and social cohesion can be accurately evaluated in both economic and social terms.

Careful attention should also focus on determining the future role of tourism in shaping the Europe which will emerge from the European Convention. There must be initiatives to ensure that tourism and tourism policy are given full recognition in terms of their economic importance and capacity to create employment, their potential contribution to culture and mutual understanding among the peoples of the world, and as a tool for creating a Citizens' Europe.

New forms of tourism which are sustainable in economic, social and environmental terms, and which all parties seek, will be determined by this set of conditions. The special contribution made by sustainable tourism to achieving the strategic objective of the Lisbon summit - "to become the most competitive and dynamic knowledge-based economy in the world, capable of sustainable economic growth with more and better jobs and greater social cohesion" - is generally recognized and must be emphasized.

Against a new, less dynamic economic backdrop in which fewer jobs are being created, the Brussels Council of 20 and 21 March 2003 sought to turn words into actions and ensure that the Union and the Member States live up to their undertakings - "we reaffirm our strong personal commitment to the timely and effective delivery of reforms across the three pillars of the Lisbon strategy - economic, social and environmental".

The Brussels Council established new priorities which, in practical terms, mean giving fresh impetus to entrepreneurship and innovation and strengthening the internal market as a means of enhancing competitiveness and placing it centre stage both within the economy in general and tourism in particular.

Tourism is widely agreed to be of great importance not only economically, but also socially and environmentally, in the European Union and worldwide. Where tourism is already well developed, people count on it to continue being what it has been in the past, a source of wealth creation, high employment and a high quality of life, while people in less-developed areas look to tourism as a potentially crucial means of escaping from poverty, securing economic progress and social development and meeting convergence objectives.

The tourism industry in the European Union comprises some two million businesses, mostly SME's, which account for about 5% of both GDP and employment. This figure varies from 3% to 8% depending on the Member State. Tourism also generates a considerable amount of activity in other sectors, such as the retail trade and specialized equipment, to a level of around one and a half times that of tourism itself. In terms of turnover, over 80% of the tourism undertaken by Europeans concerns individuals or families. The remainder is business tourism, in the broad sense. It varies, depending on the country, from barely 15% to over 30% of the total volume, the highest proportion relating to Nordic Countries. EU households earmark around one eighth of their personal expenditure for tourism-related consumption, a figure which varies relatively little from country to country.

Community tourism is largely domestic. 87% of tourism activity recorded is attributed to its own citizens with only 13 % to visitors from non-member countries. As for the tourism of EU citizens, three-quarters remain within the ED, the remaining quarter going to other parts of Europe and the world.

Tourism is one of the sectors of the European economy with the best outlook. Forecasts indicate a steady growth of tourism in Europe, stronger than the average economic growth. This is due to

factors such as the increase in time for leisure activities and its social importance, together with global economic growth (Beerli, A., & Martin, J. D., 2004).

Over the past few years 100,000 jobs a year have been created in Europe in the hotel and restaurant sectors alone. Europe, with the greatest diversity and density of tourist attractions, is the most visited tourist region in the world. Despite having a lower growth rate than the world average and than certain up-and-coming overseas destinations in particular, the volume of European tourism is expected to double over the next 20 to 25 years, with a net increase, in terms of expenditure and yield, of around 3% per year. Employment will rise by about 15% over the next ten years."

Although tourism is not directly part of common EU policy, a number of European institutions are engaged in measures and actions which affect tourism because of their horizontal nature, or which rely on tourism in order to achieve a range of major EU objectives, including sustainable development, employment, economic and social cohesion, etc.: in other words, a better quality of life for European citizens.

Tourism is a highly complex phenomenon on account of the wide variety of factors which determine its shape, organization and development. Some of the numerous factors interacting with tourism merit close attention: tourists, employment, businesses, social cohesion, stability, culture and heritage, accessibility to persons with disabilities, the environment, peace and solidarity, and the roles of the various players.

2. Tourism and Tourists

Clearly all economic and social activity needs to focus on the individual. Tourism, like any economic activity involving personal, individual and collective relations between peoples, must above all meet the needs of people, as citizens of a nation, European citizens and, ultimately, citizens of the world.

The tourist, as consumer, must be both the beneficiary of services and the source of demand under conditions favorable to the sustainability of tourism and its availability to all (Leiper N., 1990). Various initiatives can be adopted with a view to designing a form of tourism for the future which will meet these requirements.

3. Tourism and Employment

Various large-scale studies have repeatedly highlighted the enormous current impact and the extraordinary potential of tourism as a source of jobs. But in order to turn this into reality, in socially and economically sustainable terms, various conditions have to be met. The fact that tourism is an economic activity fundamentally based on personal services means that any new tourist activity generates new jobs, but tourism can only be high-quality and sustainable if it generates high-quality jobs.

Various initiatives could be adopted with a view to ensuring that in the future tourism is able to generate more and better jobs in tourist enterprises and areas.

3. Tourism and Businesses: Entrepreneurial Competitiveness and Social Responsibility of Businesses

Tourism is fundamentally a complex economic activity, a group of economic services and sectors governed by market rules and based on companies seeking competitiveness, wealth creation, and which ultimately create employment and quality of life for ordinary people, both as users and as workers in the sector (Gross, M. J., & Brown, G., 2006). If this economic activity is to be sustainable, now and in the future, a number of conditions have to be met which can be underpinned by various initiatives.

4. Tourism and Social Cohesion: Impact and Social Balance of Tourist Activity

Tourism is a powerful means of promoting contacts between different peoples, while at the same time generating economic and social well-being in tourist areas. Often, however, social relations in the local population have been affected by a perceived loss of the traditional balance, in the face of an influx of visitors exceeding several times over the number of local residents, and a consequent trend to standardization in products, including tourism products, and in social relations. Developing the potential of tourism in a positive way and reducing the risk of social or cultural disruption is the basis of socially sustainable tourism.

Maintaining socially sustainable tourism, from the point of view of the social cohesion of local areas and people, requires that a number of conditions be met by means of various initiatives.

5. Tourism and Stability: Reducing Seasonal Bias

The seasonality of tourism has been described as the sector's major outstanding issue, in that it is the cause of serious imbalances because it does not continue throughout all the potentially effective periods, with serious consequences for businesses, people employed in tourism, tourist areas, and ultimately tourism's proven capacity to generate wealth and prosperity. Seasonality first and foremost means under-utilization of physical capital (equipment, buildings, infrastructure etc.) as well as human capital, which is idle for much of the year (Smith V.L.). The result is clear: if there is no tourism, sector workers do not get paid and have to seek other activities or else join the ranks of the unemployed during the off-season.

In some cases this period of inactivity is long, in others short; in some cases it is during the winter and in others during the summer, but in almost all cases it will have damaging consequences throughout the year. In all cases the stability of employment, which is a precondition for the quality of employment, is under threat, and in other cases companies' profitability and competitiveness will be compromised by seasonality and consequent loss of revenue, which is a grave threat to the sustainability of employment and to the whole of tourist activity (Hodge R. A., 1996).

6. Tourism, Culture and Heritage

The rich cultural heritage of towns and rural areas throughout Europe is undoubtedly a major attraction for tourists and travellers. The diversity of customs and traditions of Europe's rural areas is also a source of intangible, but very real wealth, which tourism can help preserve and exploit. Some of these intangible cultural values such as craftsmanship, music, oral traditions, customs, languages, dances, rituals, festivals, traditional medicine and remedies, cuisine etc. can form an integral part of some new forms of socially sustainable tourism. Similarly, sporting events are ideally suited to tourism and to the exchange of different values between peoples (Goodwin, H.J. et al., 1997). There are two possible approaches to the relationship between tourism on the one hand and culture and heritage on the other: 1) exploiting the various aspects of this culture and heritage, with tourism as a means of maintaining, preserving and improving them, or 2) destroying these assets through irresponsible consumption. The first option is sustainable, and the second is socially unsustainable.

7. Tourism and Accessibility for People with Disabilities

Tourism has become an extremely important social phenomenon involving millions of people throughout the world, especially in Europe; not only is it an unprecedented force for wealth creation and economic progress, but also a crucial factor in improving knowledge, communication, human relations and mutual respect between different peoples. Tourism is of major benefit to society and should be within everyone's reach, with no sector of the community being excluded whatever their personal, social, economic or other circumstances. People with disabilities - 10% of the total ED population - are becoming more integrated socially and economically and hence participating more and more in tourist activities despite all the

impediments and difficulties which continue to prevent them from accessing tourist facilities and services on a regular and normal basis.

Removing and lessening these barriers is not only a must on grounds of equal rights and opportunities and non-discrimination, as championed by the ED and its Member States, but is also an effective way of including new groups of people in tourism-related activities, thus contributing to the growth of an economic sector which, especially in the southern European countries, has a direct impact on the creation of wealth and jobs in the interests of society as a whole.

8. Tourism and the Environment

In the recent past tourism and the environment have been seen as mutually antagonistic: the wealth generated by tourism was at the expense of the environment, exploitation of the best sites, preferably by the coast or in the mountains, without consideration for such factors as biodiversity, the resources already there, scale or the capacity to absorb development (Dale A., & J. B. Robinson). Faced with a difficult choice between two factors which were - wrongly - presented as mutually exclusive, the general response can be clearly seen from the situation we find ourselves in today: we opted for growth, wealth-creation, even if it meant damaging the environment. And this, paradoxically, in an activity which is based on preserving the attractiveness of nature. This undoubtedly stems from two different ways of looking at things: the short-term vision of immediate real estate profits and the long term vision of a sustainable and competitive industry (Farrell, B. H., 1992). Once again we face the need to establish conditions and initiatives conducive to new forms of environmentally sustainable tourism.

9. Tourism, Peace and Solidarity

Tourism is just the opposite of war. War means the invasion of one country by another, aggression, the destruction of nature and heritage, the humiliation and even death of human beings. Tourism on the other hand means a welcome, interaction, getting to know a place, conserving the environment, wealth - in short, peace and friendship between people. If we only love what we know, tourism, as a means of bringing people closer together, is a force for harmony and peace between nations, cultures, religions and individuals. Democracy and political and socio-economic stability must certainly contribute to this objective, in the countries tourists come from and those they visit.

Understanding between peoples and the promotion of ethical values are at the root of sustainable and responsible tourism; solidarity between peoples can grow from acquaintance as tourists.

10. Tourism and the Players in the Sector

The vast range of stakeholders involved in tourism makes it advisable to differentiate the role each plays in this complex task of defining new forms of sustainable tourism. It is the responsibility of political and institutional policymakers to define the appropriate framework in which new forms of sustainable tourism are possible and can be promoted by means of the full range of instruments at the disposal of the public authorities. The political priorities of this strategy of accessible and sustainable tourism must be geared towards ensuring that tourism is taken into account in all horizontal policies and in all relevant common policy areas.

MAIN DESTINATIONS AND TOURIST FLOWS ON THE YOUTH TRAVEL MARKET

Moisă Claudia Olimpia

“1 Decembrie 1918” University, Alba Iulia, Faculty of Science

Cordoș Mălina

“1 Decembrie 1918” University, Alba Iulia, Faculty of Science

Global tourism has seen an explosion since the ‘60s due to the post-war global economic growth and over the past two decades it recorded a significant increase, youth travel being the main component of this growth. According to experts, this type of tourism is in full evolution, young tourists representing an increasingly important segment of the global tourism market.

Many experts in the tourism industry think youth travel is the fastest growing market segment, and the provisions of the World Tourism Organization estimate that in the near future youth travel will tote up 25% of the worldwide tourism market. On one hand, this phenomenon can be explain through the cultural motivation of the young people in practicing tourism, and on the other, through the relatively low or acceptable costs of transportation, especially for the youth in well developed countries.

Keywords: youth travel, tourist flows, tourist destinations.

JEL codes: L83

More and more young people travel abroad for their vacation, to visit their friends or relatives, to study, for business or for other reasons. For many of them these travels represent their first incursion in foreign countries and are a real adventure. This movement of young people from their residence country towards various tourist destinations generate at global level a multitude of tourist flows that represent the most substantive expression of the tourism activity. Firstly, tourist flows imply a temporary movement of young people in accordance with the size of the demand, the tourist potential of that region, the distance to the chosen destination, the accessibility and prestige of the reception region.

It is difficult to identify the main countries that constitute a travel destination. While statistics for international arrivals are very well documented by the W.T.O. (World Tourism Organization) and by the majority of national tourism organizations, there are very few data about the age of the travelers. The favorite destinations of the youth must be defined by taking into account the worldwide trends in youth travel and the strategy that each country has for its tourism.

According to the W.T.O., Europe and America are the most sought after destinations by the worldwide youth, but despinde this, destinations like Asia, Africa and the Middle East have a growing market share.

According to the 2003 International Student Travel Confederation (I.S.T.C) and Association for Tourism and Leisure Education’s (A.T.L.A.S.) study regarding youth travel „*Today’s Youth Travellers: Tomorrow’s Global Nomads. New Horizons in Independent Youth and Student Travel*” in their „tourist career” youth and students visited many regions all over the world, more than half visited Northern and Southern Europe and over 40% traveled through North America and Eastern Europe.⁶⁸¹ This general situation changed slightly in the last 5 years, so in 2007,

⁶⁸¹ Richards, G., Wilson, J., *Today’s Youth Travellers: Tomorrow’s Global Nomads. New Horizons in Independent Youth and Student Travel*, International Student Travel Confederation, Amsterdam, 2003.

when a study⁶⁸² on the youth travel market was conducted by the World Tourism Organisation in collaboration with the World Youth Student & Educational Travel Confederation –WSYE TC, a modest decrease in the importance of the visited European destinations was recorded, this was largely due to the extension of the surveyed respondents at world-wide level (see figure no. 1). The regions that recorded a significant growth in the number of tourists, such as Southeast Asia and Australasia, probably benefited from a larger global distribution of the respondents in the year when the study was conducted.

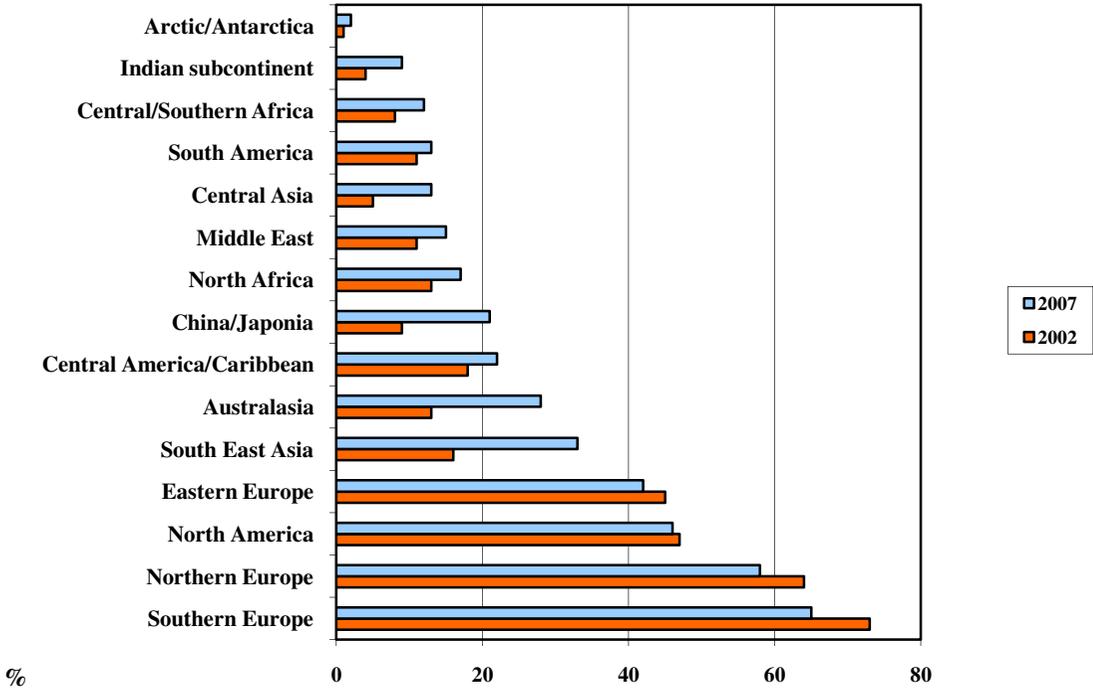

Fig. no. 1 Visited destinations during the “tourist career” in 2007 compared to 2002
 Source: World Tourism Organisation, *Youth travel matters – Understanding the Global Phenomenon of Youth Travel*, Madrid, 2008.

The regions preferred by young people as main destinations in the last major trip taken in 2002 were Northern Europe (30%), South Europe (16%), North America (16%) and Western Europe (8%), followed by Southeast Asia and Australasia (see figure no. 2).

⁶⁸² World Tourism Organisation, *Youth travel matters – Understanding the Global Phenomenon of Youth Travel*, Madrid, 2008.

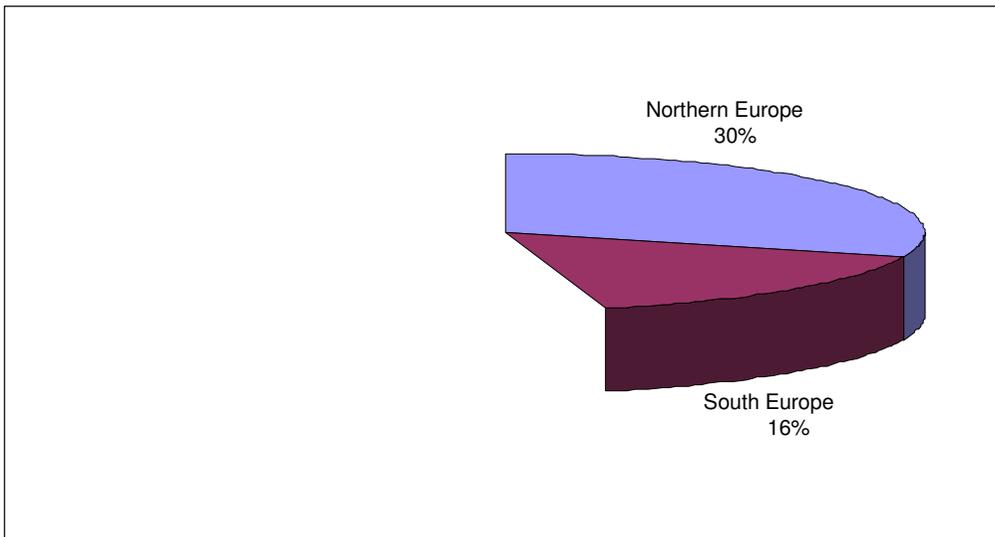

Fig. no. 2 Main tourist destinations preferred by young people in the last major trip taken in 2002

Source: Richards, G., Wilson, J., *Today's Youth Travellers: Tomorrow's Global Nomads. New Horizons in Independent Youth and Student Travel*, International Student Travel Confederation, Amsterdam, 2003.

Youth usually go back to certain tourist destination, in North America the number of tourists who visit this continent for the first time is lower than the number of tourists who return, and over 70% European regions are visited several times. The other tourist regions have a high number of tourists who come for the first time in these countries, especially in the Indian sub-continent (60% come for the first time), South America, South-Eastern Asia and Australasia (approximately 50% of the young travelers come here for the first time). These are destinations that must be seen at least "once in a life time".

The regions that are visited by a larger number of tourists with ages over 26 are South and Central Africa (44%), South and Central America (25%), the Middle East (21%) and South-Eastern Asia (20%) (see figure no. 3). These regions are considered "difficult", and this explains why experienced travelers prefer these destinations, while most young people prefer Europe and North America.

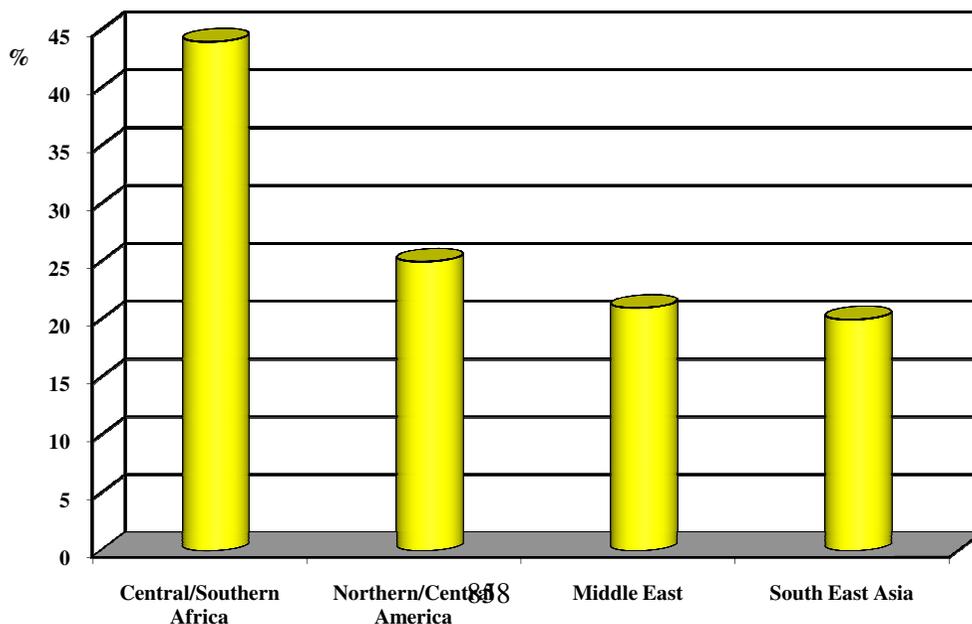

Figure no. 3 Regions frequented by young people over 26 years old

Source: Richards, G., Wilson, J., *Today's Youth Travellers: Tomorrow's Global Nomads. New Horizons in Independent Youth and Student Travel*, International Student Travel Confederation, Amsterdam, 2003.

The desire for more travel is among the most important benefits obtained by young people who visit regions with more “difficult” and more “exotic” tourist destinations, such as Southeast Asia, the Indian sub-continent, Central and South America and Central and South Africa, and *discovering other cultures* represents the least important gain of those who visit Europe and Northern America, which is due to the fact the culture of these regions is among the most globalized and familiar in the world.

Countries considered the most popular destinations on the youth travel market are Australia, United States of America and France, all being visited by over 10% of tourists, followed by Spain, Italy, Germany, Great Britain and Thailand, each with approximately 6% of the youth travel demand. These figures are correlated with statistics regarding international tourist arrivals issued by the World Tourism Organisation, which mentioned France as the main destination of 2006, USA being third.

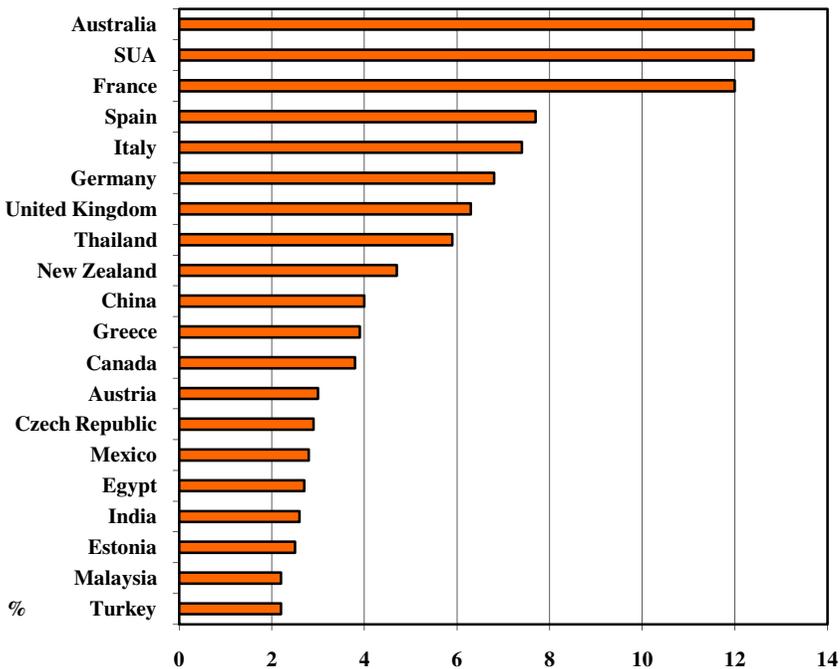

Figure no. 4 The main 20 destinations visited in the last major trip

Note: one trip can cover more than one tourist destination.

Source: Richards, G., *New Horizons II – The Young Independent Traveller 2007*, WYSE Travel Confederation, Amsterdam, 2007.

As mentioned in the paper „*Today's Youth Travellers: Tomorrow's Global Nomads. New Horizons in Independent Youth and Student Travel*”⁶⁸³, some tourist destinations tend to attract certain types of tourists more than others (there are three segments of tourists established on the youth travel market: backpackers, travellers and tourists). Destinations like Southeast Asia,

⁶⁸³ Richards, G., Wilson, J., *Today's Youth Travellers: Tomorrow's Global Nomads. New Horizons in Independent Youth and Student Travel*, International Student Travel Confederation, Amsterdam, 2003.

Australasia and South America are dominated by backpackers, while in North America and in Canada the number of travellers is higher than the number of backpackers, which could be determined by the fact these hikers are integrated in a particular group during their travel.

Among the most popular tourist destinations in 2007, Thailand, New Zealand and Australia are the main destinations for backpackers, who generally chose the ones with well developed infrastructure for youth travel. In contrast, classic tourist destinations from South Europe, such as Turkey, Spain and Greece, tend to attract more young tourists and fewer backpackers. An interesting European destination is Estonia, but because this country recently joined the European Union, it can still be perceived as an adventurous destination for some.

There seems to be a close connection between the development stage of tourism and the travelling style. Relatively “mature” destinations from Northern America and Europe record a lower number of backpackers, while new destinations have a larger number of backpackers. This could be an indicator of the “pioneer” function of young travellers, who are trail blazers for other travellers and young tourists. Backpackers also tend to visit as many countries as possible during their trip, more than any other type of traveller. In the last major trip, a backpacker visited an average of 2.4 countries, compared to 1.8 for hikers and 1.7 for tourists. *At an intra-regional level*, youth visit more different countries, thus: South-Eastern Asia (with 2.4 visited countries), Northern Europe and South America (both with 2.3 visited countries) occupy the first places in youth tourism.

As the tourist’s experience grows, people tend to travel more. Therefore, those who visit Northern Europe have previously made only five major trips compared to the eight made by those who visit Australia, China, Japan, South and Central Africa, and the over ten trips made by those who visit India and South America. This sustains the idea of a „tourist career”, Europeans usually travel first inside Europe, and then to Australasia which is considered their first inter-regional journey and then continue with less known destinations from Asia, Africa and Latin America. Young people build a “tourist career” by starting from “easy” destinations, with the most developed infrastructures for individual tourism, then go to more “adventurous” destinations. In 2007, among the destinations that attracted more experienced tourists were countries like Vietnam, Morocco, South Africa, India and Argentina, while less experienced travellers chose destinations in Europe. Although it is easier to travel to destinations to which there are flight connections or other types of transport, most young people want to avoid “the beaten track” and travel to non-tourist areas. Backpackers tend to travel especially to less visited regions, and travellers try to separate themselves from tourists through their activities at the destination.

The unsafe climate of the last years in certain regions favored some changes in the tourism industry in general and implicitly in youth travel, favoring the *development of new destinations*. For example, in 2008, overall, all the regions recorded positive results, with the exception of Europe, which saw a stagnation in the number of international arrivals. The best results belonged to Middle East (+11%), Africa (+5%) and the two Americas (+4%)⁶⁸⁴. The evolution of the “number of arrivals” indicator was negative in the last six months of 2008 both in Europe (-3%) and Asia (-3%). The two Americas (+1%), Africa (+4%) and Middle East (+5%) recorded positive results even in the second half of 2008, although the increase was much slower compared to the January-July period. The negative trend in international tourism, which manifested in the second half of 2008, grew in 2009 under the impact of the global economic crisis combined with the effects of the A(H1N1) epidemic that started in the spring of 2009. Based on the preliminary statistics collected from 140 countries of destination, compared to the same period of last year, it is estimated that world-wide international arrivals dropped by 7% in

⁶⁸⁴ UNWTO, *International Tourism Challenged by Deteriorating World Economy*, Tourism Directory 05/10/2009, <http://www.directorytourism.com>. (last accessed in 13.01.2010)

the January-July 2009 period⁶⁸⁵. In absolute terms, the global number of international arrivals reached 500 million in the first seven months of 2009, dropping from 540 million in the same period of 2008, placing this indicator at the level recorded in 2007 and 2006.

Solitary young travelers chose non-traditional destinations and are known as pioneers in this field, while youth groups tend to be more conservative when choosing a destination. They go to traditional regions, especially for their international travels, and are attracted to new destinations only through an organized event. Since estimating that these young travellers represents up to 25% of the total travelling population, the growing interest regarding new tourist regions partially reflects the spreading of the models determined by young tourists.

The tourism market is also confronting with growing competition on the global youth travel market in the sense that if established western European markets like Spain, France, Germany, Great Britain, etc., have always been preferred by young people, in the 1990-2000 period, new destinations appeared, such as Australia and Thailand, as leaders in the preferences of young travellers around the world. After 2000, new destinations, like Brazil and England, launched aggressive promotional campaigns directed at young people, which have impressive results.

A recent study of the Quebec University identified five countries as the main destinations in youth travel: Australia, France, New Zealand, Thailand and England⁶⁸⁶. All these countries identified young travelers as being an essential market segment, one that brings an important income. *Australia*, one of the leaders in youth travel, organized aggressive integrated marketing campaigns combined with other initiatives, like introducing a unique visa for the “work & travel” programs which led to attracting young people to Australasia. *New Zealand* and *England* also attract a large number of solitary young travelers with the help of promotional campaigns like: adventure tourism, cultural tourism, rest and relaxation tourism, offering accommodation services at a reasonable price and flexible work/study/travel programs. *France* successfully promoted cultural experiences and youth hostels, especially through-out young people in Europe. *Thailand* makes efforts to promote itself as a safe destination for solitary travelers, stimulating organized groups to discover the Thailand’s culture. Experts consider Germany, U.S.A and Canada as important destinations for youth travel, but none of these countries have launched marketing campaigns for the youth travel market.

The fastest growing segment on the youth travel market is represented by the young people who combine traveling with working. The majority of these young tourists take advantage of governmental programs and/or of flexible visas that allow them to work in the countries they visit, with the purpose of covering some of the expenses. United States of America are the favorite destination of most students that work and travel, followed by Australia, England and Canada.

Tourist destinations are influenced by the tourist’s country of origin, because it is clear that people usually travel first in their own country. Europe is visited by 50% of the Europeans, North America by almost 50% and the other regions by less than 20%.

As to the geographical distribution of the international youth travel, there is a concentration in the northern countries that are well developed. There are significant differences in the tourist flows, thus:

- *Canadians* visit Northern Europe and Northern America, representing also the largest number of tourist who visits Central America;
- the main destinations for young people from *South Africa* are almost exclusively North America and South Europe, with the exception of a small part who visits the Indian sub-continent and their region of residence;

⁶⁸⁵ UNWTO, *UNWTO World Tourism Barometer*, Volume 7, No. 1, January 2009, Madrid.

⁶⁸⁶ Regroupement Tourisme Jeunesse, *Étude de produits et de marchés - Le tourisme jeunesse au Québec*, Montréal, 2001.

- *English* people usually travel inside Northern and Southern Europe, but also to North America; they are among the youth that visits Central and South Africa, China and Japan;
- *Swedish* people visit in a high number destinations from Northern Europe, Southern Europe and North America, but they also visit the south-east part of Asia and Western Europe;
- the young people from *Hong Kong* more and more tend to visit Northern Europe, but also China and Japan; they also record a high number of visits to Australasia because of the geographical proximity of these two regions.

The youth travel market is still dominated by the industrialized countries in Europe, North America and the Southeast Asia, and countries like India, China or the ones in South America have a great potential to develop this form of tourism, although the development of these markets seems to be rather slow.

ICT ADOPTION – A NECESSITY FOR ROMANIAN SMES

Negruşa Adina Letiţia
Babes-Bolyai University Cluj-Napoca
Faculty of Business

Gică Oana Adriana
Babes-Bolyai University Cluj-Napoca
Faculty of Business

In today's global economy the use of ICTs technologies is key for achieving growth and competitiveness. Business can use ICT in their relationship with suppliers or customers, to process accounts, to manage the internal processes or to file taxes. Our paper is concerned with studying the use of ICT in Romanian companies in general and especially in Transylvanian SMEs. We conducted a survey among the Transylvanian SMEs with regard to their level of endowment with computers, the number of staff working full-time in IT, the activities that imply computers, the ability to process information, to plan and solve problems using computers.

Keywords: ICT, SMEs, Romania, Transylvania

JEL Classification: M15

1. Introduction

Information and communication technologies (ICT) are changing the whole perception of development, pushing forward the frontiers of communications, medicine, agriculture, energy and sources of growth which altogether are enhancing productivity and competitiveness of nations and helping them achieve higher living standards for their people. The use of ICT and technology has affected every aspect of business, transforming not only the way that business is conducted but also creating new business sectors and jobs.

There is a large consensus among scholars and policymakers that the adequate use of information and communication technology increases the competitiveness of employees and strengthens the position of companies in the global economy [8]. Due to advances in computer technology, the declining cost of systems and improved software and technological sophistication of the workforce, no longer are adaptations reserved for the technologically elite, which results in opportunities for innovation in the small firm. Also, the more flexible managerial capabilities of SMEs dictate the extent of success of IT adoption and the resulting positive effects on financial performance [5]. For this reason, smaller firms should be able to more effectively utilize IT to exploit newer technologies than their larger, less agile competitors [13].

2. ICT adoption in EU and Romanian businesses

The number of EU enterprises (with 10 or more full-time employees) that accessed the Internet using a broadband connection registered a significant growth of 37% up to 83% from 2004 to 2009. In Romania the percentage of enterprises using broadband connection to Internet was at 50% of the EU average with a 41 % in 2009. 73% of Romanian enterprises had access to the Internet in 2009 when compared to European Union countries where the percentage was 94%. The highest percentage growth of firms that had access to the Internet between 2004 and 2009 was recorded in the range of small businesses from 45% to 69%. However this percentage is below the EU average by 25%.

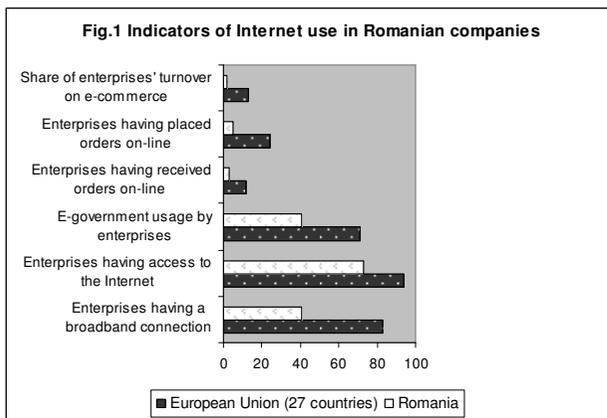

Around three quarters (71%) of EU enterprises used e-government services: the majority to obtain information and to download forms (65 % and 64 % respectively), while 55 % of

enterprises returned filled-in forms using e-government services. In 2009, in Romania, 41 % of the enterprises used e-government services mainly to obtain information (40%).

Between 2007 and 2009, in the EU, the percentage of enterprises that received orders online, decreased from 15% to 12%. In Romania this indicator maintained it's value at 3% well below the European average during this three year period. The proportion of enterprises that used the Internet to place orders to purchase goods or services decreased registered a 5% decrease to 24% between 2007 and 2009. Across the Member States, the general pattern shows a considerably higher proportion of enterprises have made purchases online, when compared to those that have received orders online (probably reflecting the greater complexity of setting up an online selling system as compared with making purchases). Romania is an exception from this pattern, the proportion of companies that have purchase goods via Internet being only with 2% higher than the percentage of enterprises that have received order online.

In 2009, in the EU, the proportion of total turnover accounted for by e-commerce via the Internet equated to 13 %. The percentage of enterprises' total turnover from E-commerce via Internet, in Romania was only 2.

The total value of the ICT market in Europe was EUR 785.7 billion in 2007, representing 6% of total GDP. The IT market (hardware, software and services) amounted to EUR 355.3 billion, while the telecommunications market represented a total value of EUR 435.6 billion.

According to a study made yearly by the Swiss organization, World Economic Forum, which evaluates how well prepared a country is to participate in the network economy by benefiting from the ICT advantages, Romania ranks for 2009-2010 at 59th position in the world, among a total of 133 countries. The Network Readiness Index is formed by points awarded for market environment, telecommunication infrastructure, law and regulations, availability and usage of Information technologies by individual

users, companies and government and public institutions.

The main motives for this low level of Romanian's Index are effectiveness and efficiency of legal framework, availability of latest technologies, companies spending on R&D and insufficiently developed infrastructure.

If we take into account that 99% from the total firms are SMEs results from this report that they are not competitive mainly due to IT infrastructure. It is obvious that Romanian SMEs are ignoring the advantages offer by new technologies or do not investing in this direction. Also the impact of the new technologies on sales still represents an insignificant percentage [23].

Some Romanian researchers identified that the most SMEs apply to small extent IT infrastructure to run business, being also a problem of mentality at managerial level and behavior culture at human resources [7]. The most purchased computer software products and applications by SMEs are those for accounting, financial and remuneration activities, those related to sales, purchasing, etc. are less implemented. Even in situations when SMEs buy IT systems for the entire departments or activities, share applications of integrated Enterprise resource Planning (ERP) is very low.

3. Research method and results

3.1. Research method

Our paper is concerned with studying the use of ICT in Romanian companies in general and especially Transylvanian SMEs. In order to describe the use of ICT by Romanian companies when compared to the countries of European Union we used secondary data from Eurostat.

For a better understanding of the Transylvania SME's attitude regarding the use of ICT we developed a quantitative study and utilized a survey research design. A structured questionnaire was developed to obtain information about SMEs ICT usage between November-December 2008. Data were collected by way of a self-administered questionnaire with the study sample comprising a number of 350 SMEs from Transylvania Region, which has been chosen using the lists of the Chamber of Commerce and Industry. The firms chosen varied by size, field of activity and number of employees. A total number of 257 completed and usable questionnaires were obtained, indicating 73.43% rate of response.

3.2. Sample characteristics

The descriptive analysis of the demographic characteristics of the SMEs is presented in Tabel 1. By size almost 14% from the firms are micro enterprises and an equal number come in the other two categories small and medium enterprises with 43 ponder.

A percent of 49.8 of the SME's are production enterprises, 25.68 % are service companies and 24.52 % are commerce enterprises.

Table 1 The structure of enterprises based on activity and number of employees

Number of employees	Main field of activity		
	<i>Production</i>	<i>Services</i>	<i>Commerce</i>
1-9	1.6%	30.3%	20.6%
10-49	39.1%	31.8%	63.5%
50-250	59.4%	37.9%	15.9%

The vast majority of the investigated SME's were founded in 1992-1996 regardless they were micro, small or medium enterprises.

3.3. Results

We start analyze with investigation about usage behavior of ICT in different aspects of their routine business activity. The results of the study show that SMEs did not developed internal technological systems for communication, 60% of the enterprises do not have Intranet network, due to their small number of employees which give the opportunity of face-to-face communication. The ICT infrastructure is well developed if we take into account the average number of work places equipped with computers of 7.33

An average of 34 % of the internal and external correspondence is conducted via E-mail.

Table 2 Mode of conducting the correspondence

	Minim	Maxim	Mean	Std. Dev.
Percentage of internal and external correspondence is done traditionally	0	100	70.723	28.97
Percentage of internal and external correspondence is done by E-mail	0	100	34.192	29.60

Investigated companies use most information technology in domains such as: accounting and financing (32%), administration (16%) and sales (14%). The less application of IT is surprisingly in R&D. This may be an explanation for the low development of this kind of activities for the SMEs. Also the number of R&D employees working full-time in IT is very small (Mean=0.81). One-way ANOVA was conducted to examine whether average number of employees in IT field differ significantly by main field of SMEs activity.

The ANOVA Test showed that there was no significant difference between the average number of employees in the IT field based on business ($F=1.033$, $p=0.357 > 0.05$).

Knowing that ICT field has a rapid rate of development and obsolete we questioned the companies whether they can keep up with the most advanced technical/technological trends regarding the application of information technology. More than 60% of the SMEs declared they use an average level technology and only 9% use advanced IT technologies. While services SMEs are the ones that use advanced IT technologies the less advanced technologies are used in production sector.

The results show a statistically significant link (Chi Square = 47.648, $df=6$, $p=0.000 < 0.1$) about average intensity (Contingency Coefficient = 0.395, $p=0.000 < 0.01$) between the main field of

activity and the level of IT technologies adopted by the enterprises. That means SMEs from service field are more orientated toward ICT novelty comparing with those activated in production. We also investigate the correlation between firm size and development level of IT technology used. Small enterprises are the ones that use more leader technologies while the micro companies use a low level IT technology (Chi Square = 12.405, $p=0.015 < 0.05$) but was not identified a correlation (either positive or negative) between the two variables (Spearman $\rho = -0.108$, $p=0.131 > 0.05$).

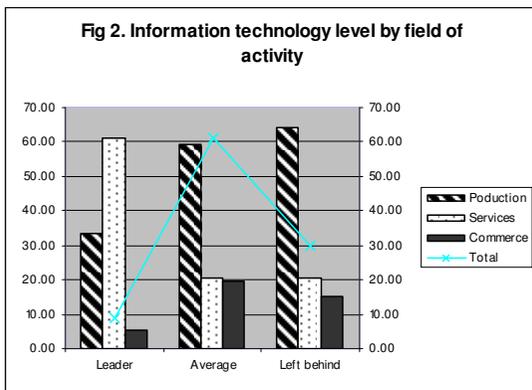

Table 3. Information technology level by company's dimension

	Leader (%)	Medium (%)	Left Behind (%)
Number of employees			
1-9	4.17	41.67	54.17
10-49	13.79	57.47	28.74
50-249	5.75	70.11	24.14

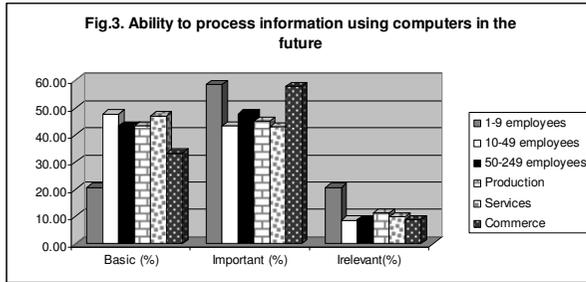

Regardless the SMEs capacity to meet the modern and actual need to process information with the help of computers resulted for more that 58% at satisfactory level. This result gives us the idea of an IT infrastructure that enables employees to be more productive and accomplish easier their work tasks due to computer using technology in data gathering and analyzing. We tested the correlations between level of this capacity of SMEs and field of their activity and size. It was not finding any significant links between, but results a higher ponders of unsatisfactory level for micro enterprises.

Another important advantage for SMEs related to computer using is the ability to plan and solve strategic aspects in their business activity coordination. Regarding to this ability the ponder of satisfactory level it is of 51%, that means only half of the firms consider that their IT technology infrastructure is appropriate for planning their business activities.

Table 4 Ability to plan and solve problems using the computer

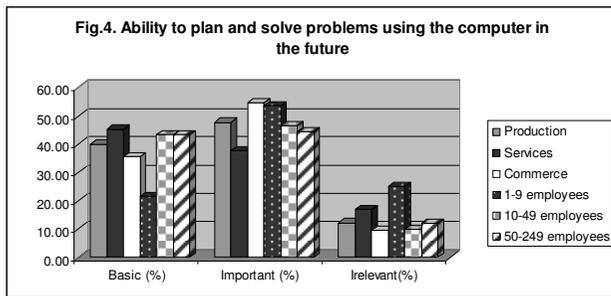

Number of employees	Satisfactory (%)	Partial (%)	Unsatisfactory (%)
1-9	37.50	25.00	37.50
10-49	52.27	32.95	14.77
50-249	54.65	33.72	11.63

However it was identified a link between company's ability to plan and solve problems using the computer and it's size (Chi Square=9.511, $p=0.049 < 0.05$) without being able to establish a correlation between the two variables.

Both micro enterprises and medium firms consider the ability to analyze information using computer important from the perspective of the future. Small firms consider this skill as a basic one. Most companies that consider these skills important for the future of the company are those in trade, while this ability is considered a basic one by most services

firms. Most companies that consider it irrelevant are acting in the field of production.

The ability to plan and solve problems using computer is considered a basic one by the companies in the field of services and by the small and medium enterprises and an important one by commerce firms and by the most of micro-enterprises. The most companies that indicated this ability to be irrelevant are services companies and micro firms.

The analysis of collected data revealed the existence of a very strong direct correlation between the ability to use computers in planning and solving problems level of modernity and the importance given to these skills in the company's future prospects (Spearman Correlation =0.543 > 0.5 , approx sig = 0.0 < 0.05). Also a direct correlation of the average intensity has been identified between the ability to process information with the help of computers level of modernity and the importance given to this skill in the future company's perspectives (Spearman Correlation =0.493, approx sig = 0.0 < 0.05). This implies unfortunately that the companies that consider these abilities level of modernity unsatisfactory also consider them to be irrelevant in the future.

4 Conclusion

ICT adoption is likely to stimulate the extensive and intensive development of both production and services companies. Regarding the extensive development, ICT offers an opportunity for Romanian companies to access new markets, regionally and globally, and to promote and sell products and domestic services electronically. Intensive development consists in lower production, administration and sales costs, due to the use of ICT, which can result in a significant increase of productivity of the factors used. The use of ICT affects firm performance primarily when accompanied by other changes and investments and without these, the economic impact of ICT

may be limited, so complementary investments in skills, organisational change and innovation are key to making ICT work,

L'AUGMENTATION DE LA RESPONSABILITÉ SOCIALE DES ENTREPRISES DE TOURISME DANS LE CONTEXTE DE LA CRISE ECONOMIQUE MONDIALE

NICULA Virgil

Faculté de Sciences Economiques

L'Université "Lucian Blaga" Sibiu, Romania

Corporate Social Responsibility has become a key concept in modern corporate culture. This paper presents the results of an exclusive consumer survey on the willingness to pay for CSR, as well as best practices from other industries and precise suggestions for the implementation and monitoring of CSR in the travel industry. The concept of CSR was introduced in Germany in the mid-1990s. Since then, the idea has prolifically developed in all directions and enjoyed a rapid rise in popularity. Measures to improve the situation at the holiday destination were also strongly supported. As regards the services on offer, guests turned their attention mainly to security in hotels, information for guests about travel safety as well as monitoring the security situation in the country of travel.

Mots clé: responsabilité sociale des entreprises, responsabilité sociale du secteur touristique, la crise économique

JEL Classification: L83, M14, L21

1. Introduction

La responsabilité sociale des entreprises, a maintenant atteint le tourisme. La responsabilité sociale des entreprises est devenu le concept-clé d'une nouvelle culture de l'entreprise. La responsabilité sociale des entreprises, tel est le plus petit consensus commun pour le terme anglophone complexe que les économistes ont forgé aux Etats- Unis il y a plus de 50 ans pour décrire les concepts du comportement responsable des chefs d'entreprise. Mais ce n'est que dans les années 90 que le terme RSE a également été introduit en Allemagne. Depuis, „il prolifère dans toutes les directions" (comme l'a publié l'hebdomadaire allemand Die Zeit) et a rapidement fait carrière. Il y a deux ans encore, une recherche sur Google ne livrait «que» 1,3 million résultats pour «Corporate Social Responsibility», actuellement il y en a 20,5 millions.

Dans son livre vert de 2001, la Commission Européenne donne la définition suivante: „La RSE est l'intégration volontaire par les entreprises de préoccupations sociales et environnementales à leurs activités et leurs relations avec leurs parties prenantes (stakeholder)". La Commission Européenne souligne non seulement la nature volontaire mais aussi la focalisation sur les activités principales d'une entreprise. De plus, c'est un consensus, à quelques détails près, que la RSE ne doit ni remplacer les dispositions légales et les conventions collectives de travail, ni libérer l'entreprise de son obligation de respecter les normes internationales, comme les Droits de l'homme ou les normes de travail de l'Organisation Internationale du Travail.

2. La responsabilité sociale des entreprises et la crise mondiale

La vague RSE a été mise en branle et a entraîné la création de réseaux d'entreprises, comme ecosense et le Forum du développement durable de l'économie allemande. L'Association fédérale des organisations patronales allemandes et l'Union fédérale de l'industrie allemande ont fondé le portail Internet csr-germany.com. Les rankings et les classements mesurent l'engagement des entreprises en matière de RSE. Mais ce ne sont pas seulement les entreprises qui participaient aux débats concernant la RSE, mais aussi les acteurs de l'Etat, des syndicats, de la science et de la

société. Le ministère fédéral du Travail a par exemple constitué récemment un forum avec 40 représentants des groupes socialement importants, dans l'objectif de conseiller le gouvernement fédéral pour toutes questions concernant le développement d'une stratégie RSE nationale. Par ailleurs, des organismes s'engagent dans le réseau CorA (Corporate Accountability) pour qu'il y ait des régularisations étatiques obligatoires.

De nombreuses entreprises ont un chargé RSE et publient des rapports de durabilité ou relatifs à la RSE. L'éventail de l'engagement va du sponsoring d'événements culturels et sportifs jusqu'aux projets pour les enfants de la rue en passant par la plantation d'arbres pour la protection du climat, par les dons et les galas de bienfaisance. Les critiques considèrent que de telles activités reflètent certes l'engagement en matière de citoyenneté d'entreprise (corporate citizenship) mais ne touchent souvent pas les activités principales. Si l'engagement RSE devait être plus qu'un simple instrument de marketing astucieux et ne pas seulement servir à améliorer l'image et la réputation d'une entreprise, alors une politique RSE crédible – selon le ministère fédéral allemand de l'Environnement, de la Protection de la nature et de la Sécurité des réacteurs – devrait englober les champs d'action suivants: „la protection de l'environnement au sein de l'entreprise, la prise en considération des intérêts des salariés, le respect de la protection de l'environnement et des conditions de travail conformes à la dignité humaine dans la chaîne de sous-traitance, une politique de produits intégrée et la protection des consommateurs". La RSE repose sur la combinaison de la compétence technologique et de la compétence sociale. Grâce à des véhicules attractifs qui consomment peu d'énergie, nous contribuons à la mobilité durable". Le dialogue avec les parties prenantes (stakeholder) fait également partie de la stratégie RSE. Outre des questions sur la définition et la stratégie, on se pose aujourd'hui des questions sur la responsabilité sociale des entreprises. Et certaines entreprises sont confrontées avec l'opinion publique parce qu'elles négligent leur responsabilité sociale (corruption, changements climatiques, travail des enfants). Les gouvernements, les médias et les organisations de citoyens font pression sur ces entreprises qui subissent des baisses douloureuses de leur chiffre d'affaires et la dégradation de leur réputation.

A cause de ces expériences et vu la crise financière actuelle qui a énormément troublé la confiance des citoyens portée aux entreprises et aux élites économiques, ce sont „outre des motifs philanthropiques et communicatifs, de plus en plus des questions stratégiques de la minimalisation des risques sociaux résultant des propres activités qui sont au premier plan" pour la gestion pratique RSE au sein des entreprises (étude des agences de conseil Pleon et IFOK). La RSE est logiquement aussi une gestion du risque, parce que celui qui pratique la prévention des risques doit développer une politique stratégique RSE, il doit construire un 'système de radar' pour repérer les futurs risques écologiques, sociaux et politiques.

Qu'en est-il maintenant de la responsabilité sociale du secteur touristique? Suite à la discussion sur les changements climatiques d'un côté et le commerce équitable de l'autre, de plus en plus d'entreprises proposent des „voyages durables" et promettent d'agir „socialement" et „écologiquement" avec responsabilité. A qui les clients peuvent-ils faire vraiment crédit? Comment peuvent-ils reconnaître les offres véritablement durables? Comparé à d'autres secteurs, le thème RSE, telle est l'estimation de tous les experts, est à quelques détails près encore terra incognita dans le secteur du tourisme. Jusqu'à présent, les stratégies de la RSE sont plutôt exceptionnelles, les rapports RSE probants sont une denrée rare, et ce sont plutôt des actions ad hoc isolées qui sont vendues comme des bonnes actions, et des projets sociaux et écologiques comme des mesures RSE. Mais la RSE dans le tourisme devrait signifier que les activités principales des entreprises touristiques soient socialement et écologiquement responsables et qu'elles soient transparentes pour que l'on sache comment et à quelles conditions le produit „voyage", qui est un assemblage de nombreux éléments d'une chaîne de valeur complexe, est réalisé. Il ne s'agit pas seulement de savoir si une entreprise réalise des bénéfices, mais surtout à quelles conditions ces bénéfices ont été gagnés.

La RSE joue un rôle décisif dans le développement durable pour une stratégie d'entreprise axée sur le rendement qui tient compte des exigences écologiques et sociales. Cela signifie, qu'outre la motivation et la promotion du personnel ainsi que le dialogue continu avec les parties prenantes, qu'il faut utiliser en personne responsable les ressources naturelles et l'environnement de nos sites et des destinations touristiques, développer et améliorer sans cesse des systèmes de gestion écologique, intégrer la qualité écologique et la qualité du produit. Dans les grands groupes industriels, ce sont les départements du marketing qui rédigent les rapports de la RSE. Le grand désavantage est qu'il n'est pas possible de comparer les rapports relatifs à la durabilité et qu'il n'existe pas une autorité externe pour en contrôler les contenus.

Le Forum Anders Reisen et tous les membres de FAR se sont certes engagés à respecter le tourisme durable avec un catalogue détaillé de critères. Par conséquent, aucun voyageur n'est en mesure de respecter tous les critères dans la pratique. C'est surtout pour le „critère vol" qu'il y a toujours des écarts (par exemple, pas de vol de plus de 2 000 kilomètres pour un séjour de moins de 14 jours). Les conséquences: des conflits au sein de l'association, pression venant de l'extérieur, diminution de la crédibilité. Pour le Forum Anders Reisen, il n'y a qu'une seule solution pour sortir de ce dilemme: doit livrer la preuve du travail de durabilité par des critères mesurables et vérifiables. Tout d'abord, les entreprises membres relèvent elles-mêmes des données relatives à toute leur chaîne de prestations, ces données sont ensuite représentées et notées dans dix indicateurs principaux; ces indicateurs-clés sont par exemple les émissions de CO₂ par hôte/jour, le taux de la chaîne de valeur locale, l'index de satisfaction des coopérateurs ainsi que l'index de durabilité des hébergements et des agences partenaires. Un expert externe indépendant examine le rapport RSE qui contient un programme d'amélioration constitutive (mesures pour améliorer les performances de durabilité). Si le résultat est positif, le voyageur obtient le certificat de qualité „CRS certified tourism" décerné pour la responsabilité de l'entreprise. Les premiers certificats RSE seront décernés pendant l'ITB Berlin 2010 à 20 membres du Forum Anders Reisen. La certification externe n'est pas seulement un instrument de marketing et un gain pour l'image de l'entreprise, mais surtout une caractéristique positive pour se distinguer des autres organisateurs qui simulent leur durabilité.

Le Forum Anders Reisen a décidé que le rapport RSE sera obligatoire avant l'année prochaine pour tous les membres. Ensuite, il y aura assez de valeurs empiriques pour effectuer une analyse comparative RSE (benchmarking) ce qui permettra de comparer les entreprises avec les indicateurs Benchmark spécifiques au secteur. En ce qui concerne la responsabilité sociale dans le tourisme, les organisateurs de voyages déjà certifiés ont beaucoup d'avance sur les autres entreprises du secteur. Mais on ne peut actuellement pas prévoir si la preuve de la durabilité apportera l'avantage compétitif espéré et des avantages sur le marché.

Le rapport RSE standard pour les organisateurs de voyages est le premier standard de ce genre dans le tourisme. En ce qui concerne les structures et les indices, l'équipe de spécialistes a misé sur les standards des systèmes de gestion internationaux EMAS et ISO, en ce qui concerne les renditions de comptes RSE elle a misé sur la Global Reporting Initiative. Mais quelles sont les chances pour que les grandes entreprises acceptent ce procédé? La conseillère de la RSE met en évidence que le rapport RSE n'est pas seulement limité aux petites et moyennes entreprises. Les grands consortiums comme TUI, Thomas Cook et REWE Touristik pourraient eux aussi y être soumis, car ces voyageurs avec leurs grandes équipes qui ont déjà la certification EMAS ou une gestion de la qualité, possèdent pour cela les capacités en personnel et financières.

Naturellement, la RSE dans le tourisme a également une dimension internationale, par exemple dans la protection des enfants. Dans le monde entier, 800 entreprises touristiques (voyageurs, chaînes hôtelières, agences réceptives) ont jusqu'à présent signé le code de comportement visant à protéger les enfants de l'exploitation sexuelle dans le tourisme. Cependant, il est difficile de faire une évaluation régulière et sérieuse des rapports annuels des entreprises participantes. La protection des enfants soit intégrée comme critère dans les deux plus importants livres de normes

internationaux de la responsabilité sociale: dans les préceptes de l'OCDE pour les entreprises multinationales et dans le Pacte Mondial (Global Compact) des Nations Unies.

Et les consommateurs? On dit dans le secteur touristique que les vacanciers s'intéressent de plus en plus aux impacts de leurs voyages sur l'environnement et sur la société. Mais est-ce que c'est vrai? Quelle importance a la responsabilité sociale des organisateurs de voyages ainsi que l'écocompatibilité et la compatibilité sociale des offres touristiques pour les vacanciers?

L'application des standards sociaux et écologiques par les organisateurs de voyages, par les compagnies aériennes et par les hôtels est un critère de qualité important pour les consommateurs.

Les vacanciers considèrent qu'un maniement précautionneux de l'environnement, la sécurité à l'arrivée et pendant le séjour, ainsi que la préservation des Droits de l'homme dans la destination, sont très importants.

Les mesures pour améliorer la situation dans les destinations ont également été très préconisées. Les mesures de protection de la nature et les actions contre l'exploitation et la prostitution des enfants dans les destinations, mais aussi le respect des standards de sécurité pour les employés des hôtels sont particulièrement importantes pour la grande majorité des vacanciers. Dans le secteur des prestations proposées, les touristes accordent beaucoup d'importance à la sécurité dans les hôtels, à l'information des voyageurs sur la sécurité des voyages ainsi qu'au contrôle de la sécurité des destinations. Aucun consommateur ne va réserver un voyage en raison des aspects de la RSE. Cependant, les mesures dans le secteur de la RSE peuvent tout à fait aider à faire son choix parmi les différentes alternatives et à se décider pour ou contre une destination ou un organisateur de voyages.

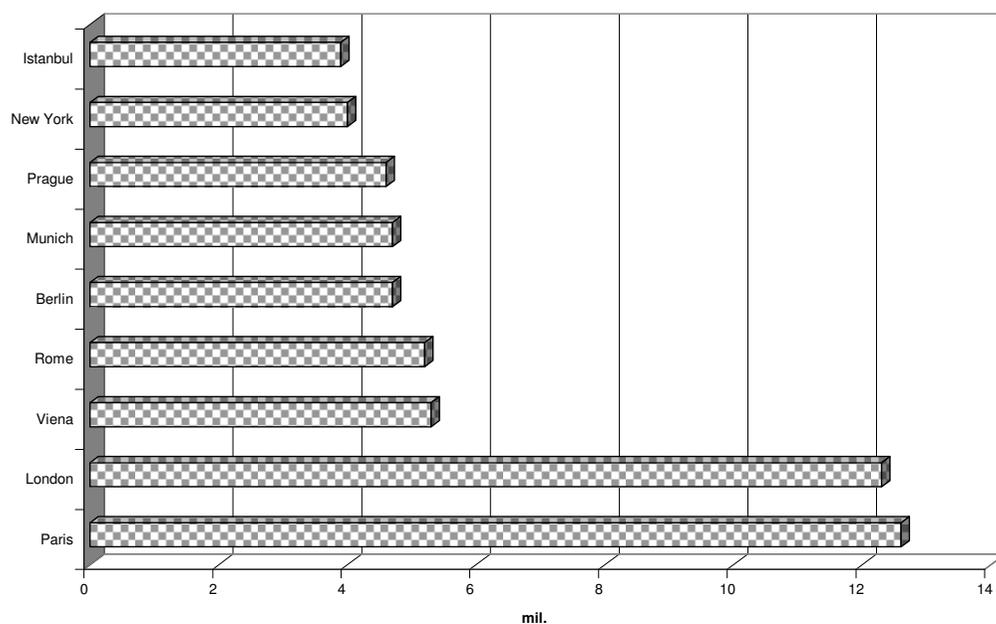

Figure 1. Les destinations favorites des européens (2009)

Source: IPK International, 2010

On parlera de la responsabilité sociale concernant les voyages d'affaires et d'agrément, elles sont devenues habituelles pour un bon nombre d'entre nous. Mais allons-nous encore avoir les moyens de nous payer des vacances demain?

Quels moyens de transport seront les plus touchés? Les touristes s'orienteront-ils ailleurs? Doit-on s'attendre à ce qu'ils renoncent à prendre l'avion? Où éviteront-ils seulement de faire des longs

trajets? Allons-nous bientôt connaître une nouvelle popularité du train et de l'autocar? Va-t-il y avoir une tendance vers l'automobile comme moyen de transport et des vacances dans des destinations proches? Les voyages en voiture vont-ils être l'ancienne/la nouvelle option de l'année 2010? Faut-il être pessimiste? Doit-on craindre que la mobilité sera sacrifiée et que la demande des produits touristiques s'effondre?

Telles sont les questions que se posent et des experts du secteur touristique discutent sur les conséquences qu'ont les prix volatiles du pétrole pour la mobilité.

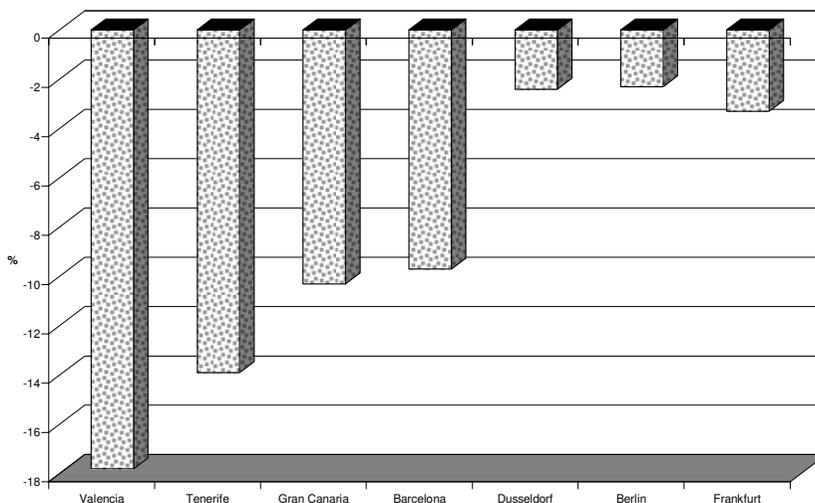

Figure 2. Quelques aéroports affectée par la crise mondiale

Source: IPK International, 2010

Actuellement, le monde traverse la plus grande récession depuis la seconde guerre mondiale et il ne veut pas risquer d'établir plus qu'une estimation prudente sur la fin possible de cette récession. Il est d'avis que les prévisions pour l'économie mondiale resteront sombres au moins jusqu'en 2010. 36 heures en septembre 2008 ont modifié le monde. Avec l'effondrement de l'Investment Bank Lehman Brothers, la raréfaction des crédits est devenue une crise financière mondiale. Cette situation est nouvelle pour tout le monde. Les modèles mis en place par les instituts financiers concernés ne garantissent cependant pas qu'ils seront rentables à moyen et à long terme. Il n'y a pas eu d'autres alternatives. Il a fallu agir tout de suite pour préserver la stabilité du système. Voilà la chronologie des faits comme suit: la crise financière a commencé avec la bulle de l'immobilier américaine; elle a éclaté et a entraîné l'industrie du bâtiment dans l'abîme. Puis la crise a englobé d'autres secteurs économiques, entre autres le secteur automobile et le secteur électronique. Entre-temps, les sous-traitants sont également touchés. Il n'y s'agit ici d'un phénomène passager et éphémère, au contraire nous sommes confrontés à un problème qui va durer. La récession va durer jusqu'en 2010. Le déficit de la demande mondiale est une conséquence de la crise du crédit. Là où la bulle du secteur immobilier a éclaté, cela va durer quelques années avant que les capacités actuellement excédentaires soient réduites. Il compte sur une période d'au moins trois ans pour les Etats-Unis. En Grande-Bretagne il faut compter plutôt sur cinq ans. Il faudra avoir encore plus de patience au Portugal et en Espagne à cause de la stagnation de la population.

Le Président américain Obama suivra une politique économique très keynésienne, et cependant l'économie américaine profitera de la nouvelle politique avec du retard. Le pays devra donc faire face on 2010 à une nouvelle année de récession catastrophique.

En Grande-Bretagne, les consommateurs ont tendance à être très prudents. C'est pour cette raison que le fisc ne devrait rembourser de l'argent que si cet argent est reversé dans le circuit

économique. En raison de la „situation keynésienne", c'est-à-dire vu le gros déficit de la demande, les Etats de l'Union européenne auraient dû prendre des mesures semblables. Ils peuvent le faire encore. L'économie japonaise représente un des grands problèmes. Le Japon traverse „une dépression". Comme le besoin des consommateurs japonais est saturé et qu'il n'est pas nécessaire d'améliorer l'infrastructure déjà très développée, il ne reste, comme moyen politique anticyclique, qu'à investir des deniers publics dans les pays en développement et les nouveaux pays industrialisés limitrophes pour que ceux-ci achètent des biens au Japon. Les jours de la globalisation et de l'économie de marché soient comptés.

Pour vraiment réactiver la globalisation, il faut rétablir la confiance et la paix entre les nations et les religions. Les consommateurs se doutent déjà de ce qui les attend dans la crise mondiale. Ils ont peur pour leur place de travail et leurs épargnes. Leur confiance dans l'économie est en train de faiblir. Jusqu'à présent, ce ne sont que les revenus supérieurs et moyens qui ressentent la tendance.

Dans de nombreux pays, le salaire n'est pas très élevé jouissent par contre de la protection de l'Etat. Dans certains cas, ils reçoivent même une aide disproportionnée du gouvernement. Ces personnes vont d'abord se demander, quand le chômage sera de plus en plus élevé, si elles peuvent vraiment se payer des vacances. Tandis que les Allemands sont prudents et mettent de côté environ dix pour cent de leur revenu, en Angleterre on aime bien vivre „à crédit".

Les dernières estimations pour 2010 renvoient à des taux de croissance réduits dans le secteur des voyages en avion. Certains marchés déclarent déjà qu'ils enregistrent des baisses dans ce secteur. L'année dernière certains vacanciers ont préféré prendre le train ou leur automobile au lieu de prendre l'avion ne signifie pas que nous avons à faire à un décalage modal. Il est plus probable que la tendance reflète seulement une baisse passagère des voyages. On doit garder d'interpréter les décalages temporaires comme tendances réelles. La même chose est valable pour le développement des différents segments touristiques. Les bons résultats obtenus pendant la saison hiver 2008/2009, suite aux excellentes conditions dues à la neige dans de nombreuses stations de ski européennes, ne sont pas une garantie que les affaires hivernales resteront robustes à long terme.

3. Conclusion

Le prix du pétrole aussi restera un facteur-clé pour la performance du secteur touristique en 2010. Les baisses radicales du prix du pétrole, depuis les valeurs de pointe de l'été 2008, ont tout d'abord permis aux compagnies aériennes à bas prix de mieux respirer. Tant que les prix n'augmenteront pas, ils seront ceux qui en profiteront – au moins à court terme. Les consommateurs vont sinon économiser en ne partant pas les week-ends et peut-être décider à long terme de ne pas prendre l'avion comme moyen de transport.

Il y a aussi trop de bureaucratie étatique et de protectionnisme national dans l'élargissement des réseaux ferroviaires. On ne peut donc pas supposer que les affaires avec les chemins de fer seront vraiment, à l'avenir, un facteur important. Dans la concurrence des compagnies aériennes, ce sera plutôt l'automobile qui gagnera face à l'avion. Surtout si de nouveaux règlements, comme l'acquisition obligatoire des certificats d'émission, entravent la croissance du trafic aérien.

En général, les Européens préféreront à court et à moyen terme réserver des voyages bon marché vers des destinations proches. A la fin de 2010, peut-être que le camping sera de nouveau populaire, ou les appartements de vacances et les auberges de jeunesse. Et pourquoi pas les voyages à bicyclette? Cette récession sera draconienne, elle va durer au moins jusqu'à la fin de l'année 2010.

Business Administration*

The purpose of this paper is to demonstrate how business environment and performance can be improved in an organization that used and implement Lean Six Sigma methodology and who create an organizational framework auspicious for theirs employees. Lean Six Sigma can be a management approach of an organization focused on quality and continuous improvement, based on the participation of all it's employees which aims to ensure long term success. It's very important for a organization to believe in the capacity of work and intellect of their employees, to invest in them, so in this way they will feel useful and will became more self confident and will help the company to move one step ahead in this very competitive market we are facing today.

Keywords: Lean, Six Sigma, knowledge management, business transformation, organisational creativity, innovation

The article's JEL code: M16

1. Introduction

"Create, improve continuously and bring innovative elements or die." This has become a crucial and critical element which is required of managers and the organizations they manage, to survive in a changing market. In a dynamic world of global competition, organizations must continuously innovate and create new products and services and adopt new technologies to the marketplace and to cope with fierce competition. Now we are not only in a new millennium but in a new era, the era of knowledge. Long-term competitive advantage depends on the construction and operation of basic skills. Resource-based orientation of an organization defines a strategic asset as one valuable and nonsubstituibil. Knowledge is seen as a strategic asset that has the potential to be a source of competitive advantage for the organization.

2. Knowledge management in business enviroment

Typically, the ability to understand human creativity, employee's creativity, to combine ideas in a unique way or to make combinations and associations between them to generate innovative field to bring more organization it is defined as creativity. Therefore, organizations must create a climate to encourage and foster positive and creative thinking of theirs employees. In other words, they must seek to eliminate organizational barriers at work that could complicate and hinder creativity. Creative potential could be triggered when the employee organization shall be provided adequate resources to guide them in their work when their work is a challenge to the intellect, when presenting a high level of autonomy and control over his work (Politis, J.D. 2004). Large organizations are increasingly turning their attention on the importance and role of knowledge on the efficiency and competitiveness. The main reason for this is concern over the

knowledge management an idea that both knowledge and application of knowledge management systems are ways in which creativity and innovation can be promoted and the knowledges extracted so to increase performance organization overall, whether it is about public, private or nonprofit sector.

Economic theories treat knowledge as a crucial economic factor. It appears, at present the tendency to achieve a new synthesis between the various approaches to economic knowledge in the form of theories of organizations based on knowledge and knowledge-based society. According to these theories, knowledge is the main source of economic organizations and, therefore, knowledge management shows a paramount importance.

Today, acquisition of an organization's success is to exchange information quickly and efficiently. Long-term competitive advantage is not rooted in physical assets and financial capital but in effective channel of intellectual capital.

The characteristic of the knowledge society is not in that it has vast amounts of information, but that in it should always know more. And ability to get to know more calls on the subject knowledge to human beings. Thus information is something external, which is available to us. Knowledge instead, is an internal development, an advance made ourselves, a practical enrichment of our existence, a potency of our operational capacity.

Competitive advantages which it holds economic organization on market no longer can be maintained only by the parameters characterizing the products or services and any investment in new technology. Excellence that provides competitive nature depends mainly on how to tap talent, professional skills and knowledge labor organization by nurturing a new culture in that economic organization.

Fierce competition in international markets causes companies to want to be one step ahead of its competitors, in other words, be smarter ensuring that properly use all available resources, make the most value relevant or, apparently, minor competitive advantage.

3. Lean Six Sigma tool

The continuously changing and diversification of products and services during the last century, due mainly to constant increase of client requirements, as well as to industrial progress and competition intensification, led not only to relatively frequent modification of the quality concept definition, but also to a consistent development of concerns of different organizations supplying products and services of the quality of their production.

To obtain that competitive advantage for organizations, Lean Six Sigma may assist them by creating, improving continuously it's processes, but also by implementing new organizational structures and processes which bring that added the organization has need to differentiate from its competitors on market.

To create a common improvement methodology you must create an integrated system for managing projects rather than separate systems for Lean or Six Sigma projects. As Juran (1989) admonished us, "improvement happens project-by-project and in no other way" (Snee, R.D. 2010). The Juran quality management philosophy focuses on three components: planning, control, and improvement. These are known as the Juran Trilogy (Montgomery, D.C. 2010).

Management must play an active role in the selection of projects for the newly trained Six Sigma teams to focus on, and also ensure that all required resources are made available (Raisinghani, 2005).

Table 1: Lean Thinking

The Fundamental Objective provide perfect value to the customer through a perfect value creation process with zero waste in:	The Fundamental Insight
-Design (concept to customer)	-Focus on each product and its value stream rather than organizations, assets, process technologies, and career paths
-Build (order to delivery)	-Ask which activities are waste and which truly create value
-Service (order to cash)	-Enhance the value & eliminate the waste to optimize the whole

Lean Six Sigma management type refers, primarily, to a structured approach in which the heart is invariably "customer voice", considering that in any economic context, not necessarily a crisis, understanding customer requirements is vital for a company.

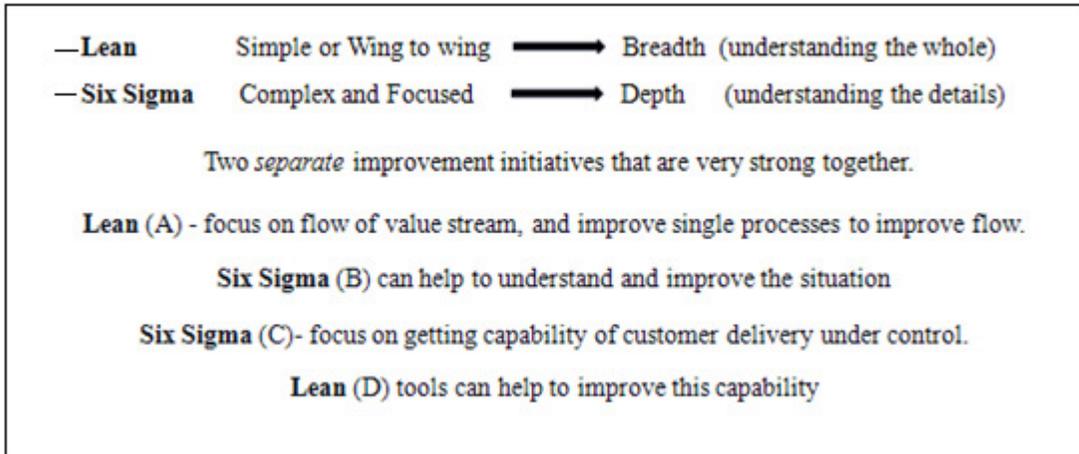

Figure 1: Lean Six Sigma interconnections

*Lean*⁶⁸⁷ (A) - Helps identify steps that **don't add value** and provides tools to eliminate them.

Lean (D) - Lean can help to improve the capability (improve phase).

*Six Sigma*⁶⁸⁸ (C) - Improves the capability of steps that do add value.

Six Sigma/Lean (B) - Lean identifies problems in **flow**. Improving the capability with Six Sigma can eliminate additional steps.

Lean Six Sigma is a methodology which is applicable both in manufacturing activity, as well as in services, and provide tools for solving a wide range of issues, whether we are talking about the speed processes, improve process's output or about cost reductions.

Although Lean and Six Sigma evolved independently, there are a number of encouraging articles discussing the use of an amalgamated approach. However, in order to drive a unified

⁶⁸⁷ Lean manufacturing extends the scope of the Toyota production philosophy by providing an enterprise-wide term that draws together the five elements of "the product development process, the supplier management process, the customer management process, and the policy focusing process for the whole enterprise".

⁶⁸⁸ The term "Six Sigma" refers to a statistical measure of defect rate within a system. Underpinned by statistical techniques, it presents a structured and systematic approach to process improvement, aiming for a reduced defect rate of 3.4 defects for every million opportunities, or Six Sigma.

methodology forward, a closer integration of the two approaches must be achieved, with significant scientific underpinning to provide a sound theoretical foundation (Pepper, 2007 cited in Pepper, M.P.J., Spedding, T.A. 2010).

4. Conclusion

The goal of any organization is to increase its customer's satisfaction by adapting services and products to new standards which are according with what clients want to receive. For that to come true they need both, Lean and Six Sigma working together in all its areas.

For a organization to adopt Lean Six Sigma is required quality improvement processes by integrating Lean principles with Six Sigma methodology as a holistic approach to continuous improvement for all the domains in which the organization operates.

To move forward to further visions such as agility and total supply chain integration, organizations will need to act as Lean as possible, providing transparency for the implementation of Six Sigma methods and techniques.

This article was prepared as part of the "Ph.D. in Economics at European knowledge standards" project co funded by European Social Fund through Sectoral Operational Programme Human Resources Development 2007-2013 coordinated by the Academy of Economic Studies, Bucharest.

Services are the most important contributor to the GDP and also the most important job generator. Countries development, usually, is based on the services sector.

The present paper is aiming to highlight the influence of the number of active enterprises in services on exports. The paper is based on a model generated using data provided by Eurostat, for 25 EU countries and for 4 services categories. Generated in Eviews 4.1, the model is correctly specified, with a R-squared value of 0.65, and revealed a validated influence of the number of enterprises active in Wholesale and retail trade; repair of motor vehicles, motorcycles and personal and household goods and in Real estate, renting and business activities on exports.

Keywords: enterprise, services, exports, European Union.

JEL Classification: C30, C40, L81, L85, L91, M19

Introduction

The term of service is reflected in different forms, depending on the context: from intangible services associated to abstract elements, such as information or knowledge, to services that involve individual action, such as health or education⁶⁸⁹. Services are defined as a human activity, with a specialized content, resulting in useful, immaterial and intangible outcome allocated to satisfy a social need⁶⁹⁰. Services are characterized by: immateriality, intangibility, storage impossibility, simultaneous production and consumption of services, non-sustainability, inseparability from the provider and user, variability and heterogeneous. Moreover, Edvardsson, Gustafsson and Roos consider the characterization of services as inseparable, heterogeneous, intangible and perishable too simplistic and state that the difference between services and products is not always so well defined⁶⁹¹. In economics, services met an evolutionary path, from infrastructure services to their approach as an experience, having as intermediate stages the support services, recreational and leisure services, educational services and services that allow

spare time saving⁶⁹². These particularities are the one that confer a certain degree of uniqueness and they support the services improvement process⁶⁹³. Because, products from primary and secondary sectors are associated with services, it is very difficult to demarcate each spectrum, highlighting the fact that services exceed the tertiary sector area, containing also intangible activities of the other two sectors (primary and secondary sectors). Lindberg and Nordin argue that the difference between goods and services is no longer clearly defined, precisely because both are given together, resulting on the one hand, products servicing, and on the other one, the services materialization⁶⁹⁴. At European Community level, the free movement of services involve the removal of barriers that hinder the free movement of people who develop independent activities, of employees, or of their families.

Methodology

Based on data provided by Eurostat, the model consisted of a multiple regression and it was generated using Eviews 4.1 program. The main purpose of the model is to emphasize a potential relation between the number of active enterprises in services and the value of exports of goods and services, for 25 EU countries. From the range of existing services, only the “Wholesale and retail trade; repair of motor vehicles, motorcycles and personal and household goods”, “Hotels and restaurants”, “Transport, storage and communication” and “Real estate, renting and business activities” categories were chosen for the model, as data only for these were identified. The analysis consisted only of 25 EU countries, namely Belgium, Bulgaria, Czech Republic, Denmark, Germany, Estonia, Greece, Spain, France, Italy, Cyprus, Latvia, Lithuania, Luxembourg, Hungary, Netherlands, Austria, Poland, Portugal, Romania, Slovenia, Slovakia, Finland, Sweden and United Kingdom. Malta and Ireland, as European Union members, weren't taken into consideration, as no data were provided for them. The list of variables used for the model was composed of:

- dependent variable: exports of goods and services (expressed in current prices in millions of euros – notation Exporturi);
- independent variables: enterprises active in Wholesale and retail trade; repair of motor vehicles, motorcycles and personal and household goods (expressed in number of enterprises - notation COM), enterprises active in Hotels and restaurants (expressed in number of enterprises - notation HOT), enterprises active in Transport, storage and communication (expressed in number of enterprises - notation TRANSP) and enterprises active in Real estate, renting and business activities (expressed in number of enterprises - notation IMOB).

Descriptive analysis of series of data

The series of data were used exactly as they were provided by Eurostat; any processing did not occur on them. The paper is based on data from the 2007 year, with the authors' intention of expanding the research on other future years.

In what concerns the value of exports of the analyzed EU countries, its mean is 192374.6 and its median is 82318 corresponding to Finland. The series is relatively heterogeneous, taking into consideration the standard deviation that registers a quite high value (257050.2), in comparison with the mean's value of 192374.6. According to Jarque-Bera, residual values are normally distributed, because the probability registers a value lower than 0.05. The asymmetry coefficient

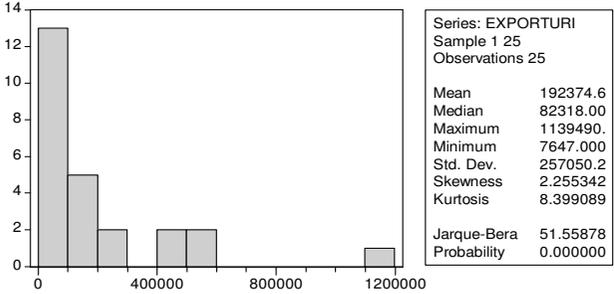

⁶⁹² Heineke, J. & Davis, M.M., 2007. The emergence of service operations management as an academic discipline. *Journal of Operations Management*, 25(2), p. 366.

⁶⁹³ Nijssen, E. J., Hillebrand, B., Vermeulen, P.A.M. & Kemp, R.G.M., 2006. Exploring product and service innovation similarities and difference. *International Journal of Research in Marketing*, 23, pp. 241-251.

⁶⁹⁴ Lindberg, N. & Nordin, F., 2008. From products to services and back again: Towards a new service procurement logic. *Industrial Marketing Management*, 37(3), pp. 292-300.

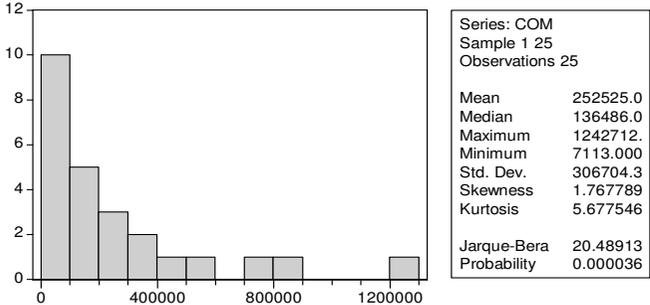

registers a value of 2.25 that suggests an asymmetric series oriented towards positive values. The flattening coefficient registers a value of 8.39 suggesting a leptokurtosis series oriented towards positive values. (Figure no. 1)

Figure no. 1: Description of Exports series of data

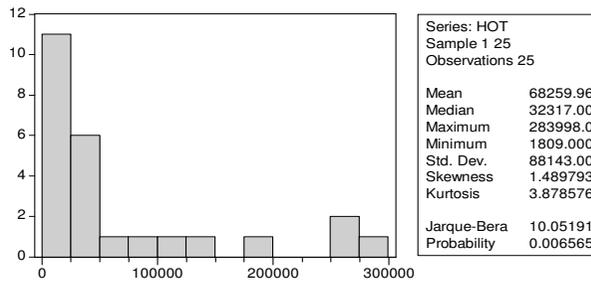

Taking into consideration the number of enterprises active in Wholesale and retail trade; repair of motor vehicles, motorcycles and personal and household goods from the analyzed EU countries, it can be appreciated that, its mean is 252525 and its median is 136486 corresponding to Belgium. The series is relatively heterogeneous, taking into consideration the standard deviation that registers a quite high value (306704.3), in comparison with the mean's value of 252525. According to Jarque-Bera, residual values are normally distributed for all the analyzed services categories, because the probability registers a value lower than 0.05. The asymmetry coefficient registers a value of 1.76 that suggests an asymmetric series oriented towards positive values. The flattening coefficient registers a value of 5.67 suggesting a leptokurtosis series oriented towards positive values. (Figure no. 2)

Figure no. 2: Description of Wholesale and retail trade; repair of motor vehicles, motorcycles and personal and household goods series of data

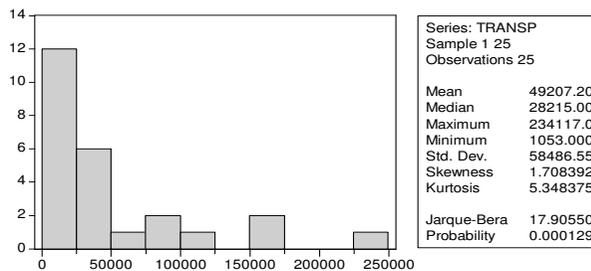

Considering the number of enterprises active in Hotels and restaurants from the analyzed EU countries, it can be appreciated that, its mean is 68259.96 and its median is 32317 corresponding to Hungary. The series is relatively heterogeneous, taking into consideration the standard deviation that registers a quite high value (88143), in comparison with the mean's value of 68259.96. The asymmetry coefficient registers a value of 1.48 that suggests an asymmetric series oriented towards positive values. The flattening coefficient registers a value of 3.87 suggesting a leptokurtosis series oriented towards positive values. (Figure no. 3)

Figure no. 3: Description of Hotels and restaurants series of data

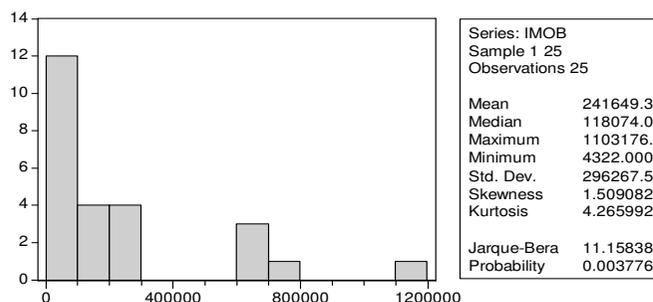

Referring to the number of enterprises active in Transport, storage and communication from the analyzed EU countries, it can be appreciated that, its mean is 49207.2 and its median is 28215 corresponding to Holland. The series is relatively heterogeneous, taking into consideration the standard deviation that registers a quite high value (58486.55), in comparison with the mean's value of 49207.2. The asymmetry coefficient registers a value of 1.70 that suggests an asymmetric series oriented towards positive values. The flattening coefficient registers a value of 5.34 suggesting a leptokurtosis series oriented towards positive values. (Figure no. 4)

Figure no. 4: Description of Transport, storage and communication series of data

Taking into consideration the number of enterprises active in Real estate, renting and business activities from the analyzed EU countries, it can be appreciated that, its mean is 241649.3 and its median is 118074 corresponding to Belgium. The series is relatively homogeneous, taking into consideration the standard deviation that registers a value (296267.5) quite close to the one of the mean (241649.3). The asymmetry coefficient registers a value of 1.50 that suggests an asymmetric series oriented towards positive values. The flattening coefficient registers a value of 4.26 suggesting a leptokurtosis series oriented towards positive values. (Figure no. 5)

Figure no. 5: Description of Real estate, renting and business activities series of data

Possible connections between active enterprises in services and exports

The model was generated using the OLS method and it was based on the following equation: $Exporturi = a + b*COM + c*HOT + d*TRANSP + e*IMOB + \epsilon$; all the variables being explained in the methodology part of the paper. Considering the results generated by the model and by substituting the obtained coefficients, the model's equation can be rewrite as follows:

$$Exporturi = 58109.75 - 1.027686*COM + 0.879749*HOT + 0.450289*TRANSP + 1.289356*IMOB$$

The results generated by the model are illustrated in table no. 1.

Table no. 1: Model's results

Dependent Variable: EXPORTURI				
Method: Least Squares				
Sample: 1 25				
Included observations: 25				
Variable	Coefficient	Std. Error	t-Statistic	Prob.
C	58109.75	44866.17	1.295180	0.2100
COM	-1.027686	0.400772	-2.564268	0.0185
TRANSP	0.450289	1.370242	0.328620	0.7459
HOT	0.879749	1.277558	0.688617	0.4990
IMOB	1.289356	0.391242	3.295548	0.0036
R-squared	0.650292	Mean dependent var	192374.6	
Adjusted R-squared	0.580351	S.D. dependent var	257050.2	
S.E. of regression	166518.0	Akaike info criterion	27.06045	
Sum squared resid	5.55E+11	Schwarz criterion	27.30423	
Log likelihood	-333.2556	F-statistic	9.297660	
Durbin-Watson stat	2.004593	Prob(F-statistic)	0.000205	

The model has been based on two hypotheses for each coefficient, namely the null hypothesis (H_0 : the coefficient = 0) and the alternative one (H_1 : the coefficient differs significantly from 0).

In order to verify the estimators' significance, the t Student test has been applied.

For the free coefficient, the estimated value is 58109.75, with a standard error of 44866.17 and a t Statistic value of 1.295180. The marginal level of significance (p-value) registers a value higher than 0.05, namely 0.21 suggesting a confirmation of the null hypothesis, implicit of the fact that the free coefficient is null.

For the coefficient associated to the COM variable, the estimated value is -1.027686, with a standard error of 0.400772 and a t Statistic value of -2.564268. The marginal level of significance (p-value) registers a value lower than 0.05, namely 0.0185 suggesting a rejection of the null hypothesis according to which the coefficient is null. Therefore, it can be considered that the

coefficient associated to the COM variable differs significantly from 0 and it has an influence of -1.027 on the dependent variable.

For the coefficient associated to the TRANSP variable, the estimated value is 0.450289, with a standard error of 1.370242 and a t Statistic value of 0.328620. The marginal level of significance (p-value) registers a value higher than 0.05, namely 0.7459 suggesting a confirmation of the null hypothesis, implicit of the fact that the coefficient is null.

For the coefficient associated to the HOT variable, the estimated value is 0.879749, with a standard error of 1.277558 and a t Statistic value of 0.688617. The marginal level of significance (p-value) registers a value higher than 0.05, namely 0.4990 suggesting a confirmation of the null hypothesis, implicit of the fact that the coefficient is null.

For the coefficient associated to the IMOB variable, the estimated value is 1.289356, with a standard error of 0.391242 and a t Statistic value of 3.295548. The marginal level of significance (p-value) registers a value lower than 0.05, namely 0.0036 suggesting a rejection of the null hypothesis according to which the coefficient is null. Therefore, it can be considered that the coefficient associated to the IMOB variable differs significantly from 0 and it has an influence of 1.289 on the dependent variable.

Therefore, as a short conclusion of the estimators' analysis, it can be stated that, from the entire model, only two independent variables have a noticeable influence on the dependent variable. In the presented model, the value of exports of goods and services is influenced only by the number of enterprises active in Wholesale and retail trade; repair of motor vehicles, motorcycles and personal and household goods and in Real estate, renting and business activities.

Also, table no. 1 illustrates the value of the Fisher test. It can be observed that the value of F Statistic is 9.297660, with a marginal level of significance of 0.000205, suggesting a correctly specified model.

A qualitative indicator of the regression model is the determined coefficient (R-squared). A value close to 1, for this coefficient, illustrates the fact that the variable Exporturi variations are mainly explained, in this model, by the variations of the variables COM and IMOB. For this model, the R-squared value is 0.650292 outlining the fact that the model adjusts correctly the data from the panel. Therefore, it can be considered that this model has been correctly specified. Durbin Watson registers a value of 2.004593 (very close to 2) highlighting an uncorrelated model's errors.

Conclusions

Services are one of the most important means of a country development because of their influence in every sector and activity of a country. Exports are not an exception to the mention situation. The model generated using data provided by Eurostat, for 25 EU countries and for 4 services categories, generated in Eviews 4.1, revealed a noticeable influence of the number of enterprises active in Wholesale and retail trade; repair of motor vehicles, motorcycles and personal and household goods and in Real estate, renting and business activities on exports, while the number of enterprises active in Hotels and restaurants and in Transport, storage and communication had no valid p-value in order to be accepted as having an influence on exports. In order to bring more arguments and improve the presented model further data and tests are necessary.

CORPORATE GOVERNANCE BASICS

Popescu Alexandra-Codruța

West University of Timișoara, Faculty of Economics and Business Administration

Aniș Cecilia-Nicoleta

West University of Timișoara, Faculty of Economics and Business Administration

In a world of profound economic transformation, one must find the appropriate tools to ensure socio-economic development, in strengthen economy. One such tool is considered to be corporate governance. This concept refers to a set of customs, processes, laws, policies and institutions, which affect how a corporation is being managed, administered or controlled. It also implies the relationships among the stakeholders involved the targets of a corporation. The main stakeholders taken into consideration are the shareholders, the management and the board of directors and others, like: employees, customers, creditors, suppliers, regulators, and the community at large. Corporate Governance is a complex concept. An important theme is the accountability of certain individuals in an organization through mechanisms that try to reduce or eliminate the principal-agent problem. Another important aspect is the economic efficiency, the shareholders' welfare.

Keywords: corporate governance, principles, mechanisms of corporate governance, cash-holding

JEL Classification: G30, G32, G38

1. Introduction

The concept of corporate governance is of high importance to the EU candidate and potential candidate countries, which want to attract investors, to enhance lender confidence, to improve corporate competitiveness. Strengthening corporate governance is essential in promoting the private sector as an engine of growth, reducing the vulnerability of developing and transition economies to financial crises, providing incentives for corporations to invest, to perform efficiently in a responsible way. The European approach is meant not only to help the accession process, but also the improve trade among the EU partner, attract investors and raise competition in the EU.

Corporate governance refers to the set of processes, customs, policies, laws, and institutions affecting the way a corporation is directed, administered or controlled. Corporate governance also includes the relationships among the many stakeholders involved and the goals for which the corporation is governed. The principal stakeholders are the shareholders, management, and the board of directors. Other stakeholders include employees, customers, creditors, suppliers, regulators, and the large community.

Corporate governance is a multi-faceted subject. An important aspect of corporate governance is to ensure the accountability of certain individuals in an organization through mechanisms that try to reduce or eliminate the principal-agent problem. A related but separate thread of discussions focuses on the impact of a corporate governance system in economic efficiency, with a strong impact on shareholders' welfare.

A first step in building sound corporate governance is to design a code of corporate governance containing standards and best practices in the field. Sort of a guide when attempting to build such codes is the *Action Plan for Modernizing European Company Law and Enhancing Corporate Governance in the EU (2003)*. This document highlighted the main reasons for which a modernizing process was needed: financial scandals, cross-border operations, the integration of EU capital markets, the quick information exchange, the development of technologies and the increase of the Member States.

Some initiatives reveal the future actions whereas corporate governance is concerned:

- Better information on the role played by institutional investors;
- Proportionality between capital and control;
- The listed companies' choice between one-tier and two-tier board structures;
- enhancing the responsibilities for financial and key non-financial statements.

The European Commission issued two reports in 2007, in which it states that all Member States had issued corporate governance codes and most codes apply on a comply-or-explain basis. However, there are some areas where the EU Recommendations had not been properly followed.

In order to set the EU Corporate Governance Standards there have been identified the key players and the key outputs. The key players are the most important EU institutions: European Parliament, European Council, and Consultative Bodies in the field of Corporate Governance, the European Corporate Governance Forum, and the Advisory Group on Corporate Governance and Company Law. The Key Outputs are the main legal documents like:

- the Green Paper – a discussion document released by the EC intended to stimulate debate and launch a process of consultation, on a particular topic, at EU level
- Position Paper – views and information presented to the Commission in response to a consultation process
- Recommendation – nonbinding act which explains current EU policy and recommends further actions.
- Regulation – act of the Council or joint act of the Council and the Parliament which has direct and general application in Member States.
- Directive – the most common type of EU legislation, not directly applicable, but may have direct effect; preferred mean of harmonization.
- Decisions – are binding in their entirety upon to whom they are addressed.

The World Bank has issued a report on the topic of corporate governance in Romania in 2004. The report assesses the corporate governance policy framework, and the enforcement and compliance practices in Romania. The report highlighted strengths and weaknesses and some policy recommendations were made.

The major issues were considered to be the effort made by Romania to join the EU and the transformation of the capital markets. The corporate governance framework in Romania has gone through a process of improvement in the late years, whereas corporate governance framework. Laws were issued to protect the minority shareholders of publicly held companies. Further improvement is a requirement and recommendations were made in this direction: a clear CNVM mandate to protect shareholders rights and help in carrying out its mandate; protection of the shareholders rights for all publicly held companies; steps to create a Corporate Governance Institute; revising the Company Law, with focus on the shareholders rights and the boards of directors.

2. OECD Principles of Corporate Governance

The OECD Principles of Corporate Governance were designed in 1999 as a set of corporate governance standards and guidelines. They were also adopted as one of the Twelve Key Standards for Sound Financial Systems by the Financial Stability Form, by the IMF/World Bank. Corporate governance is a key concept which affects the relationships among participants in the governance system. The elements which affect the shareholders of a corporation influence also the corporate behaviour. The relationships among shareholders are subject, in part, to law and regulation and, in part, to voluntary adaptation and, most importantly, to market forces.

Good corporate governance principles include rather intangible characteristics, according to ones ethics general and to the business ethics in particular, like: honesty, trust and integrity, openness, performance orientation, responsibility and accountability, mutual respect, and commitment to the organization.

The OECD Principles of Corporate Governance are:

- Ensuring the Basis for an Effective Corporate Governance Framework
- The Rights of Shareholders and Key Ownership Functions
- The Equitable Treatment of Shareholders
- The Role of Stakeholders in Corporate Governance
- Disclosure and Transparency
- The Responsibilities of the Board

a) Ensuring the Basis for an Effective Corporate Governance Framework

“The corporate governance framework should promote transparent and efficient markets, be consistent with the rule of law and clearly articulate the division of responsibilities among different supervisory, regulatory and enforcement authorities.”

The way a corporation conducts its businesses must abide by the law, by the norms and values it promotes and in perfect transparent way.

b) The Rights of Shareholders and Key Ownership Functions

“The corporate governance framework should protect and facilitate the exercise of shareholders’ rights.”

Organizations must respect the rights of their shareholders. Problems like asymmetric information and moral hazard should not manifest themselves. This is why it is important that the shareholders participate in general meetings where they can be informed with the issues they are concerned about.

c) The Equitable Treatment of Shareholders

“The corporate governance framework should ensure the equitable treatment of all shareholders, including minority and foreign shareholders. All shareholders should have the opportunity to obtain effective redress for violation of their rights.”

All shareholders are equal in a corporation whereas rights and obligations are concerned.

d) The Role of Stakeholders in Corporate Governance

“The corporate governance framework should recognize the rights of stakeholders established by law or through mutual agreements and encourage active co-operation between corporations and stakeholders in creating wealth, jobs, and the sustainability of financially sound enterprises.”

The board should be consisted of high-skilled persons capable of dealing with various business issues, who have the ability to analyze in critic way the management performance. The problem each corporation is confronted with is the appropriate mix of executive and non-executive directors, of the size and level of the organizational chart.

e) Disclosure and Transparency

“The corporate governance framework should ensure that timely and accurate disclosure is made on all material matters regarding the corporation, including the financial situation, performance, ownership, and governance of the company.”

A corporation must publicly inform all interested parties about the roles and responsibilities of the board and management, about all information concerning them and the corporation. The integrity of financial reporting must always be ensured.

f) The Responsibilities of the Board

“The corporate governance framework should ensure the strategic guidance of the company, the effective monitoring of management by the board, and the board’s accountability to the company and the shareholders.”

Ethical behaviour on behalf of the persons responsible for decision making is important not only for public relations, but is also a key factor when avoiding assuming high management risks and potential lawsuits. This is why a lot of companies design and promote their Code of conduct, because a company is bound with its staff integrity and ethics. It is important to acknowledge the risk a corporation is confronted with when it steps outside the ethical and legal boundaries.

3. Mechanisms of corporate governance

The governance mechanisms that have been studied can be characterized as being either internal or external to the firm. The internal mechanisms of primary interest are the board of directors and the equity ownership structure of the firm. The primary mechanisms are the external market for corporate control (the takeover market) and the legal/regulatory system.

3.1. Internal Governance Mechanisms

3.1.1. Boards of Directors

Corporations in most countries of the world have boards of directors. The board exists primarily to hire, fire, monitor, and compensate management, all with an eye towards maximizing shareholder value. While the board of directors is an effective corporate governance mechanism in theory, in practice its value is less clear. Boards of directors include some of the very insiders who are to be monitored; in some cases they represent a majority of the board. In addition, it is not uncommon that the CEO is also the chairperson of the board. Finally, the nature of the selection process for board members is such that management often has a strong hand in determining who the other members will be. The primary board-related issues that have been studied are board composition and executive compensation. Board composition characteristics of interest include the size and structure of the board: the number of directors that comprise the board, the fraction of these directors that are outsiders, and whether the CEO and chairperson positions are held by the same individual. Executive compensation research is concerned with the degree to which managers are compensated in ways that align their interests with those of their companies' shareholders.

3.1.2. Ownership structure

Ownership and control are rarely completely separated within any firm. The controllers frequently have some degree of ownership of the equity of the firms they control; while some owners, by virtue of the size of their equity positions, effectively have some control over the firms they own. Ownership structure is a potentially important element of corporate governance. It is reasonable to presume that greater overlap between ownership and control should lead to a reduction in conflicts of interest and, and, in this idea, to higher firm value. The relationships between ownership, control, and firm value are more complicated than that. Ownership by a company's management, for example, can serve to better align managers' interests with those of the company's shareholders. However, to the extent that managers' and shareholders' interests are not fully aligned, higher equity ownership can provide managers with greater freedom to pursue their own objectives without fear of reprisal; i.e. it can entrench managers. The ultimate effect of managerial ownership on firm value depends upon the trade-off between the alignment and entrenchment effects.

The shareholders other than management can potentially influence the actions taken by management. The problem in some corporations, with the widely-dispersed share ownership, is that individual shareholders own very small fractions of an individual firm's shares and, therefore, have little or no incentive to expend significant resources to monitor managers or seek to influence decision-making within the firm. Moreover, the free-rider problem reduces the incentives for these disparate shareholders to coordinate their actions. Individual shareholders who have more significant ownership positions have greater incentives to expend resources to monitor and influence managers.

As with ownership by managers, ownership by outside blockholders is not always a positive force from the perspective of the other shareholders. Blockholders can use their influence such that management is more likely to make decisions that increase overall shareholder value. These are the shared benefits of control; blockholders exercise them but all shareholders benefit from them. However, there are private benefits of control as well – benefits available only to block

holders. These private benefits can be innocuous from the perspective of other shareholders; e.g. a blockholder may simply enjoy the access to powerful people that comes from being a major shareholder. However, if blockholders use their control to extract corporate resources, the private benefits they receive will lead to reductions in the value of the firm to the other shareholders. The ultimate effect of blockholder ownership on measured firm value depends upon the trade-off between the shared benefits of blockholder control and any private extraction of firm value by blockholders.

In many countries of the world, the government is a significant owner of corporations. Government ownership represents an interesting hybrid of dispersed and concentrated ownership. If the government is viewed as a single entity, state-owned corporations have very concentrated ownership. Unlike private blockholders, government ownership is funded with money that ultimately belongs to the state as a whole and not to the individuals within the government that influence the actions of the firm. In this regard, the ultimate ownership of state-owned companies is, in fact, quite dispersed. Over time, there has been a trend away from state ownership of corporate assets. The conversion from state to private ownership, termed privatization, provides an interesting setting in which to examine the effects of ownership on firm performance.

3.2. External Governance Mechanisms

3.2.1. The Takeover Market

When internal control mechanisms fail to a large enough degree, that means for example when the gap between the actual value of a firm and its potential value is sufficiently negative - there is incentive for outside parties to seek control of the firm. Changes in the control of firms virtually always occur at a premium, thereby creating value for the target firm's shareholders. The mere threat of a change in control can provide management with incentives to keep firm value high, so that the value gap is not large enough to warrant an attack from the outside. The takeover market has been an important governance mechanism.

The takeover market has also its dark side for shareholders. In addition to being a potential solution to the manager/shareholder agency problem, it can be a manifestation of this problem. Managers interested in maximizing the size of their business empires can waste corporate resources by overpaying for acquisitions rather than returning cash to the shareholders.

3.2.2. The Legal/Regulatory System

La Porta, Lopez-de-Silanes, Shleifer, and Vishny (1998) are sustaining that the legal system is a fundamentally important corporate governance mechanism. They argue that the extent to which a country's laws protect investor rights and the extent to which those laws are enforced are the most basic determinants of the ways in which corporate finance and corporate governance evolve in that country. This basic idea has spawned a growing body of research that examines differing legal regimes across countries. This research allows for comparative studies of corporate governance. Given the interrelationships among the various corporate governance mechanisms, it also has the potential to provide a more complete understanding of the roles of firm-specific corporate governance mechanisms such as the board of directors and equity ownership.

4. Corporate governance and the value of cash holding - Implication of corporate governance

Jensen (1986) argues that if left unmonitored, entrenched managers may waste free cash flows. This argument is extended in some studies to cash reserves and provide empirical evidence by examining the effect of governance on the value of excess cash. The value of a monetary unit of cash is substantially less if a firm has poor corporate governance. A well governed firm has its excess resources better "fenced in," and that firms with poor corporate governance dissipate excess cash reserves more quickly on less profitable investments than those with good

governance. In short, poorly governed firms waste excess cash resources and thus destroy firm value.

A large and growing literature sustains that governance improves firm value. But much less is understood about how governance enhances firm value that means how does governance work? There is a direct link between governance and the value of an important asset of the firm: cash holdings. Governance increases firm value by improving the use of cash holdings. The results also shed light on the role of governance in cash policy. Governance has a greater influence on the use, rather than the accumulation, of cash holdings. This implies that governance impacts operating and investment decisions (how to use cash) more than financing decisions related to cash policy (how much cash to amass). One conclusion with respect to cash policy is that it may matter very little whether a firm holds excess cash—if it is well governed.

5. Instead of conclusion...Systemic problems the concept of corporate governance faces

*Corporate governance is confronted with a series of problems which can affect its effectiveness like: **the demand for information** - it is important to the corporation to have significant voting groups which can manifest power when adopting decisions; monitoring costs – people must adjust to the fact that markets do not always function efficient, that people are affected by what is called bound rationality. The EMH (efficient market hypothesis) is no longer valid and corporations must act accordingly; **supply of accounting information** – external auditing must be promoted in order to avoid imperfections in financial reporting, with a direct effect on the effectiveness of corporate governance.*

In order to ensure that this concept is of use to the corporation the employees, the management, the board of director must not only embrace the theoretical aspects, but must promote also the practical uses of applying such a concept.

Company law and corporate governance are extremely important in the context of the late crisis. It is crucial for companies to work efficiently and transparently. If not...investment will diminish and unemployment will appear. Shareholders, employees, creditors and the public are in danger of losing their resources, their trust in the market mechanisms to solve problems. In order to ensure the public confidence in the financial markets a strong corporate governance model must exist. Unfortunately, the late crisis has proven the EU steps to be more theoretical than practical, given the damage caused by the crisis on all EU financial markets.

The tourism and travel industry represents, worldwide, the most dynamic sector of activity and, at the same time, the most important job generator, as well as a source of recovering the national economies. Tourism is a complex activity because it generates the circulation of massive sums of money, thus contributing to the development of various economic activities which are favourable to the environment protection and to the globalization process emphasis. Tourism itself cannot be considered as a “positive” or “negative” action, but its very diverse consequences can be evaluated in this manner. In the process of sustainable development of tourism, it is necessary that an increased attention be paid to the quality of the touristic products, which should simultaneously offer “the taste of perfection” and “the perfection of taste”.

Keywords: touristic destination, sustainable development, touristic potential.

JEL Classification: L83, M19, Q01

Introduction

According to the unanimous acceptance, the tourism economic potential is impressive and the benefits which can be generated by a sustainable development cannot miss from any elementary calculation of a marketing planning which can minimize them, considering that tourism, a very strong instrument of development, possesses a natural synergy with the sustainable development concept.

Any research related to the tourism from a certain territory has to take into consideration the phenomenon of the markets' interdependencies. This phenomenon presupposes that no touristic market can be judged independently, without establishing connections with the other markets. The touristic research is under a permanent pressure, on the one hand because of the competition, on the other because of some circumstantial factors, with an economical character, but also extra-economical (inflation phenomena, of economic, political and geostrategic circumstance).

The economical, social, political context from Romania after 1990 has not contributed to the development of the Romanian touristic sector. Moreover, according to the conclusions of the specialists, the effects of the transition to the market economy have determined a decline in tourism, together with other sectors of the economy. Thus, the international tourism demand has registered a decreasing trend because of multiple causes, such as: the low-quality level of the offered touristic services, the lack of diversity in the touristic programs, the reduced possibilities of recreation, etc.

Analysis of the touristic destinations

Presently, the Romanian tourism is in a period of analysis and profound changes, which is motivated by the preoccupation of being competitive on the unique European market.

With the intention of increasing the quality of the tourism activity, the policies as well as the strategic objectives which will be adopted have to aim at the following:

- the continuous achievement of a touristic product of superior quality, which corresponds to the modern tourism objectives;
- the improvement in the activity of the tourism personnel and in the quality of the touristic services;
- the diversification of the leisure offer;
- encouraging the Romanian and foreign investments in the tourism activity;
- elaborating more aggressive marketing policies which would aim at creating a positive image of the country outside the borders of Romania;
- promoting a competitive Romanian tourism, comparative with the countries which have a developed tourism (Spain, France, Switzerland, etc.).

Romania occupied the 76th position out of 124, in the first world classification of tourism and travels, with a mark of 3.91 from a total of 7, between Azerbaijan and El Salvador, according to a classification made by World Economic Forum (published in March 2007), which measures the tourism development potential in various countries.

The touristic potential of Romania is composed of a variety of forms of relief, springs with mineral and thermal water, lakes used for recreation, swimming and sport fishing, a valuable hunting fund amassed in coniferous and broadleaf forests, diverse landscapes from the mountain peaks of over 2000 metres to the plains, to the seaside and the Danube Delta. The grouping of elements with touristic potential, the infrastructure and the development on the Romanian territory is the result of the connections established between man and nature along time, as a consequence of the historic and natural evolution, which has led to the separation of touristic provinces (regions, areas, centres, localities, etc.) each one reflecting a certain degree of complexity, as a touristic potential, infrastructure, as well as a way of performing the tourism activities. Consequently, the contour of touristic axes that go across various provinces, areas, centres, localities and objectives has been produced.

In this sense, there has been an individualization of the following regions: Maramures, Bucovina, Brasov, Banat, Apuseni, Buzău-Vrancea in The Carpathians and Curvature Subcarpathians, Argeş-Prahova, North Oltenia etc. within which there are areas, centres, and secondary touristic axes comprised in a certain touristic system.

Romania possesses a great variety of natural resources which form a large part of the “basic” touristic product. These include the Black Sea beaches, the Danube and the rivers, the Carpathians and other mountain chains and the Danube Delta Biosphere Reservation. There are 16 national parks and 13 natural reservations which cover 7% of the country’s surface. In Romania there is a vast biodiversity with many species of flora and fauna which are unique in Europe. Romania possesses the richest variety of large mammal species in Europe and it is a major passageway for the migration of birds. Their total surface is of 1,652,403 hectares. The tourist attractions can vary from hunting and trekking in the mountains to recreational walks and winter sports.

The Romanian structures of tourism aim at the following:

- seaside tourism;
- the Danube Delta;
- mountain resorts;
- spa resorts;
- the capital and the county capital cities.

The structures of tourism from the seaside benefit from the shortest season, open, in average per year, for less than three months. The touristic season in the Danube Delta also functions for less

than six months a year. As a tourist destination, Romania's strong points aim at the following structures: geography and environment, culture and cultural heritage, infrastructure, transport and communication.

The geography and the environment are the strong points in the natural tourism potential through: the Danube Delta biodiversity (the Biosphere reservation which belongs to the UNESCO world heritage); the diversity of the national parks and of the protected natural areas (7% of the surface of the country) with forests, lakes and unpolluted rivers; the seaside and beaches of the Black Sea; the Carpathian Mountains; the Danube River; a large number of caves; the flora and fauna diversity (large number of unique species or with the highest density in Europe, especially large carnivores); 35% of the mineral water springs in Europe and of mofettes which offer a wide array of spa treatments; temperate-continental climate; good natural conditions for tourism activities (ski, mountain trekking, equitation, cycling, water sports, etc.).

The assets in culture and cultural heritage are represented by: the diversity of the heritage objectives—convents, archaeological sites, fortified constructions, including seven objectives/areas which are included in the UNESCO world heritage; medieval citadels; rural settlements where the traditional lifestyle can be experimented; museums with various themes; impressive artistic programmes—classical as well as modern; a wide variety of festivals, traditions, folklore; legends—Dracula, etc.

From the perspective of the tourism potential in the mountains, the most imposing areas are the following: Bucegi-Postăvaru, Piatra Mare, Parâng, Cindrelul, Șureanu, Retezat – Țarcu –Muntele Mic, Semenic-Aninei, Bihor-Vlădeasa-Muntele Mare, Rodna, etc., the touristic resorts and complexes that offer great possibilities of valorisation for the winter sports, mountain trekking, cave tourism, mountain-climbing, hunting, and sport fishing, spa treatment, religious, cultural tourism, ecotourism, etc.

The spa-tourism potential is famous on the international market because of the natural treatment factors, such as: mineral waters, mud and therapeutic gases, saline bioclimate, ionised-air bioclimate, phytotherapy (herbalism), partially exploited in the national spa resorts (approx. 24) and the regional and local (or localities) spa resorts which are not certificated (approx. 36). In addition to these favouring elements, we mention the professionalism of the medics, as well as the variety of traditional Romanian spa treatments and medicines.

The touristic potential of the Black sea littoral constituted of the famous tourist resorts includes a wide array of elements, such as: the mineral waters from Mangalia, Venus, Neptun, Eforie; the sapropelic mud from Techirghiol and the peat mud from Mangalia; the chlorine-sodium filled water of Techirghiol lake; the marine bioclimate and other natural and cultural-historical tourist attractions, dissipated on approx. 70 kilometres between Capul Midia and Vama Veche.

The Danube Delta tourism potential is represented by its ecologic value, by the landscapes, fauna (ornithological and piscicultural), cruises and expeditions organised in special surroundings with cultural and economical traditions specific to the local Russian, Ukrainian and Romanian communities.

The tourism potential of the Danube River and the adjacent region impresses because of the attraction area preferred for tourism: the Danube gorge and the Iron Gates, Danube's lakes, etc.

Romania's fauna and flora potential, rich in scientifically interesting species, but also for hunting, with ecosystems unique in Europe, represents important premises for the development of the Romanian tourism.

The Romanian tourism industry is distinguishable for its speleological, hiking and climbing potential as well as for the extreme sports possibilities offered mostly by the mountainous area.

The modernization, revival and development of the Romanian tourism are influenced by the climate of Romania which favours tourism during the entire year because of the comforting thermal regime, the snowfall which allows the development of winter sports, the therapeutic value of the bioclimate being a mountain incentive.

Romania's touristic offer and programme are also favoured by the cultural-historical heritage, very representative for our county, because of the multi-millenary history of the Romanian people, crystallized due to the following:

- The existence of more than 680 values of cultural heritage of national interest, such as 197 churches and monastery ensembles, 36 monuments and architecture ensembles. 11 castles, mansions and palaces, 70 urban architectural ensembles (civil buildings), 20 historic centres and archaeological sites, etc. A large part of the historic and art monuments are values of the UNESCO World Cultural Heritage (fortified churches, churches with exterior frescos, Dacian citadels, Sighisoara citadel, etc.).
- The Romanian ethnographic and folkloric treasure of a great originality is represented by the popular architecture, specific to the Romanian villages (from Maramures, Bucovina, Oltenia, Dobrogea, Transilvania, etc.).
- The craft industry, woodwork, the art of decorating, fairs and the traditional cultural-religious manifestations also represent the offer of a touristic product with a decisive role in choosing destinations.

The revival and development directions of tourism aim also at the technical-economical potential of Romania, objectified through engineering works of art, bridges, dams, old stacks, salt mines and mines, old factories and railway station buildings, vineyards and studs, etc.

Its geo-touristic position offers Romania several advantages due to the following:

- the presence of three natural components characteristic for the landscape and the social-economical structure of the country, components of great value and entirely European: the Carpathian Mountains, the Danube River and the Black Sea;
- the touristic transit function, because Romania ensures the connexion between the countries of Central, Nordic and Eastern Europe with the ones from the southern part of the continent and from the Near and Middle East;
- the European roads network with the seven road arteries and European corridors North-South (IX) and East-West (IV), between the railroad route and the Danube River (corridor VII), that establish the connections between the countries of the continent and the Black Sea basin.

In comparison with other tourist destinations, Romania has a weaker performance especially caused by the infrastructure regarding the road transport, but also as a consequence of some precarious aspects concerning the human resources and the public perception about the importance and value of tourism.

In the analysis of the market segments and the visitors' profile it has been found that, presently, there is no data to allow the analysis of the market segmentation concerning the foreign visitors. The only source is represented by a series of ad-hoc studies, as well as the official statistic data related to the nights spent which are included in "statistic data regarding the Romanian tourism", various editions of the National Statistics Institute, only the 2002 and 2008 editions being analyzed. (Table no. 1)

Table no. 1 Tourists arrivals and nights spent by the foreign tourists, according to the location

Location	Tourists arrivals (number of tourists)			Nights spent (number of overnights)		
	2001	2007	% of the total for 2007	2001	2007	% of the total for 2007
Littoral	44469	58191	3.75	373106	346765	9.67
Spa resorts	26383	36252	2.34	149349	157594	4.39
Mountain resorts	87903	118706	7.65	212525	286323	7.98
Danube Delta	5552	20445	1.32	13543	33610	0.94

county capital cities						
Other localities and tourism itineraries	64124	173447	11.18	167338	349691	9.75
TOTAL	914509	1550957	100	2390531	3586439	100

Source: National Institute of Statistics. *Romania's Tourism*, 2002 and 2008 editions

According to the analysis, a considerable increase in all the locations in the number of tourists arrivals, from 2001 to 2007, has registered; the most spectacular being registered in “Bucharest and other county capital cities”, namely 457838 tourists. In what concerns the number of overnights, it can be observed that, in general, it registered an increase in almost all the analyzed locations, exception to this situation being the littoral location. Here, the number of overnights decreased from 2001 to 2007 by 26341 units. Regarding the other locations, the most spectacular increase of the number of overnights has been registered in “Bucharest and other county capital cities”, namely 937786 units. An interesting variation in the visitation structures of the seaside resorts and of the mountain resorts, with a larger period of the stay registered at the Black Sea than in the mountain resorts, namely, almost 10 nights compared with almost 8 nights, for 2007, which suggests that foreigners who visit the seaside do it as part of their destination, while numerous visits to the mountain resorts belong to the circuit, along with other locations.

The “Bucharest and other county capital cities” and “Other localities and tourism itineraries” categories include not only the business or official visitors, but also the ones who get an accommodation on their way to other destinations and the foreign visitors who make short shopping trips, the ones who participate to events or who visit tourist attractions.

The qualitative research performed on the ANT staff (National Tourism Authority), on the Romanian hotel staff and on the travel organisers indicates the following main market segments for the holidays in Romania:

- *pretentious—elitist*: hunting, holidays with friends on Prahova Valley, Breaza – “Davos of Romania” and the golfing capital; Danube Delta biosphere reservation; wine tasting (Transilvania, Moldova, Crişana, Maramureş);

- *cultural tourism combined with ecotourism—young professionals*: Transilvania; Maramureş; Bucovina; Litoralul Mării Negre; Delta Dunării;

- *middle-class families*: Prahova Valley; Black Sea littoral; visits in the surrounding areas in order to spend time in nature, for example with the occasion of celebrating the 1st of May;

- *visits to see the parents* for Christmas and Easter;

- *the social category called “working class”*: Black Sea littoral; countryside vacation—either at relatives, or in guesthouses; visits in the surrounding areas in order to spend time in nature; visits to see the parents for Christmas and Easter;

- *older couples*: visits to see their children, to the city; social programmes (i.e.: “a week of recovery—a week at the Black Sea littoral”); visiting the monasteries (i.e.: Bucovina monastery); museums, castles;

- *young people—in groups*: the Black Sea littoral, especially Costinesti resort and Vama Veche resort; active tourism in the Carpathian Mountains; Danube Delta; camps (Eforie Nord, Năvodari, Cetăţile din Transilvania, Rânca –în Munţii Parâng, Bucovina).

There are major variations of the types of amusement trips, between rich people and poor people. The spa resorts clients is almost entirely internal, especially elders with low income, who go to these resorts with the help of treatment tickets offered by the social system.

The low-income clients have the tendency not to choose a hotel accommodation, because they cannot afford the costs. They rent apartments, guesthouses or camps.

The collection and arrangement of the data concerning the accommodations and the degree of occupation of the lodging spaces, classified on areas and accommodation type have to be improved. We consider that a new system of data collection regarding the visitors has to be

introduced consequently to Romania's accession into the European Union, considering that the traditional opportunity of counting the visitors at the border is no longer up to date. The optimal methodology to collect these data will be complex and will have to set standards of information in certain functional directions on the entire territory, and, at the same time, supporting the improvement of these systems at the level of areas and localities.

The tourist destinations have to offer a better evaluation of the general economical impact of tourism and to allow the comparison, from the perspective of performance, with other tourist destinations.

Conclusions

Considering that the following decades will bring about significant changes in the world demographic structure (average age, percentage of the ethnic and religious groups), the trends of the international tourism demand of tourism products/ travel arrangements will develop in all the meridians of the world. The population of the world will double in the next 50 years, the life expectancy and, implicitly, the average age of the population will grow, and the seniors (retired) will have more time and resources to travel. Therefore, the tourism products demand will be elastic and the increase in the interest for touristic programs/ holidays with possibilities of knowing the culture and history of the nations of the world will present a greater interest. Even if the interest is in novel experiences, the majority of potential tourists will want to be able to continue the healthy lifestyle when travelling and the quality of the tourism offer will influence the choice of a touristic destination.

Subsequent to this analysis, in the future it is compulsory to aim at achieving a more uniform distribution of the available accommodation capacity, at the level of the country and the regions, with the purpose of ensuring a better tourism activity.

The need of effort-coordination at a regional, as well as national level in order to accomplish grand projects in the domain of the infrastructure, especially of the transport and communication, which has to be correlated with the development process of the territory, which presupposes the coordination of all the projects with the spatial implications and solving the possible conflicts occurred in this context of profound transformations of the society. In this sense, an assessment, classification and identification model of the most appropriate and efficient ways of valuing the tourism heritage has to be established, using for this purpose a multi-criterion analysis of delimitating the touristic regions, together with a crystallization of the priority actions for each particular case. In conjunction with the touristic areas delimitation, the development of the territory and the appropriate policies in tourism, we have to find solutions regarding the protection of the environment from the tourism activities with a direct impact on the environment.

The starting point in establishing the strategy for improving the position of the destination competition is constituted by the determining elements of competition, which are mainly given by the resources (natural, cultural, of capital, of infrastructure, human), by the quality and structure of bidders, by the behaviour conditions of the demand and by the adaptation of the offer. However, all these have to be correlated with the provisions of the Declaration of Rio and with the enactment of Agenda 21, according to which the sustainable development of tourism represents the global strategic option for this century. The management and the sustainable development of tourism are applicable to all the forms of tourism, in any type of destination, including mass tourism, as well as other varied segments of tourism.

QUALITY OF PUBLIC TRANSPORT SERVICES IN URBAN AREA OF ORADEA

Silaghi Simona
Universitatea din Oradea
Facultatea de Științe Economice

Intensification of public transport in urban areas due to increased mobility at regional and national levels, discrepancies among urban areas with same population and lack of statistical data related to performance and quality of public transport services are the main determinants of this paper. A separation line must be drawn between quality of services and performance indicators of public transport system. Service quality is a multi subjective outcome of an array of intangible variables. Service quality can be approached from four directions: consumer point of view, vehicle performance (including the human operator), specialized company in passenger transport, and the Government (local Councils). Availability, comfort and convenience are the two main indicators that must be evaluated by citizens as being with high grades for a good quality of urban transport services. The instrument used to gather data is the preference survey.

Keywords: service quality, performance indicators, availability, comfort, subjective outcome

L80, P46, R40

Introduction

Due to the intangible characteristics of services, defining service quality becomes an essential issue for some European countries. Quality appears as an abstract dimension, it leads to quality evaluation with specific approaches and instruments. The preference survey and the SERVQUAL method are used to gather data and evaluate quality.

The differences among public transport systems in European cities, evaluated from the point of view of number of vehicle in use and system lengths, are the starting point of this research. We consider three urban areas with approximately same number of citizens: Oradea (232.000, including metropolitan part), Graz (248.000) and Debrecen (246.000).

Oradea has a tram system on five routes; total length 37,14km double way, the mean length of a route being 7,14km. Bus network is made up by 9 routes with a total length of 54,53km. The urban transportation park includes 75 trams and 64 buses.

Grazer Stadwerke Verkehrsbetriebe AG operates 25 routes for buses, with 136 vehicles, 61 trams, and since 2005 the bus network uses bio diesel.

DKV Zrt.(Debrecen Közlekedési Zrt) is the main company responsible for the urban transport and encompasses a network of 1 tram line, 5 lines for cable buses, and 51 regular bus routes. The transportation company, member of an international holding, operates⁶⁹⁵ 21 trams, 30 cable buses, and 168 buses, on a network of 174,6km.

Data registered by the National Statistic Office of Romania shows worrying facts regarding the number of passenger transported at national and international level, and the preference for different transportation types.

Between January and September 2009 transportation decreased in subway transportation with 13%, a raise of 11,3% electric wire buses sector, decrease of 0,8% trams and 7,4% buses are noticed.

⁶⁹⁵ * * * Debrecen M. J. Város Önkormányzata, *Debrecen városi fenttartható városi közlekedési – fejlesztési terve, Tanulmányterv, p.31-32,*
http://portal.debrecen.hu/upload/File/Egyeb/dmjevKozlekedesfejlesztésiTerve_2.pdf

Between January and September 2009 transportation decreased in subway transportation with 13%, a raise of 11,3% electric wire buses sector, decrease of 0,8% trams and 7,4% buses are noticed.

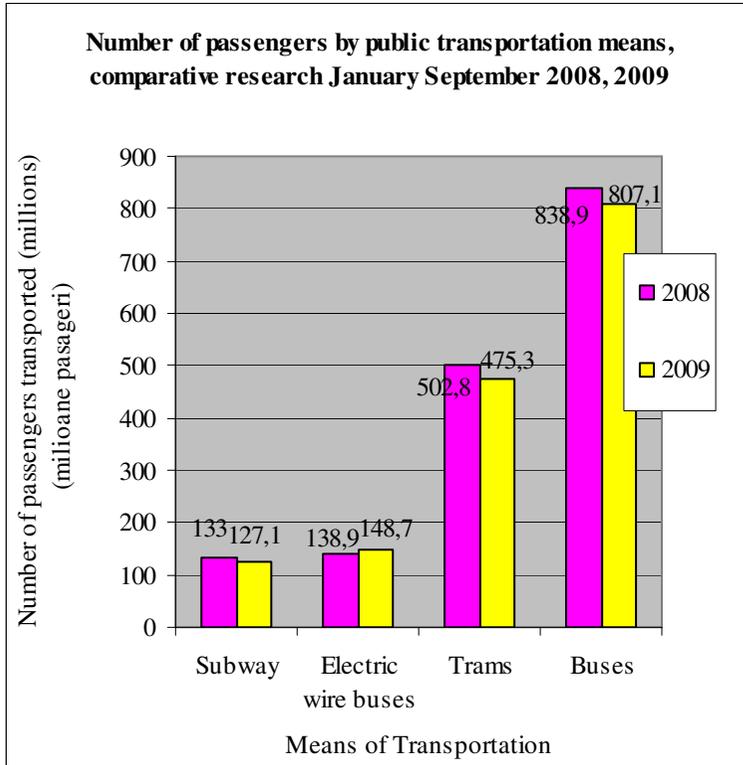

Figure 1 Number of passengers transported in public services, January-September 2008 and comparable with the same period in 2009

Since 1990, the number of passengers- intercity and international transport-decreased from 780666 thousands to 191127 thousands in 2002. 2003 and 2004 are years with stagnation somewhere between 216327 thousands and 216524 thousands passengers transported. 2005 is year of growth, 2006 an year when this number decreases, and goes up again in 2007, 2008 to reach the level of 296953 thousands passengers annually

transported⁶⁹⁶.

Data regarding quality and performance indicators of public transportation services are vaguely determined and practically inexistent.

Theoretic approach, explanation of terms

Among services rendered to population the public transportation services are taking a very important role. The public transportation of passengers is a type of transportation operation which is realized with the help of urban transport vehicles, including subway, within the administrative and geographic area of an urban territory, without crossing its borders. In developed countries this type of transport includes the services realized by school buses.

It is absolutely necessary to correlate expectations of citizens of an urban area with perceptions regarding services. The outcome is necessary to evaluate the quality of service.

Dictionaries define quality as a characteristic, dimension, and the goal of this paper is to find a definition formula for quality of public transport services. Few questions rise: When the public transport services are acceptable qualitatively? When the public transport services determine unhappy citizens? When the public transport has a superior quality?

In the case of services, subjectivity is a variable which could be economically interpreted as utility. Thus an U.S.A. study reveals (75%-80% of respondents) the mean distance that

⁶⁹⁶ * * *, *Romanian Statistical Yearbook*, National Institute of Statistics, Time Series 1990 – 2008, Chapter 17.13, Passenger Transport by Mode of Transport

passengers are willing to walk from the starting point of the journey to the first available public transportation pick up point (400m), corresponding to 5 minutes walking time.

A good is valuable or has utility component in different conditions than has to other people. Utility of a service encompasses abstract factors like: security, tangibles, assurance, empathy, sensibility. On the other hand, quality is the outcome of needs, former experiences, and “world of the mouth”. The two sides necessary for the definition of quality, expectations and perceptions, and the differences between them lead to a satisfied, unsatisfied or unhappy customer.

Assurance of good quality become the output of collaboration between public forces like Local Councils, Ministries, Government, and specialized public transportation companies, when they are invited to implement and improve the image of services rendered to citizens, in an urban area. The public welfare and the maximization of revenues for transport services are put in the balance. It is necessary to underline that a separation line must be drawn between different terms like: quality or service level and the evaluation of performances of a public transport system.

The performance of a public transport system can be measured qualitatively. It also can be measured in absolute values and usually refers to a particular aspect of the transport (cylindrical capacity for vehicles used). The service quality can be approached only from the consumer point of view.

Measuring service is an evaluation from the quantitative point of view of the consumer (effectiveness).

Service levels are evaluated usually with “A” to “F” (quantitative evaluation) for particular passengers’ perceptions. Quality of the public transport services reflects the performance of the same services.

Performance indicators of a public transport system could be: availability, service monitoring, influences on community, travel times, safety and security, construction and maintenance of vehicles, economic impact, transport capacity (number of passengers).

Measuring service quality is a procedure to be considered from the point of view of: public service consumers, the vehicle (and the driver), the private company which administrates public transport services, and the community.

Availability can be measured as spatial availability (for example: network coverage), temporal availability, information availability and capacity availability.

Comfort and convenience are the outcome of conjoint action of variables likes: travel time, hours of service, reliability, waiting time, safety and security, passenger load-available free spaces in the vehicle, vehicle’s cleanliness, the cost of transportation, and number of transits to reach final destination, comparative evaluation among other means of transportation.

An American study reveals (75%-80% of respondents) that the mean distance that passengers of public transportation are willing to walk from the start point of their journey to the first available public transportation picks up point is 400m, corresponding to 5 minutes walking time.

It is appreciated that 1 minute waiting time for public transport services is more important than 1 minute of time in the transportation vehicle⁶⁹⁷. There are cleanliness standards in San Francisco and New York .Thus inspections are undertaken to observe the accomplishments of standards in the public transportation system. Cleanliness is evaluated on the scale ranging from 1(very clean) to 7(dirty).

Methodology

The proposed instrument to gather data are the preference survey and the method to evaluate quality is SERVQUAL.

⁶⁹⁷ * * * Transit Cooperative Research Program, sponsored by The Federal Transit Administration, *Transit Capacity and Quality of Service Manual-2nd Edition*, Part 3-Quality of Service, Chapter 3 Quality of Service Factors, p.3-20, <http://onlinepubs.trb.org/onlinepubs/tcrp/tcrp100/part%203.pdf>

Before applying surveys to consumers, a brainstorming session is held to determine the most important dimension for consumers when evaluating public transportation services: availability and tangibility.

The survey consists of nineteen questions which describe the consumer of public transportation services in Oradea. Seven questions give details related to social and economical status of the consumer regarding: age, sex, occupation, studies, status, neighborhood in which lives in, and incomes. There are thirteen questions which are giving details related to: transportation type known by the consumers, the most frequently used transportation type, factors that are determinants of poor satisfaction of consumers (availability and price of tickets, delays, travel time, frequency, network coverage, hours of service, interior aspect cleanliness and odors, general appearance of the interior of the vehicle, maintenance of vehicles and stop points, technical aptitudes for vehicles and stop points, general look and behavior of personnel). Each factor reveals an abstract general quality of the service like availability or tangibility. Information regarding frequency, other means of transportation, scope of transportation, significant delays encountered and means of transportation that generated delays, availability of time schedule (as information availability) and interest for ecological type transportation methods as a sustainability matter are gathered. Respondents are invited to add their suggestions regarding improvement of actual urban transportation network.

Final data shows relations between social and economical status and urban transportation quality abstract dimensions.

The SERVQUAL method comes to complete the survey through evaluating quantitatively abstract dimensions of transport services.

This method uses 22 statements related to the five dimensions⁶⁹⁸ of any service: reliability, responsiveness, assurance, empathy, tangibility. Statements are applied to consumers before and after the service. Each statement must be evaluated on a seven point scale from “strongly agree” (grade 7) to “strongly disagree” (grade 1). A score is calculated for each pair of statements. If the score is high it means that service delivers a poor quality component. If score is low or zero, quality of service is not affected.

SERVQUAL is a comprising method which evaluates all gaps in quality of services. It appears as a subjective outcome of service delivered.

Parasuraman, Zeithaml, and Malhotra propose a third century instrument to measure data related to quality of services. Data about the service is gathered on the Internet and the instrument is called E-S-QUAL⁶⁹⁹.

The present research is evaluating quality of service as a resultant between expected and delivered quality of service, from the consumer point of view.

Findings

The most important component of public transportation services in Oradea appears to be safety and security during travel.

Zeithaml, and L.L.Berry, *SERVQUAL: A Multiple-Item Scale for Measuring Consumer Perceptions of Service Quality*, Journal of Retailing, vol.64, no.1, spring 1988, p. 12-40

⁶⁹⁹ Parasuraman, A., Valarie A. Zeithaml, and Arvind Malhotra. 2005. E-S-QUAL a multiple-item scale for assessing electronic service quality. Journal of Service Research 7: 213–233 in Eriksson Lars, Friman Margareta, Norman Ann – Catrin, *Electronic Service Quality: Public Transport Information on the Internet*, <http://www.nctr.usf.edu/jpt/pdf/JPT%2010-3%20Eriksson.pdf>

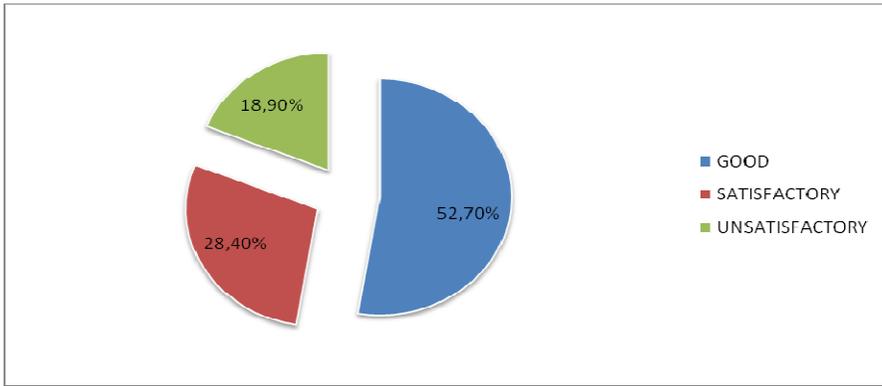

Figure 2 Resident general appreciation of the quality of public transportation in Oradea

Evaluated on a scale ranging from 1 to 5, from not important to major importance, the score of most important characteristic is 4,33. Cleanliness of stop points, convenience of time schedule seems to be equally important for respondents. Equipment and technical support, and appearance and language of employees-tangibles- received a lower score (figure 3).

Figure 3 Most important components of the public transportation service(Mean values are considered for classification)

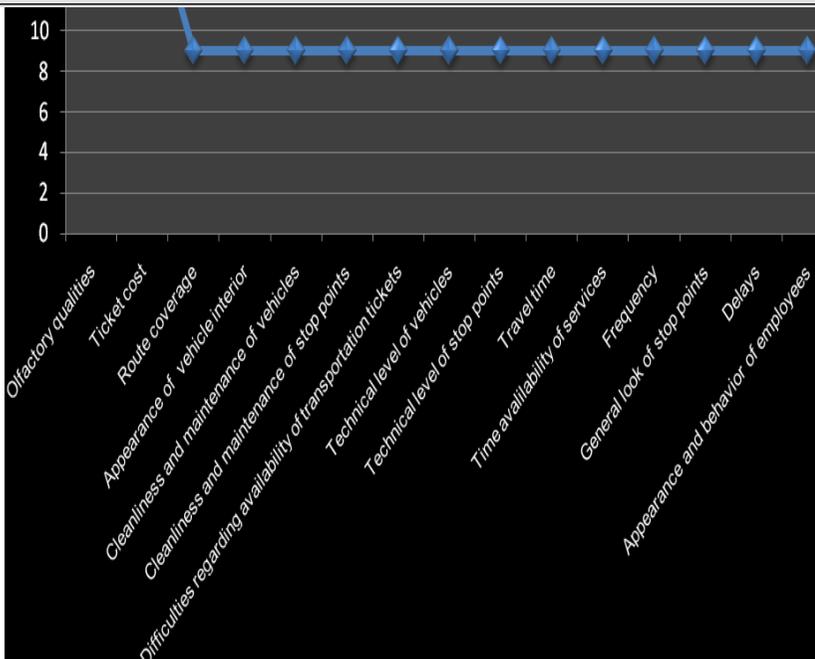

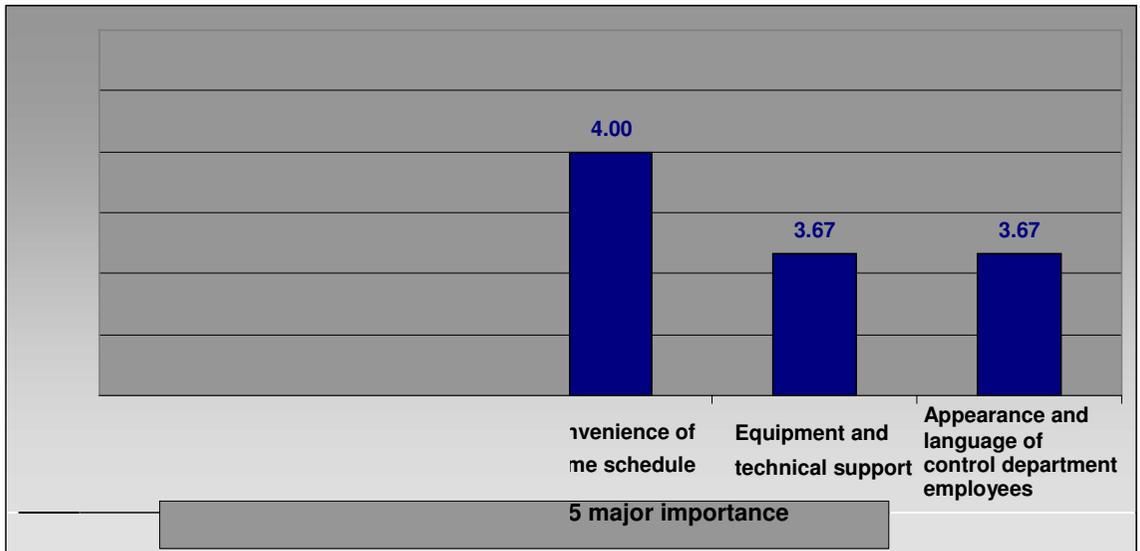

Figure 4 The case of public transportation services: Main reasons for unhappy customers

Respondents (52,7%) appreciate public transportation in Oradea as being with a good quality, 28,40% as being satisfactory and only 18,90% consider that services do not correspond to their expectations.

A major number of people consider olfactory qualities and ticket cost, factors with major importance to qualify public transportation services as being good. It is important to underline that these two factors are among the most important in a fifteen components list (figure 4). SERVQUAL application reveals details about characteristics which do reflect a poor quality of public transportation services. Olfactory qualities and cleanliness of vehicles and stop points received the highest scores. That means that quality is affected negatively because of these characteristics. Transportation companies or local councils should focus their resources to reduce the score for these characteristics. SERVQUAL should be applied again in approximately six months to re-evaluate components of quality of transportation services.

Conclusions

Recommendations regarding improvement of stop points and transportation vehicles would be: more tickets' sale points; equipment and technical base maintenance; cleanliness of vehicles. SERVQUAL can be used for evaluation and improvement of public services in any sector.. It is recommended to monitor delivered quality of services. It is important that a specialized structure should accomplish these functions. For this purpose, in most cases⁷⁰⁰ the monitoring unity is the company specialized in public transportation. Parasuraman, Zeithaml, and Malhotra propose a third century instrument to measure data related to quality of services. Data about the service is gathered on the Internet and the instrument is called E-S-QUAL⁷⁰¹.

WORKFORCE ENGAGEMENT IN A CATALOG COMPANY

Vaduva Sebastian

Emanuel University of Oradea

Fotea S. Ioan

Emanuel University of Oradea

Corcea Mihai

Emanuel University of Oradea

The paper is part of a larger research project from the new paradigm on service quality management perspective and discusses the main issues in the area of employee engagement in a national direct marketing company. Following a presentation of the engagement concept, the company's workforce is analyzed using the HumanSigma model for employee engagement assessment. The study identifies key issues that should be addressed in order to increase productivity of the company's workforce through transactional and transformational activities.

Keywords: human resources, employee engagement, relationship management

JEL: M10

1. Introduction

The strive for quality in both production and services have lead companies and organizations to develop multiple instruments to measure and improve it. The motivation did not just arise as a competitive advantage, but also as a request from customers and clients⁷⁰². Thus, we would like to present such an instrument and apply it to an emerging sector in the Romanian economy – the telemarketing services. The paper proceeds in the following manner. First of all, the concept of employee engagement is elaborated. Secondly, the area of direct marketing as an example of a service organization is considered and presented. Then one business unit of a telemarketing company is used to test the concept and some conclusions are drawn at the end.

2. Enterprise Engagement

In the last century, companies from all economic sectors have acknowledged the paramount importance of meeting and exceeding customer's expectations by producing or offering high quality goods and services. Managers concluded that there is a strong correlation between the quality of production and financial results.

Because the study of quality in service organizations has largely been overlooked by management scholars, the service sector tried to implement quality management systems proved to be excellent for the production sector.⁷⁰³ One of the quality management methods designed for manufacturing companies and implemented in the service sector is Six Sigma. Though this method was proved to yield high efficiency in the manufacturing industry it wasn't working in service organizations. For sales and service organizations Six Sigma was very difficult to be applied as a strategy for efficient quality management.⁷⁰⁴

The company's human capital is the essential aspect in building long-term profitable relationships with clients, thus HumanSigma⁷⁰⁵ offers a systematized approach for measuring, managing and

⁷⁰² Fotea, Ioan and Corcea, Mihai; *Enterprise Engagement in Higher Education Administration at Griffiths School of Management*, paper presented at Annual Research Conference at Emanuel University of Oradea, March 2010

⁷⁰³ Fleming, John H.; Asplund, Jim; *HumanSigma*, Gallup Press, 2007

⁷⁰⁴ *Ibid*, p15

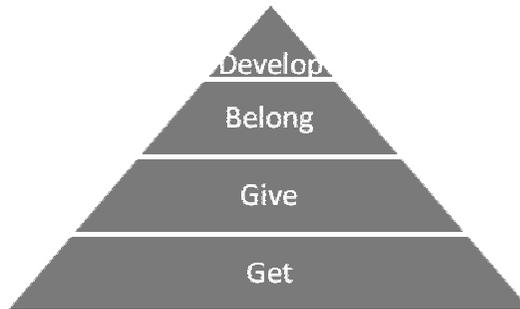

⁷⁰⁵ HumanSigma is a trademark of Gallup Organization.

improving the performance of the most valuable and volatile assets of an organization – its employees and customers.⁷⁰⁶

3. Workforce Engagement

The concept of *engagement* goes beyond satisfaction and motivation, representing a *passionate advocacy*. Such passionate advocacy that can be determined in a workforce is the first prerequisite for engaged customers with a high lifetime value.⁷⁰⁷ There are four dimensions to employee engagement that can be expressed as four questions that arise in every employee's mind, be it consciously or subconsciously: (1) what the employees get, (2) give, (3) if they belong to the workplace and (4) the extent in which they can develop themselves.⁷⁰⁸ The dimension of emotional attachment determines the level of loyalty that a customer has towards an organization that is providing her service.⁷⁰⁹ The buying decision and engagement development can be influenced for both sides of an organization's human capital – employees and customers. External and internal marketing can benefit from several psychological⁷¹⁰ elements of consumer behavior of which we shall mention the social norms, the decoy, the zero effect, methods as applicable to a wide range of service organizations – healthcare, education, retail, professional service.⁷¹¹

These four aspects of employee engagement are a mix of rational and emotional elements that must be regarded when the management team tries to develop the organization's relationship with its most important client – the employee.⁷¹² We shall therefore look into these four dimension in a little bit more detailed fashion:

What do I get? This explores how the employee perceives the level by which the company supports her regarding the technical needs he has in order to efficiently fulfill the job. Any employee that does not perceive real support from the organization will be frustrated and less productive and in time will look for such a job that will provide what she needs or want.

What do I give? This explores how the employee perceives the measure of his value to the company as well as the importance of the job he or she does. An employee who doesn't perceive that he is carrying out an important task, meaningful for the company and for himself, will be less productive than another that feels that he is making an important contribution to the company.

How much do I belong? This explores how the employee perceives the level of his integration in the company's workforce environment, senses he belongs to the team and feels accepted by his peers will not be inhibited, but rather would act normal, thus being more productive.

⁷⁰⁷ Ambler, Tim; *Marketing and the Bottom Line*, London: Financial Times/Prentice Hall, 2002

⁷⁰⁸ Ibid: 161

⁷⁰⁹ Pop, N. Al., Atașamentul clientului față de întreprindere – principală pârgie a marketingului relațional, *Marketing-Management*, anul XV, no. 1, 2005, p. 16-22

⁷¹⁰ Ariely, Dan; *Predictability Irrational: The Hidden Forces That Shape Our Decisions*, HarperCollins, 2008

⁷¹¹ Forum for People Performance Management and Measurement, *Internal Marketing Best Practice Study*, Department of Integrated Marketing Communications at Northwestern University, 2006

⁷¹² Buckingham, Marcus; Coffman, Curt; *First, brake all the rules*, PocketBooks, 2005

How do we develop? This explores how the employee perceives the number of personal development opportunities understanding if the job he is doing is part of a greater process that aims first at his own professional development – he must feel that the company contributes to a value that is independent of employment at that company.

The Gallup researchers have observed that great organizations and their managers understand excellence as part of attaining the desired results and not only conformance and execution of a job checklist. Therefore, employees are not required to do a mechanic behavior of conformance to a list of specific actions they must undergo, but instead their creativity is stimulated for attaining the established objective. Employees with high levels of engagement will be able to find efficient methods for completing their tasks without the completion of a checklist.

4. Direct marketing catalog companies

Catalog companies are sales organizations that use various channels for undertaking direct marketing activities in order to reach the customer directly and to avoid conventional channels of distribution. Direct marketing is a database-driven interactive process of directly communicating with target customers or prospects using any medium to obtain a measurable response or transaction via one or multiple channels.⁷¹³ One of the new channels of communication with the customer is telemarketing. Telemarketing is the use of the telephone to market goods or services directly to prospective customers.⁷¹⁴ The emergence of telemarketing has been observed in the last decades, when it gained the status of an important tool for sales. Telemarketing has steadily increased in use in sales organizations while management, in various sectors, faced the difficult problem of successfully implementing this tool.⁷¹⁵ As well as other direct marketing channels, telemarketing has challenged conventional means for advertising as well as traditional department stores and other retailers. Scholars affirm that advertising agencies are restructuring to accommodate a harsher reality due to the fact that direct marketing is stealing business away from traditional advertising and the growth of sales promotion and integrated marketing communications both come at the expense of traditional advertising. It can also be mentioned that targeted advertising that Google invented and promotes with their services is also reshaping the advertising industry. In a way printed catalogues – which are not new – are a printed version of the targeted advertising that Google does.⁷¹⁶

A core emphasis in the direct marketing industry falls on relational marketing, as opposed to transactional marketing approaches in traditional channels of distribution.⁷¹⁷ Catalog companies enjoy success when they build strong customer relationships. While relationship building is referred to in many different ways, the end result is the same – mutually beneficial long term bonds between buyer and seller. The success of that relationship is measured in terms of lifetime customer value.⁷¹⁸ The economic evolution of our society determined many confusions and uncertainty due to mass marketing and niches. Direct marketing cuts through this confusion and goes directly to the customer, creating a business relationship that resembles to some degree to the past in which producers and consumers met face to face without many intermediaries.⁷¹⁹

Many direct marketing companies have implemented a multichannel business model. One attractive channel for catalog companies is online sales. Direct marketing undergone by mail-

order companies takes place without the traditional intermediaries, with the help of telemarketing, mail catalogs but also web platforms that yield higher efficiencies due to existing payment processing, inventory management and also fiendly end-user interfaces.⁷²⁰

6. Case study: CATALOG COMPANY - Oradea

CATALOG COMPANY is a direct marketing organization based in Oradea which sells various products through telemarketing, catalog and a web-store. Research has been done by administering Q12 Gallup questionnaires to CATALOG COMPANY employees. We chose the Q12 questionnaire because it is a simple, yet powerful tool that reveals employee engagement and workforce conditions. After gathering data from questionnaires applied to staff, the authors of this paper have done an assessment of the current state regarding workforce engagement at CATALOG COMPANY.⁷²¹ From the 12 elements that were analyzed, two of them are under a critical condition:

Element 2, „I have the materials and equipment to do my work” is characterized by low engagement at CATALOG COMPANY and reveals the extent of organizational support with equipment and materials. Offering the employees what they need to do their job is a factor that offers the company two kinds of benefits. First, from an operations perspective means having equipment and materials that will make the work more productive. Second, being equally important, the employee must feel that the company supports him and offers him the equipment needed for efficient work – thus being a strong employee psychological motivational factor.

Element 4, praise and recognition in last seven days, is characterized by low engagement at CATALOG COMPANY showing the level of positive feedback from managers towards employees. Appraisal is important for an organization because it determines a positive climate of workplace environment representing a motivational factor. According to Gallup research this element can bring as much as a 20 percent increase in productivity. Appraisal is a very efficient motivational factor and without any financial costs. An indicator that was assessed by Gallup researchers is positive comments : negative comments ratio. According to statistics, efficient organizations show to have a 1:5.6 ratio, whereas in weak organizations the ratio is 2.8:1. Work teams that show low levels of productivity maintain a negative climate of exaggerate self-affirmation and a narrow mentality of survival. Efficient work teams are characterized by an open culture and a justified positive attitude.⁷²²

No.	Question
1	Do you know what is expected of you at work?
2	Do you have the materials and equipment you need to do your work right?
3	At work, do you have the opportunity to do what you do best every day?
4	In the last seven days, have you received recognition or praise for doing good work?
5	Does your supervisor, or someone at work, seem to care about you as a person?
6	Is there someone at work who encourages your development?
7	At work, do your opinions seem to count?
8	Does the mission/purpose of your company make you feel your job is important?
9	Are your associates (fellow employees) committed to doing quality work?
10	Do you have a best friend at work?
11	In the last six months, has someone at work talked to you about your progress?

⁷²¹ Wagner, Rodd; Harter, James; *Cele 12 elemente ale managementului performant*, Editura Allfa, 2009

⁷²² Ibid

The positive aspects of CATALOG COMPANY workforce environment are related to the fact that employees affirm they know what is expected of them at work. They also feel accepted by their colleagues, many of them having a best friend at work. The research revealed that managers have been successful in coaching employees which have affirmed that they feel encouraged and helped to develop.

7. Conclusions

In conclusion, it is very important that there are instruments, such as HumanSigma's Q¹² questionnaires that help organizations measure and evaluate performance, so as to be able to improve quality and overall their activity. Different instruments may be more suitable for different companies but the tool that has been selected revealed several areas of human resource management that need intervention.

It is our recommendation that the measure provided by HumanSigma to be applied to the company's workforce every six months in order to be able to sense changes and improvements as corrective actions are undertaken. For those areas where improvements are desirable we recommend that further analysis should be made – may be using other instruments – to determine the causes and potential solutions.

There are also several limitation of the study such as the fact that the number of employees is rather small, and the company is not among the largest in the country – so we may not extrapolate to the entire industry. It is rather a case study and an example of what the service sector companies should utilize in order to measure employee engagement.

L'ANALYSE COMPARATIVE DES FUSIONS-ACQUISITIONS AVEC LES AUTRES FORMES DE CROISSANCE DES ENTREPRISES (I- FUSIONS-ACQUISITIONS VS. CROISSANCE INTERNE)

Vancea Mariana
University of Oradea
Faculty of Economics

In order to achieve growth and development strategy, companies can choose between continuous improvement or optimization of operational and financial assets, on one hand, and on the other hand the achievement of mergers and acquisitions, as also strategic partnerships with other companies. The purpose of this paper is to analyze the company's growth and development strategy through mergers and acquisitions by comparison with that of organic growth, while highlighting the advantages and disadvantages of each type of strategy.

Keywords: company, mergers, acquisitions, organic growth

Cod JEL lucrare: L21, L25

1. Introduction

Dans le but de réaliser la stratégie de croissance et développement, les entreprises peuvent choisir entre l'amélioration et l'optimisation continue des actifs opérationnels et financiers d'une part, et la réalisation des fusions et des acquisitions ainsi que des alliances avec d'autres entreprises, d'autre part. Dans le premier cas on parle de croissance interne ou organique tandis que dans le deuxième cas on parle de croissance externe.

Les fusions-acquisitions, le principal instrument de croissance externe, représente actuellement un choix privilégié des entreprises pour se développer d'une manière indépendante. Toutefois, si au début, cette manœuvre a suscité un réel enthousiasme, les résultats s'avèrent être, dans beaucoup de cas, tout à fait décevants. Donc, quand une entreprise desire adopter une stratégie de croissance et développement, il est nécessaire d'apprécier les avantages et les inconvénients de cette option par rapport aux autres moyens de croissance alternative, comme la croissance interne ou la réalisation des alliances.

La choix entre ces options différentes se réalise en fonction des caractéristiques de l'entreprise initiatrice de l'opération mais aussi de ses options stratégiques.

La culture organisationnelle de l'entreprise et la politique menée dans le domaine des allocations des ressources et de la gestion des risques, sont aussi des facteurs-clés en ce qui concerne la choix entre les différentes stratégies possibles.

La croissance par fusions-acquisitions constitue un des principaux instruments de la croissance externe et s'oppose, par ses principes, à la politique de croissance interne.

On propose, par la suite une analyse comparative entre la stratégie de croissance par les fusions-acquisitions et la stratégie de croissance interne, en mettant en évidence les avantages et les inconvénients du chaque type de stratégie.

2. La comparaison entre les fusions-acquisitions et la croissance interne

La croissance interne suppose un développement progressif et continu de l'entreprise, fondé sur une croissance des capacités existentes ou la création de nouvelles capacités productives ou commerciales⁷²³.

⁷²³ Meier, O., Schier, (2006), *Fusions Acquisitions- Strategie, Finance, Management*, Ed. Dunod, Paris, p.10

Une multitude de théories sur les procès et les ressources stratégiques proposent l'explication de la notion de croissance de l'entreprise. Au niveau de l'entreprise, Edith Penrose⁷²⁴ voyait la croissance comme une fonction des ressources managériales, lorsque ces dirigeants ont des connaissances de spécialité, ils connaissent l'entreprise et ils savent comment utiliser d'une manière très efficiente les actifs internes et les compétences. Ensuite, en s'appuyant sur une analyse à fondement plus large, Romer⁷²⁵ considérait qu'à long terme, la croissance est déterminée par une accumulation et une transmission de connaissances.

Plus tard, les études ont accentué les théories se rapportant aux *routines organisationnelles* que Nelson et Winter⁷²⁶ les ont défini comme représentant une accumulation de connaissances et d'habilités opérationnelles de l'organisation. Les chercheurs considéraient que ces routines et l'habilité des entreprises à les renouveler, en fonction de la dynamique du marché, détermine la croissance des entreprises.

Dans l'approche de la croissance au niveau de l'entreprise, dans la perspective interne (resource-based view), l'entreprise représente une accumulation de ressources, d'actifs, de connaissances et d'habilités qu'ensemble, lui détermine la croissance et le développement⁷²⁷.

L'élément central situé à la base du choix d'une stratégie de croissance interne ou croissance externe est représenté par la réponse à la question « Ce serait mieux d'acquérir de nouvelles compétences, l'entrée sur un marché, une base de clients, des opportunités de gains, etc. ou attendre de les obtenir par les propres forces ? »⁷²⁸.

L'opposition croissance interne/croissance externe a pour but la distinction des deux options fondamentales qu'une entreprise a en ce qui concerne la croissance et le développement. Edith Penrose, dans son ouvrage « The theory of the growth of firm » a établi une différence nette entre ces deux moyens de croissance et développement des entreprises. Ainsi, elle a présenté la croissance interne et la croissance externe comme représentant deux options stratégiques différentes que l'entreprise possède à sa disposition. L'idée centrale énoncée par Penrose est celle que les prochaines opportunités de croissance ou ses limites sont générées par les ressources ou les compétences accumulées par une opération antérieure de croissance. Elle souligne le fait que la croissance interne tout comme la croissance externe présente certaines limites et que l'utilisation d'une stratégie de croissance peut avoir des conséquences sur l'utilisation d'une autre stratégie. De cette manière, Penrose considère que la signification d'une fusion (ou acquisition) peut être le mieux évaluée, dans la lumière des effets sur la croissance interne et des limites dans sa réalisation⁷²⁹.

En effet, dans le but de la croissance et du développement, une entreprise peut opter pour agrandir le capital productif, par croissance interne ou la prise du contrôle sur des actifs appartenant aux autres entreprises, par recours aux fusions-acquisitions.

On distingue deux facettes du concept de croissance de l'entreprise par les propres forces. D'une part, on parle de croissance interne lorsqu'on met l'accent sur l'accumulation de nouveaux actifs productifs et/ou commerciales et d'autre part, on parle de croissance organique lorsque l'accent est mis sur l'évolution du volume de l'activité de l'entreprise ou de ses résultats⁷³⁰.

⁷³⁰ Meier, O. et.al, (2009), *Stratégies de croissance*, Ed.Dunot, Paris, p.4

La croissance interne suppose l'agrandissement de l'entreprise par des emprunts de capital et le réinvestissement des profits des années précédentes à l'intérieur de la même entreprise. Cela détermine une croissance des capacités productives, une allocation supplémentaire de ressources humaines et une augmentation du chiffre d'affaires⁷³¹. La croissance organique peut représenter un moyen d'évaluation de la qualité de l'utilisation des ressources internes de l'entreprise par les dirigeants de l'entreprise. Lorsqu'elle est positive, elle peut indiquer une augmentation du nombre des clients au détriment des concurrents (croissance de part de marché) mais aussi une augmentation des revenus ou une extension de l'entreprise vers d'autres zones géographiques⁷³².

L'allocation des ressources financières et humaines dans la réalisation de la stratégie de croissance doit être fondée sur une augmentation de valeur soutenable pour les bénéficiaires de l'entreprise, mais cela peut demander plus de patience pour atteindre ces objectifs et pour conduire à la perte de certaines opportunités. Par l'adoption d'une stratégie de croissance interne, l'entreprise a la possibilité de garder son indépendance économique et financière. Cette stratégie convient mieux, surtout dans le cadre des stratégies de spécialisation, en adoptant une politique de renforcement ou d'augmentation des activités existantes. Ce moyen de croissance atteint pourtant rapidement ses limites, à cause des difficultés de l'entreprise à disposer de ressources internes suffisantes pour continuer à progresser et à innover. L'innovation est considérée un élément clé qui détermine la croissance interne de l'entreprise. L'innovation est vue comme un processus fondamental ou une capacité organisationnelle qui génère des connaissances organisationnelles qui conduisent, ensuite à la création de nouveaux produits et services, à une croissance interne et ultérieurement à une meilleure performance financière⁷³³.

Souvent, parce qu'on désire l'obtention d'importants résultats dans un intervalle de temps assez court, la nécessité d'utiliser, dans le processus de croissance, d'autres instruments en dehors de ceux classiques de la croissance interne, est devenue de plus en plus grande. Les transactions stratégiques deviennent ainsi un moyen par lequel les dirigeants des entreprises réalisent des changements importants à court terme⁷³⁴.

La croissance par fusions-acquisitions représente un moyen de développement qui permet à l'entreprise de contrôler des actifs déjà productifs sur le marché et détenus au début par d'autres entreprises.

Elle accorde à l'acquéreur la possibilité d'accroître rapidement sa capacité de production, déterminant une diminution de la période de maturité d'un investissement productif. Les entreprises qui ont un grand potentiel de croissance représentent souvent les cibles parfaites des opérations de croissance externe. Par contre, les entreprises dont la croissance interne est ralentie, choisissent souvent de s'agrandir en fusionnant ou en acquérant une entreprise dont la croissance est plus rapide⁷³⁵.

Les fusions-acquisitions, comme option stratégique, sont considérées comme ayant une puissante influence sur la création ou la diminution de la valeur de l'entreprise. Par opposition à la croissance interne, l'allocation de ressources pour la réalisation d'une opération de fusion-acquisition accélère le processus d'atteindre les objectifs de croissance de l'entreprise mais augmentera, en même temps, le niveau du risque si l'opération n'est pas bien structurée ou bien négociée. Généralement, le choix entre ces deux moyens de développement (croissance interne

⁷³⁵ Liodakis, M. et Pang, C., *Searching for value-enhancing acquirers* dans Gregoriou, G.N., et Renneboog, L., (2007), *International Mergers and Aquisitions Activity Since 1990*, Ed. Academic Press, Burlington, USA, p.72

ou fusions-acquisitions) est en étroite dépendance avec le type des entreprises et de la stratégie qu'on envisage. Les variables, qu'une entreprise qui désire adopter une stratégie de croissance et développement, devrait prendre en considération dans le choix d'une stratégie de croissance interne ou d'une fusion-acquisition, incluent⁷³⁶:

- la compétitivité, la fragmentation et le rythme du marché et de l'industrie;
- l'accès au capital et le coût du capital;
- les capacités spécifiques de l'équipe des dirigeants;
- la capacité et le potentiel de développement des compétences fondamentales;
- la loyauté des clients;
- le degré d'influence de la modification de conjoncture du marché sur l'entreprise;
- le degré de réglementation de l'industrie dans le cadre duquel opère l'entreprise.

Si la stratégie de croissance interne avait été une stratégie habituelle pendant la période de début du développement corporatif, actuellement, les grandes entreprises l'utilise en association avec la stratégie de croissance externe afin de consolider leur position sur le marché. La croissance interne présente l'avantage d'un risque réduit, par rapport aux fusions-acquisitions qui représentent l'instrument principal de la croissance externe. Grâce au fait que l'augmentation des capacités reste entièrement sous le contrôle de l'équipe des dirigeants existents, les risques générées par les opérations des fusions-acquisitions des autres entreprises sont évités. De cette manière, les compétences fondamentales peuvent être exploitées et valorisées avec succès. D'autre part, le mécanisme de la croissance interne est plus lent par rapport à celui de la croissance externe. La croissance externe par une fusion-acquisition d'une entreprise, représente un moyen rapide de croissance et développement par rapport à l'augmentation graduelle par des moyens internes⁷³⁷.

Dans la figure suivante sont présentés, schématiquement, les avantages, les inconvénients ainsi que les types d'entreprises concernées dans le cas des deux moyens de croissance des entreprises.

Figure 1. Les avantages et les inconvénients de la croissance interne et des fusions-acquisitions des entreprises

	Avantages	Inconvénients	Types d'entreprises principalement concernées
Croissance interne	<ul style="list-style-type: none"> - L'exploitation d'un domaine connu permettant l'emploi de l'expérience et des compétences accumulées; - Le maintien de l'identité de l'entreprise; - Le maintien de l'indépendance; - L'absence de la reorganisation ou de la restructuration. 	<ul style="list-style-type: none"> - La vulnérabilité de l'activité au cas de changement de la conjoncture ou de la maturité du marché; - Des difficultés à atteindre une dimension suffisante. 	<ul style="list-style-type: none"> - Des microentreprises, des entreprises petites et moyennes non-cotés à la bourse; - Des entreprises qui ont choisi la stratégie de spécialisation.
Croissance par fusions-acquisitions	<ul style="list-style-type: none"> - Accès rapide aux nouveaux domaines d'activités; - Développement au niveau international; - L'exploitation des synergies de coûts; - La croissance du pouvoir sur le marché de l'entreprise- la diminution de la concurrence. 	<ul style="list-style-type: none"> - Besoins élevés de capitaux; - Problèmes de coordination et contrôle des activités regroupées; - Coûts de l'intégration physique des activités (reorganisation); - L'impact psychologique de l'opération sur le 	<ul style="list-style-type: none"> - Des entreprises grandes, multinationales; - Des entreprises qui ont choisi la stratégie de la diversification ou de l'intégration verticale.

⁷³⁷ Campbell, D., Stonehouse, G. și Houston, B., *op.cit.*, p. 213

		climat social; - La difficulté de l'intégration culturelle et managérielle des entités.	
--	--	--	--

Source: Meier, O., Schier, G., (2006), *Fusions Acquisitions- Strategie, Finance, Management*, Ed. Dunod, Paris, p.11

Les atouts et les faiblesses de ces stratégies possibles doivent, par conséquent, être appréciés dans la lumière des objectifs et des contraintes des entreprises concernées. Bien qu'il s'agisse d'une logique différente, on peut souligner le fait que ces deux options ne sont pas incompatibles et sont même assez souvent associées. Les compétences-clés sont considérées être un facteur important de la croissance interne mais représente, en même temps, un fondement dans la réussite des opérations de fusions-acquisitions. Autrement dit, les fusions-acquisitions ont de grandes chances de réussite, plus si l'acquéreur maîtrise d'une manière efficiente tous les éléments du mécanisme de la croissance interne et particulièrement⁷³⁸:

- la réalisation d'un plan stratégique et d'un plan d'affaires bien structuré;
- l'élaboration des objectifs réalistes;
- l'analyse des propres activités pour identifier les points forts, les points faibles, les opportunités et les menaces qui peuvent apparaître;
- l'évaluation régulière de la valeur de ses propres actifs et de l'impact que les résultats obtenus ont sur le développement de l'entreprise;
- la capacité de réaliser d'une manière continue des changements dans le but d'améliorer la compétitivité et l'adaptation aux influences extérieures qui s'exercent sur l'entreprise.

3. Conclusions

Les limites de la croissance interne résident dans la difficulté de disposer des ressources internes nécessaires à un procès continu de développement, de progrès, d'innovation. Par conséquent, la croissance externe représente une opportunité de croissance rapide en ajoutant simplement les ressources appartenant aux autres entreprises. La perspective de la croissance et de la création de valeur dans un intervalle de temps assez court mènent à l'évidence que les fusions-acquisitions ou les alliances deviennent des moyens privilégiés de plusieurs dirigeants ou actionnaires d'entreprises, souvent au détriment de la croissance interne. Par la suite on peut conclure que trouver l'équilibre entre la croissance interne et la croissance externe d'une part et le respect de l'impératif de la création de valeur d'autre part, fait partie du choix stratégique qui appartient au top management.

L'ANALYSE COMPARATIVE DES FUSIONS-ACQUISITIONS AVEC LES AUTRES FORMES DE CROISSANCE DES ENTREPRISES (II- FUSIONS-ACQUISITIONS VS. ALLIANCES)

Vancea Mariana
University of Oradea
Faculty of Economics

Development through mergers and acquisitions is a company's external growth strategy, as well as business alliances, but these options can not be mistaken, because the characteristics, stakes and risks are fundamentally different nature. In this paper we intent to analyze mergers and acquisitions compared with other ways of the company's external growth, by presenting the main similarities and differences between them.

Keywords: company, external growth, mergers, acquisitions, business alliances

Cod JEL lucrare: L21, L25

1. Introduction

La stratégie de croissance externe se rapporte non seulement aux entreprises cotées qui recherchent la consolidation de leurs activités au niveau mondial mais aussi aux entreprises noncotées qui doivent affronter les problèmes de croissance voire même de survie. Par conséquent, elle constitue un des principaux moyens de développement que les entreprises ont à leur disposition afin d'améliorer leur position stratégique dans leur environnement.

Le principal instrument de réalisation de la croissance externe est représenté par les opérations de fusions-acquisitions des entreprises. Pourtant, il y a aussi des solutions alternatives pour la réalisation de la croissance externe notamment les alliances entre les firmes. La croissance par fusions-acquisitions est proche des autres alternatives de croissance externe, les alliances, mais elle ne peut pas être confondue avec celles-ci car les caractéristiques, les enjeux et les risques associés sont fondamentalement différents. On propose, par la suite une analyse comparative entre la stratégie de croissance par les fusions-acquisitions et la stratégie de croissance par les alliances entre les entreprises.

2. La comparaison entre les fusions-acquisitions et les alliances

Les alliances (quelque soient leurs formes- stratégique ou de marketing) se forment lorsque deux ou plusieurs entreprises décident d'unir leurs forces pour mettre en application un ou plusieurs projets importants (recherche et développement, accès à de nouveaux marchés, le partage des lignes de production, etc.) qu'elles ne pourraient pas assumer toutes seules et elles ont, surtout, un caractère contractuel⁷³⁹.

La croissance par fusions-acquisitions représente un moyen de développement qui permet à l'entreprise de contrôler des actifs déjà productifs sur le marché et détenus au début par d'autres entreprises. La notion d'alliance se rapporte à toutes les formes de combinaisons d'affaires, en dehors des fusions-acquisitions.

Ainsi, à côté des fusions-acquisitions, les affaires peuvent se combiner par joint-ventures, des alliances stratégiques, des investissements minoritaires, des échanges de participations minoritaires, des franchises ou des licences.

La création d'un *joint-venture* implique des relations de coopération dans les affaires entre deux ou plusieurs parties séparées dans le but d'atteindre des objectifs stratégiques communs. Un joint-

⁷³⁹ Gouali, M, (2009), *Fusions-Acquisitions. Les 3 Regles du Succes*, Ed.D'Organisation, Paris, p.79

venture suppose la création d'une entité juridique distincte⁷⁴⁰ ayant des objectifs nettement déterminés, tandis que chacun des partenaires continue d'exister en tant qu'entité juridique distincte. La création d'un joint-venture implique la mise en commun des compétences technologiques, scientifiques, commerciales ou logistiques dans le but de création de synergies. Un joint-venture fonctionne comme un mécanisme où chacune des pièces est dépendante de la qualité des autres. Cette exigence impose à toutes les parties composantes du partenariat la certitude que les tâches sont bien faites car dans l'ensemble il faut réaliser les objectifs qui sont à la base d'une création de joint-venture. En d'autres termes, la réussite d'un joint-venture est conditionnée par une répartition stricte des tâches entre les différents centres de décision: la définition de la stratégie appartient aux dirigeants des entreprises partenaires mais la gestion opérationnelle revient à l'équipe managériale du joint-venture. De cette façon, elle dispose d'une autonomie de décision complète et assure une continue interaction avec les dirigeants des entreprises partenaires afin que ceux-ci puissent contrôler et ajuster leur stratégie en fonction des résultats obtenus. Si les tâches et les responsabilités au niveau d'un joint-venture sont claires et acceptées par toutes les parties participantes, l'organisation deviendra efficiente et s'allignera à la stratégie élaborée. De cette manière, on évite les disfonctionnalités qui interviennent souvent suite à la superposition des périmètres opérationnels des partenaires (y compris les problèmes qui appartiennent à la culture organisationnelle). Dans certains cas, et surtout si un joint-venture s'avère être une réussite, le partenariat s'accroît et évolue fréquemment vers une fusion ou une acquisition⁷⁴¹.

Par contre, généralement, les *alliances stratégiques*, ne mènent pas à la création d'une entité juridique distincte. Elles sont des accords entre les entreprises qui désirent la réalisation de certains objectifs communs mais cela dans les circonstances de la préservation de l'autonomie stratégique et de la conservation des intérêts qui lui sont propres⁷⁴². Elles peuvent prendre la forme d'une entente en ce qui concerne la vente des produits de chaque entreprise vers les clients de l'autre entreprise ou du développement en commun d'une technologie, produit ou procès. Les termes d'un tel accord peuvent s'établir légalement ou plutôt, informel.

Les entreprises peuvent opter pour les *investissements minoritaires* dans les petites entreprises ou les start-ups dans le but du développement des produits ou technologies utiles pour les entreprises qui font ces investissements. L'entreprise qui décide d'investir est souvent représentée dans le cadre du Conseil d'Administration de l'entreprise dans laquelle elle a investi. Ces investissements peuvent être opportunistes, les investisseurs passifs arrivant à detenir, à long terme, une position au sein d'une entreprise considérée avoir un potentiel de croissance important⁷⁴³. Plus encore, le partenariat est plus serré dans le cas d'un autre type d'alliance capitalistique, plus précisément, lorsqu'on réalise un échange de participations minoritaires entre les entreprises, de sorte que, chaque partenaire obtient des participations au capital de l'autre.

Le licencement représente une méthode contractuelle de développement et d'exploitation des droits de propriété intellectuelle par le transfert du droit d'utilisation d'une tierce partie sans toutefois réaliser également le transfert de propriété⁷⁴⁴. Les accords de licence ne nécessitent pas un capital initial et représentent, pour les entreprises, un moyen convenable d'agrandir le brand vers d'autres produits ou marchés par le licencement du nom du brand vers d'autres.

La francise est une forme spéciale de l'accord de licence par laquelle un producteur (franciseur) accorde à un dealer (francisé) le privilège de lui vendre ses produits ou les services dans une

⁷⁴⁰ Faire la différence par rapport à l'achat en commun d'une société existante, qui devient après l'acquisition la propriété commune des deux partenaires (ce moyen de croissance représente un cas particulier de la croissance externe)

⁷⁴⁴ Sherman, A., Hart, M., (2006), *Mergers & Acquisitions from A to Z*, second edition, Ed. Amacom, New York, p.272

certaine zone. Dans le cadre d'un accord de franchise, le franchiseur peut offrir au franchisé une consultation, une assistance promotionnelle, financement ou d'autres bénéfices, en échange d'une partie des revenus du dernier. Les accords de franchise représentent un moyen peu coûteux par lequel le franchiseur peut s'agrandir, parce que le capital nécessaire est assuré, d'habitude, par le franchisé. De cette manière, cette stratégie est adoptée surtout par les entreprises de petites tailles qui ne disposent pas de ressources nécessaires à assurer une croissance interne⁷⁴⁵.

Selon les remarques ci-dessus, il y a une grande variété d'alternatives stratégiques qui se concentrent sur la construction d'une relation externe dans le but d'atteindre certains objectifs. Les alliances sont souvent utilisées pour atteindre des intérêts économiques communs appartenant à des groupes provenant de pays différents.

La principale différence entre les stratégies présentées au-dessus consiste dans le degré de contrôle des parties. Les fusions-acquisitions supposent le plus haut degré de contrôle tandis que les alliances impliquent un degré plus réduit de contrôle. Ainsi, par opposition à la croissance par fusions-acquisitions, les alliances permettent d'éviter une prise totale de contrôle, en respectant l'autonomie de chaque entité mais toutefois en profitant de la création des synergies⁷⁴⁶. Dans certains cas, ces stratégies sont projetées à long terme, mais dans d'autres cas elles impliquent moins d'engagements ou objectifs communs⁷⁴⁷.

Un autre élément de différenciation des stratégies possibles est représenté par l'exposition au risque. L'opération de fusion-acquisition représente un procès qui comporte un risque. Ainsi, dès la phase préalable de l'acquisition, il est possible que la cible fasse l'objet d'une surenchère et, par conséquent, malgré la signature d'un accord, il arrive qu'elle soit acquise par un concurrent. Ensuite, l'investissement peut s'avérer sans rentabilité, lorsqu'on n'obtient pas les synergies recherchées et donc l'opération ne réussit pas à créer la valeur. Par contre, les partenariats se réalisent beaucoup plus rapidement (il n'est pas nécessaire de parcourir toutes les étapes requises dans une opération de fusion-acquisition), les participants unissent leurs forces sur le fondement de réelles synergies identifiées. Les risques, tout comme les bénéfices d'ailleurs, sont partagés entre tous les partenaires. En fait, en tenant compte des synergies, des coûts d'opportunité, des risques et de la rentabilité, le choix entre les solutions possibles peut se réaliser plus facilement. Ainsi, lorsque le risque peut être assurée, les fusions-acquisitions représentent une option préférable par rapport aux alliances. Par contre, alors qu'il existe l'incertitude en ce qui concerne les risques, les alliances sont préférables. Elles offrent aux entreprises une plus grande flexibilité parce que les engagements peuvent être continués ou suspendus en fonction des résultats obtenus.

Malgré les différences qui les séparent, les fusions-acquisitions ainsi que les alliances, sous leurs différentes formes, ont pour but l'augmentation du nombre des clients et l'obtention des profits supérieurs, ces moyens de croissance ont en commun la combinaison des propres ressources afin d'augmenter et de créer la valeur à un niveau qu'elles n'auraient pas pu atteindre individuellement.

Cette similitude mène à la question logique se rapportant à la pertinence du choix de l'une ou de l'autre de ces options pour assurer la croissance externe. En analysant les facteurs qui déterminent le choix entre ces options, on prend en considération l'hypothèse qu'on va recourir aux fusions-acquisitions dans le cas où les alliances ne répondent pas aux besoins stratégiques de l'entreprise et vice-versa. Pour cela, il faut définir clairement les objectifs recherchés par l'entreprise quand elle se décide d'adopter une stratégie de croissance externe et de comparer l'apport de chaque stratégie. La réalisation de ces comparaisons présente plusieurs bénéfices:

- assure la cohérence entre la solution choisie et l'objectif désiré à être réalisé;
- favorise les chances de réussite de l'opération;

⁷⁴⁵ DePamphilis, D., *op.cit.*, p.24

⁷⁴⁶ Ceddaha, F. (2007), *Fusions Acquisitions, Évaluation, Négotiation, Ingénierie*, Ed. Economica, Paris., p.277

⁷⁴⁷ Sherman, A., Hart, M., *op.cit.*, pp.254, 256

- envoie un signal au marché pour indiquer le fait que l'initiative prise est pertinente et justifiée. Les premiers deux bénéfiques sont intrinsèques à l'entreprise, le dernier se rapporte à l'orientation de la perception du marché en faveur du choix fait⁷⁴⁸.

L'attraction majeure pour ces formes de développement, en comparaison avec les fusions-acquisitions est représentée par l'opportunité du chaque partenaire d'avoir accès aux compétences, aux produits ou aux marchés de l'autre partenaire, à un coût global plus réduit en matière de management, de temps et de financement. Les principaux inconvénients se rapportent au contrôle limité, à la nécessité de la division des profits et à la potentielle perte de quelques secrets commerciaux ou compétences en faveur des concurrents.

En pratique, si l'alliance avec apport de capital représente un succès, il est difficile de maintenir l'indépendance économique des deux entités qui ont mis en commun leurs ressources et leurs compétences, tout cela sous les yeux vigilents des actionnaires des deux entités, qui craignent que les transferts de compétences puissent porter atteinte au patrimoine. Autrement dit, tout se passe comme si les deux entités continueraient à se faire de la concurrence en ce qui concerne les clients, tandis que leurs principales fonctions de production ou de recherche sont communes. Enfin, le maintien des entités autonomes peut empêcher l'obtention d'autres synergies (surtout les synergies commerciales) qu'on pourrait obtenir facilement par une mise en commun de tous les intérêts économiques des entreprises. A cause de cela, une alliance (et surtout celle avec apport de capital) évolue souvent soit vers une approche complète des deux entités, soit vers une interruption rapide à cause du fait qu'on n'avait pas obtenu les synergies recherchées ou la collaboration entre les deux groupes n'a pas marché⁷⁴⁹.

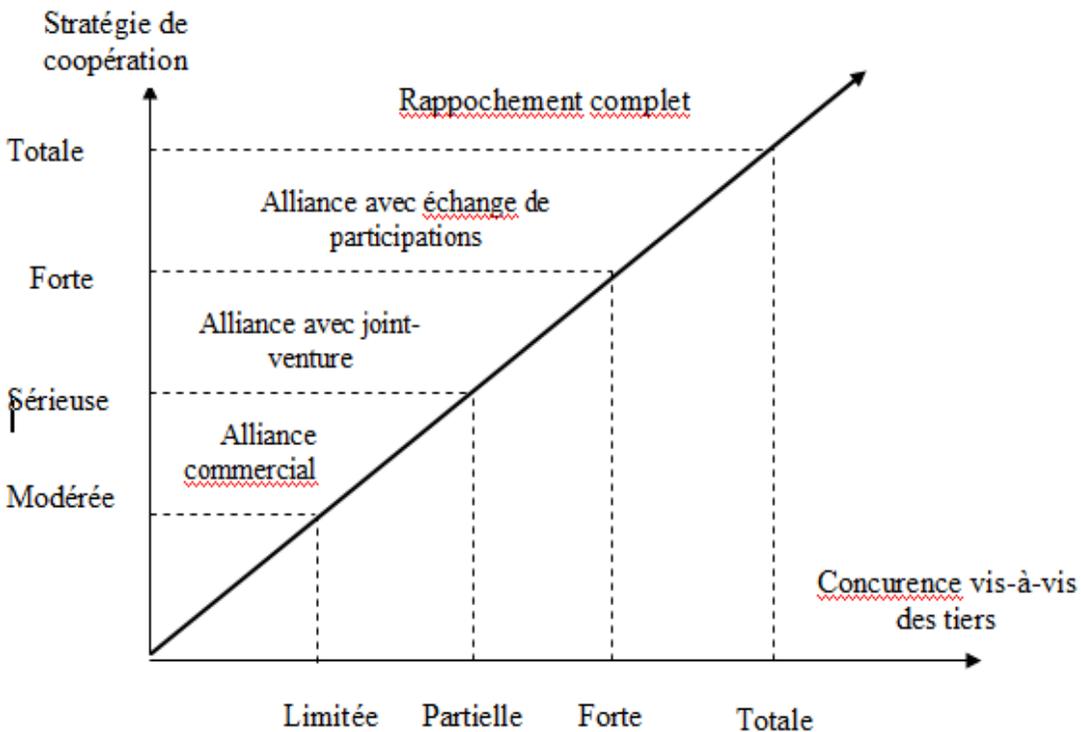

Figure nr.1. Les différents degrés de coopération dans le cadre des alliances

Source: Ceddaha, F., (2007), *Fusions Acquisitions, Évaluation, Négotiation, Ingénierie*, Ed. Economica, Paris, p.279

⁷⁴⁸ Gouali, M, *op.cit.*, p.82

⁷⁴⁹ Ceddaha, F. *op.cit.*, p.277

On peut remarquer que l'alliance n'est pas associée à une catégorie juridique déterminée et on peut, par conséquent le retrouver sous différentes formes, en commençant par la coopération commerciale (accords de licence, franchise, sous-traitance) jusqu'à la création ex nihilo d'une nouvelle structure juridique (filiale commune/joint-venture). Ce dernier représente la forme d'alliance la plus proche des opérations de fusions-acquisitions. Il s'agit d'une alliance avec apport de capital et non pas d'un accord commercial. On peut remarquer que ce moyen de croissance rappelle celui de la croissance par acquisition d'une autre entreprise, inscrivant la relation dans un cadre formel et offrant aux partenaires des avantages liés à la dimension de la nouvelle entité (par exemple réduction des coûts ou économies d'échelle) et à la coordination commune des ressources.

Comme dans le cas des fusions-acquisitions, l'alliance peut même modifier la position des acteurs économiques dans le milieu environnant et par conséquent elle est soumise aux différents mécanismes de contrôle. Enfin, par rapport à la croissance par fusions-acquisitions, ce moyen de croissance constitue une possibilité importante d'adaptation et de transformation des entreprises en fonction de l'évolution des marchés.

En dépit de ces ressemblances, les caractéristiques par lesquelles l'alliance par création d'un joint-venture diffère de l'opération de fusion-acquisition, sont⁷⁵⁰:

- l'alliance par la création d'un joint-venture réside dans la combinaison des moyens, mis à la disposition par les parties participantes, dans le but de développer une nouvelle activité, tandis que les opérations de fusions-acquisitions se caractérisent par la prise de contrôle sur les moyens de production déjà existants en fonction;
- l'alliance par création d'un joint-venture est caractérisée par l'absence d'un système d'autorité unique. Dans une alliance par création d'un joint-venture, les partenaires participent à la direction de la nouvelle entité et contribuent à la prise des décisions par leur droit de vote. L'existence d'un contrôle commun peut créer des problèmes de management lorsqu'il y a de désaccords entre les partenaires. C'est pourquoi, d'habitude, on accorde une attention particulière aux moyens et aux limites d'utilisation des ressources mais aussi aux implications qui découlent d'un renoncement à l'accord.
- dans le cas des alliances par création d'un joint-venture, la maîtrise des conflits d'intérêts devient plus délicate. On peut remarquer que, souvent, les partenaires ne renoncent pas tout à fait aux intentions opportunistes ou concurrentielles. L'alliance peut même, dans certains cas, représenter une forme de compétition déguisée dans le but d'attirer le partenaire dans un piège. Dans le cas d'un conflit stratégique, les parties doivent donc appliquer une procédure de séparation, en permettant la préservation de la valeur créée par l'alliance. Cette situation est moins problématique dans le cas d'une opération de fusion-acquisition quand, lorsque certaines difficultés apparaissent, l'autorité de droit de l'acquéreur s'exerce.
- une autre caractéristique qui distingue l'alliance par création d'un joint-venture d'une opération de fusion-acquisition consiste dans le fait que chaque partenaire garde une certaine indépendance et peut continuer, malgré l'accord, à être en concurrence sur le marché avec les autres acteurs.
- enfin, l'engagement peut se rompre librement par chaque partenaire quand les conflits stratégiques ne peuvent pas être résolus. En effet, malgré les coûts générés par la cessation de l'accord, le degré de liberté laissé aux parties en dehors de l'alliance facilite la sortie des partenaires.

3. Conclusion

⁷⁵⁰ Meier, O., Schier, (2006), *Fusions Acquisitions- Stratégie, Finance, Management*, Ed. Dunod, Paris, p.12-13

En conclusion, on peut affirmer le fait que, dans le but de réaliser des opérations de croissance externe, il est nécessaire que les entreprises réalisent une étude comparative entre les différentes possibilités qu'elles possèdent de sorte qu'elles choisissent la plus convenable. Ainsi, on peut éviter de faire de grandes erreurs qui puissent avoir des conséquences négatives sur la création de valeur pour l'entreprise.

Real convergence study began with the development of neoclassical models of growth and especially with the passage of econometric applications of these models. In this paper we present applications of indicators and patterns of convergence on the example of European Union member countries and some current economic impact assessments on European convergence process. This analysis is based on the estimated σ - and β convergence and on Markov chains. The study deals with the economic convergence of the European countries and especially the convergence of the EU countries, including Romania. In the end of the study presents several economic scenarios for a faster and easier exit from the current crisis in Romania.

Keywords: real convergence, σ -convergence, β -convergence, Markov chains.

JEL Classification: F15, C13, C15

Introduction

The convergence is an essential objective of the integration process of Romania in the European Union, minimizing gaps in the level of development that arise between Romania and the average of European Union.

There are two types of convergences: the Beta (β) and Sigma (σ) Convergence. ‘Sigma’ convergence measures the dispersion of real GDP per capita (in constant prices) between regions or countries based on standard deviation of the cross-section series (Barro 1992). When the standard deviation is falling (rising) over time, the differences of GDP per capita between regions or countries in absolute terms gradually decrease (increase) and convergence (divergence) is approached. If standard deviation does not show any clear tendency but instead, increases or decreases successively, then a mixed process of convergence and divergence is realized. A different way of measuring the ‘sigma’ convergence is to use the coefficient of variation which results by dividing the standard deviation with the mean of the sample. The coefficient of variation is a measure of relative variability and is expressed usually, as percentage and not via the units of data in which is referred. If the coefficient of variation decreases over time we have convergence otherwise we have divergence.

The ‘beta’ convergence of the neo-classical approach is obtained by a regression analysis estimating the growth of GDP per capita over a certain period of time in relation to its initial level. If the regression coefficient ‘beta’ has negative sign indicates that GDP per capita of countries with lower initial GDP per capita grow more rapidly than this of countries with higher

initial GDP per capita. The neo-classical theory presents two types of convergence: unconditional and conditional (Sala-i-Martin 1996). When all regions (or countries) converge to the same terminal point (steady-state point) the convergence is calling unconditional. In such a case, having considered that the economies do not differ significantly in terms of variables like the investment level, coefficient β is estimated without introducing structural variables. On the contrary, when the economies have different structures, it is assumed that they converge to a different steady state point. In this case convergence is calling conditional and both the coefficient β and the structural variables (influencing the level of growth of GDP per capita) are introduced in the model. According to the neo-classical model the query of why poor regions (or countries) grow faster than rich regions (or countries) can be answered by the diminishing returns to capital explanation.

A Markov chain is a multistage experiment consisting of a sequence of trials in which the state, or outcome, of each trial depends on the state of the trial that immediately precedes it. The goal in a typical problem involving Markov chain is to compute the probability that the system will be in a particular state at a specified time.

For a Markov chain with m states, the transition matrix P is the $m \times n$ matrix in which the entry p_{ij} is the probability of going from state i to state j in one step.

Convergence sigma and beta

A commonly used indicator for measuring convergence is the variation coefficient on the level of GDP/capita, denoted by σ . This indicator is used to measure Sigma convergence. It can be used to evaluate the real convergence level by measuring the dispersion of GDP/capita over a one year period, using for this purpose cross series (countries and regions). In this case, the relevance of the convergence indicator appears only when making comparisons.

In our study, we have used this indicator to measure and predict the real convergence level for all EU countries, specifically the group of EU27. Data series refers to the 1998-2007 period. The considered indicator concerning the GDP/capita variation coefficient of the EU countries shows a decrease during the entire period analyzed, from 1.6353 to 1.4835, fact that indicates the tendency of increasing convergence of the economies of the mentioned countries.

Besides Sigma indicator, expressed by the variation coefficient or standard deviation, there were numerous concerns within econometric research, a significant place being occupied by the Beta parameter estimation and interpretation of growth regression equation.

Beta indicator's values are increasing throughout the period 1999-2007, compared to 1998: they range from 1,043 to 1,358. This means that if in 1998 the indicator's GDP / capita would have increased by 1 unit, in 2007 it would have reached values of 1,358 or higher.

From 1998 to 2007, the Gini-Struck coefficient has decreasing values ranging from 0, 3207 to 0, 2909, which reveals that the indicators distribution is a relatively uniform one on all 27 EU countries.

Markov chain

Total crossing matrix between 1998 and 2007 is presented in the following table. We used nine stages for indicator GDP/inhabitants [1100-9900); [9900-18700); [18700-27500); [27500-36300); [36300-45100); [45100-53900); [53900-62700); [62700-71500); [71500-80300). All data are expressed in Euros. Based on this matrix we calculated the matrix of probability.

Probability vector is:

[1100-9900)	[9900-18700)	[18700-27500)	[27500-36300)	[36300-45100)	[45100-53900)	[53900-62700)	[62700-71500)	[71500-80300)
23.42	21.43	36.37	14.15	2.83	1.15	0.47	0.05	0.10

The forecast based on probability vector for the next three years (2008-2010) is as follows:

[1100-9900)	[9900-18700)	[18700-27500)	[27500-36300)	[36300-45100)	[45100-53900)	[53900-62700)	[62700-71500)	[71500-80300)
23.42	21.43	36.37	14.15	2.83	1.15	0.47	0.05	0.10
22.42	19.83	35.83	16.50	3.23	1.24	0.53	0.06	0.21
20.54	16.99	34.71	21.08	4.27	1.36	0.60	0.08	0.37

We can say there are increases the probability for higher stages, for example the last stage [71500-80300) increase from 0.10% in 2008 to 0.37% in 2010 and on the other hand the first stage [1100-9900) decreases from 23.42% in 2008 to 20.54% in 2010.

Conclusion

This paper has reviewed a number of methods and instruments developed for the analysis of economic and/or social inequalities and that can be used for examining disparities among EU27 countries.

One objective of the paper was to produce an update analysis of the convergence process and Markov change among EU countries. Another was to show that instruments vary significantly in terms of their specificities and qualities and that it is therefore important to be aware of their limits when measuring the extent and evolution of countries disparities within the EU. These results also underline that the analysis of convergence is in fact complex.

Finally, even if the analysis of countries disparities is conducted thoroughly, it says little about the effectiveness of EU Cohesion Policy. It is necessary to proceed to further analysis, notably by controlling other variables likely to affect the convergence process, as a proper econometric analysis would do.

The paper is intended to be primarily a factual developments illustrate the main economic indicators in the context of Romania's crisis by creating a digital picture to illustrate the main effects of the country. The idea started more from a personal desire to make a passage highlighted "the crisis, where some of it not felt it directly, seem to be amplified in an unduly by the media". Secondly, we proposed the application of an econometric model using as a set of macroeconomic indicators compiled data for Romania for the period 2000 to 2008. This will allow certain scenarios and forecasting developments in the context of model assumptions.

Keywords: crisis, model, σ -convergence, β -convergence.

JEL Classification: E01, E17, E20, E32, E40

Introduction

In early 1960, Federal Deposit Bank of St. Louis (Bari 2002) developed in an economic analysis model, which stressed the role of monetary aggregates. Initial analysis of economic data was performed using diagrams that after 1960 will be used regression techniques as a tool of analysis. Some of the quantitative research efforts were consolidated in 1970 with publication of what followed is known as "The St. Louis Model"

The model St. Louis

The first theoretical consideration that underlies the development model was the modern quantitative theory of money. The emphasis of the modern quantity theory is the behavior of economic units in response to changes in the stock of money. Moreover, the existing stock of money must be held by someone. As a result, a change in the stock of money will induce a discrepancy between the current owner and interested possession of money that will change because alternate portfolio of assets. Included in this adjustment is a change in spending on goods and services.

The second theoretical issue that has been implicit in the construction of the model, although not explicitly recognized by those who developed the model at the time, was the search and information costs on economic behavior. Information on the equilibrium price is not to gather cost and thus economic units should seek balance in market prices. As a result, prices do not necessarily have been adjusted instantaneously to the new equilibrium level in response to a step change in total spending.

As a result of these theoretical considerations, the relative impact of fiscal and monetary measures requires careful assessment. This assessment includes the differentiation between short and long, and granting special focus methods are to finance government expenditure.

Model *St. Revised Louis* "allows analysis and forecasting economic fundamentals following developments: nominal national income; level of prices; real national income; rate of employment.

The Structure of the Model

Main assumption in developing the model equations is that the evolution of nominal national income depends on the evolution of monetary and budgetary. In other words, changes in national income depend on monetary and fiscal policy. Thus, the merit of this model is that it provides information on developments in the basic macroeconomic variables in different ways of combining measures of monetary and financial policy, which allows the design of monetary policy in line with the overall objectives of economic policy in terms of income national employment and prices.

Equation of nominal national income:

$$\Delta Y_t = f_1(\Delta M_t, \dots, \Delta M_{t-n}, \Delta E_t, \dots, \Delta E_{t-n}) \quad (1)$$

Equation of price level:

$$\Delta P_t = f_2(D_t, \dots, D_{t-n}, \Delta P_t^A) \quad (2)$$

Identity equation:

$$D_t = \Delta Y_t - (X_t^F - X_{t-1}) \quad (3)$$

Identity equation of total expenditure (nominal national income):

$$\Delta Y_t = \Delta P_t + \Delta X_t \quad (4)$$

Equation of exchange rate:

$$R_t = f_3(\Delta M_t, \Delta X_t, \dots, \Delta X_{t-n}, \Delta P_t, \Delta P_t^A) \quad (5)$$

Equation predicted prices:

$$\Delta P_t^A = f_4(\Delta P_{t-1}, \dots, P_{t-n}) \quad (6)$$

Equation of unemployment rate:

$$U_t = f_5(G_t, G_{t-1}) \quad (7)$$

Deviation of GDP actually from potential GDP:

$$G_t = \frac{X_t^F - X_t}{X_t^F} \quad (8)$$

The relationship model is a fundamental equation of total expenditure. Total expenditure is determined by the actions of monetary and fiscal (spending financed from taxes or borrowing from the public). Although no details are known is that such actions affect costs. Change in total

revenue is combined with an estimate of potential production that leads to the modification application. An estimate of the anticipated price change is combined with the modification request to determine a change in the price level. To describe the model, its characteristics are summarized in relation to four key assumptions money. They are: 1. monetary actions are the dominant factor contributing to economic fluctuations; 2. Monetary actions have little, if any, lasting effect on real variables, with effects lasting only for nominal variables; 3. Fiscal actions, defined as changes in government spending with a given stock of money, have only a transitory impact on economic activity; 4. The economy is in a private stable inert.

Crisis in Romania

Under the model assumptions can build national income equation in the form of a linear econometric model multi-factorial:

$$I^{PIB} = \alpha_1 I_{t/1}^{ChGiver} + \alpha_2 I_{t/1}^M + b \quad (9)$$

Where the indicators used are: real GDP index, index of real monetary, government spending index. Therefore, we interpret the estimated parameters as to an increase of 1% of government expenditure, national income has increased in the review, on average, 0.84211%, respectively an increase of 1% of average monetary income of national increased in the range examined, on average, 0.20644%, which confirm the theoretical results of the influence of fiscal and budgetary policy.

Linear correlation coefficient is defined in the interval [-1, 1], that the value 0.964 obtained indicates a stronger linear correlation between the two variables. Test Fisher - Snedecor shows that the results are significant, with a significance threshold of 5%..

$$F_c = 39,7768 > F_{0,05;2;6} = 10,43$$

So, we can say that the model is good. Checking the significance of default and correlation coefficient of linear correlation is done using the test Fisher - Snedecor:

$$F_c = \left(\frac{n - 2 - 1}{2} \right) \frac{R^2}{1 - R^2} = 3 \cdot \frac{0,9298}{0,0702} = 13,24 > F_{0,05;2;6} = 10,43$$

Therefore, the model correctly describes the dependence of the three variables, the independent in explaining the proportion of 93% of total variation in the dependent variable.

The effects of economic crisis - evolutionary scenarios

If the equation of our revenue to perform a forecast for next year after the 2 scenarios: optimistic, and pessimistic.

If we consider the following *scenario optimistic* assumptions: government expenditure will increase in real terms by 3% and average money will increase in real terms by 5%.

For the pessimistic scenario, consider the following assumptions: government spending will decrease in real terms by 3% and average money will remain constant. Substituting the above equation for each scenario in part refrained forecast for the period 2008-2011.

Thus:

- In the optimistic scenario where the pace of growth will be 2.5%.
- If pessimistic scenario was obtained a decrease in growth of 2.5%.

Exchange Rate equation is:

$$R = \alpha_1 IPC + \alpha_2 I^{PIB} + \alpha_3 I^M + b \quad (10)$$

Where the indicators used are: interest rate, index of consumer prices, monetary mass average GDP dynamics.

The interest rate is influenced by positive and negative dynamic pricing dynamics of GDP and the monetary. All influences are analyzed in accordance with economic theory. Romanian

economy to the equilibrium interest rate is 10.12%. Influences factors are analyzed as follows: for each percentage increase in the CPI rate increases by 1.73% for a percentage of GDP growth rate falls to 0.0771% for each percentage increase in monetary leads to lower interest rates with 10.73%. The lowest influence has therefore GDP.

Coefficient of linear correlation shows that there is a strong linear correlation between variables (0,9147). Test Fisher - Snedecor shows that the results are significant, with a significance threshold of 5%.

$$F_c = 8,54 > F_{0,05;3;5} = 7,3$$

Significance $F = 0.02 <$ threshold of significance (0.05). Checking the significance of default and correlation coefficient of linear correlation is tested using the Fisher - Snedecor:

$$F_c = \left(\frac{n - 3 - 1}{3} \right) \frac{R^2}{1 - R^2} = \frac{5}{3} \cdot \frac{0,8367}{0,17} = 8,2 > F_{0,05;3;5} = 7,3$$

Therefore, the model correctly describes the dependence of the four variables in explaining the independent proportion of 83% of total variation in the dependent variable.

Scenarios development

The interest rate equation in our model build a forecast for next year after the 3 scenarios: optimistic, pessimistic and average. *If we consider the following scenario optimistic* assumptions: government expenditure will increase in real terms by 3% and average money will increase in real terms by 5% and a CPI of 4.5%. *For the pessimistic scenario*, consider the following assumptions: government spending will decrease in real terms by 3% and average money will remain constant while the CPI is 3%. Substituting the above equation for each scenario in part refrained forecast for the period 2009-2011. Solutions in the short term trends indicate libratory interest rate. Thus, the optimistic scenario where the interest rate would record a level of 8.87% in case of moderate 10.21% while the pessimistic scenario it will rise to 12.27%.

Convergence sigma and beta

A commonly used indicator for measuring convergence is the variation coefficient on the level of GDP/capita, denoted by σ . This indicator is used to measure Sigma convergence. It can be used to evaluate the real convergence level by measuring the dispersion of GDP/capita over a one year period, using for this purpose cross series (countries and regions). In this case, the relevance of the convergence indicator appears only when making comparisons.

In our study, we have used this indicator to measure and predict the real convergence level for some EU countries, specifically the group of EU 12. Data series refers to the 1998-2007 period. They will be symbolized with UE12 and are: Bulgaria, Cyprus, Czech Republic, Estonia, Hungary, Latvia, Lithuania, Malta, Poland, Romania, Slovakia, and Slovenia.

Sigma convergence values for this period are: 0,6656; 0,6774; 0,6427; 0,6098; 0,5817; 0,5692; 0,5398; 0,4918; 0,4512; 0,3841.

By analyzing the level and trend of the variation coefficient, we can conclude the following:

- The considered indicator concerning the GDP/capita variation coefficient of the EU countries shows an increase during 1998-1999. This increasing process reveals a divergent growth of the economies inside this group of countries, with the real possibility that every less developed country will strive for higher levels of development;
- During 2000-2007 the evolution of the variation coefficient of GDP / capita is a decreasing one, which indicates the tendency of increasing convergence of the economies of the mentioned countries.

Besides Sigma indicator, expressed by the variation coefficient or standard deviation, there were numerous concerns within econometric research, a significant place being occupied by the Beta parameter estimation and interpretation of growth regression equation.

Beta indicator estimated by using the regression equation, expresses the speed (rate) with which different countries achieves convergence to a steady state. This indicator studies sigma convergence in terms of evolution over time. Beta indicator's values are increasing throughout the period 1999-2007, compared to 1998: they range from 0.06889 to 0.2866. This means that if in 1998 the indicator's GDP / capita would have increased by 1 unit, in 2007 it would have reached values of 0.2866 or higher.

Conclusions

Current economic crisis, burst into the U.S. (Daianu 2008) to quickly propagated globally affecting international economic system. Put on the irresponsible policies of financial institutions, the crisis raises worrying questions about the security. Transmission of the crisis was not only geographically but also in society, the financial plan in the real economy, both social and gradually installed and psychological level. The latter seems to be the most dangerous contaminants, whereas the frozen actions practically blocking economic growth for fear and mistrust. The effects of the crisis are felt in Romania. This is seen primarily at economic indicators, which after a period of growth began to come together with this crisis on a downward trend. Regarding short-term evolution of economy and living standards in Romania, according to evolutionary scenarios outlined in the model St. Louis reviewed the pessimistic scenario (which is most likely in the current context) GDP will decrease by 2.5% and interest rate (real) will be an average of 12.27%.

This paper has reviewed a number of methods and instruments developed for the analysis of economic and/or social inequalities and that can be used for examining disparities among EU12 countries. One objective of the paper was to produce an update analysis of the convergence process among EU countries. Another was to show that instruments vary significantly in terms of their specificities and qualities and that it is therefore important to be aware of their limits when measuring the extent and evolution of countries disparities within the EU. These results also underline that the analysis of convergence is in fact complex.

METHODS AND MODELS FOR THE ANALYSIS OF THE LABOR MARKET

Botezatu Mihai Alexandru

Ministry of Labor, Family and Social Protection

Botezatu Elena

Romanian-American University, Faculty of Internal and International Commercial and Financial-Banking Relations

The labor market study involves analyzing the supply and demand for labor. The labor market is the meeting place for bidders and applicants for paid employment. Therefore, to characterize the labor market and the existing correlations in this market, one important aspect is the characterization of labor supply that depends on labor resources in general, but is particularly dependent on active population. The paper presents aspects of modeling existing labor market correlations and suggests a multiple regression model to analyze labor supply at the macroeconomic level.

Labor market, regression model, employment, statistics

J21

1. Job offer at the macroeconomic level

According to some authors, the *labor market is the most regulated and organized market*. Alfred Marshall said [1]: "It's normal that the labor market is more regulated than any other. The changes occurring here influence a good that deserves more protection than a mere commodity." On the labor market, a market with a contractual nature, relations between economic agents have evolved from confrontation and conflict to cooperation, social participation and consultation. It is a market on which the institution of collective bargaining emerged as the foundation and framework of the organization, regulation and conduct of all collective bargaining relationships at all levels - corporate, sector, branch inter-professional or national. Given the psychosocial aspects of labor and through feedback relationships with other markets, the labor market is the most sensitive and fragile market. That not only it is a repository of potential conflict, but it captures and amplifies the distortions and failures of other markets, formulating its own requirements. Thus, the labor market is conditioned by the equilibrium of all the other markets and conditions socio-political stability and balance [2].

The labor market is highly regulated in terms of legislation and scores more influences from many factors. Various national and international institutions and legal mechanisms were created over time that accelerate or hinder the labor market. Labor supply and demand are economic concepts. Instead, for sizing the labor market phenomena, we use statistical concepts. Statistical analysis of the labor market starts by delimiting the two components: labor supply and labor demand, namely active population and employed population.

According to the model of supply and demand, labor statistics can be divided into two branches: one that captures and analyzes the characteristics of labor demand (job vacancies, jobs offered by employers) and one that focuses on job offer (persons employed, unemployed or inactive). To characterize the phenomenon of labor market, we use two sets of statistical indicators: absolute and relative. Within these indicators, *the active population* is the indicator that fairly quantifies labor supply at the macroeconomic level.

Active population can be modeled taking into account several grouped factors, as Guy Caire [3] showed:

- Economic and social factors;
- Demographic factors;

- Political factors.

Demographic factors determine the total population participating in economic and social activities, the age of the persons comprising the population and their distribution on different categories of population (active, inactive, busy, etc.) [4]. Economic and social factors, in conjunction with the demographic factors, influence the activity rate, employment rate respectively, explaining in large part, the populations wish to get involved in one activity area or another. In addition to these are political factors, which directly influence migration balance, the degree of coverage of population in education, population education levels, etc.

2. Analysis model for the civil active population of Romania

In ILOs' vision, (BIM) *active population* comprises all persons regardless of sex, providing labor to produce goods and services during a specific period. McConnel and Brue [5] examine factors influencing the working population, considering: the total population, activity rates, natural increase and migration, education level and divorce rate, natural increase, marriage as important factors influencing the working population [6].

The econometric model that we propose integrates these factors, with some modifications, such as:

- Instead of *the total population* (a factor strongly correlated with other factors) *the general civil activity rate* was preferred

- Quantification of the level of education of the population was considered to be achieved by *the number of teachers*.

The data used has its source in the Romanian Statistical Yearbook 2008 and other data from the National Statistics Institute (INS), available through the Tempo Online software [7].

Table 1 shows the values of variables considered in the model, at the county level (42 counties), corresponding to the year 2007. The form of the proposed multiple regression model is [8, 9]:

$$PAC = \alpha + \beta_1 * RAGC + \beta_2 * PD + \beta_3 * SMI + \beta_4 * SME + \beta_5 * DIV + \varepsilon \quad (1)$$

where:

- **PAC** - active civil population (in number of persons) is the dependent or explained variable
- and independent variables are:
- **RAGC** - Civil overall activity rate (%)
- **DP** - teaching staff (number of persons);
- **SMI** - internal migration balance (the difference between the number of people who came from another county and the number of people who went to another county);
- **EMS** - external migration balance (the difference between the number of people who came from outside Romania and the number of people who left Romania);
- **DIV** - number of divorces
- **e** - random variable error (residue);
- **α , β_1 , β_2 , β_3 , β_4 , β_5** are regression parameters.

The independent variable *general civil activity rate (RAGC)* also called *the gross activity (RBA)* is the ratio (%) between the *active civil population (CAP)* and *the total population (P)*.

$$RAGC = \frac{PAC}{P} \times 100 \quad (2)$$

- *Teaching staff (PD)* is the second independent variable in the model. Teaching staff are individuals who are engaged in the educational system and are teaching in the educational and training process, full-time or part-time.

- *Internal migration balance (SMI)*, independent variable, which is calculated as the difference between people who have come from another county and the number of people who went to another county;

- *External migration balance (EMS)*, independent variable, which is calculated as the difference between people who come from outside Romania and the number of people who left Romania;
 - *Divorce (DIV)*, independent variable that refers to the number of divorces concluded, distributed by counties according to the last common domicile of the spouses.
 For the considered multiple linear regression model, parameter values listed in Figure 1, were estimated using the method of least squares [10].

Variable	Coefficient	Std. Error	t-Statistic	Prob.
C	-171371.4	46756.26	-3.665207	0.0008
RAGC	3035.644	781.2027	3.885859	0.0004
PD	16.95030	1.329530	12.74910	0.0000
SMI	0.748486	2.931814	0.255298	0.7999
SME	-45.16098	42.02115	-1.074720	0.2897

Durbin-Watson stat	2.358041	Prob(F-statistic)	0.000000

Fig. 1 Multiple linear regression model parameter estimation by the method of least squares

Multiple linear regression model parameter estimation:

$$PAC = \alpha + \beta_1 * RAGC + \beta_2 * PD + \beta_3 * SMI + \beta_4 * SME + \beta_5 * DIV + \varepsilon \quad (3)$$

obtained by the method of least squares are:

$$PAC = -171371.4004 + 3035.643605 * RAGC + 16.9503033 * PD + 0.7484862292 * SMI - 45.16097981 * SME + 67.54285573 * DIV$$

The estimations for the 2007 year model have the following meanings:

$\beta_1 = 3035.643605$ and shows that dependent variable *active civil population (CAP)* increases by 3036 people when *RAGC* independent variable increases by 1% and the other independent variables remain constant.

$\beta_2 = 16.9503033$ and shows that dependent variable *active civil population (CAP)* increases by 17 people when the independent variable *PD* increases by 1 and other independent variables remain constant.

$\beta_3 = 0.7484862292$ and shows that dependent variable *active civil population (CAP)* increases by 0.75 when the independent variable *SMI* increases by 1 person and the other independent variables remain constant.

$\beta_4 = -45.16097981$ and shows that the dependent variable *active civil population (CAP)* decreased on average by 45 people when the independent variable *EMS* increased by 1 and the other independent variables remain constant.

$\beta_5 = 67.54285573$ and shows that dependent variable *active civil population (CAP)* increases on average 68 people when the independent variable *DIV* increases by 1 and the other independent variables remain constant.

3. Inference in the regression model

Model parameters were estimated based on a sample of observations (2007 data by county). To generalize the results validation of both the model and model parameters is necessary. We use a materiality threshold of 5%.

Inference on model parameters:

Parameter β_1

$$H_0: \beta_1 = 0$$

$$H_1: \beta_1 \neq 0$$

P-value = 0.0004 < 5%. So, hypothesis H_0 is rejected and H_1 is accepted. RAGC significantly affects the PAC.

Parameter β_2

$$H_0: \beta_2 = 0$$

$$H_1: \beta_2 \neq 0$$

P-value = 0.0000 < 5%. So, hypothesis H_0 is rejected and H_1 is accepted. PD significantly affects the PAC.

Parameter β_3

$$H_0: \beta_3 = 0$$

$$H_1: \beta_3 \neq 0$$

P-value = 0.7999 > 5%. So, hypothesis H_0 is accepted and H_1 rejected. SMI doesn't significantly affect the PAC.

Parameter β_4

$$H_0: \beta_4 = 0$$

$$H_1: \beta_4 \neq 0$$

P-value = 0.2897 > 5%. So, hypothesis H_0 is accepted and H_1 rejected. EMS did not significantly affect the PAC.

Parameter β_5

$$H_0: \beta_5 = 0$$

$$H_1: \beta_5 \neq 0$$

P-value = 0.0000 < 5%. So, hypothesis H_0 is rejected and H_1 accepted. DIV significantly affects the PAC.

4. Model validation

The estimated value of the determination ratio $R^2 = 0,978453$ shows that in the chosen model the simultaneous change of values of independent variables explained 97.8% of the variation of the dependent variable PAC.

From the Fisher distribution table the theoretical value $F_{0,05;2,37} = 3,232$ is obtained. The calculated value of Fisher test: $F_{calc} = 326,9502$ (Figure 1), is greater than the theoretical value.

SIG parameter value calculated for the test F is less than 0.05, so the regression model is statistically significant. The following assumptions were tested for the multiple linear regression model: normality (Figure 2), homoscedasticity, no error autocorrelation, lack of collinearity for independent variables.

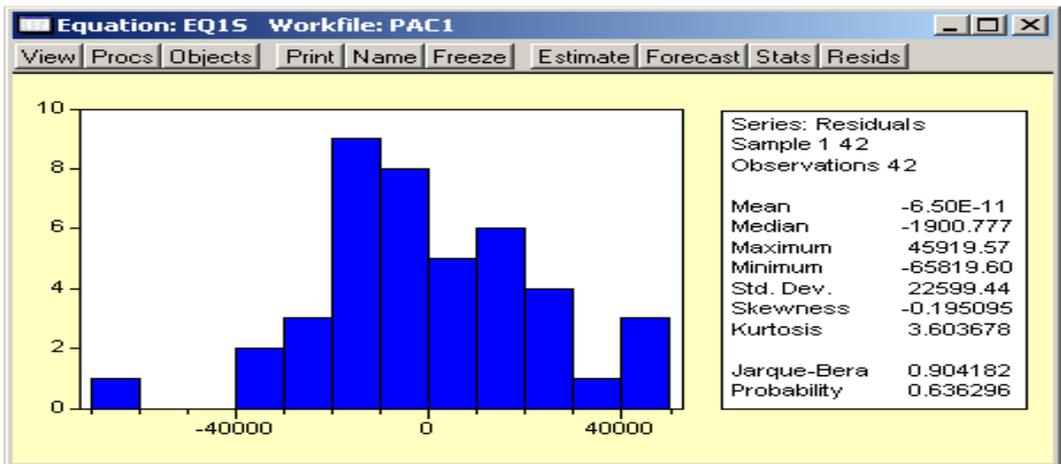

Fig 2 Histogram – Normality Test

For error distribution, the mismatch coefficient (s:skewness) is $-0,195095$, and the flattening coefficient is $3,603678$, so the JB level is $0,904182$ and the probability is $0,6362967\%$.

5. Conclusions

In conclusion, the active population in Romanian counties in 2007 is influenced both by economic variables (activity rates), variables that quantify the level of education (teaching staff) and demographic variables (number of divorces). The model showed that internal and external migration flows do not significantly influence the active civil population.

However, we must note that a counties' active population is related to the total population established in the county and, whatever the degree of influence of these factors, active population has a strict limitation, it can not exceed the total population of the county. Therefore, one can consider, for quantifying employment offer of a county, a high degree of comparability indicator, namely the rate of activity. Its progress does not take into account developments in the county population, but developments of economic and political factors, such as average wages or education level.

The State, in it's triple aspect: the economic agent (a partner of other operators), a component of the operating mechanism of economy and the arbiter of regulation of relations between supply and demand of labor - it actively intervenes on the labor market, supporting, by extra-economic and economic means, as appropriate, offer or demand for labor, trying to ensure social protection of those temporarily removed from the labor market. In this regard, economists, statisticians and experts in the fields will produce a series of such models to analyze the existing correlations in the market, so as to provide viable solutions for adjustment levers, for economic politics, social politics, demographic politics, etc..

USE OF ECONOMETRIC INSTRUMENTS IN DETERMINING THE FINANCIAL RESOURCES NEEDED FOR PROFESSIONAL SKILLS DEVELOPMENT PROJECTS

Dogar Cristian

Universitatea 1 Decembrie 1918

Facultatea de Științe

Kelemen Andrei

Universtitatea Babes-Bolyai

Facultatea de Științe Economice și Gestiunea Afacerilor

The market shows no signs of sustainable recovery after the crisis that hit the world economy in 2007, and therefore public intervention in the area of professional re-conversion is highly desirable. Public spending on training programs needs to be economically justified and closely monitored. We describe an econometric method to evaluate needed costs for training programs for professional skills development, based on a sample of pair values extracted from training projects implemented between 2008 and 2009. We find that, although the unitary value as resulted after applying the econometric model corresponds to the national available amount, by applying other types of indicators, such hour of training, can determine more efficient (less resources needed), cost-effective and effective (increased number of trained individuals for less costs) values in what regards the process of delivering training programs.

Keywords: public funding, European funds, professional skills development, training programs

Cod JEL lucrare: C53

1. Introduction

The Lisbon Strategy is put into practice in Romania through the Sectoral Operational Program for Human Resources Development which has as main objective the development of human capital and increasing competitiveness, by linking education and lifelong learning with the labor market and ensuring increased opportunities for future participation on a modern, flexible and inclusive labor market for 1,650,000 people [1]. This objective is planned to be achieved through activities that can be financed after public auctioning under the SOPHRD priority axes (PA) and key areas of intervention (KAI) [2]. The professional skills development of employees is achieved under Priority Axis (PA) no 3 “Increasing adaptability of workers and enterprises”, Key Area of Intervention (KAI) 2 “Training and support for enterprises and employees in order to promote adaptability”. This KAI has a series of national indicators, as negotiated by the Romanian Government and the European Commission, which set, on a yearly basis, the targets to be achieved and the financial allocation corresponding to the agreed indicators.

Table 1. Result indicators for KAI 3.2 under SOPHRD

Output indicators	Cumulative proposed targets								
	2007	2008	2009	2010	2011	2012	2013	2014	2015 total
Number of persons trained in the filed of work management and organization	-	1600	3300	5400	7800	10600	13500	15000	15000
Number of persons with updated and improved professional competencies	-	30500	62000	102000	148000	198700	252700	280000	280000

Total		32100	65300	107400	155800	209300	266200	295000	295000

Source: *Government of Romania. Framework Document for the Implementation of SOP HRD*

The indicators in the *Table 1.Result indicators for KAI 3.2 under SOPHRD*, as presented above, refer to employees that have been trained to update, develop and improve their professional competencies. This KAI finances intensive training courses, up to 120 hours/person. Trainings for qualification or re-qualification, which have between 360 and 1080 hours/person, are financed under KAI 2.3 of the SOPHRD [3]. Within the public policy for human resources development, through the implementation of the SOPHRD, by the end of 2015, at least 295,000 employees of active companies in Romania would have been involved in some type of intensive training. For this objective, the Romanian Government, as agreed with the European Commission, has allocated a total sum of 308,550,609 EURO, of which 229,083,655 EURO from the EU, and 40,431,555 EURO from the national budget, as illustrated in *Table 2*.

Table 2. Financial allocation for KAI 3.2 under SOPHRD

Source: *Government of Romania. Framework Document for the Implementation of SOP HRD*

The decision makers have based financial allocation nor on quantitative and/or qualitative analyses, but rather on quantitative estimation of trained employees which need professional updating and development. Using the total financial allocation (308,550,609 EURO) for this KAI and the proposed indicator (295,000 persons) in a simple calculus, one can extract the median cost value for each trained person: 1,045.93 EUR. The financial mechanism put in place to sustain professional skills development programs is provisioned under EC Regulations no 1083/2006, 1605/2002 and 2342/2002. In brief, this mechanism is based on private and public providers of professional skills development training programs which can apply for financing under this particular KAI of the SOPHRD. Under state aid schemes, enterprises can apply directly for financing and organize their own training programs.

As estimated by the authors of the Regional Plans for Labor Force Employment, during the current programming period (2007-2013), approximately 30,000 individuals in the North West Region need to have their professional skills updated and/or developed and/or improved.

2. Determining the necessary financing in the North West Region by employing a linear econometric model

Professional skills development is achieved generally at the initiative of the enterprise with the purpose to increase productivity and therefore the profit. Nevertheless, a worker's skills determine that employees's wage and sector of activity and, furthermore, high-wage sectors employ high-skill workers and offer high returns to workers' skills [4].

The level of commitment towards the constant updating of professional skills of employees depends largely on the type of organizational culture, the size, business strategy, type of management and economic environment. Nevertheless, the relation between the professional abilities of staff and productivity (hence, profit) is very direct and widely accepted. Development of general and/or specific professional skills [5], as they are defined in the Commission Regulation (EC) no. 800/2008 (General block exemption Regulation), cover the entire training area. By reporting to these definitions, external financial support for enterprises becomes a matter of public subventions, which, to be possible, needs to comply with the provisions set out in the above mentioned regulation. The Regulation lays down the limits of aid intensity [6], which, depending on the size and type of enterprise, varies between 25% and 70%.

2.1. Model identification and establishment of variables

As a general rule, training providers base their cost estimation whether on the number of hours of the activity or on the number of individuals to be trained. In each of the situations, their offers are in a linear dependency with the base used in the calculus. When determining the program indicators, decision makers have not taken into account the fact that not all types of training programs need the same, or approximately the same, resource engagements. As indicated in *Table 1*, the result indicator for KAI 3.2 under SOPHRD is the number of trained individuals and not the number of hours. Current Romanian legislation regarding professional skills development indicates that qualification training courses are defined on three levels, level 1 – 360 hours, level 2 – 720 hours, and level 3 – 1080 hours, while intensive training for acquiring new competencies may be varying between 20 – 120 hours [7].

Since an official report on the training needs at national, regional or local levels in relation with the types of employers and number of hours has not been conducted, determining the funding requirements for training cannot be carried out unless a low level of significance is accepted. With the current setup, the public policy regarding training of adults may lead to situations varying among: i) unjustified savings – achievement of proposed indicators by delivering common competencies for a sufficient number of individuals through short-term training, but with the disadvantage of leaving uncovered other types of training needs; ii) inefficient use of resources – training projects with over-estimated budgets which provide short term training programs at the costs of long-term training programs; and iii) lack of resources to cover training needs – fail to achieve indicators due to the lack of resources, regional allocation of funds not being carried out based on estimating the necessary hours of training. The list of encouraged competencies/qualifications has not been made available either, which leads to further confusions in what regards prioritization of public funded interventions.

The only indicator which allows a sufficient allocation of resources at regional level and facilitates proper auditing of the performance of the funds is the **hour of training for encouraged competencies**. An important factor in judiciously using the available funds is represented by the pace of allocating financial resources in relation with the prioritized indicators. Thus, one should first establish the profile of the local economy and, consequently, the related necessary competencies as expected by the enterprises. This would further yield in a territorial prioritization of necessary competencies, based on activities and enterprises.

The needed number of training hours can be determined by the use of an econometric model (with multiple variables) within each of the activity and/or enterprise. In this way one can accurately estimate the necessary hours of training in the tourism sector, for SMEs for professions such as cook, waitress, maid etc. The model may support a single variable in the absence of forecasted additional investments – the increase in number of cooks is not related to the increase in number of waitresses, as the intervention is programmed to solve the deficit of competencies of that particular enterprise (with the accepted hypothesis that its condition does not change as result of new capital injection). One can thus generate different settings with different economic consequences which could be taken into consideration when projecting the

impact of the political impact in the territory. The method of global utility can be employed to fundament the decision to finance training programs through public funding for certain types of enterprises, belonging to an economic sector, over other enterprises, belonging to the same or to another economic sector.

31	71,865	56

Determining the econometric model and optimizing the decision are reflected in the **effectiveness** of public policies; making available affordable resources for training programs results in **cost-effectiveness**, and **efficient** allocation of resources to obtain desired results completes the framework in which the performance of using public funding for professional skills development programs is analyzed. Such approaches, at this time, are very seldom and most of them respond to two of the above-mentioned criteria.

Organizing public calls, where the main criteria of selection is the lowest offered price, is already a reality through the implementation of Section Grants in the Council Regulation (CE) no 1605/2002 on the Financial Regulation applicable to the general budget of the European Communities. One can respond to the cost-effectiveness criteria of public funding use by the proper employment of such calls for projects.

In order to achieve the efficiency criteria we proposed to determine the necessary financing for future training in the Region North-West of Romania, by employing a linear econometric model and by using data collected in the previous programming period (pre-accession period).

The professional skills development programs during the years 2006 and 2009 and in the case of employees, have been carried out through financial allocations made available within the Phare Economic and Social Cohesion – Human Resources Development funding lines. In the North-West Region a number of 31 projects have been approved and implemented with the following pairs of values (as reflected in *Table 3. Phare pairs, 2005-2006*): budget value (endogenous value) and number of trained individuals (exogenous variable).

2.2 Estimation of the econometric model

We estimate the existence of a linear dependency between the project budget and the number of trained individuals, as illustrated by the following formula:

$y_i = a + bx_i + \varepsilon_i, i = \overline{1, n}$, where Y is the endogenous value (project budget), X is the exogenous variable (number of trained individuals) and ε is the random residual variable, which includes the effects on Y of other factors than X, but less significant than X. Taking into consideration the pairs in *Table 3. Phare pairs, 2005-2006* we can estimate the model coefficients. Thus $\hat{y} = 67726,26$, and $\hat{x} = 95,65$ and $\hat{a} = 59711.87$, respectively $\hat{b} = 83.79$. The linear model of budget dependency on indicators for a project becomes: $\mathbf{Ymed(X)} = 59711.87 + 83.79 \mathbf{X}$.

One can observe that in the considered model the project budget is made of a fix part and of a variable one, the later directly proportional with the number of trained individuals. One way to make the training costs more efficient is to impose lower limits for the number of trained individuals per project, determining thus, eventually, a decrease in the number of financed projects, which, at its turn, leads to reducing the costs which are not directly related to training costs.

Besides the punctual estimation as shown by the values obtained on the pairs of data, \hat{a} and \hat{b} , for the unknown parameters a and b , one can construct confidence intervals such as $P\left(\hat{b} - t_{\alpha/2, n-2} \sqrt{\hat{V}(\hat{b})} \leq b \leq \hat{b} + t_{\alpha/2, n-2} \sqrt{\hat{V}(\hat{b})}\right) = 1 - \alpha$, where $\alpha \leq 5\%$, is the significance threshold, $t_{\alpha/2, n-2}$, is a table value from the Table of the Student's T Distribution with $n-2$ degrees of freedom, corresponding to the probability, $\alpha/2$, and $\hat{V}(\hat{b})$ is

$$\hat{V}(\hat{b}) = \frac{\hat{s}^2}{\sum_{i=1}^n (x_i - \bar{x})^2}, \quad \hat{s}^2 \text{ being the punctual estimator of the unknown variance of the residual}$$

$$\text{variable, } \sigma^2, \text{ given by the formula, } \hat{s}^2 = \frac{\sum_{i=1}^n \hat{\epsilon}_i^2}{n-2} = \frac{\sum_{i=1}^n (y_i - \hat{a} - \hat{b}x_i)^2}{n-2} = 13316560.8.$$

Based on the values in the sample, after calculating the residuals and the values for \hat{s}^2 , we obtain for the variance of \hat{b} the estimated value **1578.919**, and for the variance of \hat{a} the estimated value **0,029898**. For $\alpha/2 = 0,025$ and 29 degrees of freedom we find, in the Table of the Student's T Distribution, the constant 2,045. Thus we can determine the numerical limits of the confidence interval both for a and for b . From here it results that $P(2,53 < b < 165.05) = 95\%$ and $P(59711,52 < a < 59712,22) = 95\%$

2.3 Model validation

The model is validated both through the test T of significance for coefficient b and through the test F for the linear correlation coefficient. Based on the result obtained on the sample, we can calculate the particular value $T_{calc} = 2,108761$. As T_{calc} does not belong to the interval $[-2,045, 2,045]$, we dismiss the null hypothesis and accept the alternative hypothesis. Consequently, $b \neq 0$, which means that X stays in the model as factor of major linear influence, for Y , the significance threshold being 5%. Based on the data obtained on the sample, we can calculate a particular value (2), $F_{calc} = 4,4468$. As 4,4468 does not belong to the interval $[0, 4,18]$, we dismiss the null hypothesis and accept the alternative hypothesis. Consequently, $R_{01} \neq 0$, which means that Y is explained in an acceptable manner by a linear model based on X , the significance threshold being 5%.

2.4 Estimates based on the model

In the hypothesis that all 30,000 individuals would be trained under one project, by a single training provider, the allocated budget could be determined by using the described linear model, as it follows: average budget for 30,000 individuals to be trained = $59711.87 + 83.79 \times 30000 = \mathbf{2.573.411,87 \text{ EUR}}$. But the model has been constructed for an average indicator of approximately 100 individuals trained per project, which means that between 2009 and 2015, providers of professional skills development programs will have trained 30,000 individuals in approximately 300 projects. This way we will have: average budget for 30,000 individuals to be trained = $300(59711.87 + 83.79 \times 100) = \mathbf{20.427.261 \text{ EUR}}$.

$$\text{Confidence interval for the forecast: } \hat{v} = \hat{s}^2 \left[1 + \frac{1}{n} + \frac{(x_{n+h} - \hat{x})^2}{\sum_{i=1}^n (x_i - \hat{x})^2} \right]$$

In the hypothesis of 100 individuals to be trained, the result is: 426159890.1 and the confidence interval for the forecast will become:

$$P\left(\hat{y}_{n+h} - t_{\alpha/2, n-2} \sqrt{\hat{V}} \leq y_{n+h} \leq \hat{y}_{n+h} + t_{\alpha/2, n-2} \sqrt{\hat{V}}\right) = 1 - \alpha$$

$P(68090.87 - 42216.24 < Y < 68090.87 + 42216.24) = 95\%$; $P(25874.63 < Y < 110307.11) = 95\%$. We observe that in order to train 30,000 individuals, within 300 projects, with a probability of 95%, the necessary financial resource will amount to 33,092,133 EUR. Based on the tested econometric model, the necessary financing for the North-West Region for training 30,000 individuals is **33,092,133 EUR**.

3. Conclusions

The sample taken into consideration for testing the econometric model is based on recent data, extracted from projects that have been implemented between 2008 and 2009, and therefore we can confidently consider that it offers an accurate image of project based training programs financed through public funding. The unitary value as resulted after applying the econometric model corresponds to the national available amount, 1103 EUR/trained individual vs. 1045.93 EUR/trained individual. Nevertheless, the ambiguity of the result indicators as they are set by the public policy implementer, generates difficulties in assuring an efficient public policy implementation framework, and, as a consequence, affecting the general performance of public funding usage. The model described here in is based on a number of trained individuals, within certain contractual provisions where the volume (result indicators) is assumed by the contract beneficiary. Applying other types of indicators, such hour of training, can normalize the information and determine more efficient (less resources needed), cost-effective and effective (increased number of trained individuals for less costs) values in what regards the process of delivering training programs. This will eventually lead to an increased impact of the public policy. Since the market shows no signs of sustainable recovery after the crisis that hit the world economy in 2007[8], public intervention in the area of professional re-conversion is highly desirable, and therefore public spending on training programs needs to be economically justified.

One of the most difficult issues that monetary authorities in many developing economies have to deal with is the management of a stable price environment. Inflation can create uncertainty, a low level of investment, and raise costs in general, thus lowering rates of growth. As a result, there exists a widespread need for understanding inflationary dynamics in any country of interest, especially in developing countries, subject to more significant and volatile price changes. This paper develops a VEC model for the Romanian economy, using CPI index and other macroeconomic data, in order to capture the transmission mechanism of inflation.

Keywords: inflation forecasting, monetary policy, developing countries, Romania, VAR model

JEL codes: E52, C32

Introduction

The primary focus of monetary policy has traditionally been the maintenance of a low and stable rate of aggregate price inflation as defined by commonly accepted measures such as the consumer price index. The underlying justification for this objective is the widespread consensus supported by numerous economic studies, that inflation is costly as it undermines real, wealth enhancing economic activity. This consensus is probably stronger today than it ever has been in the past.

The interest in empirical studies of monetary policy has increased in the last decade, possibly for the following two reasons. First, financial markets have been deregulated and monetary of the monetary policy process in a country with an inflation target may look something like the following. Official central bank inflation forecasts are presented to the public rather infrequently (e.g. in quarterly “inflation reports” as in Romania, Sweden or the U.K.). On these occasions attempts are made to measure and justify the overall stance of monetary policy, considering not only the development of inflation, but also other variables such as interest rates, the nominal exchange rate, indexes of “monetary conditions” (weighted averages of exchange and interest rates), and the “output gap” (the difference between actual and so-called potential GDP).

Forecasts of inflation will represent a key ingredient in designing policies which are geared toward the achievement of price stability. Moreover, such forecasts should be optimal in the sense that they make use of all relevant indicators and weight them correctly according to their reliability as predictors of future price developments.

Literature review

Previously, forecasting and policy analyses have been conducted using structural macroeconomic models developed along the lines of the Cowles Commission approach. These structural models, using hypothesized theoretical relations, show the main linkages in the economy. In the '40s and '50s, this was the traditional approach to econometric modeling of the monetary transmission mechanism, based on the quantitative evaluation of the impact of monetary policy on macroeconomic variables. The Cowles Commission methodology was based on the following three stages: specification and identification of the theoretical model, estimation of relevant parameters and simulation of the effects of monetary policy.

These models thus rely on economic theory, to determine the number of variables and their influence on the inflation. Under the Cowles Commission approach, if a particular structural form or parameterization that is derived from economic theory fails to be identified by the data; the parameter space is then transformed such that each point uniquely represents distinct behavioral patterns.

Two famous critiques were given by Lucas⁷⁵¹ in 1976 and Sims in 1980. Lucas notes that Cowles Commission models do not take into account expectations explicitly and expectational parameters are not stable across different policy regimes, so traditional macro-models are useless for the purpose of policy simulation. Additionally, his critique is related to the fact that this type of model „did not represent the data...did not represent theory ... were ineffective for practical purposes of forecasting and policy evaluation”⁷⁵².

Sims⁷⁵³ critique is parallel to that of Lucas', but concentrate on the status of exogeneity arbitrarily attributed to some variables to achieve identification within structural Cowles Commission models. He argues however that “having achieved identification in this way, the equations of the model are not products of distinct exercises in economic theory.”⁷⁵⁴ The fact is that in structural models, to achieve identification, restrictions are often imposed which have no theoretical justification. Further, and more importantly, Sims asserts that such restrictions are not necessary for the intended use of macromodels (i.e. forecasting and policy analysis). He argues that economic interpretation and investigation may not be possible without incorporating nonstatistical a priori information.

Since the seminal work of Sims, structural-VAR and cointegrated VAR's have been applied to economic data to forecast macro time series, study the sources of economic fluctuations, test economic theories. Additionally, the failure of the Cowles Commission approach lead to a series of methods of empirical research such as VAR approach or RBC approach.

The statistical and econometrical modeling has proven itself one of the main ways through which the inflationist phenomenon is analyzed with the purpose of bringing forth the main factors which determine the level and dynamics of inflation, the economic literature dedicated to this inflationist phenomenon in Romania being extremely rich. Some studies deepen the phenomenon analysis from the perspective of the monetary theories, others take into consideration a multitude of factors, forecasting the dynamics of the prices within some models of general equilibrium; a small number study inflation through the institutional factor and/or in correlation with the dynamics of the work market.⁷⁵⁵ In some models the shocks on the side of the offer are taken into consideration, some authors have included the world price of petrol as explanatory variable of inflation.⁷⁵⁶

⁷⁵⁶ Pelinescu, Elena, Dospinescu, A., *Modelarea ratei inflației*, Revista Oeconomica, 2006, nr. 1, p. 126-127.

In the models built on the basis of monetary theory of inflation, the authors include as variable the monetary supply (considered in the large sense through the M2 component), the output (represented either by the gross domestic product, or the industrial production) and the opportunity cost, usually through the introduction of the monetary exchange, all these start from the affirmation made by M. Friedman which argues that the inflation is exclusively tied to the currency demand, namely “the excessive growth of the monetary mass is the main and the only cause of inflation.”⁷⁵⁷

One of the most well-known models referring to the inflation in Romania is the Dobrescu model, that was developed throughout 1996-2000 and which includes between the main relations, also the ones referring to the forecasting of certain prices (expressed through the deflator of the gross domestic product, the consumer prices index and the gross capital formation prices index). For this model, the inflation calculation is done through the consumer product prices index. This was determined based on different econometrical relations in the 3 versions of the model. In the first version, this was determined by having as explanatory variable the deflator of the gross domestic product; in the model versions from 1997 and 1998, the previous level of the dependent variable was added as explanatory variable, and in the last versions the deflator of the gross domestic product and the monetary offer was used as explanatory variable.⁷⁵⁸ *The inflation calculation through the consumer product prices index finds its theoretical support in the monetary theory of Friedman and others, if the explanatory variable included in the model is the monetary one.*

In what follows some models of inflation will be presented with scientific support in the monetary theory from different perspectives. Nina Budina and her collaborators build a model of inflation forecasting for Romania, starting from the function of real demand of currency from the Cagan formulation.⁷⁵⁹ They reached the conclusion that in the analyzed period (1992-2000) as well as in the periods of price liberalization, the inflation was a monetary phenomenon. The monthly modifications of the inflation rate are explained in the study through the correction of errors mechanism in which the imbalance between the currency demand and supply plays an essential part, the changes of the exchange rate and of the controlled prices through administrative regulation being considered as having transitory effects on the evolution of the monthly rate of inflation.⁷⁶⁰

Cezar Boțel in his article “Cauzele inflației în România” analyzed the inflation in Romania by utilizing the technique of the structural autoregressive vector (SARV) and the cointegration technique. The results of his analysis have been obtained as the form of the response function to shock, of the decomposition of the variable and the tests for the detection of the Granger causality. The most important conclusion made based on this study is that the higher inflation in Romania is the result of the late reformation of the banking and real sectors, compared with other countries which are in transition.⁷⁶¹

Florin Ovidiu Bîlbîie used the Granger causality tests, the variation decomposition and the econometrical models based on the techniques of the non-structural and unrestricted autoregressive vectors in order to point out the relevant indicators that influence the inflation. The obtained results show that the most significant indicators that influence the inflation are the exchange rate and the real nongovernmental credit, followed by the monetary aggregates and the interest rate practiced by the commercial banks.⁷⁶²

⁷⁶²Ciutacu, C., Ciumara, M., Op. Cit., p. 28.

David Moore, IMF expert, studied the empirical relationship between the inflation rate, the unitary cost of the work force and the exchange rate utilizing a model of autoregressive vector (ARV). The conclusion that the author had reached is that in Romania, the inflation was determined mainly by the wage increase in the context of a low productivity, the channel of transmission used was the financial lack of discipline and the low budgetary constraint.⁷⁶³

Starting from another ARV model, Elena Pelinescu, in her article “Modelarea inflației în România”, reaches the conclusion that the factors whose modification influences inflation the most are the exchange rate and monetary supply.⁷⁶⁴ Using the models based on the method of the smallest squares or the cointegration techniques of the un-restricted autoregressive vector (UARV), Mugur Isărescu, Cornel Târhoacă and Lucian Croitoru, argued in their study the influence of certain factors on inflation, such as monetary supply, the dynamic of industrial production, the unemployment rate, the exchange rate, the real interest, lastly, underlining a strong negative correlation between inflation and unemployment.

In the study “Țintirea directă a inflației: o nouă strategie politică monetară. Cazul României” a wide range of different econometrical models are presented that have as purpose the realization of a forecast by the specialists of the National Bank of Romania in the context of a regime of aiming at the inflation. The authors consider that the forecast of inflation in Romania through econometrical models “is premature, given the frailty of the connections between the variables with characteristics of *leading indicators* and the inflation (measured through IPC, CORE1, CORE2). Together with the stabilization of the inflation on the palier of a single number and the consolidation of the macroeconomical equilibriums, the amelioration of these relations is predictable and, it follows, the possibility of utilizing the macroeconomic instrument for the realization of viable forecasts on medium turn.”⁷⁶⁵

Methodology and data

Our model is based on monthly data for inflation rate (measured by CPI), unemployment rate (UR), broad money (BM2), real interest rate on deposits (IR), nominal exchange rate (EUR/RON– EREUR) for Romania between January 1997 and February 2010⁷⁶⁶. Unemployment rate represents the structural influences on inflation, broad money as well as real interest rate on deposits captures the monetary stance, nominal exchange rate is used in order to represent imported inflation. Data were computed in Eviews.

The data were tested for stationarity, using the ADF and the Phillips and Peron method. All series have one unit root I(1). The above mentioned tests confirmed that the first difference series were stationary. The Johansen cointegration without deterministic trend test was then conducted. The Unrestricted Cointegration Rank Test (Trace) indicated three cointegrating equations at 0,05 level.

Given the results, a VECM Vector Correction Model with 3 cointegrating equations was estimated. Restrictions were placed on the coefficients of each cointegrating relation as well as on the adjustment coefficients, using the normalized cointegrating coefficients and adjustment coefficients. The VEC Granger causality /block exogeneity Wald test showed that the variables with significant impact on the evolution of CPI were EUR exchange rate, the interest rate and broad money M2. We conducted once again the Johansen cointegration without deterministic trend test. The Unrestricted Cointegration Rank Test (Trace) as well as the Unrestricted

Cointegration Rank Test (Maximum eigenvalue) indicated two cointegrating equations at 0,05 level.

The VECM Vector Correction Model with two cointegrating equations, 6 lags and deterministic trend in CE, no trend in VEC proved to be the one that captures the best the behaviour of selected variables. The diagnostic tests for the VECM equation confirmed its coefficient stability, the Jarque-Bera test did not reject the null hypothesis of a normal distribution of the residuals (at 5 percent significance level) and the Portmanteau test as well as the correlogram of squared residuals did not show any autocorrelation or ARCH in the residuals.

Graph 1. Impulse response functions between CPI inflation rate and selected variables

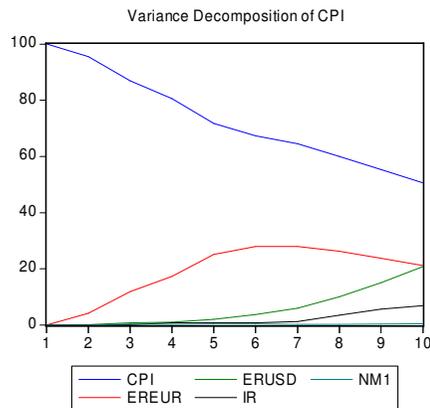

Source: authors' calculations

The dynamic property of the model is tested using variance decomposition and impulse response functions. Graph 1 shows the response of the inflation rate measured by CPI to a one unit shock to the exchange rate, narrow money, interest rate, net average wage. The x axis gives the time horizon or the duration of the shock whilst the y-axis gives the direction and intensity of the impulse or the percent variation in the dependent variable away from its base line level. This model confirms the existence of statistically significant links between the inflation rate and the selected macroeconomic variables. The reaction of CPI index is consistent with the macroeconomic data. The impulse responses meet a priori expectations in terms of the direction of impact. The graphs show that a positive shock to monetary variables or expansionary monetary policy, has a significant expansionary effect on inflation. The effect of a unit shock to base money on the cpi, occurs after approximately the first one to two months and reaching its peak between ten to twelve months.

Thereafter the cumulative effects of base money stabilize with the monthly CPI increasing by approximately one percent of its baseline level. The impact of the exchange rate is rather immediate and long lasting. A unit shock to the exchange rate causes the cpi in the first period to deviate by approximately 0.5 percent from its base level. The inflation rate accelerates rather rapidly in the first ten to twelve months as the CPI tends to a new equilibrium level. Increases in the interest rates tend to have a contractionary effect on prices. The more significant impact however manifests itself after five months with the response function trending away from zero.

Graph 2. Variance decomposition – percent of CPI variance due to

Source: author's calculations

The variance decomposition is presented in Graph 2. The statistics indicate the percentage contribution of innovations in each of the variables in the system to the variance of the CPI. The results show that shocks to the CPI itself and the exchange rate accounts for most of the variability in the CPI over all horizons. Not much can be attributed to base money, although over longer horizons its relative contribution increases.

Conclusion

In the process of conducting monetary policy analysis, central bank economists are faced with a number of empirical questions. Does the nominal exchange rate help to predict inflation? Does the nominal exchange rate adjust in response to the difference between domestic and foreign inflation, to restore some equilibrium level of the real exchange rate? How useful are various measures of the output gap and of monetary conditions? How fast do changes in monetary policy affect output and inflation? These questions concern complex relations between variables which are all endogenously and simultaneously determined in the economic system. We do certainly not expect that there is any single model that can provide the best possible answers to all relevant questions in the analysis of monetary policy, or that it yields exactly the same answers when estimated for different time periods.

While many previously used inflation forecasting models depend on exogenous variables, the VAR approach endogenously determines all the variables which make up the system. Our VECM model has proven that that the basic transmission mechanism runs from base money (via interest rates which affect the relative return on financial assets) to the exchange rate and then to prices.

BUSINESS SURVEYS – EVALUATION INSTRUMENT OF THE EUROPEAN ECONOMIC CLIMATE

Secareanu Constantin

The Romanian-American University

Business surveys or conjuncture surveys are specific statistical researches, but complementary to traditional, official statistics. While official statistics provide quantitative information regarding the level, structure and evolution of varied economic processes and phenomena, business surveys offer quality information, essential to the short term evolutionary analysis of economic indicators: the diagnosis of the current situation, the timely detection of inflexion points within the economic cycle and the rapid estimation of short term tendencies of the main macroeconomic indicators (the dynamics of the gross domestic product, the index of industrial production, etc.).

Keywords: business surveys, conjunctural balance ,confidence indicator, economic sentiment indicator

JEL classification: E32, O11

1. What are business surveys?

Comparatively to official statistics – of which's utility is undeniable, but are usually available after a certain period of time (weeks, months) – business surveys present two essential qualities:

- periodicity , usually monthly;
- operativity, the results dissemination time often being very fast, usually, a few days after the reference period.

Business surveys are quality surveys, that are addressed to managers of the companies included in the sample. They must answer a series of questions regarding the current and future situation of the unit they lead and about the economic climate in which they conduct their activity.

The primary characteristic of business surveys is that instead of exact numbers, the answer to the question is an “appreciation”, an “estimation”, an “opinion” about different aspects of the company's activity (production, contracts, production capacity, employees, prices, stocks, etc.), in the form of ordinal scales, in most cases, with three options:

- for questions regarding an indicator's level the answers can be: “above normal / normal / below normal”;
- for questions regarding the evolution in time of a phenomenon, the answers can be: “has risen / is stable / has dropped” or “will rise / will remain stable / will drop”;

Through a calculation and aggregation procedure (presented in paragraph three of the paper), the quality information provided by companies' managers is transformed in statistical indicators with a special power to reflect present reality and anticipate future short term evolutions.

So, the business surveys provide reliable and fast information, published regularly, in the form of new indicators used for describing the economic situation in the European Union and the Member States. Presently, these indicators present a growing interest, especially after the finalization of the European Union's growth process and in the condition of the present financial crisis. The Central European Bank, the Governments of the Member States, the central banks and financial institutions, the business environment and the research institutes currently use the results of business surveys for detecting and analyzing the economic conjunctural diagnostic and the estimation of the main macroeconomic indicators at a national and community level.

In this context, the existence of a conjuncture survey system at a European level has been imposed, that allows the comparison of national economies, different as development level and etherogenic from economic structures' point of view.

2. How are the business surveys in the European Union harmonized?

The business surveys are planned and take place in an organized environment (The Joint Harmonized EU Programme of Business and Consumer Surveys), so such that their results can be used for monitoring economic development, both at the Member States' level and the entire European Union and the Euro Area's level.

The mentioned programme, coordinated by DG ECFIN (Directorate General for Economic and Financial Affairs), although was launched by the decision of the European Committee all the way since 1961, has recorded a continuous rise in development, revisal and harmonization, in at least two directions:

- sectorial coverage, as activity domains in which the surveys took place and, implicitly, the

results have been published (industry – 1961, construction and investment in industry – 1966, consumption in farms – 1972, retail trade – 1984, services – 1996 and more recently

in the financial sector);

- the geographic coverage that numbers three countries that have participated in the programme; beginning in January 2007, the programme contains the 27 States.

Members of the European Union and a candidate country (Croatia); another candidate country (Turkey) have integrated themselves into the programme in May 2007.

The harmonization's objective is the production and publication of comparable data for all the Member States in such a way that it permits conducting comparisons between the business cycles of different countries as well as the aggregated calculus of composition indicators, for the European Union and at the Euro Area's level.

The harmonization is based on two principles:

- the use of harmonized questionnaires that contain the same standardized questions, in number and form, by all the Member States; still, depending on the economic specific and the analyzed sector, the questionnaires can include additional questions, conforming to the necessities of the respective country;

- the statistical researches and the transmittion of results to the European Commission (DG

ECFIN) is realized in periods and on common terms.

Business surveys have been implemented gradually in Romania, at the National Institute of Statistics, following the initiation in 1991 of the Centre of Cooperation with Economics in Transition's (CCET) programme within the Organization of Economic Cooperation and Development (OECD) and the European Commission (DG ECFIN – Bruxelles).

Business surveys have been realized at the National Institute of Statistics, first trimestrially, beginning with June 1991 for the manufacturing industry, October 1993 for construction and January 1994 for retail trade.

Following development and revision, the "European Union's business survey harmonizing Program", approved by the European Commission in November 2000, beginning with June 2002, has passed on to the National Institute of Statistics for the monthly existing business surveys' conductance, as well as the implementation of monthly surveys in services and biannual for investment and industry.

Presently, Romanian statistics provides all the necessary information following the community's requirements. As such, the obtained results are intensely used – alongside the ones from

traditional statistics – by the responsible nationals and Europeans, by the business environment and, last but not least, by the specialized mass-media.

Currently, five current surveys with monthly frequency are being organized and conducted by all the Member States of the European Union, in the following activity sectors: manufacturing industry, construction, farms' consumers, retail trade and services.

The questionnaires contain standardized questions specific to every activity sector, regarding:

- the appreciation of the actual situation overlooking:
 - the level of production, goods sales, services demands, construction works;
 - the level of underway contracts and orders;
 - the level of stocks of finished products and stocks of goods.
- the estimation of evolution in the next three months, for a series of indicators such as:
 - the evolution of production, the physical volume of product sales, service demands, construction works;
 - the evolution of production and sales prices;
 - the evolution of the number of employees.

Mostly, the questionnaires have a qualitative character, the main questions referring to appreciations, estimations and opinions from the managers and consumers.

To record the information in the research questionnaire, a large range of methods are used:

- the method of the interview, direct or by phone (done by the operators at the County's Statistical Offices);
- the method of autoregistration, in which companies' managers complete the questionnaire on paper or electronically.

3. The calculation and interpretation of indicators

Answers of a qualitative nature, obtained from research (by collecting primary data) are transformed, through a hierarchic aggregation algorithm, in two categories of quantitative indicators: conjunctural balances and composite indicators.

Conjunctural balances (CB) or short term balances are determined for every question, for every sector (manufacturing industry, construction, consumption, retail trade, services), for every class of activity within the respective sector, as well as in groups depending on the size of the companies.

The conjunctural balance (CB) for every question, at the level of each stratum of the sample is determined based on the companies answers that can be one of the three options: rise (R), stability (S), decrease (D), where $R + S + D = 100\%$.

The conjunctural balance is calculated as the procentual difference between the alternative extremes:

$$CB_{\text{stratum}} = \%Rise - \%Loss = R_{\text{stratum}} - L_{\text{stratum}}$$

R_{stratum} = the percentage of those who have chosen the positive option of the phenomenon;

L_{stratum} = the percentage of those who have chosen the negative option of the phenomenon.

To obtain representative results and considering the quality assurance of the sample, the proportions R and L are not calculated directly, based on the number of answers (positive and negative) for the questions in the questionnaire, but considering the weight of the companies that have chosen the respective alternative in the volume of activity of the stratum in the sample, so the importance of every company from one relevant indicator's point of view (turnover or the

number of employees). In this way, a greater importance is attributed to larger companies in evaluating the current economic situation and previewing future evolutions.

As a result, the conjunctural balance at each stratum's level represents the difference between the percentage of companies that have answered positively and the weight that have answered negatively:

- regarding the surveys in the manufacturing industry and construction, the weight of the n

number of employees is considered;

- regarding the surveys in retail trade and services the weight of the turnover is used.

The conjunctural balance for each question, at each of the activity classes' level and at the entire sector's level is calculated based on a plan of processing answers using – based on the situation – the weight of the number of employees of the weight of the turnover (g):

$$CB_{class} = \sum R_{stratum} \cdot g_{stratum} - \sum L_{stratum} \cdot g_{stratum} = R_{class} - L_{class}$$

$$CB_{sector} = \sum R_{class} \cdot g_{class} - \sum L_{class} \cdot g_{class} = R_{sector} - L_{sector}$$

If the answer to a question is given five options: intense rise (RR), light rise (R), stability (S), light decrease (D), heavy decrease (DD), then the conjunctural balance is calculated based on the next formula:

$$CB = \left(RR + \frac{1}{2} R \right) - \left(\frac{1}{2} D + DD \right)$$

$$RR + R + S + D + DD = 100\%$$

It's obvious that the conjunctural balance can become values in the [-100%, +100%] interval:

- if the majority of answers are negative (D), then $CB < 0$; when all the answers are negative

$$CB = -100\%;$$

- if the positive answers (R) are compensated by the negative answers (D), then $CB \approx 0$;

- if the majority of answers are positive (R), then $CB > 0$, when all the answers are positive,

$$CB = +100\%.$$

Consequently, the conjunctural balance indicates the perception of the respondents on the tendencies manifested in the present and future evolution of a phenomenon, but must not be confused with the intensity of rises and decreases of a statistical indicator (that are quantified with the help of indexes and rise/decrease rhythms).

Based on the analysis of historical data, the specialists have convened upon the next milestones for interpreting conjunctural balances (CB):

$CB \leq -41\%$	severe decrease
$-40\% < CB < -16\%$	decrease
$-15\% < CB < -6\%$	moderate decrease
$-5\% < CB < +5\%$	relative stability
$+6\% < CB < +15\%$	moderate rise
$+16\% < CB < +40\%$	rise
$CB \geq +41\%$	severe rise

Composite indicators are synthetic indicators calculated at the level of the European Commission, based on the conjunctural balances sent to the national institutes of statistics. So, through specific aggregations, a series of composite indicators are

determined, that quantify the reflected situation in the business surveys for every Member State, at the level of the European Union as well as the Euro Area.

The confidence indicator (CI) for every sector (manufacturing industry, construction, consumer, retail trade, services) and for every Member State is calculated as a simple arithmetic average of the answers (conjunctural balances) for a part of the questions. The selected questions are appreciated as being the most representative from the point of view of the correlation with the evolution of a statistical reference indicator (the analysis of the main components).

To exemplify, the confidence indicator in the manufacturing industry – which best adjusts the movements of industrial production index (IPI – considered reference indicator) – has conjunctural balances for the following three components in view: the estimation of production (CB_p), the appreciation of the contracts and demands portfolio (CB_c) and the appreciation of stocks of finite products (CB_s), these being taken from the calculation formula with a changed calculus sign; the explanation is the fact that a positive response to this indicator reflects a negative aspect.

Consequently, the industry confidence indicator (ICI) is:

$$ICI = \frac{CB_p + CB_c + (-CB_s)}{3}$$

The confidence indicators synthetically reflect perception, estimations and expectations at each sector's level (industry - ICI, construction - ICCT, consumer - ICCS, retail trade - ICRT and services - ICS).

The Economic Sentiment Indicator (ESI) is an aggregate of confidence indicators from all the five sectors (business surveys), being considered a true barometer of the national and community economic climate. It anticipates the future tendencies of the gross domestic product in each of the Member States in the European Union and in the Euro Area, following the movements of the economy as a whole.

The Economic Sentiment Indicator is determined as a ponderated arithmetic average of confidence indicators calculated at the level of each sector:

$$ESI = a \cdot ICI + b \cdot ICCT + c \cdot ICCS + d \cdot ICRT + e \cdot ICS$$

a,b,c,d,e = the allocated percentage of each sector based on the sector's representativity and the performance registered in following (adjusting) the reference variable.

The next percentage system is currently used: industry (a = 40%), construction (b = 5%), consumption (c = 20%); retail trade: (d = 5%), services (e = 30%).

The percentages are not directly applied to the five confidence indicators. These (the latter) have been calculated based on the fifteen conjunctural balances, very different as dynamics and level. In these conditions, components with a relatively high amplitude of the characteristic would dominate the evolution of the composite indicator (ESI), while other important influences, but less visible in confidence indicators, would have an insignificant impact over the ESI.

As a result, to eliminate this inconvenience and to ensure the comparability between the time cycles of conjunctural balances for all the fifteen main components, a method of standardization (normalization) is applied, that runs through the next steps:

- Each chronological series of conjunctural balances corresponding to each component transforms into a centered variable (through the difference to the average) and reduced

(through comparison to the standard deviation of the series). As a result, all the initial chronological series with the property that the average is null and the standard deviation is equal to the unit;

- The conjunctural balance of each country is determined, for each period, through the aggregation of all the components and, implicitly, of all the five conjuncture surveys' results. This result is a correct estimator of economic sentiment;
- Still, for providing analysis and interpreting data, the economic sentiment indicator (ESI) is determined through the rescale of the previously determined balance, through a variable characterized by a long term average of 100 and a standard deviation of 10.

This transformation permits the more practical interpretation of the indicator:

- If $ESI > 100$ the reflected economic sentiment is greater than the long term average;
- If $ESI < 100$ the reflected economic sentiment is lower than the long term average.

The Economic Sentiment Indicator, through its construction, synthesizes information contained within conjunctural balances and provides a measure of the business climate, as it is perceived by a large number of managers. The indicator aggregates attitudes, judgments, behaviors of economic actors in the entire economy, offering precious information about the macroeconomic conjuncture and the short term perspectives of the evolution of the gross domestic product.

The level and tendency of the ESI suggests that the evolution of the gross domestic product.

Also identified are the business cycles and the perception of the European economic climate, with a minimum point reached in March 2009 when ESI was 68 points.

After ten months of uninterrupted improvement of the ESI's level (March 2009 – January 2010), a period of recoil appears in February 2010 manifested through a stagnation at the European Union's level (only +0.2 points compared to January) and even a reduction (-0.1 points) in the Euro Area.

Still, the fact that the highlighted tendency in the last year has led to recording an ESI level very close to the long term average must be marked (97.4 points).

At the Member States' level, in February 2010, there can be identified at least four groups of countries based on the values of the ESI:

- The group of countries with the ESI level that is over 100 points, so the economic sentiment

is over the long term average (that contains the 1990-2009 period). Here we have the Nordic

states: Sweden (108.2 points), Denmark (105.7 points) and Finland (102.8 points), the most

optimistic countries as far as evaluation and anticipation of the business climate are concerned. In January 2010, this level has been reached by Italy and Poland also – but – has

not been able to maintain it in February 2010.

- The group of countries with the ESI varying between 90 and 100 points, under the level of

the long term average, but near it. Here we have fifteen Member States: from Italy (99.7

points) to Spain (90.1 points), including France (98.4 points), Great Britain (98.3 points)

and Germany (97.0 points). The presence of the biggest economies in this group explains

the general tendency at the entire European Union's level.

- The group of countries with the ESI's level between 80 and 90 points is characterized

through evaluation and anticipation still moderate in the as far as the business climate is concerned and a withheld economic sentiment, even if it is rising. Here we have six countries: from Lithuania (89.9 points), to Romania (80.9 points) and Cyprus (80.8 points).

In this group we also find Latvia, Hungary and Bulgaria.

- Finally, in the last group we have Greece, with the lowest level of economic sentiment (72.4

points), still far from the national long term average and the levels recorded by the other

Member States also.

The analysis of the data permits us to point out other interesting conclusions:

- The majority of the Member States have recorded increases in the ESI in the last year: the

fastest increase being in Denmark (+37.4 points, from 68.3 to 105.7), while in Romania, the

economic sentiment has risen with only 3.1 points (from 77.8 to 80.9);

- The only country where the ESI has decreased in the last year is Bulgaria (-2.3 points, from

88.7 to 86.4); Bulgaria's position is explained through the fact that in the reference month

(March 2009) the ESI's level was the the highest in the whole European Union, reflecting

an exaggerated optimism.

THE INFLUENCE OF THE NATIONAL MACRO-ENVIRONMENT VARIABLES ON TOURISM SERVICES CONSUMPTION

Untaru Elena

*“Transilvania” University of Brasov
Faculty of Economic Sciences*

Seitan Oana

*“Transilvania” University of Brasov
Faculty of Economic Sciences*

The present work aims analysing the influence of different factors or features on tourism services consumption. In order to achieve the main goal of the paper, the author appealed to a statistical analysis. Thus, the variables with higher influence in tourism are emphasized at the end of the work. The result of the work can be used by managers of travelling agencies and tour operators in drawing and creating a marketing strategy for the products and services they sell and provide.

Key words: tourism consumption, influences of macro-economic variables, employment rate, inflation;

JEL classification: M

1. Introduction

Traveling agencies operate in a wider area than that defined by its microenvironments. Its actions will also be marked by the existence of general factors with long-term and indirect influence, which can not change and control. Profound impact of these factors requires action adaptation of the undertaking of travel conditions, trends and structures in society and the economy it subscribes.

Given the influence exerted on different parts of macro-environment of tertiary activity, in general, this paper aims to analyze whether the national macro-environment variables are affecting tourism consumption in Romania, or not, through the selection of key components, and measuring the intensity of those that have impact on tourist consumption. For achieving such an analysis, one will appeal to statistical methods designed to highlight the extent to which a variable is considered or not influenced by other variables.

2. The analysis of the influence of macro-environment variables on tourism

Regression analysis generally is part of the multivariate methods, being at the same time, an explanatory method of analysis as a dependent variable is explained by means of independent variables.

Regression analysis describes the relationship between a dependent variable and one or more independent variables, through the means of a given model.

In the case of mass phenomena, the dependent or resultant variable is a function of more variables: $y_i = f(x_1, x_2, \dots, x_n)$ in which x_i variables are factorial features that determine more or less the variation of the resultant feature y .

In the present analysis, the resultant feature will be the outcome y expressing tourism consumption, - income from tourism - and characteristics of factorial x , representative, expressing the level of economic development at national level are:

- net average monthly nominal earnings in comparable values (euro / person);
- the employed population (absolute);
- unemployment rate (%);

- inflation rate (%);
- investment (billions of lei, constant prices);
- Romania's urban population (%);
- crime rate per 100,000 inhabitants;
- number of physicians per 10,000 population;
- number of cars in circulation (absolute);
- Romanian population (absolute);
- Gross Domestic Product per capita in comparable values (thousands).

Further, it will examine the link between income from tourism made as dependent variable reflecting tourist consumption, and the independent variables described above, which reflect the socio-economic development in Romania, the period of time had in view is 1996-2008.

Using the software package SPSS 12 for multiple regressions, we obtained the following results:

Table 1: Stepwise regression method

Variables Entered/Removed ^a			
Model	Variables Entered	Variables Removed	Method
1	ratasomaj	.	Stepwise (Criteria: Probability-of-F-to-enter <= ,050, Probability-of-F-to-remove >= ,100).
2	popocupata	.	Stepwise (Criteria: Probability-of-F-to-enter <= ,050, Probability-of-F-to-remove >= ,100).
3	investitii	.	Stepwise (Criteria: Probability-of-F-to-enter <= ,050, Probability-of-F-to-remove >= ,100).

a. Dependent Variable: incasariturism

In the above table are given the selection criteria of the three variables retained in the model. The first step is to model the variable “unemployment”, the second step is regression model with two variables, namely: “Unemployment” and “employed population” and the third step is the regression model with three variables: “unemployment rate”, “employed population” and “investment in the economy”

The summary table presented bellow, reflecting the values of determined coefficients, explains synthetic results of the three models. Thus, it appears that the first variable, “unemployment rate”, explains about 64% of the variation in earnings from tourism. In the case of the second model, variables retained “unemployment” and “employed population”, explained variation reached 93.6% and for the third model, variables retained “unemployment”, “employed population” and “investment in the economy” explained variation is 97.3%.

Table 2: Values of the determination coefficients

Model Summary

Model	R	R Square	Adjusted R Square	Std. Error of the Estimate
1	,801 ^a	,642	,609	59,51117
2	,968 ^b	,936	,923	26,35151
3	,986 ^c	,973	,964	18,08079

- a. Predictors: (Constant), ratasomaj
b. Predictors: (Constant), ratasomaj, popocupata
c. Predictors: (Constant), ratasomaj, popocupata, investitii

It is noted that the first two variables selected, namely, “unemployment” and “employed population”, largely explain the variation in earnings from tourism, while the variable “investment in the economy” explains variation in the proportion of earnings only by 3.7%, reflecting the importance of the first two components in determining tourism consumption in Romania.

From the summary of model also results that the standard error of the estimation decreases from 59.51 billion lei for the first model to 18.08 billion lei in the case of the third model.

Analysis of variance for multiple regression will be based on the results shown in table 3. It is noted that most of the total variance is generated by the regression equation. Thus, if the first model, 64.2% of total variance is explained by regression model and 35.8% by unknown factors, that represent error variance. In the case of the second model, 93.6% of the total variance is explained by regression model and 6.4% by unknown factors. In the case of the third model, 97.3% of total variance is explained by regression model and 2.7% by unknown factors.

Table 3: ANOVA variance analysis**ANOVA ^d**

Model		Sum of Squares	df	Mean Square	F	Sig.
1	Regression	69767,843	1	69767,843	19,700	,001 ^a
	Residual	38957,374	11	3541,579		
	Total	108725,2	12			
2	Regression	101781,2	2	50890,598	73,287	,000 ^b
	Residual	6944,021	10	694,402		
	Total	108725,2	12			
3	Regression	105783,0	3	35260,994	107,860	,000 ^c
	Residual	2942,235	9	326,915

- a. Predictors: (Constant), ratasomaj
b. Predictors: (Constant), ratasomaj, popocupata
c. Predictors: (Constant), ratasomaj, popocupata, investitii
d. Dependent Variable: incasariturism

Based on variance analysis, the data in the table shows an increase in the value of F calculated from 19.7 to 107.86, which strengthens the statistical significance of the regression explaining the variation in earnings from tourism.

Table 4: Regression coefficients

Coefficients

Model		Unstandardized Coefficients		Standardized Coefficients	t	Sig.
		B	Std. Error	Beta		
1	(Constant)	525,297	55,613		9,446	,000
	ratasomaj	-31,078	7,002	-,801	-4,438	,001
2	(Constant)	-858,561	205,295		-4,182	,002
	ratasomaj	-30,445	3,102	-,785	-9,815	,000
	popocupata	,00016	,000	,543	6,790	,000
3	(Constant)	-1198,458	171,113		-7,004	,000
	ratasomaj	-12,614	5,523	-,325	-2,284	,048
	popocupata	,00017	,000	,575	10,339	,000
	investitii	,679	,194	,498	3,499	,007

a. Dependent Variable: incasariturism

The table of regression coefficients includes the intercepted value and regression coefficients that generate the regression equations in the three phases:

1. $\hat{y} = 525,29 - 31,07 \cdot x_1$,
2. $\hat{y} = -858,56 - 30,44 \cdot x_1 + 0,00016 \cdot x_2$,
3. $\hat{y} = -1198,45 - 12,61 \cdot x_1 + 0,00017 \cdot x_2 + 0,679 \cdot x_3$,

where x_1 represents the unemployment rate;

x_2 represents the occupied population in economy;

x_3 represents the investments in economy;

The results of the model with two excluded variables, presented bellow indicate the excluded variables from the final model due to a very low value of calculated t , that leads to the acceptance of H_0 of the regression coefficient that is null.

Table 5: The results of the model with two excluded variables

3. Conclusions

The conclusion to be drawn from multiple regression analysis conducted under this chapter is that the main macroeconomic variables considered to have a significant impact on earnings from tourism are: unemployment, employment and investment levels in the national economy.

The most important macroeconomic variable used by multiple regression model is considered in explaining the unemployment rate of 64.2% change in earnings from tourism, followed by employment and investment, together with unemployment, explains the proportion of 97.3% change in earnings, the difference of 2.7% is explained by unknown factors.

Evolution proceeds from tourism, reported in the three macroeconomic variables will be determined as follows:

- The percentage increase in unemployment, tourism revenues will decline by approximately 12.614 million lei, while the employment in the economy and investment remain unchanged;
- The drive to increase employment in the national economy, made in tourism receipts will increase to 170,000 lei, while the unemployment rate and investment remain unchanged;
- The one billion lei increase investment in economy, tourism receipts achieved will increase by 679 million lei, while the unemployment rate and employment in the economy remain constant.

Starting from the three variables considered having a significant impact on tourism receipts, it can be said that tourism consumption in Romania is determined by the employment of people

with variable rate of unemployment and employment concerns and the level of economic development expressed through investment.

SUB-SECTION: FINANCES

AN OPTIMIZATION OF THE RISK MANAGEMENT USING DERIVATIVES

Şontea Ovidiu
ASE Bucharest

This article aims to provide a process that can be used in financial risk management by resolving problems of minimizing the risk measure (VaR) using derivatives products, bonds and options. This optimization problem was formulated in the hedging situation of a portfolio formed by an active and a put option on this active, respectively, a bond and an option on this bond.

Keywords: Risk management

The article's JEL code: G32

Options

First, we will consider a financial active that checks a classic equation

$$dS_t = \mu S_t dt + \sigma S_t dz_t,$$

where μ is the trend, σ is the active's volatility, and z_t is the brownian motion.

For a cover operation we will use a put option defined like this $P_t = P(S_t, K, r, \tau, \sigma)$, where τ is the contract period, K is the exercise price, and r interest rate.

Obviously, the option price is given by Black-Scholes model

$$P_t = K e^{-r\tau} N(-d_2) - S_t N(-d_1)$$

$$d_1 = \frac{\ln \frac{S}{K} + \left(r + \frac{\sigma^2}{2}\right) \tau}{\sigma \sqrt{\tau}}$$

$$d_2 = d_1 - \sigma \sqrt{\tau},$$

, and $N(d) = Prob(x \leq d)$ is the distribution function of the standardized normal law.

A way of using put options is by taking long positions $h_i, i = 1, \dots, n$ with n options whose exercise price $K_i, i=1, \dots, n$ so that the total price must be lower or equal with fixed C ,

$$\sum_{i=1}^n h_i P_{it} \leq C.$$

Additionally we will put the total overdraft condition $\sum_{i=1}^n h_i < 1$.

Considering that the exposure must be observed for the next τ periods, it will be necessary the measure risk characterization, VaR. We will define $VaR_{t+\tau}^\alpha$ as loss of $\alpha\%$ of a relative monetary unit to an institution exposure (financial) to invest at t moment in an active risk.

This definition must be translated into a formula, so we will consider $Y_t = \ln S_t$ and will apply lema Ito

$$dY_t = \left[\frac{1}{X_t} \mu X_t + \frac{1}{2} \left(-\frac{1}{X_t^2} \right) \sigma^2 X_t^2 \right] dt + \frac{1}{X_t} \sigma X_t dz_t = \left(\mu - \frac{1}{2} \sigma^2 \right) dt + \sigma dz_t.$$

That is

$$\ln S_t \sim N(m, \sigma^2 t), m = \ln S_0 + \left(\mu - \frac{1}{2} \sigma^2 \right) \tau,$$

And we can state that, for a position without cover, we have

$$VaR_{t+\tau}^\alpha = S_t e^{r\tau} - S_t e^{\theta(\alpha)},$$

where

$$\theta(\alpha) = \left(\mu - \frac{1}{2} \sigma^2 \right) \tau + c(\alpha) \sigma \sqrt{\tau},$$

while $c(\cdot)$ is the separation point of the two regions of the cumulative normal standard distribution.

We see that the second term of the VaR formula can be interpreted as the asset's expectation of the active will return at the $\alpha\%$ level.

In order to make the calculus easier, we shall suppose that the put option will be "in money", so we obtain

$$VaR_{t+\tau}^{\alpha} = S_t e^{r\tau} - \left[(1 - \sum_{i=1}^n h_i) S_t e^{\theta(\alpha)} + \sum_{i=1}^n h_i K_i - (\sum_{i=1}^n h_i P_{it}) e^{r\tau} \right].$$

We now can formulate an optimization problem

$$\begin{aligned} \min_{h_i, K_i} VaR_{t+\tau} \\ \sum_{i=1}^n h_i P_{it} \leq C, \\ \sum_{i=1}^n h_i < 1, h_i \geq 0, \end{aligned}$$

This means that we want the minimization of the VaR, using long positions with put options and hedging cost restrictions.

As usual, in order to draw some conclusions that later we can generalize, eventually, we shall consider the above problem as having a sole long position on a put option. We so can re-write the minimum problem

$$\begin{aligned} \min_{h, K} VaR_{t+\tau}^{\alpha} &= S_t e^{r\tau} - [(1 - h) S_t e^{\theta(\alpha)} + hK - hP_t e^{r\tau}] \\ C &= hP_t, 0 \leq h < 1. \end{aligned}$$

If we use the cost covering restriction, we shall obtain

$$\tilde{K} = arg \min_K \left\{ S_t e^{r\tau} - \left[\left(1 - \frac{C}{P_t} \right) S_t e^{\theta(\alpha)} + \frac{C}{P_t} K - C e^{r\tau} \right] \right\}.$$

We can re-write

$$\tilde{K} = arg \min_K \left\{ S_t e^{r\tau} + C e^{r\tau} - S_t e^{\theta(\alpha)} - C \left[\frac{K - S_t e^{\theta(\alpha)}}{P_t} \right] \right\}$$

which leads us to

$$\tilde{K} = arg \max_K C \left[\frac{K - S_t e^{\theta(\alpha)}}{P_t} \right] = arg \max_K \left[\frac{K - S_t e^{\theta(\alpha)}}{P_t} \right]. (*)$$

Is noticeable that $VaR_{t+\tau}^{\alpha}$ is independent from K 's selection and K optimum is determined according to the cash-flow of the active and the cover is adjusted depending of the cover's price. VaR is a linear function in relation with the expenditures with the cover, so each added monetary unit generates a decrease of the same level in VaR.

From the last relation we can deduce that the VaR's minimize is the same thing with the maximize of the difference between exertion's price and the level $\alpha\%$ of overdraft earnings relative at the price of the option put.

Intuitive, we may say that the objective function of the optimization problem can be interpreted as the rate between the cover's price and the cost of this operation. Furthermore, if the option's exercise price will decrease we will cover a larger part of distribution, but this option will become more expensive.

The optimization problem (*) requires a maxim condition

$$\frac{\partial \left(\frac{K - S_t e^{\theta(\alpha)}}{P_t} \right)}{\partial K} = 0$$

That is

$$\frac{P_t - (K - S_t e^{\theta(\alpha)}) \frac{\partial P_t}{\partial K}}{P_t^2} = 0.$$

From here

$$\tilde{K} - S_t e^{\theta(\alpha)} = \frac{P_t}{\frac{\partial P_t}{\partial K}} = \tilde{K} - S_t e^{r\tau} \frac{N(-d_1)}{N(-d_2)}$$

The last relation leads to

$$S_t e^{\theta(\alpha)} = S_t e^{r\tau} \frac{N(-d_1)}{N(-d_2)} (**)$$

Further

$$e^{\theta(\alpha)} = e^{r\tau} \frac{N(-d_1)}{N(-d_2)}$$

$$\theta(\alpha) - r\tau = \ln \frac{N(-d_1)}{N(-d_2)}.$$

We can notice that due to the inequality $\frac{N(-d_1)}{N(-d_2)} < 1$ the solution's existence \tilde{K} is provided solely for $\theta(\alpha) - r\tau \leq 0$.

More, we obtain

$$\tilde{h} = C/P(\tilde{K})$$

which means that we obtained the coverage ratio of the optimal exertion of the option price which is the relative cost to the option's value.

Bond

This time we will proceed almost the same, but we will use bonds.

We consider that we have a moment $t=0$, a zero-coupon bond which we can sell it at T moment.

If the interest rate will increase, the overdraft portfolio can lead to losses, therefore we can decide to do a cover of maximum C level. This cover can be made by buying a put option that is based on a bond, so, in the case of a strong decrease of the bond price, the option put can cover major losses. It remains to establish the choice of exercise price, price that can be chosen after the minimizing of VaR at a cover price of C .

Suppose we have an available bond $P(0, S)$ with the main $N=1$ and maturity at time S and we will cover this bond with a percentage h ($0 < h < 1$) of a put option $BP(0, T, S, K)$ with the exercise price K at time $T \leq S$.

The bond price is given by

$$P(T, S) = A(T, S) e^{-B(T, S)r(T)},$$

where $r(T)$ is rate with the parameters independent of it, $A(T, S), B(T, S) > 0$.

We will consider, like usually done, the covered portfolio formed by P bond and BP option, and its value at T moment is

$$H_T = \max(hK + (1 - h)P(T, S), P(t, S)).$$

If the option ends the contract „in money”, worst case, the one that interests us, the portfolio value will be

$$H_T = hK + (1 - h)P(T, S).$$

We can express the value of the losses as

$$L = L(r(T)) = P(0, S) + C - ((1 - h)P(T, S) + hK) =$$

$$P(0, S) + C - ((1 - h)A(T, S)e^{-B(T, S)r(T)} + hK),$$

In case in which the option is “in money”

If we note

$$F_{r(T)}^{-1}(p) = \inf\{x \in \mathbb{R} | F_{r(T)} \geq p\}, p \in [0, 1],$$

where $F_{r(T)}$ is the cumulative distribution of $r(T)$.

With risk measure we can consider

$$VaR_{\alpha, T}(L) = \inf\{l \in \mathbb{R} | \Pr(L \geq l) \geq \alpha\} = \inf\{l \in \mathbb{R} | \Pr(L(r(T)) \geq l) \geq \alpha\}.$$

L function is an inverse function and strictly increasing, which leads us to

$$VaR_{\alpha, T}(L) = \inf\{l \in \mathbb{R} | \Pr(r(T) \geq L^{-1}(l)) \geq \alpha\}.$$

Considering dual equality we have

$$\begin{aligned} VaR_{\alpha,T}(L) &= \inf\{l \in \mathbb{R} | \Pr(r(t) \leq L^{-1}(l)) \geq 1 - \alpha\} = VaR_{\alpha,T}(L) \\ &= \inf\{l \in \mathbb{R} | F_{r(T)}(L^{-1}(l)) \geq 1 - \alpha\} = L\left(F_{r(T)}^{-1}(1 - \alpha)\right). \end{aligned}$$

From previous relations we may write

$$VaR_{\alpha,T}(L) = P(0, S) + C - ((1 - h)A(T, S)e^{-B(T,S)F_{r(T)}^{-1}(1-\alpha)} + hK).$$

Like the situation treated in the first part, we will state a minimum problem

$$\begin{aligned} \min_{h,K} VaR_{\alpha,T}(L) \\ C = hBP(0, T, S, K), h \in (0,1). \end{aligned}$$

Considering function

$$\mathcal{L}(K, h, \lambda) = VaR_{\alpha,T}(L) - \lambda(C - hBP(0, T, S, K))$$

and we put the Kuhn-Tucker conditions

$$\begin{aligned} \frac{\partial \mathcal{L}}{\partial K} &= -h + h\lambda \frac{\partial BP}{\partial K}(0, T, S, K) = 0 \\ \frac{\partial \mathcal{L}}{\partial h} &= -\left(K - A(T, S)e^{-B(T,S)F_{r(T)}^{-1}(1-\alpha)}\right)\lambda BP(0, T, S, K) = 0 \\ \frac{\partial \mathcal{L}}{\partial \lambda} &= C - hBP(0, T, S, K) = 0 \\ 0 &< h < 1, \lambda > 0. \end{aligned}$$

We deduce that

$$BP(0, T, S, K) - \left(K - A(T, S)e^{-B(T,S)F_{r(T)}^{-1}(1-\alpha)}\right)\frac{\partial BP}{\partial K}(0, T, S, K) = 0.$$

It's noticeable that the optimum exertion price K^* is independent from the coverage cost C , which means that VaR is a h linear function.

Conclusions

In the article's first part we obtained the coverage ratio of the optimal exercise price of options which is the relative cost at the option's value by an optimization problem of VaR in the situation of a portfolio consisting in a financial asset and a put option.

In the second part of this article we obtained the optimal exertion price of a put option in a portfolio in which is a bond and this option. And for this result it has been created a minimum problem of VaR and the obtained result leads to the idea that VaR linear depends of the h percent of the bond cover by options.

The importance of this research can be supported by ambitious goals that are attributed to performance measurement / assessment of a company such as: improving company performance, optimization of company's management and motivating staff. In the current context of sustainable development, the performance definition, measurement and maximizing system of companies becomes a complex one. The modern business environment demands a multi-goal orientation. Profit theory is no longer a valid measure of organizational performance and neither are other approaches that only take the interests of shareholders (owners) of a company into account. Today's business environment is characterized by the increasing importance and strength of various stakeholder groups. This paper captures the current mutations brought on the line of developing a modern system of assessment of company's performance.

Keywords: sustainable development, global performance, financial indicators, non-financial indicators.

Jel Classification: M10 , M14, M21

1.Introduction

In a world of competition, which has gained increased dynamism, as a result of environmental change and increased financial risk once with increased financial and economic turmoil and with the internationalization of trade regarding goods and money, achieving "**excellence**" in business is the way of survival and development for any business in a competitive economy.

One of the ways to achieve excellence, is performance, currently is increasingly talking about **overall (global) performance**. This new approach to performance is now known as sustainable development, which has three objectives: increasing economic and financial performance of the company, development of effective environment and encouraging social development. Thus we can say that overall performance is the sum of financial and economic, ecological (environmental) and social performance.

In the current conditions of globalization of world economy, a performing company is the "enterprise that creates added value for its shareholders, satisfies customers demand, takes account of employee opinion and protects the environment. Thus, ownership is satisfied that the company achieved the desired return, customers trust the company and the quality of future products and services, employees are proud of the company where they work and the society benefits through policy adopted by the company regarding environmental protection (Jianu, 2006).

Measuring performance has been and is a constant concern of management because it represents an essential criterion for companies' survival. Current economic circumstances justify the need for renewal and improvement of performance measurement techniques and tools and selecting appropriate indicators in the steps to maximize target performance.

2. Triple Bottom Line approach on company's overall performance. Literature review.

In the current context of sustainable development, the accent regarding the issue of maximizing overall performance of the entity is put on the fact that this should happen only in the conditions in which it maximizes (optimizes) in the same time the performances for all participants in economic life of a company (stakeholders) and not just those of shareholders. In this sense, the key to driving adoption of company policies should start from the approach "Triple Bottom Line" that is maintaining a balance between the three pillars, namely:

- *Maximize economic performances* meaning maximizing performance for shareholders. This goal can be achieved based on traditional accounting financial criteria, (based on income, profitability, cash flow) or criteria derived from the theory of value creation for shareholders (Economic Value Added, Market Value Added).

- *Maximize social performance* which requires maximizing performance for all participants in economic life (stakeholders) this means from employees to the community, from suppliers to customers and from investors and creditors to state, from managers and corporate governance and maintaining the center attention of the shareholders.

- *Maximize environmental performance* which implies an activity that does not affect the surrounding community and environment, thus developing the best environmental performance in relation to the environment

Triple Bottom Line (TBL) concept developed by John Elkington in 1997, advocates the idea that a company's overall performance should be measured by its contribution to triple economic prosperity, environmental quality and social capital. Subsequently, this idea began to be widely supported by a large mass of writers, recalling only a few outstanding authors: Philip Kotler and Nancy Lee (2005), David Vogel (2005), William B. Werther, Jr. and David Chandler (2006), William C. Frederick (2006).

In Romania, there were also concerns in the direction of approaching performance from a global perspective, especially in the context of national economic approaches on the line of EU integration. We recall in this regard concerns of authors such as Niculescu M. (2003), Stancu A. & Orzan M. (2006), Ciobanu (2004, 2005, 2006), Mironiuc M. (2009), Tabara et al (2007), Siminica M. (2008).

In the current context of sustainable development, financial performance is not sufficient to assess the activity of an enterprise. This notion was extended to take into account social responsibility and societal responsibility of the company towards stakeholders, which includes environmental issues.

The concern regarding the modalities of adopting social responsibility at the company's level in the current context of sustainable development, raised concerns about their reporting in various forms, among with financial and accounting reporting. The most advanced initiative towards a credible reporting system of sustainable development is the Global Reporting Initiative (GRI). This report should provide sufficiently detailed and balanced representation of sustainability performance of organizations, including the impacts both positive and negative ones generated by it. Performance indicators developed by the GRI are divided into: *Economic performance indicators, Environmental performance indicator and Social performance indicators.*

3. Selecting performance indicators representative for the company's global performance

In literature, there is very differentiated approaches in terms of choosing the most representative indicators of overall company's performance. Meyer (2002) identified a total of 117 top-level measures that include 17 financial measures, 17 measures related to customer, 19 internal

processes related measures, 35 measures on renewal and development and 26 measures related to human resources. This supports the allegations according to which " we measure everything that walks and moves, but nothing that matters" (Neely, Austin, 2002).

3.1 Selecting performance indicators representative for the company's economical performance

Making references to economic performance, the synthetic forms of representation of a company's economic performance is around traditional concepts of profit and profitability and the modern approach, yet extremely artificial, the increase of the value of a company. Regarding synthetic performance reflected by increasing the value of a company representative indicators for the increase of the value are addressed differently in the literature as follows:

- Halpern P, Weston F & Brigham E. (1998) refers to a company's growth measured by growth rates that are designed to indicate the firm's ability to maintain its market share when the economy and industry are in a period of expansion. Most representative indicators that reflect a company's growth would be, in the authors' view the following: turnover, net profit, earnings per share and dividend yield.
 - Greuning H.V (2005: 27), making some interpretation about International Financial reporting Standards (IFRS), considers that the increase of a firm would be given by "the rate at which an entity can achieve growth, as it is determined by the retain (undistributed) of the profit and by the profitability measure with the help of return on equity (ROE)."
 - Colasse B (2009:54) defines the state of "company's growth" as "the company's capability to increase its size; it can be measured by using several criteria such as: turnover, production, value added, fixed assets, total assets'.
 - Cabinet consultancy Stern Stewart (1991) proposed as indicators able to measure de performance of a company *the economic value added (EVA)* to which they added *the market value added (MVA)*, *the Future Growth Value (FGV)* and *the Current Operations Value (COV)* (<http://www.sternstewart.com>).
 - Boston Consulting Group and HOLT Value Associates from Chicago have promoted *Total Shareholder Return (TSR)*, *Cash Flow Return on Investment (CFROI)*.
 - Applied Finance Group (AFG) have promoted the *Economic Margin (EM)* as a representative indicator for measuring the value of an entity that comes to correct distortions created by the traditional financial analysis based on accounting documents. The Economic Margin Framework is more than just a performance metric, as it encompasses a valuation system that explicitly addresses the four main value drivers of enterprise value: profitability, competition, growth, and cost of capital. Unlike traditional valuation approaches that utilize highly sensitive perpetuity assumptions, AFG's approach incorporates company specific competitive advantage periods which identify companies that may lose excess returns over time faster than their competitors.
- Based on the literature review presented above, we conclude that if we use only the classic indicators (of **profitability and return**), we can find companies which gain performances but do not create value, instead they consume an existing one. Therefore, to gain profit and, going further, to work efficiently (the increase of the effects to overcome the increase of the efforts involved), is not sufficient to lead the company to maximize their global performance. In addition, it is necessary for society to succeed in creating the new value (value added). The modern main indicators that reflect the value creation for shareholders, separated on the basis of literature covered, would be: ***Economic Value Added –EVA, Market Value added –MVA, Cash Value Added- CVA, Total Shareholders Return- TSR, Cash Flow Return on Investment – CFROI***. These indicators complement successfully indicators such as **profit (net profit, Earning per share-EPS), Profitability (ROE, ROA, ROI)** and **cash flow** in making synthetic images of company's economic performance.

3.2. Selecting performance indicators representative to reflect performance involved by corporate social responsibility adoption: social and environmental performance

There are many important non-financial aspects of performance regarding the social responsibility corporate. Identifying and analyzing non-financial performance indicators may have as object: monitoring firm performance, purchase / sale of business (business), make reports to shareholders, guiding the allocation of resources to invest, identified intangible assets held by company that impact on its performance, interest managers in the value they create for shareholders. As a result, the selection of non-financial indicators, most often, it takes into account the perspective from which business performance analysis is made. For example, for making reports to shareholders generally are elected those indicators identified as relevant to capital market investors, while the selection of non-financial indicators for assessing managers' bonuses consider the strategy adopted by the company.

Given the large number of studies on this subject we consider appropriate, to present proposed indicators for reporting on global performance by the Global Reporting Initiative (GRI) in the context of sustainable development of an organization.

A. In what follows we will focus on the **social performance indicators**. According to GRI, these social performances indicators could be:

- performance indicators on **practices and working conditions**: the appearance of employment, occupational health and safety issue, issue education and training;
- **human rights performance** indicators: nondiscrimination appearance, freedom of association issue, the issue of child labor, rights of indigenous peoples;
- indicators of **performance on society**: corporate issue, political contributions issue, conformity aspect;
- performance indicators on **product responsibility**: consumer health and safety issue, the issue relating to labeling, marketing communication aspect, conformity aspect (Mironiuc, 2008).

B. Regarding the **environmental performance indicators**, GRI select the following indicators:

- **raw material** aspect: the raw materials used per unit of product, amount of weight in the total amount of recyclable materials;
- **energy** aspect: direct and indirect energy consumption, on primary energy sources, energy savings achieved by preserving and increasing its efficiency, products and initiatives to achieve low energy services, initiatives to reduce indirect energy consumption;
- **water** issue: total consumption of water by sources, significant water sources, the percentage of reused and recycled water;
- aspect of **biodiversity**: area of owned, leased or managed land in protected areas, describing the major impacts of activities, products, services on protected areas, protected habitats, strategies for managing protected areas, the number of protected species that have habitat in protected areas of the organization;
- aspect regarding **emissions**, waste: direct and indirect total emissions of greenhouse gas per unit of product, initiatives to reduce emissions of greenhouse gas and the results achieved, emissions of harmful substances per unit of product, nitrogen dioxide, sulfur and other air emissions per unit of product, wastewater and reuse methods (recycling), ratio of hazardous waste to be imported, exported, transported, treated, fauna, flora and aquatic habitats significant destroyed by sewage and emissions from the organization;
- **appearance of products and services**: initiatives to mitigate environmental impacts exerted by products / services of the company, the ratio of products sold and the amount of packaging / materials recycled and reused, by category;
- **compliance** aspect: value of significant fines and the number of non-monetary sanctions for failure regarding environmental regulations;

– **transport** issue: a significant environmental impact caused by transportation of goods / materials used in each activity of the company and every movement of personnel;
 –**general appearance**: Environmental expenditure and investments, by type.
 Many important non-financial aspects of performance can't be measured. So, they remain outside the formal performance measurement. Contrary to financial performance measures, non-financial performance measures are less appropriate for decomposition, which results in the fact that they are unique to specific business units, whereas financial ones are common to many units.

4. Current mutations in the importance of indicators that comprise the overall company's performance

The value of non-financial metrics becomes more important than just a few years ago. A number of studies realized over the years by consulting firm Ernst & Young (Ittner, 1998) revealed that indicators measuring customer satisfaction is of increasing importance in corporate strategic planning. In 1988, 54% of businesses considered highly value these indicators, their share reaching 80% in 1991.

Another study conducted by Mavrinac for the same consulting company Ernst & Young - Center for Business Innovation, shows that only one third of investors and financial analysts propose mandatory publication, widely reported by companies, of non- financial information. In the same study was carried out and a hierarchy of key financial and non-financial indicators underlying investment decision making (see Table 1).

Table 1. Hierarchy of performance indicators

Financial analysts	Rank	Portfolio managers
Profit	1	Market growth
Cash-flow	2	Profit
Market growth	3	Cash-flow
Average performance of the segment (sector)	4	Company's ability to develop new products and services
Market share	5	Costs
Investments	6	Market share
Cost	7	Investments
Investment in research & development	8	Average performance of the segment (sector)
Strategy success	9	Investment in research & development
Company's ability to develop new products and services	10	Productivity of R & D expenditure

Source: Mavrinac S, Siesfeld G. A, 1999

Highest importance that portfolios managers attach of non-financial information may be the result of their concern to capture real-time changes taking place in different sectors, meaning the companies that operate within them. Unlike financial information reflects past performance of the business, non-financial information may be indicative of current and future profitability of the company.

More companies are including non-financial data in their annual reports or their shareholder briefings, and compensation structures continue to involve non-financial targets. According to another study conducted by *Business Systems News & Analysis* for Finance and IT (FSN) in 2007, more than a third of the respondents (37 percent) say that a company's performance is determined more by intangible assets and capabilities than by hard assets. As companies gain experience with non-financial metrics, they discover a wide range of predictive, forward-looking managerial tools. Fifty-four percent say forward-looking information is of greater value to management and the board than historical information. Customer satisfaction, innovation and

employee commitment are identified as key drivers of performance among the companies Deloitte interviewed.

If the case of Romanian companies, the study realized by Ciobanu (2006) on a sample of 60 companies from different industries showed that 62.7% of managers used in the same extent non-financial indicators and financial ones for business performance measurement, giving them 13.6% of non-financial indicators even greater importance.

5. Conclusions

One cannot evaluate organizational performances without taking organizational goals into consideration. The modern business environment demands a multi-goal orientation. Profit theory is no longer a valid measure of organizational performance and neither are other approaches that only take the interests of shareholders (owners) of a company into account. Today's business environment is characterized by the increasing importance and strength of various stakeholder groups. Recognition of the optimum combination of financial and non-financial indicators which best measure performance, or is capable of explaining or predicting future levels of performance remains an area of current concern.

FISCAL SETTLEMENTS OF INCOMES OBTAINED FROM ABROAD BY NATURAL PERSONS RESIDENT IN ROMANIA

Antonescu Mihail

“Spiru Haret” University

Faculty of Financial and Accounting Management Craiova

Buziernescu Radu

University of Craiova

Faculty of Economy and Business Administration

The resident natural persons and those who qualify for residency conditions are subject to taxation in Romania for the incomes from any source, both from Romania and from abroad. External fiscal credit can be granted in order to avoid double taxation, so that the person can be entitled to deduct from the tax on income due in Romania the tax of income paid abroad, without exceeding the share of the income tax payable in Romania related to the income from abroad. The procedure of granting external fiscal credit vary depending on different categories of income.

Keywords: resident, external fiscal credit, tax, resident natural persons, foreign states.

JEL codes: F53, H24, K34.

The income obtained from abroad by natural persons resident in Romania are taxed under the national legislation, corroborated with the provisions of conventions for avoidance of double taxation concluded between Romania and other countries. The conventions for avoidance of double taxation determine which state has the right to tax incomes of natural persons, respectively the residence state or income source state.

In order to benefit from the provisions of conventions for avoidance of double taxation the Romanian natural persons will obtain from the Romanian fiscal authority the certificate of fiscal residence (according to OMF no. 1798/1998 for approval of forms regarding the application of conventions for avoidance of double taxation and determining the powers of signing this form) which he will present to the fiscal authorities from the income source country. The certificate of fiscal residence can also be obtained by natural persons who qualify for residency conditions for three consecutive years, starting from the fourth fiscal year.

The tax on incomes obtained from abroad is owed by:

- resident natural Romanian persons that are domiciled in Romania;
- natural persons that fulfill the criteria for residence for 3 years in a row become subject on income tax starting the fourth fiscal year.

Establishment of the residence in Romania for natural persons, according to Romanian legislation

In the Romanian legislation, the notion of resident involves every natural resident person and every Romanian legal person. According to the Fiscal code a resident natural person is “any individual who meets at least one of the following conditions⁷⁶⁷:

- a) the person has his or her domicile in Romania;
- b) the center of vital interests of the person is located in Romania;

⁷⁶⁷ Law no 571/2003 regarding the Fiscal Code, with the changes and ulterior completions, Official Monitor no 927/23.12.2003.

c) the person is present in Romania for a period or periods that exceed in total 183 days during any period of 12 consecutive months ending in the calendar year in question;

d) the person is a Romanian citizen who is serving abroad as an official or employee of Romania in a foreign state.

In order to prove that the natural person has its center of vital interests located abroad, it has to present the necessary documents to the tax office to prove that incomes obtained from abroad are higher than incomes obtained from Romania and that the tax authority of the relevant State is exercising its right to consider that person as its resident on globalized income taxation and in this case the person is subject to taxation in Romania only for incomes obtained in Romania

The following persons are exempt:

- a foreign citizen with diplomatic or consular status in Romania;

a foreign citizen who is an official or employee of an international and intergovernmental organization that is accredited in Romania;

- a foreign citizen who is an official or employee of a foreign state in Romania and members of the family of such foreign citizens.

The concept of resident through The Model Convention OCDE for avoidance of double taxation

According to the Model Convention OCDE the term of “resident of a Contracting Country” represents every person that, in accordance with the country legislation, he is obliged to pay taxes in that Country, for reasons of domicile, residence, management place and any other criteria of similar nature, but excluding the persons that are subject to taxes in that country only for the income obtained from sources in that Country or for the stock situated in that Country.

In the case where the person is resident of both the Contracting Countries, there were set up the following criteria of establishing the residence, applied in the following order:

1) the person will be considered a resident of the Country that has a permanent domicile, put on her disposal; if she holds a permanent apartment in both the Countries, she will be considered resident only in the Country where her personal and economical relations are tight (the centre of vital interests). For solutioning the possible conflicts that might appear between the laws of the two countries, the first criteria which will be taken into consideration is the holding of every form of set up domicile for permanent use of the person concerned, that means that it is not taken into account a domicile that is used occasionally, or for short period. If the person has a permanent domicile in both the Contracting Countries, it is required to analyze the situation in order to decide with which of the two Countries the person concerned has closer personal and economical relationships, that means that they will be taken into account others criteria: family, her social relations, occupations, her political activities, cultural or of any other type, her place of activity, the place where she administers her properties, etc.

2) If the Country where the individual has the centre of vital interests can't be determined, or if the person concerned does not hold a permanent domicile put on her disposal in neither of the states, it will be considered that she is a resident of the Country where she has the usual address;

3) If the person has the usual address in both Countries or in none of them, it will be considered that she is resident of the country where she has the usual address.

4) If the person has the nationality of both Countries or in none of them, the competent authorities of the Contracting Countries will solve this matter amicably.

So, if the first criterion cannot apply for establishing the residence, it is applied the second one, it is repeated this algorithm until the last criterion, respectively the amicable procedure stipulated in Article 25 from the Model Convention.

Tax on incomes obtained from abroad owed in Romania by natural persons

A natural person can be subject to income tax in Romania for both local and abroad incomes if the one of the following conditions is met for three year in a row:

- the center of vital interests of the person is located in Romania;
- the person is present in Romania for a period or periods that exceed in total 183 days during any period of 12 consecutive months ending in the calendar year in question;

Documents required for establishing the center of vital interests are: copies of income declarations from the foreign state, statement concerning the situation of school children, the statement of assets, where appropriate, for members of family and other documents.

In case the incomes from the foreign state are below requirements and therefore tax residence cannot be granted, the Romanian authorities find that conditions are met in order to tax the incomes in Romania and do so, by taxing the globalised income of that natural person. Romanian authorities and authorities from the foreign state will exchange information concerning the case.

Where income from other state are not conducive to the granting of tax residence in this state and Romanian tax authority considers that the conditions for taxation in Romania, the taxpayer will be required in Romania and worldwide revenue by information exchange, Romanian authorities and other State shall inform about this case.

Starting the 4th year of compliance of one of the above conditions, the natural person is to become a fiscal resident and therefore subject to taxation in Romania for all incomes. Tax authority will issue a fiscal residence certificate also in the 4th year.

Taxpayers that live abroad and keep their domicile in Romania are subject to taxation in Romania, according to Romanian legislation, for taxable incomes obtained both in Romania and from abroad. In case they cannot fulfill its obligation they can empower a natural person or designate fiscal representative

In order to tax incomes from abroad the taxation rate (16%) is applied to the basic income determined by specific rules for each category: independent activities, commerce activities, intellectual property rights, the grant of the use of goods, dividends, interests, prizes and gambling, transfer of securities, other investments and sources of incomes from abroad.

Losses from abroad are carried over and compensates incomes of the same category or nature of incomes obtained from abroad, for each foreign country for the next 5 fiscal years.

The taxpayers that obtained incomes from abroad have to fill in form 201 “Special Declaration regarding the incomes earned abroad” and submit it to the tax office by may 15th of the year following the year they obtained the income. The sources of incomes included in form 201 “Special Declaration regarding the incomes earned abroad” are: independent activities, commerce activities, intellectual property rights, the grant of the use of goods, dividends, interests, prizes and gambling, transfer of securities, other investments and sources of incomes from abroad.

The forms regarding the incomes earned abroad have to be submitted for each foreign state and for each source of income by may 15th of the year following the year the income was obtained.

For incomes earned abroad in 2010 the taxpayers have to submit the *tax statements* by may 25th of the year following the year the income was obtained and also they have to determine the tax amount⁷⁶⁸.

External fiscal credit

The method used in Romania to avoid double taxation as it is provided by the OECD model of the Convention for avoidance of double taxation, is the credit method, by granting external fiscal

⁷⁶⁸ The Emergency Government Ordinance no. 109/07.10.2009, for the amendment and supplementation of Law no. 571/2003 regarding the Fiscal Code, published in the Official Monitor no. 689/13.10.2009.

credit for incomes obtained from abroad, which are subject to taxation in both states. By this method the tax due in the foreign state is to be deducted from the tax paid in the state of residence, under certain conditions

Credit method in terms of the OECD model of the Convention for avoidance of double taxation

The credit method takes into account the so-called legal double taxation, that means the case where the same capital or the same income is taxable in several States. In the conventions for avoidance of double taxation there is a difference between the income tax and the capital tax, there are several ways of eliminating double taxation: exemption method (complete or gradual) and the credit method (full or ordinary). By the ordinary credit method it is given the deduction from the tax owned in the residence state of an amount equal to the tax paid in the source state, but without exceeding the income tax or the capital tax calculated before the deduction is given, which is attributable, depending on the case, to the income or capital which can be taxed in the source state.

Granting the external fiscal credit according to national legislation

Resident natural persons taxpayers, who, for the same income over the same taxable period and are subject to tax income both in Romania and abroad, are entitled to the deduction of income tax due in Romania of the tax paid abroad. The amount deducted from income tax in Romania is called external fiscal credit. Having at the basis the principle of ordinary credit the national legislation provides granting external fiscal credit at the level of the tax paid abroad in association with the income from foreign source, but not exceeding the income tax due in Romania, in association with taxable income from abroad. If the taxpayer in question receives incomes from abroad from several countries, external fiscal credit allowed to be deducted from tax payable in Romania will be calculated according to the above procedure for each country and each kind of income.

The external fiscal credit is granted for the following income categories:

- a) incomes from independent activities;
- b) incomes from wages;
- c) incomes from the grant of the use of goods;
- d) incomes from investments;
- e) incomes from pensions;
- f) incomes from agricultural activities;
- g) incomes from prizes and from gambling;
- h) incomes from transfer of real estates;
- i) incomes from other sources.

Granting the external fiscal credit is made for income types as those mentioned above, only if the tax paid abroad, for the income earned abroad, was actually paid directly by the natural person or his legal representative or by withholding at the source of the payer's income. To benefit from external fiscal credit, the tax paid abroad must be proved by a document in proof, issued by:

- tax authority of the foreign state in question;
- employer, in the case of income from wages;
- other income payer, for other income categories.

At the end of the tax year concerned, the taxpayer attaches to the tax declaration the documents in proof regarding the income and the tax paid, issued by the tax authorities in the country where the income was obtained, employer or other payer, documents used to calculate the fiscal credit.

The exchange in lei of the income obtained abroad and the associated tax expressed in foreign currency units proper to the State in question, are made at the annual average rate of exchange on the currency market, reported by the National Bank of Romania, from the year the income was

earned. If the currency of that country is not listed on the National Bank, the amounts will be transformed in the following way:

- a) from the currency of the source state in an international currency such as dollars or euros, using the exchange rate from the source country;
- b) from the international currency into lei, using the average annual exchange rate of this one, expressed by the National Bank of Romania, from the year the income in question was earned.

Granting external fiscal credit for incomes from independent activities, incomes from the grant of the use of goods and incomes from agricultural activities

Natural persons that have obtained incomes from abroad and paid tax on income in that foreign state are entitled to deduct from the tax on income due in Romania the tax on income paid abroad for each source of income. The tax paid abroad which is deducted from the tax on income owed in Romania is limited at that share of the tax owed in Romania

For the incomes which have been considered abroad as obtained from the entire world, the external fiscal credit for each of these incomes is limited to the tax on income computed by applying the taxation average quote from abroad to each source of income obtained abroad but not exceeding the taxation quote provided by national legislation related to the relevant income.

The taxation average quote is computed as follows:

tax paid abroad

Taxation average quote = -----

global income obtained from abroad

The global income obtained from abroad represents all the categories of incomes which, by law of the relevant State, shall be globalized abroad.

For the incomes obtained abroad not globalized in view of their taxation, the external fiscal credit is limited to the tax on income from abroad but not exceeding the tax on income due for a similar income in Romania.

In order to grant the deduction, the amount of the external fiscal credit is compared to the tax paid abroad, taking into account the smaller amount:

- if the amount of the external fiscal credit is greater than the tax paid abroad, the amount of this tax will be recognized as being deductible
- if the amount of the external fiscal credit is less than the tax paid abroad, the amount recognized as being deductible and representing the external fiscal credit will be computed according as above.

The external fiscal is computed by the fiscal body distinctly for each source of incomes. If the incomes from abroad of the taxpayer in question are obtained from several countries, the external fiscal credit allowed to be deducted from the tax due in Romania is to be computed according to the above procedure for each source of income and each country.

Starting 2010 calculation of the external fiscal credit according to the same rules.

Granting external fiscal credit for income from investments, incomes from pension, incomes from prizes and gambling, and incomes from transfer of real estates.

External fiscal credit for these categories of income is granted comparing the foreign tax rate paid abroad to that prescribed by internal legislation for each similar income in Romania, as following:

- a) if the foreign tax rate from abroad is higher than that provided in the internal legislation for a similar income, external fiscal credit is limited to income calculated tax by applying the rate provided in the national legislation;
- b) if the tax rate from abroad is lower than tax rate for a similar income in Romania, the external fiscal credit is calculated at the level of tax paid abroad, and the annual tax remaining to be paid in Romania is calculated as the difference between tax income (which will be calculated by

applying the tax rate prescribed by national legislation) and tax income paid abroad for income earned abroad.

Granting external fiscal credit for income from wages

Even though the national legislation states that in Romania will be taxed the income obtained from employment performed abroad and paid for it by the Romanian employer, they are taxed in Romania, however, for this category of income there was no proceeding for granting the foreign tax credit, the legislature stating only that income from wages which are not taxable in Romania, are not related to the foreign tax credit.

Legislation regarding this category of income has been improved, so that starting with income earned in 2010 the following legal provisions will be taken into consideration:

„If the same income from wages is taxable both in Romania and abroad, the foreign state having the right to tax under the Convention for the avoidance of double taxation concluded by Romania with that state for income earned during the period in which Romania has not the right to tax, the competent fiscal authority will reimburse the tax withheld by the Romanian employer, at the request of Romanian resident”⁷⁶⁹. It can be inferred from these provisions that the reimbursement of tax held in Romania is conditioned by the existence of a convention for avoidance of double taxation between Romania and the State in which the natural person worked.

Analyzing the conventions for avoidance of the double taxation concluded by Romania with various states, it results that income from employment activities performed in another state, which are paid by a Romanian employer and are not borne by a permanent head office that this one has in the foreign State, are taxable in the foreign State only if the natural person receiving the income is present in the foreign State for a period or periods exceeding on the whole 183 days in any 12 month period starting or ending in the calendar year in question.

Therefore, for tax refund in Romania it is taken into consideration only the situation when between Romania and the State where the person has developed his activity there is a convention for avoidance of the double taxation.

Conclusions

For taxation of income from abroad, it will first be determined whether the beneficiary of income is Romanian resident, according to the criteria for residence under national legislation, in conjunction with the provisions of conventions for avoidance of double taxation. After declaring this income, their taxation will be achieved, taking into consideration the granting of the foreign tax credit, taking into account the nature of income earned abroad and presenting the documents in proof on payment of the tax abroad. In Romania, avoidance of double taxation on income earned abroad by Romanian natural persons is done by ordinary credit method, method which is provided for both the conventions for avoidance of double taxation and in national tax legislation.

VAT TAXATION OF INTRA-COMMUNITY SUPPLIES AND ACQUISITIONS OF SERVICES

Antonescu Mihail

“Spiru Haret” University

Faculty of Financial and Accounting Management Craiova

Antonescu Ligia

University of Craiova

Faculty of Economy and Business Administration

As of January 1st, 2010, as a result of the transposition in the national legislation of the Council Directive 2008/8/CE of 12.02.2008 for the amendment of the Directive 2006/112/CE regarding the place of the supply of services, new notions of tax law have arisen, namely intra-community acquisitions of services and intra-community supply of services. The transposition in the national legislation⁷⁷⁰ of the new CE directives in the field of the VAT aims not only at the way the place of the supply of services is determined, but also at the changes regarding the person subject to taxation, tax registration, declarative obligations, etc.

Keywords: supply of services, acquisition of services, registration for VAT purposes, intra-community services, recapitulative statement.

JEL codes: H25, K34.

The place of the intra-community supply of services

One of the conditions required by law for the operations within the value added tax to be taxable in Romania is that *the place of supply of services should be deemed as being in Romania.*

As a general rule, the place of the supply of services towards a taxable person acting as such is the place where the person receiving the services has established the registered office for his/her business. If the services are supplied to a fixed headquarters of the taxable person, located in a place other than the one where the person has the headquarters of his/her business, the place for the supply of services is the place of that fixed headquarter of the person receiving the services.

In the case of the fixed headquarters wherefrom the services come, in order to qualify as fixed headquarters of a taxable person, the degree of permanence and its structure with respect to the technical and human resources must be sufficient to provide taxable services on a regular basis. In the case of the fixed headquarter receiving the services, in order for it to be qualified as a fixed headquarter of a taxable person, it must meet the same conditions.

A taxable person having the headquarters of his/her business outside Romania, *but settled in Romania* by fixed office/office, the place for the service supply will be deemed the place where the beneficiary has established his/her business headquarters, or , as the case may be, a fixed headquarters situated in another state, if the beneficiary can submit enough proofs to the service provider that these services have been provided to the headquarters of his/her business, or to a fixed headquarters established in another state, and not to the fixed office/offices in Romania;

A taxable person having the headquarters of his/her business in Romania, *but has established fixed office/offices outside Romania*, it shall be deemed that the place for the supply of services is the fixed headquarters whereto the services are provided, if the beneficiary can present enough evidence to the provider in order to prove that these services have not been provided to the headquarters of his/her business in Romania, but to the fixed office/office outside Romania.

⁷⁷⁰ Emergency Government Ordinance no. 109/07.10.2009, for the amendment and supplementation of Law no. 571/2003 regarding the Fiscal Code, published in the Official Gazette no. 689/13.10.2009.

In case of the services provided by a taxable person not settled in Romania to a taxable person having his/her registered office in Romania, it shall be deemed that the place of the supply is not in Romania, if the beneficiary can prove that the service is provided to a fixed office located outside Romania.

The services for which the general rule for the establishment of the supply is applied, which are supplied by the providers settled in Romania to beneficiaries who are taxable persons settled on the territory of the Community, are called *intra-community service providers*.

The services received by a taxable person settled in Romania from a provider, a taxable person settled in the community but not in Romania, are called *intra-community acquisitions of services*. The general rule for the establishment of the place of supply is not applied for the following services:

- the services carried out with respect to the real assets, including the services provided by real estate agents and experts, of accommodation in the hotel sector or in sectors with similar function, as well as holiday camps or camping places, for the granting of user's right of real estate, for services of preparation and coordination of the construction works, as well as services provided by architects and companies supplying construction site supervision;
- services of passenger transport;
- services regarding cultural, artistic, sports, scientific, educational, entertainment or similar activities, such as fares and exhibitions, including the services provided by the organisers of these activities;
- restaurant and catering services, except for those actually provided onboard ships, aircrafts or trains during a part of a passenger transport operation carried out within the Community;
- short-term leasing services of a means of transport.

A taxable person also carrying out activities or operations that are not considered taxable according to the legal provisions is considered a taxable person for all the services received.

Moreover, a non-taxable legal person registered only for VAT purposes or registered for VAT purposes for intra-community acquisitions of goods or services, is considered to be a taxable person for all the services received.

The person bound to pay the value added tax is the taxable person providing services, except for the cases where the beneficiary is bound to pay the tax.

The tax is owed by any taxable person, including by the non-taxable legal person registered for VAT purposes, which is a beneficiary of the taxable services purchased within the community. The tax is owed including if the beneficiary, taxable person settled in Romania, has not honoured his/her obligation or being registered for VAT purposes.

The registration of the taxable persons for VAT purposes

The taxable person having the headquarters of his/her business outside Romania, but settled in Romania by a fixed office, is bound to request the registration for VAT purposes in Romania, as follows:

- before the reception of the services, if he/she is going to receive, for the fixed office in Romania, services provided by a taxable person settled in another Member State (*intra-community acquisition of services*), the latter being bound to pay a tax in Romania;
- before the supply of the services, if he/she is going to provide the services from the fixed office in Romania for a beneficiary taxable person settled in another Member State (*intra-community supply of services*), bound to pay the tax in the other Member State;

The taxable person having the headquarters of his/her business outside Romania and settled in Romania by several fixed offices without legal personality will be identified by a single registration code for tax purposes. To this end, the taxable person will appoint one of the fixed offices on the Romanian territory that would submit the tax deduction and be liable for all the VAT obligations of all the fixed offices settled in Romania.

The taxable person having the headquarters of his/her business in Romania, not registered and not having the obligation of registration for VAT purposes and not already registered for intra-community acquisitions of goods or for intra-community acquisitions of services, is bound to be registered for VAT purposes if he/she provided services with the place in another Member State (*intra-community supply of services*), before the supply of the service.

The taxable person having the headquarters of his/her business settled in Romania, not registered or having the obligation of being normally registered for VAT purposes, not already registered for intra-community acquisitions of goods or for intra-community supply of services, is bound to be registered for VAT purposes if receiving services with the place in Romania (*intra-community acquisition of services*), before the reception of those services, because this person is bound to pay the tax in Romania.

The registration will be deemed valid as of the registration application.

The persons registered according to the above cannot communicate this code for the deliveries of goods or supply of services carried out to other people, as it is communicated to other people only for intra-community supply of services and for intra-community acquisitions of services.

The public institutions that are normally registered for VAT purposes, for their entire activity or only for part of the structure, will not apply for the registration for VAT purposes for intra-community acquisitions of services or for intra-community supply of services. They will communicate the normal registration code for VAT purposes, whether the acquisitions are meant to be used for the activity carried out in the capacity of public authority, for which the public institution does not have the capacity of taxable person, or for activities for which the public institution has the capacity of taxable person.

Any public institution not normally registered for VAT purposes, but which has been given a registration code for VAT purposes for intra-community acquisitions and supply of services will be deemed a taxable person only with respect to the establishment of the place for the service supply.

The fiscal period and the declarative obligations

The taxable persons using the calendar trimester as fiscal period are not bound to use the month as fiscal period if they carry out intra-community acquisitions of services.

The persons normally registered for VAT purposes must submit to the authorised fiscal agencies, for each fiscal period, a tax deduction, until the 25th, inclusive of the next month of the one in which that fiscal period ends.

The operations regarding the intra-community supply and acquisitions of services are distinctly emphasized in the tax deduction, the intra-community acquisitions of services being emphasized both as deductible tax and as collected tax.

The taxable persons who are not registered and who need not be normally registered for VAT purposes, whether or not they are registered for intra-community acquisitions of goods and services, as well as the non-taxable legal person registered for VAT purposes for intra-community acquisitions of goods or for services, which are the beneficiaries of the services having the place of supply in Romania and which are supplied by taxable persons without residence on the territory of Romania, but settled within the Community, submit the special tax deduction for intra-community acquisitions of services until the 25th of the next month after the one in which the exigibility of the operations arises.

Any taxable person normally registered for VAT purposes or only for intra-community acquisitions of goods or for services must draw up and submit with the authorised fiscal agencies, until the 15th, inclusively, of the next month of a calendar month, a recapitulative statement which should mention:

- the supply of services carried out to the benefit of taxable persons not settled in Romania, but settled in the Community, others than those exempt of VAT in the Member State where they are

taxable, for which the tax exigibility has arisen in that calendar month;

-acquisitions of services carried by taxable persons in Romania who have the obligation of paying the tax, for whom the tax exigibility arose in that month, from taxable persons not settled in Romania, but settled in the Community.

In the case of the supply of services carried out to the benefit of taxable persons not settled in Romania, but settled in the Community, the provider will report in the recapitulative statement only the services that do not get tax exemption in the Member State where they are taxable. To this end, the operation will be deemed tax-exempt in the Member State where it is taxable if that operation were tax exempt in Romania. If in Romania the tax exemption is not applicable, the provider is exonerated of the obligation of declaring that service in the recapitulative statement if he/she receives an official confirmation from the fiscal authority of the Member State where the operation is taxable, wherefrom it should result that in that Member State a tax exemption is applied.

The beneficiaries of the taxable persons in Romania have the obligation of declaring in the recapitulative statement the intra-community acquisitions of services, provided by the taxable persons not settled in Romania, but settled in the Community, when they have the obligation of paying the tax for those services, respectively when no tax exemption is applied for that service.

Conclusions

The new regulations of the Fiscal Code and the methodological rules issued for its application, especially those regarding the intra-community services have imposed the issue of new orders from the President of the National Agency of Fiscal Administration that would harmonize their contents with the new regulations. We hope that all these changes, along with the change of the declaration periods, especially the monthly submission of the recapitulative statement will contribute to the increase of the efficiency in the administration of the value added tax and, implicitly, to the increase in the fiscal output of this tax.

CONSIDERATIONS REGARDING TO THE LAW OF FISCAL-BUDGETARY RESPONSIBILITY

Ardeleanu-Popa Carmen
University of Oradea
Faculty of Law
Private Law Department

Cîrmaciu Diana
University of Oradea
Faculty of Law
Public Law Department

A law of fiscal-budgetary responsibility which is firmly based and structured can outline the general parameters which can constitute the basis of creation of some decisions in sustainable fiscal politics through stipulating fiscal principles, rules concerning with budgetary incomes, public debts, deficits, expenses and risk management.

Keywords: objectives, principles, legal definitions, fiscal council

Code JEL: K34

Fiscal responsibility is essential to creating a better, stronger, more prosperous nation for the next generation. The choices we make today will determine our children's future.

It is known the fact that the main goal of the fiscal politics is concerned with reaching credibility and stability of the public finances, though this cannot be reached only through the followings:

- continuation of fiscal consolidation in the direction to accomplish the target deficit of 3% from the gross domestic product (GDP) to structural measures which assure sustainability for a medium⁷⁷¹;
- promotion of an anti-cyclical fiscal politics which can offer sustainability for the process of economic increase;

⁷⁷¹ We must take into consideration the fact that the Economic and Financial Affairs Council (ECOFIN) edited recommendations for Romania regarding to the measures which will be taken to correct the excessive public deficit, reevaluating in the same time the established calendar to reduce it under 3% from the gross domestic product (GDP), which is the reference value established by the EU Treaty. Practically the Economic and Financial Affairs Council (ECOFIN) extended the correction period of the deficit, taking into consideration the damage in the economy of the country, more sever than the level which was foreseen, beginning with July 2009, when it was initialized the procedure of excessive deficit, and the Council edited their initial recommendations.

The Council urged Romania to reduce its deficit to 3% from the gross domestic product until year 2012 instead of 2011, presenting a strategy to reduce the deficit and establishing the date of 16 August 2010 as limit term to apply these corrective measures.

The excessive deficit procedure is governed by the Article 126 of the Treaty and the Council Regulation regarding the acceleration and clarification of the excessive deficit procedure implementation. The excessive deficit procedure sets down the criteria and the deadlines for the European Council (ECOFIN) to adopt a decision regarding the existence of an excessive deficit. The excessive deficit Procedure is initiated when the actual or forecasted deficit exceeds the 3% of GDP ceiling, except the situation when the deviation is of an exceptional and temporary nature outside of the control area of the respective member state and has a major impact on the fiscal position, or due to a major contraction of the economic activity – <http://discutii.mfinante.ro/statistic - 26.04.2010> /15.00

-efficiency of control and increase of the responsibility of the units which are outside the central administration (local authorities, auto-financing institutions and companies of the state) even to reduce the arrears of the state;

-reform of fiscal administration;

-increase of the efficiency of the fiscal-budgetary politics and the improvement of its predictability taking into consideration the fact that stability and predictability of the fiscal-budgetary system represents directive principles for a viable economy.

The institution of the frame-politics which assure sustainability⁷⁷² and fiscal predictability for long term presumes the promotion and the adoption of the Law of fiscal responsibility, taking into consideration the fact that the fiscal-budgetary politics promoted in the last years had demonstrated the evident fragility of the institutional frame and the lack of some adequate rules which could diminish the discretionary fiscal space.

The Law of fiscal responsibility outlines the principles by which the fiscal-budgetary politics will be guided to respect the long-term objectives of the European Union and the standards which must be fulfilled to create an added value for stability and economical increase.

The necessity of adopting the Law of fiscal responsibility⁷⁷³ is related to the requested conditions for closing the loan adjustment with the International Monetary Fund⁷⁷⁴, but it is an important moment for Romania because through this normative document are established some „normal things” which were not respected, becoming exceptions.

At the other hand even the harmonization of the fiscal-budgetary politics of the member states of the European Union urges the implementation, with continual and permanent character, of a severe and unconditional fiscal-budgetary discipline, realized practically through the adoption of this law. The Law of fiscal-budgetary responsibility aims to assure predictability in spending the public money.

At the same time Law no. 69/2010 has as regulation object the establishment of a legal frame which allows to assure and maintain a strict, clearly defined financial-budgetary discipline, which being respected offers the opportunity that the public finances could be efficiently managed.

The legal foresights created this way are applicable⁷⁷⁵ for authorities, institutions and public entities foreseen by *art. 2 point 30 of Law no. 500/2002* regarding to public finances (like The Parliament, the Presidential Administration, the Ministries, the other organs of specialty in public administration, other public authorities, the autonomous public institutions, like the institutions coordinated by these and financed either integrally by the budget of state, by the social insurance

⁷⁷² For realizing the sustainability of public finances through fiscal sustainability it must be applied some measures which imply the reduction of expenses, without influencing the vulnerable groups, avoidance of the increase of taxes (which would have a negative impact upon the employment of the labor and upon investments).

⁷⁷³ Law no. 69 from 16 April 2010 of fiscal budgetary responsibility, published in the Official Monitor of Romania No. 252 from 20 April 2010.

⁷⁷⁴ Together with the Law of unique salary of the budgetary personal (respectively Law no. 330 from 5 November 2009 regarding to the unitary salary of the employees paid from public funds, published in the Official Monitor of Romania no. 762 from 9 November 2009) and Law of the reform of the system of pensions.

⁷⁷⁵ Art. 2 of Law no. 69/2010.

budget of the state, by budget of special funds; or by own income and subventions offered by the budget of state, the budget of social insurance of the state, the budget of special funds; or integrally by own incomes) respectively by *art. 2 point 39 of Law no. 273/2006* regarding to local public finances (the general name of local public institutions, including villages, cities, towns, the sectors of Bucharest, districts, the city of Bucharest, institutions and public services under the control of these, with judicial person, financed either integrally by the local budget, or by own incomes) *like to other entities* finances in proportion of over 50% by public funds, established according to European norms.

For the exact conceptual clarification of some notions the legislator tried to define some notions like fiscal-budgetary strategy, the general consolidated budget⁷⁷⁶, primary expenses of the general consolidated budget, economic cycle, expenses with employees etc.

The legal principles of the fiscal-budgetary politics are the following:

-the principle of transparence regarding to the establishment of fiscal-budgetary objectives and the application of the fiscal and budgetary politics, the Government and the authorities being obliged to publish and maintain in debate for a reasonable period of time all the necessary information which allow to evaluate the implementation method of the fiscal and budgetary politics, the results of these and the situation of the central public finances and that of the local one;

-the principle of stability;

-the principle of fiscal responsibility;

-the principle of equity;

-the principle of efficiency⁷⁷⁷;

-the principle of the efficient management of the employment expenses paid by public funds.

In the content of art. 5 of Law no. 69/2010 there are also treated the objectives of the fiscal-budgetary politics, respectively:

-to maintain the public depts. At a sustainable level for a medium or long-term⁷⁷⁸;

-realizing of a sold of budget generally consolidated near to zero for the period of economic cycle, in the same time with assuring the competitiveness of the country;

-the prudent management of the resources and of the entered obligations of the public sector and of the fiscal-budgetary risks;

⁷⁷⁶ We must mention that in form of project, the Law of fiscal-budgetary responsibility defined at art. 3 point 2 the notion of general consolidated budget as being „the ensemble of the component budgets of the aggregated and consolidated budgetary system to create an unitary thing: the budget of state, the budget of social insurance of state, the budgets of special funds , **local budgets...**” but the Commission for budget, finances and banks of the Parliament of Romania considered opportune to substitute the notion of local budgets with the notion of central budget of the administrative-territorial units, and invoked as reason in this sense the necessity for clearer definitions in the sphere of the general consolidated budget and the possibility to review these in conformity with the European norms and with the evolutions in the administration of the public funds.

⁷⁷⁷To include all the non-repayable funds offered for Romania, including the communitarian and other programs, whose donors of non-repayable funds are not member of the European Union, the Commission for budget, finances and banks of the Parliament of Romania had changed the definition of the content of *the principle of efficiency*, replacing paragraph „financed by funds offered by the European Union” with the text „financed by **non-repayable** funds offered by the European Union or by other **donators**”

⁷⁷⁸ The establishment of a medium/long term for the maintenance of the public dept at a sustainable level must be done because a strategy must foresee a longer period.

-maintaining and adequate level of the budgetary resources for the payment of service of public dept;

-assuring the predictability of the quota and of the basis of taxation level.

The efficiency and the positive evolution of the fiscal-budgetary politics will be assured also by respecting some established fiscal rules in the matter of the sold of the general consolidated budget, the total expenses of the general consolidated budget (including the annual rate of growth of these) etc.

In the matter of employment costs, the Government, the credit accountants and any authority with attributions of elaborating politics and payment agreements from the public sector must assure itself that all these politics are in concordance with the principles of fiscal responsibility, with fiscal rules, as with the objectives and limits of the fiscal-budgetary strategy.

Also trough Law no. 69/2010 are promoted essential rules in the matter of budgetary rectifications and to solve the problem of the excessive expenses and that of the overrating of incomes, there must be elaborated and implemented a credible *fiscal-budgetary strategy* for 3 years, which must include macroeconomic⁷⁷⁹ frame, fiscal-budgetary frame, a frame of expenses for a medium term and a declaration of responsibility⁷⁸⁰.

The fiscal-budgetary strategy must be a key document of politics which must offer information and objectives allowing a better process of taking decision in the annual budgetary process even for a medium period, which can be elaborated by the Government and approved by the Parliament. Compliance towards the fiscal strategy will be followed through reports of semester and annual progress which must deliver the feed-back for the Government upon any adjustment which could be proven to be necessary to respect the aims and the limits. The reports and controls done by the Ministry of Public Finances and by the Government contributes to the promotion and increasing of the transparence of the fiscal-budgetary politics (in this sense we can mention as example: the obligation of the Ministry of Public Finances to publish a semester report referring to the economic and budgetary situation, a report about the final budgetary execution, the obligation of the Government to publish a report about the economic and budgetary situation at the end of their mandate etc).

The law foresees also the creation of a Fiscal Council compound by 5 members⁷⁸¹ nominated by the decision of the Parliament at the proposal of the National Bank of Romania, the Romanian

⁷⁷⁹ According to law (art. 19 of Law no. 69/2010) the macroeconomic frame contains information about:

-situation of macro economy and prognoses: for the actual budgetary year and for 3 ulterior years, the concrete results of the last 2 budgetary years, referring to: the gross domestic product and its components; indicators of consume prices and deflation of the gross domestic product; unemployment and labor; the position of current account of the balance of payments; premises which create the basis of the prognoses; a declaration regarding to the concordance or differences towards the prognoses of the European Commission;

-macroeconomic prognoses for a medium term which influence fiscal politics.

⁷⁸⁰ The responsibility declaration will contain a declaration signed by the Prime Minister and by the Minister of Public Finances, where it is certified the correctness and integrity of information about the fiscal-budgetary strategy and its conformity with the law, the aims and limits of the fiscal rules and the respect of the principles of fiscal responsibility.

⁷⁸¹ Their mandate lasts 9 years, and they cannot be elected once again at the end of this period. The conditions which must be fulfilled to become a member of the Fiscal Council are the following:

-the person must have clean judicial and fiscal criminal report;

-the person must have Romanian citizenship and right to vote;

-the person must be graduate of university studies in economic domain;

-the person must have good reputation and professional experience in the domain of economic, budgetary or financial politics;

-minimum 10 year professional experience.

The membership of the Fiscal Council is over in the following situations:

Academy, the Academy of Economic Studies, the Romanian Bank Institute and the Romanian Association of Banks, which must assure their support to assure the quality of the macroeconomic and budgetary prognosis and the fact that the budgetary politics are in accordance with the principles of fiscal responsibility.

The sanctions introduced in case of breaking some foresights of Law no. 69/2010 are represented by contravention amendments, but by art. 52 it is shown that „the breaking of the legal foresights by the members of the Government implied the joint political responsibility of the other members of Government, according to the foresights of the Romanian Constitution, republished and to Law no. 115/1999 regarding to the ministerial responsibility, republished with the ulterior modifications”⁷⁸².

In conclusion, we show that reaching some smaller budgetary deficits assumes the considerable modification of the budgetary process, and also reforms of the income and expenses politics, and the essential component of the medium-term strategy is represented by the law of fiscal-budgetary responsibility which:

- established better elaboration procedures of the multi-annual budgets;
- establishes limits regarding to the budgetary rectifications done during the year;
- foresees fiscal rules regarding to total expenses, employment expenses and budgetary deficit;
- creates a Fiscal Council which assures an independent and professional analysis of the macroeconomic and budgetary prognosis;
- creates an emission and management frame of the guarantees and obligations.

Financial rates, financial position, strategy, financial structure

Cod JEL: G32

1. Background Information

Finance is the application of economic principles and concepts to business decision-making and problem solving. The field of finance can be considered to comprise three broad categories: financial management, investments, and financial institutions.

(i) *Financial management.* Sometimes called corporate finance or business finance, this area of finance is concerned primarily with financial decision-making within a business entity. Financial management decisions include maintaining cash balances, extending credit, acquiring other firms, borrowing from banks, and issuing stocks and bonds.

(ii) *Investments.* This area of finance focuses on the behavior of financial markets and the pricing of securities. An investment manager's tasks, for example, may include valuing common stocks, selecting securities for a pension fund, or measuring a portfolio's performance.

(iii) *Financial institutions.* This area of finance deals with banks and other firms that specialize in bringing the suppliers of funds together with the users of funds. For example, a manager of a bank may make decisions regarding granting loans, managing cash balances, setting interest rates on loans, and dealing with government regulations.

No matter the particular category of finance, business situations that call for the application of the theories and tools of finance generally involve either investing (using funds) or financing (raising funds). Managers who work in any of these three areas rely on the same basic knowledge of finance.

Financial analysis is "a tool of financial management. It consists of the evaluation of the financial condition and operating performance of a business firm, an industry, or even the economy, and the forecasting of its future condition and performance. It is, in other words, a means for examining risk and expected return."⁷⁸³ Data for financial analysis may come from other areas

⁷⁸³ Frank J. Fabozzi, Pamela P. Peterson, **Financial Management and Analysis**, Second Edition, John Wiley & Sons, Inc., Hoboken, New Jersey, 2003, p. 5

within the firm, such as marketing and production departments, from the firm’s own accounting data, or from financial information vendors such as “Moody’s Investors Service” and “Standard & Poor’s Corporation”. Financial publications such as “Business Week”, “Forbes”, “Fortune”, and the “Wall Street Journal” also publish financial data (concerning individual firms) and economic data (concerning industries, markets, and economies), much of which is now also available on the Internet.

The financial/economic analysis sponsored and used by the economic manager can be viewed within a broad hierarchy of decision-making needs. The diagram in Figure 1.1 shows four key areas in the typical business where financial/economic analysis is a necessary ingredient. This conceptual pyramid rests on the broadest area: day-to-day decisions and operational planning. It successively rises via strategy development, investment analysis and capital structure planning, on to performance assessment and incentives, and finally to valuation and investor communication. Each of these areas contains challenges and issues in the practice of analysis and decision-making that the economic manager must address.

Figure 1.1 Area for Financial/Economic Analysis

(Source: Erich A. Helfert, Financial Analysis: Tools and Techniques, McGraw-Hill, 2001, p. 10)

Despite the great variety of issues faced every day by managers of different businesses, management tasks are so similar in principle that we can effectively group all business decisions into three basic areas: the investment of resources; the operation of the business using these resources; the proper mix of financing that fund these resources. Figure 2 reflects the continuous interrelationship of these three areas.

Figure 2 The Three Basic Business Decisions

(Source: Erich A. Helfert, Financial Analysis: Tools and Techniques, McGraw-Hill, 2001, p 24)

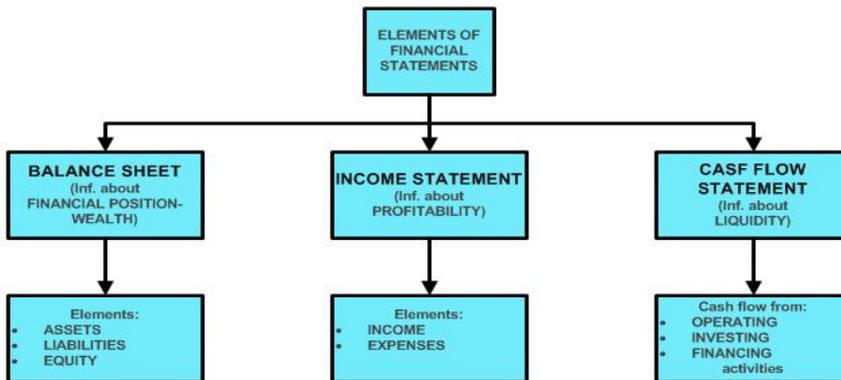

2. Financial Statements in IT Enterprises

In the process of financial/economic analysis, a variety of formal or informal data are normally reviewed and tested for their relevance to the specific purpose of the analysis. The most common form in which basic financial information is available publicly, unless a company is privately held, is the set of financial statements issued under guidelines of the Financial Accounting

Standards Board (FASB) in the case of USA, or issued under guidelines of the International Accounting Standards Board (IASB) for the countries of the European Union and other countries like for example Hong Kong, Australia, Russia, and Singapore. Such a set of statements usually contains balance sheets as of given dates, income statements for given periods, and cash flow statements for the same periods. A special statement highlighting changes in owners' equity on the balance sheet is commonly provided as well.

Financial statements are summaries of the operating, financing, and investment activities of a business. Financial statements should provide information useful to both investors and creditors in making credit, investment, and other business decisions. And this usefulness means that investors and creditors can use these statements to predict, compare, and evaluate the amount, timing, and uncertainty of potential cash flows. In other words, financial statements provide the information needed to assess a company's future earnings and therefore the cash flows expected to result from those earnings. In Figure 3 there is a depiction of the financial statements and of its most important elements.

Figure 3 Elements of Financial Statements

2.1. The Balance Sheet Source of Information for Financial Position Analysis

The balance sheet, prepared as of a specific date, records the categories and amounts of assets employed by the business (the resources committed) and the offsetting liabilities incurred to lenders and owners (the funds obtained). Also called the “statement of financial condition” or “statement of financial position”, it must always balance. By definition, “the recorded value of the total assets invested in the business at any point in time must be matched precisely by the recorded liabilities and owners' equity supporting these assets.”⁷⁸⁴ Liabilities are specific obligations that represent claims against the assets of the business, ranking ahead of the owners in repayment priority. In contrast, the recorded shareholders' equity in effect represents a residual claim of the owners on the remaining assets after all liabilities have been subtracted.

The major categories of assets, or resources committed, are⁷⁸⁵:

- (i) **Current assets** (items that turn over in the normal course of business within a relatively short period of time, such as cash, marketable securities, accounts receivable, and inventories).
- (ii) **Fixed assets** (such as land, mineral resources, buildings, equipment, machinery, and vehicles), all of which are used over a longer time frame.
- (iii) **Other assets**, such as deposits, patents, and various intangibles, including goodwill that arose from an acquisition.

Major sources of the funds obtained are:

⁷⁸⁴ Erich A. Helfert, **Financial Analysis: Tools and Techniques**, McGraw-Hill, 2001, p 38

⁷⁸⁵ **ACCA-F7 Financial Reporting (Int)**, Cromwell Press Trowbridge Wiltshire, 2008, p. A 1.4

(i) **Current liabilities**, which are obligations to vendors, tax authorities, employees, and lenders due within one year or less.

(ii) **Long-term liabilities**, which are a variety of debt instruments repayable beyond one year, such as bonds, loans, and mortgages.

(iii) **Owners' (shareholders') equity**, which represents the recorded net amount of funds contributed by various classes of owners of the business as well as the accumulated earnings retained in the business after payment of dividends.

Balance sheets are static in that, like snapshots, they reflect conditions on the date of their preparation. They're also cumulative because they represent the effects of all decisions and transactions that have taken place since the inception of the business and have been accounted for up to the date of preparation.

2.2. The Income Statement and the Financial Performance Analysis of the IT Enterprises

The income statement⁷⁸⁶ reflects the effect of management's operating decisions on business performance and the resulting accounting profit or loss for the owners of the business over a specified period of time. The profit or loss calculated in the statement increases or decreases owners' equity on the balance sheet. Thus, the income statement is a necessary adjunct to the balance sheet in explaining this major component of change in owners' equity, and it provides a variety of performance assessment information. The income statement also referred to as the "operating statement", "earnings statement", or "profit and loss statement", displays the revenues recognized for a specific period, and the costs and expenses charged against these revenues, including write-offs (depreciation and amortization of various assets) and taxes. Revenues and costs involve elements such as: sales for cash or credit; purchases of goods for resale or manufacture, or cost of services provided; general and administrative expenses; sales and marketing expenses; research and development costs.

The income statement represents the best effort of the firm's accountants to match the relevant items of revenue with the relevant items of cost and expense for the period, a process which involves accrual accounting and extensive use of allocation of prior and future revenues and costs. Among the judgmental areas involving costs are: recognizing the incidence of revenues received in advance or delayed in time; depreciation of assets being used over more periods than the current reporting period; cost of goods purchased or manufactured in previous periods; proper allocation of general expenses to a specific period.

2.3. The Cash Flow Statement Used in the Changes in Financial Position Analysis

Because we are interested in the combined effects of investment, operating, and financing decisions, analyzing both the income statement for the period and the balance sheets at the beginning and the end of the period together provides more basic insights than either statement alone. Management decisions not only affect the profit for the period, but cause accompanying changes in most assets and liabilities, particularly in the accounts making up working capital, such as cash, receivables, inventories, and current payables. The statement that captures both the current operating results and the accompanying changes in the balance sheet is the "cash flow statement", "statement of cash flows", or "funds flow statement". It gives us a dynamic picture of the ultimate changes in cash resulting from the combined decisions made during a given period.

The cash flow statement thus offers a ready overview of the combined cash impact of all management decisions during the period. The user can judge both the magnitude and the relationships of these cash movements, such as the company's ability to fund investment needs from operational results, the magnitude and appropriateness of financing changes, and disproportional movements in working capital needs. Observing the cash flow patterns can

⁷⁸⁶ : *ACCA-F7 Financial Reporting (Int)*, Cromwell Press Trowbridge Wiltshire, 2008,p. A 1.4

stimulate questions about the effectiveness of management strategies as well as the quality of operational decisions. The amount of detail can vary widely, depending on the nature of the business and the different types of movements emphasized.

3. Conclusions

As we saw above financial reporting system IT firms do not differ from annual financial reporting system provided by IFRS. Such system is based on three pillars namely the balance sheet, income statement and cash flows.

Information provided by balance are static information while the information provided by profit and loss and cash flows are dynamic information.

Data from annual financial reports are used in financial analysis of IT companies, using methods and techniques among which the most important is the method rates.

The conduct of the fiscal administration regarding the simplification and modernization of the systems of statements and payment of tax obligations is a necessary task to improve the relationship between the fiscal administration and the taxpayers, and also to induce efficiency regarding the management of fiscal duties in a single system. Regrouping the collecting of taxes under a single administration by taking over the functions of the social security administration has been the cornerstone of establishing a simplified tax administration. Improving the methods of compulsory enforcement of tax claims, the implementation of the management by objectives and the improvement of performance indicators of the fiscal administration activity, are considered to be the commitment of the fiscal body regarding the process of improving the collection of public financial resources.

Keywords: management of statements, budgetary arrears, efficient collection, fiscal indiscipline, performance indexes

JEL code: G, H21, H30

1. Introduction

The decision of the fiscal administration concerns the specialization of the management of large taxpayers, because a careful analysis of the contribution of budgetary resources at the level of the general consolidated budget for 2004 indicates a contribution of 44.4% of large taxpayers to the total revenue collection, with a personnel structure of only 187 posts. Moreover, administering large taxpayers involves more complex issues than for most taxpayers. This is the reason for which the administration of the largest contributors was entrusted to a specialized structure.

At the level of the territorial fiscal bodies began, together with the establishment of the National Agency for Fiscal Administration (NAFA), a necessary process of management improvement, by the progressive development of a method of management by objectives, thus adopting the modern management that exists in most developed countries.

The development of this management model required the implementation, since the year NAFA was set up, of a system of **performance indicators**, of a set of 12 indicators covering the major fields of the activity of the fiscal administration, among which:

- The degree of voluntary compliance of taxpayers to declare budgetary obligations.
- The degree of voluntary compliance of taxpayers to pay the budgetary obligations.
- The share of the amounts collected in full and on time, in the total amount expected as declared.
- The share of notifications received from taxpayers, who responded within less than 20 days.
- The share of solutions for admittance or dissolving in the total of solutions given by the review bodies responsible for settling solutions of appeals.
- The share of appeals resolved in the favor of NAFA, by the courts.

- The share of appeals filed by taxpayers in the total of foreclosures issued and the documents prepared for the fiscal inspection.
- The level of arrears collection in the case of large taxpayers.
- The percentage of budget revenues collected by the procedure of compulsory enforcement.
- The average annual number of documents of control signed by an inspector.
- The additional amounts incurred to the general consolidated budget.
- The additional amounts incurred as a result of tax audit reports, which correspond to an inspector.

NAFA and each of its component structures at central and territorial level must then engage in a performance plan to achieve goals regarding the development of such indicators considered a priority and determinants in assessing the degree of achievement of the annual targets of the fiscal management distributed to each of the territorial fiscal unit.

Considering the NAFA objectives as reference, which set the targets to be achieved by the national fiscal administration, each territorial structure (district, sector) is building its own performance plan. This way, the targets in the plan direct the activity of the staff in the territorial fiscal unit, leading towards focusing on what needs to be made to fit the broad lines of development and modernization of the fiscal administration. This approach involves a broad participation and raises responsibility among employees at all levels, a collective effort to increase the performance of the entire activity of the fiscal administration.

NAFA's mission is to ensure the means necessary to finance the operation of the state, the basic duty of the fiscal administration in a broad sense that subscribes to achieving the budget revenue by applying two principles:

- First, equal treatment of taxpayers regarding taxes is fundamental and should guide the entire activity of the fiscal administration, so that every taxpayer is sure of being charged a fair contribution and will accept the very principle of the tax.
- The second is that of efficiency: that, as any administrative action in a modern country, the administration of taxes and social contributions should be made at the lowest cost. It's not just about performing a cheaper service, but also at higher standards, the taxpayers being entitled to benefit from a public service of quality.

2. Conclusions

The rate-setting of activities and of the work of the fiscal administration on specific types of activities and on each person separately, aiming at increasing productivity in all the activities of the administration, required to define the three priority guidelines of the National Agency for Fiscal Administration:

- To encourage voluntary compliance, by providing a better administration of taxes and social contributions.
- To promote a quality fiscal control, more oriented towards risk sectors.
- To increase the efficiency of collecting the taxes and social contributions in order to guarantee the necessary budgetary revenue.

The encouraging of voluntary compliance, by providing a better administration of taxes and social contributions, was made based on the feature of the tax system in Romania, which is a declarative one, and relies on the statements made by each taxpayer. This way, the efforts of the administration have set the frames to establish a system of statement for budgetary obligations, so that a maximum number of taxpayers should pay the amounts due to legal term.

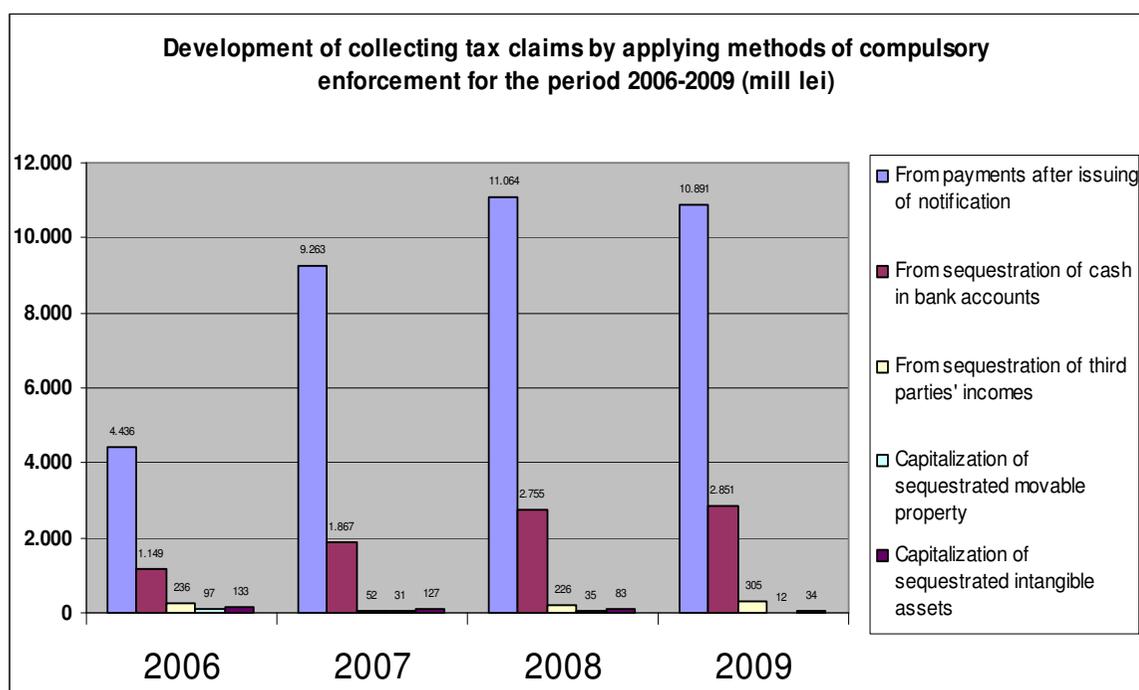

The management of the respective statements is a complex process, which allows the setting of taxes and eventually of refunds for any surplus of payment, such as the income tax refund or the VAT, for example.

The procedure of simplifying the activities of the fiscal administration continued through the suppression of the previous systematic review of requests for reimbursement of VAT credit, the

repayment period being reduced for the taxpayers who are not at risk of fraud. Through this procedure they resort to the electronic information and accomplish the concentration of the activity for setting solutions for VAT refunds in a department of risk analysis.

In order to analyze the voluntary compliance of taxpayers regarding statements and payment a timetable was established, and as a result, all territorial units will analyze the nonconformities for the same period and will automatically draw up notifications for non-submission of declarations and summons for lack of payment of overdue budgetary obligations. This will be achieved by modernizing the record on taxpayers.

In terms of **budgetary arrears**, increasing the degree of collecting by procedures of compulsory enforcement procedures mainly constituted the priority action taken by NAFA, and publishing on the website of the Ministry of a list of small and medium taxpayers with large debts was another objective of ensuring the transparency of the fiscal administration, with the consequence of determining the effect of preventing the formation of new arrears.

Source: www.anaf.ro NAFA report of performance

The working out of a record of the economic agents who registered tax debts, at the level of every territorial unit level, has allowed the development of a system for the monitoring and analysis of achieved revenues to the general consolidated budget, for reporting the results achieved in the collection process at the level of the objectives set by performance indicators and for taking measures to avoid the formation of new budgetary arrears, through a wider use of bankruptcy proceedings and the renunciation of granting payment facilities.

Pursuing performance in all the activities of NAFA, targeting positive results and better and better quality from one year to another, reflects a new culture in the activity of the fiscal administration. The approach related to the annual performance Plan of NAFA takes into consideration the following developments:

- The system of performance indicators should be improved by refining the existing indicators, and especially by introducing new indicators. The complex activities related to

administering the state's revenue will be assessed based on more representative indicators and will be boosted by establishing attractive targets.

- The level for which targets will be set will increase, because at least a medium term vision will ensure the necessary consistency in the management of the fiscal policy.

The detailed knowledge of the current situation and of the potential of the territorial structures, through the performance indicators, will be an essential prerequisite for grounding the major decisions that will guide the evolution of the fiscal administration.

There is the need to improve the budgetary revenue collection and shift them towards the most sensitive and important sectors regarding the budget revenue: the large debtors must be more insistently pursued, and the action of collection should be, especially for this category of taxpayers, more aggressive.

The activities of NAFA and of the territorial structures rely especially on information of fiscal nature, and it is vital that these should be correct. Continuous upgrading of the IT system has allowed in particular extending the reporting of fiscal obligations through the Internet.

We consider that the NAFA reform should be accompanied by a new vision regarding **the collection** of revenues to the general consolidated budget in the jurisdiction of the territorial fiscal structures – which, according to the Regulation on the organization and operation of NAFA, are empowered to collect fiscal claims and to apply the compulsory enforcement of budget revenues, thus, essential for carrying out NAFA's basic mission, they should express their option regarding the adoption of the following fiscal administration principles:

- Voluntary fulfillment of tax obligations by as many taxpayers as possible.

- To decrease the number of taxpayers - customers of the collecting measures, using particular methods of compulsory enforcement.

- Efficient management of taxpayers.

- Lowering the cost of the current activity regarding collection and the special ones resulted from applying the performing measures for every leu collected to the general consolidated budget of the state.

- Minimizing the losses representing overdue fiscal claims, subtracted from the fiscal record due to causes of insolvency and bankruptcy and other reasons not attributable to the fiscal unit.

- Reduction of overdue budget arrears and current arrears made up from the current fiscal year's debit.

- The management of specializing the taxpayers according to the criterion of size and revenue share paid to the general consolidated budget in accordance with the social importance.

The implementation of NAFA's IT program was considered a fundamental milestone in modernizing the fiscal administration through the usage of the IT application Management Information System of Fiscal Claims, which allowed the keeping of a log according to taxpayers on separate subsystems, the analytical leadership - distinct for each type of fiscal claim of the analytical evidence on taxpayer and of possible fiscal claims, accessories for increasing taxes due to delay, the analytical management of compulsory enforcement, facilities for payment, VAT refunds, offsets, the fiscal claims being in a stage of adjournment or insolvency, as well as the synthetic result of the process of fiscal administration, through the automatic transfer of data based on IT applications.

Regarding the granting of facilities for payment, we consider that the fiscal administration should apply the principle of equality between taxpayers regarding taxes, a principle which should be endorsed, promoted and enacted by the Tax Procedure Code and to represent the coordinating vector of the entire array of fiscal administration procedures both regarding the collection of state revenues through fair and non-discriminatory tax regime applied to all taxpayers, and especially in improving the business environment and encouraging competition by eliminating discriminatory tax incentives and facilities for payment.

For the collection of budget revenues the rapid acknowledgement of the situation of overdue payments is essential in order to effectively decide which is the method to prevent and/or regulate the lack of payment, and of the arrears' reduction, adapted to every taxpayer.

To discourage the accumulation of **budgetary arrears** by corporate taxpayers, NAFA updates and publishes quarterly, on their website, the list of large taxpayers and the list of small and medium taxpayers who register overdue budgetary obligations, and their collection arrangements applied by the bodies of enforcement.

The NAFA priority axes, on which the entire activity is based, is aimed at three major strategic objectives that govern its current and future actions, contained in the larger strategic guidelines set by the Government in the governing program.

First, **to prevent the elusion of taxes**, a vital stage regarding importance and the first from a chronological point of view in the process of fiscal administration: the taxpayers' assistance and providing optimal conditions for statements and payment will encourage voluntary compliance, will push for fiscal discipline.

Secondly, **an efficient and rapid collection**, which should treat taxpayers equally, will not allow deferred payment and will avoid the creation of those budgetary arrears whose likelihood to become income to the budget decreases in time.

Finally, NAFA should **suppress any phenomenon of fiscal indiscipline**, to ensure a healthy business environment in which the economic agents should engage in fair competition and in which the market law should not be distorted by taxpayers who do not pay their budgetary obligations.

We consider that in order to modernize fiscal administration there should be accomplished the decentralization of the administrative decision and also the transparency of the management process, objectives which have not found a correct application at the level of the territorial structures of the fiscal administration, the willingness of the Executive regarding decentralization being only in a declarative stage. The current organizational structure of NAFA reflects the concentration of the administrative decision at the level of the 21 general directorates of the Agency, both in the human resources management and especially in the ability to adapt the collecting methods and techniques to the development of the economic situation, but mostly to the budgetary constraints and to the need to induce efficiency regarding public expenditure.

INSURANCE OF BANKING OPERATIONAL RISK

Bençe Corneliu
University of Oradea
The Faculty of Economics

The current financial crisis is not a singular event in the history of crisis episodes. The essential difference between past episodes of financial turmoil and the actual crisis is the unprecedented severity, the pace of contagion and its global size. Financial markets have been seriously disturbed, threatening the robustness of financial institutions and their ability to meet current needs to properly manage the risk. One such risk is operational risk, which has become an important source of loss for credit institutions. In this context, the main purpose of this study is to present the best techniques and methods of managing this risk, less addressed problem in the literature from our country.

Keywords: operational risk, coverage, damage

Cod JEL lucrare: G22

1. Insurance as means of protection against operational risk

The Basel Agreement on required minimal capital acknowledges the role insurance can play in diminishing the financial impact of the operational losses of a bank. In a more and more competitive environment, as that of the bank industry, the transfer of risk to an insurer can contribute to the bettering of performance indicators and of cash flows, preventing crisis situations. Moreover, the insurance proper can be accompanied by connected services of risk management, which would allow a bank to more properly define its own risk profile.

In the consulting document on operational risk, promoted by the Basel Committee in 2001, it is acknowledged that insurance can be seen as a tool of diminishing the financial impact of operational risks of banks. In the acceptance of this document, the diminishing of the financial impact refers to the fact that concluding a specific insurance against operational risks can lead to a lower level of necessary minimal capital allocated to this risk category.

Still, it is pointed out that the market of insurance against operational risks itself passes through a stage in its development and maturation, so that banks can find themselves in the situation of replacing the operational risk by a counterparty risk.

2. Products of insurance against operational risks

Although they occur in a standardized form, these policies undergo several adaptations - depending on the demands of the insured customer - in that some clauses get eliminated and several supplementary ones are introduced, all with specific reflection in the price level.

- *Employment Practices Liability* (employer's liability) - covers compensation to be paid by the insured because of violation of labour law (discrimination, breach of employment contract etc.).

- *Non-Financial Property* - covers the usual risks that can affect the goods in the property of the insured (fire, earthquake etc.).

- *Unauthorized Trading* (unauthorized transactions) - provides unauthorized transactions that may constitute fraud by computer or fraudulent registrations;

- *General and Other Liability* (general liability and other liabilities).

3. Advantages of operational risk insurances

In essence, the role of insurance is to transfer the financial impact of a risk or a combination of risks from one entity to another. Strictly speaking, to transfer risk is not a way to control risk (control includes avoiding, preventing or reducing risk events). By insurance, the financial impact of a risk event is simply transferred to another entity, under the established terms. Concluding insurance against a particular risk, the bank relies on the ability of the insurer to provide compensation according to agreed conditions, so that risk transfer decision can be considered a financing decision.

Insurance as a risk reduction tool, helps the bank to avoid or mitigate the loss (financial or of any other nature) generated by the production of a risk. Theoretically, the benefits that a bank can obtain from contracting insurance against risks are related, on one hand, to the occurrence of a predictable cash flow and, on the other hand, to the avoidance of catastrophic losses.

Large and unpredictable operational losses can dramatically reduce the liquidity of a bank, to exhausting the capital allocated.

By buying a policy of insurance against operational risks, the bank pays an insurance premium in exchange to which it is granted compensation in case of production of a certain risk. This means that insurance against operational risks enables a bank to eliminate or reduce large fluctuations in cash flow caused by high and unpredictable operational losses.

A decrease of cash flow fluctuations also generates other benefits for the bank in that it improves incomes and then increases the bank's market value.

Another advantage refers to avoiding catastrophic situations, by the fact that insurance covers large operational losses that would lead to insolvability.

Although some banks (especially large international ones) have developed their own systems for operational risk management, the practice shows that an insurer has more resources and expertise in this field, acquired as a consequence of administrating a large portfolio of risks taken from clients in various sectors of activity.

By contracting an insurance policy against operational risks, banks transfer the risk to insurers and benefit, on one hand, from effective services and, on the other hand, from a qualified monitoring.

The first aspect is based on the object of activity of an insurer, namely evaluation, control and financing of the risks. Thus, large insurance companies have an advantage over banks from data available, experience and the size of the portfolios of the risks administrated. For banks, it may be more efficient in terms of cost to outsource certain elements of the risk management program to insurance companies. Insurers provide services of damage assessment and coverage, besides legal consulting and administration services (such as the collection of compensation).

The second aspect refers to the fact that, in some cases, shareholders may request the bank management to invest in risk management activities more than the latter would be willing to spend. Therefore, it is difficult for shareholders to monitor management behaviour and make sure it fulfils its tasks. In this case, one possible solution lies in an insurance contract, so that monitoring tasks would be in the insurer's duty.

The monitoring activity performed by the insurer supports, in fact, the manifestation of market forces. The risk must be regarded as any other commodity and it can be traded. Problems arise when individuals or groups interested in the activity of a bank (e.g. certain shareholders or the management itself) take advantage from the position they hold and expose the others to risks improperly remunerated.

4. Factors influencing the decision of insurance against operational risks

The decision of a bank to conclude a contract of insurance against operational risks depends on many factors that influence both the potential benefits it will obtain and the size of insurable risks. Synthetically, these factors regard:

- **The size of bank** - has a major influence on the decision of insurance against operational risks. There are differences of approach between a large bank and a small one, both in terms of potential benefits, and in terms of the insurable risks. It is difficult to judge whether the advantages of the insurance are bigger for one category or for another.

In general, smaller banks have lower equity and free cash flow and, consequently, are more vulnerable to losses from operational risks. Often they have neither a dispersion of risks, nor the funds necessary to develop their own risk management systems to such a degree of complexity that it could equal the monitoring performed under the terms of the insurance contract.

At contrast, large banks have the resources to perform a proper management of operational risks themselves. However, large banks often opt for the insurance solution to protect their income against losses from operational risks, especially when they affect investors' confidence or would lead to the overtaking of that bank.

Putting together and managing large or unusual operational risks of several banks by one insurer is almost always more beneficial than individual administration of those risks within one bank. It is also cheaper for a large bank to transfer the daily administration of relatively common and low-impact risks to an insurer, especially if the market of the insurance for that risk is competitive.

The bank's risk profile - the new Basel II agreement states that the level and types of risk identified in various business segments vary. It is possible that these differences affect the nature of the insurability of the risks associated to a business segment (e.g. in default of data and sizes of the losses). Besides determining the size of the minimum capital required, the bank's risk profile also influences its ability to contract itself a good quality and cost advantageous insurance against operational risks.

- **Time horizon for the management / shareholders.** The benefits of insurance require a certain while to become perceptible. If a bank renounces at an insurance contract, it may see a short-term advantage because it saves the insurance premium.

The extent to which a bank can cover the immediate expense of the insurance premium, in exchange for a benefit that may materialize only in the long term, depends on the time horizon the management or the shareholders aim. Those implied on a long term are, generally, more in favour to the solution offered by insurance than those who have immediate interests.

- **The interested parties' attitude towards risk.** The more the groups interested in the activity and the results of a bank (management, shareholders, etc.) show a bigger aversion to risk, the more appealing the solution of the insurance will be to them. The empirical results show that the attitudes toward risks of the groups interested in the bank's activity influence the entire strategy of risk management.

- **Bank rating.** The better the rating, the lower the refinancing cost the bank will support. In such circumstances, banks with very good rating can opt to finance losses by contracting credits rather than insurance. This aspect, though, needs further detailing, as the bank can be immediately demoted when it incurs a considerable loss that was not subject of insurance and, consequently, its access to financing becomes more restrictive.

5. The new Basel II agreement - the role of insurances in the management of operational risk and the impact of the required capital of the bank

5.1. impact of insurances upon required minimum capital

Regarding the new Basel II agreement, two acceptations have developed among bankers, related to the impact of insurances on the required minimum capital.

The first implies that any effort to improve the risk management should be viewed independently from the request of capital. Consequently, insurance should not affect the required minimum capital.

The second acceptance implies that, on the contrary, banks have to be provided incentives in order to improve risk management own systems. Consequently, insurance has to be considered when reckoning the required minimum capital. Many bankers and insurers believe that insurance should be treated as an instrument of reducing the required minimum capital and, in this case, the problem boils down to establishing how much of the insured amount will be deducted from the level of the required capital.

Given the complexity of Basel II, resulting from the recognition of the three criteria for determining the minimum capital level within Pillar I (basic approach, standard approach and the one based on its own system of risk measurement), we need to define, first, the notion of "minimum capital".

Secondly, it should be clarified if a number of instruments, namely insurance contracts concluded by banks, can contribute to the reduction of this required minimum capital.

The second pillar of the Basel II Agreement allows regulators to increase the required capital. Yet, from this perspective, banks should be permitted to rely on the insurances contracted for lowering their capital charge.

The third pillar covers the issue of transparency and control through market forces. Given the benefits of risk monitoring and control, insurance could play a relevant role in the management of banking risks.

Banks with an efficient management could resort to complex insurances of the cart type by which they could assure a higher level of protection and their reporting would improve their rating, driving to the reduction of the cost of the capital raised.

Currently, the market of insurances against operational risks undergoes a process of development and adaptation, so that we can eliminate the disadvantages and maximize the benefits brought to banks. For example, new cart type insurance products provide protection against more risks and solve a part of the problems related to gaps and redundancies arising from the use of traditional insurance.

Basel II agreement needs to provide a flexible framework that allows banks to use insurance as an effective tool for operational risk management.

The new agreement will have to regulate if and to what extent insurance against operational risks is compulsory. For example, the fidelity insurance that cover all risks - operational and non-operational - is mandatory in the U.S.A. and in several other countries (including Britain), which do have reduced schemes of depositors' protection.

From the perspective of the risk management, Basel II agreement should contribute to the production of a competitive environment where market forces could act efficiently and effectively. For this, the regulators should provide regulatory infrastructure and leave the task of monitoring the method of applying regulations to insurance companies and to risk rating agencies.

Insurance companies are very interested to support banks in their bettering of risk prevention and reduction activities. Incidentally, the rating agencies already provide independent external evaluations.

Regulators will be able to direct their limited resources on those banks that have problems from the point of view of the insurers and the risk rating agencies.

One of the objectives of Basel II agreement, that of assuring more transparency to financial environment, could be achieved by publishing the risk rating awarded to banks for the policies of insurance against operational risk, as well as the rating of debt securities. These require, though, a closer cooperation between regulators and the risk rating agencies because, unlike these agencies, public authorities do not publish the awarded ratings.

The regulatory and supervisory authorities collect data on operational risks to determine the required minimum capital and it would be useful that, as far as possible, data should be disseminated to be further useful when concluding insurance contracts and for standardization. This would grant that relevant and properly classified data are considered which would demand a more rigorous calculation of insurance premiums, fewer exclusion clauses and higher compensation limits.

Basel II Agreement also puts forward the risks associated to outsourced activities such as communication systems and those for payment and settlement⁷⁸⁷.

The traditional approach used in insurances, the one of covering known risks, generates a series of complaints from banks, because, in the circumstance of alert creation of new products and services, it appears to be essentially reactive. Nevertheless, this reactive attitude allows the emergence of unforeseen gaps in covering operational risks due to changes in technology, knowledge and economic environment situation.

Although a series of renowned international insurers have adopted a pro-active attitude in what the offer of operational risks insurance is regarded, the level of demand for such products is neither known nor easy to estimate. Previously, the insurance companies have created the insurance against fraudulent transactions - considering that it is useful to banks - and found that the demand was virtually non-existent. To avoid situations like those mentioned, you need a constructive dialogue between representatives of banks, insurers and regulatory authorities, in order to clearly identify the products that the market requires and is willing to pay.

At the level of the insurance market, there is a more and more obvious manifestation of the necessity to standardize the documentation for damage in case of losses from operational risk. This would diminish the possibility of disputes and would be a guarantee (for regulators and banks) of the fact that the losses proven will be covered in accordance to the insurance contracted.

This would also help to develop alternative products for protection against risk, because standard products could be traded on the capital market and offered to a much larger public, by means of securitization.

However, a cautious approach is necessary, because an excessive standardization may suppress the development of product and affect the efficient functioning of the market. În plus, schimbarea continua a cererii clientilor face dificila crearea unor polite de asigurare pe deplin standardizate. In addition, the continuous change in the customers' demand makes it difficult to create fully standardized insurance policies.

5.2. The attitude of the banks towards the solution of insurance

When contracting an insurance against operational risks, a bank has to first see to what extent this contributes to the increase of its value on the market and look beyond costs.

Concluding an insurance contract can increase the market value (most frequently measured on the basis of the market price of the actions) by predictability of the cash flow, preventing a financial catastrophe, assistance in monitoring and controlling risks and use of a management instrument of effective risk in what price is regarded.

It is relevant to point out that the simple contracting of an insurance for reducing the required minimum capital does not automatically lead to an increase in the market value of the bank, especially when the opportunity is lower. Contracting an insurance must be justified by the fact

⁷⁸⁷ Dedu V., Nechif R., "Banking Risk Management in the Light of Basel II", Theoretical and Applied Economics - 2 / 2010 (543), p.114

that it brings benefits and services the bank cannot develop by itself, under the condition of cost efficiency.

The management of the bank should plead in front of the shareholders for the necessity of concluding insurances against the operational risks, insisting on the fact that these represent an efficient instrument of monitoring and controlling.

The use of specific insurance policies is in itself a credible signal of undertaking proper management of risks.

CURRENT COORDINATES OF THE ROMANIAN INSURANCE MARKET

Bențe Corneliu
University of Oradea
The Faculty of Economics

Although the insurance activity is well known to the Romanian market ever since the 14th century, when insurance was all about mutual help, this activity evolved rapidly in the period before the First World War and in the period between the World Wars, and it manifested itself as the entrance on the market of insurance companies representatives from countries as Austria, Italy, Great Britain. facultative insurance.

Keywords: gross written premiums, gross paid indemnities, market

Cod JEL lucrare: G22

In 1989 the change in the political system came about with significant changes in the insurance industry. Certain types of insurance which previously were compulsory became facultative. From the point of view of the insurance market's offer, the year 1989 meant also the end of state monopoly, ADAS seized its activity and its portfolio was taken over by three companies that later on were privatized – Asigurarea Romaneasca SA, Astra SA, and Carom SA. The beginning of "the new era" for the Romanian market represents the year 2000 when the law concerning the supervision of the insurance market was implemented, and the Insurance Supervisory Commission was set up; better improvements have been registered. Since then, the Romanian insurance market recorded a constant growth, as we can see in the following table:

Table 1
Insurance market ratios

		2000	2001	2002	2003	2004	2005	2006	2007
Number of insurers		70	47	45	40	40	39	41	42
Volume of subscribed premiums	Mil USD	311	344	500	610	1051	1508	1970	2630
Penetration degree	% GDP	0,85	0,87	1,09	1,06	1,44	1,55	1,67	1,84

Source: Badea D. G., Novac L. E., "Romanian Insurance Market Facing Globalization Process", Theoretical and Applied Economics., 2008, vol. 9(526), p.62

In 2006, the total volume of insurance premiums reached 1.62 billion Euros, a nominal increase of 23.68% compared to 2005, when the volume of premiums recorded 1.21 billion Euros, being the second year in which the threshold of 1 billion Euros was exceeded.

In 2007, 42 insurance companies centralized a total volume of gross written premiums of 2.15 billion Euros with a nominal increase of 25.07% compared to the level of 2006. As structure, 79.9% of the total premiums was generated by the general insurance (an increase of 24.73% in the volume of premiums subscribed compared to 2006), whereas the life insurance brought about

only 20.1% (a more accentuated increase – related to the increase in the general insurance – of 26.46% compared to 2006).

At the level of European Union, the Romanian insurance market had in 2007 the fastest growth in the entire Europe, overcoming other significant markets in the region, such as Poland. With a growth rate of 33% in Euros, the local insurance market had the greatest dynamics among the 33 member states of CEA – Comite Europeen des Assurances.

In the last 15 years, the insurance market increased 30 times in terms of gross insurance premiums subscribed and even though the motor insurance continue to have a significant weight, it can be noticed an accelerated increase of other property insurance, credit insurance and health insurance⁷⁸⁸.

In 2009, there were 43 insurance companies on the market. Of these, 19 companies ran non-life insurance, 12 ran life assurance and another 12 had a composite structure of their business: life & non-life.

As we are still crossing the global economic crisis, CEIOPS analyses show that the insurance market in European Union has not proved to be a source of systemic risk for the financial sector, still the global crisis affect it by diminishing the written premiums or decreasing the value of the investments on the financial or capital market.

The analysis of data submitted by insurance companies for 2009, show that written premiums to the level of the insurance market in Romania (non-life and life) were at a slightly lower level than the one in 2008, of 1.1%, an increase of 2.03% for non-life insurance and a decrease of 13% on life insurance.

1.Gross written premiums (GWP)

The total volume of gross written premiums in 2009 of nonlife insurance and life assurance was 8.837,01 million lei, dropping from 99,42 million lei, compared to the same period last year.

1.1. GWP for non-life insurance

GWP volume of insurance in 2009 was of 7.211,68 million lei, representing 81.60% of total GWP for the two categories of insurance.

Compared with 2008, the premiums for non-life insurance recorded a nominal increase of 2.03% and the growth was of 143,51 million lei.

While gross written premiums for (Casco), recorded a drop of 231,02 million lei, the motor third party liability insurance (MTPL) registered a growth of 392,65 million lei.

In 2009, auto Insurance related to the insurance of land vehicles other than railway rolling stocks (Casco) and MTPL hold a significant share in the total amount of GWP (77.13%), although they recorded a growth rate reduction of 6.49% from the previous year.

Higher rates of growth, recorded the following two classes, whose premiums grew with amounts between 5 and 20 million lei: class XV – Surety ship insurance security guarantees (+158.59%), XII class - Liability insurance for ships (+93.67%).

Gross written premiums for insurance against financial loss registered a downward trend in 2009, dropping by 39.20% compared to 2008, leading to decrease the share of them in total non-life insurance GWP of up to 1.6 %.

This situation was due to a more expensive lending and reducing or stopping the granting of loans charged by credit institutions.

⁷⁸⁸ Badea D. G., Novac L. E., “Romanian Insurance Market Facing Globalization Process”, Theoretical and Applied Economics., 2008, vol. 9(526), p.65

Source: Insurance Supervision Commission, Newsletter, no. 1/2010, p. 16

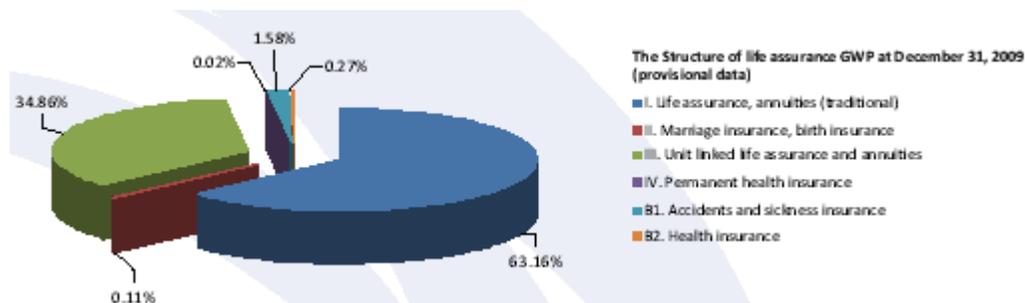

Figure 2: The structure of life insurance GWP at 31.12.2009

Source: Insurance Supervision Commission, Newsletter, no. 1/2010, p. 16

I.2. GWP for life assurance

The total volume of GWP in 2009, for life assurance amounted to 1625,32 million lei in 2009, representing 18.38% of the total volume of gross written premiums. GWP for life assurance were of 242,79 million lei (13%) lower than in 2008⁷⁸⁹.

This situation was generated by the negative trend of the traditional life assurance products assigned to Class I life assurance, representing 63.15% of total written premiums for life assurance, mainly due to the significant decrease in purchasing power of the population.

In terms of class structure, class I – traditional life assurance and class III – annuities related to investment funds hold together a share of 98.01% of total amount of GWP.

However the premiums related to class I decreased with 21.92% in 2009, in comparison with the previous year, in absolute terms with 288,41 million lei, while the premiums for the class III (unit linked) recorded a nominal growth of 8.9 % (with 44,80 million RON), compared to 2008.

In comparison with the previous year, accidents and sickness life insurance registered a growth of 14.42%, while permanent health insurance (class IV) registered a growth of 7.54%, although the two classes represent only up to 1, 5%, of total amount of GWP of life assurance.

⁷⁸⁹ Insurance Supervision Commission, Newsletter, no. 1/2010, p.17

2. Gross paid indemnities (GPI)

The volume of gross paid indemnities for the two categories of insurance was of 5861, 63 million lei, an increase of 26.36% compared to the year 2008.

3. Gross technical reserves

Of the provisional data provided by insurers, we can notice that on 31.12.2009 insurers had gross technical reserves for non-life worth 6900,42 million lei, up 7.6% compared with 31.12. 2008. For life insurance, on 31.12.2009 insurers had gross technical reserves set up in the amount of 3.889,48 million lei, (+13.60%) of the value recorded at the end of the previous year.

4. Conclusions

If the economy is returning to growth in 2010, the insurance market could begin, in the second half of this year, to experiment a slight increase, so that, in December, the gap recorded in 2009 to be recovered.

But if the pessimistic scenario, in which we will see a sharp decline in macroeconomic indicators, will occur, the insurance market would end 2010 at a similar level of gross written premiums as the one registered at the end of the last year.

Insurance industry is directly connected to the development of the main economic branches and is also depending on consumption, which last year saw a slump.

Insurance Supervisory Commission analysis shows, however, that this market could end 2010 on an addition of at least 5%, given that the need for protection began to be increasingly conscious of potential consumers.

What meant year 2009 for the insurance market, both for the companies and the Insurance Supervisory Commission? Rapid reactions, strategy changes, a more prudent risk management, significant infusions of capital, changes to some regulations, in order to enhance the protection of the policyholders, the introduction of new procedures, such as the “Bonus–Malus” system.

Unfortunately, the insurance market in Romania continues to be dependent on MTPL and CASCO segment, given that it generates over 60% of the gross written premiums for non-life insurance market.

Meanwhile, in Romania, life insurance segment, the one that makes the rule of the industry on the full grown markets, is still feeble. Moreover, in 2009, life insurance proved to be the most exposed to the crisis.

The wave of redemptions and termination of contracts, started towards the end of 2008, still it was tempered in the latest quarter of the last year.

Since 2007, the local insurance companies apply the Solvency I while preparing for Solvency II. Together with the accounting standards IFRS, Solvency II is going to dramatically reshape insurance and reinsurance industry in Romania, to boost competitiveness and professionalism.

When it is to be implemented, Solvency II will lead to a change in the way the supervisors are working. Insurers and reinsurers are going to be evaluated according to the existing risks in their portfolios, their assets and liabilities being quantified by economic principles. The implementation of Solvency II will mainly increase the consumers’ confidence in insurance products, as the solvency model enables early detection of possible shortcomings and to further adapt the risk management process. It is of a high importance that policyholders believe that the insurers are willing to accomplish their commitments. Insurance companies, under the careful supervision of the Insurance Supervisory Commission, are responsible for generating and maintaining that trust.

The continuous improvement of the insurance premiums, the insurance density and the insurance penetration rate (annual amount of Euros paid on average by an inhabitant) support the importance of this sector of activity in the total economy of Romania.

CONCEPTUAL CLARIFICATIONS REGARDING THE FINANCIAL CONTROL

Boța Moisin Anton – Florin
University of Pitești
Economic Science Faculty

Măgură Cerasela
University of Pitești
Economic Science Faculty

In this paper, the author presents the concept of financial control, distinguishing between financial supervision and tax control based on the analysis of relations finance - Public finance - taxation, namely, financial law - tax law.

Keywords: public finance, control, tax.

JEL Classification: N20.

1. GENERAL CONSIDERATIONS ON FINANCIAL CONTROL

1.1. The concept of control

The Control, in general, plays an important role in any economy of any state, it is a basic tool of management for all segments of society. The activity of control is in all the phases of processes taking place in society, from their planning, their progress and impact assessment.

The origin of *control* is found in a Latin word phrase „*contra rolus*”, which expresses the activity of comparing, checking duplicates of the original act, entrusted - in this respect - to another person. In a synthetic speech, the phrase „*contra rolus*” means „checking an act after the original check”⁷⁹⁰.

More broadly, in its semantic sense, control is „a continuous or periodic review of an activity, a situation to watch them march and take action to improve”⁷⁹¹. Meanwhile, the *control* means „further monitoring moral and material, and possession of an activity, a situation or a process of comparing facts with the required or planned, and the enterprise of collective approaches, so that achievements are in accordance with predetermined goals”⁷⁹².

Under its various aspects, human activity has been subject to control since ancient times. The power of control of man, suspected occurrence of a particular predisposition to evil man to other people, need the good and / or had (owners) to protect their interests affected by the bad guys and not having ”.

By newer days, other purposes have become increasingly important: *efficiency* (to control what goes wrong to go through measures to improve the operational order, tactical or strategic), *legality* (compliance verification established by law and application of sanctions, if any), *opportunity* (the events are appropriate circumstances and situations)⁷⁹³.

In the specialised literature we meet other acceptable definitions regarding the control, namely:

- The Francophone sense according to „Le Petit Larousse - Dictionnaire encyclopedique, Paris, Larousse, 1975 ”, „control is a check, a careful inspection of the correctness of an act”.

⁷⁹⁰ M. Ghiță - „The financial control, a component of economy”, Universitaria Publishing House, Craiova, 1995, page 6.

⁷⁹¹ *** „Romanian Language Dictionary”, Academic Publishing House, Bucharest, 1975.

⁷⁹² Ionel Bostan - „, The financial control”, Economic Publishing House, Bucharest, 1999, page 6.

⁷⁹³ Ionel Bostan - „, The financial control”, Polirom Publishing House, Iași, 2000, page 11.

- The Anglo – Saxon sense according to „, The New Merriam - Webster Dictionary, Merriam - Webster Inc., Publishers, Springfield, Massachusetts, 1989 ”, „, supervisory control is the action of someone, something, an examination or the power to control an instrument for regulating a mechanism. ”

The need for control is determined by objective reasons and above all, forms of ownership, commodity production and action of specific laws economy.

Control has been and continues to be one of the factors that have influenced and stimulated progress⁷⁹⁴, always people with admiration on the achievements of their predecessors and contemporaries, subjecting them to rigorous examination, which led to change and progress.

In addition to the original meaning, *the concept of control* has gained more meaning over time: *the continuous or periodic review* of an activity, a situation they are going to track and take improvement measures, surveillance, moral and material; *to rule* , *to dominate* an activity or situation; *periodic verification of knowledge*; *careful inspection of the correctness* of an act.

Finally, the *control* is an activity that provides data and information derived from the findings *before, during* or *after* the execution of an operation aimed at the prevention of irregularities or deficiencies, in wich their correction and establishing liability, where applicable .

The control is an activity that the findings before, during or after the execution of operations, is providing data and information about them, with the final goal of preventing irregularities and deficiencies - lack of conformity to predetermined rules - and their correction and determination of liability if case⁷⁹⁵.

In practice, the control is obvious in all social fields, from politics and obviously in the economic sphere where economic control is revealed primarily by financial control.

1.2. Financial supervision and tax control: definition.

The relationship between finance, public finance and taxation. Relationship between financial law - tax law.

1.2.1. Financial control: definition

Starting from the notion of control and by developments in the economy - which it belongs - *financial control* - its defined „*as the action to determine the status of activities represented in financial and accounting documents, by reporting these representations to the provisions laws that have been defined*”⁷⁹⁶.

Analyzing the above definition that audit work *is more* than one action to the need to check the status of knowledge of certain economic phenomenon and pursued to address the effects of deviations from certain statutory provisions.

Specifically, the financial control shall examine the way in which the financial terms of objectives and programs undertaken by different public bodies, in order to prevent them or to discover any irregularities, errors, deficiencies, correct them and to avoid them in the future.

In the sphere of public finance law, financial control covers all the legal rules governing social relations - the legal relations of financial law are set in relation to control the *formation, administration and use* of public financial resources (state and / or administrative units of territories) and that are intended to correct the acts and transactions and other compliance and default rules⁷⁹⁷.

⁷⁹⁴ Dan – Drosu Şaguna - „, Financial and tax treaty law”, All Beck Publishing House, Bucharest, 2001, page 329.

⁷⁹⁵ Doina Petică Roman - „, Public Financial Law”, Tribuna Press House and Publishing House, Sibiu, 2003, page 222.

⁷⁹⁶ P.Popeangă, G.Popeangă - „,Financial and tax control”, C.E.C.C.A.R. Publishing House, Bucharest, 2004, page 19.

⁷⁹⁷ See Doina Petică – Roman, op.cit., page 223.

The economic literature has formulated various definitions of the financial control, a common denominator of them is the fact that relations in the sphere of financial control is a *component* of the relations which arise in connection with the state's financial resources.

Thus, Professor Ioan Gliga defined the financial control as „*a compliance and enforcement activities conform to norms of financial conducted with the purpose of restoring legality, training and use made of public money funds and hence the purpose of establishing liability and application of legal coercion cases of violation of financial law*”⁷⁹⁸.

Professor Dan Drosu-Şaguna defined the financial control as „*a component of economic control, which is to know how material and financial resources are managed by public companies, the form for spending public money, ensure financial balance, achieving economic efficiency, development of national economy, the achievement of social progress*”⁷⁹⁹.

In his work, public finance law "(Printing Press House and Tribune, Sibiu, 2003), Mrs. Professor Doina Petică - Roman makes the distinction between financial control and public financial control, defining *the public financial control* as being „*a component of financial control activity to verify how is formed the public financial funding and how the public patrimony is managed*⁸⁰⁰, to ensure a good financial management with the purpose of restoring legality in situations of violation of legal rules”⁸⁰¹.

The *training, management and efficient* use of public money are *crucial* to achieving the major objectives of the State, both economic and social, but are *determined* to a large extent, by the efficiency of activities developed by *financial control*.

From the definitions above, we conclude that the financial control activity serves a triple system of interest namely:

1. Financial control is the instrument through the effects of prevention and settlement failures that can occur at any time in activities within an economic unit, serves the interests of the state in achieving its long-term fiscal policy.
2. Financial control serves the interests of economic operators who organize it and carry it through *both* the prevention of situations of failure in the management of heritage, and especially the work of remedying violations of legal provisions established.
3. Financial control serves the interests of economic entities marketing partner, which gives precise information on the economic situation of economic unit and are concerned for a possible partnership.

1.2.2. The relationship between finance, public finance and taxation. The financial law - tax law relationship.

Definition of fiscal law

In the analysis of definitions given to the financial control we can see the following observations⁸⁰²:

- a) Through *financial control* occurs the inspection of the establishment of public revenue. Since the formation of public revenues is on account of *taxes and other revenue* of public budgets, the legal rules governing these issues are covered in theory as the *tax law*, subdivision belonging to *financial law*. Therefore, *tax law* is a component of *financial law*, just as *taxation* is part of the *science of Finance*. Taking *finances* - the financial relationships – as a *whole*, *public finances* are

⁷⁹⁸ Ioan Gliga - „Financial Law, Humanitas Publishing House, Bucharest, 1998, page 380.

⁷⁹⁹ Dan Drosu-Şaguna - „Financial and tax treaty law”, All Beck Publishing House, Bucharest, 2001, page 329-330.

⁸⁰⁰ Public property means all rights and obligations at a time, of state administrative units - regional public entities or their economic value, acquired or assumed in any way (Doina Petică - Roman, op.cit., Page 226)

⁸⁰¹ Doina Petică – Roman, op.cit., page 224.

⁸⁰² See Doina Petică – Roman, op.cit. 225-227.

the *part* (and the private finance too) in the public finances, *taxation* is also *part* (the *taxation* is a component of *public finances*, which is a component of finance in its sense). Even so, considering the entire *financial law* as a whole and the relationship between *tax law* and *financial supervision*, by analogy the relationship between financial supervision and tax control is a relationship of the *whole to part*.

Financial Control reflects the *inspection* of the establishment of public revenues through taxes, respectively, verifying the *fulfillment* of tax obligations by taxpayers.

b) Through *financial control* we can check how *to use* the *public revenue / public funds*, regardless of the quality of public or private entity to receive the funds. In addition to checking the *constitution* of government revenue - work carried out through *fiscal control - financial control* (as a whole), and we can also check how public revenues are used. The ultimate goal of *using public revenues* is the satisfaction of needs and general interests, which is why it is imperative to verify the use of these public revenues because it is natural that the requirements are respected by *legality, regularity, economy, efficiency and effectiveness*.

c) The financial control occurs inspection of the *management of public property* - understood as whole and the rights and obligations of the administrative units - territories to public goods in their field and / or private, at one time, value economic, acquired or assumed in any way. In this case, *financial control aimed* is protecting public property against losses caused by natural wear (erosion), waste, abuse or fraud.

2. Conclusion

We can define the *financial control*, as a component of economic control, meaning the activity of verification provisions and operations, which has the objective of knowledge of the *state*, the way they are *formed, managed and employed* the material and financial means (by public companies - which are state entities and the administrative - territorial) - in other words - how to do and spending public money in order to achieve an efficiency of economic life - social, ensure financial balance, the national economy, achievement of social progress and restore the rule of law .

The formation / construction of public revenues is mainly on account of *taxes and other revenue* of public budgets to regulate such matters are the responsibility of *tax law*, a subdivision of financial law. In the context of *fiscality, fiscal control* - reflects the inspection of the establishment of public revenues through taxes, and verifying the fulfillment of tax obligations by taxpayers.

As the French author, Fr. Querol, assessing the effectiveness of a state „depends first of its propensity to tax product to enter the public pay offices and therefore to ensure that citizens do not avoid their tax obligations. For this, it - has endowed with a certain tool: *fiscal control*”⁸⁰³. The tool ensures the supremacy of state tax sovereignty⁸⁰⁴.

In addition to fiscal control, *financial control* also comprises checking how public revenues are *used*, and inspection of the management of public property.

As tax law is part of the financial law, so, fiscal control is part of financial control.

SOME CONCLUSIONS REGARDING THE HISTORICAL EVOLUTION OF FINANCE IN THE PRESENT TERRITORY OF ROMANIA

Boța Moisin Anton – Florin
University of Pitești
Economic Science Faculty

Măgură Cerasela
University of Pitești
Economic Science Faculty

In the present article the authors are debating the historical evolution of finance from its beginning until its present. The importance of the theme is given by the fact that the appearance of finance was due to the appearance of the state, when the state treasury was confused with the welfare of the Lord, and when taxes are introduced for the first time.

Keywords: evolution, taxes, revenue, period.

JEL Classification: N20

1. Introduction

If elements of economic and commercial nature, existed in the current romanian space of time removed, resulting - after developing the state and money - the emergence of the first elements of finance, about their financial relationships - we speak - with reference to our territory inhabited by the romanian people - just as when mainstream form of cash contributions, which chronologically puts us on the mid-nineteenth century, since the modern era⁸⁰⁵.

Therefore, the changes in the elements of finance – from the beginning of the first millennium - to **finance / financial relations** - equipped with a **real tax system** - in the mid-nineteenth century - is a long and complex process, influenced by the concrete conditions of society, the changes in social systems - economic, ideological and political trend.

The tax system contains all the financial funds in place, bounded on an economic level and links between these movements constituted financial resources generated by operations (also called financial flows). Fiscal relations ensures the funds, but their orientation, so fiscality is evident in the distribution process, by mobilizing the various channels of resources available to state, representing a part of the finance functions namely the allocation.

2. The historical evolution of finances in the present territory of Romania

2.1. The medieval period

In a work entitled, „History of the Romanian public economy”, National Culture Publishing House, Bucharest, 1924, the author, George N. Leon says (page 11), „Financial History of Romania can not be studied only by the foundation of the principalities, because the Romanian people lived before them, with an organization determined by the conditions of existence of time. Whether we lived freely in some parts, whether they lived in dependence of other nations, he experienced a tax debt for us is a great interest to investigate the Romanian people with household public relations, whatever the latter was.

In the same work quoted by Professor George N. Leon, we have an overview of the obligations which it imposes the **Tatars** oppressed peoples of Eastern area, „he came from Russia a comissar to charge of regulation. He took the first of three children, one from the three carried it with him putting to slavery all unmarried people, men or women and all those who did not had

⁸⁰⁵ Idem, page 12.

how to gain life or pay the **capitation**. The remaining population was counted: small and great, rich and poor, old and young had to pay the same capitation of five skins: a white bearskin, a marten skin, the skin of a beaver and a ferret skin Mongolian officials came in, to change the tribute settlement and administration. They put one man to ten contributors, over one hundred one centurion, over one thousand and one mias who steals responsible for fulfillment of the capitation. Exception were only priests, monks and nuns”.

„A document from 1222 tells us that Andrew II, king of Hungary, nodded the Teutonic Knights the right to bring salt on ships on the Olt and Mureș River, saving them from the tax they pay to pass through Romania (per terra Balcanum). This proves that the romanians, since the first half of XIII century, had organized a country economically, collecting customs duties which of course served to cover collective needs. It is beyond any doubt that in this period the needs of the princes is confused with the needs of the state”⁸⁰⁶.

2.2. The Principalities period

Public expenditure were made to society, but were almost exclusively expenditure made by the Lord that was required to ensure the rule of law and ensure peace. He repress sight and force arbitrary, paid employment related to services for the Princely Court, supporting the Church and social establishments. Revenues are restricted areas consist mainly of its operation, the taxes mentioned above, changed from year to year or repeated in the same year with the change of the Lord. The Lord is the master and all his goods were between public property and private possessions of the prince no distinction confusing the state treasury.

Most people were peasants and lived in country villages as differentiated by the fall: the royal villages, monastery villages - donated by the Lord to the monasteries, with all obligations – the villages of Noblemen - donated noblemen, and free villages composed of free men, named „**Moșneni**” in Valahia and „**Răzeși**” in Moldova.

The people who were not free were called „**rumâni**” or „**neighbors**” and were tied to the land, the estate or gentleman.

The „**rumâni**” have to his master, three kinds of tasks: the „bucket”, giveing and labor⁸⁰⁷.

The „**buckets**” represent some of the products made by „rumâni” on the land of the noblemen due to grain for hay and live with different names: from wine yards, cowing etc.. The „buckets” were **paid** by free people, in size and structure, thanks to tithe for all products of the earth.

The **giveing** is an obligation that was due only to beehives, sheep and pigs.

The **labor** is required to work without pay in farming, transport, to live, to repairing houses of the noblemen.

Outside sharecrop basis, free men were also forced to perform work on the estates of noblemen / prince / monastery, twelve days a year, and by the seventeenth century, this requirement had to perform a twenty four days a year.

In addition to free people, there were other categories of people, such as **courtiers**, „**călărași**”, „**hânsarii**”, „**darabanii**”, „**plăieși**” and **hunting men**, they were royal retainers. Plăieșii were exploiting forests in exchange for the duty to guard the borders, darabanii lived and fed on royal seats in exchange for warlike service. In general, the various royal servants were various services in exchange for lowering taxes to the ruler and the noblemens.

Valahia and Moldavia were the grain yards of Turkey, hence feeding the Sublime Gate with grain, sheep and beef and other food providing the empire.

When the Ottoman Empire was at war, the principalities were obliged to send people to certain services, transport, building bridges and various other labor.

⁸⁰⁶ George N. Leon - „ The history of politic economy at romanians”, National Culture Publishing House, Bucharest, 1924, page 17.

⁸⁰⁷ I. Vlădeanu - „About pays and taxes. The tax.”, „Cartea Românească” Publishing House, Bucharest, 1925.

„The Hungarian entry into the country, conquered land was divided between different Hungarian families, making their joint property. But besides these owners are in the country a free people, native, who lived under her own organization, to enjoy various privileges and engaged in the cultivation of land (Romania), trade and crafts (chassis) and, finally, the crowd Slavs who lived to the owners and worked for the benefit of the master.”⁸⁰⁸

The current Romanian territory, but also in other areas / regions where Romanian living, social relations were feudal. Financial structures were rudimentary, characterized by arbitrary distribution of tax burden based on the principle of distribution of step in step, to family, without any economic justification. There is no regular collection or a real financial device, sound, financial structure of the relationship marked by the nobility, the church, clergy, by rule or royalty.

2.3. The Middle Ages

Given the fact that Constantin Mavrocordat was a gentleman who depended on the Phanariot „goodwill” of the Great Gate, „goodwill” that was ensured by substantial amount and because the Lord himself, certainly not during his reign, but while he hold his lordship, exploit the situation to increase his own wealth; it happened that the Lord himself violate some provisions of the reform, raising the toll of five to six times a year instead of four and even ahead of schedule.

To increase revenue, Constantine Mavrocordat was worried about the increase in the number of taxpayers, by abolishing in Valahia (at 7.VIII.1746) and Moldavia (in 6.IV.1749) the serfs, not by releasing them, but to give fresh land release, which was they remain in a state close dependence on the noblemen.

From the russian withdrawal from Moldavia (in 1812) and annexation of half of the territory, in conditions of generalized poverty, there was a number of significant migration of population: 400.000 inhabitants took refuge in Russia, 300.000 in Serbia and 75.000 in Bulgaria, so number of taxpayers is reduced drastically, leading the Valahian country with approx. 800.000 inhabitants, and Moldavia about 500.000 inhabitants.

In these conditions, the Valahian government ensured attracting new resources to the budget, after the Revolution of 1821, will resort to **loans**. Thus, Valahia is forced **to resort to loans from monasteries**, with interest of five thalers to bag a month, ensuring in this way, attracting the amount of 23.550 thalers (equal to 70,650 ROL). The Moldavia resorted to **loans from the noblemen**⁸⁰⁹.

2.4. To the modern period

By the introduction of the Organic Laws it took the first steps towards a modern tax system rests on the base. Thus, it was done to fix the state spending each year, they set the taxes and revenues to meet expenses, they established rules of collecting tribute and rules after the Treasury was to realize its activities.

The draft regulation is initially introduced some regulations on land tax (for the first time), as a direct release of land, and some tax regulations like stamp tax, which is pursuing two objectives on the one hand increase state revenues, and secondly, reduce the number of lawsuits pending. These provisions - **the land tax and stamp duty** - will be adopted in the final text of the Regulations, due to the opposition of the noblemen.

⁸⁰⁸ George N. Leon, op.cit., page 40.

⁸⁰⁹ Drept exemplu se poate da cazul căminarului Constantin Boteanu, care a împrumutat statul, conform unei chitanțe, cu suma de „150 lei, adică una sută cincizeci lei [...], în trebuința cheltuielilor țării, cu vadă de doi ani și cu dobânda legiuită și la împlinirea vadei să i se plătească atât capetele cât și dobânda” (Enciclopedia României, 1936, pag.737)

2.5. The modern period

The change of regime in Russia by the end of 1917, Romania has asked the allies for collective security vaults by Moscow, guarantee granted to February 21, 1918. Despite this guarantee, Romania failed even to this day to recover than a tiny part of those values.

In this respect, the main aspects that characterize this period are:

In 1921, the government Averescu having as Finance Minister Nicolae Titulescu (between June 13, 1920 and December 16, 1921) will launch a series of laws (even a program), aimed at reforming public finances in Romania and unify systems imposition. Thus, the proposed reform of Nicolae Titulescu, passed by the Romanian Parliament in July 1921, contained several laws namely:

- **The direct contributions law, by the creation of progressive taxation on income**, it had an modern economic content, aiming to ensure some fiscal and social equity, based on a set of principles, such as requiring actual income made in the declaration taxpayer, progressive and proportional taxation, the introduction of the minimum taxable.

- **The progressive tax on wealth and enrichment of the war**. This tax should be levied on net wealth companies and apply the text of the law provisions, which were there any kind of joint stock companies, cooperative societies and companies limited by shares, including foreign companies limited by shares with branches in Romania.

By this measure, proposed by Titulescu nationalization policy with tax authorities, a policy of nationalization of the country's resources and private capital for the benefit of the community.

Also, this tax would affect the assets acquired during the war, those who have benefited from significant increases in their wealth or have achieved great wealth during the war, should contribute to state revenue with some of them. By law, revenues derived from the application of this tax was intended to liquidate damages of war and internal debt amortization. **This tax**, although acquired parliamentary approval **was not applied in practice**.

- **The luxury tax and turnover**, which is - at that time - new to the Romanian tax system.

In fact, it is a tax on gross turnover, including its base and other taxes hidden costs. The tax charge is based on the idea of a commodity, whenever it passes - by selling a hand to another (taxation, in cascade "or" snowball ", " tax on tax ").

- **The progressive inheritance tax** is a tax placed on the transfer of wealth will affect the gradual concession and property, according to its size.

In 1923, the Finance Minister function was occupied by Vintilă Brătianu, by adopting **the law direct taxes on income tax proportion** is achieved true unification of direct contributions. The new system of direct taxes was based on the idea of imposing real incomes made by individuals or companies. Tax effort largest banks way back, then trade and agriculture, and finally, the last position, with the lowest tax burden, industry.

Brief overview of major tax and specific postwar period and the totalitarian state (socialist state)

The highest yield tax is the tax on income population, which, according to the taxable base is divided into: income tax amounts and tax on non-agricultural income agricultural sources.

- Tax on non-agricultural sources is initially perceived, from workers, officials, scientists, letters and art, self-employed, artisans, merchants and owners of workshops. Imposition was personal, the tax for each person in the party who obtained income. For owners of workshops provide a global tax with progressive rates, to discourage and make them give up these activities. From 1972 to appeal the imposition of those paying distinguished by progressive rates. Some craftsmen who practiced walking activities the quarter due to a flat tax.

- Tax on income earned from agricultural activities was placed on the income of the cooperative, with remuneration of Agricultural Production Cooperatives and on their personal income households and households income on individual producers of the hills and mountains

that was noncollective property. At first the imposition of rules is based on income so-called „middle-income” per square, livestock, differentiated the five groups of districts, depending on climatic and soil conditions. In setting take into account middle income category of land use: arable land, irrigated gardens, orchards, vineyards, meadows, forests, swamps.

Between 1969 - 1971, imposing income from farms has undergone many changes, the orientation of fiscal policy in this area is to discourage land tenure.

- Income tax on collectivist cooperative organizations

Handicraft cooperatives, consumer cooperatives and agricultural production cooperatives due to the state budget, a progressive tax, the installments, depending on the size of the income benefit base is actually made.

- The tax on collective farms land was charged in the period 1955 - 1968 and calculate the fixed amount per square of land, divided into five groups according to their quality. Since 1969 this tax was dropped, and replaced with a tax on the income of members.

- Tax benefit of joint ventures, much like commercial tax profit and dividend of enterprises established after 1995. The base tax benefit of joint ventures is determined by the difference between revenues and expenses, then to be taken is deducted from the reserve fund (5% of the benefit each year and 25% of capital invested). Annual taxable benefit so calculated was required to share 30%, and that was transferred abroad, there was a 10% tax.

- The tax on buildings is set for all types of buildings: houses, business buildings, commercial premises, institutions, etc.. and is supported by individuals and units of various forms of socialist, tax rates differ according to purpose buildings (0.45% - 1.50% of the building). The tax is paid in two equal half-yearly installments.

- Urban land tax is levied on land built and Non-built cities, belonging to individuals and legal persons. Tax is calculated in fixed amounts per square meter of land, depending on location and the use of the land. Budgetary institutions were exempt from this tax.

- Tax on land belonging to the state was about exclusive for state ownership of land.

- Tax on vehicles and animals was collected for individuals having mechanical or animal traction vehicles. The fee was determined based on engine capacity, the number of animals for traction and by the characteristics of the vehicles.

- Flat fees for use of public places are paid by individuals who sell goods, products or objects, in fairs or public spaces.

- Stamp duty fees are charged for natural persons and legal entities that use the services of the state, through its institutions: state arbitration, the State Notary, judges, etc..

- Tax on goods movement is an indirect tax placed on prices of goods of any kind, although the communist period is not recognized the quality of consumption tax. In fact, it was a tax on gross turnover with its known disadvantage, is applied in a single stage of making the goods, usually the manufacturer, the single tax type. He, however rise to the phenomenon of tax to tax because some materials, some parts, included in the cost of the new product to the purchase price which included the tax on the movement of goods. It applies to the wholesale price and vary according to industry types, from 0.50% to 22.50% aiming at an adjustment of yield on branches of national economy.

The tax on movements of goods are received from the cooperative organizations, during the recovery of agricultural products by units of the food industry. These products are bought at different prices depending on the source of supply, but prices were delivering unique manufacturing enterprises. The difference is paid to the state budget as this tax was not - necessary for export goods and investment. The tax is due monthly, but paid decade, wages, or sometimes daily.

- Tax adjustment was introduced in 1970 aimed at removing excessive profitability, its economic content is the same as the tax on movements, but is charged in all cases to domestic production.

- Collection of net production by the company is a tax introduced in 1978, sat on the added value to the price of goods, which are calculated based on net production and other indicators of physical production and value, to encourage and stimulate a higher return businesses, without taking into account the economic base. Although it was recognized as an indirect tax levies to the company net production was a net turnover tax calculated by the analytical method, by adding added value features are redemption amount, asimilate their wages and benefits, taxes and other items Net income. The tax being another tax on gross turnover - that the tax on movements.
- Duties were imposed on imports and exports, in accordance with international agreements and conventions concluded by Romania as a country member of the Monetary Union and other countries were presented to the Customs Code.

3. Conclusions

The financial economy is an economy feudal regalian type field, in which state power is broken in pieces of many fiefdoms.

In the Middle Ages, the legal sovereignty and financial sovereignty - tax are charged by private individuals. In many medieval taxes there are **categories of taxes**. So there were: **the rights of lords for property** (tithe, quinquagesima); **and workers to individuals rights on people** (military service, labor, etc.); **the rights on acts of civil life** (on any property tranfer on inheritance, marriage, etc.); **the rights on the acts of trade and craft** (customs duties, taxes on guilds, etc.); **mint mark rights** and other rights of lords, the clergy and royalty.

All these rights, outside of military service, were not public but were private, particularly for the benefit of feudalism. As these requirements are only partly served the community and is paid mostly in kind and in labor, so they were not a tax but being as a **financial rights over the subjects**.

In an intuitive attempt to define financial distress in the public sector, it can be represented by the turbulence over the normal rhythm of indicators' evolution in the public revenues, due to the influence of exogenous factors coming from the real economy, the behavior of taxpayers as well as to other influencing factors. This way of defining financial distress makes it possible to measuring its composing elements, such as: the turbulence and the influence of exogenous factors. The application of financial distress tests for the public budgetary indicators and the notification of its existence can be of real use for the central and local governments, taxation policy.

Keywords: local government revenues, public taxation, financial distress

JEL Classification: G17 - Financial Forecasting, H21 - Efficiency; Optimal Taxation, G01 - Financial Crises

1. Introduction:

The central governments but also the local ones are presently interested to identify the best solutions for successfully dealing with the global economical crisis, which deteriorated the public budgets, financially contaminating them with the virus of chronic budgetary deficits.

Having this reality, the global economical crisis, the central governments put in practice budgetary policies oriented most of the times towards constraints applied to the operational costs of the governmental device and called for momentary solutions, to solve the crisis of budgetary deficits through public loans⁸¹⁰.

But the problem of public loans is easy to explain when these, in crisis times, assure the financing of public investments; on the other hand, the same loans are very controversial when they assure the financing of consumption costs. A budgetary policy of covering the budgetary deficits through public loans destined for consumption costs (pensions, the salaries of those working for the state) make the experts shiver, having serious consequences on long term on the macro-economical balance of a country.

In fact, the classic and modern economical theories show that for crisis periods, the immediate solutions at hand for the central governments is to support the public investments with implications regarding the jobs increasing and indirect support of the investments in the business sector. The essence of public investments is that through the development of public utilities infrastructure the business investments are to be supported so that the *automated propelling stimulus* for the increase of budgetary revenues is generated. The multiplier of the public

⁸¹⁰ Boloș Marcel, (2006), *Bugetul și contabilitatea comunităților locale – între starea actuală și posibilitățile de îmbunătățire*, Ed. Economică, p.40

investments cannot lead to multiplying the budgetary revenues unless through investments in the business sector⁸¹¹.

In this period of global economical crisis some conclusions are to be learned, written on paper along the time as a matter of fact by the experts in public finances, briefly as follows:

-the budgetary revenues are connected to the real economy, having as main communication channels the percepts and taxes;

-a turbulence generated in the companies' activity on the goods and services markets leads to a turbulence in the public budget expressed most often as budgetary deficits;

-the central governments, during crisis times put in operation budgetary policies which aimed at constraints applied to the operational costs, and naturally supported the investments in the public sector⁸¹²;

-by accident but as a real fact, some central governments, lacking other solutions for the moment, to avoid the financial collapse appealed to public loans to support the consumption costs (pensions and/or the salaries of those working for the state)⁸¹³.

When the momentary solutions, to avoid the financial collapse, were to support the consumption costs from the public loans, was nothing else than the clear fact of weakened economies, not able to produce public revenues to support the consumption public costs. This uncontested reality leads to the idea that a characterization of the national economies can be done through the situations resulted from comparing the public revenues (percepts and taxes from the business sector) with the public consumption costs (operational) which can be expressed as follows:

-percepts and taxes collected from the business environment / the public consumption costs (operational) the national economies have the capacity to generate public revenues, the central governments can develop and support the public investments as an essential condition for keeping a living standard accepted by the population;

-percepts and taxes collected from the business environment / the public consumption costs (operational), the central governments are in the critical point indicating the imminence of starting a crisis, whose causes can be the uncontrolled increase of the public costs or on the contrary a decrease of the economical growth rhythm registered at local level;

-percepts and taxes collected from the business environment / the public consumption costs (operational) indicate the existence of a crisis, regardless of its nature (financial or global economic) or can be the result of uncontrolled policy of growing the public costs.

The third situation is the subject of our research to indicate the conditions of financial distress existent on the market and its influence on public revenues, with immediate consequences as is already known on budgetary deficits of central governments.

The experience demonstrated that during the periods without crisis, the local and central governments appealed most of the times to the necessary tools to support the economical development as a solution for the budgetary deficits sometimes hard to control. Moreover, to respond to the existent needs in the public sector, the governments, especially in pre-electoral periods, supported the salaries increase for the persons working in the public sector, which on long term added consumption costs and an unreasonable support of the budgetary deficits.

All economic theories, regardless it is about the classic or modern theories were elaborated for the situations existent at that time. Therefore during the economic boom periods the crisis situations were not taken into account, as well as the inverse situation is also valid. We know only by intuition if during economic boom times the prudential reserves would have been good to

stock, even if in currency, for the governments to intervene in crisis situations. We don not know if during crisis times some anti-crisis measures have to be taken and not protection measures against the crisis. There are questions, answers, dilemmas which experts in economical sciences should solve even if to adapt the results of their research to the economical reality.

2. What is financial distress and how we measure it?

It is obvious that any interested reader, in the simplest terms would define the distress as a discomfort situation generated by the existence of undesired events, which negatively influence the people's behavior and sometimes their welfare. The distress was conscious for the people in Eastern Europe mostly in the same time with reaching the market economy, when the lack of jobs, unemployment danger, the decrease of the purchase power led to a stressful situation which on long term influenced the welfare of people and generally of the whole population.

How the population protects itself from the forms of stress? The most frequent protection forms against stress is to economize (to make reserves) which offer the individuals a mental comfort that in any situation "*the money can help them*". But forming the reserves is only possible when the economies register situations of economical growths, except the fact that the individuals, during economical boom, have a bigger tendency towards consumption. In crisis times, avoiding stress is almost impossible mostly by the individuals lacking reserves or financial investments. They cannot fight against the stress, being practically condemned to support the negative consequences of crisis manifestations.

It is interesting to study the companies' behavior during economic boom but also during crisis times. The reality showed that during economic boom, in the lack of a solid business, the business people in Eastern Europe were attracted by the short-term gains, being caught in the whirlpool of *speculative businesses*⁸¹⁴. For example, the most frequent expression forms of speculative businesses were the businesses in the construction field but also those resulted from the currency exchange speculations. The speculative businesses worked, true on short term, but most of the times the investors endured, afterwards, the negative consequences of crises and of disappearance of speculative businesses from the market. The behavior of the business environment, in the lack of the speculative businesses, for the boom economic times can be characterized through an emphasized inclination towards investments, and not for making reserves, as we would be tempted to say about a future prudential-pessimist investor⁸¹⁵. In fact if the market would be dominated by the pessimist investors, than the progress, economical growth, welfare would be only theoretical concepts forgotten in the dusty drawers of science. Can we talk about a stress of the business environment during economic boom? The answer is yes only it is a positive form of stress caused by the desire of reaching the development rhythm expected by the investors.

During crisis times, the same business environment in Eastern Europe, in the lack of an alarming culture but also protection against the unwanted impact of crisis, adopts different forms of sheltering against the devastating effects of crisis. Slowing down of the business growth rhythm and the operation at the damage limit is the most frequent type of behavior met among the investors. The recent global economical crisis made the proof of this type of behavior which eventually led to cutting off jobs, the growth of the unemployment level, reducing the volume of the business, etc. Moreover, in the same crisis times the companies, which during economical boom speculatively made businesses, rapidly gave up in the fight with the crisis, closing their doors. The result is that the number of companies going bankrupt rose exponentially. We would be tempted to say that the crisis times are useful for the business sector as it cleans off the "sick

⁸¹⁴ Fabozzi J. Frank, Peterson Pamela, (2003), *Financial Management and Analysis*, 2nd ed., John Wiley & Sons, Inc, USA, pp.35-134.

⁸¹⁵ Gibbons Robert, (1992), *Game Theory for Applied Economists*, Princeton University Press, New Jersey, pp.45-60.

companies". The financial contagiousness of crisis leads even partially to the health condition of the business sector. Is the stress present during crisis times at the level of the business sector? The answer is again yes. Stress has now a negative component, the investors being worried by the protection form they should implement to successfully cope with the unwanted effects of crisis. But the public economy functions connected to the real economy. Any shock in the real economy is inducted into the public one the same as any economic boom in the real economy leads to a boom, if not so intense, in the public economy. It is a vital connection for the public sector whose financial resources are rooted in the real economy⁸¹⁶.

The complex mechanisms of the public services cannot function without a real feeding with percepts and taxes at the necessary level for these services to work. But so as the behavior of the business sector and population is different during crisis times, so as the governments' behavior is different. During crisis times the governments' concern is to control the operational costs of the governmental system and support the public investments. But all these budgetary policies are translated eventually in almost chaotic budgetary deficits, which according to economical theories must finance public investments having only one alternative accepted by specialists to be covered and that is to contract public loans.

In economic boom periods, the same governments, legitimately, are tempted to support the public investments with a double aim: to improve the living standards of the population and to indirectly support, through public utilities infrastructure, the business sector. It is also true that in the same economical boom periods the central governments to gain popularity exceed of generosity and increase the pensions and salaries of those working for the state, but this type of measures must be accompanied by a constant growth of economy to avoid the financial collapse in the public sector. The state of financial distress, as we would be tempted to appreciate only intuitively is also present during economical boom and respectively crisis. This state of financial distress can be understood in a first stage, without considering scientific arguments, as being a malfunction of the normal rhythm of evolution regarding the indicators in the public sector.

This way of defining the financial distress makes that this to have two base defining elements, in our approach and that are: the turbulence and the influence of exogenous factors.

Measuring the financial distress in the public sector and the study of the exogenous factors which determined it help the central governments mostly to adopt anti-crisis measures which could stop the decline of the studied indicator and could lead to its re-launching, with an impact on the macro-economical balance. To prove scientifically the measuring technique of the financial distress the *revenue tax* was considered as indicator in the public sector. As already known the revenue tax is used both for measuring the economical growth at the level of a region/ state and for deducting it between budgets with the help of shared taxes. The study of this indicator's evolution, permanently leads to obtaining information related to the dynamics of employed people but also to information related to the evolution of the salary gains of the employed people at the level of a locality.

Consequently for measuring the financial distress the following stages were taken into account:

- the revenue tax is calculated by the companies and is transferred to the state budget after which by deduction, with the help of shared taxes, is transferred, based on some deducted quotas, to the state budget and to the local budgets;

- each budget where was transferred registers a certain level of the collection noted with (I_{impv}) , for each period of calculation (t_0, t_1, \dots, t_n) ; usually in the case of revenue tax the period of calculation is equal to the calendar month;

⁸¹⁶ Baker, (2003), *Notes for Mathematics, Groups, symmetry and fractals*, Department of Mathematics, University of Glasgow, p.60

-for the series of data constituted the simple arithmetical mean was determined, to identify the average level of the encashment from the revenue tax, using the formula: $I_{impv}^- = \sum_{i=1}^{12} \frac{I_{impvi}}{i}$;

-based on the data series and the arithmetical mean the mean square deviation was established $\sigma^2 = \frac{1}{n} (I_{impvi} - I_{impv}^-)^2$ and the mean deviation ($\sigma = \sqrt{\sigma^2}$) with the aim of establishing the deviation of encashment as to the mean, in normal conditions, without financial distress⁸¹⁷;

-for each budget type (state or local) which collects revenue tax at least two influence factors are important: the evolution of the number of employed people and the average revenue they make;

-the scenarios of financial distress were simulated, by subtracting the number of employed people and the average revenue, respecting the constraint according to which the wage cannot be lower under the average national wage, so that the mean square deviation resulted from the modification of the two indicators, respectively the number of the employed people and the average revenue per person, to embrace consecutively values of $\pm 2\sigma$, $\pm 3\sigma$; For these variations of the two indicators in the conditions of the modification of mean deviation with values of $\pm 2\sigma$, $\pm 3\sigma$, different levels of encashment were registered.⁸¹⁸

The following results were obtained which were validated by the results of the research and that are:

-the financial distress is a phenomenon that characterizes the turbulence of the indicators in the public sector as to the normal evolution rhythm which can be measured with the help of mean square deviation (σ_b) and intervene for the values between ($I_b \pm 2\sigma$);

-the financial distress is determined usually by the influence exogenous factors of the budgetary indicator and is the result of continuous modifications registered by the exogenous factors in the conditions of registering turbulences in the activity of companies or taxpayers;

-the presence of financial distress for a certain budgetary indicator allows the public authorities to adopt policies of avoiding the risk or to diminish or even remove the risk involved by the negative impact caused by turbulence on the normal evolution of the studied public indicator.

3. Measuring the value of budgetary indicators in conditions of financial stress

For each budgetary indicator studied in conditions of financial stress is interested to analyze its value registered when subjected to the stress test.

Why is the stress test necessary? The stress test can indicate the values of the budgetary indicator beyond which, the values registered by the indicator, can lead to the registration of some budgetary deficits that could often be beyond control and for which the volume of public loans to be contracted leads to the substantial growth of the public debt level.

In the case of revenue tax for example, the value of this indicator in financial distress conditions implies knowing the limits for which the encashment of the revenue tax reach the stress limit. Respecting the research methodology for measuring the financial distress such a limit of financial distress is reached when the encashment of the revenue tax register values of the mean square deviation over $\pm 2\sigma$ according to the formula:

$$N_s \times S_l \times \% p \text{ Im } pv(1 - g_i) = 2 \left(\sqrt{\frac{\sum_{i=1}^n (\text{Im } p_i - \overline{\text{Im } p})^2}{n}} \right) \quad (1)$$

⁸¹⁷ Kolmogorov N., Fomin S., (1970), Introductory real analysis, Dover Publications, New York, p. 45

⁸¹⁸ Greene William, (2003), Econometric Analysis, 5th Ed., Prentice Hall, USA, pp.23-45.

Raising to second power and considering the level of encashment 100% the equation indicating the maximum level of revenue tax encashment can be obtained, after which the financial distress conditions are registered, leading to very serious turbulences of the macro-economical balance.

$$N_s^2 \times S_i^2 \times 0,16^2 = 2 \left(\frac{(\text{Im } p_i - \overline{\text{Im } p})^2 + \dots + (\text{Im } p_i - \overline{\text{Im } p})^2}{n} \right) \quad (2)$$

By re-arranging the terms of the quadratic equation of above we obtain the value of revenue tax in conditions of financial distress whose solutions are the following:

$$\text{Im } p_i = \frac{4 \text{Im } p \pm \sqrt{16 \text{Im } p^2 - 8(\text{Im } p^2 - N_s^2 \times S_i^2 \times 0,16)}}{4} \quad (3)$$

The results of applying the research methodology are presented in the case below. If we note the values of the revenue tax indicator in financial distress conditions with ($\text{Im } p_{sf}$) and its mean values with ($\overline{\text{Im } p}$) the conclusion is that the values between ($\text{Im } p \pm \text{Im } p_{sf}$) are securing values which are not affected by the action of influence exogenous factors of the budgetary indicator in condition of financial distress.

4. Conclusions

The existence of financial distress for any studied budgetary indicators is a reality that cannot be contested. Essentially the financial distress of any budgetary indicator indicates that state of turbulence registered by the indicator as to its normal rhythm of evolution, caused most often by the existence of exogenous factors.

Measuring the financial distress can be done for any budgetary indicator with the help of mean square deviation, and the determination of the distress condition can take place by simulating the modification of the influence exogenous factors of the budgetary indicator. By repetitive simulations of the influence factors we reached the conclusion that a condition of financial distress for a budgetary indicator intervenes when the values of the mean square deviation registered are equal to $\pm 2\sigma$. These values of the mean square deviation are registered when the studied exogenous influence factors of the budgetary indicator are modified. Any exceed of these values of the mean square deviation can lead to the study of other phenomena such as turbulences and chaos.

Each of the studied budgetary indicators register certain limit values for the existence of financial distress beyond which other phenomena occur, and that can be researched with the help of tools offered by the science of statistics or econometrics. These values of budgetary indicators noted with (I_{sf}) offer information related to the safety channels, inside which the budgetary indicators are not affected by the existence of financial distress. The safety channels have values comprised between $(I_b \pm I_{sf})$, and outside the range of these values the budgetary indicators can signal the existence of turbulences or even chaos with devastating effects on the budgetary balances.

Financial distress testst are used for measuring the existence of influence exogenous factors can be detected which on long term can lead to deterioration of the financial condition of the countries or regions of a country. The anti-crisis measures can be identified in due time to diminish as possible the devastating effects of the global economical crisis.

However the financial distress tests have some limits. They can detect the presence of the financial virus established, it is true, through research as present when the budgetary indicators register certain values, but these do not identify the exogenous factors that determine the existence of distress nor the intensity or the level of the influence of exogenous factors on financial distress.

A SHORT ANALYSIS ON THE SENSITIVITY OF TAX REVENUES IN ROMANIA DURING 2000 - 2009

Bunescu Liliana

*Lucian Blaga University of Sibiu
Faculty of Economics*

Mihaiu Diana Marieta

*Lucian Blaga University of Sibiu
Faculty of Economics*

From a temporal perspective, the collected tax revenues for the public budget know a number of changes in terms of flow and collection rates due to changes in factors of influence. The most used method to measure the response, the sensitivity of tax revenue to any changes of a variable is elasticity. This paper seeks to briefly examine the sensitivity of tax revenues to changes occurring in terms of gross domestic product and tax burden in Romania during 2000 to 2009. After analysis, we believe that a pattern regarding the sensitivity of tax revenues to the modification of a factor can not be created, tax elasticity developments and alternations of elasticity / inelasticity are not based on a uniform rule, they differ from country to country, and even in the same country from one period to another.

Keywords: tax elasticity, tax burden, tax revenues

JEL Classification: H 23, H 30

1. Introduction

Taxes generate the biggest part of public resources and that is not a novelty. Currently, both theorists and practitioners` concerns are increasingly focusing on the question of the relative sizing of tax compared to its base of calculation and also compared to the source of taxes, source which is ultimately reduced and expressed in the purchasing power of taxpayers. Taxpayers are more interested in the net incomes and the extent to which these are affected by taxes. Tax burden indicates the degree of taxation, meaning the extent to which taxpayers as a whole, society, economy supports a range of taxes, such as compulsory levies, imposed and charged by the state through legal compulsion. Tax burden and the degree of taxation is a way of sizing the tax incidence.

2. Sensitivity of tax revenues based on GDP

From a time perspective (short or long), tax revenues collected by the national public budget know a number of changes in terms of flow and collection rates due to changes of factors of influence. The analysis of the impact of changes in the factors of influence can be made by studying their magnitude. The most frequently used method of measuring the response, the sensitivity of tax revenue to the change of a variable, is elasticity. It can be measured by a coefficient of elasticity of tax revenues based on GDP and the tax rate, considering other factors unchanged (*caeteris paribus*).

The elasticity of tax revenues based on GDP is the response or reaction of tax revenues to the movement or fluctuation in GDP. A null value of tax elasticity indicates that a variation towards infinity of GDP will determine an incomplete collecting of tax revenues as a result of the self-defense reaction of the taxpayer in front of taxes. Tax elasticity indicates the ratio of relative change in tax revenue and relative change in GDP for a particular country. It expresses the sensitivity of direct and indirect tax levies to changes of GDP or other conditions of public revenues (tax rate). The issue of quantify the degree of tax elasticity was questioned by other

authors: Singer (1968), Chand and Wolf (1973), Khan (1973), Artus (1974) or Ehdai Jaber (1990), each one developing an econometric model of measurement.

The coefficient of elasticity of tax revenues ($E_{t/PIB}$) indicates the degree, fraction or percentage of changes in compulsory levies based on the changes in GDP or other conditions of tax revenues (eg. tax rate). The general form of the coefficient of tax elasticity based on GDP is as follows:

$$\text{Where: } \begin{matrix} V_f & - & \text{tax revenues} \\ PIB & - & \text{GDP (gross domestic product)} \end{matrix} \quad E_{t/PIB} = \frac{\frac{\Delta\%V_f}{V_f0} \times 100}{\frac{\Delta\%PIB}{PIB0} \times 100} = \frac{\Delta V_f}{V_f0} \div \frac{\Delta PIB}{PIB0} = \frac{\Delta V_f}{\Delta PIB} \times \frac{PIB0}{V_f0}$$

Tax elasticity based on GDP calculates how strongly tax revenues collected for the national public budget reacts to a change of one percentage of the GDP, tax revenues being characterized by elasticity or inelasticity, depending on the result of the calculated coefficient of elasticity. It may tend to infinity, may be higher, lower or equal to 1 or may tend to zero causing the framing tax revenue in a particular category of elasticity.

Let's consider the following table where budget executions in matter of public revenues in Romania during 2006 – 2009 are centralized. Data was collected from the General Consolidated Budget, which is why the heading "tax income" does not include contributions owed by taxpayers for state social security, health or unemployment, but only taxes levied by the state budget or local budgets. Considering that the taxpayer, individual or legal person, has to burden of not only levies in the form of taxes, but also social contributions, we will analyze tax elasticity based on GDP, differentiated by tax levies in the form of taxes and by total tax levies, including social contributions.

Table no.1 Evolution of budgetary indicators of the General Consolidated Budget of Romania 2006-2009

							Million RON	
Year	Tax revenues GCB	GDP	Direct taxes	Indirect taxes	Social contributions	Total tax levy (GCB)	$E_{t/PIB}^{819}$	$E_{t/PIB}^{820}$
2009	88324.3	505503.0	35207.6	53116.7	47872.0	136196.3	3.72	2.69
2008	94044.4	513904.0	36283.0	57761.6	48419.8	142464.2	0.73	0.75
2007	76365.8	390800.0	26319.0	46061.2	38843.0	115208.8	1.21	1.17
2006	63792.4	335900.0	19105.2	39448.0	32981.4	96773.8	-	-

Provisional Execution of Consolidated General Budget

The analysis of the sensitivity of tax revenues to changes of 1% of GDP in 2006-2009 showed an elasticity coefficient with a positive sign, regardless of the the considered amounts included in the numerator, which reflects a directly proportional relationship between GDP and compulsory levies. In other words, the two indicators moved in the same direction but not in the same rhythm. A positive economic growth is followed by the same effect of tax levies, while decreasing the amount of GDP resulted in a decrease in the amount of tax liabilities collected by the state.

The type of tax elasticity is not monotonous, but it varies from year to year, alternating phases in which tax revenues are elastic or inelastic in relation to GDP. In 2008-2009 tax liabilities collected by public authorities are characterized by elasticity, with a coefficient of elasticity above the figure 1, of 2,69. This indicates that the decrease of GDP in 2009 compared to 2008, of

⁸¹⁹ Elasticity coefficient of tax revenue (excluding social contributions) based on GDP.

⁸²⁰ Elasticity coefficient of tax revenue (including social contributions) based on GDP.

1,63 percent, generated an even wider change, also negative, of tax liabilities (taxes, fees, contributions) collected at the aggregate level, of 4,4 percent. In 2007-2008 the calculations show a subunit coefficient of tax elasticity based on GDP, of 0,75, therefore mandatory levies are inelastic, an increase of 31.5% of GDP generated a smaller increase of fiscal public revenues, of 23,66%. The period 2007-2006 is characterized by an almost monotonous tax elasticity, the two indicators evolved at about the same pace, but in the same direction.

Differentiated analysis of tax elasticity, including or excluding social contributions, determines us to say that taxes have a higher degree of flexibility, they are more sensitive to changes in GDP. The coefficient of elasticity in 2008-2009 of 3,72, indicates that a decrease of 1.7% of GDP generated in 2009 a deeper reduction of the amounts collected as taxes by 7.1%, ie 4 times higher. The deficiency of statistical public information regarding Romania's General Consolidated Budget in the last 10 years, but especially their delayed publication, determines us to analyze tax sensitivity based on tax levies made by the three components of the National Public Budgets.

Table no. 2 Evolution of tax revenue from National Public Budget and tax elasticity in Romania between 2000 and 2009

million RON						
Year	State budget	State social security budget	Local budgets	Total tax revenues	GDP	$E_{t/PIB}$

Source: Statistical Yearbook of Romania from 2001-2008 and Provisional Execution of Consolidated Budget for 2008 and 2009, Ministry of Finance and own calculations

As can be seen in the table above, tax obligations in Romania are characterized by the predominance of unitary tax elasticity (2008, 2007, 2005, 2004), but there are years with high sensitivity to tax (2009, 2006, 2003) and years with inelastic tax obligations (2007, 2002, 2001). Highest degree of elasticity in the last 10 years in Romania was registered in 2009 compared to 2008, recession brought with it a more rapid decrease of tax levies for the National Public Budget compared with that of gross domestic product in the same period. Highest degree of tax inelasticity occurred in 2001, of 0,61, a 45,2% increase in GDP generated an increase of only 27,7% of compulsory levies made on behalf of the National Public Budget.

Static or dynamic analysis of tax elasticity in Romania has no relevance without addressing certain issues of comparison at international levels, European level to be exact. From this point of view we are interested to compare the degree of tax elasticity in Romania with the average recorded in the 27 member states of the European Union. The average tax elasticity of tax liability based on GDP in the EU-27 was 0,17 during 2008/2007, ie we face inelasticity. The positive sign of the tax sensitivity coefficient indicates a trend in the same sense of aggregate GDP in the European community and of taxes and contributions owed by all taxpayers, individuals or legal people, community residents. The increase of GDP of the European Union in 2008 with 1% to 12.506.778,5 million EURO, generated a positive development of tax levies of

only 0,2% to 5.026.047 million EURO. From a structural point of view we can see a strong inelasticity in the case of direct taxes, which tend to zero in 2008 (0,15). A change in the GDP of the EU-27 generates an evolution in the same direction, but much smaller, of levies from direct taxes. EU-27 is characterized by a high degree of sensitivity between GDP and social security taxes collected by member countries, namely between GDP and indirect taxes. A change of 1% of GDP generally results of the European Union countries to collect with more than 1% of social contributions in their social security system. Noteworthy is the negative sign of the coefficient of tax elasticity of indirect taxes, which means that the increase of GDP by 1% resulted in the reduction of consumption taxes by 2,4%.

Romania presents a situation opposite to the European Union average in 2007-2008. In the of our country indirect taxes are the most sensitive to GDP changes, recording a unitary elasticity (1,01). Instead, tax inelasticity is specific for indirect taxes, the people being tempted to make long-term savings, than to consume.

3. Sensitivity of tax revenues based on fiscal pressure

Tax elasticity can also be approached in terms of the relationship of tax revenues – tax burden. The coefficient of elasticity of tax revenue based on tax rate ($E_{t/RF}$) is calculated as a ratio between the percentage of changes in direct and indirect tax revenues and the percentage of changes in tax rate, while the other factors that influence tax revenues remain unchanged (caeteris paribus).

Where: Vf- tax revenues
RF – tax rate (tax burden)

$$E_{t/RF} = \frac{\frac{\Delta \% Vf}{Vf0} \times 100}{\frac{\Delta \% RF}{RF0} \times 100} = \frac{\Delta Vf}{Vf0} \div \frac{\Delta RF}{RF0} = \frac{\Delta Vf}{\Delta RF} \times \frac{RF0}{Vf0}$$

It should be noted that the tax elasticity measures the change in percentages, not absolute value (monetary unit), which allows comparisons across time and space. To determine the tax elasticity we need to know the evolution in time of the amounts collected by the public budget as taxes and contributions. During 2000-2007 all European Union member states have experienced an upward trend of compulsory levies on taxpayers. Is this due to the increase of tax burden?

Table no. 3 Structural tax burden in Romania 2000-2007

Year	2000	2001	2002	2003	2004	2005	2006	2007
Tax burden (Including social contributions)	30.4	28.9	28.1	27.7	27.3	27.9	28.6	29.4
Tax burden (Excluding social contributions)	19.3	17.8	17.4	18.2	18.1	18.2	18.8	19.5
Indirect tax burden	12.2	11.4	11.6	12.3	11.7	12.9	12.7	12.8
Direct tax burden	7.9	6.4	5.8	6.0	6.4	5.3	6.1	6.8
Social contributions` burden	11.2	11.1	10.7	9.5	9.2	9.7	9.8	9.9

Source: European Commission, Taxation Trends 2009

After analyzing the relationship between tax burden and the dynamic of tax revenues (including social contributions) in the EU-27 and Romania, we find that there may be a double correlation between the two indicators: a direct relationship - increase of tax burden is followed by the increase of the amount of collected tax revenues, which corresponds to the economic zone of the Laffer Curve (since 2003 for the EU-27 and in Romania after 2005), indirect relationship - increasing the tax burden creates a self defense reaction of taxpayers who are no longer willing to pay tax obligations and restrict their activities, thus revenues collected by authorities decrease, which corresponds to the non-economic area of the Laffer Curve, (EU-27 in 2001-2002, Romania in 2001-2004).

In the 27 European Union member states, during 2005-2007, there were recorded coefficients of elasticity higher than one and with a positive sign, indicating a directly proportional evolution of tax burden and tax liabilities collected on average by the 27 member states, a change of 1,4% of the first indicator causes a broader change of the second one, of over 5%. The most striking development was recorded in 2006 compared with 2005, when an increase in the tax burden of 0,3% from 36,9% in 2005 to 37% in 2006, was accompanied by an increase in tax revenue of 6,93%.

The evolution of tax revenue elasticity based on tax burden in Romania has achieved the same trend with the EU average, the years 2001-2004 were characterized by reductions in tax burdens that have resulted in additional sums to the public budget, while during 2005 - 2007 we witnessed an evolution in the same sense of tax burden and the amounts collected. It should be noted that Romania records very high values of elasticity coefficients when compared with the average of the EU-27, which leads us to say that compulsory levies in Romania are extremely sensitive to changes of tax burden, much more sensitive than in other cases, the Romanian taxpayer quickly reacting to any change of the tax burden he has to bear. The period of inversely proportional relationship of the two indicators in Romania, between 2001-2004, stands out through a spectacular evolution in 2003, and 2004, when the gradual reductions with a few percents of the tax burden were accompanied by increases of the amounts collected to the budget of over 20%. In 2003, for example, a reduction of tax burden by 1,4% resulted in a positive response of taxpayers, they payed with 28,21% more tax liability to the public budget than the previous year, a situation favorable to Romania. These developments can be explained by the fact that in the same period Romania saw a record number of newly established companies on the fund of the law of microenterprises. We must also note tax elasticity after 2005 when, although tax burden started to rise, Romanians continued to bear it. In this case we deal with a high sensitivity to changes in two indicators (coefficients with values above one), but slightly lower than in the previous cases of reverse evolution of the two indicators. For example, in 2007, an increase of Romanians' tax burden of 2,8% generated a positive reaction of the amounts levied by the state of 22,31%, 8 times more sensitive.

To summarize the ideas above, we can not create patterns regarding the sensitivity of tax revenues to the modification rates of tax burden , developments of elasticity coefficients and alternations of elasticity / inelasticity are not based on a uniform rule, they differ from country to country, and even in the same country from one period to another. Compared to Europeans who react favorably to a tightening tax burden rather than tax relaxation, Romanians react favorably to tax relaxation rather than a tighten one.

4. Conclusions

Knowing the form of tax elasticity is important in the process of decision making about a country's fiscal policy because it allows the determination of the development of total tax revenues collected by the central authorities. Besides the two variables studied above, we can identify a number of other factors that positively or negatively influence tax elasticity, such as the level and nature of tax rates, the sensitivity of tax matter, tax facilities and penalties, the administration of tax claims, the level of fiscal education of tax payers, tax information in all economic and social policies.

Tax burden may be regarded as the part of income that taxpayers surrender to the State as mandatory levies. Looking at tax burden as a mathematical expression of the ratio between tax and aggregate economic indicators is in fact designed to express tax return. The increase of taxes above certain limits incentives not work, investments and savings, but prelongs a crisis, already installed. Also, the increase of tax burden is a prerequisite for conflict and doesn't generate motivation to work. Most tax liability encourages illegal employment and tax evasion. Reduced

tax burden can be obtained on the basis of tax reforms which should aim at increasing the tax base while reducing tax rates without depriving the state budget of the revenues it needs.

THE EFFECTS OF FINANCING SOURCES COSTS OVER THE FINANCIAL AND OPERATIONAL RISK

Chirilă Emil

University of Oradea

Faculty of Economics

The selection of the financing sources of an enterprise constitutes a major problem for the managerial finance field with influences over the economic-financial performances. The theoretical and practical studies did not provide to the scientific research field the proper identification of the representative models for managing the capital structure and to evaluate the real costs for the financing sources.

The liquidity crisis by which are confronted the Romanian companies nowadays, relevant situation for the actual period, imposes the need for correlation and optimization of the capital structure and identification of the financial and operational risks at the level of the enterprises and at the level of the representative responsibility centres in order to valorise at a maximum level the existing financial potential..

Keywords: Cost of the Capital, Financial Risk, Operational Risk, Centre of responsibility.

JEL Code: G32, G31, C53, G11

The main criteria for selection of the financial sources, according to the financial theory and practice are: **cost of capital, financial profitability and the exceeding of the liquidity flow**. Accurate estimation of the capital cost is important for maximizing the market value of the company and for implementation of the investment decisions, leasing, buy back of the own stocks, adoption of a circulating funds policy.

Depending on the level on which is applied, is realized a distinction between the *opportunity cost of the capital*, defined at the level of the investment projects and the weighted average cost of capital, at the level of the company.

Also depending the initial hypothesis and the proposed goal, to the cost of capital are attributed several interpretations. Thus, starting from the *net present value* criteria, the cost of the capital was considered for a long time to be the rate of interest and was used in the capital flow discounting techniques. The actualization rate was defined as the long term interest rate existing on the market. This explanation was used because the financial studies were realized considering a perfect financial market.

Just later was outlined the dependency of the discount rate by the interest rate of the low risk investments, existed on the financial market and by the risk represented by the company or by the project. The evaluation of the risk premium can be realized taking into consideration the influence of the financial structure.

Existence of two decision centres within the company: the managers on one side, and the shareholders, on the other sides, parties which don't have the same motivation, are leading to the distinction of two *cost of capital categories: explicit*, the effective costs sustained by the company and *implicit*, such as the minimum profitability rate required by the shareholders in order to justify the investment of their capital.

The capital investors and creditors are pursuing the remuneration of the capital at a higher profitability, over the average one offered by the financial market, in order to increase their wealth. The managers are acting in the interest of the capital investors, in order to grow the total value of the company, by reduction of the own and borrowed capital costs. One of the ways for reduction is to increase the proportion of the investors which require low remuneration of the

capital, which can lead to the increase of the debt, the loans being obtained at a lower cost than the capital of the shareholders.

In these conditions the **financial risk is increasing the operational risk**, so the total risk of the shareholders' capital is increasing, which endows them to request a higher remuneration rate. It imposed the determination of the global cost of the capital as a weighted average of the costs attributed to all sources of capital.

The global cost of capital (own internal and external and also borrowed) is not an historic cost, but an expectation for remuneration of capital investors, with its help being expressed the market value of the company.

Weighted average cost of capital represents the total amount of own and borrowed capital, corrected with their proportion in the total capital of the company before taxation:

Are considered two main groups of financial sources:

- **Own capital: internal**, obtained thorough auto-financing on the bases of reinvesting a part of the net profit and **external**, received through emission of new shares or by increasing the value of existing ones.
- **Borrowed capital**, such as bank loans, commercial loans offered by the business partners (if are obtained as grants and are not taken into consideration when counting the debts within the weighted average cost of capital formula), discounting loans based on bearer securities, collateral loans, leasing.

The fiscal asymmetry between the interest (deductible) and profit which belongs to the shareholders (un-deductible), **determines fiscal economies at the indebted company**, proportionate with the size of the interests and with the profit taxation rate: $(Dob \times \tau)$, average cost of the capital, being calculated based on the following formula:

$$k_{ec} = k_e \times \frac{CPR}{CPR + DAT} + k_d \times (1 - \tau) \times \frac{DAT}{CPR + DAT}$$

Where:

- k_{ec} = weighted average cost of capital;
- k_e = cost of own capital(equity), which is the profitability awaited by the shareholders;
- k_d = cost of borrowed capital.
- τ = profit taxation rate

For the enterprises which are quoted on the stock market is recommended **to be used market values both for estimation of the value of debts and also for estimation of the value of their own capital on capitalization basis**, which confers an objective and close to reality expression of the opportunity cost of the capital.

The cost of the capital, being an indicator which cannot be calculated objectively and coherently, being based on forecasts with high level of uncertainty, is considered an opportunity cost, which expresses simultaneously the situation of the company through the financial market as a result of its financial policy and of the pursued investment policy and it depends by two important factors:

- **financial structure** (share of owned and borrowed capital in total capital), reflecting the proportion of participating funding sources into the total capital of the company. Distinguished as **permanent capital** (long-term CPR and DAT) used to fund the investment cycle and **short-term capital**, proposed particularly for financing the operating cycle;

- **Specific costs of various components of capital**, especially distinguishing between equity and borrowed capital, the cost of which varies significantly and influence each other

The literature is addressing separately the four major components of capital: **loan, preference shares, reinvested or accumulated earnings and issuance of ordinary shares**.

On determining the marginal cost of each funding source, the composite cost of capital is essentially a marginal cost. **Self-financing is the most reliable source in terms of profitability**, involving also some costs.

Accumulated profits are a component of equity and have a profitability ratio approximately equal to that of external capital, some authors consider that there are only **three major sources of capital**: credit component, preferred shares and ordinary shares. The formula for calculating the average cost of capital is:

$$k_{ec} = k_d \times (1 - \tau) \frac{D}{C} + k_p \times \frac{P}{C} + k_e \times \frac{E}{C}$$

where:

D = market value of nonconvertible debt;

P = market value of nonconvertible preferred shares;

E = Equity market value;

k_d = interest rate on loans (loan capital);

k_p = the cost of preference shares component;

k_e = opportunity cost of owned capital;

C = D + P + E, total value of the capital;

$k_d \times (1 - \tau)$ = cost of the credit component after payment of the tax.

Other possible sources may be taken into consideration according to a specific combination of funding sources of the company: **leasing (operating or capital), convertible debt, convertible preferred shares, warrants or shares held by employees or managers, as stock programs - options**.

Capital cost estimation problems have contributed to the formulation of widely accepted views of scholars and practitioners. The most important are listed below.

- Cost of capital of a company is defined through the rate of remuneration of the different funding sources. The concept is directly related to the rate of return on investment projects having as minimum limit the capital costs, in order to maintain the same market rate for the company shares.

- Based on risk preferences, cost of capital is difficult to estimate, but can be determined by the dividend discount model on an indefinite duration or by the model for valuing financial assets, Capital Assets Pricing Model (CAPM).

- Among the modern methods proposed for estimating of the future evolution of capital costs are included the artificial neural networks and genetic algorithms with a limited scope.

- Cost of debt is given by the actualization rate, which equals the amount received from lending with cash outflows due to credit process, identified as the interest rate.

- Costs of other sources have specific determinations, the cost of the retained benefits which is approximated as being equal to that of own capital (equity), depreciation cost and preference shares cost with the debt costs. Cost of convertible bonds is a probabilistic mix between debt and

equity costs, leasing costs and subsidies cost are also approximated by the cost of debt, with differentiations according to existing regulations.

- Weighted average cost of capital is calculated as a weighted average cost of financing sources used by the company.
- Usage of weighted average cost as the rate of actualization is justified under fulfillment of certain requirements, relating mainly to maintain the level of risk, both economically and financially.
- When investment projects differ substantially in terms of risk, the weighted average cost needs to be adjusted.

Limitations of the usage of **weighted average cost of capital** can be divided into two broad categories:

- **First category**, linked to the method of calculation of its composing elements and even of its own, is determined as a weighted average cost of different funding sources. One problem is the use of weighted average cost of capital after the deduction of profit taxes or before deducting them. Most authors believe that the real cost of capital is that which is calculated before the tax deduction but which takes into account the savings from taxation induced by credit, but there are authors who only consider cost of capital only after tax deduction, arguing that the capital suppliers are interested only in the amounts to be divided between them, as interest and dividends.
- **The second category** refers to the identification of weighted average cost updated with the actualization rate used in selecting investment projects, within the net present value and internal rate of return criteria

Calculation of capital cost is also a controversial topic. Shareholders' expectations cannot be quantified and differ greatly from person to person. Costs of special categories of resources such as grants, depreciation and even retained benefits, which given the fact that are not explicit costs have received different interpretations. Because they are part of the owned capital, often, their costs are compared with the return required by shareholders.

Approach to the financial risk in terms of the effect of borrowed capital, generating interest expense, which have a fixed, insensible at the alteration of the volume of activity. This requires the approach of the financial structure in line with capital costs.

The financial risk refers to the additional variability of the net income per share caused by turning to fixed cost of financing, such as bank loans and loans from bond issues. Fixed capital cost generates financial obligations which must be fulfilled by the company, regardless the size of its gross operating income. Under these conditions, increasing borrowing costs takes to an increase in the company's fixed costs. To cover these costs, the company must obtain an additional gross operating result.

The level and evolution of the financial risk are important for managers and shareholders. Managers are interested by the financial risk in order to optimize the financial structure, respectively to combine the equity with the borrowed capital in order to minimize the weighted average cost of invested capital. Shareholders are interested in the size of the financial risk to establish the remunerations which are requested for investing funds in the company. The earnings are closely correlated with the risk they bear.

The financial risk can be measured using two indicators: **the position indicator**, based on the breakeven level, and the **financial leverage ratio**.

Break even, or minimum critical turnover (CAcr), reflects that volume of the activity of the company needed to ensure that revenues from sales fully cover operating expenses, without profit and it's based on clustering the operating expenses into variable and fixed expenses and is determined using the formula:

$$CA_{cr} = \frac{Cf}{1 - \frac{Cv}{CA}} = \frac{Cf}{1 - Rv} = \frac{Cf}{Rmv} ,$$

where:

Cf – fixed operating costs;

CA - total turnover of the company;

Cv – firm's total variable costs;

Rv – rate of total variable costs;

Rmv – margin rate of total variable costs.

Financial risk analysis, taking into account the financial costs with interest, which have a fixed character are modifying the formula as follows:

$$CA' = \frac{Cf + Dob}{1 - \frac{Cv}{CA}} = \frac{Cf + Dob}{1 - Rv} = \frac{Cf + Dob}{Rmv} ,$$

where:

CA' – critical turnover;

Dob – Interest expenses

Critical turnover (CA') shows which is the level of the sales volumes which have to be registered by a company to cover all fixed costs, both operating and those with interest payment. For financial risk assessment, it can be calculated the **position indicator** to break even level, both as absolute value(α) as well as a relative value($\alpha\%$), as follows:

$$\alpha = CA_1 - CA' ;$$

$$\alpha\% = \frac{CA_1 - CA'}{CA'} \times 100$$

where:

CA₁ – actual turnover.

Position indicator in absolute value, called also as the safety margin expresses the existing gap between the actual turnover achieved during the reported period and turnover corresponding to the overall breakeven level(Ca '). The greater this gap, the firm will have a greater flexibility and adaptability to short and medium term developments recorded in the economic sector where it operates, which will enable it to cover the fixed operating expenses and the interest costs from the total margin account of the variable costs, with no danger of loss occurrence.

The higher are the values of this indicator, the lower will be the financial risk registered by the company and vice versa. **The relative size position indicator**, expresses in percentages the gap between actual turnover and the one associated to the critical point.

Financial risk analysis, may consider, in addition to the cost of borrowed capital and the owned capital cost, in these conditions, in addition to covering the fixed operational and financial expenses, the company must to cover from the margin variable costs (turnover minus variable costs), both the cost of borrowed capital, and of the self-owned capital. Considering that this cost has a constant character, the breakeven formula (the critical turnover - CA") becomes:

$$CA'' = \frac{Cf + Dob + Ckpr}{1 - \frac{Cv}{CA}} = \frac{CFt}{1 - Rv} = \frac{CFt}{Rmv},$$

where:

CKpr – equity cost;

CFt – Total fixed costs (operating, interest and equity).

Critical turnover, set the by the new relationship, shows the value of sales volume which a company must make it in order to cover its fixed operating costs, but also the fixed financial cost of the invested capital (financial debt and equity), evaluation of financial risk using the same position indicators:

$$\alpha'' = Ca_1 - Ca'';$$

$$\alpha''\% = \frac{Ca_1 - Ca''}{Ca'} \times 100$$

The position indicators signifies the difference between the total turnover and the one which allows integrally covering of the operational and financing costs regarding the sold production, exceeding this threshold realizes value for the shareholders.

Positive position indicator means that operating expenses, interest, own capital cost was fully covered and all variable costs associated with the production margin that exceeds the threshold value represent an increase to the profitability of the company after deducting the income tax.

In these conditions it's increasing the value of position indicators, in the management process, in developing and implementing financial policy, allowing the establishment of a direct correlation between sales volume and the total expenditures regarding the production and financing of goods which form are the main active objective of the company.

CONSIDERATION REGARDING TO THE FISCAL REGULATIONS IN SOME EUROPEAN STATES

Cîrmaciu Diana

Universitatea din Oradea

Facultatea de Științe Juridice

Ardeleanu-Popa Carmen

Universitatea din Oradea

Facultatea de Științe Juridice

It can be observed, that the member states of the European Union were guided to implement some reforms in the domain of fiscal politics, the aim of which would constitute in fighting and eliminating the “damaging” fiscal competition, of the differences regarding to indirect fiscality, etc.

Without this political fiscal instrument coordinated by the members of the European Union, the free traffic of capitals could be transformed into a determinant factor of the cross-border fraud.

Keywords: tax law, financial crisis, regulatory framework for Tax

Cod JEL: K34

From the foresights of the institutional Treaty of the European Community (CE Treaty) we outline the fact that at a fiscal level, the national sovereignty is manifested (with some exceptions) through the fact that the national Governments and not the European Union are those who make decisions upon the taxes which must be paid by their citizens. This way, the primary objective of the European Union is to assure that the national fiscal regulations respect the general orientation of the Union and that these regulations show no disloyal advantages for some companies from a country in front of their competitors from an other, the communitarian fiscal politics sustaining the principle of unique market and that of the free traffic of capitals.

It is known the fact that the taxes are contributions created to finance public expenses, but the priorities in the matter of expenses are different in every member state, and the European Union does not intervene, in the condition that these must be maintained in reasonable limits. In the context and under the condition of some prudent actions in the matter of economical politics, the member states have great freedom in deciding how to spend their money and what taxes are applied to finance their expenses.

Though, in the matter of indirect taxation it is assessed the legislative harmonization, because this type of fiscality influences the free traffic of goods, the free practice of services – the indirect taxes are contained by the final prices of goods and services, so that it increases the risk of the distortion of the communitarian transactions; that’s why the legal dispositions are more fixed in the matter of harmonization of the fiscal politics.

For the majority of the legal aspects in the domain of direct fiscality there is no need for a harmonization, so that these are at the appreciation of the member states of the European Union, also respecting the principle of subsidiarity.

Having in attention these facts we try to make a concise presentation of some elements of fiscality from some member states of the European Union..

The *Austrian* tendencies in the fiscal matter have been manifested in the direction of diminution of the taxes between the period 2008/2012. More concrete, the principal aspects applied by the fiscal reform from year 2009 aims the followings:

-reduction of tax rates on salaries and income⁸²¹ – Austria using the progressive method of taxation, in this case⁸²²;

-increase of the exemption limit and changes concerning the reduced tax rate of other receipts;

-increase of the child tax credit from € 50.90 to € 58.40/month;

-analogue adjustment of the single-parent tax credit;

-introduction of a child tax-free amount of € 220/child/year;

-deductibility of child care costs up to € 2,300/child/year for children up to an age of 10;

-tax exemption for employers' subsidies for child care up to € 500/child/year;

-change from the tax-free amount for profits invested by entrepreneurs subject to accounting to a tax-free amount for profits as from 2010: the tax-free amount will be increased from 10 % to 13 % and the requirement for investing profits will be abolished up to € 30,000;

-abolishment of the preferential taxation for retained profits as from 2010;

-abolishment of the preferential tax treatment of stock options as from 1 April 2009;

-tax deductibility of donations for humanitarian purposes, for development cooperation and emergency aid up to 10 % of the profits or income of the previous year;

-increase of the maximum deductible amount of contributions to churches to € 200 as from 2009.

The economical crisis have affected France too, in the moment when this country had already confronted with the increase of the budget deficit – this way there were also outlined difficulties in fiscal matters. In case of the taxation⁸²³ of the incomes of physical persons, the scheme of progressive taxation is presented this way (fractions of taxable incomes of the physical persons; the taxable income is divided according to a fiscal domicile, for example, into one part in case of a single person, into two parts in case of a married couple, etc.):

Table no.1

Fractions of taxable income (one part)	Rate
up to 5852 euro	0%
from 5852 euro to 11673 euro	5,5%
from 11673 euro to 25926 euro	14%
from 25926 euro to 69505 euro	30%
over 69505 euro	40%

In the German fiscal spectrum it is observed the introduction, beginning with January 1st 2009, of the tax restrained through stop by the source, upon the incomes of the capital⁸²⁴. Also, an other important moment was the adoption , at the end of 2008, of the reform plan of the system of

⁸²¹ The Income Tax Act covers the following seven categories of income: income from agriculture and forestry; income from self-employment; income from trade or business (*categories of business income or income from profit*); income from employment; income from investment of capital; income from rental and leasing; other income (*income from receipts over expenditures or categories of non-business income*).

⁸²² Among the effects of this measure it is outlined the fact that, whereas in 2008 2.54 million people out of 6.535 million taxpayers did not pay any taxes on salaries/income, from 1 January 2009 2.7 million people no longer pay taxes on salaries/income.

⁸²³ It must be mentioned that the need for taxation is asserted in art. 13 of the 1789 Declaration of the Rights of Man and of the Citizen: „for the maintenance of the public force, and for administrative expenses, a general tax is indispensable [...]”, adding that „it must be equally distributed among all citizens, in proportion to their ability to pay”. Article 14 of the Declaration states that „all citizens have the right to ascertain, by themselves or through their representatives, the need for a public tax, to consent to it freely, to watch over its use, and to determine its proportion, basis, collection and duration”.

Unlike other mandatory levies, *taxes may be assessed and collected only by virtue of an act of the legislature*, i.e. Parliament.

⁸²⁴ Named „*Abgeltungsteuer*”.

heritage taxes – the modifications aiming especially the evaluation rules of the inherited properties.

The last aspect discussed referring to the actual state of the German legal frame of taxation is regarding to a decision of the Constitutional Court (2008), through which there were declared unconstitutional the dispositions referring to the deduction of costs of transport to the working place. According to those foresights, the tax-payers could not deduct their costs in case when they lived no farther then 20 km from the working place, a contractual amount could be directly deducted for every kilometer of transport which crossed this limit. The constitutional Court had considered that this is an arbitrary limit which breaks the basic regulation of the equal treatment in the front of the law. As a consequence, every tax-payer has the right for deduction by a contractual amount for every kilometer.

In the *Italian* fiscality we must mention the taxation rates of the incomes, as follows:

Table no.2

Taxable income	Rate	IRPEF⁸²⁵ –income tax for individuals
up to 15000 euros	23%	23% of income
more than 15000 and up to 28000 euros	27%	3450 + 27% on the part exceeding 15000 euros
more than 28000 and up to 55000 euros	38%	6960 + 38% on the part exceeding 28000 euros
more than 55000 and up to 75000 euros	41%	17220 + 41% on the part exceeding 55000 euros
more than 75000 euros	43%	25420 + 43% on the part exceeding 75000 euros

Also in 2006 (exactly on October 3rd 2006) the legal frame for inheritance and donations was excepted. The heirs and legatees who benefit from the following property and rights shall pay this tax:

- real estate and rights from real estate. The evaluation of the property is done by multiplying the cadastral revenue by the relevant updated coefficients (see below the calculation of the cadastral value to work out the cadastral and mortgage tax);
- shares in the capital of a company (the value is given by the net equity);
- bonds (excluding government bonds);
- companies (the value is given by the net equity without evaluating immovable goods and good will);
- credits and money;
- movable goods (jewels, furniture).

The taxable base is made up of the *total net value* of the hereditary assets, that is to say of the value of the property and the rights object of the inheritance, net of liabilities and deductible expenses (debts of the deceased, medical expenses and funeral expenses).

The inheritance tax is determined by the office which applies different rates according to the degree of kinship of the heir.

In our presentation we are also dealing with some fiscal aspects from Grand Duchy of Luxembourg, which has tried a long period of time to increase his global competitiveness. These effort were materialized in an extremely high political and social stability, in a coherent legal frame, in a direct and favorable fiscal environment. In 2009 for *tax-payers physical* (Law no. 19

⁸²⁵ That is applied on the following incomes: real estate income; capital gains; income from self-employment; income from employment; corporate income; other incomes.

from December 2008⁸²⁶) and for companies, there were introduced new positive measures in the fiscal matter (for example through adoption of Law from 19 December 2008⁸²⁷).

For the physical person tax-payers⁸²⁸ the new thing is represented by a better consideration of the inflation by introducing the new fiscal credits, the better payment method of the children allocation, sustaining the donations for some charity organizations and the annulment of the taxes restrained by the payment of debts by some saving institutions.

The directions of the fiscal politics(implying fiscal legislation) elaborated by the Ministry of Public Finances with the cooperation of the three fiscal administrations („Administration des contributions directes du Grand-Duché de Luxembourg”, „Administration de l’Enregistrement et des Domaines” and „Administration des douanes et accise”) will aim even in the future to assure the balance of public finances.

In the fiscal system from Bulgaria, an important moment was represented by the introduction of the unique level of taxation⁸²⁹ (10%), this being the lowest taxation level of the personal incomes in Europe; the system of unique level of taxation have registered positive effects because the simple method of calculations, the equal treatment of tax-payers, the low level of taxation. In these conditions it was considered, that the adopted fiscal politics had a primordial role in the economical development of Bulgaria, especially in 2008.

The fiscal system of Croatia had not registered essential modifications in the last period, the main fiscal incomes of the state having as source the tax on the personal incomes, the company taxation, the Value Added Tax and excise duties. Though, we must mention that from the total amount of these fiscal incomes, the greatest part is registered by VAT.

In the Dutch tax system, the rate for income from employment and home ownership is a progressive rate that is charged over four „brackets”. As a result, the private taxpayer will pay a proportionally higher amount of tax as his income increases. tax rates in 2008.

Table no.3

Taxable income from employment and home ownership	Tax rate ⁸³⁰
up to 17 579 euro inclusive	2.45%
17579 euro to 31589 euro inclusive	10.70%
31589 euro to 53860 euro inclusive	42.00%

⁸²⁶ „Journal Officiel du Grand-Duché de Luxembourg”, no. 198, from 23. dec. 2008, p. 2622-2629.

⁸²⁷ „Journal Officiel du Grand-Duché de Luxembourg”, no. 207, from 24 dec. 2008.

⁸²⁸ We are referring to the matter of income taxation. According to this legal dispositions tax-payers are:
 -resident taxpayers, i.e. those physical persons who have their domicile or normal place of residence in Luxembourg. Luxembourg residents are taxable on their worldwide income.
 -non resident taxpayers, i.e. those physical persons who have no domicile or normal place of residence in Luxembourg. Non residents are taxable on income arising from Luxembourg sources only. Taxable income consists in the total net income less special expenses.; but only the following categories of income are taken into account for the determination of total net income: trade and business income; agriculture and forestry income; income from independent professional services; net income from employment; net income from pensions and annuities; net income from capital and investments; net income from rentals and leases; sundry net income.

⁸²⁹ *Law on taxes on the income of natural persons* (01.01.2007), with the ulterior modifications and completions.

⁸³⁰ Tax rates in 2008.

53860 euro and more	52.00%
---------------------	--------

Not at least we try to present concisely the main elements of the Hungarian legal frame in the fiscal domain, represented mainly by: [Act XCII of 2003 on the Rules of Taxation](#); [Act CXVII of 1995 on Personal Income Tax](#); [Act CXXVII of 2007 on Value Added Tax](#); [Act LXXXI of 1996 on Corporate Tax and Dividend Tax](#); [Act XLIII of 2002 on Simplified Entrepreneurial Tax](#); [Act CXX of 2005 on Simplified Contribution to Public Revenues](#); [Act LIX of 2006 on the Introduction of the Special Tax and Bankers' Contribution Intended to Improve the Balance of Public Finances](#); [Act XCIII of 1990 on Duties](#); [Act LXXXVII of 2003 on Consumer Price Subsidies](#); [Act XXXIV of 1991 on Gambling Operations](#).

In the domain of taxation of physical persons the legal regulations outline the following categories of taxable incomes:

-incomes to be consolidated: income from activities other than self-employment, income from activities of self-employment and other incomes to be consolidated;

-incomes taxed separately: (in-kind benefits, capital gains, income from private businesses and income from rental of real estate). In case of the incomes from the first category the taxation is represented in the following way: the rate for the combined tax base that is under 5 million HUF is 17 %, for incomes higher than 5 million HUF a fixed amount of 850.000 HUF + a percent of 32% for the amounts over 5 million HUF⁸³¹.

In the matter of taxation on income/profit of judicial persons we mention that pursuant to the Corporate Tax Act, the following are deemed resident taxpayers:

-companies established under Hungarian law (thus, firms established under the Act on Business Associations: joint stock company, limited liability company (Kft.), joint company (Kv.), general partnership (Kkt.), limited partnership (Bt.) and other organizations (foundations, associations);

-non-resident taxpayers performing entrepreneurial activities at business premises in Hungary.

No group taxation is permitted under Hungarian law and in general the tax year corresponds to the calendar year.

We can observe that in every state, the fiscal politics are based on the national public budget, the budgetary expenses and incomes, constituted in great part by taxes and fees, will influence the destiny of the national economy (even on communitarian level, the economical politics are implemented through monetary and fiscal politics – form here originating the particular importance of the establishment of the general frame of these regulations).

⁸³¹ Beginning with 01.0.2011 there will be modifications by the quantum of the tax, this way for the incomes under 15 million HUF there will be a percent of 17%, and for the higher incomes then 15 million HUF, the tax will be a fix amount of 2.550.000 HUF + a percent of 32% for the amounts over 15 million HUF.

THE IMPACT OF THE ECONOMIC CRISIS ON CREDIT INSURANCE

The insurance domain is one of the most complex and extensive areas of the market. However this field is very risk exposed especially in this period of economic instability. One of the most non-performant insurance products at this time is the credit insurance. Due to inability to pay and increasing bad loans, insurance companies have decided to remove these products from their portfolio. We believe that the signs that led to this situation have been very visible for a long time, but the insurance market players refused to give too much importance to them because they based their operations on the artificial strength of the whole system. In this paper we want to show how things have evolved on the credit insurance market as compared to the general insurance market, and if the present situation could have been anticipated and avoided.

Keywords: crisis, inflation, hazard, credits, performance, panel data.

JEL Code: G22, G21, C23

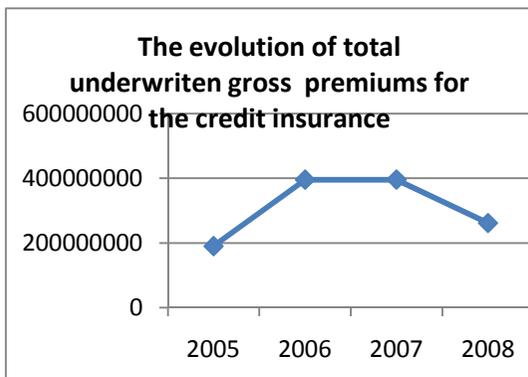

In these times of economic instability the players belonging to both the national and international financial market attempt to protect themselves as effectively as they can against the risks. Thus, an important help should arise from the insurance companies, which should offer viable products for covering the credit risk. Credit insurance should protect financial institutions from the possible occurrence of bad loans. Increasingly more people are late in paying bank lending rates, so that, in June 2009, the total amount of rates paid with a delay of less than 30 days was of 817 million lei. Meanwhile, according to the National Bank of Romania, the delays of more than 30 days had accumulated to 4.98 million lei. Compared with the same month of the last year, 2008, the rates of late payments rose almost 4 times. Simultaneously with these payment delays, the share of overdue debts in the total balance of loans rose to 2.58% in June. All these after in June 2009 the level was of 1.17% and at the end of the year it reached 1.47%. In addition, the number of debtors is still growing. According to the data centralized by the Credit Bureau in late June, more than 600,000 individual clients had more than 30 days delays on payments. At the same moment the total amount of the population's debts of loans smaller than 20,000 lei was of 1.8 billion lei. A recent study carried out by Deutsche Bank warned that the rate of bad loans might get to 15-20% by midyear, in Romania and Bulgaria. In addition to increasing bad debts, banks continue to face a decreased demand for loans. According to a study released by GfK Romania this year, Romanians fear that they would no longer be able to pay their debts.

In Romania, most insurance companies provide specialized products to cover the credit risk. However, as it would be proved by the following analysis, these products have a relatively low

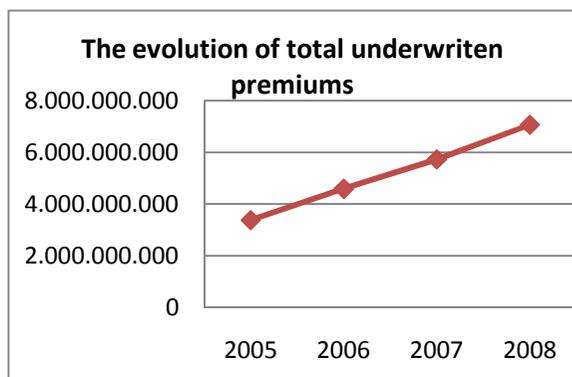

weight in the total subscribed insurances and their share in the total insurance subscriptions is in a continuous decline. It is interesting to see how these types of insurance have evolved in recent years, and most important we have to analyze how the insurance companies have acted before the start of the economic crisis. During the reported period (2005-2008) a steady decline in the share of the credit insurance in the total gross subscribed premiums for the general insurances may be observed. On the other hand, the total gross premiums subscribed for generale insurances by insurance companies have been continually increasing. From the graphs below we may see that the total underwritten gross premiums have a much higher growth rhythm, while the credit insurance underwritten premiums in the first phase, 2005-2006, have sharply increased then showed a constant trend, 2006-2007, and then have fallen, 2007-2008. These premiums have decreased mainly due to the economic conjuncture especially because insurers have made a more careful selection of risks. Furthermore, the credit insurance premiums have decreased by 51.79% as compared to the 2007, so this trend diminished their share in the total written gross premiums of general insurance by 2.7% in 2008 compared to 6.9% in 2007, respectively 8.6% in 2006.

Fig.1 The evolution of total gross underwritten premiums for the credit insurance.

Fig. 2 The evolution of total underwritten premiums

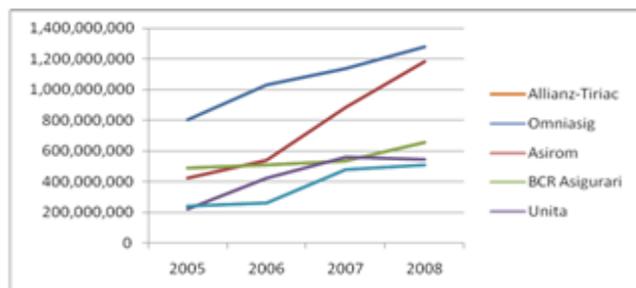

Source: Authors' processing

Source: Authors' processing

Throughout the examined period the market leader, having a share of 18.09% from the total written gross premiums of 2008 was the Alliant Tiriac Company, its premiums summing up to 1,278,805,131 lei. It is followed by companies like Omnisig, Asiom, Astra Insurance, as it may be seen from the following chart:

Fig. 3 The evolution of total gross underwritten premiums for 2005-2008(lei)

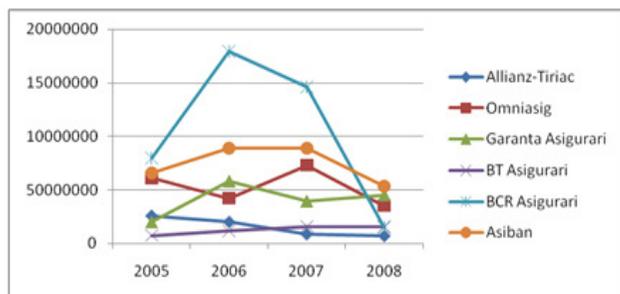

Source: Authors analysis

Despite the fact that the global economic situation is in a precarious situation, insurance companies still manage to increase the amount of gross written premiums. As is may be seen, Omnisig recorded by far the most impressive growth during 2006-2008. This can be put mainly on the account of two considerents. A first hypothesis is that the company would offer a wide range of products for all categories of customers at a lower price than its competitors. However we do not think this strategy could have such a big impact on the gross written premiums. In

addition, we tend to believe that Omnisig reduced the level of risk analysis so they could give insurance policies much easier. This policy may prove to be detrimental, because the insurance premium does not cover the intensity of the risk. Cristian Constantinescu, general manager of Allianz-Tiriac Insurance and chairman of the National Association of Insurance and Reinsurance Companies from Romania (UNSAR) said in mid-2007 "competition, as it is in Romania, is not linked to the consumer insurance, because there is no culture for insurance. Beside the price, nobody looks at anything. It is absolutely absurd to have large price differences both at the same insurance product. Nobody can understand some of these prices. At this time the competition is absolutely unfair. There is competition, but it subscribes only for the sake of subscribing whiteout considering the consequences. That's what happens now, according to the results from the market companies".

Next we will present the way that these market leader companies have addressed the problem of providing credit insurance:

Source: Author analysis

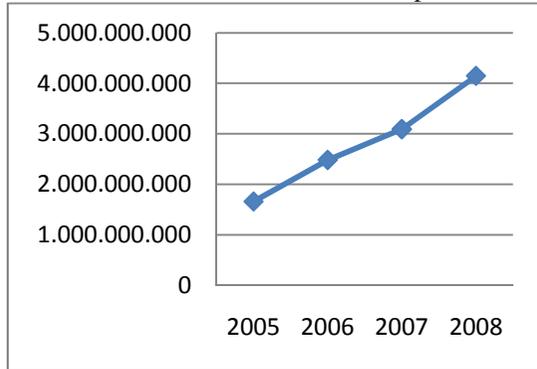

Fig. 4 The evolution of the gross premiums for the credit insurance for 2005-2008(lei)

It may be noted that although Allianz-Tiriac is the insurance market leader, the gross written premiums for credit insurance are rather reduced. The market leader of this area, accounting for 28.13% of the market, is Asiban which is not even located in the top 5 companies of the insurance market. This graph points out that among companies to offer credit

insurance products there are included insurance companies which are components of financial groups. The sharpest decrease in revenues from credit insurance premiums is recorded by BCR Insurance. This sinuous evolution is based also on the company's management. While the banks were willing to give credits to anyone, the credit insurance market was seen as a great opportunity to get profits. Excluding the risks assumed, once with the increasing outstanding loans, insurance companies began to record significant losses. Thus, many companies have reduced the activity of the insurance sector. The strongest example is BCR Insurances, which currently does not offer credit insurance products. Oscillations in the evolution of gross premiums for credit insurance have been registered by all the companies of the market, the exception being BT Insurances which managed to attain a sustained and constant evolution. Mainly the financial groups are currently trying to quit unprofitable products and one of the first products to be waived were the credit insurances. This may be a consequence of two things. Primarily due to the economic context, the number of loans fell sharply and this insurance has not been needed on the market. A second factor could be a psychological one, caused by the panic from the banking sector. So the insurance company has not given insurance policies as easily as before, quantifying more carefully the risks that the company is exposed to.

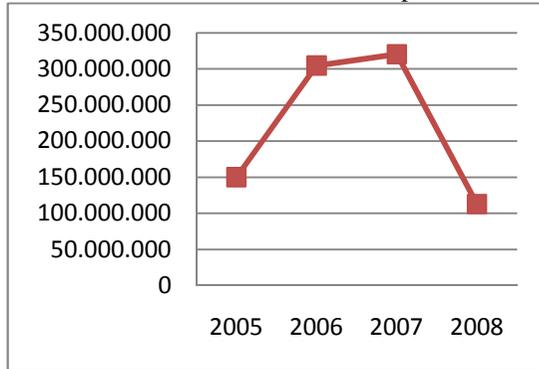

To relate how these insurance policies are covering the insured risks we must analyze the level of indemnities paid by insurance companies..

Fig. 5 Gross paid indemnities for the credit insurance in the 2005-2008 period

Source: Authors' processing

Fig. 6 Total gross paid indemnities in the 2005-2008 period

Source: Authors' processing

A sharp decrease of 2008 gross paid indemnities for the credit insurances may be noticed while the total indemnities are constantly increasing. But the insurance field has always been an atypical industry. In the current economic context, insurances are still the field that manages to attract the most money from the economy. Total gross underwritten premiums in 2008 increased by 23.42% compared to 2007 while the level of indemnities rose by 34.05%. The trend for insurers is to pull out the non-performant products from their portfolio. Thus the gross written premiums for credit insurance fell by 40% in 2008 compared to 2007 and indemnities fell by more than 65% during the same period, after in 2007 they recorded a growth of 5%.

Another important indicator to be assessed is the rate of damage. This indicator can be determined for each type of insurance, with particular importance in assessing the financial and economic results of the insurance company. When this indicator records high values, the financial situation is unfavorable for the insurer.

Next we will present how the damage rate for general insurances evolved by comparison with the credit insurances. The damage rate for general insurance records a constant trend during the period under review, recording a growth from 49.16% to 58.62%. Not the same thing may be observed about the damage rate for de credit insurances which recorded much higher values. Thus the highest rate was recorded in 2007 with a value of 80.96%, and then it decreased to a value of 59.21%.

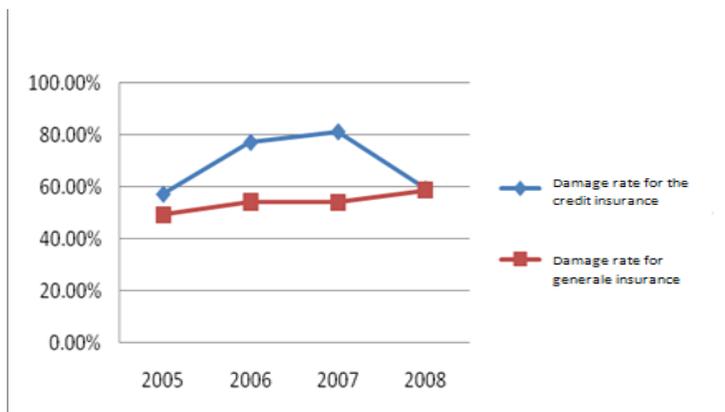

Fig. 7 Evolution of the damage rate in 2005-2008

Source: Author analysis

By analyzing the indexes with a fixed base it is observed that, in 2008 as compared to 2005 General Insurance damage rate grew with 19.24%. Unlike this, we can see that on the analyzed period, at the credit insurance, in 2008 as compared to 2005, it registered an increase of only 3.39%. Even if the damage rate on general insurance grew a lot more, it shows a certain constant trend from year to year, while not the same thing may be said about the damage rate on credit insurance, which records a much higher fluctuation from one year to another.

In the case of the formerly presented indicators we'd also verify the hypothesis of an existing correlation between the volume of gross written premiums in credit insurance and the total volume of gross written premiums in general insurances, by using panel data⁸³². For this purpose, we created a database containing data corresponding to the six insurance societies who managed to maintain their top position on the credit insurance market, i.e. Alliantz-Tiriac, Asiban, BCR Insurance, BT Insurance Garanta and Omiasig, with respect to the gross written premiums on credit insurances and the total volume of gross written premiums for general insurances, during the 2005-2008 years, information that were taken from the annual reports of the Insurance Supervisory Commission in Romania. These models were at first estimated with the method of least squares for panel data (Pooled OLS), then with a model with constant effects (Fixed Effect Model FEM) and a random effects model (Random Effect Model - REM). In order to estimate the parameters of the built models the Gretl⁸³³ software package was used.

For this purpose, the following notations were used:

V_1 = gross written premiums in credit insurance, the endogenous variable, in lei;

V_2 = gross written premiums in credit insurance, the exogenous variable, in lei;

u = residual variable.

The following econometrical linear model was built:

$$V_1 = f(V_2) + u \Rightarrow V_1 = a_0 + b_0 * V_2 + u$$

Analyzing the results obtained with these three models, using data for these six societies, we see that they are significant. In order to choose between the estimator obtained with the Pooled OLS model for panel data and the one obtained with the constant effect model, an F^{834} test was performed, based on the hypothesis that all free terms are constant and we could see that the best estimator is the one obtained in the case of the fixed effects model. The Random effect model assumes that the medium individual effect is framed in the constant term, and the error term includes the unobserved individual effect⁸³⁵. Still, an optimum answer must be given to the *what panel method should be used?* question. In order to test these last two models, with fixed and random effects, we use the Hausman test⁸³⁶. Through this test the existence of the efficiency and inconsistency of estimators (for the models) is verified.

⁸³² Panel data models allow a single coefficient to summarize the impact of a variable upon a group of time series dependent variables (a group of companies, countries, regions) and the estimation of specific coefficients (constant or independent variables coefficients) for each time series considered as dependent variable - fixed effects.

⁸³³ Gnu Regression, Econometrics and Time-series Library is a platform software for econometrical analysis.

⁸³⁴ If the calculated value of F statistics is higher than the table value, then the null hypothesis of free terms equality is rejected. In this condition we may say that fixed-effect model is preferable to the common constant model.

⁸³⁵ In the case of this model we consider that the societies differ in relation to the linear relationship between the two data sets, by random error series.

⁸³⁶ If the statistical value is higher than a table value, then the null hypothesis is rejected, considering that, in this case, the second model is more suitable for analyzing the relationship between the two variables. Hausman, J. (1978), Specific Tests in Econometrics, 46.

After the simulations on the panel with fixed effects method, the free term a_0 obtained had the value 33782900 (0.0310**⁸³⁷) and b_0 had the value 0.0259427 (0.4137). So, we may say that, at a V_2 increase of 1 lei, V_1 will increase with approximately 0.026 lei. R^2 has the value 0.527216, so the exogenous variable considered explains only 53% of the endogenous variable, and definitely there are other factors which influence V_1 . Also, the graphics for the experimental and theoretical values of V_1 , the volumes of the gross written premiums for credit insurance, are as follows:

Fig.8. Experimental values of V_1 and the ones adjusted through the model

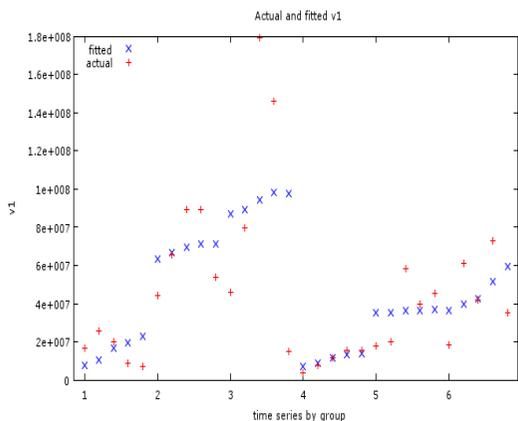

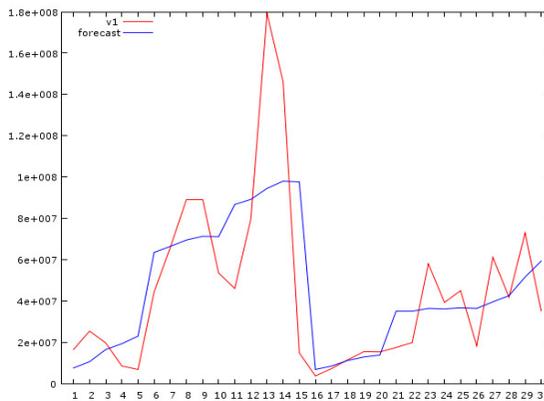

Fig.9 Experimental values of V_1 and the ones adjusted through model

Conclusions

It is a certainty that insurances represent a necessarily "evil". Their main mission is to protect its customers from any risks that may arise from their activities. But as in any other field, there must be a clearly defined limit. This limit is placed between the insured risk and insurance premium. There must be a close connection between them, so that insurance companies could still be interested in continuing their activity on the market, and the clients to continue to rely on these types of services.

In this field, the management of the insurance companies is essential. According to the manager aversion towards risk, the company may have different objectives. Thus, if the manager wants to obtain a high market share he will decrease the risk assessment requirements in order to attract more customers, which will lead to a too much exposure of the company. You may see this in these times of crisis, when insurance companies are forced to compensate the recipients of the credit insurance. Due to the large number of debtors, many insurance companies are in a difficult situation. In order to get rid of these portfolios, insurers turn to reinsurance companies, to minimize the risks.

We think that this difficult period for the global economy and the national one should lead the insurance companies to a more mature, professional and responsible analysis before they offer an insurance policy subscription. We don't think that the insurance companies should give up covering certain insurance products, like the credit insurance, just because bank loans undergo through difficult times. This is not a solution. A new correct system of risk coverage correlated tariffs should be created, and also should be better correlated with the different coverage risk situations so that the customer won't have to suffer when the insurers decide that their profit rates are too low and they should withdraw from the market.

EFFICIENCY AUDIT WITHIN THE SOCIAL HEALTH INSURANCE SYSTEM. HOSPITAL SERVICES PROVIDERS IN ROMANIA

Dobra Iulian Bogdan

„1 Decembrie 1918” University of Alba Iulia

Faculty of Science

Given how the healthcare sector records a continuous rise of costs, decision factors and theoreticians try to develop policies that will contribute to the improving the way resources are used.

Keywords: performance auditing, efficiency, DRG

JEL codes: I11, I12, I18

Introduction

In literature it is well known that the goal of performance audits is to provide information and to ensure the management manner of public resources. This type of audit assesses: “the economy, efficiency and effectiveness of managing public entities by examining the used resource, the information systems and the supply of information, including performance indicators, the monitoring of the results and observing the law and the ethics”⁸³⁸. The most known ways to measure performance are the three traditional Es: economy (*to minimize consumption of inputs*), efficiency (*the relations between inputs and outputs*) and effectiveness (*results compared to expectations*)⁸³⁹.

The present paper tries to determine the performance level recorded by several hospital services providers with the help of one of the three indicators, namely efficiency.

Literature review

Economy, efficiency and effectiveness have been a major concern for all the governments in trying to reform and modernize healthcare systems. It seems the 3Es were adopted as “raison d’être” of the intervention of public authorities in areas like healthcare⁸⁴⁰.

There are authors like Hollingsworth & Peacock (2009) that provide a comprehensive overview of stochastic frontier studies which attempted to measure efficiency in hospital or other health services.

Liu & Mills (2007) shows that organizational (hospital) efficiency can be measured by: multidimensional weighted ratio analysis: “outputs are measured by using one indicator derived by converting all types of outputs into an output equivalent, and that the inputs are measured by using either the total cost measure or an input equivalent”⁸⁴¹, or by production function analysis used to: “estimate the output elasticity from which scale effects can be derived; elasticity of the input substitution that can be used to measure allocative efficiency in combination with the input prices; and efficiency”⁸⁴².

Research methodology

In order to conduct this research, we did a documentation based on various analyses, studies, practice handbooks regarding the efficiency of hospital service suppliers. At the same time, the specialized literature, the current legislation, as well as the practical aspects met in the contracting and reporting activity of medical services by providers was also taken into account.

Regarding the size of the sample, we mention that during the analyzed period, 2005-2009, of a total of 68 hospital services providers, which are included in the category of municipal hospitals, 12 units (17.65%) were subjected to analysis. At the same time, it was considered useful that the sample is composed of municipal hospitals that operate in the same development region (Center Regional Development Agency⁸⁴³). Given that the indicators underlying the analysis of the present study have relatively similar values, we believe that the results of the research can't be distorted significantly.

The indicator according to which the over 80% of hospital services providers contracted budgets with the second credit accountants (Health Insurance Houses) is tariff value for solved case (Diagnosis Related Groups - DRG). According to the law (e.g. Framework Agreement), this indicator is considered a quantitative indicator due to the specific indicators that are included in its structure. The calculus formula for contracted DRG is the Number of discharged cases (NDC) – which is negotiated with the Health Insurance House, multiplied by the Case-mix index from the previous year (CMI) – stipulated in the norms, and multiplied by the Tariff on average case (TAC) – stipulated in the norms. Starting from the calculus formula highlighted above, we tried to conduct a study based on empirical indicators (achieved values of the indicators).

Case study

In the first stage of research, we determined the tariff value for solved case (DRG_{aMH}) achieved by each hospital service provider by multiplying the number of achieved discharged cases ($NDCa$) with the achieved Case-mix Index ($CMIA$) and the achieved tariff on average case ($TACa$) as follows:

$$DRG_{aMH} = NDCa * CMIA * TACa \quad (1)$$

Source: data processed by the author according to the Framework Agreement, 2010

The dynamic of the tariff value for solved case (DRGr)

DRG_{aMH}	13.894.688,48	13.166.258,47	9.474.522,42	7.288.393,00	5.871.645,58

Source: data processed by the author, 2010

In the next stage, with the help of the relation below, we determined the hospital healthcare service provider that in the last five years recorded the closest value to: the average number of discharged cases, the case-mix index of the tariff on solved case, as follows:

$$f_{MH} = \min(|I_{eMH} - \overline{I_{eMH}}|) \quad (2)$$

Source: data processed by the author, 2010

where:

f_{MH} – the minimum value of the efficiency indicator of the municipal hospital compared to the average

I_{eMH} – the efficiency indicator achieved by the municipal hospital

$\overline{I_{eMH}}$ – the average value of the achieved efficiency indicators

In order to determine which organization has the best value of the f_{MH} function, we determined the values for each indicator (for the number of discharged cases -; the case-mix index - f_{CMIaMH} ; tariff on average case - f_{TACaMH}). The summary of these values, calculated based on the data in Annex no. 1, is highlighted in the following table:

Evolution of the smallest deviation from the minimum value of the analyzed indicators

Table no. 2

Indicator\Year	2009	2008	2007	2006	2005
No of achieved discharged cases f_{NDCaMH}	118	180	323	303	135
Case-mix Index f_{CMIaMH}	0,0030	0,0387	0,0042	0,0052	0,0022
Tariff on average case f_{TACaMH}	8,46	8,46	20,33	3,58	3,44

Source: data processed by the author, 2010

By comparing the data in table no. 2 with the values recorded by each provider, the following aspects can be observed:

-for the Indicator “number of achieved discharged cases” (**NDCa**) there are two hospital units that obtained in the analyzed period the smallest deviations from the average (f_{NDCaMH}), namely Sighișoara Municipal Hospital (with 118 cases in 2009, 180 in 2008, 323 in 2007, and 135 in 2005);

-for the achieved Case-Mix Index (**CMIA**), of all the providers, two obtained the smallest deviations from the average (f_{CMIaMH}) in the same period, namely Reghin Municipal Hospital (0.042 in 2009, 0.0462 in 2008, 0.0110 in 2007 and 0.0165 in 2006) and Mediaș Municipal Hospital (0.0052 in 2006 and 0.0022 in 2005);

-for the tariff on average case indicator (**TACa**), of all the providers, five recorded the smallest deviations from the average (f_{TACaMH}) in the analyzed period. In this case also we can see that Reghin Hospital had relatively low values of the indicator compared to the average: 34.33 lei in 2007, 40.62 lei in 2006 and 35.56 lei in 2005.

After processing the data in Annex no. 1 with the help of relation number 2, the following values were obtained the values from Table no. 3.

It can be noticed that during those five years the entity with the most representative values compared to the average if Reghin Municipal Hospital (RMH). Even if in 2006 and 2007 it recorded slightly higher values in comparison to the other units, it ranks second in both periods. Consequently, based on what was revealed before, we believe that RMH can be considered the best performer among the providers and the entity at the base of determining the efficiency indicator for the tariff on solved case for the analyzed municipal hospitals.

The minimum value of DRG_{aMH} in the 2005-2009 period

Table no. 3

Provider\ Year	2009 -lei-	2008 -lei-	2007 -lei-	2006 -lei-	2005 -lei-

MMH	4.746.315,64	3.753.239,26	2.301.042,98	489.007,67	846.627,23
$f_{DRG_{aMH}}$	428.776	154.732	196.412	181.926	229.809

Source: data processed by the author, 2010

In the last stage of the study, starting from the formula for determining efficiency, known in economic theory as the ratio between the obtained results and the used resources; the specific criteria of efficiency audit pursued by the Supreme Audit Institutions (SAI) and the data processed previously, we established the following calculation method for the efficiency of the analyzed hospital ($e_{DRG_{aMH}}$) units:

$$e_{DRG_{aMH}} = \frac{DRG_{aMH}}{DRG_{aPMH}} \quad (3)$$

where:

$e_{DRG_{aMH}}$ – the efficiency indicator tariff on solved case of the municipal hospital

DRG_{aMH} –Diagnosis Related Groups produced by the municipal hospital

DRG_{aPMH} –Diagnosis Related Groups produced by the performing municipal hospital

Following the calculus of the efficiency indicator at the level of each MH, in the examined period, based on the data in Annex no. 1, we obtained the values from Tabel no. 4.

Therefore, we can see that during the analyzed period most providers have recorded values higher than the level considered optimum (≥ 1) for the studied efficiency indicator. Of the municipal hospitals with high values, two are more evident: Odorhoiu Secuiesc Municipal

Hospital had a value of the efficiency indicator that exceeded 2 in the year 2005, and for the other years it recorded values over 1.8; Târnăveni Municipal Hospital recorded values from 1.21 (2005) to 9.7 (2007) and in the last year the value was 1.48. At the opposite pole are three municipal hospitals that recorded during the same period much lower values compared to the optimum level: Săcele Municipal Hospital had values between 0.1 in 2005 and 0.34 in 2009; Codlea Municipal Hospital recorded values between 0.43 in 2005 and 0.27 in 2006 and 2009; and Toplița Municipal Hospital has values raging from 0.65 in the first year and 0.68 in the last year.

The evolution of the efficiency indicator e_{DRGaMH} during the 2005-2009 period

Table no.4

Provider \ Year	2009	2008	2007	2006	2005

Conclusions

It is known that resources within the healthcare system are limited, regardless of the type of the system or of the organization and functioning economic system of the trade economy, which is why it is *completely immoral to waste them*. An inefficient use of resources in a certain area implicitly determines a lack of services in other areas where they are truly needed. Therefore, it is *a moral requirement* to identify the most efficient manner of organization for all healthcare services and to use *economic rationality* at their level.

At the same time, in literature, it is known that efficiency is related to economy. Also, regarding economy, as well as efficiency, the central concerns are related to the deployed resources. The main question is if these resources were used in an optimum or satisfying manner or if the identical or similar results, in terms of quality, could have been achieved with less resources.

Therefore, next to the indicators calculated in this study (efficiency), we believe that in practice, in order to determine performance for a hospital services provider, the economy, as well as effectiveness, must be taken into account.

Therefore, next to the indicators calculated within this study (efficiency), we believe that in practice, in order to determine the performance of a hospital services provider, the economy, effectiveness, as well as quality indicators must be taken into account (e.g. clinical infections).

THE ANALYSIS OF ABSORPTION CAPACITY OF EUROPEAN FUNDING IN THE NORTH WESTERN REGION OF ROMANIA

Droj Laurentiu
University of Oradea
Faculty of Economics

This paper analyzes the Romanian absorption capacity of the funds allocated through the REGIO programme, which is part of ERDF programme. Within the paper are presented the concept of absorption capacity and several opinions regarding its main composing elements. Also the Regio programme, its main axis and its budget is briefly presented. In the last chapter of the analysis a thorough analysis of the implementation of REGIO in the Romanian North-West Region was carried out and several causes for the low absorption of European Funds have been identified.. The process of improving the absorption capacity of European Funds is still at the beginning in Romania and will certainly become an important issue over the following years at all levels of the Romanian society and at the level of the European Funding Authorities as well.

Key words: Absorption capacity, European Union, European funds, Structural Funds, European Regional Development Fund, Financial allocation

The article's JEL code: F15, F36, E61, D78, H77, O23

1. Introduction

The Structural Funds and the Cohesion Fund are financial instruments of the policy of economic and social cohesion. These instruments support the reduction of the gap between the development of different regions from the member states and promote, to this purpose, the economic and social cohesion. The general rules for the Structural Funds and the Cohesion Fund were set by the *EU Council Regulation no. 1083/2006 June 2006*, which defines the general framework for the European Regional Development Fund, European Social Fund and for the Cohesion Fund (European Council, 2006). The eight East European EU member states that joined in 2004, along with Bulgaria and Romania—the “EU10”—are set to receive a huge amount of support from the EU in 2007-13. The eight more seasoned “new member states” will see their funding allocations almost double, and the jump in funding for Bulgaria and Romania compared to the pre-accession funds they had been receiving will be even more sizeable (Economist Intelligence Unit, 2007).

Total funds allocated to the EU10 for 2007-2013

Country	Total assistance (billion (euro))	Per capita assistance (euro)	% of the GDP
The Czech Republic	26,686	2.627	3.5
Estonia	3,393	2.555	4.1
Hungary	25,307	2.561	3.9
Latvia	4,001	1.751	3.9
Lithuania	6,775	2.041	4.2
Poland	67,284	1.773	3.6
Slovakia	11,507	2.102	3.9
Slovenia	4,102	2.082	2.0
Bulgaria	6,674	901	4.0
Romania	19,668	911	3.2
TOTAL	175,397	1.930	3.6

Figure 1. Total funds allocated to the EU 10 for 2007-2013 (Economist Intelligence Unit, 2007).

Despite the EU10 have also been busy building new institutions and training staff to improve their “absorption capacity”— the ability to manage and organise the spending effectively, is still under much debate and questioning both from their citizens and from old member states as well.

2. Defining the absorption capacity

The absorption capacity is generally defined as the “capacity of the countries on low incomes to absorb productively a large volume of foreign aid”, the central issue here being to prioritize the granted aid (Bourguignon and Sundberg, 2006). From this perspective and taking into account the beneficiaries of the international aid, the absorption capacity relates to the general functionality of the particular state, to the adjustment of obvious dysfunctions and to the adoption of minimal administrative and economic standards(Cace et al, 2009).

The analysis by Boot et al, 2001, is the first to systematically put forward the notion of absorption capacity. It has defined it as “the extent to which a member state is able to fully spend in an effective and efficient way the allocated financial resources from the Structural Funds” (Boot, de Veet, Feeks, 2001). On this basis three more specific factors of absorption capacity have been established(Wostner, 2008):

- The *macroeconomic absorption capacity*, which would be defined and measured in terms of GDP;
- The *managerial-administrative absorption capacity* which refers to the abilities and skills of central, regional and local authorities to prepare acceptable plans, programmes, and projects in due time, to decide on programmes and projects, to arrange the co-ordination among the principal partners, to cope with the vast amount of administrative and reporting paperwork required by the Commission, and to finance and supervise implementation properly, avoiding fraud as far as possible.
- Finally, the *financial absorption capacity*, which refers to the ability to co-finance EU supported programmes and projects, to plan and guarantee these national contributions in multi-annual budgets, and to collect these contributions from several partners, interested in a programme or project.

3. Regional Operational Programme - the main infrastructure financing tool of the European Union in Romania

The Regional Operational Programme 2007 - 2013 (REGIO) is one of the main Romanian operational programmes agreed with the European Union and a very important tool for implementing the national strategy and the regional development policies. It is applicable to all eight development regions of Romania. The overall objective of the ROP consists of "supporting and promoting sustainable local development, both economically and socially, in the regions of Romania, by improving the conditions of infrastructure and business environment, which support economic growth". This means that the ROP's aim is to reduce economic and social development disparities between the more developed regions and the less developed ones. (Romanian Government, 2007). As mentioned above and presented in the figure bellow Romania has eight development regions: which contain between four to seven counties(Region 1 to 7) and the Ilfov County of the capital city of Bucharest(Region Eight).

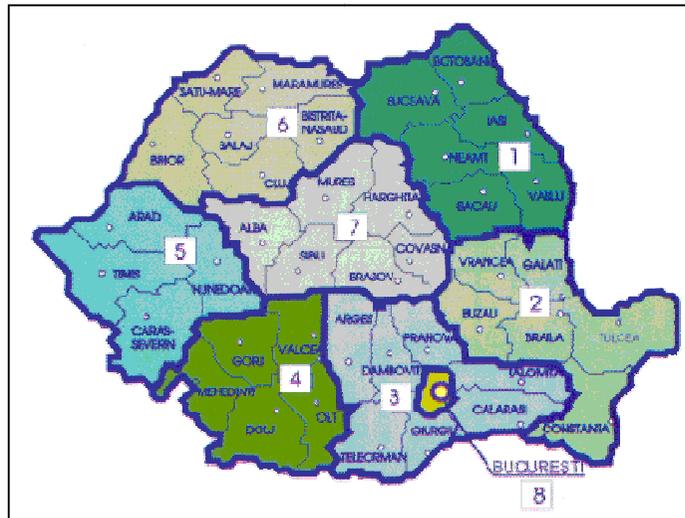

Figure 2. Development Regions – Romania (Romanian Government, 2007)

The Regional Operational Programme in Romania is financed within one of the structural funds of the European Union – the European Regional Development Fund (ERDF). This fund supports EU regions with a GDP per capita below 75% of the European average.

The total budget allocated to the ROP is approximately 4.4 billion Euros in the first 7 years after accession (2007-2013). EU funding represents approximately 84% of the ROP budget. The rest comes from national funds, public co-financing (14%) and private co-financing (2%).

The distribution of funds is done on the priority axes of the Regional Operational Programme. Each priority axis is allocated a certain budget and includes a number of key areas of intervention whose target is the achievement of development objectives.

It is expected that the implementation of this programme will create better conditions for the economic and social balanced territorial development of all Romanian Regions and for urban growth poles able to spread the development.

The balanced development of all the counties regions will be achieved through an integrated approach, based on a combination of public investments in the local infrastructure, active policies to stimulate business activities and support for the valorisation of the local resources, by the following priority axes:

- Support to sustainable development of urban growth poles
- Improvement of regional and local transport infrastructure
- Improvement of social infrastructure
- Strengthening the regional and local business environment
- Sustainable development and promotion of tourism
- Technical assistance.

In order to ensure the implementation of the actions within the program an amount of almost 4.4 billion Euros have been allocated between the six Priority Axis of the fund:

Priority Axis	EU Contribution	National Public Contribution	Total Public Contribution
Support to sustainable development of urban growth poles	1 117 806 529	273 365 256	1 391 171 785
Improvement of regional and local transport infrastructure	758 355 021	118 355 985	876 711 006
Improvement of social infrastructure	558 903 260	98 629 992	657 533 252
Strengthening the regional and local business environment	633 423 700	76 471 117	709 894 817
Sustainable development and promotion of tourism	558 903 264	57 862 924	616 766 188
Technical Assistance	98 629 988	32 876 662	131 506 650
Total	3 726 021 762	657 561 936	4 383 583 698

Figure 3. Regio - Breakdown of finances by priority axis (European Union - 2007)

From this amount of 4.4 billion Euros an amount of 536.41 million Euros are directly allocated to the North-West Region as presented in the programming documents of the Regio Programme (Ministerul Dezvoltării Regionale și Turismului, 2007). North-West Region has a surface of 34,159 sqkm, accounting for 14.3% of the total surface of the country. It comprises six counties (NUTS 3): Bihor, Bistrita-Nasaud, Cluj, Maramures, Satu Mare and Salaj. North-West Region's network of localities comprises of 42 towns and cities and 1,802 villages, grouped in 402 communes. Out of the towns and cities, four of them have a population over 100,000 inhabitants (Cluj-Napoca – 310,194 inhabitants, Oradea – 206,223, Baia Mare – 140,937 and Satu Mare – 115,197), nine between 20-100,000 inhabitants and 29 less than 20,000 inhabitants.

4. Absorption capacity in the North-West Region

To the North-West region of Romania as described above was allocated from the Regio Programme 2007-2013 an amount of 536.41 million Euros. The allocations of funds are distributed between the five implementation axis of the programme. Based on a Report presented by the North Western Region Development (Agency Agentia de Dezvoltare Regională Nord-Vest, 2010), which is dated on 31.03.2010, was assessed the current state of the REGIO funds contracting till that date. As will be presented in the table below the current state of the contracting within the programme for all five axis is in this moment under 24% from the total budget.

Regional Operational Programme - Axis	Amount allocated (mill EUR)	Amount requested (mill EUR)	Amount contracted (mill EUR)	Amount contracted %
Axis 1 - Support to sustainable development of urban growth poles	168,19	82,32	0	0,00%
Axis 2 - Improvement of regional and local transport infrastructure	105,99	218,02	95,33	89,94%
Axis 3 - Improvement of social infrastructure	79,50	161,66	11,65	14,65%
- 3.1 Improvement of Health Infrastructure	20,99	42,68	1,97	9,39%
- 3.2 Improvement of Social Services Infrastructure	12,03	21,06	3,1	25,77%
- 3.3 Improvement of Emergency Infrastructure	12,03	9,79	0	0,00%
- 3.4 Improvement of Education Infrastructure	34,45	88,13	6,58	19,10%
Axis 4 - Strengthening the regional and local business environment	96,19	48,00	4,4	4,57%
- 4.1 Development of sustainable business support structures	33,17	27,77	0	0,00%
- 4.2 Rehabilitation of unused polluted industrial sites	28,46	0,00	0	0,00%
- 4.3 Support the development of micro-enterprises	34,56	20,23	4,4	12,73%
Axis 5 - Sustainable development and promotion of tourism	86,54	109,31	16,84	19,46%
- 5.1 Restoration and valorization of cultural heritage	28,46	42,78	15,35	53,94%
- 5.2 Creation, development, modernization of the tourism infrastructure	39,90	66,09	1,05	2,63%
- 5.3 Promotion of Tourism	18,18	0,44	0,44	2,42%
Total	536,41	619,31	128,22	23,90%

Figure no 3 The status at 31.03.2010 of Regio Programme in North-West Region

As observed from the table above the biggest contracted amount are on the Axis 2 Improvement of Regional and Local Transport Infrastructure where are contracted 95.33 million Euro from the total of 105.99 million Euros, a 89.94% from the budget of the Axis.

The other Axis have contracted between 0%(Axis 1) and 19.46% on the Axis 5. The biggest concern comes from the Sub-Axis 4.2 Rehabilitation of polluted industrial sites where no projects have been proposed even if the total budget of this action is 28.46 million Euros. Large delays in evaluation and contracting of projects have been registered also in Axis 1 or sub-axis such as 3.1, 3.2, 3.4, 4.1, 5.1 and 5.2. In these cases despite the large amount of funds requested, sometimes over 250% over the allocated budget, the evaluation of the projects and contracting procedure are delaying the implementation of the projects. For example even if 82.32 million Euros have been requested on Axis 1 or 27.77 million Euros have been requested on Sub-axis 4.1 no projects have been contracted yet. In other cases even if the amount requested was much higher than the funds allocated (Axis 3.1, 3.2, 3.4 or 5.2) modest evaluation and contracting rates have been achieved: between 2.63%(Axis 5.2) and 25.77%(Axis 3.2). In the same time can be mentioned the delays in presenting feasible financing projects by the beneficiaries. And since 2010 is the half of the contracting period 2007-2013 all these analyzed facts demonstrate a low capacity of absorption of European Funding by the Romanian stakeholders.

The most important reasons identified for these facts as reflected within the analysis from this paper and from the numerous studies(Fundația Șoros Romania, 2009 or Departamentul pentru Afaceri Europene, 2009). Most of the factors causing a lower than expected absorption capacity in Romania can be summarized in the following lines:

- Slow actions of the institutions specialized in analysis and contracting of the financing projects
- Lack of proper specialized staff in the fields of European funded projects accession and management, mostly at the level of the beneficiaries
- Low level of information, low expertise and very low qualifications of the beneficiaries regarding the accession and management of European funded projects
- “Low percentage” of contracting specialized external consultancy at the level of the beneficiaries with direct effects over the low capacity for absorption of external financing, the lack of professional approach regarding the proposal and contracting of European projects, and the quality of the proposed projects.
- Low reaction at the level of beneficiaries and management authorities regarding the process of elaboration, proposing for financing or evaluation and contracting of projects
- Low request or wrong established eligibility criteria for some of the proposed financing programs causing low interest from the stakeholders, as in the case of REGIO – 4.2.
- The “continuous” modification and completion of the eligibility conditions imposed both to the beneficiary and to the project, most of the times after the financing round is open, causing the beneficiaries costly modification of the projects, or even causing the impossibility for the submission of the project or in some cases submitted projects to be declared not eligible.
- Low financial and management capacity of the beneficiary. Some of the proposed projects lack the co-financing in order to be implemented.

In order to correct these inconsistencies and to increase the absorption capacity for the programme direct actions should be taken both at the level at the management authorities and at the level of beneficiaries.

5. Conclusions

This paper tried to analyze the Romanian absorption capacity of the funds allocated through the REGIO programme, which is part of ERDF programme. Within the paper was presented the concept of absorption capacity and several opinions regarding its main elements: macroeconomic absorption capacity, managerial-administrative absorption capacity and financial absorption

capacity. Also the Regio programme, its main axis and its budget was briefly presented. In the last chapter of the analysis a thorough analysis of the implementation of REGIO in the Romanian North-West Region was carried out and several causes for the low absorption of European Funds have been identified. Since these causes are directly threatening the successful accession of EU a direct action should be taken both at the level of Programme Management Authorities and at the level of the beneficiaries. The process of improving the absorption capacity of European Funds is still at the beginning in Romania and will certainly become an important issue over the following years at all levels of the Romanian society and at the level of the European Funding Authorities as well.

FINANCIAL INDICATORS FOR THE IMPLEMENTATION OF AN EUROPEAN FUNDED INVESTMENT PROJECT UNDER SOP IEC PROGRAMME – CASE STUDY OF A ROMANIAN SME

Droj Laurentiu
University of Oradea
Faculty of Economics

The European Integration came with new challenges for the Romanian enterprises especially for the SMEs, the opportunities arising from operating on the European Single Market and the possibility for accession of European Regional Development Funds. The main programme designed to offer access for small, medium and large Romanian enterprises to European funding is the Sectorial Operational Programme “Increase of Economic Competitiveness”- SOP IEC. This paper will analyze the area of intervention “D1.1. Productive and environment friendly investments and preparation for market competition in which Romanian SMEs” are competing to access European funding in order to develop their activities or to extend them into new ones. One of the main challenges for these SMEs is to generate, fulfil and to respect the financial indicators of the programme, which are part of the financial analysis of the project.

Key words: Financial Analysis, Cost benefit Analysis, European Union, Financial Simulation, Structural Funds, SOP IEC

The article’s JEL code: D61, D92, O22, G38, O19, F36

1. Introduction

The European Integration came with new challenges for the Romanian enterprises especially for the SMEs, the opportunities arising from operating on the European Single Market and the areas eligible for the European Regional Development Funds (Droj, 2009). The Sectorial Operational Programme “Increase of Economic Competitiveness” (further referred to as SOP IEC) is one of the seven instruments (Operational Programs), which offer the financial support for the consolidation and modernization of productive sector through investments. The SOP IEC aims to strengthen the strategic focus of the Economic and Social Cohesion policies across Romania, and to make the correct and appropriate linkages to the European policies and the Lisbon Strategy for growth and job creation.

The **general objective** of SOP is the increase of Romanian companies’ productivity, in compliance with the principle of sustainable development, and to reduce the disparities compared to the average productivity of the European Union (Guvernul României, 2009). The target is an average annual growth of GDP per employed person by about 5.5%. This will allow Romania to reach an approximate of 55% of the EU average productivity by 2015.

The specific objectives of the SOP “Increase of Economic Competitiveness” are:

- Consolidation and environment-friendly development of the Romanian productive sector,
- Establishment of a favorable environment for sustainable enterprises’ development,
- Increase of the R&D capacity, stimulation of the cooperation between RDI institutions and enterprises, and increase of enterprises’ access to RDI
- Valorization of the IC&T potential and its application in the public (administration) and private sector (enterprises, citizens)
- Increased energy efficiency and sustainable development of the energy sector

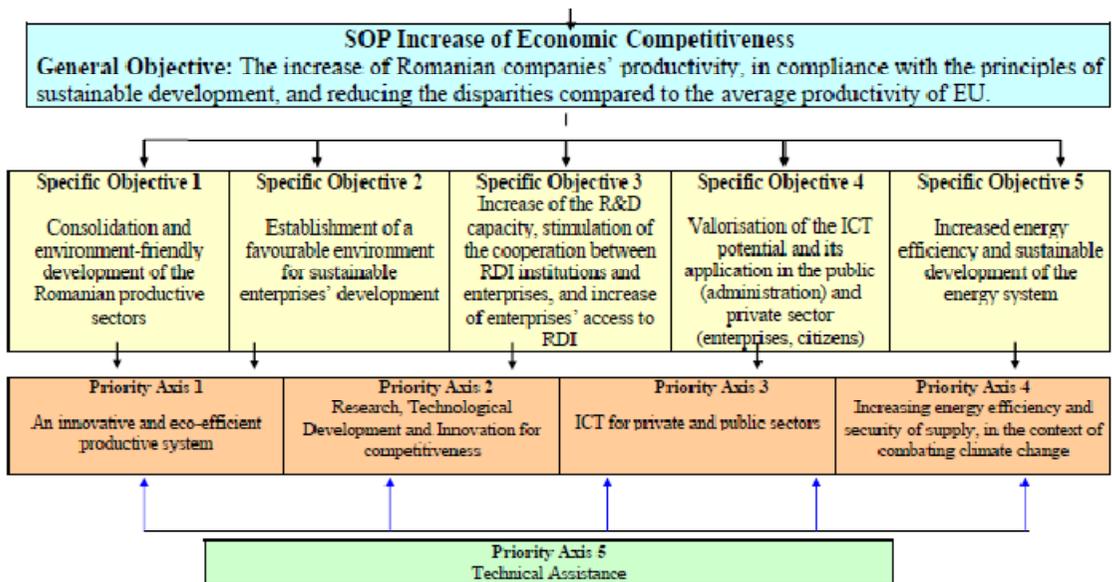

Figure 1. SOP Increase of Economic Competitiveness

(Extracted and adapted from the *Framework Document - Sectorial Operational Programme "Increase of Economic Competitiveness"*)

Taking into account both the identified possibilities for improvement of the competitive position of Romanian companies and the areas eligible for the European Regional Development Funds support, the following Priority axes have been identified in the SOP IEC:

- Priority Axis 1: An innovative and eco-efficient productive system
- Priority Axis 2: Research, Technological Development and Innovation for competitiveness
- Priority Axis 3: ICT for private and public sectors
- Priority Axis 4: Increasing energy efficiency and security of supply, in the context of combating climate change
- Priority Axis 5: Technical Assistance

2. Short presentation of the Area of Intervention SOP IEC "D1.1. Productive and environment friendly investments and preparation for market competition, especially of SMEs."

The Priority Axis 1: An innovative and eco-efficient productive system of the Sectorial Operational Programme "Increase of Economic Competitiveness" refers to the efforts of supporting enterprises, especially SMEs, and will concentrate both on improving the market conditions linked to the development of the industrial base, in order to revive the business environment and generate new innovative enterprises, as well as on developing of the business sector, improving the access to capital and fostering technological development.

From the above mentioned areas of intervention the main instrument of the SOP IEC in order to support and finance quality improvement of the production processes of the Romanian companies is the area of intervention "D1.1. Productive and environment friendly investments and preparation for market competition, especially of SMEs."

The specific objective of this key area is represented by the consolidation and sustainable growth of the Romanian productive sector can be accomplished through:

- Revival of the productive sector based on extension and modernization, by investments in new technology, equipment, machineries and by acquisition of patents, trademarks, licenses,

- Innovation of production both concerning the production processes and the products,
- Adaptation to European and International Standards and certification of management systems,
- Access of the Romanian companies to new markets
- Promotion of sustainable development, decreasing of the negative impact on the environment and growing the international competitiveness.

3. Financial Analysis – Case study of an investment project proposed to be financed within the SOP IEC D 1.1

3.1 Establishing of the eligible company and the methodology for elaboration of financial analysis

In order to access European Funding within the SOP IEC D1.1. Programme the companies have to generate, fulfil and to respect the key financial indicators of the programme. The main purpose of the financial analysis is to use the project cash flow forecasts to calculate suitable net return indicators. The main financial indicators over which projects are selected for financing within the programme are: the Financial Net Present Value (FNPV) and the Financial Internal Rate of Return (FRR), respectively in terms of return on the investment cost, FNPV(K) and FRR(K). The methodology used for the determination of the financial return is the Discounted Cash Flow (DCF) approach. This implies some assumptions:

- only cash inflows and outflows are considered (depreciation, reserves and other accounting items which do not correspond to actual flows are disregarded);
- the determination of the project cash flows should be based on the incremental approach, i.e. on the basis of the differences in the costs and benefits between the scenario with the project (do-something alternative) and the counterfactual scenario without the project considered in the option analysis;
- the aggregation of cash flows occurring during different years requires the adoption of an appropriate financial discount rate in order to calculate the present value of the future cash flows.

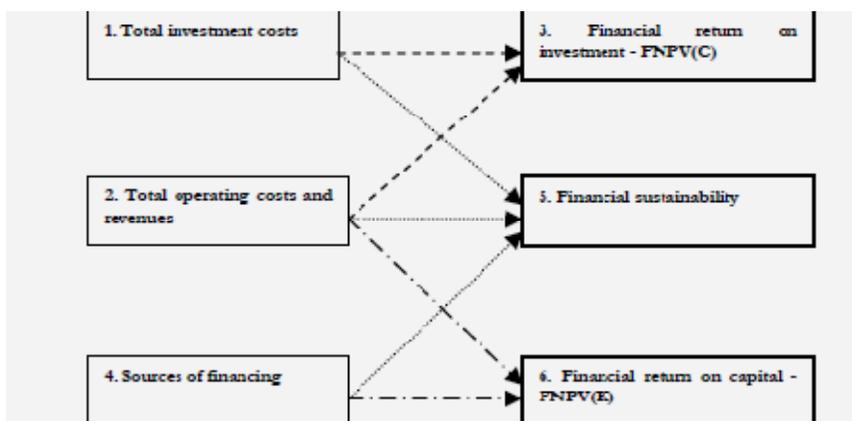

Figure 2 Structure of Financial Analysis

As seen in the Figure no. 3 the financial analysis should be carried out through subsequent, interlinked, accounts:

1. total investment costs
2. total operating costs and revenues
3. sources of financing

4. financial sustainability

5. financial return on the national capital: FNPV(K) and FRR(K)

According to the Guide of ROP IEC Programme, in order to obtain financing for an investment project FNPV(K) is requested to be higher than 0 and FRR(K) to be between 0 and 13.

$$FNPV = \sum_{t=0}^n a_t S_t = \frac{S_0}{(1+i)^0} + \frac{S_1}{(1+i)^1} + \dots + \frac{S_n}{(1+i)^n}$$

A simulation has been created over a project proposed by a company which we will define it as SC Test Company SRL, registered in Romania and eligible to access the programme. The company operates in the field of construction and is proposing for financing, in SOP Increase Economic Competitiveness, Priority axis 1, a project with the purpose of increasing its own competitiveness and production capacity by acquisition of a excavator on tracks and a compactor cylinder. The project proposed for financing should demonstrate its feasibility and sustainability through the income generated by the usage of the new equipment.

3.2 Financial Analysis

The first step within the financial analysis is the option analysis. EU Regulations require the proposer to provide the results of feasibility and option analysis (European Commission, 2008). The main result of such analysis is to identify the most promising option on which detailed CBA should be carried out. Sometimes this selection process is managed as part of the preparation on an operational programme or master plan. Once the feasible ‘do-minimum’ and a small number of ‘do-something’ alternatives have been identified, simplified CBA should be carried out for each option in order to rank them. A simplified CBA usually implies focusing only on the key financial and economic tables (see below), with rough estimates of the data, because in a differential approach the absolute values of the variables involved are less important than in a fully developed comparison of alternatives. The calculation of the financial and economic performance indicators must be made with the incremental net benefits technique, which considers the differences in the costs and benefits between the do something alternative(s) and a single counterfactual without the project.

As mentioned above the first analyses made for SC Test Company SRL were the comparison between the inertial scenario – case in which the equipment won’t be bought and the second scenario in the case of implementing the project with European financing.

Indicator	Year						NPV
	0	1	2	3	4	5	
Scenario with project – operational profit	275.653	602.010	565.098	537.826	490.554	440.602	2.452.337
Inertial scenario - operational profit	275.653	546.306	455.610	351.628	254.326	158.669	1.768.097

Figure 3 Option Analysis

As observed in the above table, the business plan prepared for the application form demonstrates that the annual net revenue in all five years of analysis is positive. The operational profit connected only to activities generated by the project increases exponentially in the period analyzed: 44.912 RON (year I), 53.000 RON (year II), 60.728 RON (year III), 63.456 RON (year IV), 73.504 RON (year V). For the proposed project the imposed discount rate is 5%.

Also extremely relevant is the analyses of the Cumulated Net Present Value which continuously increases reaching in the fifth year of analysis the amount of 2.452.337 RON for the entire company in scenario with project and 241.050 RON for activities related just to the project which also reflects an extremely high sustainability.

Year	Operational Cost	Total Benefit	Coefficient of Actualization	Actualized Operational Cost	Actualized Total Benefit	Net income	Present net income
0	0	0	0,952381	0	0	0,00	0,00
1	179.888	224.800	0,907029	163.164	203.900	44.912,00	40.736,51
2	199.000	252.000	0,863838	171.904	217.687	53.000,00	45.783,39
3	226.472	287.200	0,822702	186.319	236.280	60.728,00	49.961,08
4	258.944	322.400	0,783526	202.889	252.609	63.456,00	49.719,44
5	288.096	361.600	0,746215	214.982	269.831	73.504,00	54.849,82
TOTAL	X	X	X	939.258	1.180.308	X	X

Figure 4 Total operating costs and revenues generated by the project

Another important indicator in evaluation of the sustainability of the project is the annual turnover which continuously rises during the five years of analysis. Also can be observed that the annual turnover in the scenario with the financing project in comparison with the inertial scenario is increasing continuously reaching 8.4% in the fifth year.

As mentioned above the main financial indicators over which projects are selected for financing within the programme are: the Financial Net Present Value (FNPV) and the Financial Internal Rate of Return (FRR), respectively in terms of return on the investment cost, FNPV(K) and FRR(K). Below is presented the Financial Internal Rate of Return of the investment as calculated for the project.

Year	Cost of investment	Operational Cost	Total Cost	Total Benefit	Coefficient of Actualization	Actualized Operational Cost	Actualized Total Benefit	Net present value	Cumulated Net present value
0	432.684	0	432.684	0	0,91407	395.506	0	-395.506	-395.506
1	0	179.888	179.888	224.800	0,83553	150.303	187.829	37.526	-357.981
2	0	199.000	199.000	252.000	0,76374	151.985	192.464	40.478	-317.502
3	0	226.472	226.472	287.200	0,69812	158.105	200.500	42.395	-275.107
4	0	258.944	258.944	322.400	0,63813	165.242	205.735	40.494	-234.613
5	-329.576	288.096	-41.480	361.600	0,58330	-24.195	210.923	235.119	505
TOTAL		X	X	X	X	996.946	997.451	X	X

FRR/K=9,40%

Figure 5 Financial Internal Rate of Return on the National Capital FRR(K)

The financial internal rate of return for the investment, strictly connected with the activities generated by the project is 9.4% which shows that the project is eligible for financing.

The last step of the project is to establish the maximum proposed financing using the financial gap method. In order to do that the first step was to estimate the residual value which was calculated using Gordon method, was estimated for an average yearly rate of growth of 14%.

So the estimated residual value considered for the project is -329.576 lei.

Year	Total Cost of investment	IAF	Present investment cost	Total costs	Total benefits	Residual Value	Net income	Present net income
0	1.442.280	0,95	1.373.600	0,00	0,00		0,00	0,00
1		0,91	0,00	179.888,00	224.800,00		44.912,00	40.736,51
2		0,86	0,00	199.000,00	252.000,00		53.000,00	45.783,39
3		0,82	0,00	226.472,00	287.200,00		60.728,00	49.961,08
4		0,78	0,00	258.944,00	322.400,00		63.456,00	49.719,44
5		0,75	0,00	288.096,00	361.600,00		73.504,00	54.849,82
6		0,71	0			-329.575,00	-329.575,00	-234.222,80
Total	1.442.280		1.373.600	1.152.400	1.448.000	-329.575,	-33.975	6.827,43
	Estimated financing value			1.033.378				

Figure 6 Financial Internal Rate of Return on the National Capital FRR(K)

As observed from the above table the proposed value for financing is 1,033,378 RON and the main financial indicators for the project are: financial internal rate of return for the investment - 9.41% and FNPV is 241.050 Ron for the project and 2.452.337 RON for the entire enterprise. In these conditions, according the provisions of the ROP IEC guideline the project has been proposed for financing.

4. Conclusion

The European Integration came with new challenges for the Romanian enterprises especially for the SMEs, the opportunities arising from operating on the European Single Market and the possibility for accession of European Regional Development Funds. The main programme designed to offer access for small, medium and large Romanian enterprises to European funding is the SOP IEC. This paper analyzed the main financial indicators which have to be achieved by a project in order to be proposed for financing and also presented a case study of a Romanian company which successful realized a financial analysis and was later accepted for contracting, under this programme.

THE ACCOUNTING PROCESS FOR ACCESSING EUROPEAN FUNDS

Durgheu (Cioara) Liliana Marcela
Camera de Conturi Bihor

Kolozsi Lucia
Camera de Conturi Bihor

The beneficiaries of structural funds are various entities¹ that can be classified on different criteria, and keeping the accounts for these entities can raise certain problems. Keeping accounts in Romania is organized in a double circuit. Information given to third parties, also used by the economic entity is supplied by financial accounting, and the confidential information, used only by the economic entity is supplied by management accounting. In accounting, reflecting the accession and the use of European funds by the economic entity, taking into consideration the classification of various entities, is done distinctly.

Keywords: structural funds, funds accounting, beneficiary entities

The beneficiary entities can be identified without approaching these exhaustive aspects, just by covering the entities classification on various criteria. A first classification can be done in terms of the great sectors in which the enterprises activate:

- 1.Primary sector – agriculture, extractive industry etc.;
- 2.Secondary sector – enterprises affiliated to industry and construction;
- 3.Tertiary sector – enterprises that have as an activity object commerce, transport, tourism, banking, insurance, teaching, health. In terms of the people who invest in its activity, we have:

- 1.Private companies – companies where the investor is represented by one or more individuals (private persons);
- 2.Public companies – the ones whose activities are possible exclusively because of public investments;
- 3.Mixed companies – companies with both private and public investors.

In terms of production management:

- individual production entities are the ones where a unique product or a small number of unique products are manufactured with the same technology;
- series production entities which produce batches of goods using a certain recipe or technology with a periodical change in the technological process (equipment, tools, confections etc.);⁸⁴⁴
- entities with mass production are the entities which manufacture, for long periods of time and in great amounts, one or more goods with the same recipe, technologies and equipments (sugar, bread, oil etc.).

According to the 1752/2005 Decree (presently OMFP 3055/2009) for approving the accounting regulations pursuant to European directives, entities are separated into two categories:

- large and very large entities;
- medium and small entities.

The tie-break criteria for these entities are: total assets (3.650.000 Euros), turnover (7.300.000 Euros), and the average number of employees during the financial year (50).

The accounting law makes the following assignation regarding the accounting management and administration: trading companies, national ventures, autonomous administrations, research-

⁸⁴⁴ We mention that Order 1752/2005 uses the concept of entity and not the traders, asset unit, enterprise, etc.

development national institutes, co-operative companies and other types of legal persons, are obliged to conduct and organize their own accounting, meaning financial accounting, according to present law, and management accounting adapted to the businesses characteristics. Public institutions, associations, and other legal persons with and without patrimonial purpose, and also natural persons that is involved in an income generating activity, also have the obligation to organize and conduct their own accounting, meaning financial accounting and if it is necessary, management accounting⁸⁴⁵.

The accounting process for Romanian entities is organized in a double circuit. Information given to third parties, also used by the economic entity is supplied by financial accounting, and the confidential information, used only by the economic entity is supplied by management accounting. Book-keeping for the entities is provided by the Accounting Law no.82/1991, re-edited as following:

- legal persons conduct their accounting in distinct departments, run by an economic manager, chief accountant or some other person commissioned to do so. This person must have superior economic studies;
- accounting can be also done based on a contract with natural persons or legal persons that are authorized according to O.G. no.65/1994 regarding the management for the accounting expertise and authorized accountants.

The responsibility for an inadequate application of the accounting regulations is taken upon the economic manager, the chief accountant or other commissioners, together with the subordinate personnel. If the accounting process is led based on a contract with an authorized legal or natural person, member of the Chamber of Experts Accountants and Authorized Accountants of Romania, responsibility is taken by them, according to the law and the articles of the contract.

Getting back to the types of entities, in the specialized literature, patrimonial units in which we organize and conduct accounting, are divided as following:

- economic units;
- public institutions – state organisms created in order to conduct certain social-cultural activities, not carrying out productive activities;
- humanitarian organizations built upon the liberty of association or participation principle, and they carry out political, social-cultural, religious, and some economic activities. In this category we have: political parties, syndicates, professional associations, cults, charity associations, associations and foundations.

Objectifying, the non-refundable structural funds eligible beneficiaries could be: any farmer, legal or natural person, that carries out agricultural activities, and who operates on the country's boundaries, its' size is equal or greater than 2 UDE⁸⁴⁶ and the entity has to be registered at the Register of Farms/Agricultural Register. Practically, the categories of beneficiaries which can access funds are:

- Authorized Natural Person, according to the 300/2004 Law with its following modifications;
- Family Association with integral private capital, according to the 15/1990 Law, with its following modifications;
- Trading Companies, according to the 31/1990 Law, re-edited, meaning: Partnership Firms, Limited Partnership/Commandite, Joint-Stock Companies, Companies with Limited Abilities;

⁸⁴⁵ Accounting Law no. 82/1991 republished, Official Gazette, Pag. 454/2008.

⁸⁴⁶ Economic size unit (ESU) is the unit expressing the economic size of farm standard gross margin determined by the farm (Commission Decision. 85/377/EEC). Economic size unit value is 1.200 Euros. In relation to farm size have shown a previous subparagraph its way down, both nationally and also internationally.

- Trading Companies with integral private capital, according to the 15/1990 Law and its following modifications;
- Agricultural Cooperative Companies, according to the 1/2005 Law;
- Manufacturers Group, according to the 338/2005 Law, but only with the condition that investments are used for the purpose of the groups interests. Manufacturers Groups are economic organizations (legal persons with a lucrative purpose and economic management) that run on their own statute.
- Agricultural Cooperative, according to the 566/2004 Law.

Theoretically, all of the entities listed above can become structural funds beneficiaries. But practically, structural programs are presented using guides where all the possible beneficiaries are presented, for example: private entities (micro-enterprises, small and medium enterprises), public institutions (schools, local public authorities), etc.

The reflection of the receiving and use of the non-refundable finances⁸⁴⁷ in the accounting is done following the existing standards. This is because in Romania, book-keeping is organized according to standards emitted by authorities and not based on general principles and rules.

The economic agents that benefit from the financial contribution of the European Community are obliged to keep track of the received and used finances using distinct analytical accounts.

Once our country adhered to the European Union, we had to adopt the community's *acquis* in our financial and budgetary area. The normative act about the Financial Rules regarding the European Community's general budget, no.1605/2002 and the Detailed Standards of implementing no.2342/2002 represent a very important regulation concerning what the EU believes to be an honest work regarding the financial responsibility in the public area administration. Being applicable for the European Commission Budget, it automatically has legal effects when talking about managing the EU financed project, implemented by member countries. In Romania, these Financial Rules has been implemented starting 2003, following the approval of the new Public Finance Law, no.500/2002, setting out a new environment for elaborating and managing the budget, establishing the role and responsibilities of the credit sequencers and leaders of the accounting-finance departments, carrying out the public funds administrative control, in the context of applying the principle of transparency and healthy financial management, and especially the principle of efficiency and effectiveness. The Accounting Law no.82/1991 modified by the Public Finance Law no.500/2202 have created a legal frame for the development and improvement of the management and performance of the public accounting system in Romania, that also has to follow new European demands:

- managing and presenting the accounts based on the determined right principle (of commitments);
- applying the general international accounting principles when making the financial standings;
- developing accounting destined for the cost of the programs.

In order to accomplish these demands, Romania has already been helped by the EU through a twinning-light program, when Scottish experts have evaluated the current system and handed out important recommendations regarding the introduction of some vital elements for the commitments accounting: registering debtors and creditors according to accrual basis, reevaluation and amortization of immobile assets, building provisions. Some recommendations have already been materialized through The Governments' Ordinance no.81/2003 and its applicability standards, in public institutions, reevaluation of immobile assets already being carried-out. Its results have been included in the balance sheet of December 31st 2003, and

⁸⁴⁷ Order no. 875 of June 16, 2000 approving the specifications to reflect the accounting operations of receiving and using funds from the European Community financial contribution and co-related funds, Official Gazette 377/2000.

starting January 1st 2004 all public institutions calculate and register the amortization of immobile assets.

To accomplish its role, the state organizes a vast network of public institutions. According to the Public Finance Law, the area of public institutions includes: the Parliament, The Presidential Administration, the Ministries, other central and local bodies of the state administration and institutions under it. Public institutions present a number of characteristics reckless of the area of activity, management etc. :

- patrimonial units of the state-at-law which carry out a political or executive activity, representing the power and state administration into society. Public institutions are bodies that compose, at a local or central level, the power apparatus and the state administration;

- the patrimonies of the public institutions are attributed to the public and private state patrimonies, or to local territorial administrative units. Public institutions built on an juridical paper inherit juridical personality needed for the patrimony administration and for taking commitments;

- as opposed to economic agents which create their patrimony based on subscribed and paid capital, public institutions do not include the economic category of joint stock. We cannot find joint stock in the patrimonial structures of a financial institution because they only have the quality of allotted patrimony administrators, whose proprietor is the state, represented by the Government and Local Committees. Public institutions do have a certain patrimony of material and pecuniary resources that they have to use respecting the legal standards and with maximum efficiency;

- managers of public institutions who are entitled to manage budgetary resources have the title of credit sequencers;

- expenditures of public institutions are financed under the form of budgetary credits. The use of budgetary credits has to be justified by the administrator at the end of every fiscal year;

- are not organized based on the principles of auto-management, because they receive monetary resources from the budget in order to accomplish their tasks, also having the obligation to pour to the budget all the tax incomes or other incomes obtained as a result of their activity. They have the right to partially retain these incomes in order to self-finance their activity;

- the public institutions objectives, provided by their statute aim the accomplishment of public service, but without aiming for profit. Public institutions are non-profit units that do not have lucrativeness indicators;

- in order for public services to function, public institutions need permanent capital that they obtain through budgetary credits for capital expenditures. The development and modernization of this capital through investments is also done using budgetary resources.

- the financial planning for these units is done using a budget.

There are two forms in which public accounting can exist: current public accounting and centralized public accounting. Current public accounting is organized and carried out by each institution in order to correctly register all patrimonial operations. According to the re-edited Accounting Law, all public institutions whose administrators have the title of credit sequencers are obliged to keep the books. The administrator holds the responsibility for accounting.

Centralized public accounting or periodical accounting is carried out by centralizing the annual and periodical financial situations. This accounting type works for superior credit sequencers and fiscal bodies, during the period of financial standings presentations and embodies data already centralized, given by the current budgetary accounting. Accounting the operations regarding the non-refundable financial contribution from the European Community is done in Euros and in national currency, at the INFO-Euro currency. The INFO-Euro currency represents an exchange rate between Euro and a national currency; it is communicated by the European Central Bank and can be found on the European's Commission website. The INFO-Euro is used for registering the current month operation (n) it is the exchange rate from the penultimate working day of the

antecedent month (n-1). This exchange rate is used by all public institutions that carry out activities financed through community funds: agents and implementing authorities, final beneficiary institutions like: goods, service or liquidity. Monetary elements expressed in Euros: liquidities and bank deposits, claims and credits are reevaluated at least once every trimester, when doing the financial statements, using the INFO-Euro exchange rate from the penultimate working day of the month when the financial statements are carried out.

Territorial - administrative units that have contracted, law accordingly, loans for financing non-refundable projects, have carried out payments and then received non-refundable external funds, in order to reimburse those loans, will fill out Appendix 15 "The account of budget execution of foreign loans - Expenses", Appendix. 16 "The account of the budget execution of domestic credit - Expenditure payments from loans" and Appendix 18 "The account of public execution of external grants funds - Expenditures" for payments made from these funds, including repayment of loans. The payments from external non-refundable funds are registered on Appendix 3 and 4 "Cash-flow Status", when it is carried out by the Contracting and Payment Department. Grant payments from foreign funds, reported by public institutions are in Appendix 6 "The account of execution for the public institution - Expenses", Appendix 7 "The account of execution of the public budget - Expenses", Appendix 18 "The account of the budget implementation of reimbursable external funds - Expenses" will be agreed with the data records of agencies / authorities for implementation, ie those included in special situations the transmitted direction of the Ministry of Finance. Through the normative papers earlier mentioned, we are trying to level our public accounting to European Standards, without neglecting the two key aspects of the reform:

- professional development of ministries and other bodies of the central and local administration specialists, and forming the trainers from the National Administration Institute and the eight regional centers for professional training, and none the less of managers from public institutions;
- evaluating the necessary of software and hardware for all public institutions, in order for the accounting process to be entirely computer processed, with on-line reporting facilities.

This way, the accounting process will give away complete information regarding the patrimony and the income and expenditure budget execution for managers in the central and local administration. They can use this information to improve the assets and funds management.

Financial statements are documents through which information regarding the financial position is presented (assets, liabilities, patrimony). Also they reflect performances, changes in the patrimonial structure and the company's cash-flow.

In Romania, financial statements are carried out following models established by the state authority, the Ministry of Public Finance

Bigger entities have to work out the following components:

- balance;
- profit and loss account;
- changes in the patrimony;
- cash-flow;
- explanatory notes for the annual financial statements.

Small and medium entities have to work out the following components:

- short balance;
- changes in the patrimony;
- explanatory notes for the short annual financial statements.

Optionally, small and medium entities can carry out a brief for the patrimonial changes or/and the cash-flow.

Europeanization and internationalization are major phenomenon that leads the way for the Romanian accounting system evolution, in order to harmonize it with the European Directives and converge with the Accounting International Standards. The aim is to control the financial

integrity of the patrimony and its results, through material integrity control and just dimensioning. In order to characterize an entity's activity during a certain period of time, we have to centralize and synthesize it under the shape of general information from the accounting process, this being one of the accounting's objectives, as a main component of the economic-informational system. The seamless presentation of accounting data is imposed by need of a precise structural representation of the financial position, the financial performance and other information regarding the entity's activity during a fiscal year. This purpose is accomplished through synthetic documents under the form of financial statements.

In conclusion, in the case of funds beneficiaries, the objective of financial statements is to mirror correctly and faithfully all of the elements with detailing in explanatory notes, especially under a narrative form.

In this paper is realized an theoretical and empirical approach regarding density and penetration on accident & health premiums. The analysis is performed on a sample of 33 countries and a horizon of 5 years (2004, 2005, 2006, 2007 and 2008), being tested 2 linear regression models. The results of study confirm a relationship between level of economic development and accident & health insurance activity insurance, but exclude the existence of the relationship between penetration factor and this type of insurance.

Keywords: insurance, accident & health premiums, density, penetration

JEL codes: G22, H51, H89

1. Introduction

The impact of the economic crisis has materialized in the stagnation of the volume of subscribed insurance premiums in general, and of accident & health insurance premiums especially. The most pressing problems are those related to legislation at the European and national level. Also, the implementation of health reform in some countries, the continuation of pension reforms, insurance deductibility and solvency requirements are a few of the other problems which must be solved in the future.

According to the Solvency II Directive, the Solvency Capital Requirements (SCR) correspond to the economic capital needed to limit the probability of ruin to 0,5%. That's why, insurance and reinsurance undertakings must identify their overall loss distribution. In order to determine the Solvency II economic capital, each company can use the standard formula or an internal model (global or partial). Internal model, calibration of SCR, MCR (Minimum Capital Requirement) and technical provisions, different set of premium and reserve risk etc. represent major problems for the European Commission (EC). That's why, on April 15, 2010 the EC released a draft technical specification for QIS 5 (Fifth Quantitative Impact Study), in which Romania was invited to participate (after its participation on QIS 4).

On April 8, 2010 the Committee of European Insurance and Occupational Pensions Supervisors (CEIOPS) provided Consultation Paper 72 "Draft Level 2 Advice on Calibration of the health underwriting risk" defines efficiency indicators for health insurance. This paper supplied the propose calibration of the health underwriting risk module (premium and reserve sub-module). With this consultation paper, CEIOPS has endeavored to establish the increased market transparency through greater disclosure and reporting requirements, according Pillar III of Solvency II.

The preparations made by the Romania for the implementation of the health reform and the importance of insurance sector to economic growth represent the two main arguments of our

choice for the subject of this paper. In addition, EC considered that the premium risk and reserve risk stresses for accident and sickness obligations remain higher on European level.

2. Fundamental concepts of insurance density and penetration

The situation of the insurance market can be appreciated by using quantitative and qualitative indicators, among the latter the most important being the density and penetration.

Insurance density is expressed as the ratio between the total direct gross premiums collected and the total number of the inhabitants (population) of that country, expressing the average per capita.

Penetration of insurance is a synthetic indicator. It shows the contribution of insurance sector to the creation of GDP (gross domestic product). It is calculated as the ratio between the amount of direct gross premiums and GDP.

So, density and penetration ratios are two important indicators which demonstrate the efficiency of the insurance in general. We propose to use these indicators for the field of health insurance. In order to determine their values we use only accident & health premiums, GDP and population on the level of one country in a certain year under study. Several studies were conducted to uncover the relationship between them and other factors. The results were influenced by the application of health reform in some countries. Also, the development of insurance industry and wage changes influenced the conclusions made by the specialists. We present some of these studies available to us in the next section.

3. Literature review

Density and penetration insurance continues to be interesting subjects for specialist's researches. For example, Enz (2000) proposed the S-curve relation between per-capita income and insurance penetration. The results of Ma & Pope (2008) study show a positive relationship between international insurer participation and increased insurance penetration and density. Their empirical results imply that a strong presence of international insurers may enhance the importance of the insurance industry and increase the demand for insurance products within a given national market.

On the other hand, Zheng *et al.* (2009) proposed a new method, Benchmark Ratio of Insurance Penetration (BRIP) for comparing insurance growth across different countries, which not takes into account the overall scale of the insurance market of each country but also considers the population, economy and the relationship between the insurance penetration and stage of economic development.

Regarding our country, Badea & Novac (2008) believes that the continuous improvement of the insurance premiums, the insurance density and the insurance penetration rate support the importance of this sector of activity in the total economy. As the Romanian market became more sophisticated, the offer became more stable and the concentration of the market began to reduce itself as a response to the European insurers that entered our market.

The growth of health insurance is strongly correlated to the health reform applied in different countries. The appearance of health private insurance and the application of different characteristic schemes were generated and led to amendments and wage changes. These problems were also investigated by the specialists.

Buchmueller & Liu (2006) explored the effect of state-level underwriting reforms on health maintenance organizations (HMO) penetration in the small group health insurance market. They identified reform effects by exploiting cross-state variation in the timing and content of reform legislation and by using mid-sized and large employers, which were not affected by the legislation, as within-state control groups. The results of their study suggest a positive relationship between insurance market regulations and HMO penetration.

Danuletiu & Danuletiu (2006) inquired the evolution of Romanian insurance market and highlighted trends that characterized it (such as density and penetration ratio). Vistnes *et al.*

(2006) has explored the nature of employer decisions with respect to the employee premium contributions used for family health insurance coverage.

Scintee and Vladescu (2006) examined the health financing reform in Romania in order to find out to what extent the expected results were achieved, what were the main factors that influenced the reform process and in what way the main unsolved problems are to be sorted out.

Knott & Rich (2006) provide an overview of the development of the private-public, segmented health care system in the United States. They examined health policy by analyzing political values and institutions, which allows them to assess the strengths and weaknesses of the health care system and serves as a basis for recommending politically feasible options for reform in the future.

Schneider *et al.* (2007) quantify the extent of market concentration among physician organizations (POs) and health plans (HPs) and examine the relationship between concentration and prices.

Sen & Madheswaran (2007) shows in their study that GDP and Per capita GDP are often highly correlated with the proxy variables measuring insurance demand – density and penetration.

4. Hypotheses, variables and data sources

As we explained in the previous section, the level of economic development is connected to the health insurance market. Therefore we issue the following hypothesis:

H: The level of economic development is positively associated with health insurance.

Since we are interested on the effect of several economic factors on life insurance activity, we developed the following variables:

- Proxies for insurance activity: *density of accident and health premiums* computed as Accident and health premiums subscribed / Population (EUR/inhabitant) and *penetration of accident and health premiums* computed as Accident and health premiums subscribed / GDP (%)
- Proxy for level of economic development: *GDP per capita* (EUR/inhabitant).

The underlying econometric model is:

$$\text{Insurance activity} = \alpha_0 + \alpha_1 \text{Level of economic development} + \varepsilon$$

which can be expressed in the following two models:

$$\text{Density} = \alpha_0 + \alpha_1 \text{GDP per capita} + \varepsilon \quad (\text{Model 1})$$

$$\text{Penetration} = \alpha_0 + \alpha_1 \text{GDP per capita} + \varepsilon \quad (\text{Model 2})$$

Our sample comprises 33 European countries. To enhance the robustness of the research we collected data for 5 years (from 2004 to 2008) the source of data being <http://www.cea.eu>.

5. Data Analysis and Discussion of Results

For the analysis of our data we used SPSS 16.0 software. Since we lack the necessary space here to discuss the technical issues related to the analysis (please see Table 1 for these details), we explain the steps as we generated the findings.

According to our findings, GDP per capita is positively associated with the insurance activity proxies on various significance levels as t-values are positive, but the computed significance is acceptable only in years 2004 and 2005, as Panel A and B shows below. This influence cannot be statistically proved in the years to come (2006, 2007 and 2008) due to the scattered data; the reason we believe is the sample size, which is too small for this type of analysis.

Table 1. Results generated

Panel A. Model 1					
	2008	2007	2006	2005	2004

<i>Adj R²</i>	0.041	0.031	0.040	0.156	0.184
<i>t</i>	1.516	1.406	1.514	2.597	2.826
<i>(Signif.)</i>	(0.140)	(0.170)	(0.140)	(0.014)	(0.008)
<i>Expected sign</i>	+	+	+	+	+

Panel B. Model 2					
	2008	2007	2006	2005	2004
<i>Adj R²</i>	0.005	0.002	0.003	0.048	0.072
<i>t</i>	1.079	0.955	1.046	1.600	1.850
<i>(Signif.)</i>	(0.290)	(0.347)	(0.304)	(0.120)	(0.074)
<i>Expected sign</i>	+	+	+	+	+

According to model 1 GDP per capita is associated with Density. Our findings confirm that the relationship is positive in the entire period as expected ($t > 0$), but the significance of this relationship can be proved only for the years 2004 and 2005 (level of significance is 0.014 and 0.008 respectively). Based on this model the hypothesis may be accepted.

Model 2 expresses the relationship between penetration and GDP per capita. Our findings suggest there is some relationship between these factors, but the strength of this influence is rather low. The results show that only in year 2004 there is an acceptable significance level for the t-value (0.074). Therefore, this model does not provide empirical evidence for our hypothesis, which should be rejected based on these results.

However, on the basis of model 1 we accept the hypothesis that the level of economic development is positively associated with accident & health insurance with the amendment, that this relationship must be more deeply explored in the last three years in order to obtain more relevant statistical data.

6. Conclusions

The current financial crisis shows that the parameters for certain risk categories need to be adjusted, complex corporate structures and investment strategies examined in detail. Insurance domain is influenced by this crisis.

Financial services organizations face yet another major challenge in the European Union's new directive for insurers. Solvency II will have a profound influence on capital budgeting and risk management for these undertakings. Insurers should perform additional multi-period calculations for truly optimize their risk, because solvency capital requirements become higher according to substantially stress parameters proposed by QIS 5.

Implementation of health reform in some European countries transforms accident & health insurance in the European topical issue at this moment. Even if, nowadays, it represents an insignificant part of insurance activity, we believe that it will have a positive evolution in the future. For defining efficiency in insurance activity we can use some indicators, among which density and penetration are very important.

According to Consultation Paper of CEIOPS 72 "Draft Level 2 Advice on Calibration of the health underwriting risk" insurance penetration is used to measure the degree that a certain insurance product (covering individual or group risk) is acquired in the population. Health underwriting risk are split into 3 categories:

- Health insurance obligations pursued on a similar basis to that of life insurance (SLT Health);
- Health insurance obligations not pursued on a similar basis to that of life insurance (Non SLT Health);
- Health insurance obligations Catastrophe risk (Health CAT).

Differences in laws and in organization between public and private health systems across Europe have consequences on the variety of the types of products offered in each member state. These country specificities would be best captured by the allowance of entity specific parameters in the calculation of the health risk charge.

CEIOPS is aware of the diversity that characterizes health system across Europe. That's why it is taking into account the specificities of the different regimes. The result of this understanding is the comprehensive pool in health insurance.

In our study, we proposed to analyze the relationship between level of economic development and accident & health insurance activity. Our empirical findings suggest that there is a positive relationship between these factors (results for model 1 in Table 1). The results however could not be confirmed by model 2 for the penetration factor (which is another proxy for accident & health insurance activity), which is obviously one of the limits of this paper. We are aware that this study must be extended to other countries, possibly other years in order to increase the robustness of the conclusions, which is also our recommendation for further research.

LA BONNE GOUVERNANCE DANS LE DOMAINE FISCAL

Maria Zenovia Grigore

Facultatea de Științe Economice

Andrei Diamandescu
Universitatea Nicolae Titulescu București
Facultatea de Științe Economice

The good governance in the tax area (i.e. more transparency, exchange of information at all levels, effective cross-border cooperation and fair tax competition) is the key element in rebuilding the global economy after the 2008 financial collapse.

This paper presents for consideration a series of steps to promote good governance in the tax area, entailing action both within and outside the European Union.

A better coordination of EU Member States' positions in their bilateral tax treaties with third countries and in international fora is necessary to ensure greater leverage in dealings with non-cooperative countries.

Keywords: fiscalité, bonne gouvernance, coopération fiscale, paradis fiscaux, évasion fiscale

The article's JEL code: H21; H26

1. Introduction

L'ouverture des frontières a facilité la libre circulation des capitaux mais aussi la fraude et l'évasion fiscales au sein de paradis fiscaux et centres financiers internationaux trop peu réglementés, qui refusent de reconnaître les principes de transparence et d'échange d'informations.

La crise économique et financière actuelle a accentué les préoccupations quant à la viabilité des systèmes fiscaux face à la mondialisation. La promotion de la bonne gouvernance dans le domaine fiscal est aujourd'hui reconnue comme la manière adéquate de répondre à ces préoccupations. L'Union européenne et ses partenaires ont un intérêt commun majeur à encourager la coopération fiscale et l'adoption de normes communes sur une base géographique aussi large que possible. Nombreuses initiatives visant la coopération internationale en matière fiscale ont été prises aux réunions européennes et mondiales comme:

- le Conseil Ecofin de 14 mai 2008⁸⁴⁸;
- le sommet du G-20⁸⁴⁹ en novembre 2008;
- le Conseil Ecofin de décembre 2008;
- le sommet du G-20 du 14 mars 2009;
- le Conseil européen des 19 et 20 mars 2009;
- le sommet du G-20 de Londres du 2 avril 2009,

⁸⁴⁸ La gouvernance dans le domaine fiscal a été définie pour la première fois dans les conclusions du Conseil Ecofin du 14 mai 2008 comme étant fondée sur les principes de transparence, d'échange d'informations et de concurrence fiscale loyale.

⁸⁴⁹ Le Groupe des 20 (ou G20) est un forum économique qui a été créé en 1999. Les membres du G20 sont représentés par les ministres des finances et les directeurs des banques centrales des 20 pays ou organisation suivants: Afrique du Sud, Allemagne, Arabie saoudite, Argentine, Australie, Brésil, Canada, Chine, Corée du Sud, États-Unis, France, Inde, Indonésie, Italie, Japon, Mexique, Royaume-Uni, Russie, Turquie et Union européenne.

- le sommet du G-20 de Pittsburgh du 24 et 25 septembre 2009.

Des conclusions de ces rencontres émergent la volonté de prendre des mesures à l'encontre des juridictions qui ne coopèrent pas, y compris les paradis fiscaux, en appliquant des sanctions visant à protéger les finances publiques et les systèmes financiers.

Les efforts d'amélioration de la coopération fiscale déployés au sein de l'Union européenne se fondent en grande partie sur les principes qui régissent depuis plusieurs années l'action de l'OCDE contre la concurrence fiscale dommageable. Le travail de l'OCDE dans ce domaine vise deux aspects.

D'une part, il s'agit de recenser, en vue de leur démantèlement, les régimes fiscaux préférentiels des 30 pays membres de l'OCDE, sur la base de critères similaires à ceux définis par le code de conduite de l'Union européenne dans le domaine de la fiscalité des entreprises.

D'autre part, l'OCDE a étendu son travail aux pays non-membres de l'Organisation, y compris un certain nombre de «paradis fiscaux»⁸⁵⁰, et obtenu, de la part de 35 de ces juridictions, un engagement politique en faveur de la mise en place d'une coopération loyale avec les membres de l'OCDE en ce qui concerne la transparence et l'échange d'informations dans le domaine fiscal.

La «Déclaration de Doha sur le financement du développement», adoptée à l'occasion de la conférence internationale de suivi sur le financement du développement [1], organisée par les Nations unies, contient un ferme engagement de la Commission européenne en faveur des réformes fiscales et appelle à consentir davantage d'efforts pour accroître les recettes fiscales en modernisant les systèmes fiscaux, en améliorant le recouvrement de l'impôt, en élargissant l'assiette fiscale et en luttant vigoureusement contre la fraude fiscale.

2. La nécessité de la bonne gouvernance dans le domaine fiscal

Parmi les facteurs qui plaident en faveur de l'amélioration de la coopération internationale au sein de l'Union européenne et à l'échelon international si l'on veut qu'elle soit efficace on peut distinguer:

- L'absence de bonne gouvernance dans le domaine fiscal encourage la fraude fiscale et l'évasion fiscale et grève lourdement les budgets nationaux et le système des ressources propres de l'Union européenne, d'un montant estimé par la presse économique entre 2 et 2,5% du PIB annuel de l'Union, soit entre 200 et 250 milliards d'euros.

- La mondialisation a compliqué la lutte contre la fraude fiscale à l'échelle internationale. Un grand nombre de multinationales se sont organisées pour tirer parti de l'évasion fiscale dans les divers territoires où elles exercent leurs activités; la disparité des régimes fiscaux d'un territoire à l'autre favorise les entreprises de grande taille, d'envergure internationale ou de création ancienne au détriment des entreprises de petite taille, d'envergure nationale ou de création récente.

- Il est fréquent que les pays en développement, précisément en raison du manque de gouvernance dans le domaine fiscal, ne disposent pas de la légitimité ou de l'autorité nécessaire pour taxer leurs citoyens; dans la définition de sa politique de gouvernance dans le domaine fiscal, l'Union européenne doit tenir compte des problèmes particuliers auxquels se heurtent les pays en développement et qu'elle doit les aider à surmonter ces problèmes.

⁸⁵⁰ Dans le rapport de 1998 intitulé «Concurrence fiscale dommageable – un problème mondial.» l'OCDE retient quatre critères essentiels qui permettent de déterminer si une juridiction est un paradis fiscal: i) l'absence d'impôt ou le prélèvement d'impôts minimes uniquement; ii) le manque de transparence; iii) l'existence de dispositions législatives ou de pratiques administratives empêchant un véritable échange de renseignements avec d'autres pays sur les contribuables bénéficiant de l'absence ou de la faiblesse de l'imposition dans cette juridiction; iv) l'absence d'obligation d'exercer une activité substantielle.

- L'action conjointe du G20 et des Nations unies, ainsi que les efforts réalisés dans le cadre des initiatives dirigées par l'OCDE ont débouché sur quelques résultats prometteurs en matière de gouvernance dans le domaine fiscal, mais ces résultats restent insuffisants pour faire face aux défis que représentent les paradis fiscaux et les centres bancaires extraterritoriaux (offshore) et ils doivent être suivis d'actions déterminantes, efficaces et cohérentes.
- L'OCDE évalue actuellement le montant des capitaux privés présents dans les paradis fiscaux à près de 1 000 000 000 000 USD (mille milliards USD), soit un montant cinq fois plus élevé qu'il y a vingt ans; plus d'un million de sociétés, principalement des États-Unis et des États membres de l'Union européenne, ont leur siège social dans des pays abritant ces paradis fiscaux.
- Il est prouvé que la crise financière a été engendrée en partie par de nouvelles formes d'instruments financiers complexes et de produits dérivés placés, dans une large mesure, dans des fonds domiciliés dans des territoires caractérisés par le secret des opérations; la crise financière a mis en évidence les risques liés aux paradis fiscaux et les conséquences de l'absence de bonne gouvernance dans le domaine fiscal.

3. Coopération fiscale au sein de l'Union européenne

Le marché intérieur est régi par des règles communes, notamment en matière de droit des sociétés et de fiscalité [2], qui doivent permettre aux entreprises et aux particuliers de tirer un parti maximal de l'ouverture des frontières. Ces règles ont notamment permis de réduire les coûts liés au respect de la réglementation et d'encourager les investissements transfrontaliers.

La législation communautaire laisse aux États membres une grande latitude dans la conception de leurs systèmes de fiscalité directe, de sorte qu'ils puissent les adapter en fonction d'objectifs et d'impératifs nationaux. Toutefois, au cours de la dernière décennie, ils sont convenus de différents mécanismes permettant d'enrayer l'érosion des assiettes fiscales et d'éliminer les distorsions dans la répartition des investissements. Ils ont par là reconnu que, seules, les actions nationales et bilatérales ne peuvent résoudre qu'une partie des problèmes liés à l'érosion fiscale, et qu'une coopération à l'échelle de l'Union européenne est essentielle.

Sur le plan juridique, la bonne gouvernance a déjà trouvé matière à application au travers de directives existantes:

- la directive sur la coopération administrative [3], qui prévoit l'échange d'informations entre autorités fiscales dans le domaine de la fiscalité directe;
- la directive relative l'assistance mutuelle au recouvrement de créances fiscales [4], qui établit un système dans lequel un État membre peut demander l'assistance d'un autre État membre aux fins du recouvrement de créances relatives à des taxes, impôts, droits ou autres prélèvements;
- la directive sur la fiscalité de l'épargne [5], qui garantit, moyennant certaines dérogations temporaires pendant une période transitoire, l'échange automatique entre les États membres des informations détenues par les banques.

A côté de ces instruments législatifs relatifs à la coopération administrative, existe aussi un accord politique entre les États membres visant à supprimer, au travers du Code de conduite dans le domaine de la fiscalité des entreprises, des mesures fiscales dommageables [6].

Ce dispositif est également complété par la vigilance de la Commission européenne à détecter et démanteler tout régime fiscal constitutif d'une aide d'Etat, problématique bien connue au Grand-Duché de Luxembourg [7], [8].

Au sein de l'Union européenne, la première grande série d'actions concernant la généralisation de la gouvernance dans le domaine fiscal vise à moderniser l'arsenal législatif existant.

En novembre 2008, la Commission a déposé une proposition de réforme de la directive sur la fiscalité de l'épargne, dont le but est de combler les lacunes existantes et de mieux prévenir l'évasion fiscale. Cette proposition entend également supprimer les distorsions présentes sur le marché entre produits financiers équivalents et limiter les formalités administratives imposées aux agents payeurs. [9]

Quant aux directives sur la coopération administrative et l'assistance mutuelle en matière de recouvrement de créances, elles sont en cours d'examen par le Parlement européen, qui devrait rendre son avis début 2010. Les amendements aux propositions proposent explicitement de supprimer le recours au secret bancaire, lequel permet d'éviter l'échange d'informations à des fins fiscales entre les administrations fiscales des États membres, la coopération entre États membres aux impôts de toute nature et l'instauration de l'échange automatique d'informations comme règle générale. [10] [11]

Hormis ces trois propositions, le Conseil poursuit également ses travaux sur la base d'un programme de travail révisé sur le code de conduite relatif à la fiscalité des entreprises adopté en novembre 2008. Le groupe de travail a accepté de poursuivre ses travaux sur la lutte contre les abus, la transparence et l'échange d'informations dans le domaine de l'établissement des prix de cession interne ainsi que sur les relations avec les pays tiers. Au titre de ce code, qui s'applique tant aux États membres qu'à leurs territoires dépendants ou associés, plus de 400 mesures relatives à la fiscalité des entreprises ont été évaluées et plus de 100 d'entre elles, jugées dommageables, ont été abrogées ou modifiées.

4. Coopération fiscale internationale

Au niveau international, la Commission européenne cherche de conférer à la bonne gouvernance un champ d'application le plus large possible.

L'un des instruments auquel l'Union européenne peut avoir recours pour encourager la bonne gouvernance dans le domaine fiscal dans les pays tiers est de négocier avec eux des accords sur la fraude fiscale qui comportent une clause d'échange d'informations. La Commission a engagé la négociation d'un accord de ce genre avec le Liechtenstein, qui a abandonné sa position de refus de toute coopération pour adopter une attitude coopérative.

Les mesures d'incitation financières que prévoit le 10^e Fonds européen de développement pour une série de pays des Caraïbes et du Pacifique constituent également un bon moyen d'encourager l'adoption des principes de bonne gouvernance. La Commission européenne a décidé de ne venir plus en aide à des pays en développement qui ne disposent pas d'une législation fiscale guidée par les principes de transparence, d'échange d'informations et de concurrence fiscale loyale.

Enfin, la Commission européenne veut promouvoir une approche internationale commune entre États membres en matière de mesures anti-abus visant à combattre plus efficacement ceux des pays tiers qui ne se conformeraient pas à ces standards internationaux communément acceptés. Lors de son sommet du 2 avril 2009, le G20 a dressé la liste d'une série de mesures de rétorsion possibles: renforcement des critères de divulgation d'informations de la part des contribuables et des établissements financiers, retenue à la source, refus des déductions de certains frais, révision de la stratégie des conventions fiscales, révision, par les établissements financiers internationaux, de leurs stratégies d'investissement, révision des programmes d'aide bilatéraux. [12] À Pittsburgh (les 24 et 25 septembre 2009), les dirigeants du G20 ont déclaré que les mesures de rétorsion à l'encontre des paradis fiscaux devraient être appliquées à compter de mars 2010.

5. Propositions pour renforcer le principe de bonne gouvernance dans le domaine fiscal au sein de l'Union européenne et à l'échelle internationale

Pour encourager la bonne gouvernance dans le domaine fiscal, il faut à la fois améliorer celle-ci au sein de l'Union européenne et mener des actions ciblant les pays tiers.

On estime que les actions suivantes sont nécessaires:

- l'Union européenne doit examiner diverses formes de sanctions et d'incitations, comme par exemple: l'instauration d'un prélèvement spécial sur toutes les opérations en direction ou en provenance de territoires qui refusent de coopérer, l'absence de reconnaissance par l'Union du statut juridique des sociétés constituées sur des territoires qui refusent de coopérer ou

l'interdiction faite aux établissements financiers de l'Union de créer ou de conserver des filiales ou des succursales sur des territoires qui refusent de coopérer;

- la création d'un système d'incitation adéquat pour le recouvrement des créances fiscales transfrontalières afin d'augmenter le taux actuel de recouvrement, qui n'est que de 5 %, en attribuant une proportion équitable des créances fiscales à l'administration qui les a recouvrées pour le compte de l'État membre demandeur, d'une part, et à l'administration de l'État membre demandeur, d'autre part;

- l'Union européenne devrait prendre des mesures pour prévenir le recours abusif au principe de résidence dans le cadre de régimes de propriété et de domiciliation fictives par lesquels des sociétés écrans ou des sociétés holding sans aucune activité permettent à leurs propriétaires de ne pas être imposés dans le pays où ils sont domiciliés;

- l'Union européenne devrait adopter, lors de l'application des mesures de lutte contre les abus, une approche commune effective, loyale et fondée sur la notion de montage artificiel définie par la Cour de justice;

- l'Union européenne devrait mettre en place un cadre cohérent de bonne gouvernance dans le domaine fiscal applicable à la politique européenne de voisinage, à la politique d'élargissement et à la politique de coopération au développement [13]; il est nécessaire d'établir un lien entre, d'une part, le soutien financier de l'Union européenne et le degré d'accès aux marchés communautaires dont bénéficient certains pays et, d'autre part, le niveau de coopération qu'offrent ces pays en ce qui concerne les principes de la bonne gouvernance dans le domaine fiscal; l'Union européenne devrait prendre en considération aussi fournir de l'assistance technique nécessaire pour aider les pays concernés à respecter leurs engagements en matière de bonne gouvernance dans le domaine fiscal; si un pays le demande, l'assistance technique pourrait également concerner la conception d'un système fiscal efficace permettant à ce pays de mieux tirer parti des ressources dont il dispose;

- l'Union européenne devrait réviser les normes comptables actuelles pour accroître la transparence; la mise en place d'une assiette commune consolidée pour l'impôt des sociétés contribuerait à résoudre, au sein de l'Union européenne, les questions de double imposition et des prix de cession interne au sein des groupes consolidés;

- les États membres doivent coordonner leurs politiques fiscales afin de renforcer l'application des règles de lutte contre l'évasion fiscale; il importe de veiller à ce que, par leurs conventions fiscales bilatérales, les États membres ne créent pas de possibilités de contournement des directives communautaires ou de la législation fiscale d'autres États membres. Dans le même temps, l'existence d'obligations de bonne gouvernance dans les accords conclus entre l'Union européenne et les pays tiers conférerait aux États membres un pouvoir de négociation plus grand dans leurs pourparlers bilatéraux avec ces pays;

- les États membres devraient également définir une approche plus unifiée envers les pays tiers, selon que ceux-ci appliquent ou non les principes de la bonne gouvernance dans le domaine fiscal. Ainsi, un pays qui applique ces principes pourrait être retiré des «listes noires» nationales des États membres afin qu'il ne fasse plus l'objet de mesures anti-abus pour les pratiques fiscales concernées. À l'inverse, les juridictions qui ne mettent pas en œuvre de façon satisfaisante les aspects clés de bonne gouvernance dans le domaine fiscal appliqués par les États membres de l'Union européenne pourraient faire l'objet de mesures de rétorsion coordonnées. [14].

6. Conclusions

D'une manière générale, le cadre législatif et réglementaire de l'Union européenne en matière de coopération fiscale peut être jugé satisfaisant: des directives en matière de fiscalité de l'épargne, d'assistance mutuelle et de recouvrement des créances fiscales ont été adoptées ou sont en cours d'examen. Reste à savoir comment et avec quelle diligence les États membres mettront ces règles communautaires en application.

Il est important de promouvoir la bonne gouvernance dans le domaine fiscal à la fois en dehors et au sein de l'Union européenne, tant au niveau communautaire qu'à celui des États membres. Si l'on améliore la bonne gouvernance dans le domaine fiscal au sein de l'Union, les États membres en retireront des avantages et l'Union pourra plus facilement convaincre les autres juridictions d'établir avec elle une coopération administrative efficace. Les États membres devraient en conséquence adopter dès que possible les propositions de la Commission européenne relatives aux directives sur l'assistance mutuelle en matière de recouvrement des créances et sur la fiscalité de l'épargne, et continuer à accorder l'attention nécessaire au démantèlement des régimes fiscaux dommageables dans le domaine de la fiscalité directe.

Le renforcement de la cohérence et de la coordination des politiques au niveau de l'Union européenne permettra de promouvoir la bonne gouvernance dans le domaine fiscal sur une base géographique plus large. L'objectif de l'Union européenne est de faire en sorte que l'approfondissement des relations économiques entre l'Union et les juridictions partenaires s'accompagne d'un accord sur les principes de la bonne gouvernance dans le domaine fiscal, suivi, le cas échéant, d'accords de coopération en matière fiscale.

Tout en respectant pleinement le principe de subsidiarité, il est nécessaire d'assurer davantage de cohérence entre la position des différents États membres dans les organismes internationaux traitant la fiscalité et les principes de bonne gouvernance définis d'un commun accord, tels que ceux établis dans les conventions fiscales bilatérales avec les pays tiers et au sein des organismes internationaux. Il faudra pour cela mettre en place une coopération accrue au niveau de l'Union européenne afin de garantir que la dynamique engagée en faveur d'une coopération plus ouverte et constructive en matière fiscale se poursuive au niveau mondial.

En conclusion, on attire l'attention sur la nécessité de garantir une transposition rapide au niveau national des directives déjà adoptées, d'accélérer la procédure pour celles qui sont en cours d'examen, d'appliquer des politiques plus cohérentes et mieux coordonnées au niveau de l'Union européenne et enfin d'assurer une plus grande cohérence entre les positions des différents États membres et les principes établis en matière de bonne gouvernance.

BUDGETARY CLASSIFICATIONS' ROLE IN PUBLIC FINANCIAL MANAGEMENT

Gyorgy Attila

Bucharest Academy of Economic Studies

Faculty of Finance, Assurance, Banks and Stock Exchanges

Gyorgy Adina Cristina

Bucharest Academy of Economic Studies

Research Department

Budgetary classifications are a vital condition for a sound budgetary management. To be a good and useful classification, some rules should be respected. The international experience could offer us guiding lines which contribute to this purpose. In our paper we tried to present some basic elements of a budgetary classification, stressing on their utility in practice: financial management, reporting, on various criteria, and electronic processing. In last part is presented a functional example of such a classification which proved its utility in Romanian public financial sector. This work was supported by CNCISIS-UEFISCSU, project number PNII-IDEI 1780/2008.

Keywords: budgetary classification, public financial indicators; principle of specialization

JEL: H6 - National Budget, Deficit, and Debt

1. Introduction

Any modern budget should be structured unitarily using general accepted criteria. The need of coherent structure is justified by the role of public budget in financial life of every state, local community or public institution. All countries improved their classifications in order to respond in the best way to their needs.

Budgetary classification is used in all stages of budgetary process: drafting budget proposals, execution of revenues and expenses, and reporting the result after budgetary year ends. The records made on classifications are used for statistical reports related to budgetary indicators.

A frequently used budgetary principle is specialization. This principle imposes using classifications for data ordered uniquely, in a logic way, and permitting comparisons in time. All budgetary processes are easier to unfurl if indicators have codes which respect classification order.

Nowadays classification tries to restructure indicators such a manner than budgets to help management, not to represent an obstacle. In budgetary management, line item budgets are less recommended because could reduce the efficiency of activities by imposing financial barriers to management. So, a too analytical classification should be used only in reporting, not in budgeting. Execution part of the budget should be dynamic, the managers having the right to decide expenses respecting the global ceilings imposed by budgets. Reporting part should be more explicit, using the whole classification items, being in consonance with other recent issues (accrual approach, chart of accounts correlations etc.).

The control level imposes classification complexity. If revenue recording is simpler because administration has to separate revenues on tax types, expense recording should be more complex because the control is multi-parametrical and stricter in order to assure efficient usage of public funds. A sound system of budget classification should at a minimum comprise a classification of revenues into various categories, and administrative, economic, and functional classifications of expenditures (Jacobs et al., 2009).

2. Taxonomy

Budgetary classifications should contribute to a better public fund management. This is why, in practice, are used different types of classifications: each trying to present different approaches of grouping the component indicators. The main questions should answer the revenues grouped on budgetary classifications are: What tax/income is paid? Which budget benefit form certain tax? and Who was the taxpayer?. The main questions should answer the expenses grouped on budgetary classifications are: Why is the money being spent? What is being purchased? and Where is the money being spent? (HISD, 2009).

The needs come from practice impose the type of classification used. The correlation between main classifications and purposes are presented below.

Table 1: Correlation between classifications and purposes

Classification criteria	Purpose
Function (only for expenses)	Historical analysis and policy formulation
Organization	Accountability and budget ration
Economic category	Statistics (GFS) and object (i.e., line item), for compliance controls and economic analysis
Program, activity, and output (only for expenses)	For policy formulation and performance accountability

Source: after Salvatore Schiavo-Campo and Daniel Tommasi - Managing Government Expenditure

Functional classification is largely used in order to present the expenditures grouped on domains. The standard functional classification was set up by United Nations and is known as COFOG. The ten divisions of the classification cover all the functions of the government. Majority of states and financial institutions developed their own classifications on COFOG.

Organizational (known also as institutional or administrative) classification presents the subordination relations between different institutions. These classifications are highly volatile because subordination systems are frequently changing, institutions are merging or splitting up, or changing their names. The role of this classification is to establish responsibilities for institutions regarding public fund usage.

Economic classification groups revenues on every tax type collected to the budget, and expenditures on destination. GAO emphasized the disadvantage of expenses' economic classification by not presenting the motivation of used amounts, but only destination (GAO, 1994).

Program classification is a policy oriented instrument helping public management to have a separate financial management on each policy, activity, or output. Classifying expenditures by program can serve two purposes: (1) identifying and clarifying the goals and objectives of government spending and (2) monitoring operational performance through performance indicators, which may relate to the inputs, outputs, or outcomes of a particular program (Jacobs et al., 2009).

Resource classification is used when budgetary systems have numerous components. Each component represents a resource and a separate gesture is required. In most nations' case the state budget is distinct from local budgets and from social security budgets.

Geographic location classification helps to obtain budgetary data from territorial point of view. For international comparisons the national data are used; for EU analysis the regional data are vital; for national level studies territorially divided information use geographical classifications.

Classifications on beneficiaries are used to monitor and evidence the beneficiaries of the public funds. Usually this classification is useful at donor budgets (budgets which assure numerous subsidies to different budgets which represent recipient budgets).

3. Characteristics

A budgetary classification should respect some basic principles. If not, applying classification become impossible driving to errors or incorrect interpretations. A sound budgetary classification should be:

- structured;
- comprehensive;
- non-redundant;
- open.

Structured classification have a clear and logical order of items inside classification, general categories are subdivided into specific ones. Usually, revenues are grouped on sources, while expenses on destinations, domains, institutions, and so on. For different levels of details are created parts, chapters, subchapters, articles, alignments etc.

A comprehensive classification means that any revenue or expense to be present in the classification. Most of them have after each main category a special position for other revenues or expenses in which are included small, insignificant, exceptional, and new (unknown at the moment of creating) revenues or expenses;

Non-redundancy (mutual exclusivity) imposes a clear separation between different items in the classification. For a unitary approach, classification issuers could present general rules of introducing revenues and expenses on classification, explanatory notes, and/or examples which help users to make no mistakes or wrong enclosure.

Because public financial indicators are changing in time, classifications should be open, respectively them should permit changes and new entries. A dynamic public sector must have a dynamic budgetary classification which keeps pace with public economy.

4. Coding

A classification can be used in practice by coding the indicators contained in it. The codification systems are vital for electronic processing of data. IT systems can make real time reports filtering and grouping information in base of codes used by budgetary classifications.

Coding systems used for budgetary classifications should contain several code modules, each placed uniquely in the code's structure. If a section is not applicable, there should be also coded (usually using zeros) in order not to move next sections from their positions.

Romanian coding system is presented below. This system was introduced in 2006 and was replacing a similar one from 1995. The coding sections were created in base of Public Finance Act and Local Public Finance Act which introduce the classification criteria. The codes are exclusively numeric, having at least two digit sections.

Table 2: Revenue coding in Romania

Structure	Meaning	Example
2 digit coding revenue chapter	Revenue chapters represent the main category of revenue	01 – corporate taxes 03 – personal taxes 07 – property taxes
2 digit coding for beneficiary budget	Each type of budget is coded	01 – state budget 02 – local budgets

2 digit coding revenue subchapters	Each chapter is subdivided in subchapters	07.02.01 – tax on buildings collected to the local budgets
2 digit coding revenue line	Some revenues are detailed also by lines. If not, the budgetary coding skip it and the IBAN coding use double X letters	07.02.01.02 – tax on buildings collected to the local budgets from legal persons
3-10 digit coding for taxpayer of beneficiary	Taxes collected by central administration are coded with taxpayer’s fiscal code (usually same with VAT code); other taxes are coded on beneficiary code (the fiscal code of the institution which collect that revenue)	07.02.01.02.12345678 – tax on buildings collected to the local budgets from legal persons; beneficiary local authority is that which have fiscal code 12345678

Source: synopsis based on RMFO no. 1954/2005

Table 3: Revenue coding in Romania

Structure	Meaning	Example
2 digit coding expense chapter	Expense chapters represent the domains established on the functional classification. In Romania COFOG represented the reference	51 – public authorities 65 – education 66 – health
2 digit coding the budget	Each type of budget is coded same to revenues	01 – state budget 02 – local budgets
2 digit coding expense titles	Expense titles represent the expense type established on the economic classification	10 – wages 20 – goods and services 71 – investments
3-10 digit coding the responsible institution	Each institution which spend public money is recorded on organisational classification	65.02.10.234567 – wages paid by a school (having the fiscal code 234567) from local budget

Source: synopsis based on RMFO no. 1954/2005

Analyzing the Romanian coding system, we can conclude that it respect the general guiding lines proposed by international financial institutions (especially IMF and UN). Coding systems permit to identify the revenues and expenses on the main classifications’ structure.

Conclusions

Budgetary classifications are vital for every budgetary management, especially nowadays when IT systems are largely used to record financial flows from public sector. A good structured

classification can become a useful management tool, while a faulty classification could be an impediment in managing institution's financial activity.

Internationally accepted guiding classifications are recommended in order to assure comparable information between countries and regions. In this respect, the initiative was taken by International Monetary Fund and United Nations, with a very positive result.

The most important things that we recommend related to public classifications are: (i) create professional classifications based on international guidelines in order to assure international comparability without other adjustments; (ii) every country and institution should adapt own classifications, but not renouncing to general guidelines; (iii) in execution classifications should be used at chapter level, and in reporting at most detailed level.

ANNUAL FINANCIAL STATEMENTS – A SOURCE FOR THE FINANCIAL DECISIONS OF INSOLVENT COMPANIES

Hada Tedor

"1 Decembrie 1918" University, Alba Iulia, Romania

Faculty of Science

The paper presents the importance of financial statements in determining the insolvency of a company. The first part of the article presents a case study and the main signals of bankruptcy: negative working capital, negative equity capitals, losses, etc. In the end of the paper we detail issues that are not observable and that are related to the actual management of the company.

Key words: working capital, working capital need, treasury, equity capitals, annual financial statements

JEL classification: G33

In Romania, the structure of annual financial statements was regulated by OMFP no. 94/2000 and 306/2000, then by OMFP no. 1752/2005 and recently by OMFP no. 3055/2009 and includes:

- the balance sheet;
- the short balance;
- the profit and loss account;
- the statement of changes in equity capital;
- the statement of cash flows;
- Notes.

Economically, it is useful for the economic agents to determine those indicators that can prevent insolvency based on the analysis of the data in the annual financial statements. The specialized literature presents for this purpose models like: the Z score recommended by E. Altman, the Canon Holder model, the model of William Beaver, the model of the Central Bank of France and the Cematt model. More recently, commercial banks have bankruptcy risk assessment methods, such as: the method of the Romanian Commercial Bank, the method of the Romanian Development Bank – Groupe Societe Generale, the method of Transilvania Bank, the method of Raiffeisen Bank, which are methods tailored for Romanian economy, with obvious results in the diagnosis of bankruptcy.

Although the causes that determine bankruptcy are varied, we believe that some have decisive influences in this regard, such as:

- the lack of order contracts after 1990;
- outdated technology;
- inadequate legislation for privatization;
- persistence of strikes;
- low productivity;
- property claims;
- inadequate price policies;
- Stock production; etc.

Steve Robinson in the book "Financial Management"⁸⁵¹ shows the easily identifiable problems based on annual financial statements, such as:

- the massive increase of the credit account (debts);

⁸⁵¹ Steve Robinson, *Financial Management*, Teora Publishing, Bucharest, 2005, p. 147

- the substantial increase in stock (inventory);
- reduction in liquidity;
- increasing the amounts borrowed;
- cutting back on future investments;
- Reduction in paid dividends.

Next, we will present the balance sheet structure of an economic agent⁸⁵² for two consecutive reporting periods. Therefore:

	N	-lei- N+1
The debit structure		
Total fixed assets, of which:	365408,0	238526,5
- intangible assets	-	-
- tangible assets, of which:	365310,0	238428,5
- freehold land	105451,2	-
- buildings	248743,0	235212,8
- plant and machinery	4998,2	2591,0
- motor vehicles	4109,7	624,7
- other fixed assets	-	-
- tangible assets in progress	2007,9	-
- financial assets	-98,0	-98,0
Total current assets, of which:	52289,2	33929,7
Inventory:	11638,7	
- raw materials	5744,7	
- semi-finished goods	5004,6	
- goods purchased for resale	35,0	
- packaging materials	854,4	
Other current assets, of which:	40650,5	33929,7
- clients and similar accounts	38182,4	33741,7
- other claims	1829,2	-
- investment papers	100,0	100,0
- bank accounts	7,2	13,0
- petty cash in lei	531,7	74,1
- other values	-	0,9
Suspense account	13699,2	-
TOTAL ASSET	431396,4	272456,2
		lei
The credit structure	N	N+1
Equity capitals, of which:	-208005,6	-1030585,5
- social capital	733701,2	595000,0
- uncovered loss	-	-939968,3
- loss	-943123,8	-685617,2
- other funds	1417,0	-
Long-term loans	147526,4	181565,7
Suppliers and similar accounts	43627,3	28047,7
Creditor clients	2289,2	1155,0

⁸⁵² Data are real

Other debts	445959,1	1092273,3
TOTAL LIABILITIES	431396,4	272456,2

Based on the comparative data of the two consecutive balances, the following can be highlighted:

- regarding intangible assets, freehold lands in the year N+1 was missing because lands were retroceded to their owners;
- the inventory was exploited, so in the year N+1 the company had no stock;
- clients and similar accounts dropped from 40650,5 lei to 33929,7 lei;
- suspense accounts have not occurred in the year N+1;
- from -208005,6 lei in the year N, equity capitals reached -1030585,5 lei, so the net asset is negative;
- long-term loans increased from 147526,4 lei to 181565,7 lei;
- unpaid supplied recorded a drop from 43627,3 lei to 28047,7 lei;
- other debts grew 2.5 times.

By calculating the net working capital with the help of the two known methods, results:

a) $NWC = \text{Permanent capital} - \text{Assets}$

b) $NWC = \text{Assets} - \text{Short-term debts}$

For the year N, we have:

a) $NWC_N = -208005,6 + 147526,4 - 365408,0 = -425887,2$

b) $NWC = 52289,2 + 13699,2 - (43627,3 + 2289,2 + 445959,1) = 65988,4 - 491875,6 = -425887,2$

For the year N+1, we have:

a) $NWC_{N+1} = -1030585,5 + 181565,7 - 238526,5 = -1087546,3$

b) $NWC_{N+1} = 33929,7 - 1121476 = -1087546,3$

The working capital in the year N, as well as in the year N+1, is negative and represents a signal that the company is in difficulty, and the working capital, as the main financing source of the current assets, can't finance these assets.

Next, we'll determine the company's treasury in the two analyzed years. In order to do this, we'll determine:

The need for working capital = Stocks + Claims – Operating debts, and it will result:

Year N: $11638,7 + 38182,4 + 1829,2 + 13699,2 - (43627,3 + 2289,2 + 445959,1) = 65349,5 - 491875,6 = -426526,1$

Year N+1: $WC_{Need} = 0 + 33741,7 - (28047,1 + 1155,0 + 1092273,3) = 33741,7 - 1121476 = -1087734,3$

The treasury has values in the two analyzed years:

Treasury = NetWC – WCNeed

Year N: $T = -425887,2 + 426526,1 = 638,9$

Treasury = Availability – Treasury credits = $100 + 7,2 + 531,7 = 638,9$

Year N+1: $T = -1087546,3 + 1087734,3 = 188,0$

$T = 100 + 13,0 + 74,1 + 0,9 = 188,0$

The values of the treasury in year N, as well as in year N+1, are low. The companies used drawn-in sources for financing, meaning delaying the payment of short-term debts.

Indicator	Year N	Year N+1
TOTAL operating revenue, of which:	-257463,7	125015,5
- revenues from sale of goods	8567,1	782,9
- sold production	423442,2	53479,6
- turnover	432009,3	54262,5

- stored production income	-689473,0	37503,0
- revenue from tangible assets production		33250
Operating expenses, of which:	670195,9	531739,8
- goods for resale	7470,9	726,2
- total material expenses	182126,2	66415,9
- third party services expenses	13244,6	22600,7
- taxes, duties and similar expenses	5341,3	340564,8
- total personnel expenses	111175,5	88763,2
- other operating expenses	394776	-
- adjustment expenses for fixed assets (depreciation)	311359,8	12669,0
Operating loss:	927659,6	406724,3
Total financial revenues, of which:	11,5	77264,4
- interest income	11,5	46,8
- other financial revenues	-	77217,6
Financial expenses, of which:	73892,1	71740,5
- interest expenses	73892,1	48335,5
- other financial expenses		23405,0
Financial profit		5523,9
Financial loss	73880,6	
Extraordinary revenues	59436,6	12951,5
Extraordinary expenses	1020,2	297368,3
Extraordinary profit	58416,4	-
Extraordinary loss		284416,8
Total revenues	-198015,6	215231,4
Total expenses	745108,2	900848,6
Total loss	943123,8	685617,2

By analyzing the data in the profit and loss account, the following will result:

- the operating revenues in the year N were negative due to the income from the stored production (debit balance);
- the operating revenues in the year N+1 were 125015,5 lei, being influenced by the revenues from the tangible asset production of 33250 lei;
- the operating expenses were higher than revenues in the two analyzed years;
- personnel expenses in the year N+1 were higher than the turnover, which were economically unjustified;
- operating losses were recorded in both years;
- the financial activity recorded loss in the year N, but brought financial profit in the year N+1;
- the extraordinary activity brought profit in year N, and extraordinary loss in the year N+1.

Overall, loss was achieved in both years.

Mihaela Onofrei, in the book “Financial Management”⁸⁵³ shows that “managers must identify early the signs of deteriorating financial statements of the enterprise, such as:

⁸⁵³ Mihaela Onofrei, *Financial Management*, C.H. Beck Publishing, 2006, p. 115

- achieving negative financial results;
- the existence of negative working capital;
- the inability to reimburse credits at maturity;
- the bankruptcy of suppliers and clients important for the enterprise;
- reduced availability or unavailability of a manager;
- the persistence of strikes.”

Steve Robinson⁸⁵⁴ shows that “they are problems difficult to identify”, so these “accounts do not reveal everything” and he goes on to mention the list of events that announce bankruptcy:

- accounting norms and practices – other than the ones that are standard – compared to the norms of the competition and with the norms existent in the concerned sector;
- fast increase of the sales volume, of the main accounts, of the working capital;
- the inability to reimburse credits at maturity;
- the inability to draw-up in time the financial reports and the account statements;
- combining the functions of the chairmen and chief executive, especially when these functions are associated with a large package of own shares;
- leading and charming personalities that are acting as managers of the company;
- frequent resignations from the managing board;
- sale of shares belonging to the company director (in the *Financial Times* magazine, for the companies listed in the UK), especially right before „closing” (seven weeks before announcing the financial results of the company);
- transition from asset acquisition to leasing;
- predatory behaviour of the management;
- unexplained transactions between the subsidiaries of a company.

We believe that since the company recorded negative operating revenues, negative working capital, losses and unjustified values in the year N, bankruptcy was imminent.

STATE BUDGET AND FISCAL POLICY INSTRUMENTS TO ACHIEVE ITS

Haralambie George Alin

Universitatea Petrol-Gaze Ploiești, Faculty Economic Science

This paper presents the tools for carrying out the fiscal budget in Romania. An effective fiscal policy involves increasing budget revenues and reduce their costs of collection. Public expenditure, taxes and debt are tools of fiscal policy to achieve economic stability budget. They are also presented the interdependencies between fiscal policy and budget.

Key words: budget, collecting, fiscal policy, fiscal efficiency, public revenues;

Introduction

Every state, regardless of size or level of economic development interfere in the economy by the agency of fiscal policy for securing his financial resources in order to fulfil his functions but also to impel the development of economic sectors and also to dishearten the fiscal fraud.

The mains (principals) instruments witch the state can use to intervine in the economy are in the majority of the countries untaxes and taxes, which the state collect through various ways from the tax payers.

In Romania, as in the majority of the countries, the role of taxes manifest on the financial plan, they are the main means of raising public financial resources, that are necessary for financing public expenditures needed for collectives requirements.

Fiscal policy is a very important component of the financial policy, which is responsible for the collecting of public financial resources like untaxes and taxes. One definition in this direction was that of Condor Ioan who consider that "fiscal policy include (involve, contain) the total (ensemble) principles regarding the establishing and collecting the untaxes, taxes and other public revenues, which characterize the state option concerning and taxes"⁸⁵⁵. Gheorghe Manolescu claims, also, that "fiscal policy is constituted within the framework of public authority activity of establishing and utilizing the resources needed for public consumption and for the supply of public goods and services"⁸⁵⁶. Through fiscal policy is established the volume and source of public revenues, the methods of take over who will be utilized, the objectives to be follow and also the possibilityts that can be used to achive all these goals.

From these definitions result that fiscal policy represent a mechanism of taking over a part of the revenues earn by the economic agents, households and enterprises, for raising of funds who are necessary for public expenditures. The bundle between taxes and public expenditures was pointed by Paul A Samuelson, who see fiscal policy like "a process consisting in manipulating taxes and public expenditures"⁸⁵⁷ saying also that these is influencing the general distribution of national product between consumption and investments.

The objectives of fiscal policy

The budgetary policy influence macroeconomic objectives-production fluctuation, of prices and that of unemployment, fact that require to tackle this policy in connection with the fiscal policy, because both of them are elaborated at the same time by the public authorities. The fiscal policy of a state is reflected yearly by his budget. Within the framework of fiscal policy the priority is the establishment on one hand of the total volume of expenditures, on the other hand of the way

⁸⁵⁵ Condor, I., Fiscal law, published by Lumina Lex Bucurest, 2002, pg. 71.

⁸⁵⁶ Manolescu Gh., Economic policy. Drafts, instruments, experiments, published by Economic, Bucurest, 1997, pg. 265.

⁸⁵⁷ Samuelson, P.A., Political economy, published by Teora, Bucurest, 2001, pg. 364.

in which they can be financed those expenditures: from fiscal sources or by contracting some loans, each of these ones generating different economic effects.

The rationality of the fiscal policy decisions require to respect the following principles of taxation: currency, equity, honesty, efficiency and the convenience of taxation.

It comes out that ascertained the increasing of public expenditures included in the over-all budget from year to year, the accomplishment of state functions requires the adoption of a unitary fiscal-budgetary policy, who suppose that public revenues and expenditures can be approach in a unitary manner.

The fiscal policy is strongly connected with the ability of public authorities to use taxation and public expenditures to influence the national economy.

The fiscal system, with all his implications and functionalities, can not function without the existence of the fiscal machine-the engine who put in motion the fiscal mechanism. He must answer some morals and ethics demands in order to make the fiscal burden fair and not overwhelming, therefore more reasonable.

In keeping with special literature a reasonable fiscal system must fulfil some functions like: rally public revenues, stimulating economic function, social and control function, stimulate saving and investments in the private sector.

On the social plan the fiscal policy is utilized for reduction of inequalities between revenues of taxpayers, the taxation for taxpayers with big revenues being heavyer. Simultaneously the unfortunate taxpayers are protected through the agency of tax exemption. These ones are granted in order personalize taxation, by realizing a connection between revenues and taxes.

The objectives of the fiscal policy are: regulate market position and relaunch of the economy, restructure economic sector and economic growth, improvement of productive sector. In order to achive these goals, the state must reduce the fiscal burden simultaneously with a increase in public expenditures in a period economic crisis, while in a period of economic boom he must rise tax rates and also cut down expenses made from national budget.

The main problem of Romania fiscal policy in the area of revenues is finding a balance between the necessity of increasing revenues by raising rates as a principal source for covering expenditures, who are directioned towards to diminish poverty, and also the necessity of supporting business environment, who represent the principal factor for economic growth.

In this sense growing up revenues more rapidly than inflation rate and also the adjusting the fiscal burden at a level which is favourable for the development of business environment and investment capital will be an opportunity.

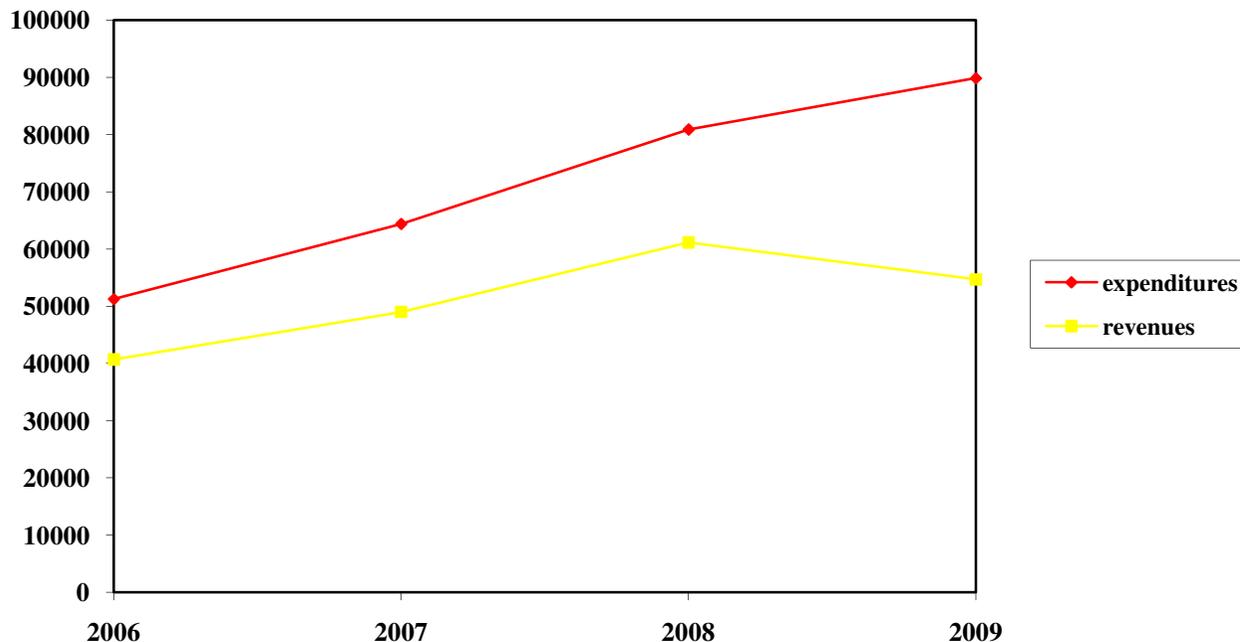

The method of analysis of the fiscal policy in Romania was based on the dates provided by Ministry of Public Finances.

The evolution of revenues and expenditures belonging to the national budget in the period 2006-2009

The revenues belonging to national budget increased between 2006-2008. In 2009 due to the economic crisis who affected Romania they drop significantly. By analysing the informations in the chart bellow we can observe that the public expenditure grew more rapidly than the revenues due to the poorly management of the public funds. One explication for the growth of revenues in the period 2006-2008 is the better gathering of fiscal revenues.

Figure 1. The evolution of revenues and expenditures belonging to the national budget in the period 2006-2009

The evolution of revenues and expenditures belonging to the national budget in the period 2006-2009

The data from below presents the execution of the state budget during the period 2006-2009.

Table 1. Revenues execution of the state budget

lei million

INDICATORS	2006	2007	2008	2009
REVENUES-TOTAL	40698,1	48984,6	61151,0	54678,4
1. Fiscal revenues	37900,1	44916,7	55133,6	48152,9
Tax on income, profit and capital earnings of which:	14122	14615,9	18563,2	15539,7

Source of the dates; Ministry of Public Finances.

lei million

From the analysis of the dates from above we can observe that the fiscal revenues are holding a weight of over 90%, especially those who are proceeding from taxes and duties on goods and services (approximately 59% from the total revenues). Those who are proceeding from tax on income, profit and capital earnings represent approximately 30% from the total revenues, fact that shows the interest of the public authorities to let at the disposal of the private individuals and economic agents a bigger part from their revenues, in order to stimulate saving and investments in the private sector. This objective was attained by the introduction in the year 2005 of 16% unique quota taxation, thing that had led to a decrease of public revenues from tax on income, profit and capital earnings. But the introduction of profit minimum tax in the year 2009 was a mistake because a lot of economic agents closed down their business, fact that had repercussions on revenues attracted on the national budget from profit tax because they drop with 20%. Also we can see that the revenues from value added tax had diminished significantly because the people had to restrain their consumption of goods in this period of economic recession. The revenues from excise duties are significantly bigger from year to year because the exchange rate for euro/ron and the specific excise tax increased. The estimated revenues for 2010 are 66.654,3 million lei, much bigger than those of the year 2009 but the expenditures are 101.678,4 million lei with a budgetary deficit of 35.024,1 millions lei.

Upon close examination of the current expenditures we can observe that they grew every year. These ones are non-productive representing a definitive consumption of GDP. By opposite, capital expenditures (those ones who made for the development and modernization of public sector) diminished in this period of time. They are materialized in investments in the sphere of material or non-material production.

Measures taken by the state in order to reduce budget deficit

The state must take urgent actions in order to reduce current expenditures and also to increase capital expenditures who will generate further revenues, as a part of programme of reducing budget deficit. Some steps were made in this direction but there are a lots of thing to be made in the next years (for example a growth of the productive rate in the public sector).

The main objective for the fiscal policy during this period of time was maintaining budgetary deficit at a lower level by bettering gathering public revenues. There are still a lots of steps to be made in order to eradicate tax avoidance. First of all the fiscal authorities must render more frequent controls in order to uncover those persons who elude from payment their taxes to the budget. Another problem of fiscal policy is the frequent changes of fiscal legislation in force who made the taxpayer reluctant in opening a business.

The consequence of taxation pressure over the consumption, over production factors-labor and capital, represent an important element with a view to improving the tax system. By comparison with the others state from European Union, tax burden in Romania is much smaller. The fiscal rate IN Romania although it is smaller By comparison with the others state from European Union, cannot be appreciated without taking into consideration the level of GDP per person, who is smaller than that of others EU countries.

By observing the way in which the budgetary fiscal revenues evolved in the analysed period, both from the point of view of structures and weight of these, we can say that the fiscal policy promoted until the present day did not brought the stability needed for the development of a lasting and harmonious economic environment and none a real growth in the national budget revenues.

The state was forced to establish new taxes in order to cover the difference between growth of public expenses and that of public revenues who was smaller, by increasing tax burden.

Beginning with the year 2009, the budgetary policy is pursuing the correction of external and internal unbalances who has been let to amplify in the economy. This is a part of the macroeconomic program adopted in april 2009 as a response to the aid flow granted to Romania by the European Union, International Monetary Fund and others. In accordance with this program we forecast a budget deficit of 7% of GDP due to economic downturn. By reducing the country's budget deficit for 2010, and adopting a much more prudent fiscal policy, Romania would signal to the International Monetary Fund and foreign investors that the country was adjusting to the downturn in the external environment.

Conclusions

The state budget for the year 2010 is not realistic in the current condition of economic slowdown. The perspectives on the romanian economy on the short term are negative. Simultaneously the tightening of global credit lines will undoubtedly led to a decrease of the foreign capital invested in Romania, fact who will have repercusion over financing its current account deficit - which significantly adds to the risk of a depreciation of RON/EUR.

As to budgetary policy, government had one tough choices to make between raising budgetary revenues through tax increases or slashing expenditure (current expenditure) from national budget by mass dismissals from the public sector and by reducing public expenses with goods and services, finally the executive authority chose the second one who is very unpopular among the people. The preferred action from a macroeconomic standpoint is to cut non-productivity orientated spending. On the short time the adopted measure lead to unemployment, decrease of revenues as a result of some cancellations of pays rise who where given until decembre 2009.

In general, it does not seem particularly prudent to raise taxes in a period of slowing economic growth.

As a conclusion we can say that fiscal policy must be conceived like a combination between the stimulative elements and those restrictions in order to achive macroeconomic stability, materialized in the accomplishment of a lasting economic growth, in circumstance of deflation, of maintaining current account deficit in reasonable boundary who can be financed and that of consolidation foreign exchange reserves.

Faculty of Economics and Business Administration

Fiscal administration seeks rapid intervention in the action of preventing the formation of budgetary arrears and accomplishing public financial resources at the time scheduled by the fiscal authorities to collect public financial resources. The establishing of the immediate measure blocking of bank accounts of economic agents who recorded debt to the consolidated general budget of the state, is an essential measure necessary to avoid the forward slip of other creditors, debt recovery actions, having as consequence the preventing of taxpayers as state debtors to organize their insolvency. The present study aims to draw attention upon the effects of blocking the bank accounts on the evolution of budgetary revenues through enforcement measures during 2006-2009, and the registering of more favorable results regarding collection should take into account the immediate legitimate interest of the budgeted creditor, but should also make sure that the rights of taxpayers are observed.

Keywords: bank account sequestration, compulsory enforcement, state-financed creditor, establishment of sequestration, sequestration of third party.

JEL code: G2, H2, H3

1. Introduction

Sequestration is the method of compulsory enforcement by which the fiscal creditor pursues, on behalf of his tax claim, the amounts that a third person owes the prosecuted debtor.

This involves blocking the actions of the sequestered third party, who is in his turn the debtor of the prosecuted taxpayer, of the amounts owed by the latter and the direct payment to the pursuing creditor.

The establishment of sequestration creates a legal relationship between the **state-financed creditor** (the state through the fiscal administration, a local community, etc.) and the **sequestered third party**, the legal relationship grafted on the existence of two other legal relationships: one between the creditor and the and, respectively, between the tax duty's debtor - as a creditor - and the sequestered third party.

Compulsory enforcement by sequestration may extend to any traceable amounts representing income and cash in lei and foreign currencies, securities or other intangible movable property owned and / or due under any title to the debtor by third parties or which are to become due to the debtor and / or will get hold of in future on the basis of the existing legal relationships.

The amounts representing the incomes of the debtor as a natural person, accomplished as an employee, in the form of salaries and other forms of periodic income resulting from employment, pensions of any kind, as well as any aid or benefit of special purpose are subject to prosecution only in the conditions foreseen in art.409 in the Code of Civil Procedure.

2. Sequestration of bank accounts

The sequestration is established by the executing agency by establishing a notice of the attachment, which is transmitted sequestrated third party, by registered letter, accompanied by proof of receipt along with a certified copy of the writ of compulsory enforcement. The sequestration is not subject to validation. The debtor will also be informed about the **establishment of sequestration.**

After the establishment of sequestration the sequestrated third party is required to make statutory deductions immediately and transfer the amount into an account designated by the executionary body to the full recovery of the budget debt, while communicating in writing about the existence of other creditors.

The sequestration involves three parties in opposition: one who administers or request its application (in this case, the Administration through its implementing agency) called the creditor, who is obliged to him/her - called sequestrated debtor, and sequestrated third party (the taxpayer's debtor).

3. Conclusions

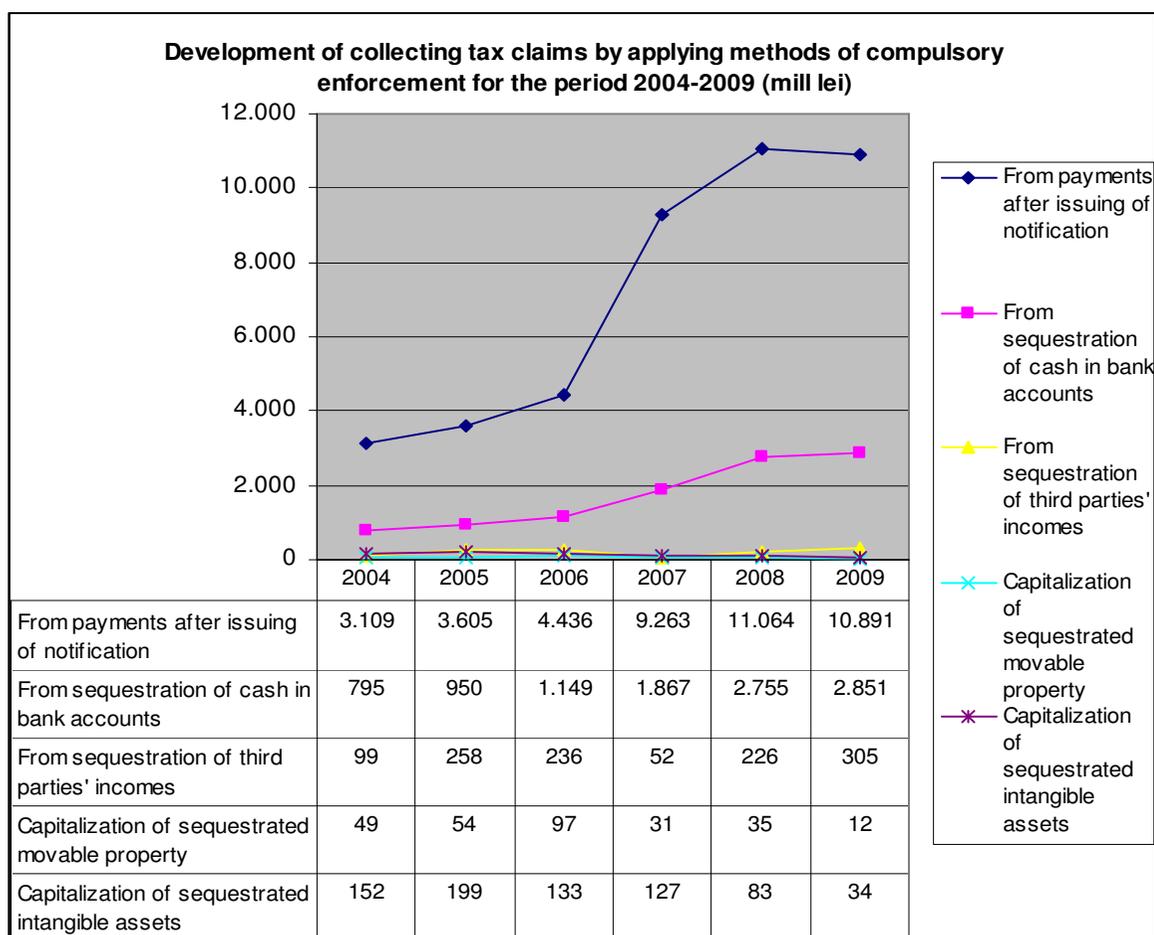

The collection of tax claims is a priority activity of the National Agency of Fiscal Administration, which seeks to rapid intervention within the action of preventing the formation of budgetary arrears and the acquiring of public financial resources to meet the deadlines set by the fiscal authorities to support the budget implementation at the level of public services according to the budget forecasts regarding the grounding of public institutions' budgets.

The premises of reaching the indicators regarding the collecting of budget revenues through the proceedings of compulsory enforcement of the sequestration of bank accounts should, according to our opinion, follow several directions of medium-term action such as:

- Development of IT systems for managing tax claims, including in the menu of the IT application the subsystems of fighting tax claims through the procedure of sequestration so as to ensure a complete collection of tax claims with the correct identification of the source of sequestrated incomes from accounts blocked by the executionary bodies.
- The setting-up of a database at the level of the National Agency of Fiscal Administration by the interaction and collaboration of public institutions, banks, central and local public authorities to enable the fiscal bodies the rapid identification of movable and intangible assets, as well as the incomes of taxpayers –debtors of the state, by the help of the responsible fiscal management structures.
- The organization of a database on administrative and fiscal solutions issued in situations of judicial action on established tax claims and the administrative and fiscal jurisprudence rendered by competent judicial courts in the cases of eliminating measures relating to the enforcement of tax claims, a database available to all civil servants in the administrative body, granting access to setting up unitary practices of management.
- The improvement of procedures for allocating the causes of prosecution and compulsory enforcement of pursued tax claims on inspectors, allowing a hierarchical control of performing the duties specific to public office and thus raising the specific responsibility of the territorial fiscal body.
- Development of educational guid books on collecting tax debts on methods of enforcement, which should focus on specific aspects of implementation and enforcement measures, to identify new measures of raising government revenue collection in a term not exceeding 15 days over the tax duty's due date.
- Development of existing procedures, development of brochures and other instruments to regulate the recovery of goods seized, the distribution of amounts aquired by capitalization or, according to case, by blocking the bank accounts for overdue tax debts.

- Establishing a system of **performance indicators** to measure the rate of budget revenues collected by compulsory enforcement measures for potential taxpayers from among debtors and in the process of monitoring the state's revenue collection procedure.
- *Identification and improvement of criteria for granting the scores for risk assessment regarding the collection of tax claims, within an IT integrated system / subsystem for risk analysis on incidents regarding lack of returns, allowing access at any time to the frame of taxpayers who have debts, and who increase **the risk of not succeeding to collect the tax claims**, subject to the application of functional measures of collecting and compulsory enforcement.*

The compulsory enforcement by income sequestration, either cash in RON or foreign currency belonging to the debtor or owed to him by a third party or legal entity is the most easily realizable blocking of debtor's incomes by the office fiscal executioners. The IT applications for the tax claims' administration should be improved by including a subsystem for generating within the entire database of notifications regarding the sequestration of cash (executionary form MPF-NAFA code 14.13.12.99 / a) towards every bank at which the debtor taxpayers dispose of bank accounts.

Source: www.anaf.ro NAFA report of performance

Enhancing the measure of blocking the incomes in bank accounts by setting up the sequestration on debtor taxpayers' bank accounts mostly was the method of compulsory enforcement which contributed to the acquiring of budgetary resources. If in 2006 the returns by sequestration of bank accounts stood at 1148.68 million lei, the efforts of public administration by their NAFA

territorial offices were materialized by the blocking of bank accounts in 2007, the amount collected this way rising to 1866.99 million lei for the state's consolidated budget.

The computer issuing of the notifications regarding sequestration of bank accounts and monitoring the collection of tax claims reached a peak in 2008 with the issuance of a number of 1,645,026 notifications establishing bank sequestration, by which 2754.98 million lei were compulsory collected, the results being far superior to those registered by the fiscal administration in the previous years.

The year 2009 represented the turning point regarding the special administration of taxpayers, including the management system of large and average taxpayers and also of new taxpayers, so that at the end of the year the 1434 largest taxpayers, respectively the 19,114 average taxpayers have supported the general consolidated budget with 60% of the revenue. The contribution of the measure of blocking revenues from budget accounts was not neglected, and by issuing a number of 1,813,391 notifications regarding bank sequestration the amount of 2850.68 million lei was collected for the general consolidated budget of the state, given the conditions of the increasing financial difficulties of businesses as a result of the deepening of the economic crisis in Romania. To better fulfill its mission regarding the collecting of public money NAFA through the territorial fiscal agency will require better future planning of the revenues administered also by the increased efficiency in all areas. This way, strengthening the budget revenue forecasting methods and therefore genuine implementation of performance contracts, will be crucial prerequisites for optimizing results in the collection of public financial resources.

We consider that the procedure of tax claim sequestration allows the state-financed creditor to recover the tax claims by blocking the tax claim that the debtor has towards a third party in the hands of the latter (sequestered third party). Like other ways of compulsory enforcement, this procedure is justified by the lien mentioned in the Civil Code of the creditor on the property of his debtor; the debtor's assets consisting of not only the possessions of the holder, but also the debtor's tax claims which represent intangible property rights.

Abstract: In this paper I have tried to create a global image of the macroeconomic phenomena which are the landmarks of the beginning of this millennium: globalization, the economic-financial crisis and their impact on the contributions to social security state budget. This paper aims at presenting the effects of the economic-financial crisis on the state budget based on the analysis of the evolution of the revenue to the social security budget in connection with this contemporary phenomenon, taking into account the financial element as well as the measures adopted by the Romanian government in order to fight the effects of the crisis. The economic crisis of the new millennium has modified the role of the state because the dimension of the difficulties (unemployment, bankruptcies, etc.) has given the governments the mission of stabilizing the economy so as to bring a remedy to the recession.

Keywords: Social security contributions, budget, revenue;

JEL Code: G32

Introduction*The public powers have been forced to intervene in the economy in order to deal with the rise of unemployment and the state intervention has accelerated due to difficulties in integrating the active citizens into the world of work.*

Finding a solution to this financial crisis involves many options in terms of policies going from macroeconomic level (including monetary policy and the fiscal one) to microeconomic (including the recapitalization of the financial institutions, regulations for capital adequacy and the requirements of the corporate governance), with reforms that vary in depth. At the level of fiscal policy, the state intervened in this period on different levels and the significant changes have been felt including in the field of state social security.

Taxes represent one of the oldest financial sources, which appeared once the state organization has been finalized with the purpose to supply the financial resources necessary to ensure the state functions. If we consider the obligativity of the taxes, then *"their payment to the state is a duty imposed to all physical and juridical persons who attain revenue from a certain source or possess a certain kind of property for which, according to law, they owe taxes"*⁸⁵⁸.

In a different perspective, the tax is a pecuniary levy imposed to private persons by the state, as definite title and without immediate and direct counter performance, in order to cover the expenses⁸⁵⁹.

1.1. Contribution rates

⁸⁵⁸ Văcărel I. and collaborators – Public Finances, 4th edition, Didactical and Pedagogical Publishing House, Bucharest, 2006, p.408.

⁸⁵⁹ Cătinianu F., Șeulean Victoria, Donath Liliana – Public Finances, Mirton Publishing House, Timișoara, 1997, p. 191

Among these contributions are included the contributions of the enterprise to social security, the contribution of the enterprise and the personnel to the unemployment insurance fund, the contribution of the personnel to supplementary pension.

Social security contributions (in Romanian CAS) can be determined as follows:

CAS = gross salary attained x tax rate

From 1 January 2009 contribution rates related to salaries were increased (compared with those valid in December 2008), then from 1 February 2009 they were increased again.

Contribution rates valid from 01.02.2009 are as follows:

CAS employer (for normal working conditions): 20,8%

CAS employee: 10,5%

Starting with 2009, contributions rates to social security are⁸⁶⁰:

- a. 31,3% for normal working conditions, owed by employer and employees, out of which 10,5% owed by employees and 20,8% owed by employers;
- b. 36,3% for special working conditions, owed by employer and employees, out of which 10,5% owed by employees and 25,8% owed by employers;
- c. 41,3% for special working conditions, owed by employer and employees, out of which 10,5% owed by employees and 30,8% owed by employers;

Contribution to social health insurance (in Romanian CASS)

The social health insurance fund consists of the contribution to social health insurance owed and paid by the employers and the contribution to social health insurance owed and supported by the insured persons.

Health insurance, the contribution of the employer: 5,2%

Health insurance, the contribution of the employee: 5,5%

Other contributions:

Holidays and benefits fund: 0,85%

Unemployment fund, the contribution of the employer: 0,5%

Unemployment fund, the contribution of the employee: 0,5%

Employees' guarantee fund: 0,25%

ITM commission (usual case): 0,75%

Work accidents and professional diseases: cf. code CAEN (0,15% - 0,85%)

Revenue tax (after deductions): 16%

The biggest increase affects the contribution of the employer to the state pension fund (Romanian CAS), which raised by 2,8 percent, from 18% in December 2008 to 20,8% in February 2009, which represents a relative increase of 15,55% for the expenses of the companies with the CAS owed by the employer.

For special working conditions from 1 February 2009 the contribution of the employer became 25,8%, and for special conditions it became 30,8%.

The contribution of the personnel to the pension fund (CAS) rose as well, but less, with 1 percent, from 9,5% to 10,5%, which represents a relative increase of 10,53%.

As follows I will present a comparative table which illustrates the modifications to each contribution between December 2008 – February 2009.

Table 1.1. Contribution rates to state social security

Contribution	2008	January 2009	February 2009	Rate for 2010
CAS - employer	18.00%	18.50%	20.80%	20.80%
CAS - employee	9.50%	9.50%	10.50%	10.50%
Health insurance -employer	5.20%	5.20%	5.20%	5.20%
Health insurance - employee	5.50%	5.50%	5.50%	5.50%

⁸⁶⁰ According to OUG 226/30.12.2009 concerning financial budgetary measures - M.O. 899/31.12.2008

Holidays and benefits fund	0.85%	0.85%	0.85%	0.85%
Unemployment - employer	0.50%	0.50%	0.50%	0.50%
Unemployment - employee	0.50%	0.50%	0.50%	0.50%
ITM commission	0.75%	0.75%	0.75%	0.75%

This last modification of the CAS rates was made through the Law of the social security state budget⁸⁶¹.

The year 2010 has brought the following modifications:

- the medium gross salary used for the fundamentation of the social security state budget has been raised from 1693 lei to 1836 lei;
- the death aid rate has been raised from 1702 lei to 1836 lei for the insured persons and the pensioners and from 851 lei to 981 lei for members of the family of the insured persons or the pensioners.

1.2. The evolution of the budgetary revenue from contributions to insurance

1.2.1. The dynamics of the budgetary revenue from contributions to insurance for 2006-2009

In presenting the dynamics of the budgetary revenue from contributions to insurance I have tried to give a global image of the level attained by these categories of taxes in the period analysed.

The data are grouped for a period of four years (2006-2009), making a comparison between the state budget before the financial crisis and the budget affected by the economic environment we are going through.

The present revenue of the state budget consists of:

- contributions of the employers including contributions to social security fund owed by employers and by unemployed people;
- contributions of the employers to insurance for work accidents and professional diseases;
- contributions of the employees:
- contributions to social security owed by insured people;
- the contribution of other insured people;
- optional contributions of the insured people;
- contributions to insurance for work accidents and professional diseases;
- contributions to social security private funds;
- repayment contributions to state social security.

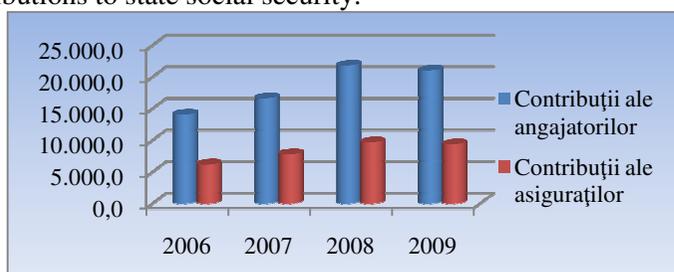

Fig. 1.1. The evolution of the main categories of budgetary revenue from insurance contributions

The general evolution of the contributions to social security was a positive one for the period 2006-2009. The employers' contributions rose in 2007 in comparison with the previous year by aprox. 18,34%, which represents an increase of aprox. 2.574 million lei. The sums owed to the state budget by the insured people rose more rapidly by 26,3% but with more reduced sums of 1.620 million lei due to the reduced rates owed of the employees. The period 2007-2008 faced a continuous growth of the contributions to social security. Thus, the contributions owed by employers rose in 2008 as compared with 2007 by 31,1%, respectively by 5.166 million lei, and as compared with 2006 the growth reached the value of 7.740 million lei, respectively 55,14%.

⁸⁶¹ Law no. 19 per 2009, published in Official Monitor no. 122 from 27.02.2009.

If the revenue to the state budget coming from the employers' contributions grew significantly in the period 2006-2008, the revenue coming from the employees' contributions slowed down its rhythm of growth. Thus, in 2008 as compared with 2007, the employees' contributions rose by only 24,1% compared with 26,35% in the period 2006-2007. In absolute values the evolution of the employees' contributions in 2008 can be translated through an actual growth of 1.876 million lei.

2009 is the year in which both the global crisis and the legislative changes have noticeable effects either in deficits or in increases that are below the levels expected in the previous years. In numbers, 2009 brings a decrease in the budgetary revenue coming both from employers' and employees' contributions compared with the previous period. In percentage the employers' contributions to social security fall by 3,6 % in 2009 as compared with 2008, a small decrease with serious repercussions on the decisions adopted by the government in the field of social security. The absolute decrease of the contributions owed by the employers is of 786,4 million lei. The employees' contributions decrease as well but in a slower rhythm of 3,2%, respectively with 309,9 million lei.

1.2.2. The importance of the social security contributions to the budgetary revenues

The contributions to social security are included in the category of fiscal revenue and contribute to forming the state budget revenues.

In general, the fiscal revenue represents approximately over 90% of the total budgetary revenue. Due to this, the social security contributions to the state budget revenues are extremely important, showing how much they contributed to attaining these revenues.

Moreover, the social security contribution is considered the most important of all the categories of obligatory contributions because "in exchange of this contribution the state commits itself to paying the public pension, this system being based on the principle of social solidarity, the contributions paid by active persons during a budgetary period being the source of payment of the pensions during the same period"⁸⁶². Thus, it is easy to notice how any disequilibrium either concerning the active persons' contribution or the number of pensioners can have negative effects on the public system of pensions.

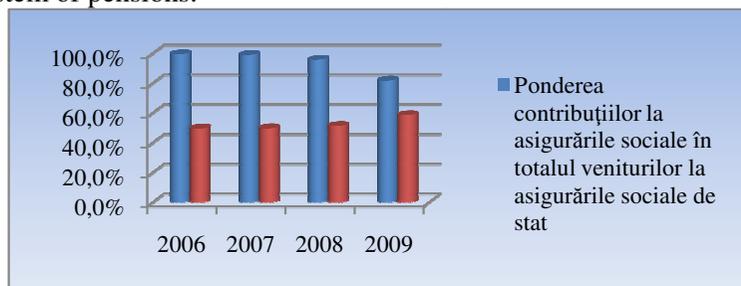

Fig.1.2. Percentages of the social security contributions from the total budgetary revenues

It can be observed from the previous chart that the percentage of the social security contributions from the total revenues to the state social security for the period analysed is in continuous decrease from 99,5% in 2006 to 81,8% in 2009, respectively a 20% decrease for the entire period. However, the most significant change takes place in 2009 when the percentage of the social security contributions from the total revenues to the state social security decreases from 95,8% to 81,8% due mostly to a decrease of the sums coming from social security contributions and a steady increase of the total revenues to the state social security.

The losses registered by the social security contributions from the total revenues to the state social security in 2008 and 2009 can be explained by the subventions given from the state budget.

⁸⁶² Iulian Viorel Brașoveanu – Analyses of the fiscal policy in Romania and other states of EU, ASE Publishing House, București, 2009, page 79.

Thus the increasing trend registered by the total revenues to the state social security was attained due to some government subventions of 1.379,6 million lei in 2008, respectively 5.397,5 million lei in 2009. These subventions supported the rhythm of growth of the present revenues to the state social security in order to minimise the effects of the small increase and even the decrease registered in these categories of revenues in this period.

A more significant indicator for us, the percentage of the social security contributions from the total budgetary revenues has an opposite evolution. This growth is in the period analysed from 49,6% in 2006 to 58,6% in 2009.

Although this indicator has an ascending trend, the rise is not really positive because at the same time the level of budgetary revenues in general has decreased. Thus, after an increase of approximately 50% in the period 2006-2008, the total budgetary revenues decreased in 2009 by 15,3%, respectively by 9,392,5 million lei.

This led to an increase in percentage of the social security contributions from the total budgetary revenues and gave this rise a negative character. The growth of this indicator could have generated a favourable situation if it had happened together with an increase of the level of social security contributions at a more rapid pace than the increase of budgetary revenues but it did not happen in this case.

1.2.3. The structure of the social security state revenues in the period 2006-2009

Regarding revenues to the social security state budget, the fiscal revenues occupy the central place, with over 90% of the total resources at the state's disposal. The governmental policy in this field can be observed in the structure of these revenues.

The values of each category of contributions to the social security state budget are presented in figures 1.3. Employers' contributions and 1.4. Insured people's contributions

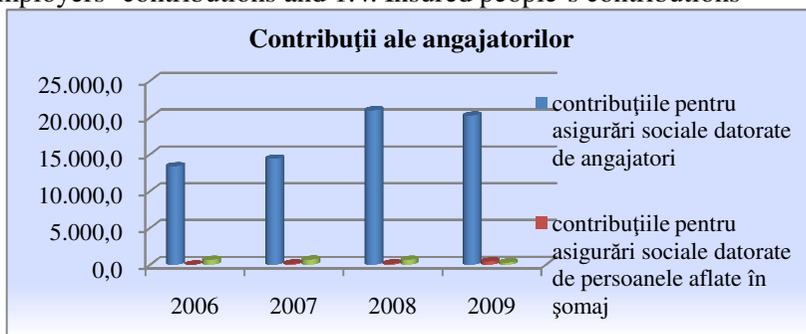

Fig.1.3. Employers' contributions

It can be observed here the major importance held by the social security contributions owed by employers in forming the revenue to the social security state budget. For the whole period analysed the percentage was 85%. The smallest value of just 86,7% compared with the total contributions owed by employers was registered in 2007 and for the years 2006, 2008 and 2009 their value does not go under 95% of the total.

The contributions to the social security owed by unemployed people and the contributions to insurance for work accidents and professional diseases reach less significant values. For the first category the tendency is of growth with the maximum value of 442,8 million lei in 2009, a value which is much higher than the values of the previous years. For the second category of contributions the general tendency is of decrease, a normal evolution for the times we live in and which will be developed in the following pages.

Moreover, one of the measures adopted by the government to fight these effects consisted in extending the period of receiving unemployment benefits with three months for 2009 and tax exemption for employers' and employees' social security contributions for maximum three months if the employees are on technical unemployment.

The measures adopted by the government which are meant to reduce the effects of the economic-financial crisis led to these oscillations of the sums collected for the social security state budget but they managed to save a small number of work places. The initial plan to create work places stipulated more measured which were abandoned on the way among which tax exemption for social contributions for hiring an unemployed person with a salary of maximum 1.000 lei.

The main objective of the economic policies is macroeconomic stability and realizing the most important structural reforms so as to create the proper conditions for a positive evolution of the Romanian economy. In the field of public finances it is desired to achieve a reduced budgetary deficit both through changes in the fiscal legislation and through improving the collection of budgetary revenues and arrears.

This study presents the valuation scheme of a flexographic printing industry firm. The industry, the technology used and most importantly the firm being young ones, it is not possible to use the classical comparable valuation methods. The new approach in this matter is to use as benchmark financial ratios not those related to the price of the firm (as P/E, P/S, P/BV, P/CF, P/CAPEX), but those related to the structure of the income statement, financial and operating leverage using 13 Romanian and 6 Hungarian reference firms' data. Our main contribution to this line of research is to solve the problem of lack of reference data regarding the price, the benchmark companies not being listed on any stock exchange.

Keywords: mergers and acquisitions, corporate valuation, free cash flow, comparable valuation method, benchmarking

JEL codes: G31, G32, G34

Introduction

The purpose of the study is – from a theoretical point of view – to present how an acquisition target's value could be estimated with the help of a modified comparable valuation method the firm being part of a young industry, the classical financial ratios used in the comparable valuation methods not being available and – from a practical point of view – to estimate the theoretical price an acquirer might pay for our analyzed firm, a Romanian flexographic printing firm with a two year past. As stated by numerous financial analysts, valuing companies early in the life cycle is difficult, partly because of the absence of operating history and partly because most young firms do not make it through these early stages to success, this being the main reason for which we choose comparable valuation methods as a base for our valuation. We look for solutions that could offer us a way out from an apparent lack of benchmark data.

Damodaran (2009) enumerates a range of practices that come into play in the most common approach used to value young firms, which is the venture capital approach:

- Top line and bottom line, no detail:

It is difficult to estimate the details on cash flow and reinvestment for young companies. Consequently, many valuations of young companies focus on the top line (revenues) and the bottom line (earnings, and usually equity earnings), with little or no attention paid to either the intermediate items or the reinvestment requirements.

- Focus on the short term, rather than the long term:

The uncertainty we feel about the estimates that we make for young companies become even greater as we go further out in time. Many analysts use this as a rationale for cutting short the estimation period, using only three to five years of forecasts in the valuation.

- Mixing relative with intrinsic valuation:

To deal with the inability to estimate cash flows beyond short time periods, analysts who value young companies use relative valuation as a crutch. Thus, the value at the end of the forecast period is often estimated by applying an exit multiple to the expected revenues or earnings in that year and the value of that multiple is itself estimated by looking at what publicly traded companies in the business trade at right now.⁸⁶⁴

- Discount rate as the vehicle for all uncertainty:

The risks associated with investing in a young company include not only the traditional factors – earnings volatility and sensitivity to macroeconomic conditions, for example – but also the likelihood that the firm will not survive to make a run at commercial success. When valuing private businesses, analysts often hike up discount rates to reflect all of the concerns that they have about the firm, including the likelihood that the firm will not make it.

- Ad hoc and arbitrary adjustments for differences in equity claims:

Equity claims in young businesses can have different rights when it comes to cash flow and control and have varying degrees of illiquidity.

Our main goal is to value the company from an acquirer's point of view who, being in the same industry, can deal much easily with many of the difficulties enumerated reducing many of the risk factors and sources of uncertainty.⁸⁶⁵

Brief Review of the Empirical Literature on Benchmarking

Comparable valuation methods consist in the comparison of valuation multiples and operating metrics for a target company to those of different firms in a peer group. Peers may be grouped based on different criteria, such as industry, company size, or growth, this being the base of the benchmarking process.

The popularity of the multiple valuation methods can be attributed to their relative simplicity compared to other company valuation methods like discounted cash flow techniques. As we will show, we think that the two methods can be combined to achieve our goal, especially in case of a company which's stocks is not traded on any stock exchange and is part of a young industry whose companies are not listed on stock exchanges.

Several studies and surveys demonstrate that practitioners frequently use financial ratios or multiples for the valuation of companies (see Graham and Harvey, 2001, Manigart et al., 2000, Lie and Lie, 2002, Liu et al., 2002, Courteau, 2003, Asquith et al., 2005, Roosenboom, 2007, Fidanza, 2008, Mînjînă, 2009). It also turns out to be surprisingly successful in comparative empirical studies by Kaplan and Ruback (1995) and Gilson et al. (2000).

In his study focusing on equity valuation using multiples, Fernandez's (2001) basic conclusion is that multiples almost always have a broad dispersion, which is why valuations performed using multiples may be highly debatable. However, Fernandez shows that multiples are useful in a second stage of any valuation: after performing the valuation using another method, a comparison with the multiples of comparable firms enables financial analysts to gauge the valuation performed and identify differences between the firm valued, and the firms it is compared with. These are the two approaches that we would like to merge in our valuation method: usage of financial ratios while utilizing another valuation method. Dittmann and Weiner (2006) investigate the which comparables selection method generates the most precise forecasts when valuing companies with the enterprise value to EBIT multiple, while Henschke and Homburg's study (2009) addresses the problem of differences between firms and the impact on valuations based on multiples. They investigate the extent to which industry-based multiples ignore additional firm-

⁸⁶⁴ This will be the base idea of our study, too.

⁸⁶⁵ Damodaran, A., 2009. Valuing Young, Start-up and Growth Companies: Estimation Issues and Valuation Challenges

specific information and develop measures for identifying peer groups that are not comparable with the target firm. They find that differences between firms lead to systematic errors in the value estimates of different multiples but that these errors can be predicted very accurately by comparing the financial ratios of the target firm with the financial ratios of its peer group. They show that when adequately controlling for differences between firms, valuation accuracy is improved substantially and all considered value drivers perform almost equally well. Mînjină's paper (2009) examines the valuation performances of seven multiples on a sample of Bucharest Stock Exchange-listed firms. Mînjină finds that accuracy levels of multiple valuations are generally lower than those obtained using the same methods on more developed capital markets.

Financial Analysis of the Target Company

Before analyzing the financial data concerning our firm, we have to choose the benchmark data that we are going to use as reference. We analyzed 13 Romanian and 6 Hungarian firms from the flexographic printing industry chosen partially taking into consideration the findings of Dittmann and Weiner (2006) and Henschke and Homburg (2009) being partly influenced by the available data.

Table 1: Simplified Income Statement of the analyzed firm (RON)

	2008	Jan.-July 2009
Operating revenue	2506587	2286148
Operating expenses	3369880	2750791
Suppliers	1646825	1592776
Employees	718482	488066
Services (including depreciation)	1004573	669949
Operating result	-863293	-464643
Financial revenue	37714	5616
Financial cost	641278	144825
Financial result	-603564	-139209
Income before income taxes	-1466857	-603852
Net income	-1466857	-603852

Source: The firm's official financial statements

The first striking observation is that the firm is in loss. In fact, one of the main problems in estimating a recently started business's price is typically the fact that most of these firms are not bringing any benefit to the equity owners in the first years of their existence. The gross margin is negative, while the benchmark data show positive values. The question that has to be answered is how we value a company in a similar situation.

The second also surprising fact that we can observe that not only the net income is negative, but also the operating result, the oddity of this situation being strengthened by the fact that we didn't find this situation at none of the benchmark firms we analyzed. In the next section our goal will be to solve this valuation problem.

Table 2: Financial ratios of the analyzed firm and benchmark averages in Romania and Hungary

Ratio	Hungary	Romania	Our Firm
Sales/Employees (RON)	350.000	280.000	105.000
Gross margin (%)	6,5%	0.5%	-26,35%
Operating margin (%)	11,5%	n.a.	-20%

An important measure of the efficiency of a firm is the sales/productive employees ratio. The problem is that while it is much easier to procure the total number of employees of a firm, it is rather difficult to do the same with the number of productive employees. But supposing that the proportion of the productive and non-productive employees does not vary substantially from one firm to another, we will calculate the ratio by dividing the total sales (operating revenue) by the total number of employees. The values of the ratios show large disparities especially between the analyzed firm and the benchmark ones: our firm's sales/employees ratio is one third of the benchmark data.

The problems that we can read out from the ratios calculated from the data found in the income statement plus a few technical data are:

- There is a 50% unused capacity in the firm – which explains the low value of sales/employee ratio and the negative value of the operating margin (the operating expenses including depreciation)
 - Either the material costs are too high, or the firm's price calculation method is incorrect – confirmed by the negative value of the operating margin
 - The benchmark data also show that the employee expenses divided by the total number of employees (average expense per employee) is much higher at our firm than in the case of the benchmark firms
 - The lease contract proposes a 6 year payback period, although the investment's payback period is higher, which causes financing problems on medium run
 - The benchmark data also show that the collection period at our firm is much higher

Methods of Optimization from the Acquirer's Point of View, Synergy Possibilities

Resulting from the problems enumerated above, we cannot predict future cash flows without optimizing the data affected. Otherwise the firm would not be worth more than its equity which is negative by the time of the analysis – the only possibility would be to sell the data base and network of the clients of the firm – a small amount oppositely to the potential of the firm. We will make further calculations with the assumption that no enterprise would buy this firm to operate it as it operated before the acquisition. The optimization possibilities come from the benchmark data that we worked with also at the financial analysis of the target company - in order to make the most of this company from a financial point of view one should:

- Utilize to the maximum the capacity of the machines - the buyer should be in a lack of capacity (which would increase the Sales or Operating Revenues with 100%)
- Optimize the operating margin by introducing a new price calculation method and/or by reducing material costs
 - Introducing a new performance-based wage calculation method
 - Renegotiate the terms of the lease contract by prolonging the payback period or perform an equity infusion (the acquirer)
 - Shorten the collection period by introducing some discipline through a more complex commercial credit system using a pre-defined discount system for early cash collection and establishing clear procedures and default interests for those who exceed the expiration of the commercial credit

We can also enumerate a few synergy possibilities for the buyer:

- Joint logistics
- Joint administrative personnel
- Better territorial coverage
- Better knowledge of the technology

- Better sales opportunities

All these factors lead to a better cost management and higher revenue.

Calculation of the Free Cash Flow

In the course of the free cash flow (FCF) calculation we assumed that we can benefit from all of the optimization and synergy possibilities listed above and we assume that in the course of the next 6 years no substantial investment will be made. All the other maintenance costs are included in the operating expenses.

Table 3: FCF calculation

Indicator	2010	2011	2012	2013	2014	2015
Growth rate	56%	10%	7%	7%	5%	5%
Operating revenue	7406734	8110767	8678520	9286017	9750318	10237834
Operating expenses	7061682	7566360	8004684	8474815	8831479	9206813
Operating result	345051	544407	673836	811202	918839	1031020
Income tax without tax shield	0	0	0	129792	147014	164963

Depreciation	689277	678272	667444	656788	646302	635983
Increase in net working capital	178200	165726	129729	138670	106315	111526
FCF	856128	1056953	1211550	1199527	1311812	1390515

Source: Authors' calculations

Estimation of the Discount Rate

We use the weighted average cost of capital (WACC) as discount rate, with an optimized debt-equity ratio. To estimate the expected rate of return of the shareholders we use the capital asset pricing model (CAPM). For the change in the WACC caused by the change in leverage throughout the years, we either use Miles and Ezzell's method, or, if we also want to include the operating leverage change too, we can use the numerous levered-unlevered beta corrections found on the market (Modigliani and Miller, Harris and Pringle, Damodaran, Myers, practitioners). For the first year of the forecasted period:

$$\text{CAPM: } E(r_e)_{2010} = E(r_f) + \beta * [E(r_m) - E(r_f)] = 6,5\%^{866} + 1,24 * (13\% - 6,5\%) = 14,56\%$$

$$\text{WACC} = r_e * E/V + r_D * (1 - T_c) * D/V = 14,56\% * 45\% + 10\%^{867} * (1 - 16\%) * 55\% = 11,172\%$$

Estimation of the Firm's Value – Results and Conclusion

Using the classical FCF derivation method we find that:

Table 3: FCF calculation

Indicator	2010	2011	2012	2013	2014	2015	2016
WACC	11,17%	11,30%	11,45%	11,70%	12,10%	12,40%	
Dicounted FCF	770094	853229	875188	770544	741043	689569	
Terminal value							2453533
Firm value	7153198						
Debt value	4071000						
Addit.cap.requirement	716000

⁸⁶⁷ 5,5% in Euro

(equity infusion)

Equity value after the
merger 2366198

Source: Authors' calculations

Knowing that no method will determine a single price for the target; the outcome of the analysis will be a range of values: [2 000 000 – 2 700 000]. This is the approximate interval the price will move in – we tend to consider the lower limit more realistic because all the optimized data might not be possible to pursue.

NATIONAL EXPERIENCES REGARDING CORPORATE GOVERNANCE – „PROPER PRACTICE” CODES

Kolozsi Lucia

Camera de Conturi Bihor

Durgheu Liliana

Camera de Conturi Bihor

This paper is about the principles of proper governance codes, which even though have blossomed in all parts of the world for more than a decade, the degree in which companies adopt the codes vary in different countries, and the decision to adopt a certain code does not automatically guarantee efficient corporate governance. The paper tries to identify the mechanisms needed for implementing the codes and that will lead to higher efficiency.

Key words: corporate governance, proper practice codes, efficient management

Cod JEL: G38

1.Introduction.

In 1978 the first country which issued a code of proper governance was the United States, the second country was Hong Kong in 1989, then the pace of issuance increased, especially after 1992 when the UK Cadbury Report was issued. By mid 2008, in 30 years, 64 countries have issued 196 separate codes of proper governance, some countries having more than one code of proper governance (The most notable being the United Kingdom and the United States with 25 codes each) others having only one code (such as Argentina or Austria) issuers of which are joint investors, employers associations, professional associations and governments, stock markets and their regulators⁸⁶⁸. It seems that there is a link between the development of capital markets and the number of codes issued. Countries with capital markets not only larger but deeper, have more codes of proper governance, proper governance need increases with increasing numbers of public firms because agency problems occur between dispersed owners, and managers or between majority and minority shareholders. Spreading codes for proper governance in the world was aided by stimulating international entities such as the World Bank and Organization for Economic Cooperation and Development (OECD), which began to emphasize the need to improve corporate governance institutions in general and in particular to help countries to grow and develop.

2. General principles.

General principles of proper governance structure refers to: a balance between executive and non-executive directors, a clear division of responsibilities between the chairman and chief executive, need to provide timely and quality information to management, formal and transparent procedure for appointment of new executives, balanced and understandable financial reporting and internal control system to maintain a good quality.

On how the codes are implemented once are developed and adopted as a guiding principle of government has identified two mechanisms for implementing the code - mandatory or voluntary regulation. Classic examples of two alternative approaches to implement codes are law-for

⁸⁶⁸ Aguilera,Ruth& Cuervo-Cazurra,A.(2009), *Codes of Proper governance*, în *An International Review*Vol 17, Issue3, p376-387

example, Sarbanes-Oxley Act of 2002, the U.S. and an approach “to comply or explain”-for example, the UK Combined Code in 2003. Although most of Proper governance Codes have similar problems, the specific content of codes for proper governance varies significantly across countries, by capturing the needs of different corporate governance systems. Implementation of codes increased over time, firms tend to adopt a growing percentage of codes recommendations despite their voluntary nature.

Although proper governance codes have been developed worldwide for more than a decade, the extents to which companies adopt codes vary across countries, and the decision to adopt a code does not give an automaticall guarantee of effective corporate governance. Thus in the UK British companies listed on London Stock Exchange met to a large extent Cadbury Report recommendations, the degree of compliance with the UK Combined Code is developing over time. Regarding the assessment of compliance with the provisions of the German Code of Proper governance for a significant proportion of companies complying with these provisions, almost half of them are already implementing the full German Code as the company’s guiding principle. Extending the analysis shows a high level of acceptance of recommendations of codes and a marked willingness to comply in the future, institutional environment and, in particular, capital market development resulting in large part the degree of monitoring compliance with the code, even if just for informal and legitimation.

3. Experiences regarding corporate governance.

All studies of proper governance stress the importance and growing interest shown for this area. Codes of proper governance became a central issue in politics and scientific research. To a fad that would disappear once the new ideas appear, codes of proper governance have increased relevance and continue to spread worldwide. Has also made a considerable progress on understanding the various code of proper governance worldwide, companies adopting codes, and code impact on performance.

From what was shown most codes tend to agree with the mechanisms that support more effective governance, and Board with independent members and the creation of committees, however, cross-national differences are significant. For example, the codes vary greatly because they are developed to address corporate governance issues that are specific to a particular country. Whereas such codes issued in different countries actually have different recommendations, comparing their adoption and effectiveness in improving corporate governance throughout the country faces severe limitations because it used different standards.

Another interesting aspect is that the issuers would outline codes; codes are issued by the stock exchange of countries, executives of associations, employers associations, investors and investor associations, professional associations or governments. These different types of issuers have different objectives and therefore codes that will create separate targets. Thus, recommendations on best practice Board considered the behavior largely dependent on the issuer. Similar applicability of proper governance vary dramatically as issuers, speaking directly to the debate between the effectiveness of regulations mild versus harsh legislation. The government and the stock exchanges have the power to impose penalties for non-compliance practices. In contrast, investors and investor associations have only the power to impose practices through shareholder activism at meetings, while other borrowers - associations of principals, professional associations and employers associations - have a limited ability to persuade companies to follow the recommendations codes.

It should not be neglected the importance of transnational institutions for the creation and dissemination of proper governance. Such transnational institutions like the World Bank and OECD have actively promoted proper governance by helping developing countries understand how to improve corporate governance practices. These trans-national issuers by promoting a common set of practice, regardless of country characteristics, may indirectly contribute to the

convergence of codes across national governance practices. In other words, it moves to a particular model of corporate governance (eg, Anglo-Saxon or Continental), but to a model of governance more generally global.

It must be noted that the recommendations contained in Codes of proper governance have evolved over time as some corporate governance issues are resolved other problems occur instead. This development problem that the codes treat was treated with revision of previous codes and new codes addressing governance issues new and different. This co-evolution of corporate governance issues and content codes emphasizes another source of differences across countries and codes developed in each country. Countries with sophisticated capital markets require more advanced codes recommendations, while countries with small capital markets probably require simpler code addressing basic problems.

Research concerns the causes of corporate failures after the crisis of the '80 in Britain, manifested by Sir Adrian Cadbury, have resulted in the Cadbury Report in 1992. Subsequently, other reports have come in support of Lord Sir Adrian Cadbury Report, outlining the idea of critical weaknesses that manifest themselves in top management. Cadbury Code, issued in 1992, established the first basic rules of running a company take the form of 19 recommendations to achieve increased efficiency while nondiscriminatory behavior to shareholders.

The Paul Ruttman report was published in 1993 that consider how to implement the recommendations of Cadbury, concluding that any stock exchange listed company should report on internal control.

Published standards of public life by Lord Nolan in 1994 reiterate the need for developing an ethical public sector; Nolan code representing a solid set of seven principles that should guide public life.

Richard Greenbury report in 1995 contained a code of proper practice wage determination and disclosure of directors, while establishing the need for a remuneration committee, to avoid poor performance and even establish compensation mechanisms for their enforcement. In the same year Ronnie Hampel report was to amend and improve certain references from Cadbury Report on the structure of boards, the role of director's nonexecutive role of shareholders.

Based on the recommendations provided by the Cadbury report and other observations on corporate governance, published in 1998 *the combined code* has become a mandatory requirement for listed companies' shares.

Charlie Mc Creevy launches the „*explain or apply principle*”, that companies are obliged to justify any deviation from corporate governance codes.

In October 1998 the finance ministries of member countries of the G7 called for transparency, quality, consistency and comparability of information on capital markets, bringing the Organization for Economic Cooperation and Development (OECD), in collaboration with the international regulatory bodies to complete by May 1999 drawing up a code of principles for sound management of firms. In 1999 the OECD published its corporate governance principles, recognized by the Financial Stability Forum as one in the 12 basic standards for sound financial systems. These principles formed an essential part of the Collection of Standards and Codes conducted by the World Bank and International Monetary Fund. International Organization of Securities Commissions with other private sector bodies as the International Corporate Governance Network (ICGN International Corporate Governance Network) has adopted these principles. In addition to many national codes on corporate governance principles have been a reference point. Revision of OECD principles made in 2004, was born from the need to adapt to economic and political change, following consultations with officials and non-OECD countries, members of various professional bodies and business representatives from trade unions and civil

society, additions being particularly information related to transparency and board responsibilities and remuneration of the administration board⁸⁶⁹.

Corporate governance systems have specific features of developing economies how they apply their culture. Thus, if German corporate governance model is based on the internal control system is centered on the existence of strong shareholders, based on high concentration of capital, as manifested by shareholders that are linked by common corporate interests, while at the same time take part in both its management and control („insiders”), being focused on the banking system, banks exercising strong influence and control over the companies, in contrast to Anglo-Saxon model is characterized by dispersion of capital, the chief financier stock market, transparency of information, lack of involvement of public authorities in the economic environment, the significant role of accounting existence of a stable economic environment, high levels of liquidity, customary law system, common law.

Corporate governance system in North America is a traditional model that is based on three levels and two legal relationships: a legal relationship is established between shareholders and directors, under a contract of mandate (agency in common law) and the second is legal established between directors and managers, managers have the authority derived from that of administrators. In this model, called model maximizing shareholder income, the entire company is focused on risk capital provider, which is also the residual income claimant. Shareholders select the board of the Company. Decision making system based on: Actions means a vote and elect management board decisions are assumed to maximize the value of shares held by shareholders. Share value is based on the present value of the projection of future dividends, the net profit derived. These models to Japanese corporate governance system is distinguished by its features, the main feature being that the groups of „keiretsu” - groups representing economic results from the combination of several companies through cross holdings (English cross equity) firms within the meaning representation Grouping the boards of other entities⁸⁷⁰, containing one or more central entities (eng.core members) class with small affiliated companies. Characteristic of these types of groups is given multidimensional cooperation between entities that are part of the pool. In this context frequently encounter dialing mechanisms for funding the banking entity in the group, or to transfer employees from the same landing value of the group, or the existence of an entity specializing in the marketing of products made in the group (specifically trade houses called Japanese „sogo sosa”) observing the strong influence of Japanese culture.

Examination of issues of corporate governance convergence is both relevant and necessary, is interesting to study the principles that can justify, primarily Anglo-American model, with a shareholder orientation and the foreign financing and, secondly, the continental European model Japanese and characterized by a greater orientation toward policy makers and funding from the inside.

Convergence of corporate governance refers to the tendency of corporate governance models, specifically national or supranational, to merge their practices and theoretical perspectives. Complete convergence implies that national differences would disappear and eventually a universal model of corporate governance be adopted.

Although there argue that convergence is manifested by the Anglo-American model, these voices argue, would be superior to its alternatives, the specific failures of the Anglo-American corporate governance, corporate success in the party concerned, interior-oriented systems and economic

⁸⁶⁹ OECD,(2004), *Principles Of Corporate Guvernance*, ediția revizuită, disponibil la <http://www.oecd.org.html>

⁸⁷⁰ Mușetescu, R.(2006) „Integrarea globală a piețelor financiare și impactul asupra guvernanței corporative a firmelor locale” Jurnalul Economic, p 73-90

development in regions outside the Anglo-American states that would be difficult to transfer to a private practice of corporate governance from one context to another and expect ca aceasta să funcționeze eficient. Also introducing mechanisms such as the U.S. takeover of management discipline in Germany or Japan would be extremely disruptive for managerial incentives and screening systems present there.

Although manifestations of convergence differences remain for decades, the trend is to consider globalization as a convergence of corporate governance. Arguments both pro and against convergence there certainly is that, in essence, although convergence would create the conditions for efficiency should be based on the need for diversity. Other factors outside the economic legal and they are in deeper social norms underlying various governance structures. Thus culture is beyond the law and economic systems, cultural diversity teaching against convergence. Model of corporate governance around the world have drawn as culture to give a much more accurate and useful. However, the idea that legal structures and economic rules that the Constitution corporate governance systems are the culture, and therefore justified the possibility that corporate governance models differ between cultures, could be related to cultural relativism. As far as cultural relativism claims that different values may be held by different groups, it involves imposing constraints on the values of a group to another group. This concept is closely related to the actions and arguments of moral relativism that works, however, at both individual, and group (cultural and / or national).

We can identify in corporate governance, above legal and economic structures, a set of values, attitudes and / or fundamental beliefs. Understanding this basic morality may therefore provide penetration into corporate governance structures, moral principles and philosophies that can be most easily identified with the most prominent models of corporate governance from the Anglo-American model, followed by continental and Japanese models.

Not be said that corporate governance failures necessarily follow these patterns in Anglo-American or European countries - there are too many differences between companies and the above theoretical discussion was limited to traditional extremes. Yet in some ways, the morality that underpins corporate governance can be seen now in successful companies. Although specific reference to corporate governance annual reports focus specifically on issues management, there are other aspects of these reports involve broader perspective on corporate governance.

We can conclude that business and morality are not always considered ordinary partners. Few would suggest, however, that business relations would be possible without some minimum of trust and fairness. Similarly, it is not unreasonable to argue that directors have certain moral obligations to those who provide funding, regardless of their legal requirements and enforcement capacities. In turn, the corporation may be seen as a mechanism that contributed significantly to society in the past and has the potential to continue to do so, all over the world. Despite differences in approaches to both theoretical and the practical application of corporate governance in different jurisdictions, there is a certain extent a common morality of corporate governance. Successful operation of the corporations is generally considered beneficial because it provides different socio-economic „goods”. The four „virtues” of corporate governance responsibility, accountability, clarity and transparency are accepted as characteristics of good corporate governance not only in the 30 OECD countries, but in others as well.

A closer examination of the principles that support corporate governance patterns prevailing Anglo-American and the Continental European / Japanese suggests that differences in the relationship between corporations and society. Differences in underlying models of corporate governance lead to the question whether it is appropriate consider the convergence of these models.

EFFECTIVE TAX BURDEN BORNE BY COMPANIES: A REVIEW AND A NEW METHODOLOGY

Lazăr Sebastian

„Al. I. Cuza” University of Iași

Faculty of Economics and Business Administration

Measuring the effective tax burden of companies was appealing to many famous economists. The present paper makes a review of the methodology used in assessing the tax burden of companies, and starting from this point, proposes a new framework based on micro backward-looking methodology, which extends the fiscal variables taken into account by considering the tax savings generated by alternative ways of personnel remuneration such various vouchers granted to employers. This line of research is in accordance with the extension of tax incentives granted to companies that lower the fiscal burden, but are not taken into consideration when computing the effective tax rate borne by companies. Some partial results of the research show that the magnitude of such tax incentives can be quite significant, but the research has to be extended to a larger sample of firms.

Keywords: effective tax burden, micro backward-looking methodology, alternative ways of personnel remuneration

JEL codes: H22, H25

Effective tax burden: a review

The problem of tax incidence on corporations is one of large interest in the academic world, having its beginnings in the works of Modigliani and Miller. Later, important contributions were made by Hall and Jorgenson, Harberger, Stiglitz, King, DeAngelo and Masulis, Auerbach, Poterba, Devereux, Shah, Summers, Desai and many others. An excellent review can be found in Graham, John R.⁸⁷¹. Key areas of interest focused on the incidence of taxation on financial structure (Modigliani & Miller, Stiglitz, DeAngelo & Masulis), the enterprise value (Auerbach), the cost and return on investment (Hall & Jorgenson, Summers), the location of enterprises and investment (Devereux, Shah), the fiscal adjustment and financial results (Desai), etc. One can notice a tendency to extend the tax variables taken into account: if the initial research aimed at taking into account only corporate income tax, later the research area was expanded by including the dividend tax, capital gains tax, in pursuing the integration of corporate income tax and personal income tax, and thus determine the tax incidence both on companies level and investors level. Also, the diversification of fiscal techniques resulted in taking into consideration various tax incentives such investment tax credit.

In line with these developments, in the context of globalization in recent years, research conducted worldwide focused on determination of effective tax rates of companies, which often is very different than statutory rate set by the existing legal framework. Enterprises have become increasingly concerned to maximize available tax benefits, and decreasing tax liabilities through legal means of payment (tax sheltering).

Currently, there are two major orientations to determine the average effective tax rate borne by companies:

⁸⁷¹ Graham, John R. - A Review of Taxes and Corporate Finance, *Foundations and Trends in Finance*, Vol 1, No. 7 (2006).

The first orientation is based on data from financial reports (so-called micro backward-looking methodology), in which effective tax rate is determined as the ratio between tax liabilities and income (profits) current. Important contributions were made by Collins and Shackelford⁸⁷², Buijink, W., Janssen, B., Schols, Y.⁸⁷³ and Nicodème, G.⁸⁷⁴.

Collins, J.H. and D.A. Shackelford (1995) manage to classify countries surveyed in decreasing order of the tax burden borne by companies in the following order: Japan, UK, USA and Canada. They also show their evolution over time of these effective tax rates, at the confluence of the reduction in statutory tax rates and increase the tax base.

The study of Buijink, W., Janssen, B., Schols, Y. (2002) is among the first ones based on the consolidated financial information of EU companies that try to capture their real tax burden. They see the difference between statutory tax rate and effective rate as an indicator of fiscal facilities that benefit enterprises. They calculated three types of effective tax rates: tax / taxable income, tax / net turnover, tax - deferred tax / taxable income. Their conclusions are: tax facilities differ substantially among EU countries and the differences between effective tax rates among member states are greater than those between statutory rates.

Gaetan Nicodème (2007) compared effective tax rates for 11 EU countries (EU 15 less Greece, Luxembourg, Ireland and UK), USA and Japan. He uses the unconsolidated financial information to better capture the specific national tax framework and expand the number of companies included in survey. The conclusions he reached may be summarized as follows: in Europe, the effective tax rates, calculated after Martinez-Mongay (2000)⁸⁷⁵, as the ratio between tax and gross operating profit are no higher than those the U.S. and Japan; over the period of the 90's, although increased, the effective tax rates in Europe remained significantly below those of two other major economic powers. In Europe, countries with the highest taxation are Germany, Italy, Denmark and the Netherlands, while in Austria and Sweden (surprisingly) the tax burden of companies is lower. Also, energy and water sector, transportation and communication enjoy an easy fiscal charge, while trade is charged more heavily.

The second orientation is based on neoclassical investment theory, where the average effective tax rate depends on effective marginal tax rate and capital cost (user cost of capital - see Hall and Jorgenson) - so-called micro forward-looking methodology. It aims to assess effective tax burden supported by investment projects, based on a methodology initiated by King and Fullerton⁸⁷⁶ and further developed by Devereux and Griffith⁸⁷⁷. Recent developments of this methodology takes into account restrictions imposed by tax

⁸⁷² Collins, J.H. and D.A. Shackelford (1995) - Corporate Domicile and Average Effective Tax Rates: The Cases of Canada, Japan, the UK and USA, *International Tax and Public Finance*, Vol 2, 55-83.

⁸⁷³ Buijink, W., Janssen, B., Schols, Y. (2002) - Evidence of the effect of domicile on corporate average effective tax rates in the European Union, *Journal of International Accounting, Auditing and Taxation*, 11, 115-130.

⁸⁷⁴ Nicodème, G. (2007) - Comparing Effective Corporate Tax Rates, *Frontiers in Finance and Economics*, Volume 4 (2007), Issue 2, 102-131.

⁸⁷⁵ Martinez-Mongay, C. - The ECFIN Effective Tax Rates, Properties and Comparisons with Other Tax Indicators, *Economic Paper*, No 146, European Commission.

⁸⁷⁶ King, MA and D. Fullerton (1984) - *The Taxation of Income from Capital*, Chicago: University of Chicago Press.

⁸⁷⁷ Devereux, Michael P. and Rachel Griffith (1999) - *The Taxation of Discrete Investment Choices*, Revision 2 - The Institute For Fiscal Studies *Working Paper Series* No. W98/16.

authorities in some countries to not affect the net result with tax savings realized by the enterprise as a result of various facilities that can benefit (Polito, Vito, 2009⁸⁷⁸).

Research conducted worldwide is based heavily on this methodology. Even European Commission⁸⁷⁹.

The study of Oestereicher, Andreas, Timo Reister and Christoph Spengel (2009)⁸⁸⁰, based on a powerful research tool called European Tax Analyzer - ETA - developed by the research team at ZEW (Center for European Economic Research) Mannheim, contains Romania's situation in terms of effective average tax burden of Romanian companies. According to the methodology Devereux & Griffith, Romania ranks 4 in Europe, both in large enterprises, and small and medium size enterprises. But the study did not consider social contributions, which, in our opinion, would be likely to fundamentally change the conclusions.

The new methodology regarding effective tax burden

The methodology proposed consists in determining effective tax rates by taking into account tax incentives and tax savings generated by various instruments such alternative personnel remuneration. The same company may have different financial ratios in the absence/presence of these tax incentives/savings, and this is likely to lead to further clarification on the incidence of fiscal variables on financial management of enterprises. At this point, it should be noted that researches undertaken so far *not quantify the alternative ways of personnel remuneration in determining the overall effective tax rate of enterprises*. The effective tax rate we propose is based on micro backward-looking methodology and is computed as a *ratio between taxes paid by companies and gross operating profit*. When sizing the taxes borne by companies we consider tax savings generated by alternative personnel remuneration. Basically, we will compute the effective tax rates in these two ways and will try to identify the differences between them and the impact of such tax incentives on overall performances of companies. The decision of a company to pay its employers using alternative forms such different kind of vouchers bears a strong tax incentive, as these vouchers can not borne any social contributions payments. Thus, the effective tax rate is smaller than that of a company who decides to pay its employers in cash.

$$ETR_1 = \frac{Taxes}{Gross_operating_profit}$$

$$ETR_2 = \frac{Taxes - Tax_savings}{Gross_operating_profit}$$

The tax savings generated by alternative personnel remuneration (such meal vouchers) have to be computed. The general belief says that this form of remuneration is negligible,

⁸⁷⁸ Polito, Vito (2009) - Measuring the Effective Tax Burden in the Real World, *Fiscal Studies*, Volume 30, Number 2, June 2009, pp 247-278 (32), Blackwell Publishing).

⁸⁷⁹ Commission of the European Communities (2001) - Company Taxation in the Internal Market, available at

http://ec.europa.eu/taxation_customs/resources/documents/company_tax_study_en.pdf.

⁸⁸⁰ Oestereicher, Andreas, Timo Reister and Christoph Spengel (2009), Common Corporate Tax Base (CCTB) and Effective Tax burdens in the EU Member States, *ZEW Discussion Paper*, No. 09-026, Mannheim, available at <ftp://ftp.zew.de/pub/zew-docs/dp/dp09026.pdf> and later in *World Tax Journal*, 46-66).

but we will show that its magnitude is underestimated, and the effects on the overall performance of a company may be quite significant. We use gross operating profit as it is more relevant for company's core activities. The tax savings incurred by meal vouchers remuneration are depicted in the following formula:

$$TS = c_g MV, \text{ where,}$$

c_g = global social contributions rate;

MV = meal vouchers granted to employers.

In principle, data concerning meal vouchers granted to employers are available in the financial reports of listed companies. Social contributions borne by companies include those for pensions, unemployment, medical services, work accidents and occupational diseases, vacations and indemnities, and for payment of wage claims. The rates usually vary on annual basis depending on fiscal legislation.

In order to compute the effective tax rates in the two variants depicted above, we will use the financial data for Aerostar company for fiscal years 2007 and 2008.

Table no. 1. Relevant financial data for Aerostar company during 2007 and 2008

		2007	2008
1	Gross operating profit (RON)	10,021,848	6,666,747
2	Corporate income tax (RON)	771,691	1,581,534
3	Other taxes (RON)	1,068,799	1,062,281
4	Social contributions (RON)	11,121,992	12,047,148
5	Meal vouchers (RON)	2,737,340	2,855,417
6	Global social contributions rate (RON)	31.6%	29.35%
7	Tax savings (RON)	864,999.44	838,064.88
8	$ETR_1 (2+3)/1$	18.36%	39.66%
9	$ETR_2 (2+3-7)/1$	9.73%	27.62%
10	Tax savings/Gross operating profit (7/1)	8.63%	12.57%

Source of data: S.C. Aerostar S.A. Financial Reports available at <http://www.aerostar.ro/financiar.php?PHPSESSID=a6deb4c8d97d80f06a5a67108a2b29fb;>

One can notice the differences between the two effective tax rates, which are quite significant (from 18.36% to 9.73% in 2007, respectively from 39.66% to 27.62% in 2008). Moreover, if the company did not choose to pay the employers using vouchers, its gross operating profit would have been lower by 8.63 percents and 12.57 percents respectively. So, using such alternative personnel remunerations schemes determines an increase in gross operating profit, as the company capitalizes the tax savings generated by such instruments.

This is only one example that illustrates this new methodology that we proposed. To be relevant, the study must be extended by taking into consideration a sample of companies for which data are available. Generally, listed companies provide such data, so, this may be a good starting point. Unfortunately, there is no source of data that can provide all-in-one information related to tax incentives granted to companies in various forms, and, by consequence, such a study will have to surpass the difficulty of getting the necessary data.

EXCISES HARMONIZATION IN THE CONTEXT OF ECONOMIC CRISIS IN ROMANIA

This article tries to present the major aspects concerning the excise harmonization in the context of economic crisis in Romania. The paper realizes an analysis of the harmonization steps in the European space underlining the current situation when the revenues from excises represent a valuable source of financing the public expenditures. In Romania the harmonization process is not accomplished entirely, but the last increasing of the excises are due to this process.

Keywords: excise duty, tax harmonization, tax revenues

Cod JEL: H23, H3, G18.

Introduction

Excise duty is an indirect tax, a consumption tax payable on certain categories of goods including alcoholic beverages, gasoline, tobacco products, coffee, electricity and certain other items. The tax is payable on import and sales of locally produced items on the domestic market and is set as fixed euros amount per unit ("specific excises") or as a percentage of a specified taxable base (ad-valorem tax). Excise taxes have an important role in the budgetary and fiscal policy of every government because are used not only for obtaining the public revenues, but also for other purposes like to discourage consumption of specific commodities; taxes on alcoholic beverages and tobacco products are the obvious examples. Tobacco taxes can be considered as instruments for adjusting externalities through increasing the price by an amount that corresponds to the measured externalities. The same situation can be considered for the energy excises when the negative externalities- pollution- can be reduced through the revenues obtained from this excises. The issue of tax harmonization is a continue process for all EU member states. Even if the excise duty revenues have only 3.1% of GDP and 10% of the total revenues in the 2009 in Romania, the importance and the consequences of excises are considerable for our economy. In the European Union countries the highest share of excises revenues in gross domestic product is in Bulgaria 5.8 % of GDP and for EU the average is 2.5 %.

First issue is excise harmonization, a continuously process for Romanian fiscal system. According to the harmonization process in Romania, we have few directions for realizing excises harmonization:

- a minimum tax rate;
- taxation object: establishing the categories of goods and services imposed with excise;
- collecting procedures for transport, depositing and commercializing the goods imposed with excises.

Why is so important the harmonization process of excises? The answer is: because of the consequences and the major impact of this process from economic and social perspectives. The

major consequence is price increasing, not only for the products imposed with excises, but also for many other categories of goods whose price includes indirectly excises. For instance, fuels excises can be considered inflationary, because conduct to a generalized price increase. On the other hand excises on alcoholic drinks and tobacco are used for protecting the population health. The impact of increasing these excises is not always reducing the harmful consumption. But, instead increasing excises has a major impact of tax evasion. For instance, for cigarettes the excise rate was 64euros/1000 cigarettes and now is 74 euros and because of this excise increase many economic agents prefer to commercialize the cigarettes without paying the excise duty. Another consequence of excise harmonization is removing the luxury excises starting with this year 2010. How proper is this measure for our budget in this period of economic crisis when the budgetary expenditures cannot be covered because of the lack of fiscal revenues? For these arguments our research tries to evaluate the current situation of excises in Romania comparative with other states member of EU with similar harmonization process.

Harmonization process

The main objective of excises harmonization was to establish minimum rates of taxes for avoiding price distortions in the European Union. The aim of the state is to reduce consumption especially referring to the environment protection (e.g. from energetic products and electricity in the area of excise taxes) or the negative externalities (e.g. medical costs of smokers) which are not included in the price of product. Only in the case of zero elasticity of supply and demand it is possible to reduce overconsumption. In this case excise taxes increase the effectivity of tax system.

Another problem is regressivity of excise taxes. Consumption of products, which are liable to excise taxes at taxpayer with the increase of his income, reduces it. Taxpayers with low incomes face relatively higher tax burden. Moreover, it is proved that the consumption of tobacco and alcohol is relatively higher at poor people or countries.

In the European Union space excises harmonization represents a special issues imposed by the follow reasons:

- even if excises are not general consumption taxes like VAT, are applied on fuels. This category of goods represents in the now days an essential raw material necessary for realizing any products, thus we have excises indirectly in almost of the goods. For this reason an increasing or a decreasing of excise tax rate produces chain effects in the prices and can leads to some intercommunity distortions between EU countries;
- the role of excises in tax competition is significant because this category of taxes can induce the propensity of the member states for the reduced tax rates.

So, in this context we have the first measure to excise harmonization in 1993, in the EU quite late, because the excises have a reduced role comparing with VAT in the budgetary revenues. In relation to internal market a number of directives were adopting in this field. All the systems of excise duties have been implemented in the EU as a part of the internal market since 1st January 1993.

Excises harmonization is based on the follow instruments: object harmonization, tax base harmonization, tax rates coordination and fiscal procedures harmonization. The next table illustrates this level of excises harmonization and the main results for European Union.

Table no. 1

Harmonization level	Explications	Results
Tax object	Defining the products imposed: alcoholic beverages, manufactured tobacco products and energy products (motor fuels and heating fuels, such as petrol and gasoline, electricity, natural gas, coal and coke).	The members states have the right to impose excises on the other products, but only if this excises not imply custom duties procedures. But this kind of excises is discouraged because the receipts are very low.
Taxation base	Defining the taxation base and establishing the exemptions.	The taxation base was established as the maximum retail selling price for cigarettes, Plato degree for beer, hectoliters for alcohol. The exemptions are mentioned for every category, for instance for the energy products used as raw materials.
Tax rates	Even if minimum tax rates were introduced in 1993, there are may variation (for ex. for cigarettes we have a variation factor from 4 to 1 between the countries with minimum and maximum tax rates for excises) ⁸⁸¹ .	For some countries was established a schedule for tax rates increase, is the situation of Romania also. The maximum tax rate for excise cigarettes is in Ireland 260 Euros/1000 cigarettes and minimum is in Poland only 64 Euros.
Fiscal procedures	The taxable event is generally the production and the import in EU of excisable goods. The tax liability is suspended until the moment of consumption.	Thus was established fiscal warehouse regime under national fiscal authorities.

EU legislation in the area of excise duties on these products was mainly adopted in the context of the establishment of the Internal Market on 1 January 1993, which involved the abolition of controls of a fiscal nature at internal borders between Member States. This legislation, which has been further developed since, can be divided into three main categories according to the European Commission:

- The structure of the tax to be applied to a particular group of products. The structure of taxation means the definition of the product categories, the way in which the excise duty is calculated (e.g. per hl; per degree alcohol; per 1000 pieces, etc.), the scope of possible exemptions, etc.
- The minimum rates of duty that Member States have to respect for each type of product. Above those minimum rates, Member States can freely fix their own rate levels.
- General provisions that apply across the product categories. These provisions concern in particular the production, storage and movement between Member States of excise products.

⁸⁸¹ Negrescu D., Comănescu A., (2007), *Fiscal Harmonisation Trends in the European Union. Challenges for Romania*, Study no. 5, Project SPOS 2007 – Strategy and Policies Studies, European Institute of Romania, București

The initial idea was to harmonize both the structure and the tax rates of excise duties system. The harmonization efforts were (as well as in case of the value added tax harmonization) transferred rather to the structural field and only the minimum tax rates were set.

Analogically to VAT, the principle of destination was selected for the excise duties – goods subjected to excise duties are taxed in the country of consumption so that there would be no market deformation (principle of origin with existence of different tax rates does not ensure the tax neutrality). With effect from 1st January 1993 tax base harmonization is ensured by the uniform custom tariff and since the same date the minimum tax rates has been set.

Excise duties harmonization in the EU is based on three groups of directives⁸⁸²:

- **horizontal directive: directive no. 92/12/EEC**, which serves as general regulation for the production, holding and transport of products subjected to excise duty;
- **structural directive** – related to harmonization of structure of excise duties; is structuralizing excise duties into excise duty on mineral oils, alcohols and alcoholic beverages and tobacco;
- **four directives on approximation of tax rates of** above introduced excise duties.

Current situation of excises in Romania

Excise duty is a consumption tax payable on certain categories of goods including alcoholic beverages, gasoline, tobacco products, coffee, electricity and certain other items, considered luxury products, but excluded from taxation starting with this year. The tax is payable on import and sales of locally produced items on the domestic market and is set as fixed EUR amount per unit or as a percentage of a specified taxable base. The excise duties in respect to the main categories of goods are given in EUR in the table below:

Table no. 2

CATEGORY OF GOODS	EXCISE DUTY RATES FOR 2010
Alcoholic products	Up to EUR 750 per hl
Cigarettes	EUR 48.5/1000 cigarettes +22% of the declared maximum retail price= EUR 74.01/1000 cigarettes
Car fuels	EUR 347- EUR547 per ton
Electricity	EUR 0.5 or EUR 1/MWh
Coffee	EUR 153- EUR 900 per ton

Taxpayers are normally required to submit monthly tax returns and pay the excise duties for excisable goods by the 25th of the following month, with certain exceptions. In case of imported goods, the related excise duty, if applicable, should be paid at the time of making import declaration at customs.

The fiscal warehouse regime allows the production, transformation and/or storage of products subject to harmonized excise duties (e.g., beer, wines, other fermented beverages, intermediary

⁸⁸² European Commission, http://ec.europa.eu/taxation_customs/taxation/excise_duties/

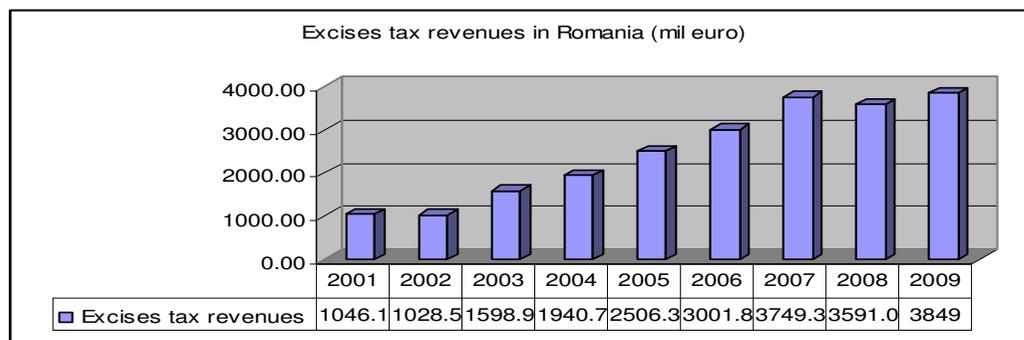

products, ethyl alcohol, tobacco products, and mineral oils) without the payment of related excise duties. Generally, the fiscal warehouse regime cannot be used for retail sale of such products.

The Fiscal Code allows production (and storage) of electricity and natural gas outside fiscal warehouses. In certain condition, the excisable goods could be moved under an excise duty suspension regime within the territory of the Community. The movement of the excisable goods under the suspension of excise duty must be covered by an administrative document and be supervised by national authorities. For this purposes, a computerized system for monitoring movements of the harmonized excisable goods under suspension excise duty within the Community, named EMCS (Excise Movement and Control System) will be implemented starting with 1 April 2010. Starting with 2010 non-harmonized excise taxes – consumption levies on luxury products – are removed, except for those charged on coffee.

Methodology and results of excises analysis in Romania

Our analysis starts with the evolution of tax receipts from excises, beginning with 2001 until 2009. The absolute data reflect an upward trend until 2008, when the Romania has to face to economic crisis, but the trend is resumed in 2009.

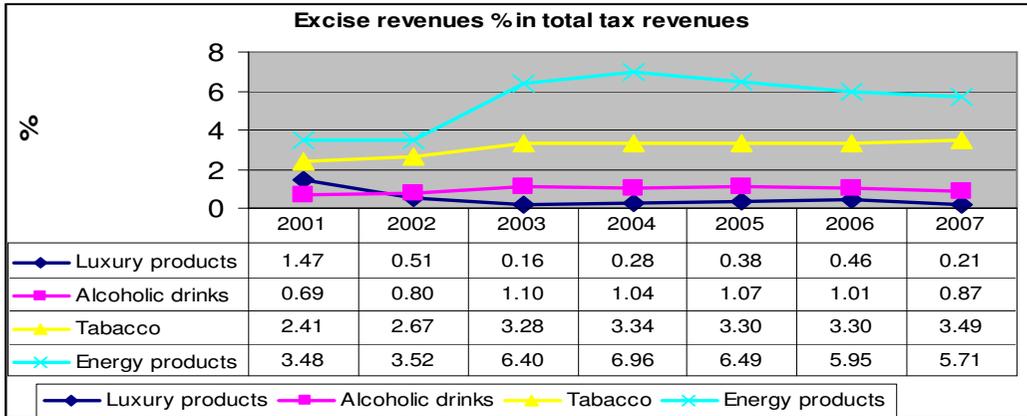

Figure 1

Source: The author's calculation based on the Eurostat and Finance Minister Data

The structural analysis of excise tax receipts is more important because reveals the major categories of goods which provides revenues for the budget. In the next figure is a structural evolution based on the classification of excises: harmonized excises applied of three categories of goods: alcoholic drinks, tobacco, energy products and non-harmonized excises for luxury products. For all harmonized excises the receipts as % of total revenues have upward trends from 2001 until 2007.

Figure 2

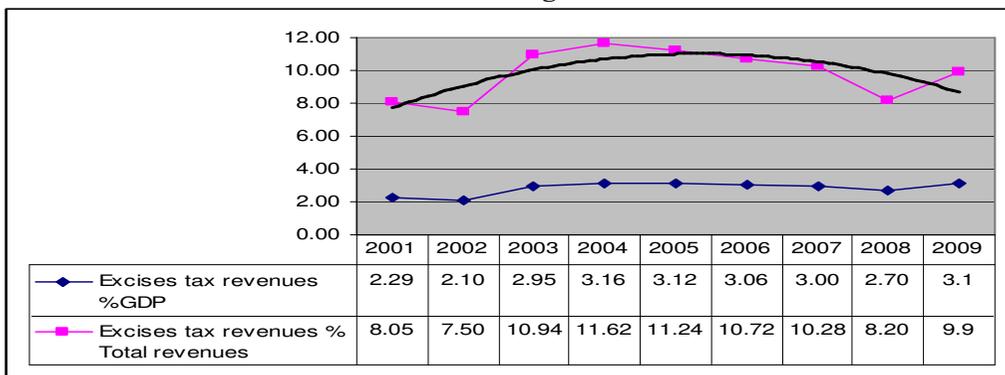

Source: The author’s calculation based on the Eurostat and Finance Minister Data

Only the excises on luxury goods have decreased from 1.47% of the total revenues to 0.21%, reflecting the lower importance in financing the public expenditures. This trend is explained by increasing the tax evasion in the case of luxury goods. Removing this luxury excises means a small decrease of tax receipts, but in the economic crisis every source of revenues is important. More than that luxury excises are a good mean to realize the fiscal equity and are not regressive like a possible increasing of VAT rate.

Excises for energy products are a reliable source of revenues, more than a half of the excises receipts are from this category, almost 6% of the total revenues. These excises also have the greatest inflationary impact reflected in the price increasing for the majority of goods.

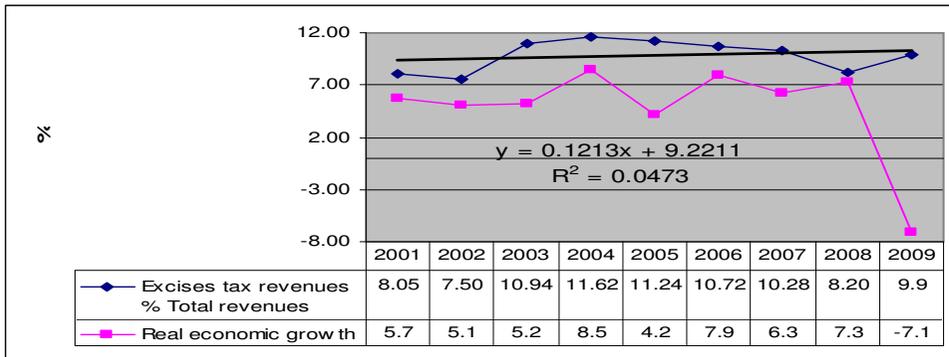

Figure 3

Source: The author’s calculation based on the Eurostat and Finance Minister Data

Evolution of excise tax revenues as % of GDP varies from 2.3 % in 2001 to 3.1 in 2009 with slight variations, with an important decrease in 2008. The impact of economic crisis had an important decrease of all tax revenues, especially in the case of VAT and corporate taxes.

Figure 4 Correlation between excises and economic growth

We try to verify the correlation between the economy evolution and excises receipts for 2001-2009 in Romania. But from the previously figure we have a low correlation between economic growth and excises, this low correlation is explained through the fact that excises revenues are a stable source of public budget financing, because are imposed on the goods with inelastic demand and for this reason the evolution of economy has a reduced impact of excise receipts.

Conclusion

Removing excises for luxury goods is not a proper decision for this period of economic crisis, when countries like Greece increase these excises for obtaining many revenues for financing the budget deficit. The decision to scrap the excise on luxury goods occurs at a time when some tax advisers suggested the authorities an extra charge on luxury products such as expensive buildings and cars, in order to collect more money to the budget strapped by the crisis. On the other hand, the harmonization process has to be accomplished in conformity with EU requirements.

INFORMATION ASYMMETRY THEORY IN CORPORATE GOVERNANCE SYSTEMS

Boloş Marcel

The evolution of corporate ownership structure, in particular the resolution of asymmetric information among stockholders, managers and creditors, requires very complex research. This paper aims to investigate how asymmetric information determines stakeholders to behave and how financial decision bears upon the performance of the organization.

JEL classification: G1, G3

Keywords: asymmetric information, financial decision making, corporate performance, leverage, stockholders.

1. Introduction

Modern theories converge on the idea that the objective pursued by stakeholders is to maximize corporate value. In 2004 the OECD issued a document, *The OECD Principles of Corporate Governance*, that underlines that corporations need to be run, primordial, in the interest of shareholders (OECD 1999, 2004). This means that the old concerns in the field, as to maximize profit in terms of cost of production, have been abandoned and now the emphasis is on this new paradigm of maximizing corporate value. But this aim is achieved when trends of the corporate value are increasing, since the value of shares plenary comprises the performance of companies. Hence shareholders choosing investments that generates a high return will tend to force corporations to seek a high return.

But in the corporate governance systems, the company is seen as a set of expectations that each stakeholder establish in their relationship with the company. This is like a sort of polycentric vision of the corporate governance systems, having in the center the company around which stakeholders attempt to govern.

Regardless of the theories underlying corporate governance systems, there is a system which generates flows between the company and stackholders that regardless of their nature (informational, financial, material, etc...) has a number of features formed on the basis of apparently conflicting interests that exists between the company and its stackholders.

When referring to streams caused by company-shareholder relationship (Jensen, Merckling 1976) it is not surprising that shareholders will seek to identify forms (dividend or earnings differentials in the price of the shares) to recover the fastest way possible the capital they have invested. In turn the company will try during it's development periods to convince shareholders to let at its disposal financial resources that could be distributed as dividends to avoid the possible risk of de-capitalization of the company. Yet this conflict of interests between the company and its shareholders may affect in a long-term the companies performance. Actually identifying this

conflict of interest and resolving it through a specific management approach can lead to long term sustainability of corporate performance.

Interesting are also the flows caused by the relationship between the company and its suppliers, respectively its customers. Its a category of flows formed upstream the company, between the company and its suppliers in which the society acts as the client and it legitimately aims to obtain raw materials at the best price and the best quality. The other party, the supplier, is convinced that when the transaction took place he has obtained the best price. Conflicting interests of companies and suppliers are more than obvious. While the price is "high and low" because the supplier is confident that the price he gets is a price that meets his interests (meaning good) while the company is confident that the material is obtained with the lowest price that will lead to selling prices of its products accepted by its consumers.

The same apparently conflicting interests can be found in the company-customer relationship (Flynn et al, 1990). But this time the company is in a position to deliver products and services at prices they considered to satisfy at least the companies stakeholders interests. On the other hand the consumer, who in the new theory governing the markets, in which the consumer is considered "the king", is convinced that through the transaction he has received the highest quality product and at the appropriate price.

Analysis of these flows may continue with the study of the relationship between the company and its financial creditors (Morellec, Schurhoff 2010). Usually this category of flows appears under the development and the investment financing of the company for business expansion. What kind of interests are manifested in these types of flows? Financial creditors are interested in obtaining the best interest for the capital which they provided to the company. Or such interest is borne by the selling prices of goods and services produced by the company so that the pressure exercised on the consumer, which may at any time to change its supplier of products and services. Furthermore the company hopes to obtain a gain from the investment made and financed by its financial creditor, so from the net profit and the amortization to be able to repay the loan and interest due to the financial creditor. The implications of this category of flows doesn't stop here. Because the interest will erode the profits of shareholders they will require that the rate of return they expect to be satisfied after debt repayment to financial creditors at least equal to the duration over which the loan was incurred to finance investments required. And there are conflicting interests. Financial lender considers the loan offered at the best interest rate while the company is convinced that she contracted a liability at an interest rate as low. This category of conflicting interests must be supplemented by the interest that the shareholders show, they give up the lender for financial gain, so that for long term they can increase their earnings to.

Flows of goods and services or financial resources are not considered limited. They may be supplemented by flows between the company and human resources (its labor force) or between the company and the state as beneficiary of taxes. These flows of links regardless of their nature are governed by information held by human resources who are responsible with taking the decisions. The information is held in a different way by individuals making their behavior also different. This is the first step that leads us to believe that any flow links between the company and its stakeholders, are based on elements of information asymmetry leading to different behaviors of individuals with influence over the medium and long term on the companies performance.

An agency relationship develops whenever there is a relationship between economic actors and the welfare of one person depends on the actions of the other party; that is, when the welfare of the principal is influenced by the action (or inaction) of the agent (Howard, Snowdon 2005).

A first attempt to define the asymmetry of information in corporate governance theory shows that it is in possession of information in different ways by individuals involved in running streams between the stakeholders and the company, under which individuals have different behaviors and different decisions which may affect the performance of companies.

It is the objective pursued by this research to study factors governing the flow of information asymmetry between the company and stakeholders that are based on the corporate governance system.

2. Information asymmetry and individual behavior in corporate governance system

In the previous paragraph we tried to outline the definition of informational asymmetry in the corporate governance system, which revealed that individuals involved in all streams of links between the company and stakeholders do not have the same information, at the same point of time. This means that individuals will have different behaviors and can take different decisions that may impact on company performance.

Therefore in the theory of information asymmetry, the information that individuals have it's important and the decisions they can take with the information they hold. Place a natural and legitimate question for the companies stakeholders namely: How to measure information asymmetry and its impact on the companies performances?

In an attempt to measure information asymmetry there were taken as the basis for the research the most important flows in the corporate governance system, namely: flow links between the company and its shareholders. In a first step we examined the information asymmetry between the two shareholders who invest in financial markets. To generate the ecuational model of measurement for the information asymmetry we was established the following research hypotheses:

- a) on the financial market there are two investors who are characterized by information asymmetry, according to information they hold about companies where they are to invest;
- b) each investor has a certain amount of information on which companies are to invest and has some form of rate expectations on earnings that they hope one will get from the capital that they invested;
- c) each company provides a standard volume of information covered by the Securities Commission's financial market and while each company has a certain volume of information that is standardized to provide a certain visibility.

Suppose that between the two investors there is an information asymmetry arising from holding a different volume of information for the investor (I_1) against investor (I_2), so that the first investor holds information of the standardized rate of net profit that the company provides to its investors ($InfI_1$) while the second investor has the same information on the net gain rate ($InfI_2 = InfI_1$). Both information are part of standardized information and the same for any two investors. In addition to the first, second investor is aware that one of the companies on the capital market is to develop an investment that will lead to an increase in long-term gains to be granted to investors every year during the period of investment. This information is denoted $InfI_2^1$.

The two investors are subject to information asymmetry because the volume of information they hold is different. The first investor has the amount of information that is equal to $InfI_1$, while the second investor has a volume of information formed by the addition of $InfI_2 + InfI_2^1$. Absolute deviation $\Delta InfI = InfI_2 + InfI_2^1 - InfI_1 = InfI_2^1$ is the form of measurement of information asymmetry in which the first investor is to the second investor. If $\Delta InfI = 0$ we can say about the two investors that they have the same volume of information and are not in situations of information asymmetry.

The question that appears, is determined by how the two investors will behave. To answer this question it is essential a thorough analysis of investor expectations that the two have. Yet expectations are determined by the common interest they have. If investors are rational when

they will watch the market to have a capital gains rate to meet their expectations (Kothari, Nikolaev, Loutschina, 2006). The rate of earnings is an standardized information and is provided freely for those two investors.

To address the behavior problem of the two investors in a situation of information asymmetry is necessary to establish the level of information $NInfI$, for which the two investors will act the same. Regarding this level of information that determines the behavior of the two investors we can distinguish a few situations in which, depending on the information, the investors will take the same decisions or contrary their decisions will be opposite, namely:

The first situation corresponds to a common level of expectations for both investors and the rate of gain that the company offers meets the interests rate they seek. Their expectations are met by the rate of gain (r_c) that the company offers, so although they are in a situation of information asymmetry they decide to invest in shares that the company offers. The conclusion that emerges is that in situations of information asymmetry investor behavior is the same if their expectations are the same.

The second situation corresponds to different levels of earnings that investors expect from their investments. Thus if the rate of gain noted (r_{c1}) that the first investor expects and (r_{c2}) the rate of gain expected by the second investor, and with (r_c) the rate of success the company provides, we will identify the following types of behavior caused by information asymmetry:

a) If the rate of earnings provided by the company is above the expectations of both investors, even in the situation of information asymmetry they will take the decision to invest in company shares;

b) If the rate of earnings provided by the company is below the expectations of both investors then their behavior will be different, the first investor will not invest in company shares because of the fact that it offers a rate of return to capital that would not meet his demands expected for the invested capital. While the second investor is in the same situation as the first, that the expected rate of return is below its requirements, yet he knows that from the investment in the company is next to be obtained a bonus for its shareholders so that, after the company's investment the expectations of its shareholders would be fully realized. The second investor who finds himself in a information asymmetry, decides to invest in the financial market, so he acquires a volume of actions, depending on his available capital.

If we note +1 the situations of where investors that are in a situation of information asymmetry decide to invest in financial markets and -1 where investors chose not to invest when they are in a situation of information asymmetry, form the function of informational asymmetry, in which information is marked $Inf_1, Inf_2, \dots, Inf_n$ the function will look like this:

$$f(Inf_i) = \begin{cases} 1 & \text{if } r_c \geq r_{c1}; r_{c2} \text{ si } \Delta Inf \neq 0 \\ 0 & \text{if } r_c = r_{c1}; r_{c2} \text{ si } \Delta Inf \neq 0 \\ -1 & \text{if } r_c < r_{c2} \text{ si } \Delta Inf \neq 0 \end{cases}$$

Limits for this function established by information asymmetry, are determined the function refers to a market where there are only two investors who are really in a situation of information asymmetry but also is considered the situation where the two do not communicate with each other, no exchange of information between them taking place. Information asymmetry research will continue at a later stage, a market consisting of N investors, where the asymmetry function can establish investment trends that investors are investing in a company, taking into account that the function market information asymmetry is determined by existing investors in the financial market crowd.

3. Implications of informational asymmetry on the possible performance of the company

It is important to investigate the implications the asymmetry information has on the companies performance. But this implications are determined precisely because the two financial market investors are in a situation of information asymmetry leading to different behaviors. So assume that both investors decide to invest in the company. This corresponds to a value of function of information asymmetry equal to +2, respectively $f(InfI) = +2$ and a situation where $r_c \geq r_{c1}; r_{c2}$ and if the volume of investments made by the two investors are noted $V_1 = N_1 \times V_p$ and $V_2 = N_2 \times V_p$, this means that the company will attract from the capital market a level of financial resources equal to $V = (N_1 + N_2) \times V_p$. Thus, the impact on company performance is determined by the cost savings that the company would be contracted out if the same level of resources for the banking market would pay an interest rate level equal to r_d . Let us denote by k_a the cost shares, this means that the difference between the interest rate margin and cost actions will determine the cost of the two funding sources denoted m_f .

In these circumstances, if $m_f \geq 0$ we are where the information asymmetry will lead to cost savings equal to $E_c = (r_d - k_a)(N_1 + N_2) \times V_p$, which will have a positive influence on company performance, while $m_f < 0$ will cause a negative impact on company performance as determined by the same formula for cost savings. This may correspond to the opportunity to procure funding sources for the banking market as the interest rate is lower to cost operations. Or cost shares can be found in this situation only when the expected rates of earnings investors are characterized by irrational exuberance.

If both investors are subject to information asymmetry and one of them decides to invest and the other identifies other investment opportunities on financial markets then this situation is characterized by the fact that the rate of gain that although the company offers lower rates to gain both investors, however, the second investor hope that he will gain a bonus if the company will achieve the investment expansion that is planned, so he will make the investment.

For this situation, an investor decides to invest and the other gives up the information asymmetry function has the value $f(InfI) = 0$, while $r_c < r_{c1}; r_c \geq r_{c2}$ and the volume of investment that the two investors make is determined by the second investor who buys shares $V_2 = N_2 \times V_p$. The company is in a situation where to procure the necessary financial resources, the lack of investment which would have made the first investor will procure from the banking market which as is known to pay an interest equal to r_d .

Cost savings is also lower than in the first situation analyzed and will be determined using the formula $E_c = (r_d - k_a)N_2 \times V_p$ with specific situations for positive margin financing, where the positive effect on company performance, while negative margin financing there will be a deterioration in company performance.

The cases analyzed concern the impact on companies performances, being limiting in terms of the number of investors who invest on the financial markets. But the information asymmetry specific to the companies stakeholders can be analyzed in conjunction with other indicators of profitability which usually are followed by the stakeholders. Actually eliminating the negative impact that information asymmetry has on company performance can be achieved only by increasing access to non-standard information available about the company. And by increasing the visibility of information that the company offers its stakeholders, there is the risk that the different interpretation of the information provided by the company, investors not to behave the same.

For a market with two investors in a situation of information asymmetry the results obtained upon the companies performance are very different, drew the conclusion was that information asymmetry influence the performance of companies even if they record a performance attractive for investors.

4. Conclusions

Corporate governance system consists of flow links that are established between the company and its stakeholders, involving material, human and financial resources in order to help maximize business value. Link flows are based on information moved from the company to its stakeholders in which most often manifests conflicting interests. The price of raw materials necessary for the company, for example, may both large and small from the market perspective but also from the company's suppliers perspective.

This information is not shared proportionally between stakeholders making it appear the concept of information asymmetry that defines the state in which two individuals at the same time not have the same amount of information. This fact makes the two investors have different behaviors depending on the information they hold and the expectations they have. Information asymmetry function has a value equal to +1 when the investor decides to invest in the company, or this happens only if the profit rate they offer is superior to the investors expectations. Information asymmetry function has a value equal to -1 when the rate of earnings provided by the company is below the hoped value for by investors. There is however a situation where although the function of information asymmetry is equal to -1, the investor decides to invest in the company since he has information that in the next period the company would develop investment to expand business activity and thereby ensure that earnings growth are to meet long-term investor interests. Information asymmetry impact on company performance is also a very interesting research topic. It was found that there are situations for positive values of the function of information asymmetry, which causes a positive impact on company performance and company value equal to the indirect cost savings resulting from resorting to other categories of funding sources, such as te banking market. There are also situations where information asymmetry has a negative impact on company performance because not all investors choose to invest in the company or investors' expectations contrast ratio is above the interest rate charged on the banking market.

Model has also limitations. It refers to a market which consists of two investors which in reality there isn't, but respecting the hypothesis that the specimen could be extended to N investors. Also to consider the hypothesis that investors do not communicate among themselves and develop links between the flows from the company and its shareholders. Future research about information asymmetry should continue to expand the market for N investors, taking into account the fact that they communicate among themselves and with the expansion flow links that are established between the company and the other categories of stakeholders, underlying modern business activity.

RECONSIDERING THE FUNDING SOURCES FOR THE HEALTH SYSTEM IN ROMANIA

Mihaiu Diana Marieta

Bunescu Liliana

“Lucian Blaga” University of Sibiu, Faculty of Economic Sciences

An optimal health system must ensure that all citizens have free access to medical services, and to determine the effective use of funds. We therefore reach the conclusion that the health financing system that best meets the optimal criteria is the public one. We believe that a system of public health funding should be based not only on contributions, but also on funding from the state budget; therefore it should combine the two public sources. If it were based solely on contributions, then the earnings should be volatile towards the economic cyclicality, and would not ensure the fiscal sustainability of the system. The private health financing system should be based on private insurances, and not on direct payments as it is in the current case, private insurances should have a predominantly complementary nature (covering the co-payments for those that are forced to bear them), and only in the case of rich people it can be substituted.

Keywords: public expenditure, health expenditure, private health insurance, social health insurances.

JEL Classification: H51

The sources of financing the health expenditures are divided into two main categories: the public sources and the private sources (direct payments from patients to health providers ; immersive for drugs and certain medical services; the procured funds by non-governmental organizations that can carry out charitable activities in health care domain; private health insurances; direct payments made by private companies), these sources combine together in order to finance health in proportions that vary from country to country.

According to the data published by the World Health Organization in the paper “The World Health Statistics 2009”, the average health expenditure worldwide in the year 2006 accounted for 8.7% of GDP. Extremes occurred in the U.S., with 15.3% of GDP, and in Southeast Asia, of only 3.4% of GDP. In absolute size, the health spending per capita averaged about \$ 716, the highest level being in the U.S. of \$ 6,719, and the lowest in Southeast Asia, of \$ 31. The European average is 8.4% of GDP to health, funded at a rate of 75.6% from public funds, 24.4% from private sources, the private health insurances amount on average to 22.1% from the total of all the private sources of funding and expenditure per capita on health is \$ 1,756⁸⁸³.

Romania granted to health in 2006, a rate of 4.5% of GDP, going down from the levels in the year 2000 by 5.3%. In a rate of approximately 77%, the health expenditures are covered by public funds, from which 85% come from the health insurance contributions, while 23% from private funds, the external funds in 2006 were being invalid. The private funds come at a rate of 96.8% from direct payments of the beneficiaries of health services (out-of-pocket payments); the private health insurances own only 1.7% of all private funds.

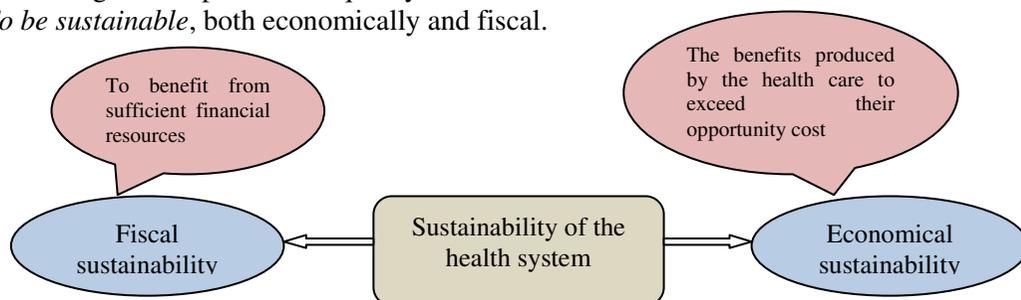

The health expenditure per capita in Romania is of \$ 256, hovering well below the world average of \$ 716, and to the European average of \$ 1,756. Denmark, for example, gives a rate of 10.8% of GDP, financed at a rate of 86% from the public funds, and the expenditure per capita is of \$

⁸⁸³ Date preluata din lucrarea World Health Statistics 2009, publicată de World Health Organization, pag. 107-117.

5,447; Luxembourg allocates 7.3% of GDP, the public funding is 91%, the private one of 9% is based on a proportion of 18.7% on the private health insurances and the expense per capita is of \$ 6,506. *It is noticed that Romania is still far from these values, so the definite conclusion is that the level of health financing must be increased, both on public resources and on the expense of the private sources, this can be done by increasing the private health insurances, which in Romania own an insignificant share.*

An effective system of financing needs to be found, that would meet the actual needs and that would ensure that no citizen makes a considerable financial effort that significantly reduces its standard of living when they get sick⁸⁸⁴, so, the system **should respect the following principles**⁸⁸⁵:

- *The ability to generate sufficient resources*, through which comprehensive and quality services will be provided to the citizens.
- *To ensure fairness*, both in terms of establishing a system of financial resources (equity in financing) and also providing health services to the population (with equity access) so that each person should contribute according to his income and anyone would have free access to the health services.
- *Risk pooling*⁸⁸⁶, this means aggregating risks over time and between citizens, criterion based on the premise that no individual may predict the time and severity of his illness, so he cannot individually manage this risk of illness, that is why it is appropriate to be centrally managed in an institutional setting. Arguments in favor of the healthcare risk aggregation are based on considerations of fairness and efficiency.
- *To ensure efficiency*, both in collecting resources (administrative costs low) and in the distribution phase (maximum effect on unit cost).
- *To help ensure quality of service*, this criterion is closely related to the adequacy of funding and its sustainability. Through a lack of funding it will not be able to acquire the latest technology, the skilled personnel cannot be adequately motivated and all these have a negative impact on the quality of healthcare.
- *To be sustainable*, both economically and fiscal.

In building an optimal system of financing health we must start from identifying the **beneficiaries** of the health services, namely:

- A first direct beneficiary from the health services is the **individual**, because the quality and longevity of his life is determined by his health.
- **Private enterprises** because they are benefiting from the intellectual and physical capabilities of employees and a healthy person will have a higher yield from an illnesed one, which eventually translates into higher profit. And the enterprises using labor to operate bring damage to the health of employees, and therefore their involvement is needed in the health financing system.

⁸⁸⁴ *The European Health Report 2009*- Health and Health System, elaborat de World Health Organization Regional Office for Europe.

⁸⁸⁵ Murgea Mihaela Narcisa - *Modalități de finanțare a sistemelor de sănătate* , pag.322-324.

⁸⁸⁶ Peter C. Smith și Sopia N. Witter - *Risk Pooling in Health Care Financing: The Implications for Health System Performance*, The World Bank, 2004.

- *The society as a whole*, because a healthy population has an increased productivity, a greater innovation capacity, which stimulates growth and technological progress, with direct impact on enhancing national competitiveness.

Starting from the health service users there can be identified *sources of financing* the health system, namely:

- *The public funds* due to the benefits enjoyed by the society. In Romania, the state funds these services, both on account of taxes, general taxes, special purpose health fees collected from the state budget and local budgets and on account of the contributions paid by employees and employers to the national health insurance fund. Note that over 85% of public funds come from the national fund for health insurance; the actual financing from the state budget is reduced to 15% from the public funds, meaning 0.67% of GDP. The question is whether these funds are sufficient to ensure the funding system, under which the private finance is only 23% of the total funding, and relies on direct payments to individuals. The reality provides the answer to this so-called dilemma. Funds are by far not enough. On one hand because the percentage of GDP is much lower compared to the developed countries of the Union, on the other hand the GDP in Romania is lower than in other countries, except Bulgaria. What can be done to improve the situation? *A first proposal* is to undertake measures to reduce the undeclared work. If this is successful, then the revenue from the health insurance contributions will automatically increase. *A second proposal* is to apply the health insurance contributions to the pensions that are above the minimum wage, not just to those over 1,000 lei, as all employees, regardless of their income level and age and health state pay contributions and it would be fair that pensioners with pensions above the minimum wage to help, given the fact that they consume a large portion of these services. *A third proposal* is that the state recognizes the importance of a viable system of health and welfare that ensures the citizens welfare and the country's economic and social progress, to recognize health, along with education as a national priority, and to act accordingly, increasing the proportion allocated to the health budget because funding should support new medical equipment and the construction of new hospitals, to create a quality infrastructure; and the current rate, of less than 1% of GDP allocated from the state budget is very low. To attract new financial resources to health domain, the government introduced the levy of vice, on alcohol and tobacco, and the clawback system. It remains to be seen whether these mechanisms will give the expected results. But I believe that the vice tax (for cigarettes the sum of 10 Euros/1.000 cigarettes; for cigars with € 10 euro/1.000 pieces; for smoking tobacco the sum of 13 Euros / kg; for beverages drinks 2 Euros / per liter of pure alcohol⁸⁸⁷) will do nothing but increase tax evasion and the smuggling of such products, leading to lower revenue from excise duties. *Applying the clawback system* starting with October 1 2009, in order to collect additional funds necessary to fund the health system in view of its under-funding in Romania to the EU average, but this system is poorly understood, and applied in its current form, will generate adverse effects. As it is understood in Romania and how is implemented this clawback system requires that all medicinal products manufacturers which unfold once Romanian market to help fund the public health system by 5% to 11% from the revenues from the sale of medicines . Applying the clawback system in its current form will lead to both reducing the number of pharmaceutical companies and the number of products available on the Romanian market, which will affect the industry, and especially the patients. In the developed countries this clawback system is used, but is seen as a safety mechanism in case of exceeding the budgets approved by producers and financiers and it applies "only to what exceeds the initial budget and is funded through the reimbursement system"⁸⁸⁸.

⁸⁸⁷ Legea 95/2006 actualizată.

⁸⁸⁸ <http://www.capital.ro/articol/sistemul-clawback-poate-duce-la-disparitia-a-30-din-medicamente-26490.html>.

- ***From the private sources of health financing***, which should come from both individuals and legal entities that must be involved in the process of health financing. A solution for this conclusion would be to boost the private health insurance by individuals and / or employers, as benefits offered to employees, but that would not come to the detriment of the social insurances. The private health insurances are very poorly developed in Romania, compared to the other EU countries, or with the U.S. ones, where these insurances represent the peak in this area, the U.S. health insurances are largely private, the state funds this service only for disadvantaged people and for people over 65 years, but the U.S. is not the model that we should follow, because although it has the highest allocation to health per capita, many citizens are not caught in any health insurance scheme, a fact that has serious consequences, which shows the disadvantages of this system.

The private health insurances in Romania, in the year 2008 represented only 1% of the total insurance market in Romania, but this is a market that has potential in the future. Such insurances are relatively new on the Romanian market, they entered our market only in 2005, and the number of companies offering this product was low. Analyzing the situation of the private insurances in the European countries, it notes that they are contracted by people with a higher education, and a high financial strength, rising barriers for the elderly and the sick, because the private health insurance companies follow a risk selection, regardless of fairness, of freedom of access to services, their purpose being to obtain the highest profit possible. It is however necessary to develop the private health insurance sector, which will increase the quality of the services provided, but will also have a role that will reduce the out of pocket payments made by individuals, and the informal ones, that affects the living standards especially for the poor and their access to such services. The private health insurances can be complementary, meaning they provide financing for public services of health and medicines, or can be auxiliary, meaning they cover medical services not offered by the public health system, or in some cases (eg Germany) foster the social ones.

The potential benefits to determine the need for private health insurance concerns: limiting the public spending for health, increasing the choice among consumers of such services, stimulating private initiative in providing health services, stimulating competition between the public and the private sector involved in increasing the quality of services, increasing choices for people with a good financial standing⁸⁸⁹.

The co-payments should be set carefully so that they would achieve its desire "to give value for money", but do not to impede the access to the medical services for disadvantaged people. In this respect it should be maintained some exceptions from the payment of the co-payments, which will be borne by the state budget for the poor people, whether or not they are retired, and for the chronic patients.

Another form of health financing from private sources, involving citizens and economic agents are the ***subscriptions to private health clinics***, that recorded a higher rising than the private health insurance system in Romania. In 2008, the subscriptions to private clinics value in Romania were about 3.6 times higher than the private insurances. These subscriptions are purchased by individuals, but as practice has shown, these were purchased in proportion of over 70% by legal entities because of the obligation to ensure the occupational health services for employees. Gradually, however, given that employers want to give employees other benefits in addition to those included in the mandatory occupational medicine, that have extended the service plan, this was also due to the fact that these subscriptions are fully deductible for the employer. The private health insurances are not so attractive for employers towards their

⁸⁸⁹Sarah Thomson, Thomas Foubister, Elias Mossialos - ***Financing Health Care in the EU. Challenges and Policy Responses***, European Observatory on Health Systems and Policies, 2009, pag. 57.

subscriptions due to their limited deductibility (250 Euros per year per employee, what exceeds is considered a non-deductible expense). However, the range of health services offered by subscription is smaller than those offered by the private health insurance, and are subject to a single clinic, while the insurance gives the customer the liberty to choose from several medical clinics.

Conclusions

An optimal health system must ensure that all citizens have free access to medical services, and to determine the effective use of funds. A comparative analysis of the situation from various countries concluded that this goal can be achieved only through a system of public financing. For example, if the U.S. health financing is largely private, but even with the highest health expenditure per capita in the world, has the highest rate of people who do not receive any form of health insurance: nor from the private insurance because they don't have enough money, nor from the public one because they are not poor enough.

It is advisable to increase the interest in the private health insurance, particularly among people with a good financial situation, and should be viewed as a mean of raising necessary revenue for funding health, especially in Romania where we notice that the sector suffers from acute underfunding. However, so that it is not understood that I support the disengagement of the states involvement in financing the health system because it is entirely appropriate for the state to involve itself in order to ensure the fairness of the system, because the private health insurance companies, which are profit driven, will be interested to attract healthy persons, meaning with low risks and a high income.

Related to the clawback system, the Romanian government should stop this tax applied in its current form, as it does nothing but harm the private initiative. This system should be applied, as it was originally conceived, and as it is used in other countries, as a safety mechanism, in exceptional cases.

The direct payments used in sizeable proportion in Romania for funding health from private sources, whether represented by the full payment of the service, or by co-payments, affect the people's free access to these services. The poor or the elderly could reduce the consumption of such necessary care due to the inability to pay, and the reality in the countries applying these co-payments as forms of financing has proven that this lead to no considerable increase in funds for health, nor enhanced the quality of the services, that's why we must maintain some exceptions from their payment, or they must be even eliminated.

France can be considered as a model in terms of health financing system, the state covers between 70-80% of health expenditures, the rest being covered from private sources, mainly from private health insurances. Thus it succeeds to take care of the health of the middle class and poor people, allowing the rich to pay for high quality health services. This should be the objective of Romania also. The German system is similar to this one, in Germany all persons are obliged to a health insurance, but health insurance is mandatory only for those with an annual income under 48 000 Euros. People who have an annual income above this limit (less than 20% of total population) may choose to end a private health insurance, that takes the place of the public one, about 75% of them decide to remain in the public system, and only 10% of the population have private insurance.

We therefore reach the conclusion that the health financing system that best meets the optimal criteria is the public one, but here a problem arises, namely, the structure of the public financing system, should rely on the social health insurance contributions, or on the funding from the state budget from general taxes. I believe that a system of public health funding should be based not only on contributions, but also on funding from the state budget; therefore it should combine the two public sources. If it were based solely on contributions, then the earnings should be volatile towards the economic cyclicity, and would not ensure the fiscal sustainability of the system. The contribution revenues are sharply reduced in periods of recession, when the unemployment

increases, also, the underground economy and the illegal employment also affect these samplings.

In the current case of Romania, it is appropriate to extend the funding from the state budget, which is currently very low, approximately 15% of the total public funding for health system relies too much on the contributions to the social health insurance borne by employers, employees and by some retirees. The state must bear to ensure the people that do not participate to the contributory system and also the capital expenditures and investments in the Romanian health system should be a priority for the government because it is obvious the lack of modern equipment, inadequate hospital beds, and these real problems cannot be solved in the absence of adequate financial support from the state. In a funding system based primarily on social security contributions, strengthening the states involvement through funding from the state budget contributes to increase the financial protection of the health system but also increases the equity in terms of populations access to health services⁸⁹⁰.

The private health financing system should be based on private insurances, and not on direct payments as it is in the current case, private insurances should have a predominantly complementary nature (covering the co-payments for those that are forced to bear them), and only in the case of rich people it can be substituted, but in this case the mandatory health insurance should be imposed, so that there are no persons that would not receive any form of health insurance.

THE SELECTION OF OBJECTIVES BY FISCAL POLITICS

Morar Ioan Dan
University of Oradea
Faculty of Economic Sciences

Summary: The multitude of fiscal politics` objectives supposes a rational and a well-informed selection of them. Fiscal politics handle specific instruments and levers , producing effects which are hard enough to be quantified and reactions, which most of the time are unforeseen by the payers in their quality as productive or final consumers. The perfection of the proposed alternatives is necessary on the one hand , but hard to be realized on the other hand.

The substantiation of fiscal politics aims two types of decisions, irrespective of the time horizon for which the politics promote the objective. Namely, it refers to the changes inside the fiscal system and, on the other hand , to the changes that are produced in payers` behavior.

The changes inside the fiscal system on their turn , will be materialized in legislative adjustments and in adjustments of fiscal procedures.

Fiscal legislation based especially on Fiscal Code (Law 571/ 2003) also contains other secondary normative acts, such as orders, government decisions, methodological norms and fiscal law` s application instructions.

Taxes settled on the settlements specific to the domain generate different and sometimes even opposite conditions of senses, but they also influence the environment, which is the social and economic one , especially and the payers` behavior particularly.

Influences on the behalf of taxes will also manifest on fiscal system , on budgetary one in extension and on institutional system in general.

The most important reactions , from the fiscal politics point of view , are those that proceed from economic agents.

Taxes, the functionality of fiscal system, its relations with the payers and influences looked on economy are settled by juridical laws, specific subjective laws.

The functionality of fiscal system alters depending on the functionality of each undermechanism for each tax partly.

As any mechanism , the taxes mechanism too can be burden by the influences from economic environment. Some of these , such as repeated updates of fiscal legislation , fiscal dodge , measures of fiscal harmonization , reconciliation of accounting evidence with the fiscal one, the system of transfer prices, and others are some actual issues of the present fiscality.

- 1) Too thick adjustments of fiscal legislation produce incoherence in the activity of office workers in the fiscal domain and in the same time produce difficulties for payers who, on their turn, spend an important part of their precious time for maintaining their relation with fiscal organ.
- 2) Different fiscal pressure for physical persons and for the juridical ones generates different effects on payers , influencing their decisions regarding the kind of tax and the chosen contributions to be owed.

If tax benefit payers who owe proportional quotation benefited by a huge decrease of fiscality degree, just as economic agents of microindustrial units type , not the same thing can be said about payers, physical persons , even in the conditions in which proportional quotation took place of the progressive quotations in trance starting with the year 2005. It cannot be said the same thing because the incomes of physical persons , especially those realized by work, are liable to contributions to social insurances budget, to health insurances budget, to unemployment insurances budget and also to special

funds , of risks and accidents , of insurance of salary lacks and others, specific to some domains of activity.

- 3) Fiscal advantages and fiscal constraints , in the 3rd place, present a specific and direct influence on payers.

It is known from daily life that tax payer is interested first of all by avoiding the fiscal law and by acceptance of the possible advantages offered by it.

Fiscal advantages are grouped in two components , namely fiscal deductions and decreases of taxes. Fiscal deductions are parts of taxed basis , incomes , property , expenses, activities, exonerated from imposition, sometimes conditioned or other times unconditioned.

Fiscal deduce riles from imposable base as incomes are found in fiscal practice as scot free income, as personal decreases, as monthly fixed sums, or conditioned by the existence in payer`s intersidereal of other persons without incomes, as well as contributions and social dues, syndicate dues or parts of monthly or annual incomes conditioned by the expense of these incomes, these being justified with payment documents of different kinds.

Decreases to taxes payment represent parts of calculated taxes which, according to fiscal law, are not paid. If the deductions are 100% , we talk about the exemption from taxes, even if it was calculated depending on legislative settlements.

Iffiscaldeductions are handled with a view to a selective encouraging of consumption, fiscal decreases are destined to encouraging of offer.

Encouraging the consumption on fiscal ways aims especially the tax on physical persons` incomes , actually aims the unproductive consumption , but also the productive one by warming up of the demand.

Global and familial imposition of physical persons` incomes offers multiple possibilities of encouraging the expense of incomes and sometimes of saving.

Decreases on tax payment are most of the time conditioned by the benefit reinvestment , by the sale of the production at export or other similar conditions.

In the same category is included the external fiscal credit which actually aims paid tax abroad and which will be recognized till the tax level that would have been paid in the country, actually an usual credit (the procedure of usual credit).

Such a fiscal measure regarding the exemption from taxes on reinvested benefitis settled by Law 329/ 2009 , witha well- established aim, that of encouraging the production of offer by sustaining the productive consumption. This fiscal measure with an effect of lever , otherwise salutary, must be looked at by the viewpoint of evolution of production structure in the next few years, period that will pick up all the results of the politics promoted in this way.

But the next question is put, namely, if and for how long, the initial structure of production will not suffer modifications at consumers` demand. On what period of time will resist the same structure of raising the production as a result of tax` reinvestment.

The main issue is that of perfection of fiscal politics alternatives and of choosing of its orientation to consumatory fiscal politics or to that which aims the offer.

Most of the time fiscal politics end with unexpected results, different from the initial intentions. For example, we do not know without a projective documentation , if still after an year or more , consumers will buy objects of domestic use with current facilities , or simpler, we do not know if the next year too, the sales of beer -xxl- will raise. The most exposed domains to such a dissolution are the high-tech ones. Sometime the simpler measures can be more efficient than decreasing or increasing of fiscal charge.

We have to emphasize that in this context another problem appears , undetached by fiscal politics , namely the problem of fiscal equity, a large issue which from quantitative reasons, we put it off for another study of specialization.

Also, the issue of budgetary finance is bound up directly with the evolution of budgetary returns as a result of changes in fiscal politics. The budgetary deficit at which it comes to as a result of increasing the expenses and / or reducing the taxes ` level can lead to a rapid increase of public debt.

Credits for financing the budgetary deficit can determine the increasing of interest rate , fact which determines the economic agents (sellers and buyers) to loan less and, at the same time, to spend less than they have planned to , thus fiscal politics directed to offer will cancel the measures directed to consumption.

More than that, the issue of rate interest comes to light, without which fiscal politics cannot be promoted , no matter of its orientation. Influences from and to rate interest are known especially from the context of keinesian politics.

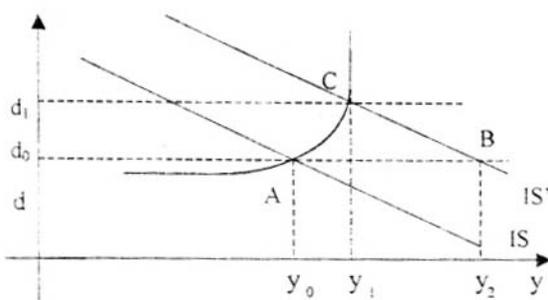

The most important aim would be maintaining under control the report between offer and demand , and if we have in mind a macroeconomic model of a closed economy, with a public sector included in it, than the equilibrium on properties and services market takes place , when the aggregate demand is equal to the aggregate offer.

If the fiscality increases , that the state `s incomes increase too, and also increase the productive and unproductive expenses. Through the mediation of consumption, the aggregate expenses (G) will be influenced directly.

$$\Delta Y = \Delta G \left(\frac{1}{1-m} \right)$$

In which $\left(\frac{1}{1-m} \right)$ is the multiplier of government expenses.

But if the taxes decline, the aggregate expenses will be decreased and the multiplier of taxes will have a negative sign , because by the increase of taxes the intern product is decreased and conversely, so it is a conversely proportional relation .

Y = I.G.P. (internal gross product)

D = the interest rate

If the fiscality rate grows, the IS curve will move towards left with the value of taxes ` increase multiplied with the fiscal multiplier. The effects will be reverse, leading to a reduction of economic activity. Fiscal politics can be such conceived that the action of fiscal multipliers and of public expenses to generate the least negative effects and the most searched ones. Of the tax as

instrument of random regulation of some given economic situations or of some social reports and it has secondary consequences of the followed aim, namely, that of complication of the fiscal system and of rendering more difficult of fiscal activity or appears the risk of reverse or belated effect, which once released cannot be controlled or eliminated.

The modifications of fiscal laws suppose a certain time and the rhythm of changes in fiscal politics is not always the wanted one . that is why when it is decided a choice of a variable in fiscal part, it is necessary an analysis of effort as well as of this change effect on short time or in the future. These decisions are marked by the permanent and acute need of resources at the state budget, fact which generate difficulties and conditions in the most efficient choice of modalityways of financing the public needs and the state budget especially.

There are three possibilities of financing them : from taxes, public credits and currency emission. It seems that financing from taxes is the most efficient modality of counteract the random effects, but with results on long time , because fiscal laws remain operative on longer periods of time usually.

In an economy lacked of economic increase and of an absolute unutilisation of labor , with a temperate fiscality (fiscal neutrality) , the only possibility to relaunch the economy is to increase the public expenses, followed by an increase of global demand and of consumption.

Not all the time the effects of government politics are the expected ones and at least the following two reasons have to be referred to,for whichfiscal politics could have unexpected and unwanted effects, namely, allowing the govern to have a deficit the constraints on expenses and the politic responsibility of those who take decisions regarding the budget are modified (that leads to huge and successive deficits , as well as to rapid increase of public debt) , in order to cover the expenses that outrun the incomes fromtaxes , state has to borrow money. This credit for financing the budgetary deficit can determine the increase of interest rate, fact which willbe felt in the activity of economic agents.

They will ask less credits and will spend less than they would have wanted to.

The system of budgetary expenses and incomes makes up the basis of a detailed analysis of a country ` ssocial –economic situation , following to be established the imposed measures for macroeconomic regulation.

REASONS ABOUT THE CONCILIATION OF NET ACCOUNTING RESULT WITH FISCALITY

Morar Ioan Dan
University of Oradea
Faculty of Economics

The determination of the result of fiscal exercise supposes the utilization of accounting information just like they are offered by financial situations elaborated at the end of the yearly financial exercise. The net accounting result is adjusted such as Fiscal Code asks to be, on the account of non-deductible fiscally expenses and of scot free incomes. In this context the harmonization of fiscal settlements with the accounting ones supposes the joining of knowledge and techniques specific to these two domains.

The accounting information lies at the basis of the establishing the net accounting result and, finally, of the fiscal result. The net accounting result represents the difference between incomes and expenses at the end of financial exercise, inclusively the expenses with the taxbenefit, actually, represents the final balance of the account of benefit and loses.

Fiscal law does not totally know the expenses that sanctioned the accounting result, so that this will be adjusted according to the fiscal law with so-called non-deductible expenses and with untaxed incomes. In this context contability is a source of information for fiscality, and on the other side, these two have on their basis different principles and rules.

Each payer, juridical persons, but also authorized physical persons, elaborate financial situations and fiscal declarations, more than that, they are obliged by the operative legislation for those two domains. Thus, according to the point 12 of Methodological norms of application of Law no. 571/ 2003 regarding Fiscal Code, approved by Government Decision no. 44/ 2004, incomes and expenses that are considered in the establishing the untaxed benefit are those registered in contability according to the accounting settlements stipulated in Contability's Law no. 82 / 1991, republished, with further modifications and completions, as well as any other elements similar to incomes and expenses, from which are deduced untaxed incomes and are added non-deductible expenses, according to the stipulations of article 21 of Fiscal Code.

The basis of this relation is bound up directly with the calculation of taxed benefit, as taxed basis for tax benefit. As it is known the legislation that correspond to tax benefit, as well as in general, modifies itself at short periods of time, while the accounting settlements have a more reduced dynamics.

As fiscal legislation differs in simple adjustments from the accounting one, the instrument of adjustment – conciliation is fiscal declaration, by which accounting result is adjusted to the level of fiscal law's demands.

Contability, on its turn, offers a conciliation solution between those two results by the application of IAS 12 – Tax benefit. This norm presents the modality of reconciliation between accounting benefit and the fiscal one, the used instrument being the tax on adjourned benefit, also for intermediary reports IAS 34 is applied – Intermediary financial report.

It is known that accounting result is determined by closing the incomes and expenses accounts, as a result of recognitions in the exercise's result according to the operative accounting settlements.

But as a rule, fiscal result differs from the accounting one and in these cases for establishing the tax benefit it is necessary to process the information from the accounting evidence by elaborating an account of fiscal evidence in which will be included all the adjustments made on the accounting result in establishing the tax benefit and inclusively of owed tax benefit.

For establishing the adjourned tax benefit, the economic agent has to recognize a credit or a debt, in conditions in which it is possible that the retrieving or the discount of the accounting value of a debt to determine the effectuation of some bigger or less future payments regarding the current tax benefit, than it would normally be their value if such a retrieving or discount would not have fiscal consequences.

The conciliation contability – fiscality in the context of this standard supposes a certain treatment regarding the bodily and non-bodily immobilizations, financial immobilizations, stocks, depreciations and provisions, own capitals, interest expenses, incomes from the rate of exchange differences, registered in the contability of current tax benefit and of the adjourned one and some others of the same kind bounded up with the active and passive patrimonial entities.

The main aim of this scientific approach in this domain is to discover and to delimitate the generating connections of organizational potential and of efficiency between taxes that form the actual fiscal system and the connections between the components of fiscal system and between this and payers.

We consider that a special importance in the adjustment of accounting result, has the interpretation of non-deductible and partly non-deductible expenses. Thus, the protocol expenses are deductible according to a quota of 2% applied upon the difference that results from the total of taxed incomes and the total of the expenses added to taxed incomes, others than the protocol expenses and expenses with tax benefit, expenses on official trip pays accorded to employers for official trips in Romania and abroad, it is deductible according to a quota of 2,5 times the legal level established for public situations. Social expenses are deductible according to a quota of 2% applied on the value of expenses with staff salaries, responsibilities, in the bounds established by the speciality organs of central administration, expenses representing meal tickets, accorded by employers, are deductible depending on the limit established by annual budgetary law.

Also, the made expenses, in the name of an employee to the schemes of optional pensions, in the limit of a sum representing the equivalent in RON of 200 EURO in a fiscal year for each participant, expenses with the premiums of voluntary health insurance, are deductible in the limit of a sum representing the equivalent in RON of 200 EURO in a fiscal year for each participant.

Other expensive partially deductible are those for functioning, entertaining and repairing of the job dwellings, expenses of functioning, entertaining and repairing an added premises in the own dwelling of a physical person, used for personal purpose, deductible in the limit that corresponds to the surfaces put at the society's disposal in the base of contracts made between parts, expenses of functioning, entertaining and repairing of the cars used by the leaders and managers of juridical persons, deductible reduced at the most one car to a physical person with such responsibilities.

More expenses are not deductible in their totality as registered expenses and which sanctioned the result of the exercise, such as expenses on tax benefit, inclusively those representing differences from previous years or from last year, as well as paid taxes abroad.

Are non-deductible taxes with restraint at source paid in the name of physical and juridical persons which are not resident for the incomes realized in Romania. Expenses on adjourned tax profit, registered by payer, are also non-deductible.

Expenses with the goods as stocks established absent in financial administration or degraded and non-imputable, inclusively the tax on corresponding added value, expense with the non-repaid value of bodily actives which are not in the administration or are destroyed, for which have not been made insurance contracts, also it is not a deductible fiscally expense, inclusively the tax on corresponding added value. The expense with the non-repaid value of bodily actives which are absent in administration or destroyed, that surpluses to the retrieved value on the basis of insurance contracts that were made, inclusively the tax on corresponding added value, depending on the case, it is not deductible fiscally.

Expenses representing losses of value of participation titles, as a result of the social capital's value reduction at the commercial society at which are owned the titles or as a result of quotation's modification on exchanging market, are not deductible expenses at the calculation of taxed benefit, because beforehand they had been deductible and thus the deductivity would double and fiscal result would be falsified. The expenses representing the value of participation titles, transactioned or cessioned, do not come under the incidence of these stipulations.

In the case of sales of the participation titles, taxed benefit is determined as difference between the value obtained from the sale and the nominal value in case of 1st sale or the acquisition price or fiscal value defined according to art. 27 of Fiscal Code.

At the removal from financial administration of the participation titles it can be used one of the methods used for removal from financial administration of the stocks.

In order to deduct the expenses with the services of management, consulting, assistance or other services it has to be accomplished in the same time more conditions, namely, services have to be efficiently performed, to be executed on the base of a contract which to contain data concerning the performants, the execution dates, the explanation of made services, as well as the prices, respectively the total value of the contract and the separation of this kind of expenses to be made on the whole period of contract progress or on the period of realization of contract's objective; the effective performance of services is justified by works situations, reports reception, work reports, market studies or any other corresponding materials.

For the services of management, consulting and technical assistance performed by those persons that are not resident, but are affiliated to payer, at the analysis of transaction for establishing the expenses' deductivity, we have to refer to the involved parts, to the nature of performed services, to the recognition elements of expenses and incomes on the basis of explanatory documents which to certify the performance of these services.

Other expenses, such as those with interest and with exchanging differences or those with repayment suppose a more special treatment and Fiscal Code gives the proper attention to these expenses, namely: expenses with interest are totally deductible in case in which the capital obligation extent is less or equal to three. The capital obligation extent is established as report between the borrowed capital with term of repayment after an year and own capital, as average of the values extant at the beginning of the year and at the end of the period for which is established the tax benefit. By borrowed capital we understand all the credits and loans with term of repayment after an year.

If the capital obligation extent is above three, the expenses with interest and with net loss from the currency differences are not deductible.

In the case in which expenses with currency differences of the payer outrun the incomes from currency differences, this difference will be considered as an expense with interest.

For the deduction of expenses with currency differences are taken into considerations those corresponding to credits that compete for establishing the capital obligation extent.

In the case of credits obtained from other states, the deductible interests are limited to the level of reference interest of National Romanian Bank, adequate to the last month of the quarter, for credits in RON and the level of rate interest of 9 % for credits in foreign currency.

The deduction of repayment expenses is limited depending on repayment system.

Expenses adequate to acquisition, producing, building, installing or bettering of repaid fixed means are recovering from fiscal viewpoint by the deduction of repayment.

The deduction of expenses with provisions' setting up supposes a consideration from two parts, namely, firstly as a deductible expense or a non-deductive one for the part that does not respect the deduction conditions and secondly are considered as reserves for the protected objective.

Expenses with the added value tax for the given free or for sales under the market price are not deductible and in the same time it puts a special issue from fiscal viewpoint, namely, the added value tax is a consumption tax that is not included into the goods' price, but it only consorts it,

and still the means of taxes` administration encroach upon the general procedures and rules specific to some well – individualized taxes.

The consumption taxes are now included into the goods` price , an abnormality at least as significant as the exemption from added value taxes without a deduction right , which also is included into prices although the general rule does not suppose that.

The adjustment of net accounting result with the stipulations of fiscal laws represents one of the issues of conciliation between contability and fiscality, a large enough problem regarding the proportion of the operations specific to payers , but also to fiscal organs bound to the elaboration of fiscal declaration regarding the tax benefit and to their processing and control.

The relation contability – fiscality would be simpler and easier to conciliate if the fiscal legislation would be simpler and would prove a bigger independence than the accounting evidence.

In the present paper the authors show the modality of analysing the IT entities using Du Pont method.

Key words: Return On Equity, Return On Assets, Leverage

Cod JEL: G32

1. Introduction

Ratio analysis is the method or process by which the relationship of items or group of items in the financial statement are computed, determined and presented. Ratio analysis can be used both in trend and static analysis. There are several ratios at the disposal of an analyst but their group of ratio he would prefer depends on the purpose and the objective of analysis.

A ratio “is one figure express in terms of another figure. It is a mathematical yardstick that measures the relationship two figures, which are related to each other and mutually interdependent.”⁸⁹¹ As accounting ratio is an expression relating two figures or accounts or two sets of account heads or group contain in the financial statements.

Ratio is work out to analyze the following aspects of business organization such as: solvency, stability, profitability etc. In the next figure is a depiction of the ratio analysis relationships with specific aspects of business organization.

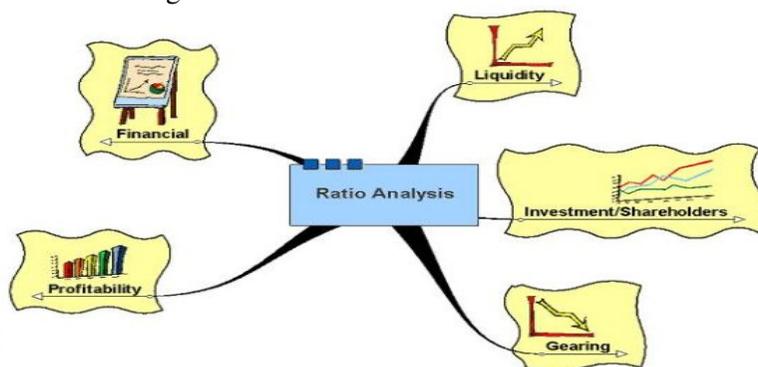

Figure 0. Ratio Analysis

(Source: <http://pakistanmba.jimdo.com/>)

⁸⁹¹ <http://pakistanmba.jimdo.com/>

In interpreting the ratio of a particular firm, the analyst cannot reach any fruitful conclusion unless the calculated ratio is compared with some predetermined standard.

2. Case study

Our research is based on the financial information for the I.R.I.S. Group (Belgium), Sybase (USA), Access Commerce (France), BMC Software (USA), Sopheon (Netherlands), Keyware Technologies (Belgium), Lectra (France), Linedata Services (France), Esker (France) and Dassault Systems (France).

All the companies presented in this essay are listed to the New York Stock Exchange, under the technology industry, software and computer service sector.

Financial ratios are usually used to evaluate five aspects of operating performance and financial condition: return on investment, liquidity, profitability, activity and financial leverage. We have applied these ratios to the software cluster, based on financial reports.

In this study we present the financial analysis ratios based on Du Pont System.

The returns on investment ratios give us a “bottom line” on the performance of the cluster, but don’t tell us anything about the “why” behind this performance. For an understanding of the “why”, a method that is useful in examining the source of performance is the Du Pont System⁸⁹². The Du Pont System is a method of breaking down return ratios into their components to determine which areas are responsible for a firm’s performance.

$$ROA = \frac{EBIT}{Total\ Asset} = \frac{EBIT}{Sales} * \frac{Sales}{Total\ Asset} = ROS * Asset\ Turnover.$$

Return on sales (ROS) or operating profit margin, indicates the percentage of each sales euro represented by operating income. Asset turnover indicates the number of sales euro produced by each euro invested in operating assets. In the next table is a depiction of the ROA, ROS and asset turnover for the five years of the analysis.

Year	ROA	ROS	Asset Turnover
2004	6,48	11,45	0.5655
2005	4,92	8,53	0.5766
2006	6,66	11,69	0.5701
2007	7,71	14,27	0.5405
2008	8,85	15,61	0.5671

Table 0-1 Return on Asset’s Components

We can see that although the asset turnover increased from 2004 to 2008 (from 0.5655 to 0.5671), ROS increased (from 11,45% to 15,61%) and the ROA increased a lot (from 6,48% to 8,85%).

The return on assets ratio that uses net income can be broken down into its components in a

similar manner: $ROA = \frac{Net\ Income}{Sales} * \frac{Sales}{Total\ Asset} = Net\ Profit\ Margin * Asset\ Turnover$

We can relate the basic earning power ratio to the return on assets, recognizing that:⁸⁹³

$$Net\ Income = Earnings\ Before\ Tax * (1 - Tax\ Rate).$$

It results that:

$$Net\ Income = EBIT * \frac{Earnings\ Before\ Tax}{EBIT} * (1 - Tax\ Rate). \text{ Therefore, we can say that:}$$

$$Net\ Income = EBIT * Equity's\ Share\ of\ Earnings * Tax\ Retention\ %.$$

⁸⁹² This method of analyzing return ratios in terms of profit margin and turnover ratios, referred to as the Du Pont System, is credited to the E.I. Du Pont Corporation, whose management developed a system of breaking down return ratios into their components. This is due to American Management Association, *Executive Committee Control Charts*, AMA Management Bulletin No. 6, 1960, p. 22

⁸⁹³ Frank J. Fabozzi, Pamela P. Peterson, **Financial Management and Analysis**, Second Edition, John Wiley & Sons, Inc., Hoboken, New Jersey, 2003, p. 727

Going back to ROA, we will obtain the following expression:

$$ROA = \frac{EBIT}{Sales} * \frac{Sales}{TotalAssets} * \frac{EarningsBeforeTax}{EBIT} * (1 - TaxRate)$$

Therefore, we can say that: ROA=ROS*Asset Turnover*Equity's Share of Earnings*Tax Retention.

The breakdown of a return-on-equity ratio requires a bit more decomposition:

$$ROE = \frac{NetIncome}{Shareholders' Equity} \text{ and } ROA = \frac{NetIncome}{TotalAssets}$$

$$ROE = ROA * \frac{TotalAssets}{Shareholders' Equity}$$

It results that: The ratio of total assets to shareholders' equity is referred to as the equity multiplier. The equity multiplier, therefore, captures the effects of how a company finances its assets, referred to as its financial leverage.

ROE=ROA*(Equity Multiplier or Financial Leverage).

$$ROE = \frac{NetIncome}{Sales} * \frac{Sales}{TotalAssets} * \frac{TotalAssets}{Shareholders' Equity}$$

It results that:

ROE=Net profit Margin*Asset Turnover*Equity Multiplier.

Applying this break down (of ROE) to the software cluster, it results the next table:

Year	ROE	Net Profit Margin	Asset Turnover	Financial Leverage or Equity Multiplier
2004	8,74	8.46	0.5655	1.8275
2005	7,59	6.77	0.5766	1.9436
2006	11,27	9.38	0.5701	2.1058
2007	11,84	9.90	0.5405	2.2134
2008	15,50	12.28	0.5671	2.2269

Table 0-2 Return on Equity's Components

Considering the above mentioned break down on, we calculated ROE by using its components, to determine which areas are responsible for the increase/decrease of ROE.

We see that although the asset turnover increased (from 56,55% in 2004 to 56,71% in 2008) and although the use of financial leverage increased also (from 1,82 in 2004 to 2,22 in 2008), net profit margin also increased (from 8,46% in 2005 to 12,28% in 2008), and the return on equity also increased from 8,74% in 2005 to 15,50% in 2008).

3. Conclusions

Looking at the calculated financial ratios, in conjunction with industry and economic data, we can make judgments about past and future financial performance and condition.

On the other hand, the Du Pont system breaks down return ratios into their profit margin and activity ratios, allowing us to analyze changes in return on investments.

These ratios are related closely to a firm's operating cycle, which tells us how long it takes a firm to turn its investment in current assets back into cash.

Profitability ratios tell us how well a firm manages its assets, typically in terms of the proportion of revenues that are left over after expenses.

AGRICULTURAL INSURANCES – MEANS OF DEVELOPPING THE ROMANIAN AGRICULTURE AMONG THE E.U. COUNTRIES

Nan Anca

Babeş-Bolyai University, Faculty of Economics and Business Administration, Cluj-Napoca

Borza Georgiana

Babeş-Bolyai University, Faculty of Economics and Business Administration, Cluj-Napoca

The experience of the developed countries has shown that it is completely delusional to try and create a modern agriculture without the powerful development of agricultural insurances.

Agriculture has always been one of the most important economic branches in Romania, as it has the highest value of all European countries by GDP (8-12%). This field represents an important direction in the economic development, especially due to the high potential of the agricultural development in the E.U. countries.

The present paper tries to illustrate the potential of agricultural insurances, their necessity, the general presentation of the domestic agricultural insurance market and that of the European Union's as well as the search for viable solutions of development in agriculture by the aid of insurances.

Keywords: agricultural insurances, agriculture, the European Union.

JEL Classification: G22, G19, Q14.

1. Introduction

Agricultural insurances are an important means of developing the Romanian agriculture among the EU countries. The reasons are the following: according to statistics, of the entire Romania territory of 23,8 million hectares the Romanian agricultural area is 14,7 million hectares (61,7%) out which only 9,4 million hectares are agricultural areas utilized for farming. Romania is the seventh European country in terms of agricultural area (after Spain, France, Great Britain, Germany, Italy, Poland) and the fifth in terms of agricultural area utilized for farming (after Spain, France, Germany and Poland)⁸⁹⁴. This makes the problem of rural development of great national and international relevance, as it also focuses on our country's huge economic potential among the EU member states.

In this context, Romania can become a strong competitor on the European Market if it knows how to use its resources and the EU financial support. Furthermore, the developed countries have proved that a successful agriculture cannot exist without a strong development of agricultural insurances, which are still not given the right status, though lately they have been granted more attention than usually.

2. The necessity of agricultural insurances

Insurances represent an element of reducing the economic uncertainty and a means of resuming the temporarily suspended activity. Insurances do not reduce the variety risks, but people are better prepared to face them. In the context of a free, undirected economy, any personal investment is exposed to risks and uncertainty; especially in agriculture where, due to specific problems regarding the production process – the large output cycle, the slow turning of capital, the rate of profit which is much lower compared to other economic branches – a strong protection of investments is required.

Agricultural insurances are extremely useful, because risks appear due to uncontrollable climatic changes. Hence, a modern agriculture with insurance services develops as farmers begin to change their way of thinking and understand that insurance means protecting themselves and

⁸⁹⁴ General view on Romania's agriculture and rural development, <http://www.madr.ro>.

most of all, protecting their agricultural investment. In our country, agricultural producers have restricted access to insuring their production, mainly because of the lack of financial possibilities to pay the insurance premium. In this case, insurances are accessible only to (trading) companies or to experienced economic agents. The bigger the natural disasters in the past years, the greater the necessity of insurance is, especially if we take into account the negative effect and the caused damages in economy.

3. Tapping the potential of agricultural insurance

The potential of agricultural insurances is high even if at present this type of business gives modest outputs. It will start to develop when agricultural producers become aware of the dangers their agricultural holding might be in and of the need of insurances to help them resume their temporarily suspended activity.

We may say that the Romanian market for agricultural insurances is emerging, and may become very successful in the industry of insurances. This market requires fair products adapted to the farmers' needs and possibilities, products that should represent a balance between the price of the policy, paid by the insurant, and the higher and higher risk in the crop, paid by the insurer. Although our country has some exceptional primary agricultural resources, due to both climatic conditions and to the agricultural area utilized for farming which is far more extended than in the European Community, the agriculture sector is still one of the most unprivileged fields.

If at present only 17% of the agricultural area utilized for farming is part of a form of insurance, and the average percentage in the European Community is approximately 65-70% of the insured potential, it is apparent that in Romania there is still a part of 48-53% (to meet the standards of the European Economic Community countries) of the insurable potential likely to be taken into consideration for insuring. The success of the rapid development of the agricultural insurance sector is mainly determined by the legislative coherence in the field of agriculture and, last but not least, by the ability of the insurance companies to offer insurance products of high quality and to treat their clients as partners of a shared, profitable business for both parties⁸⁹⁵.

4. The Romanian agricultural insurances

By means of an efficient development of rural areas, it is essential that the insurance industry should be responsible with the farmers' protection and with reducing costs from public money. The acceleration of agricultural crises, as a result of more and more frequent climatic changes in Romania (mainly the excessive drought, floods in extensive areas, strong storms) is the primary cause of all loss in the Romanian agriculture. The lack of investments in this field, the insecurity of the country's awarding grants to the agricultural producers, as well as the refusal of the insurance companies to comprise in the portfolio insurance such catastrophic risks as droughts and floods have led to a major deadlock in agriculture.

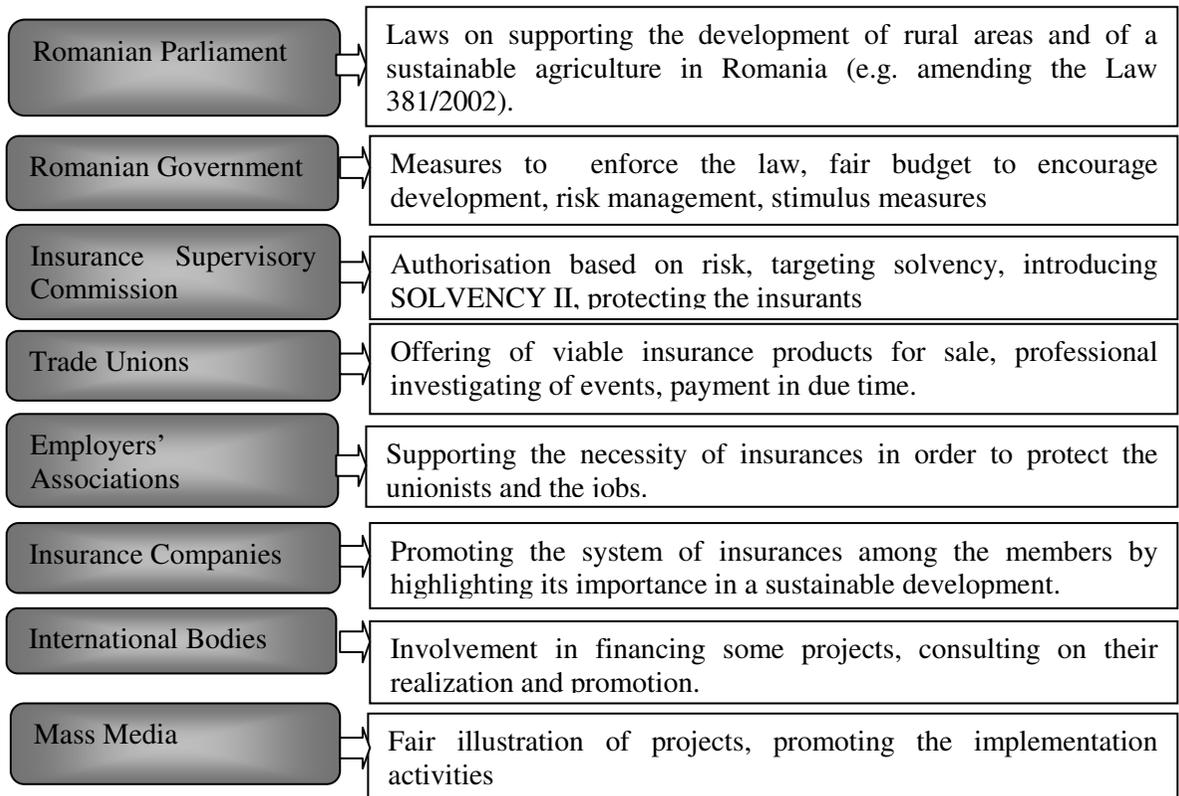

Romania is a great agricultural power; it is the world's sixth country with an exceptional potential, and we must try to fully exploit it⁸⁹⁶. The new European context requires an active system of insuring the farming, especially if we consider the fact that Romania is four times less insured than the European standards state.

In order for the insurance system in the rural areas to be successful, one must apply the following:

⁸⁹⁵ Ionete Andreea, *Interviu cu Anghel Burghilă*, <http://www.lasig.ro>, (2008).

⁸⁹⁶ Eremia C., *Protejarea producătorului agricol prin asigurare*, *Lumea Satului*, no. 21, (2008).

Figure no 1: Who has to be involved in the insurance system of a professional rural area?

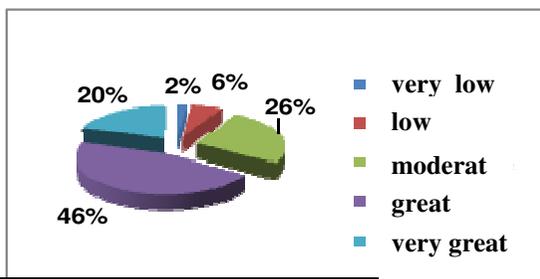

Source: Ciobotaru P.N., *Managementul riscurilor în agricultură*, <http://www.xprimm.ro>, (2009).

One question that may arise is if enforcing a complex program of transferring the financial risks is a solution to bring the economic sector afloat.

Thus, the Government should take part in improving legislation on agricultural insurances as well as in paying compensations; it should create secure and stable conditions in order to help improve the activity in this branch of the national economy. It is necessary that, regardless the conditions, the producers should preserve the ability to resume the production activity and to ensure constant market supply with foodstuffs. Locally, regionally and nationally, the food market should not be put at risk. It is also important that the role of the associations of producers in the development and efficient working of an agricultural insurance system in rural areas increase⁸⁹⁷.

Opinion Poll...

Graphic no.1: To what extent are insurances a solution in supporting the development of the Romanian agricultural sector?

According to Sergiu Costache's consumer survey 'To what extent are insurances a solution in supporting the development of the Romanian agricultural sector?' published in The National Conference of Agricultural Insurances in march 2009, most of the people who have taken the survey consider that insurances are a

⁸⁹⁷ Tabără V., *Cu natura nu te joci...*, Lumea Satului, Nr. 7,(2009).

solution for developing the national agricultural sector.

Source: Costache S., *Sondaj de opinie*, <http://www.xprimm.ro>, (2009).

5. A European perspective on agricultural insurances

In the European Union countries, the Government directly supports the sector of agricultural insurances by giving 50-80% of the insurance premiums related to natural risks. As for the major risks whose effects lead to important losses of agricultural productions on a large scale, the Government should take responsibility in supporting the farmers with the help of a specially created and administered fund. Such funds are: The National Solidarity Fund in Italy, The National Agricultural Disaster Guarantee Fund in France and The National Insurance Fund in Agriculture in Spain.

In the European Union countries, the governments give compensations by paying huge amounts of money for the insurance funds, which could not have been definitely paid by the private sector (insurance/reinsurance companies). Farmers are granted access to these funds only if they buy the insurance policy related to the natural risks that take place on confined areas. It is important that, by supporting the farmers' insurance policies, the government should bring its contribution to the stabilization of the production, as well as to the farmers' incomes and to the functionality of the insurance system of the rural areas' activities.

Spain is the country with the best developed agricultural insurance system in Europe, and most of the risks that might lead to a declining output are covered by insurance. The government, the farmers' associations and the insurers have agreed on the fact that a system of insurance for farmers, determined by a specific law, is the best solution to the management of the agricultural catastrophic losses.

France, Italy, Austria and Luxemburg also have a viable insurance system, and the loss of production is covered by insurance for most risks. The generally accepted solution is that of a basic insurance, for hail, to which a supplement for insuring the output is added; this supplement is partially paid by the government and it is useful for the most important risks that are characteristics to each and every one of the above-mentioned countries.

In Portugal and Sweden, as well as in most of the Central and Eastern European countries such as Bulgaria, the Czech Republic, Hungary, Romania, Slovakia and Slovenia, there is a basic insurance to which one can supplementary add, if available, an insurance for combined risks. This means that only hail and a small number of natural risks are covered by insurance.

There are also other countries in which the insurance for hail or other types of insurance for single risk are the only ones available. On markets as Belgium, Germany, Holland or Great Britain, the demand for other types of agricultural insurances is almost inexistent. Furthermore, there are no public subsidy formulae for agricultural insurances.

North-European countries are generally characterizes by a low level of demand for agricultural insurances, but solutions are still given in some countries: one example is 'the Corp Compensation Scheme' in Finland, whose role is to compensate for production losses caused by catastrophic natural risks.

A particular case is that of the systems in Greece and Cyprus, where there is a public system of agricultural compulsory insurance.

If the specialists' forecasts will prove to be true, in 2050 the European countries will have a different agricultural profit, which will lead to a different risk management scheme and, implicitly, to the need of adapting the insurance systems⁸⁹⁸.

⁸⁹⁸Ghetu, Daniela, "Agricultura asigurărilor. Sisteme de asigurări agricole din Uniunea Europeană", in PRIMM Asigurari & Pensi, no. 8 (2008), p. 16-19.

Unlike the European Union market, agricultural insurances in our countries are cheaper and not so common. In Italy, more than 905 of the agricultural area is insured, while in our country only 1 million out of 9 million hectares is insured.

In Italy, there is a tradition that people do not even sign the policy. They take out a multiannual policy for 5-10 years and when the policy expires, the insured's duty is to send the insurer a note in which he states that he agrees to renew the policy and the sum he pays to do so.

There is a big difference so as to the taxes. If in Italy the value of the insurance is no less than 6% of the entire insured money, in Spain it is 7%, in Holland, more than 9%, in Romania there are companies that do it for 0,8-0,9%. The average is 2,5%.

The insurers explain the low taxes by stating that some companies have bidden for very low prices so as to enter the market. But the insureds have become accustomed with these taxes and look for the best offer. Yet, the important agricultural insurance companies do not accept negotiations of this type, although the risk of not fulfilling the target is high⁸⁹⁹.

6. Promoting agricultural insurances

With a view to have a competitive agriculture and insurance system there are two categories of solutions: some that depend on the insurance companies and some that depend on the regulatory authorities in the domain, here referring to the Insurance Supervisory Commission and the Minister of Agriculture.

Some of the measures that could stimulate the development of agricultural insurances are:

- one of the measures is the granting of at least 50% of the insurance premium;
- improving existing legislation in this field, because it has a particular feature that needs special attention (e.g. by amending Law 381/2002);
 - paying for the losses in due time, so that the farmers could resume their temporarily suspended activity;
 - the need of reconsidering the product offer by the insurers and adapting them to the farmers' needs and possibilities;
 - reorganizing the insurance system by means of a public-private partnership or other methods such as the Ministry's imposing of minimum taxes, based on risk management, or the companies' taking over of catastrophic risks, taking into account the country's involvement in creating a fund that would cover these risks or a reinsurance company for agriculture.

7. Conclusions

Agricultural insurances play a significant role in stimulating agricultural investments and stabilizing the agricultural farmers' incomes. Granting the insurance premiums may be a starting point in a sustainable development of both the agricultural insurance sector and the Romanian agriculture.

The potential of agricultural insurances is high even if at present this type of business gives modest outputs. It will start to develop when agricultural producers become aware of the dangers their agricultural holding might be in and of the need of insurances to help them resume their temporarily suspended activity. Thus, we have to highlight the development of the energy crop insurances (for instance, rapeseed).

Agricultural insurances are influenced by the division of the real property, the creation of a large number of private producers whose output is non-productive, the abandoning of farms and the lack of financial support from the Government and the banks. Moreover, the lack of high technology, of financial support for agricultural producers, as well as the poor information on

⁸⁹⁹ European funds will give an impulse to agricultural insurances, <http://www.asigurari.ro>, (2008).

insurance given to the farmers are the main obstacles in developing the agriculture and the agricultural insurance market.

Dunărea de Jos University Galați
Faculty of Economics

The financial crisis in Romania has expressed in an eloquent manner and meant large negative effects, such as external factors generated by trigger of the financial crisis in Romania in October 2008 and internal factors for society that fundamentally influenced the decreasing of funding in 2009.

Promotion of private initiative is, in our opinion, one of the methods that attenuate the financial effort of state for social segment which generates costs and, is producing revenue for the state. In this paper we promote the idea of opening a fundamental process of restructuring the SME's management mentality, that of safeguarding of the enterprises with existing instruments, but also with new proposals to the Government, for regeneration as soon as possible of the country's economic and human factors capable of working.

Keywords: bankruptcy, SME, Reorganization, companies, crisis, fusion.

JEL code: G - Financial Economics. G01 - Financial Crises.

1. The influence of internal and external factors on financial indicators in 2009

-Global economic recession has affected all Romanian companies, from largest to smallest. Moreover, access to the funds that the bank could provide for business was locked by the state. Basically, through the Ministry of Finance which borrowed from private banks almost all the money from market to pay salaries and pension budget, the Government, indirectly, locked the national economy. Thousands of companies throughout the country unreasonably have long waited the repayment of VAT to which they were entitled, and that the financial taxation delayed to make it, deadlines being exceeded with months. Instead, for every invoice issued, but not received, the state further requires for firms to pay VAT de-capitalising them and pushing them towards bankruptcy. Establishing flat tax to be paid even by companies which were not registered profit, has determined in 2009, that 120.509 companies to suspend its activities.

-Currency depreciation; it equaled or exceeded the substantial discounts of cars sellers that showed discounts and promotional prices about 30 - 40%.

-Transactions with new cars had a significant rebound, and volumes were decreases of 50% or even 60% compared to the same period last year, some car dealers being forced to close their showrooms and to lay off some employees.

-Romanians real income levels have been affected by currency depreciation: those who had paid rates have experienced the strongest rate shock. Payment amounts were not to be neglected, the rates increased from one quarter to another and even 30%, while nominal revenues remained constant or even declined in condition of rising unemployment. This could lead only to overdue and late payment, short-term liquidity problems, increasing leases terminated, an influx of requests to reschedule the payment obligations.

-Decrease of the credit line

2. Financial crisis outside Romania

Except Poland, where the number of bankruptcies in the first nine months of 2009 remained below 1.000, in all other countries, the recession has felled many SMEs. Romania is by far the most affected, given that in the first six months of 2009, over 100.000 SMEs went into bankruptcy, from a total of 600.000 registered at the ministry.

Germany. German SME's bankruptcies mean problems for Europe. Germany's economic recovery could slow because more and more midsize companies - the skeleton of industry - can not face with market's conditions and bankruptcy. This situation has a negative impact on euro area, under the condition in which, according to The Wall Street Journal, Germany, has the largest economy on the continent⁹⁰⁰.

In **Poland**, 497 companies have declared bankruptcy in the first nine months of the year 2009 compared with 317 during the entire 2008, according to Coface, the credit insurer. In the first half of 2009 the SME sector has been hit by falling demand and by the tighter credit conditions.

In **Hungary**, SMEs have been affected by evaporation of demand and by reducing the access to financing, but unlike Poland, the current situation shows no improvement. Industrial production continues to be 20% lower than in 2008, and SMEs production has fallen by a fifth.

In the **Czech Republic**, 6591 entities (companies and individuals) were asked in the first nine months of 2009, the reorganizing under bankruptcy protection, up 70% compared to last year. 58% of all complaints are made by companies, according to Creditreform, credit agency. Czech Union of SMEs said that access to credit is the main problem with which is facing the sector. Lack of funding leads to postponement or cancellation of investment plans.

3. The situation of economic crisis in Romania

Usually the financial crisis means an economic environment that is characterized by an acute lack of liquidity, which goes to more expensive credit bank. In Romania the beginning and end of crisis is marked by certain indicators that presented in Fig. no. 1.

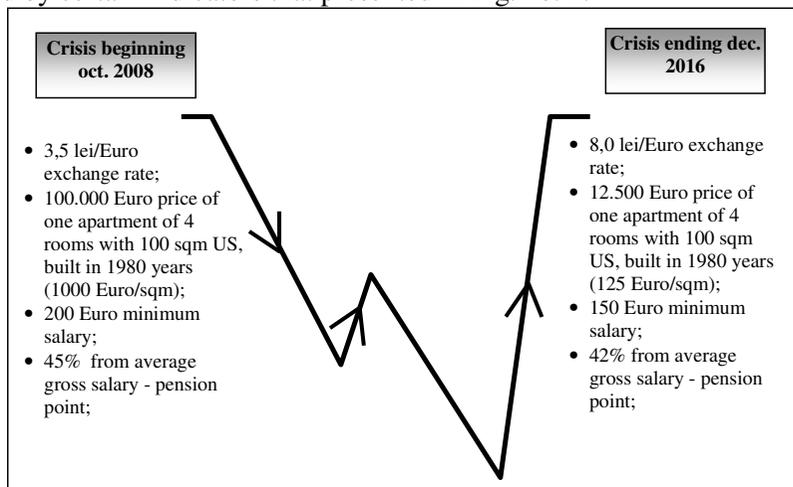

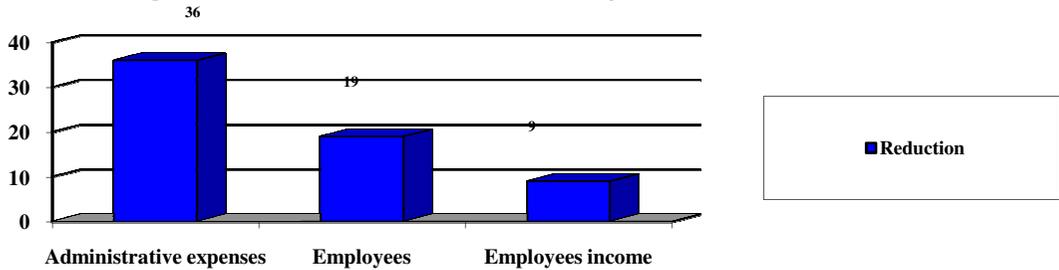

Fig. no. 1. Features of the financial crisis in Romania

In **Romania**, 90% of SME's are affected by economic and financial crisis, difficult economic situation leading to increased number of bankruptcies. Among the measures that companies have taken to decrease the impact of economic crisis, 36% of them have reduced administrative costs, 19% have reduced the number of employees and 9% have reduced the income of employees, as represented in the chart below.

⁹⁰⁰ <http://www.zf.ro/business-international>.

Fig. no. 2. Anticrisis measures taken by Romanians SME's

Year 2010 has not yet good signs for Small and Medium Private Enterprises in Romania. Last year alone, over 190 thousand SMEs and authorized individuals have ceased. Specifically, we present in table from below, cases that favor bankruptcy and measures to avoid bankruptcy, some of them being even proposed by SME and NCPSMER (National Council of Private Small and Medium Enterprises in Romania), as measures for the economic crisis.

Causes that promote SMEs Bankruptcy	Measures to avoid SME's bankruptcy
<ul style="list-style-type: none"> -Depreciation of national currency. -Lower transaction with cars. -Decrease real estate transaction. -Reduce your credit line. -Reduced access to financing and funding hinder. -High costs of interest. -Exports decline. -Low income. -Increasing the CAS's costs. -Introduction of minimum tax. -Sales decrease. -Price increases. -Incapacity of paying. -Entering into insolvency. -Declining real incomes of Romanians. 	<ul style="list-style-type: none"> -Reducing costs through layoffs. -Employee salary reduction. -Reducing administrative costs. -Icing liquidity. -Simple bookkeeping and halving the tax on buildings⁹⁰¹. -Allocating of minimum 0.5% of GDP for the foundation and development programs for SME's⁹⁰². -Widespread of the absence of taxation of reinvested profits and reinvested dividends. -Ministry of SMEs of programs on an emergency immediately after the 2009 budget approval. -VAT payment when goods are delivered, services are rendered or works are executed. -Elimination of abusive controls on companies. - Encouraging exports through subsidies. -Creating Counter-Guarantee Fund of the credits in the first half of 2009. -Significant and urgent reducing of extra-taxation. -Simplification of procedures for accessing structural funds and increasing access to consulting services in this area⁹⁰³.

4. Anti-crisis measures taken by Government

⁹⁰¹ <http://www.financiarul.com>, April 1th, 2010.

⁹⁰² <http://www.newschannel.ro/stiri/masuri-anti-criza-pentru-imm-uri>.

⁹⁰³ Idem.

Boc government took steps that led to the cancellation of firms. By eliminating the taxation for microenterprises with 3% of incomes, Boc government put most common obstacle to self-employment solutions. In addition, by introducing flat tax, hundreds of thousands of small companies, generally with a single employee, were closed.

Also, there are many companies that are in bankruptcy, but have not yet said so. Many require judicial protection, asking for insolvency, to be safe from creditors.

Among **crisis measures** already taken by the Government is allocating the largest share of GDP over the past 20 years, for investment, facilities for hiring unemployed and purchase of nearly 17.000 homes through "First Home" program.

Continuing Rabla program, building houses for rural specialists, rehabilitation of thermal and county road blocks, First Silo Program, NHA housing selling to tenants, supporting SMEs and local authorities which are accessing EU funds by providing state guarantees and technical unemployment are other measures already taken by the Government and presented by Emil Boc.

Among the measures to support businesses, the premier noted reinvested taxed profits, deferred payment of outstanding obligations, accelerating tax refund, state aid, incentives for energy and chemical industry, reducing taxes and tariffs parafiscal. Among crisis measures, Emil Boc recalled including VAT at 19% and maintaining a flat at 16%⁹⁰⁴.

But all these measures seem not to be the best and not sufficient for the effective exercise of SMEs because, due to other measures adopted by the Government such as the introduction of flat tax, there are favorable conditions for progress.

5. Considerations on anti-crisis measures

Experts say the biggest problem of business is restricted access to credit, and bad news is that banks will not finance companies resumed in 2010, because it will analyze the situation of companies which will seeking loans on the balance sheet situation of 2009, which "looks disastrous."

On the other hand, banks have their own reasons to think twice before approving a loan. In 2009, arrears over 90 days were recorded in loans, over three times higher than in 2008 and represented 75% of all amounts due.

Neither in terms of tax payment obligations to the state, companies did not do better. Experts recommend to the companies with debts of more than 30 thousand lei and debts to the budget over 30 days, to avoid insolvency and forced execution by preventive composition with regulated by Law 381/2009. Preventive composition is an amicable settlement between the debtor and creditors that hold at least two thirds of the value of receivables.

5.1. How to put protected from insolvency?

According to the law, insolvency or bankruptcy of the debtor's assets are characterized by insufficient cash funds available to pay outstanding debts.

It is considered that it may declare bankruptcy when the debtor, after 30 days in arrears, has not paid its debt to one or more creditors. Bankruptcy is imminent when the debtor proves that it can not pay at maturity, outstanding debt incurred with the funds available from the due date.

For companies trying to save his business, the next step is the **process of reorganization**.

6. Reorganization - measure against bankruptcy risk for SMEs

In the current economic situation is expected as part of economic agents continue to encounter difficulties in activity and even to go insolvent.

Unfortunately, most of those traders who go into insolvency, unnecessarily are trying to recover the activity of society through their own efforts, without resort to specialized

⁹⁰⁴ Source: Wall-Street.ro.

consultants in the field and without the use of legal provisions designed just for protection. Such attempts of recovery leads mostly with a failure, so that society finally comes to bankruptcy, without any possibility of economic recovery.

Law no. 85/2006 of insolvency ("Insolvency Law") specifically provides judicial reorganization, as a extent of recovery of economic activity of a company in a state insolvency or in impending insolvency, being real chance of recovery and continuing a business that normally would be under bankruptcy.

6.1. Reorganization procedure in the Romanian legislation

Unlike the laws of other states, Romanian legislation does not regulate the judicial reorganization procedure, which still can not remove a conventional reorganization. This method of reorganization involves, in practice, debtor negotiations with major creditors on rescheduling the debt payment, but in such a procedure the debtor has no legal protection⁹⁰⁵.

Judicial reorganization, aim the "redressing of the debtor and payment of liabilities in terms of restructuring the company and its activity"⁹⁰⁶, and saving in this way, a company in default, but still viable.

Judicial reorganization is triggered by an application for entry in insolvency which the debtor in insolvency or in a state of imminent insolvency or a creditor, submit to the Court. In this application the company must accompany the several pieces, among which the declaration by the debtor and shows its intention to enter into the reorganization procedure.

After introducing the application and verification of documents submitted by the debtor, if the legal requirements are met, the judge will order the opening of the general procedure. By this decision to initiate proceedings, the judge will appoint an judicial administrator. To qualify the reorganization procedure it must be proposed such a plan by the debtor, by the judicial administrator or by the creditors. **The plan should contain concrete ways to restructure the company, which may take the form either the debtor's restructuring and continuing future business or liquidation as part of the debtor, or a combination of two previously proposed methods.**

Reorganization of the company closes when you have met all payment obligations assumed by the reorganization plan.

6.2. Advantages of entry into reorganization proceedings

There are several advantages of opening the reorganization procedure for a company in difficulty, such as:

- From the date of opening of the reorganization law there **are suspended all judicial or extrajudicial actions** aiming to achieve claims against the debtor or his property. Thus, under art. 36 of Law no. 85/2006, the law suspended all judicial or extrajudicial actions to achieve the claims against the debtor or his property, so that no creditor can no longer operate separate companies in insolvency proceedings to recover his claim. Also under this article there are suspended any levy of execution or attachment of company accounts. All payments made during the insolvency proceedings will be made by a single bank account, which can not be stopped.
- **No longer pay outstanding debts than under a reorganization plan without paying interest or penalties.** From the opening of proceedings, under art. 41 of Law no. 85/2006, no interest rate, increase penalty or charge will not be added to claims arising, prior to the opening of proceedings (excluding guaranteed debt). Thus, by stopping the flow of interest and penalties, it is prevented the increasing liability company.
- The possibility of **rescheduling payment of debts** by creditors, etc.

⁹⁰⁵ <http://www.avocatnet.ro>.

⁹⁰⁶ Csaba Bela Nász – The opening of insolvency procedure, C.H.Beck Publisher, Bucharest, 2009, pag. 42

- The company that was willing to open insolvency proceedings may be subject to judicial reorganization under a reorganization plan, through which can be obtained in certain circumstances or may even require, rescheduling of payments to creditors during the reorganization, which may take up to three years, with possibility of extension for another year.
- In judicial reorganization, the debtor business is conducted by a special administrator named by the company management, who may even be the administrator. Thus, leadership activities of the debtor may remain in the hands of the debtor's former management bodies, which are best placed to continue the company's activities. Their work is supervised by the judicial administrator.
- According to art. 77 of Law no. 85/2006, applications for the recovery procedure or other rights shall be exempt from stamp duty, which is an advantage in making steps to recovery.
- In the judicial reorganization, the company operates on the principle "business as usual", remaining an economic market player, and can keep customer brand and heritage.
- During insolvency, the company does not pay and does not charge VAT.

7. Mergers - another measure to counter the risk of bankruptcy during the crisis

Fusion is a "technical and legal process through which the restructuring of companies is done"⁹⁰⁷, when two or more companies come together to form a single society. Fusion brings benefits related to strengthening of the company's market, getting a larger share local market or even expansion into other geographic regions. Another advantage of fusion is related to business saving and personnel rescue in conditions of market competition and its impact on business. Vertical integration of business is another benefit of the fusion, so that it shortens the chain of production and distribution. For example, a furniture manufacturer may purchase a wood supplier to eliminate the problem of raw material acquisition. Because it will be reduced certain costs, it will increase company's profits. Another advantage of the fusion is diversifying its product portfolio by launching its own range or buying a player that already offers that product. Fusion also offers an advantage in terms of taxation.

FOREIGN INVESTMENT INFLUENCE ON OWNERSHIP AND CONTROL IN JAPANESE FIRMS

Nistor Ioan Alin

“Babes-Bolyai” University, Cluj-Napoca

Faculty of Business

Corporate equity structure, whether is in a market-based system like US or a bank-based system like Japan is prone to changes due to foreign investment. Protection from outside investors varies greatly around these systems. Where protection is good, market-based systems flourish. These systems have certain advantages as they appear to foster innovation and to encourage the release of capital from declining industries. Bank-based systems may be better suited to established industries. These systems also help protect individuals from direct exposure to stock market risk. But, no matter the system, agency problems are inevitable. The paper looks at the past changes of the Japanese corporate ownership composition under the influence of foreign investment.

Keywords: Economic Systems, Capital and Ownership Structure, Corporate Governance

JEL Classification: G32, P51

Who owns a corporation? In the US or UK, we would just answer „stockholders”. Some stockholders have more influence than others, but simply because they own more shares. In other countries ownership is more complex. US have a market based system because it has large stock and bond markets. Japan has a bank-based system because most debt financing comes from banks. Japanese households bear relatively little equity risk. Most of their savings go into bank accounts. The role of banks goes far beyond just lending money. They are tied-up in an extensive cross-shareholding within group companies.

Protection from outside investors varies greatly around the world. Where protection is good, market-based systems flourish. These systems have certain advantages as they appear to foster innovation and to encourage the release of capital from declining industries. Bank-based systems may be better suited to established industries. These systems also help protect individuals from direct exposure to stock market risk. No matter of the system, agency problems are inevitable. That is why we can never expect managers to give 100% weight to shareholders’ interest and none to their own. Laws and regulations can specify what managers can’t do but can’t tell them what they should do. Once managers have discretion, they will consider their self interest as well as investors’ interest.

Corporate governance systems vary around the world. These differences result from different legal systems, systems of corporate finance and corporate ownership as well as divergent norms around the firm’s responsibilities to its various stakeholders. (Dore 2000). While much research has considered how these differences originated and why they persist (Hall and Soskice 2001, Jackson 2002), less research has considered what happens when different systems of corporate governance come into direct contact. These different systems of corporate governance came into direct contact in Japan. Perhaps the latest example would be the acquisition of the Lehman Brothers brokerage operations by Nomura in 2008.

Foreign ownership of shares of Japanese firms increased from about 10.5% in 1996 to 28% in 2007 and then dropped to 23.6% in 2009 (TSE 2010). This increase in foreign ownership came as shareholders, primarily banks and insurance companies – slowly sold their shares as a response to financial crisis and changing of accounting standards. While financial institutions held 41.1% of all shares in 1996, by 2009, their share ownership had dropped to 32.4% (TSE 2009).

This change in ownership brought two very different notions of corporate governance into direct conflict. In Japan, shareholders tend to be stakeholders with long term interest in the firm, in addition to the expected return on their equity investment. Banks, for example, held shares as part of a broader relationship of managing financial transactions and supplying loans. Corporations held shares of their suppliers and buyers. These interconnected and complementary sets of relationships supported the fundamental attributes of the corporate Japanese system.

Foreign portfolio investors, on the other hand, had very different interests. They stood apart from the Japanese corporate relational system and had less interest in ongoing business relationships with Japanese firms. These foreign portfolio investors were familiar with the shareholders movements from USA and Europe.

Trends in foreign investment in Japan

From 1996 to 2008, the percentage of publicly listed Japanese shares held by foreigners have continuously increased from 10.5% in 1996 to 28% in 2007, then to drop to 23.6% by 2009. The increase in foreign share ownership in Japan reflected a larger worldwide trend. Foreign ownership of listed French firms increased from approximately 12% to 42.3%, while ownership of shares in the UK by foreigners increased from about 17.2% to 36.3% in the 2007. These numbers indicate that this increase in foreign investment was not limited to Japan, but was a worldwide phenomenon. One of the reasons could be the rise of the institutional investors, especially pensions funds. (P. Druker 1997). This trend accelerated as the money managed by institutions increased and as pensions became more willing to invest their funds in equity.

In the 1990s, US investors invested 94% of their assets domestically, while UK investors kept 82% of their assets in the UK (Useem 1998). Slowly moving into the 2000 years, institutional investors began to move their money abroad, as investors were looking to diversify their portfolios across currencies and economies.

The leading foreign investors in Japan were American and European, especially UK funds (Shirota 2002). Most foreigners were institutional investors. In 2009, only 0.5% of foreign investors in Japanese publicly listed equities were individual investors. (TSE 2009).

Foreign direct investment, where foreign investors take a large and strategic stake in a Japanese firm or set up their own operations, received much publicity. Among the one that received the most attention was the Renault's purchase of a controlling stake in Nissan. Signed in 1999, the Renault-Nissan Alliance has built a unique business model that has created significant value for both companies. These investments made by foreign funds had effect on corporate governance and other economic and financial reforms.

A study made by the American Chamber of Commerce in Japan indicated that foreign direct investment in Japan, defined as strategic investment with the intention of transferring management resources and know-how, was quite low in an international comparison. In 2006, foreign direct investment in Japan was 1.1% of GDP, while that in the UK was 32.4%, Germany was 22.4% and US 27.9%.

Composition of Ownership

To further explore the identities and objectives of foreign stockholders we examined the ownership of the Tokyo Stock Exchange First Section non-financial firms in 2008. In 11 firms, foreigners had controlling stakes of over 50%, while foreigners owned over 33.3% of an additional 34 firms (this is the level that allows for veto rights over board decisions). In a substantial number of firms, foreign ownership was over 10%. We identified cases in which the purpose of the foreign shareholder could be classified as strategic. These were cases in which a foreign corporation (not a bank or investment fund) was one of the top 10 shareholder and the investment was for strategic, rather than portfolio purposes. Especially in auto and pharma

sectors, foreign investors could be considered strategic. These leaves a substantial number of large and well-known firms of whose shares 30% or more were in the hands of foreign portfolio investors, including Sony or Canon, table 1.

Foreign investors had very different interest from the majority of Japanese investors. They had different set of obligations to their beneficiaries than Japanese funds. The US pensions had clear obligations of fiduciary duty mandated by law, as well as the UK funds. Furthermore, in most cases foreign investors were investing purely for return on investment, where Japanese investors were often wrapped in a web of other ties and obligations with the firms whose shares they held, and their own affiliated banks and corporations. Japanese institutional investors tended to be closely linked to banks or to corporations that had other interests in the firms that they were investing (Hiraki 2003).

Source: TSE 2010 Statistical Highlights

Institutional investors, such as trust banks, tended to have close equity relationships with banks, and would vote according to the interest of its affiliated bank, which was likely to have close lending relationship with the firm. A corporate pension fund might hold shares in an important business partner of the corporation and would not dare to press too hard as a shareholder. Thus, Japanese domestic institutional investors were part of a system of close relationships that went beyond shareholding stakes and thus were unlikely to demand the same level of returns, as an investor that was looking only at the return on investment, table 2.

Table 2. Share ownership by type of investor

Source: TSE 2010 Statistical Highlights

Foreign investors in Japan could influence firms to adopt their desired corporate governance practices through exit – the threat of selling their shares – and through formal and informal exercise of voice – exercising voting rights and making their opinions known through less formal channels. The threat of exit, as well as more informal channels, exercise of voice, provided more effective ways of influence. Foreigners were less likely to wield influence through exercising voting rights, though this had begun to change in the 2000s.

Corporate governance practices

For the past 8 years, the Japan Corporate Governance Index Research Institute surveyed Tokyo Stock Exchange First Section firms in their corporate governance practices. Based on these surveys, the JCGIndex measures how close a firm's governance adheres to Anglo-American standards. Practices evaluated include how a firm sets its performance objectives, accountability of the CEO, structure of the board of directors (size, independence, responsibilities), compensation system, management of subsidiaries, internal audit and control, and disclosure and transparency.

The JCGIndex ranges from 0 to 100. A firm that would receive 100 points, would have a significant number of independent directors on its board, and a board that had adopted a committee structure (of audit, compensation, and nominating committees dominated by independent directors). The firm would set its performance goals based on matrices valued by shareholder (return on invested capital) and the CEO would be accountable for achieving these goals, table 3.

Firms that scored higher on the JCGIndex tended to have larger percentages of foreign ownership. Another important aspect would be that firms that scored high in board structure and function, had higher levels of foreign ownership than low scoring firms. Firms that received high scores on this component had relatively high levels of board independence as measured by presence of independent directors, criteria for board appointments and the ability and authority of the board to monitor the CEO.

Table 3. JCGIndex Japan 2008

Category	Mean/Total	Achievement rate
----------	------------	------------------

	possible points	(mean/total possible points)
Corporate objectives and CEO responsibility	10.6/28	37.9% (36.9%)
Structure and function of the board of directors	10.7/25	42.8% (36.9%)
Management system	17.2/27	63.7% (61.7%)
Transparency and communication with shareholders	13.4/20	67.0% (67.3%)

Source: JCGR Corporate Governance Survey 2008 Final Report (at the date when this article was written, the 2009 Survey was not yet released)

These correlations between the JCGindex and its various subcomponents and foreign ownership demonstrate an association, but not causation. In other words, it is not clear from these results whether foreign investors gravitated to firms that were closer to an Anglo-American ideal of governance. We can only presume that corporate governance issues were a key focus of questions by foreign investors, suggesting that at least some of the causation was due to foreign investors pressuring firms to change.

Conclusion

We examined the foreign portfolio investors and their effect on corporate governance in Japanese firms and observed that:

- Foreign portfolio ownership of Japanese equity increased significantly
- Foreign investors were advocates of Anglo-American style corporate governance
- Foreign investors influenced Japanese firms both through exit and voice. Their propensity to buy and sell shares gave them strong influence over share price in general and made exit a particular threat to firms.
- There has been a clear relationship between foreign investors and practices related to corporate governance

Though it is impossible to establish a definitive direction of causation between foreign ownership and corporate governance practices, it is clear that the increase in foreign ownership was linked to the transformation of corporate governance practices in Japan since the early 1990s. Whether foreigners actually influenced firms to change their governance practices or firms changed their governance practices to attract more foreign investors, increased board independence, disclosure and transparency, downsizing and asset divestiture occurred in response to an increase in foreign portfolio investment in Japan.

While the research presented suggested that foreign investors are associated with a shift towards Anglo-American governance practices in Japan, this does not mean that there is likely to be wholesale convergence and that Japan is on course to be exactly like the US. How much is Japanese corporate governance going to change is hard to tell, there are several scenarios, but for sure we will see changes in the years to come.

The average cost of debt is negatively related with size, tangibility, firm growth, the leverage ratio, and the ratio of long- to short-term debt and positively to profitability. We find that the recent international crisis did have a significant impact on the set of firms in our sample, but affected the way in which leverage and the interest to debt ratio relate to firm fundamentals. In this article, we want to study the impact of financial crisis on the cost of capital using a sample of construction companies.

Keywords: asset pricing cost of capital, financial crisis, CAPM

Cod JEL: G12, G01, G14

1. Introduction

An appealing feature of the subprime crisis for research purposes is that it stands as a purely exogenous shock on the corporate sector, the crisis had its origin in the U.S. housing sector. In inquiring about the influence of financing factors on real investments, it is extremely difficult to disentangle supply and demand forces. For instance, a given observed contraction in real assets may be forced by the withdrawal of lending flows by their suppliers or to a voluntary corporate decision to stay aside from the credit market after the reevaluation of expected cash flows in the midst of an economic downturn. Even an exogenous credit supply shock like the one taking place since 2007-2008 may have reshaped the demand for funds in response to a widespread wave of pessimism.

The problems on the international financial markets affected the construction industry, which was heavily dependent on banking credit. Non-residential construction, which accounts for half of the construction output, was strongly hit, while residential decreased only slightly in 2009 and civil engineering, which depends on public funding, was the only one maintaining above the line.

The construction sector in Romania climbed 6.9% in december 2009, in comparison to a month before, recording the biggest leap in the European Union. The total decrease in 2009 year in comparison to the last year was 15.1%. In chart no. 1, we present the evolution of constructions during 2005-2009.

Babeş-Bolyai University, Cluj-Napoca, Romania

Chart no. 1

Evolution of the value of construction during 2005-2009

Source: www.insse.ro

Since december 2008, however, construction dropped 7.1%, Romania ranking 8 in the EU. In november, Romania recorded the third decline in the construction sector in the EU – 18.9% - in comparison with the same months of 2008. Apart from Romania, the only EU country to record a growth in the construction sector was Spain – 6.2%. The biggest declines were recorded in Slovakia (-11.3%), Slovenia (-8.1%) and Bulgaria (-7.9%).

2. Methodology research

We propose to study the impact of financial crisis on the cost of capital. We choose the construction sector (construction of buildings and civil engineering), because it is one of the most affected sectors of the economy. The sample includes ten companies, which are listed on Bucharest Stock Exchange: Impact Developer & Contractor S.A. (IMP), Cominco S.A. Bucuresti (COBS), Comnord S.A. Bucuresti (COSC), Concefa S.A. Sibiu (COFI), Constructii Bihor S.A. Oradea (COBJ), Imotrust S.A. Arad (ARCV), Socot S.A. Tg. Mures (SCTO), S.C. Transilvania Constructii S.A. (COTR), Compania Energopetrol S.A. (ENP), Condmag S.A. (COMI).

To determine the cost of capital, we use the capital assets pricing model (CAPM) and weighted average cost of capital (WACC).

2.1 Cost of equity

The cost of equity can be defined as the minimum rate of return that a company must earn on the equity-financed portion of its investments in order to leave unchanged the market price of its stock. Most companies use the Capital Asset Pricing Model (CAPM) to calculate their cost of equity capital. In the CAPM definition, the cost of equity is equal to the return on risk-free securities plus the company’s systematic risk (beta) multiplied by the market risk premium:

$$\overline{R}_a = R_f + \beta_a * (\overline{R}_M - R_f);$$

Where:

R_f = Risk free rate

β_a = Beta of the security

\overline{R}_M = Expected market return

$R_f - \overline{R}_M$ = Premium risk

The general idea behind CAPM is that investors need to be compensated in two ways: time value of money and risk. The time value of money is represented by the risk-free rate in the formula and compensates the investors for placing money in any investment over a period of time. The

other half of the formula represents risk and calculates the amount of compensation the investor needs for taking on additional risk. This is calculated by taking a risk measure (beta) that compares the returns of the asset to the market over a period of time and to the market premium risk.

The CAPM says that the expected return of a security or a portfolio equals the rate on a risk-free security plus a risk premium. If this expected return does not meet or beat the required return, then the investment should not be undertaken. The security market line plots the results of the CAPM for all different risks (betas).

Beta coefficient is a measure of the volatility, or systematic risk, of a security or a portfolio in comparison to the market as a whole. Beta is the tendency of a security's returns to respond to swings in the market. A beta of 1 indicates that the security's price will move with the market. A beta of less than 1 means that the security will be less volatile than the market. A beta of greater than 1 indicates that the security's price will be more volatile than the market. For example, if a stock's beta is 1.2, it's theoretically 20% more volatile than the market. Many utilities stocks have a beta of less than 1, offering the possibility of a higher rate of return, but also posing more risk. The formula for the beta of an asset within a portfolio is:

$$\beta = \frac{Cov(R_a, R_M)}{Var(R_M)} ;$$

Where:

R_a = the rate return of the asset

R_M = the rate return of the market.

Risk-free rate is the amount obtained from investing in securities considered free from credit risk, such as government bonds from developed countries. The interest rate of U.S. Treasury Bills is frequently used as a proxy for the risk-free rate.

The equity market risk premium represents the returns investors expect to compensate them for taking extra risk by investing in the stock market over and above the risk-free rate. In other words, it is the difference between the risk-free rate and the market rate. It is a highly contentious figure. Many commentators argue that it has gone up due to the notion that holding shares has become more risky.

2.2 Weighted Average Cost of Capital

Weighted Average Cost of Capital is an average representing the expected return on all of a company's securities. Each source of capital, such as stocks, bonds, and other debt, is assigned a required rate of return, and then these required rates of return are weighted in proportion to the share each source of capital contributes to the company's capital structure. The resulting rate is what the firm would use as a minimum for evaluating a capital project or investment:

$$WACC = \frac{E}{V} * Re + \frac{D}{V} * Rd * (1 - Tc) ;$$

Where:

Re = cost of equity

Rd = cost of debt

E = market value of firm's equity

D = market value of firm's debt

V = E + D

Tc = corporate tax rate

The WACC of a firm increases as the beta and rate of return on equity increases, as an increase in WACC notes a decrease in valuation and a higher risk.

Broadly speaking, a company's assets are financed by either debt or equity. WACC is the average of the costs of these sources of financing, each of which is weighted by its respective use in the given situation. By taking a weighted average, we can see how much interest the company has to pay for every dollar it finances. A firm's WACC is the overall required return on the firm as a whole and, as such, it is often used internally by company directors to determine the economic feasibility of expansionary opportunities and mergers. It is the appropriate discount rate to use for cash flows with risk that is similar to that of the overall firm.

Compared to cost of equity, cost of debt is fairly straightforward to calculate. The rate applied to determine the cost of debt (R_d) should be the current market rate the company is paying on its debt. If the company is not paying market rates, an appropriate market rate payable by the company should be estimated. The measure can also give investors an idea as to the riskiness of the company compared to others, because riskier companies generally have a higher cost of debt. As companies benefit from the tax deductions available on interest paid, the net cost of the debt is actually the interest paid less the tax savings resulting from the tax-deductible interest payment. Therefore, the after-tax cost of debt is $R_d (1 - \text{corporate tax rate})$.

3. Data and estimation

The sample of ten companies is studied during the period 2005-2009. We select the companies whose stock price increased significantly, respectively they had a significant market capitalization and volume of transactions on the Bucharest Stock Exchange, during the analyzed period.

For the coefficient Beta, we use the daily stock return prices of the analyzed companies and the daily returns of BET index during 2002-2009. The Beta coefficient is determined individually for each year. Thus for 2005, we consider daily stock return from 2002-2005. We consider the daily stock return from 2003-2006 for the beta coefficient from 2006. We kept this method of calculation for all five years. Table nr.1 lists the beta coefficient values during 2005-2009.

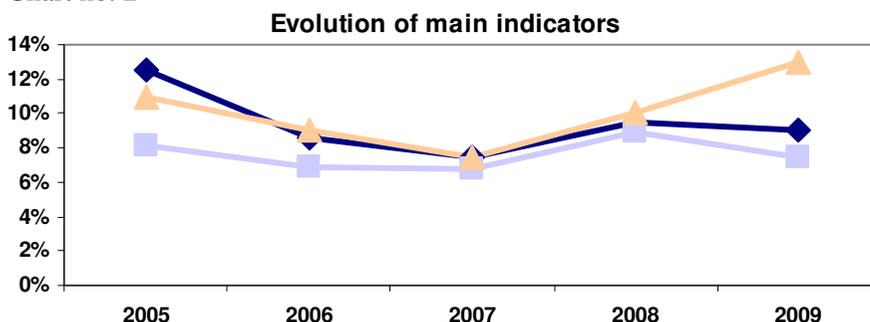

Table no. 1

Evolution of coefficient BETA					
Tiker	2005	2006	2007	2008	2009
IMP	0.610	0.592	0.709	1.048	-1.671

Chart no. 2 contains values of the indicators that we need to use for the Capital Assets Pricing Model. The free risk rates are taken from National Bank of Romania. The risk premiums and cost of debt are obtained from Moody's reports.

Chart no. 2

Source: <http://pages.stern.nyu.edu>, www.reuters.com, www.bnr.ro

Using the CAPM and the data from the previous two tables we obtained the cost of equity for the companies from our sample. In table no. 2 we show the obtained values. We can see the strong impact of the financial crisis on the cost of equity. In 2006, its value decreased from the previous year, but from 2007 year to 2009 year, resumed its upward trend.

Table no. 2

Cost of equity					
Tiker	2005	2006	2007	2008	2009
IMP	17.49%	12.71%	12.34%	18.83%	-3.48%
COBS	12.76%	10.66%	10.10%	14.95%	14.07%
COSC	11.16%	9.19%	8.83%	14.59%	14.49%

SCTO	11.53%	8.87%	9.15%	11.78%	13.48%
COTR	12.07%	5.96%	4.08%	7.30%	7.67%
ENP	16.55%	11.80%	10.06%	12.16%	12.33%
COMI	12.71%	9.83%	8.89%	14.10%	14.88%

Source: Author`s calculations

During 2005-2007, the cost of capital decreased significantly from 25% (Comnord S.A.) to 66% (Transilvania Constructii). In this period the construction sector had a favorable environment. In 2008, the value of construction and assembly works in Romania increased by 34% nominally (26% in real terms), to RON 83bn (€22.5bn). The fastest growing segment was non-residential, which increased by 37%. The situation is due to the fact that Romania, a country with a very rapidly developing economy, needed mainly non-residential buildings, such as office space for services and industrial buildings. Structural works are by far the ones covering the largest share of costs of a construction project, followed by installation and equipment and site preparations. The smallest shares are held by finishings and rental of construction equipment.

The cost of capital increased, during 2007-2008, from 21% (Compania Energopetrol) to 79% (Transilvania Constructii) due to the appearance of the financial crisis. The crisis had a negative effect on the cost of equity, stock returns and private physical investment. In 2009, we can see that the growth is not so big, it is from 1% (Compania Energopetrol) to 21% (Imotrust Arad, Concefa Sibiu).

The value of the cost of capital for Impact Developer company is small, because its stock price decreased significantly during 2007-2009 (its value was under the nominal value of the stock).

4. Conclusions

Increasingly more companies found that loans can not be consider a certainty. It seems that more restrictive lending standards and rising interest rates are "new rule" not only on international markets, but also in Romania. A feature of Romanian companies is that they rely primarily on financial banks institutions, calling rarely to publicly traded bonds. As the liquidity crisis continues to limit available funds on international capital markets, the ability of banks to provide capital is affected.

The cost of debt constitutes a key transmission channel from macroeconomic shocks to the corporate sector, with a direct bearing on firms' growth and probability of default, a better understanding of its drivers should be welcome.

Construction was the most important factor of the strong economic growth of Romania over the past several years. However, the problems on the international financial markets affected the construction industry.

The segment which will continue to grow in 2010 is civil engineering. As Romania will face a falloff in GDP in 2009, the government will want to overcome its effects by increasing public spending, and infrastructure is a top destination for state-funded investments. For that, the funding coming mainly from the EU has to be unblocked, by improving and simplifying procedures which have been dragging investments in infrastructure – particularly in the case of road construction, which accounts for roughly half of the civil engineering construction output. Additionally, civil engineering construction can benefit from the lower prices of construction materials compared to the past few years.

We propose for next studies to use a bigger sample and to study the impact of crisis on companies cost of capital by the methods of Godfrey and Espinosa (1996), Erb, Harvey and Viskanta (1996), Damodaran (1998) and Estrada (2000).

FISCAL FEDERALISM AND FISCAL DECENTRALIZATION IN AN ENLARGED EUROPEAN UNION

Oprea Florin

„Alexandru Ioan Cuza” University of Iași

Faculty of Economics and Business Administration

Fiscal competition and tax harmonisation are two of the main current issues in the enlarged European Union. Achieving these goals and thus improving the EU economic governance is partially dependent by the way we understand and practice the so-called fiscal federalism and fiscal decentralization at the national and European level. Our paper aims to emphasize the similitude and differences between fiscal federalism and fiscal decentralization and revealing the way in which the functioning of the European Union is affected by them.

Keywords: fiscal federalism, fiscal decentralization, financial autonomy

JEL Code: H77

The Legal Content of Fiscal Federalism and Fiscal Decentralization

The matter of fiscal federalism is not new, but its complexity and its special implications upon the functionality of public budgetary systems, and implicitly upon the mobilization and the judicious use of public financial resources, determine its being brought to attention in many contemporary works regarding the European integration process. As concept, fiscal federalism is often related to fiscal decentralization and sometimes even considered similar to it, although the two notions appear as different due to their own formulation. Thus, decentralization would mean, as its name itself suggests, the fact that power naturally belongs to the centre, which decides to transfer it to the lower levels, for reasons related to a better management of local interests or at least more adequate to the preferences of the members of the local community. On the other hand, fiscal federalism would imply the pre-existence of competence sharing in what concerns the mobilization of public revenue, (fiscal) decentralization not being necessary any longer, at least at first sight. In other words, the federal system of power structuring is intrinsically based on a larger decentralization than the unitary state system of organization. Such a view is false, because practice shows that there are very decentralized unitary states (e.g. Denmark, The Netherlands), as well as very centralized federal states (Austria). Because decentralization (fiscal, implicitly) is inherently possible and present, just as centralization, in any state community, the problem that arises is to differentiate it from federalism (implicitly fiscal). In what concerns us, we believe that the main differentiating element of the two notions is the legal and not the economic content. Thus, the federal organization of certain states is, as the case may be, either the product of the tradition of state organization or the result of applying certain requirements for making the management of public sector problems more efficient. Federalism, as a (constitutional) state organization method, supposes an allocation in essence of (public) political power by delimiting it on several levels, ensuring its constitutional and decisional sanction for each of the entities forming the state, by means of their own Constitution and their own decisional bodies, even in what concerns the ability to legislate (at the level of each federal state). One may notice, in these conditions, that, within the federal type of state organization, it becomes essential the fact that the constitutive states are independent, as the decision-making autonomy of the main government levels (federal and federated) is sanctioned by means of the fundamental document, simultaneously and differently allotted both at the central level and at the level of the constitutive states of the federation and protected from any possible decision-making conflicts by

means of the bicameral structure of the Parliaments. Actually, while federalism is a constitutional way of organizing public power, which affects both the legislative power and the executive and judicial ones, decentralization is a (main) way of exercising power, which only applies to the executive power.

The Economic Content of Fiscal Federalism and Fiscal Decentralization

However, in what concerns the economic approach, what is essential for the federal organization of public power (the presence of a separate Constitution at the level of each federated state) loses its significance, the important thing being the fact that each government level has its own competence in managing and providing public services, which is essentially something in common with decentralization, as a principle of exercising the executive power. In these conditions, fiscal federalism is defined as a set of principles which stand at the basis of delimiting revenue sources and budget expenditures between the central level and the inferior government levels, sometimes even without taking into account the type of state organization. This set of principles, which may be applied to the relationships between the components of the public budget system on the revenue side, whatever the form of organization of public power from the point of view of state structure, leads to the practical implementation of what we call “fiscal decentralization”, manifesting, in practice, in the form of a general (normative) framework that this requirement takes. It is this framework, through its concrete implementation in the European states, which individually start to promote it because of the necessity to satisfy certain “national” internal requirements, that may determine, in the context of the European integration process, a series of undesirable dysfunctions (distorted competition, fiscal evasion, limited fiscal harmonization, etc.). These potential negative effects are first a result of the fact that the principles under discussion are applicable or applied differently in each state, with differences noted especially between the unitary and the federal states, as they are not able to represent a “universal recipe”. Although “universalization” of the set of principles considered to be the content of fiscal federalism (in the sense of them being universally recognized) may be found in the related literature and in practice, each of these principles involves a certain degree of relativity, in the sense that it has to be connected to the requirements and the actual reality in each state. Moreover, one and the same principle may be interpreted and applied more or less nuanced, thus leading to a particular way of promoting fiscal decentralization. For example, the subsidiarity principle applied to the mobilization of budget revenues or the principle of assuring a certain level of local autonomy involve judgements that are subjective in their nature, regarding the extent and the beneficial effects of allowing competences to the local government level, thus leading to different manners of applying subsidiarity and to different interpretations of the degree of local autonomy. On the other hand, the theoretical foundations of fiscal federalism and its applicability are still submitted to observations and reconsiderations, sometimes even by those who put them forward (Richard Musgrave, Charles M. Tiebout, W.E. Oates), “a second generation” of fiscal federalism being invoked.

Fiscal Federalism at National and European Level

Beyond the conceptual differences that we presented, the economic content of the two notions is relatively close, referring to delineating the competences of central and local authorities related to their “rights” regarding the mobilization of public revenues and their use, and, according to some, “the big challenge is to ensure a transparent financing system for sub-national administrations”⁹⁰⁹. We notice that, according to such a view, what is considered to be essential to fiscal federalism is the relationship between public authorities on different levels, which

⁹⁰⁹ Moșteanu, T., Iacob, M., *Fiscal Federalism*, Theoretical and Applied Economics, 2007, vol. 11, p. 21, <http://econpapers.repec.org/>

consists in financially involving the one at the superior level in order to support, if necessary, the authorities at the inferior levels. From this point of view, an analogy may be made between “internal” and “international” fiscal federalism, the latter concerning the relationship between national and supranational authorities or international organizations (in international finances). Judged by appearances, such a manner of practising financial relations would not be related to fiscal federalism, because the latter has a legal (constitutional) basis which lends it a regular and compulsory character, while the involvement of the international organizations has an optional, incidental character, involving both the request from the national authorities and the acceptance of the international organization. However, we notice that phenomena such as global warming or world security, which concern all nations, not only some of them, objectively determine a joint, even unitary, approach to solving such needs, by means of common supranational institutions or organizations. This phenomenon, related to such mutations as globalization or the European integration, gives rise to the need to establish separate revenue sources for supranational authorities, able to ensure the resolution of the problems in their competence, which sets the basis for building a system typical for “fiscal federalism”. In the specific context of the European Union organization and functioning, some claim that the establishment of a European tax system is just a matter of time⁹¹⁰. A convincing example in this respect is considered to be the action mechanism specific to the European Union, in which the common institutions manage problems for the benefit of all Member-States, thus taking over financial resources to its own budget from the resources of the states involved, in the context in which many of the tax-related decisions are harmonized by means of normative documents issued at this level. Although the prevailing view is that total relinquishment of fiscal authority is not something that can be taken into consideration, the decisions regarding taxation (especially indirect) are at least partially in the competence of the Union, which is exactly what forms the core of fiscal federalism. The existence of a system in which the competences regarding the management of certain problems are attributed to national and European-level authorities on a differentiated or complementary basis, combined with the presence of a taxation and intergovernmental grant framework can only be qualified as fiscal federalism. However, in the related literature there are also some studies that dispute the presence and the applicability of fiscal federalism in the European Union, either in the larger context of multilevel governance finances⁹¹¹, or considering that it exceeds the conventional framework of fiscal federalism by being exceedingly decentralized⁹¹². The argument they put forward is that, in attributing the functions to the different government levels (in this case, to national and European-level authorities), the reasons specific to fiscal federalism (such as macroeconomic stabilization, which central authorities must have in view) are subject to a different interpretation, in the sense that only the monetary policy may be decided at the supranational level and not the fiscal policy. The argument may be considered valid, but it must be approached in a cautious manner. It must be noticed that the authors in question themselves mention as a premise for the analysis that fiscal federalism is not a set of universally applicable rules, but rather a set of benchmarks to follow (on a differentiated basis, o.n.) in delimiting the competences related to the management, taxation and spending of the financial resources thus mobilized. As a result, we believe that the analogy between “internal” and “international” fiscal federalism subsists, with the note that in the latter case the implementation method is different. The different manner of promoting fiscal federalism at the supranational level has an explanation which is as simple as it is convincing: as long as the relationships of public power are differently

⁹¹⁰ Moșteanu, T., Iacob, M., *Fiscal Federalism*, Theoretical and Applied Economics, 2007, vol. 11, p. 21, <http://econpapers.repec.org/>.

⁹¹¹ Oates, W., *Fiscal Federalism and European Union: Some Reflections*, Societa Italiana di Economia Pubblica, 2002, <http://www.unipv.it/websiep/wp/132.pdf>, p. 2

⁹¹² Eichgreen, B., *Saving Europe's Automatic Stabilisers*, in Baimbridge, M., ș.a., *The Impact of the Euro - Debating Britain's Future*, Macmillan, London, 2000.

legally sanctioned at the internal level and at the level of international cooperation, the attribution of the competences of taxation, spending or management of public matters outlined based on these relationships will be, in its turn, different. It is without doubt that the attribution of some competences, such as macroeconomic stabilization or the redistribution of revenues meant to prevent poverty or to protect those with low income, to the supranational (European) level may have weaker effects than the management of these aspects by the national government levels, but this does not affect the core of fiscal federalism. Moreover, the rules applicable to fiscal federalism promote subsidiarity, which requires that a certain task be attributed to the government level closest to the place (level) where the problem has arisen, on condition that the management of the problem in question cannot be better dealt with at a superior level (in order to avoid distortions). In other words, if the distinctiveness of the relations between the European Union and its Member-States requires that certain aspects such as those mentioned above be managed by the national authorities, we are talking about fiscal federalism.

In the context of the European integration process, taking into account the characteristics of the political and administrative organization of this entity compared with the known composite forms of state or with the unitary states, until not long ago, the prevailing view was that, at least from the point of view of budgetary revenues (in effect, of taxation), the transfer of the decision-making process in this respect to the Union level would be a forbidden and inadequate assignment of “sovereignty”, considering that as long as taxes are the main support (from a financial point of view) of the sovereign manifestation of states, no member-nation would be willing to give up such rights. However, it can be noted that, if the presence into a functional association in the genre of the European Union is desired, whatever (legal, constitutional) qualification we may confer to it as a form of organization, it is first necessary that all the parties involved take on a relative “loss” from the point of view of decision-making power, because the minimum consensus necessary to any such association in order for it to function in good conditions may not be otherwise gained. In our case, it can be noted that generous objectives such as ensuring free circulation, undistorted competition, a high living standard, at similar levels in the member countries, are accepted on a large scale, but it is not always admitted that reaching them involves a joint action of the Member-States, conceived for reasons of coherence and unity of action at the supranational level, of the Union. In other words, just as the Member-States, especially the unitary states, ensure their functionality and compatibility between the different interest and government levels by means of a minimum degree of centralization (reduced by decentralization, local autonomy, subsidiarity), the European Union is able to efficiently reach its shared objectives in a similar way. This opinion is also confirmed in practice (at least partially in what concerns the Member-States), due to the use of the single currency, and the unity of the monetary policy designed and promoted by the European Central Bank⁹¹³.

Taking into account the previously set forth arguments, we believe that the opinion expressed by the majority of those interested in the matters related to the working of the European Union in the sense that sovereignty cannot be relinquished, especially at the fiscal level, must be reconsidered. A first argument is that the decision-making right in certain areas at the European level lacks efficiency as long as there aren't any efficient implementation instruments. An eloquent example in this regard may be the evolution of the last years in what concerns the budget deficit, in some of the Member-States of the European Union, ironically and almost paradoxically exactly those considered as the initiators of the rule regarding the 3% limit on the budget deficit. States such as France, Italy or Germany are recording budget deficits that exceed this limit, at the same time with a breach of the rule regarding the maximum indebtedness level of 60% of the GDP (in the case of Italy, over 100% in 2007), which, according to the rules, would lead to these countries

⁹¹³ Oates, W., *Fiscal competition and European Union: contrasting perspectives*, *Regional Science and Urban Economics*, no. 31, 2001, pp. 133-45.

facing financial sanctions. Faced with such a situation, the countries in question proposed as a method of resolution, without asking for the rule to be removed, that the causes of the deficit be separately analyzed for each state. For example, Germany invoked the use of 4% of the GDP for the necessities of reunification, at the same time proposing that the contributions to the Community budget may not be taken into consideration, and President Chirac put forward the productive character of certain expenditures which would justify their being taken out of the calculation when determining the budget deficit (“the research and development expenditures of today ... are the riches of tomorrow”). In these conditions, it can be noted that the lack of an efficient instrument of constraining the actions of the national authorities may give rise to dysfunctions at the Union level, being necessary to attribute extended competences to this level. In the case of direct taxation of income, although we agree with the idea that macroeconomic stabilization for 27 countries simultaneously at the Union level would not necessarily be more efficient than the separate action, at the national level, we have to remark that, in the present conditions, there is a fiscal competition which may lead to distortions in allocating resources. The single rate implemented by some European states, without any restriction, is generating differences that may have negative effects. Although it is not entirely necessary that the European Union implement the so-called „European taxes”, as there are problems mainly related to recording and evaluating the taxable matter, determining the tax value, levying or keeping track of and collecting tax claims, it is obviously necessary to harmonize taxation bases or direct tax rates. Two mentions must be made: harmonizing does not automatically mean “standardizing” (in the sense of setting the same taxation rate at the level of all the states, but only setting ranges between which these rates may vary), and harmonizing taxation rates without harmonizing taxation bases (for example, the unitary setting of the elements that stand at the basis of calculating the taxable profit) would strip the entire action of its efficiency. This statement has its origin in ascertaining that economic and budgetary systems are not based, in their functionality, solely on related decisions of a subjective, administrative nature, but have at their basis the so-called system of incorporated stabilizers, which first includes the taxes applied by the Member-States. Their reaction to the economic context may be a beneficial one as long as, in their position, the reasons they started from took into consideration the future implications on other Member-States (taking into account, first, the action of economic operators in the context of free circulation). Moreover, we believe that the indispensability of establishing a system such as fiscal federalism within the European Union derives from accepted economical reasons, knowing that the fiscal policy (in its narrow meaning, of tax policy) and the monetary policy must be considered related parts of the general, economic and social policy of a state entity; their positive effect can only be ensured as long as the measures devised and promoted for each of the two areas are harmonized and lead to (or support) similar results and are not opposed, annihilating each other’s desired effects. In this respect, the free practice, by the Member-States, in the absence of a constraint which is possible under a fiscal federalism type of organization, of expansionist fiscal policies may lead to inflationist effects, thus harming the effectiveness of targeting inflation through the European monetary policy.

From another perspective, that of understanding taxes (beside public expenditures) as a means of achieving solidarity between the members of the entity in question, we notice that in what concerns the European Union, tax is not yet perceived as such an instrument, interstate solidarity being rather limited, still⁹¹⁴. As a matter of fact, in most cases, redistribution of resources within the European Union is discussed only from the perspective of the expenditures supported by the Union budget, without the necessary reference to related resources and the implications of their collection based on the product generated in the Member-States, the matter

⁹¹⁴ Collignon, S., *The European Republic – Reflections on the Political Economy of a Future Constitution*, London, 2003, pp. 104-105

of the resources of the Union budget being the object of separate discussions. The positions expressed in this regard are often contradictory: on the one hand, they say that the Union does not have any competences related to direct taxation (especially of income); on the other hand, they require that financial resources be attributed through the system of supranational transfers. Such opinions are also favoured by the fact that, in the context of the absence of disruptive phenomena (at least until now, when the financial crisis is settling in more and more), which would require that more attention be paid to (macro)economic adjustment and stabilization, the European Union as well as the Member-States have channelled their attention primarily to the aspect of the redistribution of resources (for example, by means of the structural funds, which have economic and social cohesion as a purpose).

Conclusions

In conclusion, we think that fiscal federalism cannot be considered in any way a phenomenon incompatible with the European organization or an inhibiting factor for it. It must necessarily be designed and promoted at this level, without it being understood that it should be applied in its conventional formula, which is not allowed by the characteristic itself of the political and administrative organization of the European Union. Centralization becomes an absolutely necessary trend in the Union, but it must be carefully applied and must not be in any way interpreted as a possibility or a potential danger of “levelling” the Member-States of the Union, by excessively reducing or erasing national differences. The management of asymmetries in the economic and social development at the Union level, as well as of the transfer of undesirable effects from some states to others in the context of free circulation (especially of workers and capitals), requires, in an absolutely rational and necessary manner, that the European Union takes on extended competences and that the Member-States recognize to a larger extent the importance of interstate solidarity and joint action.

THE IMPACT OF FINANCING POLICY ON THE COMPANY'S VALUE

Pirtea Marilen

National and international financial system offers companies a wide range of funding sources. The choice of one or more of the available sources and their combination are major aspects of the company's financing policy. Managers must keep in mind that the call to one or other of potential funding sources is not a minor and independent decision, but has profound implications on the company's value. Weighted average cost of capital can be used as the discount rate or the selection of investment projects.

Keywords: financing policy, cost of capital, capital structure, company's value.

JEL code: G32

1. Introduction

Financing policy at microeconomic level is significantly influenced by how the economic mechanisms function at regional, national and even global. Romania is characterized by a relatively unstable socio-economic situation and, which raises serious toll on the business results of Romanian companies, irrespective of quality management at the microeconomic level. Considering the specifics of economic and financial environment in the context of analysis of the influence these areas have on the the finance decision at microeconomic level, one cannot ignore elements such as inflation, changes in interest rates or exchange rate in economy⁹¹⁵.

Although these macroeconomic factors are especially useful for the substantiation of policy finance companies, there are other factors that influence financing policy, factors related to the company's internal environment. Taking into account these observations, and various other related to financing policies, we may wonder why some sectors of the activity tend to have companies with a high rate of borrowing compared to other sectors. But analyzing the role of the financial lever, the cost sources of funding or fees paid by the company, we can explain these changes in borrowing rates, and how the company's value is affected by the financing policy.⁹¹⁶ Among these factors, we consider the cost of financing sources as the primary factor in foundation financing policy, having the greatest impact on company results and hence on its value.

Financing policy, which underpins the company's capital formation, is mostly assumed by the company's management and less by the "providers" of capital (shareholders, creditors). This can be achieved in two ways: internal financing and external financing. But each of these sources implies a specific cost to achieve them, cost which the manager should know, considering also the indirect implications of choosing one or other of these financing arrangements.

⁹¹⁵ Oprean Camelia, *An analyses of Romanian companies financing decision under macroeconomic influences*, MPRA Paper No 14716, 2008.

2. The cost of financing sources – essential factor of company policy

Due to its crucial role in all production factors, capital has a privileged position in all theoretical approaches aimed by business activity⁹¹⁷. So, we can appreciate the capital as all funding sources available to the company that can be used to purchase all the elements of the asset⁹¹⁸. Considering the source of the company's capital is composed primarily of two components: equity and debt.

2.3.1 The cost of equity – determination methods

Equity cost represents the rate of return required by shareholders is the company to pay for their investment in the company. If the rate of return is lower than the opportunity cost, then the business value decreases, and if the rate of return is higher than the opportunity cost, then the business value increases. The rate of return expected by shareholders is an opportunity cost based on expected return of investors to invest the same risk. In the absence of resale transactions of existing shares, shareholders will earn dividends only. If the future flow of dividends is known, the discount rate that equales the present value of dividends by the current price action will be the required rate of return for investors. The difficulty of the model lies in determining the exact level of future dividends. Therefore, research in the field tried to find ways of estimating this rate of return expected by investors, which the most significant are presented in the following table:

Table 1

Methods for determining the cost of equity

Crt. Nr.	Method	Formula
1	Gordon-Shapiro Model	$k_e = \frac{D_1}{V_0} + g \quad (1)$ <p>: $\frac{D_1}{V_0}$ = the dividend yield per share g = the growth rate of dividend per share.</p>
2	Model of determining by PER (market capitalization ratio)	$PER = \frac{1}{Rrf} = \frac{1}{k_e} \quad (4) \quad k_e = \frac{d * (1 + g)}{V_t / EPS_t} + g \quad (5)$ <p>: d – dividend rate EPS_t – earnings per share at time t V_t/EPS_t = PER_t</p>
3	Capital Asset Pricing Model (CAPM)	$k_e = Rf + \beta * [E(\bar{R}) - Rf] \quad (6)$ <p>: Rf – risk-free interest rate β – Title volatility, systematic risk expression relative to market portfolio E(\bar{R}) – expected return on market portfolio</p>
4	Arbitrage Pricing Theory Model (APT)	$k_e = Rf + \sum_{k=1}^K b_{ik} * \bar{\lambda}_{ik} \quad (7)$ <p>: b_{ik} – sensitivity coefficient of the company at the risk factor k $\bar{\lambda}_k = \sum_{t=1}^T \lambda_{kt}$ - average risk premium in the period under review T – number of periods analyzed</p>

2.3.2 The cost of lent capital - determination methods

To estimate the cost of borrowed capital can be used two types of methods:

A. A company's exogenous methods such as:

- Negotiations with potential manufacturers;
- Based on market interest rates on loans with similar risk issued instruments;
- Based on actual interest rate subsidy payed by firms in the same sector.

B. A company's endogenous methods:

In addition to exogenous methods, the company can estimate the cost of debt taking into consideration the interest rates on loans issued by the company, called yield to maturity method, YTM. Yield to maturity is the interest rate that would be won by one investor on similar instruments, which bought the title at the current price and that keeps it until maturity.⁹¹⁹ The cost of borrowed capital will increase over the yield to maturity under the impact of administrative costs, the various fees involved with a new issue. In these circumstances, the cost of debt (k_d), under the impact of taxation, is given by the following formula:

$$k_d = YTM * (1 - I_\pi) \quad (11)$$

I_π – profit tax rate

One of the significant risks that are facing the creditors of companies is the risk of default by the company issuing debt (bankruptcy risk). Effect of bankruptcy risk should be considered in determining the discount rate, but also the expected value of cash-flow analysis of investment project sites. In these circumstances, estimating the expected profitability by the creditors imposes the determination of the payments' sensitivity, depending on the macroeconomic indicators. Therefore, a second method for determining the cost of debt is the CAPM model, which involves calculating the β coefficient for debts:

$$k_{dat,t} = Rf_t + \beta_{dat} * [E(\bar{R}) - Rf_t] \quad (12)$$

unde: Rf_t – rate of return on a risk-free bond at time t

$E(\bar{R}) - Rf_t$ - risk premium for the market portfolio at time t

⁹¹⁹ Stancu I., *Finanțe*, ediția a IV-a, Ed. Economică, București, 2007.

Using this formula, however, leads to determining the expected value of return to creditors, that is usually different from the actual value. The report of the two values is determined by the risk of non-payment of obligations to creditors and the likelihood of bankruptcy. In case of the two events, then the actual amount will be less than expected value, otherwise being above the expected value.

2.3.3 The weighted average cost of capital -influence on the company's financing policy

Choosing a means of funding is determined on the one hand by its cost and secondly by the company's current financial structure.⁹²⁰ Optimal financial structure corresponds to the minimum cost of used capital, weighted average cost (WAC) being determined using the following relation:

$$WAC = \sum_{i=1}^t w_i * k_i \quad (13)$$

unde: w_i – shared capital, by the sources of origin
 k_i -the cost of the i source of financing
 t – the number of financing sources

The principle underlying the determination of weighted average cost of capital calculation takes into account the WAC in accordance with how the cash-flows that have to be updated are denominated. For this, the following elements should be considered:

1. The taxation of cash-flows. If these are taxed, then the CPM will be determined after taxation its parts:

$$WAC = k_{debt} * (1 - I_{\pi}) * \frac{Debts}{Total\ capital} + k_e * \frac{Equity}{Total\ capital} \quad (14)$$

2. Using nominal rates, if cash-flows are expressed in nominal sizes.

WAC can be used as discount rate in assessing cash-flows of a company's investment projects. Using WAC as the discount rate is an appropriate valuation method based on updating the sites of future cash flow, because the whole value of the company has invested capital (own or borrowed). Thus, the economic asset value will be given by:

$$V_0 = \sum_{t=1}^n \frac{CF_t}{(1 + WAC)^t} + \frac{VR_n}{(1 + WAC)^n} + V_{ar} \quad (15)$$

unde: CF – cash-flows of the company, on the three types of activities
 V_{ar} – value of redundant assets

WAC calculation proves its usefulness also in selecting investment projects, being the minimum threshold below which investors will not accept to fall, representing an investment return required for the company that has an identical risk of the same company as a whole. If the new project has the same risk as a whole company, then WAC can be used in determining the net present value (NPV), as a criterion for selection of investment projects:

$$NPV = \sum_{t=1}^n \frac{CF_t}{(1 + WAC)^t} - I_0 \quad (16)$$

unde: I_0 – value of initial investment
 CF_t – annual forecast cash-flows forecast, after tax.

⁹²⁰ Pirtea M., Cristea H., Nicolescu Cristina, Boțoc C., *Managementul financiar al companiei*, Ed. Mirton, Timișoara, 2010.

If the investment project has a different risk than the company's, then the discount rate of cash flow may differ from the value of the company's WAC. In this case, the CAPM model is recommended for determining the discount rate, in which the right SML (Security Market Line) is the geometrical point of all updated rates of investments, proportionally to the risk adjusted to the rates of investment.

3. Creating value – effect of the company's decisions

Intelligent investment decisions make the shareholders richer. For example, if a company can borrow 8%, when the interest rate is 9%, then it can be said that the company manager did a good deed for shareholders.

Unfortunately, this is easier to be said than done. The problem is that financial markets competition is more intense than in most product markets. On product markets, generally, businesses can find competitive advantages that allow positive NPV investments. For example, a company may have only a few competitors who specialize in the same line of business and in the same geographical area. Or can be able to seize the patent, technology or on the recognition and customer loyalty. All these offer the opportunity to obtain higher profits and to find positive NPV projects⁹²¹.

But there are few protected niche in the financial markets and you can not patent issuance of new securities. In addition, you are facing on these markets always a fast-moving competition, including all other companies seeking capital, not even considering the state, the local administrations, the financial institutions, the foreign and individuals companies ranging from New York, Tokyo or London funding. Investors who have a surplus capital are many and intelligent. Most likely, these investors assess the value of securities at least as well as issuers.

Of course, when a company calls to loans, it wants that the borrowed resources to cost less than market interest rate. But if the loan is a good deal for shareholders, it must be a bad deal for creditors. So there is a dilemma linked to how a company is likely to deceive investors constantly forcing them to pay a surcharge for the securities issued. The answer is very obvious, very small, generally companies should assume that they issue securities which are sold at true value.

But the real value is a slippery potential expression, the actual final value does not mean future value, because differences may occur between predictions and the actual recorded level (we do not expect investors to be observers by chance). Fair value reflects a price which includes all current information available to investors on an efficient capital market, all securities being valued at a fair price. In such circumstances, the sale of securities at market price can never be a positive NPV transaction

4. Conclusions

Funding sources must be selected in accordance with the objectives to finance and economic environment in which it operates. Also, the company's financial strategy must always follow the indicators "net income per share", "gross dividend per share" or realistic "net dividend per share" because any investor bases his investment decisions according to actual earnings.

For a capital investment to be justified, the profitability of invested resources must at least equal the same risk return investment alternatives, and we formulate the idea that the cost of capital is an opportunity cost.

If WAC analysis is performed in terms of business, then we are talking in terms of cost that you must pay for dispende sources of funding. But analysis can be performed from the perspective of investors who wish to obtain a certain gain from their investment in the company, and then talk in terms of profitability.

All these hypotheses argues that it is hard to win or lose based on funding strategies, either smart or stupid. It is difficult to win, which means finding cheap sources for funding, because investors demand fair market conditions. At the same time, it's hard to lose, because competition among investors prevent any of them, in terms of requirements, rather than reasonable conditions.

Calculating the value added by the additive method (analytical) study concerns the component value through creative participation factors to be paid.

Keywords: Value-added methods, factors

Cod JEL:G32

Introduction

Value added (VA) is represented and expressed as the entity in the economic cycle through its activities within a specified period, usually the financial year.

The indicator measures the entity's economic- financial performance, growth of value added index to show a tendency to it than that of the production year and it is in continuous growth.

The importance of value-added analysis is reflected in the following aspects:

- Value added is the main source of self-financing economic activity;
- Value added is the source of remuneration of staff;
- Value added is the source for financing the budget;
- Value added is the source to increase reserves for the entity.

Determining the value added by the additive method

Additive or analytical method is a method which involves adding the structural distribution of newly created value, which includes: personnel expenses = wages and social protection expenditure = (PE); taxes and no VAT charges (T+C) ; financial costs (FC); depreciation of fixed assets (DFA); and net added value (NAV) after deducting depreciation.

In this respect, there are two possibilities for calculating the value added:

1) Based on net income for the year

VA = Personnel expenses + expenses, taxes, and similar taxes (including income tax) + financial expenses+ adjustments to financial expenses: tangible and intangible assets + other operating expenses (compensation expense) + extraordinary expenses+ net income. Minus: other operating income, financial income, extraordinary income and income from operating subsidies.

2) Based on results of operations

VA = personnel expenses + expenses, taxes, and similar taxes + other operating + value adjustments of tangible assets + adjustments on provisions+ operating result.
Minus: other operating income.

Calculation models emphasize the role of investment consumption represented by depreciation expense and provision for depreciation of assets, which reflects the contribution of production equipment along with other factors to create gross value added(GVA).

By excluding depreciation and provisions for impairment of assets (DIA), obtain net value added:

$NVA = GVA - DIA$

NVA = Net value added

GVA = Gross Value Added

DIA = depreciation and provisions for impairment of assets

The model for calculating the value added provided by the analytical method allows analysis of: the factors increase or decrease, the value added structure depending on the capital intake and its allocation to pay labor and capital inputs contributing to the new value created.

Value added factor analysis aims to increase or decrease factors that depend on structural elements of the indicator considered.

For example, the value added calculated by the analytical method based on net income, uses data from the following table:

Table 1

Nr. crt.	CALCULATION ELEMENTS -lei-	Financial year		Deviations (±Δ)	Indices (%)
		Previous	Current

14.	Gross value added (GVA)	9523201	13133573	+3610372	137,91
15.	Net value added (NVA)	8166641	11677303	+3510662	142,99

$GVA = PE + (T+C) + FE + VATI + VAA + AP + OOE + EXC + NR - OOI - EXI - ROG - FI$

1. Changing the value added:

$$\Delta GVA = GVA_1 - GVA_0 = 13.133.573 - 9.523.201 = +3.610.372 \text{ lei}$$

$$(\Delta r = I_{GVA} - 100 = 137,91 - 100 = +37,91\%)$$

2. Factors influencing are:

$$\Delta = \Delta PE + \Delta(T+C) + \Delta FE + \Delta VATI + \Delta VAA + \Delta AP + \Delta OOE + \Delta EXC + \Delta RH + \Delta OOI + \Delta EXI + \Delta ROG + \Delta FI, \text{ în care:}$$

$$\begin{aligned}
\Delta PE &= PE_1 - PE_0 = +979.056 \text{ lei} \\
&(\Delta rPE = 979056/9523201 * 100 = +10.28\%) \\
\Delta(T+C) &= (T_1+C_1) - (T_0+C_0) = 4912292 - 3726156 = +1186136 \text{ lei} \\
&(\Delta r(T+C) = 1186136/9523201 * 100 = +12.46\%) \\
\Delta FE &= FE_1 - FE_0 = 1.837.828 - 1.044.330 = +793.498 \text{ lei} \\
&(\Delta rFE = 793498/9523201 * 100 = +8.33\%) \\
\Delta VATI &= VATI_1 - VATI_0 = 1.456.270 - 1.356.560 = +99.710 \text{ lei} \\
&(\Delta rVATI = 99710/9523201 * 100 = +1.05\%) \\
\Delta VAA &= VAA_1 - VAA_0 = 121.300 - 135.200 = -13.900 \text{ lei} \\
&(\Delta rVAA = -13900/9523201 * 100 = -0.15\%) \\
\Delta AP &= AP_1 - AP_0 = 195.300 - 256.300 = -61.000 \text{ lei} \\
&(\Delta rAP = -61000/9523201 * 100 = -0.64\%) \\
\Delta OOE &= OOE_1 - OOE_0 = 132.273 - 159.445 = -27.172 \text{ lei} \\
&(\Delta rOOE = -27172/9523201 * 100 = -0.29\%) \\
\Delta EXC &= EXC_1 - EXC_0 = 104.530 - 98.450 = +6080 \text{ lei} \\
&(\Delta rEXC = 6080/9523201 * 100 = +0.06\%) \\
\Delta NR &= NR_1 - NR_0 = 8.223.928 - 4.431.192 = +3.792.736 \text{ lei} \\
&(\Delta rNR = 3792736/9523201 * 100 = +39.83\%) \\
\Delta OOI &= OOI_0 - OOI_1 = 2.277.610 - 3.592.006 = -1.314.396 \text{ lei} \\
&(\Delta rOOI = -1314396/9523201 * 100 = -13.80\%) \\
\Delta EXI &= EXI_0 - EXI_1 = 118.930 - 123.450 = -4.520 \text{ lei} \\
&(\Delta rEXI = -4520/9523201 * 100 = -0.05\%) \\
\Delta ROG &= ROG_0 - ROG_1 = 1.265.400 - 2.562.456 = -1.297.056 \text{ lei} \\
&(\Delta rROG = -1297056/9523201 * 100 = -13.62\%) \\
\Delta FI &= FI_0 - FI_1 = 1.379.870 - 1.908.670 = -528.800 \text{ lei} \\
&(\Delta rFI = -528800/9523201 * 100 = -5.55\%)
\end{aligned}$$

By summing, we verify the equality:

$$\begin{aligned}
&\Delta PE + \Delta(T+C) + \Delta FE + \Delta VATI + \Delta VAA + \Delta AP + \Delta OOE + \Delta EXC + \Delta RH + \Delta OOI + \Delta EXI + \\
&\Delta ROG + \Delta FI = 979.056 + 1.186.136 + 793.498 + 99.710 - 13.900 - 61.000 - 27.172 + 6.080 + \\
&3.792.736 - 1.314.396 - 4.520 - 1.297.056 - 528.800 = +3.610.372 \text{ lei} = \Delta \\
&(10,28 + 12,46 + 8,33 + 1,05 - 0,15 - 0,64 - 0,29 + 0,06 + 39,83 - 13,80 - 0,05 - 13,62 - 5,55 \\
&= +37,91\% = \Delta r)
\end{aligned}$$

Conclusions

Changing the value added is the consequence of the increase or decrease of the elements of distribution.

Taxes, as items of expenditure are factors influencing the net result of the company and hence, are influential factors in increasing or decreasing the value added. Structural analysis of the value added concerns shares of participation of the allocation of elements to create added value, which reflects the contribution of each input corresponding intake.

Labour contribution

$$LC = \text{Personnel expenses/Value added} * 100$$

Contribution to State

$$CS = \text{Taxes, charges/Value added} * 100$$

Contributing to creditors

$$CC = \text{Financial expenses} / \text{Value added} * 100$$

Contribution to investment

$$CI = \text{Depreciation and provisions} / \text{Value added} * 100$$

Contribution to business

$$CB = \text{Net result} / \text{Value added} * 100$$

The structure of the value added reflects shares of participation from the capital intake to achieving new value created, given the fact that the increase in value added cointerests all participants in the life of the entity.

1) *Personnel undertaking*: the personnel costs directly attributable to the form of salaries or indirect form of social benefits and shares profits

2) *Intake capital*: the interest paid to creditors and dividends paid to shareholders

3) *State*: through taxes and corporation tax receipts

4) *Undertaking*: depreciation and wear itself by offsetting assets through depreciation and provisions for depreciation and self-financing their development

Factors of value added incorporate two distinct parts: one corresponding added cost for the enterprise and another that is a sampling of results. Added cost is the cost of the undertaking's activity, which it added to goods and services purchased from outside.

Sampling result is net income component and it is distributed to the inputs in the form of dividends, income tax, self-financing.

Analyzed as a sum of added costs and interest in the result, the value added provides an insight into the evolution of these costs, hence useful for management.

The structure of value added depending on the contribution of capital intake, on components, given the costs of product additions and deductions, is made by a scheme that requires prior knowledge of the distribution of the net profit by destination: legal reserves, their sources of financing (self-financing), worker participation in profits and dividends to shareholders.

Intake capital are: working with personnel costs and employee participation in profits; creditors and shareholders through dividends and financial costs; the state through taxes including income tax and enterprise, through depreciation and provisions for depreciation, the result put in question reserve self-financing.

Table 2

Value added	=	Added costs	+	Shares in the result
I. Work	=	Personnel expenses	+	Profit participants
II. Capital shareholders	=	Financial expenses	+	Dividends
III. State	=	Taxes, charges	+	Tax income
IV. Enterprise	=	Depreciation	+	Self-financing

Distribution of added value, calculated by the analytical method, based on equity and share intake according to the structure pattern leads to: added costs and levies in each corresponding product.

Value added structured like this, is on one hand a performance indicator, since it allows to assess the effectiveness of the company for its actions, and the second is an indicator of the degree of economic integration, given the external input consumption.

PRIVATE EQUITY – CHALLENGE OR A CHANCE?

Radu Ioana

Babes Bolyai University, Cluj Napoca

Faculty of Economic Sciences and Business Administration

Nistor Ioan

Babes Bolyai University, Cluj Napoca

Faculty of Economic Sciences and Business Administration

The purpose of this study is to present the advantages and the opportunities of the private equity funds impact on the Romanian economy, and also identifies the economic disadvantages that can derive from applied strategies. For this reason we can consider private equity as a challenge and a chance at the same time, because beginning with choosing the investment domain, sector, company and the investment strategies the private equity funds can drive to performance for the investee companies, and implicit can have an important impact on the business environment and not in the least to the entire economy.

Keywords: private equity, involvement, economic and social implications, investment cycle, divestment;

JEL classification: G24, G34, E44

1. Introduction

Given that financing of a company in need of capital can't be realised by own sources, bank loans or on behalf of "the 3 F's" (Family, Friends or Fools), new forms of financing have been created such as account funding through venture capital funds and/or private equity.

In the current economic context, the private equity industry has become a solution of solving the lack of liquidity for various companies because this industry plays an active role on the entire market that can have an major impact on rehabilitating the states economies which have been affected by the financial crisis.

This industry is considered an alternative source of financing for companies that are target for investment funds and also represents a good way of investing on long term, during all stages of the business – from start-up strategies to expansion or replacement strategies. Beside this, private equity financing has become more attractive because these funds have and may provide financial resources for companies in need of large amount of money. This funds have the necessary amounts on behalf of the advantageous strategies applied on the exit, that have provided substantial benefits for up to several times the amount originally invested.

This situation has been considered as an alternative in the context that banks (the most used financing sources till nowadays) have increased the costs of borrowed capital and have roughen the borrowing conditions as a derived response to the actual lack of liquidity on the economy.

2. Private equity advantages

In the actual economic context, the industry of private equity is considered to play an active role in the rehabilitation of the economies affected by the financial crisis, by providing important sources of liquidity in the economy that cannot be obtained through in debt. Private equity is to be a long term investment during all stages of business - starting with initiative strategies up to corporate restructuring strategies.

Through time, has been set that the private equity backed companies have obtained several benefits, such as:

- Retrieving cash from selling a stake of the company to an investment fund, cash in need to accelerate the development of the company. Thus, in addition to bank loans, another option is to attract financing for companies in the ownership of a private equity fund.

- Once a company has been absorbed by the fund and becomes a portfolio company, investment funds bring along professionalization, new practices, new people and market experience.

Considering the recent evolution of the private equity industry, this financing form has created a particularly environment around it. It has been said that because of this, economy has been entered into „private equity era” (Stoica V, Corbu I, 2006), situation that has several advantages, such as:

- Industrial structure is renewed rapidly due to technological progress which shortens the life cycle of products and consequently the life cycle of investments;
- Medium and long term loans can not meet new industry requirements which give rise to very high financial risks;
- Frameworks and company employees want to be more empowered and to participate actively in increasing the capital firm.

3. Private equity actions – Case of Sicomed - Zentiva

In representing the efficiency of the involvement of investment funds in the companies targeted, this article will continue with the Sicomed Bucharest company case study and the observation of the financial indicators in relation to the evolution of the employees.

Indicator	1999	2000	2001	2002	2003	2004	2005	2006	2007	2008
-RON- Turnover	6155164 5	7936937 0	10104600 0	12745544 1	14580000 0	17534766 4	19231316 4	24209661 8	19399664 0	21850584 8

<i>Period before SCD taking over from the private equity</i>		<i>SCD private equity take-over period</i>	<i>The period of the Fund involvement and the restructuring of the merged company</i>				<i>Fund Exit and the taken from SCD - Zentiva</i>	<i>The company's reorganization under the Sicomed – Zentiva's merger</i>		

Source: www.zentiva.com, www.mfinante.ro

Considering the involvement of fund investment in the company we can say that: both entities can benefit from - the fund as a result of leaving it at a momentum can multiply their initial investment several times and the company which benefits from the investment fund, receives a major influx of cash on account of the amounts invested, amounts that can ensure the recovery and / or development of the business.

Actually, if we refer to the situation after the fund had exit from Sicomed, followed by the takeover by Zentiva, Czech Republic, another company in the same line of business, Sicomed has received:

- Restructuring – starting with the restructuring and the redevelopment of the technological infrastructure and the working environment up to the management and staff restructuring;
- Replacement of the production lines with some new ones, modern and which fulfill the latest requirements as far as manufacturing conditions are concerned, which are associated with specific production of medicines;

- Development of new production lines, due to changes in the portfolio of products that are designed to be completed by the Romanian company;

- Introduction of new principles of organizational culture;

Besides these positive aspects, undoubtedly negative sides appeared that have resulted on account of the impossibility of full integration of the old society Sicomed in the standards and the Fund's investment strategies and also into the acquiring company. These aspects can be observed in the reduction of the number of staff employed after 2000, the year of the involvement of the fund.

4. Private Equity Involvement during the Investing Process and Exit time

On one hand, it has been observed that the companies have registered a growth of financial wealth, in terms of high turnarounds, high profits and a better financial position on market, the implementation of new technologies, etc, a situation that is comparable with all the benefits that can derive from a positive involvement of a private equity fund.

Analyzing the related data on the economic impact of private equity industry (PE thereafter), namely the data from *PricewaterhouseCoopers (PwC)* report on the Economic and Social Impact of the private equity funds we intend to verify if the conclusions presented on the reviewed report are common with the real situation of Romanian PE backed companies.

The PWC report sustains that private equity industry has a positive influence on the economy, it contributes to revitalization and restructuring of the existing industrial companies and it consists in financial support and growth potential. For this reason, the private equity industry has become an important pillar of the global economy.

At European level, following the involvement of these funds in the economy, there have been significant increases related to the rate of employment in the sectors covered by these funds, as it follows:

Table 2 - The increase of employment in Europe by sector of activity

<i>The number of employees in companies funded by private equity & venture capital investment</i>	<i>% of increases</i>
Biotechnology	+46,9%
Medical services and pharmaceuticals	+46,3%
Electronics and telecommunications	+38%
Industry	+25,2%
Production of goods for consumption	3,9%
The average employment	+30,5%

Source: Processing by PWC Report on the Economic and Social Impact of the private equity funds

The research report, provided by Technical University of Munich in November 2005, has demonstrated the contribution of investment funds such as Private Equity and Venture Capital on the labor market. Thus, from an empirical study examining the number of new jobs created over the period 2000-2004 showed that were created over 1 million funded companies hiring in Europe, including over 430 000 jobs were created in companies financed by buyouts, and about 630 000 jobs were created among companies backed by venture capital infusions.

Furthermore, the employment rate in the analyzed period, 2000-2004, it was increased with an average of 5.4%. Specifically, it was increased 8 times over the average increase of employment in Europe (0.7%)

In these circumstances, it was the found that private equity firms create more jobs than listed companies (a 5.5% annual growth in Europe between 2001-2004, compared with average annual growth of 0.7% for countries EU), or, most often improves the performance of portfolio companies. Beside all this, the profitability of the portfolio is sometimes higher than similar companies listed, which, ultimately, helps millions of people who contribute to pension funds that represent the largest category of institutional investors.

Therefore, since the PWC report presents the positive aspects of the private equity economic impact, we can assume that as well, can be expected negative aspect. Beginning with this assumption, the study attempts to identify the effects of the private equity involvement in the Romania`s economy by observing this aspects on a private equity backed company (i.e. Sicomed - Zentiva).

In the case of Sicomed the turnover`s growing evolution, presented in the figure 1, with an average of 21% per year (in real terms a growth of 3% over the inflation rate) demonstrates the positive involvement of the fund in the investee company, a company that has benefit of restructuring strategies (organizational, managerial, technological, etc).

Figure 1. The turnover`s and profit`s evolution from investment (2000) up to divestment of the fund (2005) – case of Sicomed - Zentiva

On the other hand, from a social point of view, the Romanian companies that have been embedded in a fund portfolio, have registered an unfavorable influence among the number of employees, although private equity funds have developed a number of advantages on business investment and restructuring.

In other words, these funds have acted only in terms of economic efficiency of these companies on short and medium term, instead the human factor became the one that required restructuring. On account of the restructurement of the company following the management change, some production lines are altered and the funds were put into position of reducing the number of employees through layoffs since the funds involvement (through operations like takeover or buyout). In the following figure it can be observed the evolution of the number of employees while the funds involvement (from 2000 to 2005) and after the Sicomed acquisition of Zentiva in 2005.

During the involvement of the investment fund, starting with 2000 were dismissed over 50% of employees to over 2,000 employees reading in 2005 when it reached a total of 918 employees. All these staff reductions were justified by the management by the need for a restructuring plan in the Romanian company Sicomed Bucharest. In compensation, all the layoffs were redeemed by the inclusion in a social project organized by the company and named "Advice and assistance for reintegration" of over 1 million EUR. The employees included in this restructuring program have obtained a financial redemption - they had to choose between the receipt of four compensatory wages or inclusion in this project for six months, while receiving a monthly salary and professional services capabilities assessment, training courses, setting job interviews, offering legal advice and financial consultances for starting new for businesses.

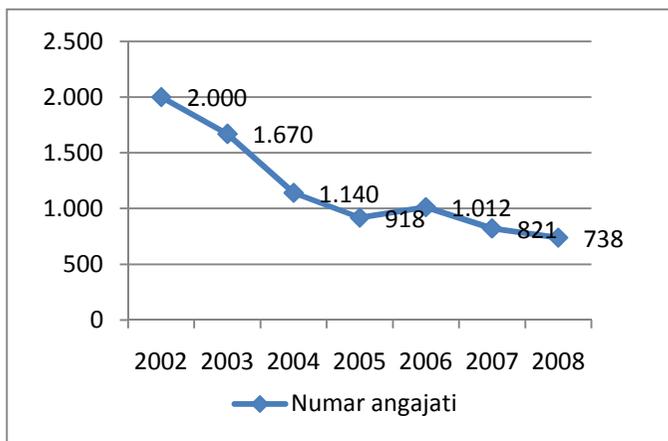

Figure 2 - The employees evolution for Sicomed & Zentiva between 2000-2008

As you can see in figure 2, throughout the involvement of the fund, the number of employees was reduced from year to year, with an average decrease of about 22% per year. The largest number of redundancies being made in 2004, at a rate of decrease in the number of employees with over 31%.

After 2005, with Zentiva's involvement in Sicomed activities, as the beginning of any company, the first year (2006) was marked by the recording of a growth in the number of employees. Employability was at the level of 10.24% higher than in 2005. However, in the coming years, 2007 and 2008 the restructuring continued, with rates of redundancy of 18.87% and 10.11%. Also, in 2007 the reducing of the number of employees took place that is from 1012 (2006) to 821 employees at the end of 2007, change that was realized with proper wage compensation for redundants.

Some personnel changes were made also for reviewing and modifying the market wage level at the standards of group Zentiva - changes that have increased staff costs by over 30% in 2007, which led to the redundancies.

Throughout those 4 years since the formation Sicomed-Zentiva were made redundant 200 people, the current number of employees was only 738 people in the recent report of the company.

With reference to the entire period analyzed, from 2000-2008, during the involvement of the fund and after the divestment of the fund from the company, the number of employees has been reduced from over 2,000 employees to 738, with a medium reduction in staff of 63.1%.

For Sicomed, the investee company, the employees reduction has become a favorable part, because this restructuring process has led to higher turnarounds, results that can be translated in terms of productivity growth and efficiency.

This downsizing cannot be limited solely to the Sicomed-Zentiva business case, it can influence in a certain way all the economic activity. Any redundancy in the number of employed people in the economy could increase the unoccupied population (i.e. the number of unemployed). Reducing the number of employees only in the Sicomed with over 63%, above the European average employability of 30%, generates an average vacancy rate of over 30%, which may show that the reduction in the number of employees in Sicomed has increased by 30% unemployment rate at the industry level, or even in Bucharest, with the assumption that employability rate that it is reached at European level it's also reached in Romania.

5. Macroeconomic implications

Reducing significantly the number of employees due to the influence of these funds, and the corresponding increase in unemployment rate on their behalf, has implications not only on the labor market (through loss of jobs increases the number of unemployed), but also on economy as

a whole. Job cuts will lead to a decreasing of the income, which will result in reducing the demand for goods and services as a result of reduced household consumption in their care to spend and save money. Moreover, at the macroeconomic level, it may record a restriction of activity on account of the inability of covering the supply of goods and services by reducing the demand for them. Subsequently, the lack of activity is to be registered due to degradation of the national production assessed by reducing the level of GDP, with direct consequences for national economic growth. Reducing domestic production will reduce economic growth. That is the recording of negative growth rates, and even economic downturns, that is a stage forerunner of economic crisis.

It should be noted that this study was summarized only to the economic and social implication driven by the involvement of a investment fund of PE in a Romanian company only. The withdraw of these conclusions to a macroeconomic level, has been realized with the purpose of observing the possible incidences on to the macroeconomic indicators, especially if the case of Sicomed Zentiva might be registered by other entities.

Moreover, the negative social implications of company activities must be completed by all the effects observed - that relate to the growth of the business and financial results assessment.

Surprisingly, on account of the number of employees, Sicomed has registered continuously an increasing turnover from year to year. The same situation could be noticed at the profit level, as reviewed in the figure 1. For this reason, we can make positive assessments related to reducing the number of employees – this downsizing, which is due to the re-engineering process and restructuring strategies, has been made in order to have an efficient production, rationalizing the use of resources, to facilitate labor, to reduce medium costs, etc.

Noting all these facts, it has to be said that the restructuring of staff, in this case, was set to be a social cost into/through the innovation and technical progress, cost that is going to lead later to higher competition between companies, and to a continuous improvement of products (diversification and/or quality improvement standard), all into the development of each business. Assessments related to effects of the crisis that influence the reduction of the number of employees can not be done yet, because these personnel changes have been found to have a rationale mean that relate directly to the restructure of the activities and to the replacement of manufacturing technologies, and not on account of restriction of activity.

CURRENT TRENDS IN TAX HARMONIZATION AND COMPETITION WITHIN THE EUROPEAN UNION

Sabău-Popa Diana Claudia

University of Oradea, Faculty of Economic Sciences, Finance-Accountancy Department

Kulcsar-Pop Edina

University of Oradea, Faculty of Economic Sciences, Finance-Accountancy Department,

Gherman Adela-Teodora

This article treats on the fiscal harmonization process within the European Union being indispensable for assuring loyalty in the competition on its single market, given the fact that different system of taxation had direct and powerful impact on the prices level and on choosing the location for production and distribution activities.

Both direct and indirect taxation distort the four fundamental freedoms of the single market. Most of the European Union's regulations regarding fiscal harmonization resemble to the Directive regarding especially the indirect taxes: VAT, Excises.

The fiscal reforms from the member states have to be conceived in such a manner that they take into account the necessity of fiscal harmonization on EU level, creating a reasonable compromise between each country's sovereignty and the desideratum of removing fiscal barriers from the normal functioning of the single market.

Keywords: fiscal harmonization, fiscal reform, VAT, income tax, fiscal europeanization

JEL codes: H21, F36

1. Considerations on fiscal pressures within the European Union

If we take a brief look back in time at the Romanian fiscal system during the transition period, an important stage in the evolution of Romanian fiscal system represents the fiscal reform from 2005, when one has replaced the progressive tax on individuals incomes with a 16% flat rate and the reduction of the income tax from 25% to 16%, which lead to an increase of fiscal incomes with about 7% of GDP. The objects of the reforms depended on the support of the fair distribution of the profit as a result of economic increase, business climate improvement and consolidation of Romanian competition.

The Romanian particularity, in comparison with the old EU member states, before the 1st May 2004 consists in the incomes structures raised from the national budget. In Romania, as well as in the other recently adhered Central and Eastern European countries, the fiscal incomes are mainly composed of indirect taxes – VAT, excises, customs duty, while in the old EU member states, the distribution of the three tax categories – direct taxes, indirect taxes, social contributions to the incomes – is relatively close.

Table no. 1: The evolution of fiscal incomes from VAT (% of GDP) in the period 2000-2008

	2000	2001	2002	2003	2004	2005	2006	2007	2008
EU- 27	7	6.8	6.8	6.8	6.8	6.9	7	7.1	6.9
Belgium	7.2	6.9	6.9	6.8	6.9	7.1	7.1	7.1	7
Bulgaria	9.7	9.1	9.2	9.8	10.7	12.1	12.4	12.1	11.5
Denmark	9.6	9.6	9.6	9.6	9.8	10.1	10.3	10.4	10.1
France	7.3	7.2	7.1	7.1	7.2	7.3	7.3	7.2	7
Austria	8.1	8.1	8.2	8	8	8	7.7	7.7	7.8

VAT represents one of the most important income resources, but in creating the national and the EU budget. European Union's average is 6.9% of GDP. From receipt point of view, Romania exceeds the European average with 8,1% of GDP, the countries with the highest fiscal incomes being Denmark and Bulgaria.

Table no. 2: Evolution of fiscal pressure (% of GDP) in the period 2004-2008

	2004	2005	2006	2007	2008
EU- 27	40.1	40.4	40.9	40.9	40.5
Belgium	46.9	46.9	46.5	46	46.5
Bulgaria	33.1	34.0	33.2	34.2	33.3
Denmark	50	51.7	50.5	49.9	49
France	45	45.4	45.7	44.9	44.6
Austria	44.9	43.9	43.5	43.8	44.4
Romania	27.7	28.5	29.2	29.8	29.4
Great Britain	36.7	37.6	38.4	38.1	38.9

Source: <http://epp.eurostat.ec.europa.eu/>

From the table above we can remark that the Romanian fiscal system is at an average level in comparison with the European Union's countries, being considerably under the fiscal pressure⁹²² level of France and Denmark. A higher fiscal pressure is specific to the developed countries: Belgium, France, Austria. Although the fiscal pressure in Romania is under the EU-27 average of 40,5%, from tax payers' point of view it is high. When analysing the fiscal pressure of some EU countries we have to take into account their development level, the purchasing power of the country; according to these criteria Romania can be still considered a country with a developing economy, in comparison with the developed countries: France, Germany, Austria, etc.

Further on, we limit our analysis to only three European Union countries: Bulgaria, France and Romania. The reason of choosing these states consisted in the fact that Bulgaria adhered to the UE in 2007, as well as Romania who has a fiscal system similar to that from France. The analysed tax types are: tax on the incomes of persons, profit tax and VAT.

Bulgaria

The tendency of the tax on the persons incomes is in decrease reaching in 2008 a share of 10%. The proportional single tax rate is perceived on the incomes from six different sources, existing only a few fiscal exemptions. This rate is applied both on the incomes of the resident persons and on the incomes made in Bulgaria by non-resident persons. Pensions and other payments made from the social assurances budget are exempted from taxes. Similarly, the incomes resulting from interests of the savings deposited in banks in Bulgaria or other EU country are excepted from imposition.

During the last decade, the taxation of commercial societies' profits in Bulgaria became more and more profitable for the development of businesses. From a 40% rate in 1995 for large companies, the rate has been reduced almost each year, reaching a rate of 10% on the 1st of January 2007. There exists even exemptions from taxation even up to 50% for initial investments and the investments in computers, softwares and mobile phones. The investments in new assets for the purpose of promoting the energetic efficiency benefits from an exemption of 50% from the profit tax. Another measure of business encouragement, effective since the 1st of January 2009, is the

⁹²² We've taken into account the fiscal pressure calculated generally as a report between the fiscal incomes+social contributions and VAT

exemption for 5 years from tax payment for those who make profit from the following activities: agriculture, hi-tech, infrastructure.

The VAT standard rate has been reduced from 22% to 20%. The rate reduced to 7% is applied for the accommodation in hotel if it is about an organised travel.

France

Since 1999, one of the main purposes of fiscal policies was to reduce the taxes on the incomes from salaries, taking into account the specific situation of each family. The tax on the income of persons is perceived annually on the income resulting from any sources, in progressive rates on instalments. In 2008, the maximum rate was 40% applied to the incomes higher than 69.505 Euro. A remarkable character is the high number of the applied exemptions. The incomes resulting from investments, such as bank interests, incomes resulting from the profits on the capital market are charged with a proportional rate of 16%.

The profit tax affects each profit made in France by the companies and other legal entities, the standard rate being 33,33%. The large companies with an asset turnover exceeding the threshold of 7.630.000 Euro and with a taxable profit of 2.289.000 Euro have to pay a surtax with a 3.3% additional rate.

France has a VAT standard rate of 19.6% and two reduced rates. A reduced rate of 5.5% is applied to the absolutely necessary products and on the restaurant services and the reduced rate of 2.1% for newspapers, plays and approved medicines.

Romania

Since 2005, the tax rate on the incomes of persons are proportional, unique of 16%. This rate is applied to the incomes resulting from independent activities, from the concession of goods, from salaries and agricultural activities. Moreover, the incomes of the employees whose main activity represents software development are exempted from income tax payments. Benefits in kind are charged normally. The incomes from pensions are charged with 16% , but only those exceeding 1000 RON/month, that is about 235 euro.⁹²³

Since 2005, the profit of commercial societies is also charged with the same proportional, unique 16% rate, reduced from 25%. In the context of international financial crisis and the current government's desire to limit tax dodging, there has been introduced since April 2009 a minimal tax on the profit of commercial societies, established according to the total incomes registered at the end of the last year.

Romania has a VAT standard rate of 19%, two reduced rates, one of 9% and one of 5%. The 9% rate is used for medicines, medical equipments, books, newspapers, the right to access some cultural and hotel accommodation services, while the 5% rate is applied for providing social and some private housings.

2. Current trends regarding tax harmonization within the European Union

At the same time with the intensification of European economic integration, persons and individuals gain a greater freedom to benefit from the opportunities given by foreign economies. Thus, international fiscal competition increases together with the increase of capital and work force mobility. Fiscal harmonization proves indispensable for assuring loyalty in the competition on the EU single market, given the fact that the different system of taxation has a direct and powerful impact on the level of prices and on the choice of the investment's location. At the same time, it is an extremely complicated process because the modification agreed on the tax affects the entire national fiscal system.

⁹²³ Romania's Fiscal Code up dated

Fiscal harmonization ambitions can be thus categorized on three levels.⁹²⁴ Two of them would be the avoidance of immediate imbalance resulting from the opening of borders, EU fiscal system smoothing⁹²⁵. Both direct and indirect taxes distort the main four freedoms of the EU single market. But the most EU directives refer to VAT and excises, which are indirect taxes. Concerning the direct taxes, EU's *acquis* regards the profit tax, capital gains tax and less the tax on the incomes of persons. Most of the dispositions regarding direct taxes are left at each state's disposal, a fact that represents an attribute of their sovereignty. From the point of view of the harmonization of taxation elements, we can refer to several aspects: kind of taxes, imposition rate, taxation base and way of management.

According to a study one reached the conclusion that the more developed countries, such as France or Germany, having large taxation base, are for the harmonization of direct taxes, in comparison with the less developed countries which are skeptical regarding the process of harmonization of these taxation categories. Romanian fiscal system integrates itself in the typology of East-European fiscal system, rendering this market more attractive by means of a direct taxation, more reduced in comparison with the Western-European fiscal system.

Fiscal disparities at EU level determined the European Commission to initiate the implement of a common system of taxation of the profit made by the companies located on the European Union's territory. The system has the determined purpose to remove fiscal obstacles between European transactions. This probably represents the beginning of the fiscal europeanization. The fiscal europeanization can also have the meaning of dependence of the European Union's main institutions. Thus, there would gradually lose the national fiscal autonomies, or parts of them, and the fiscal system would no longer represent a national problem, but a Community problem.

A European measure in fiscal harmonization represents the implement of the common consolidated base of the profit tax (Common Consolidated Corporate Tax Base, or CCCTB), having as main object to facilitate the economic operations realised by the companies from the European Union, but it has no compulsory character, but an optional one. The application of the common base means actually the use of some common regulations regarding the calculation of taxation base for the profits made by the EU companies.

The Commission's proposition for a common base of taxable profit at EU level, letting continually the freedom to national governments to establish their own rate of profit tax is pragmatic and reasonable. This would simplify the profit taxation of the companies which carry on their activities on EU territory, without affecting the competition and restricting the freedom of national governments to establish tax rates considered adequate.

The common consolidated corporate tax base is not the only object of the European Union concerning the fiscal harmonization of direct taxes, but it has also in view to create a common taxation system, applicable to fusions, divisions, assets assigning and shares changing within companies belonging to different EU member states and a common profit tax system among offices and head-quarters.

3. European Union's fiscal paradises – a form of disloyal fiscal competition

A major problem that the European economy is confronting with represents the fiscal paradises, known also as fiscal shelters or "fiscal heavens". Actually these are key-areas of the European economy through which there are circulating freely and continually financial flows drawn as a magnet by the facilities offered by these areas. We can appreciate the fact that these have represented actually the stimulus of the capital migration at international level and even the fiscal europeanization. Generally these are characterized by globally specializing in different services,

⁹²⁴ H. Sterdyniak, M - H. Blonde, G. Comilleau, J. Le Cacheux, J. Le Dear, *Vers une fiscalite europeenne*, Ed. Economica, Paris, 1991, p. 79-97.

⁹²⁵ Tulai C., Șerbu Simona, *Fiscalitate comparată și armonizări fiscale*, Editura Casa Cărții de Știință, Cluj-Napoca, 2005, p.136-138.

mainly bank services, serving the interests of multinational companies. These constitute the meeting point of "white money" with "black money", implying no discrimination, even though these fiscal shelters have strict laws concerning "black" money laundering to assure that financial institutions headquartered there are not used illicitly. Moreover, they have special departments investigating any possible regulation violation. The offshore banks have strict methods of "acknowledging the client", the well known anonymous accounts are just a myth.

Within the European Union we can meet several fiscal paradises, such as Luxembourg, Cyprus or Malta. Some EU member states have become "black" money laundering centres without being fiscal paradises such as Latvia, Poland or even Romania.

There are also "fiscal heavens" outside the Community absorbing important financial flows from the European Union, such as Liechtenstein, being one of the most old fiscal paradises from the world and offering the best services of private banking in the entire world. The case of Switzerland, very well known, constitutes a problem for the European Commission, fighting with the removal of Swiss fiscal system. Monaco is a fiscal paradise more oriented towards persons, as it is not charging incomes, dividends or direct line of successions or capital increase of persons. Thus, the lack of taxes has drawn a high number of "tax refugees" from the European Union, having money earned mainly outside of Monaco.

We consider that the current global economic and financial crisis is due partly to these "black holes" of global economy, because there exist many companies having repatriated their profits in offshore centres and, thus, the states they have invested in lost possible considerable budget resources, achieving a "chain" reaction: budgetary persons have no longer been well enough remunerated in order they may pay their loan rate, the banks confronted with serious financial problems because of many bad credits, leading to the release of global crisis. The lack of a political will to put an end to these "black holes" of financial globalisation makes them to flourish and to put into danger the global financial stability. The developed countries tolerated and are still tolerating the existence of these fiscal paradises because they assure profits to the large companies, but they don't see the long term effects of this phenomenon. We cannot ignore the fiscal paradises when debating a global problem, taking into account the fact that analysts assert that about 70% of the tolerated monetary volume are circulating from the shade of fiscal paradises. Thus, as long as there are fiscal paradises, there will also exist economic crisis. Their cycles are legitimate as long as the problem of fiscal paradises is not removed.

4. Conclusions

By means of the European System Accounts (ESA95) it has been tried to bring to a common denominator the classification of national accounts and within the taxes and EU contributions. The European system of national and regional accounts is a compatible framework on international accountancy level for the systematic and detailed description of a total economy, as well as of its components and relations with other economies. ESA95 is according to the revised orientations from the entire world regarding accountancy at national level, System of National Accounts (1993 SNA, or simply SNA).⁵

Within the European Union's common fiscal policy there exist also the tendency of modernizing Community and national regulations concerning VAT, as well as the stimulation from fiscal point of view of the research-development field or the resources use according to the Community principles of long-lasting development.

Since quite a long time, rumours are heard about the introduction of a common tax in the European Union which shall finance EU's activity. But the institutional (especially the unanimity regulation of the member states discussed again in the Treaty of Lisbon), technical and political

⁵ <http://circa.europa.eu/irc/dsis/nfaccount/info/data/ESA95/en/titelen.htm>

(fear from federalism and budgetary derivation) obstacles still remain numerous and, thus, the introduction of such a resource seems less realist for medium term.

Regarding the recently debated fiscal standardization, there exists a series of arguments for, among which: the necessity of fiscal debureaucratization, as a component of institutional debureaucratization; a step towards the legislative fiscal stability at national level; a state's foreign business would adapt itself more easily to the economic environment of that country; many conventions at international level would no longer be necessary; the smoothing of fiscal legislation would support a better circulation of monetary capitals and, as a consequent, of the main three freedoms and, of course, the fact that there would be no longer divergence, fiscal contrasts at European level, between areas with high fiscal relaxation and those with too much fiscal pressure. Of course, this standardization would be carried into effect only after the ending of national fiscal reforms and only for long term. On Utopian scheme, a fiscal union would be established.

THE AUDIT OF THE EUROPEAN FUNDS - THE ROMANIAN CASE PARTICULARITIES

Țară Ioan Gheorghe
University of Oradea, Romania
Faculty of Economics

The European funds are committed to improving the economic and financial state of the eastern European countries. Therefore they have to be performing spent. The financial audit has an extremely important duty from this point of view. In Romania case there are some particularities which are, at the same time, the possible ways to improve the financial audit activity as well. The vital thing among them is to improve the independence of the financial audit and to take in account the necessary report between internal and external audit. A proposal is made here.

Keywords: financial audit, internal audit, external audit, the Authority of Audit, the European fund, Court of Accounts.

Paper JEL code: M42

The European funds as a lever for the economic growth of the European Union newly entered members

The enlargement process of The European Union needed to be well prepared from many points of view. Among them, those referring to the economic and financial aspects have been considered extremely important. Therefore, The European organisms have decided to give financial support, in order to improve their economic state, to the countries that ask for becoming members of The European Union. It is mainly the case of the eastern European countries that, in a huge majority, inherited a poor economic situation.

Romania, as a country that gained its freedom in 1989, expressed its will to become member of the European Union immediately after nineties. It lasted more than sixteen years and needed both financial support and a long period of exhausting efforts for negotiations. Starting with the January the 1st of 2007 Romania managed to meet the conditions and entered European Union as a fully-rights member. Since than a new European Union policy concerning the financial support has been applied.

There have been two kinds of supporting funds like that: pre-adhesion funds and post-adhesion funds. They actually have had a similar goal, mainly to help the country in restructuring the economic sector and in adopting the European rules concerning the economic and political organization, the rules that are called “the European acquis”. In this way the European funds have been used as a lever to improve the economic infrastructure and to bring a better performance in financial sector. Nevertheless the post-adhesion funds aimed at giving help differently from those of the former period.

The types of the European funds in Romania case and their objectives

The funds that Romania has received from The European Union came differently in type and goal before 2007 from since then. Thus, the former funds referring to the previous period of 2007 consisted in:

- Funds under the SAPARD program (The Special Pre-Adhesion Program for Agriculture and Rural Development) which is a financial support coming from the European Community (the European Counsel decision, number 1268/1999). It was given for the period of 2000 - 2006 in an amount of 153.000 thousand euro annually. The objective of the entire Program consists in:

- to set up a necessary frame for a performing agriculture implementation
- to take over the EU community acquis regarding the agricultural free market

Over the course of the all these funds the Romanian government have had to contribute an overage of 25% from the sum of the funds. That is why the accessed funds have been, sometime, much less than that in right. According with the Agency for the Fishing and Rural Development Payment, at the end of 2008, only 84.05 % have been consumed from the entire amount of the allotted 1,521,450 thousand euros over the period of 2000-2006. Romania has not had the financial possibilities to access all of the funds because of its financial state. That means, however, that in this period, a 1,521,450 thousand euros was allotted for the Romanian economic growth despite the fact that only 1,278,740 thousand euros has been really paid.

- ISPA– Instrument for the Pre-Adhesion Structural Politics – a programme that began with January of 2000 as a result of the European Council decision, 1267/1999. With the allotted 2,783,864 thousand euros till December of 2008 the programme aimed at:

- improving the internal standards of the environment so as they comply with those of the European Union
- connecting the internal transportation webs with those of the Europe

- PHARE– Help for the Economic Reconstruction of Poland and Hungary – which brought to Romania, accordingly with the Finance Ministry report, at December of 2008, 1,187,955 thousand euros mainly for the purpose of:

- developing of the democracy, human rights and minorities respect
- achieving public administration and justice system reform
- improving the over- border cooperation

On the other hand, the tools for the financial support delivery have been wealthy diversified and improved after the January of 2007. Thus, essentially one can identify the following instruments which are still working in order to provide European funds for the Romania's economic, financial and social sectors:

- The European Agricultural Fund for Rural Development which provide money for developing all the agricultural activities and rural infrastructure.
- The European Fund for Agricultural Guaranty that is in charge with the stimulation of the agricultural products export accordingly with the European standards.
- The Structural and Cohesion Funds which are compounded from three accurate-purposed funds such as:
 - The European Fund for Regional Development for giving financial support to those regions that are less developed in fields such as: education and health system infrastructure and local economy
 - The Social European Fund that backs measures to fight against unemployment and for improving the quality of the life
 - The Cohesion Fund as a structural instrument to give money for improving the infrastructure and the environment for those countries that realize a GDP of less than 90% from the European average

All these funds have to be spent in accordance with their specific objectives and within a total compliance of the European Commission rules. Therefore, a requirement that was strongly asked even from the beginning of the adhesion negotiations referred to an effective control on the spending process of the both internal public money and especially for that coming from European Union. It is to watch over the regularity, reality and transparency of the money spending process. To comply with such a demand Romania set up, since 2005, a new special organism in charge with the external financial audit on the European funds. This is called The Audit Authority and is working within The Romania Court of Accounts. Its organization and competences had to and should have to enable it to meet both the European Commission requirements concerning the

needed reasonable assurance on the legality and the performance of money spending process and, at the same time and not less important, the financial audit international standards.

The Audit Authority as an independent organism on European funds external financial audit

In order to audit all the European funds and to give a positive answer to European Commission demands concerning the external audit as a duty of any member of European Union Romania decided to set up The Audit Authority.

This is an independent organism inside The Romania Court of Accounts in charge with so-called external public audit on European funds both pre and post adhesion process. It is thought to work independently from The Court of Accounts and from any other institutions dealing with the European funds management. It is organized both at the central and regional level and actually belongs to The Romania Court of Accounts just administratively. All the professional rules and proceedings are similar with those of The European Court of Accounts and in accordance with the European Commission requirements.

According to its special law, The Audit Authority has a wide range of competences which are to make sure it successfully manages to be a real audit institution. By the law, they quite accurately are:

- to assess the conformity of the control and management systems for the European Programs internal institutions in charged
- verifications upon all the expenses statements of the entities in charge with the European funds management
- reports to European Commission concerning the irregularities found over the course of the money spending process
- control of the reality and legality of that part of money coming from national participation
- issues the so-called audit certificate upon the annual financial statements of those entities that use money
- follow-up regarding the recommendations issued at the end of the audit missions

The law states also that the Audit Authority is entitled to ask for documents and information to any entity which, in a way, may have a connection with the European funds.

It is committed to carrying different types of audit missions, such as:

- audit of conformity aiming at giving a reasonable assurance that the management and control systems work properly at any program level
- audit of system called to identify the strengths and weaknesses of the different systems involved in programmes application
- audit of the transactions having as objective to give reasonable assurances that financial statements which are sent to European Commission are accurately made up
- audit at the end of any programme with the goal of issuing the “closing declaration”

The most important thing defining The Audit Authority activity consists in being an independent audit institution and, as a result, its financial audit activity complies with the demands of international standards. The independence as an ethical principle is a real one and it is secured by the followings:

- it is an external audit and therefore it is alleged to have no material, moral, social or any other kind of connections with those audited. It is really possible to be avoided any interests conflicts as a result of its external statute. All the advantages of the external audit comparative with the internal audit, from this point of view, are possible
- being organized inside The Romania Court of Accounts, beside The Parliament, it is financed by the public money so that there is not possible any negotiation, concerning financial aspects between the auditors and those audited. More than that, it is not at all

possible any agreement, between those two parts, concerning the facts such as: whether or not to be audited, what is the period of time that has to be audited, which is the exact, date the audit mission takes place, which is the cost of the audit. If such things do not intervene in the audit activity it surely is more independent, more trustful and more effective

Taking in account the way of how the independence principle is enforced in both organization of The Audit Authority and in the performing process of audit (its competences) one may conclude that European funds have the right conditions to be audited. How the things are going practically? What might it be done to improve the activity of the entire audit on external funds so as to increase the performance in using them? Being still at its beginning, one could think of some methods, to make it more effective. On this purpose we have to look into The Audit Authority reported results and to compare them with the real expectations.

Conclusions and proposals

As we can see Romania made real progresses as far as the financial audit on the European funds are concerned both in its organization and in an effective exercising. Nevertheless, the European Commission and Romania as well are interested in a more effectiveness and not less important in enforcing all the principles regarding the financial audit so as they are issued and approved by the international professional organisms. In our opinion, toward both directions there are still reserves to be exploited so that the performance of the using process of the European funds to be improved. We refer to the principles of the Ethic Code and to International Standards of Audit.

The International Standards state that there is an important connection between internal and external audit. It is also known how important internal audit for a performing management is, as it is stated by the Corporate Governance Code. Professionally, each of those two forms of financial audit - external and internal audit - has their own functions and therefore, they have to work independently not rejecting of each other. From the management performance point of view, in any field, it is compulsory to organize and perform the internal audit in order to give assurances and advice to the management representatives that their goal will be accomplished. The internal audit is also responsible, in the International Standards vision, with the entire internal control of any entity.

The Authority of Audit is thought to work beside Court of Accounts as an external financial audit. It performs the functions of an external audit and, as we put down, it has a more independence than any other types of audit. As we could see the main goal of an external audit consists in giving assurances that the money are legally or properly spent. In case of the European funds, the purpose of the external audit is mainly to certify that the rules of the European Commission regarding the spending process of money are applied. In this situation the external audit of the European funds appears as a certification organism.

Taking in account the specificity of the internal audit and the connection between it and the external audit it appears that it is also a real need for an internal audit concerning the European funds. The main purpose of any internal audit, accordingly with the international standards, is to give assurances and advice for management so that it accomplishes its goal.

In case of the Romania financial audit on the funds coming from the European Union there is only an external audit exercised by the Authority of Audit. Despite the fact that it is well organized and effectively performed it can not carry out the functions of the internal audit.

There are many governmental agencies which deal with the European funds. In many cases the Government is in charge with the responsibilities of accessing European funds and with their spending. Therefore it is necessary the Government to organize and exercise its own audit which would be an internal audit. Its main goal would be to help governmental agencies management to improve their internal control system so that to be able to prevent the irregularities in spending process of the European funds. As usually the internal audit would give advice to management

system in improving the internal control in order to cover all the risks concerning external funds matter.

As it is obvious enough by studying the last report of the Court of Accounts, referring to the European funds spent during the 2008, there are many and diversified irregularities the external auditors found. It is too late such mistakes to be discovered only after a year or more as it occurs in case of the Authority of Audit. If an internal audit, inside the Government, had been organized it would have been able to contribute to an effective internal control at the agencies level so that many if not all of the irregularities to be previously stopped.

Our proposal from this point of view goes to one of the following variants: either to set up a new financial audit inside the Government having the functions of the internal audit or passing the Authority of Audit from Court of Accounts to the Government changing at the same time its actual functions of the external audit into those of an internal audit. The external financial audit would be exercised, in this last case, by the Court of Accounts itself. It would not be need for any change of the Court of Accounts law because it states such competencies being, from this point of view, in accordance with other such institutions from Europe. It is not less important to notice that in this case a certain superposition of competencies of those two institutions (Court of Accounts and Authority of Audit) concerning the European funds audit would disappear.

The more accuracy the better effectiveness of the financial audit activity.

Abstract

Solvency ratio is the best known indicator of banking prudence, with the priority to ensure the ability of credit institutions to meet the borrowers default and mitigate competitive inequalities between different national systems.

Key words: caution, solvency, own funds

Cod JEL:G32

Introduction

Banking capital is the necessary tool to protect the bank in case of unexpected losses. As a restriction on capital adequacy of banks is, in fact, determining the size of conventional capital according to certain criteria that were proposed and accepted by the partners.

Basel agreement established the capital adequacy system, namely:

- minimum capital requirements are related to credit risk, depending on the structure of bank assets. It creates a specific relationship: the more risky loans, the capital requirement is higher;
- shareholders intake is considered the most important type of capital, each bank itself must participate with a minimum rate required depending on the degree of risk;
- minimum total capital requirements are set at 8% of total risk weighted assets;
- risk for off-balance sheet transactions is included in the calculation by converting specific commitments in equivalent credits;
- capital requirements were roughly standardized between countries, which removes the competitive advantage that banks in a country could have on banks in other countries, according to the rules or different accounting systems.

Solvency ratio, of capital adequacy, has been an ongoing concern of bank management and prudential regulations, due to its significance on bank soundness and safety deposit. Furthermore, it has an important competitive dimension, well capitalized banks are more attractive and competitive to attract resources and to expand business.

Solvency ratio 1

Under existing banking legislation⁹²⁶, banks are required to compute and report NBR solvency level indicators, which is determined as follows:

⁹²⁶ 26/04/1999 NBR Norms No. 8, to limit credit risk of banks published in M.Of.nr.245 of 1.06.1999

-Indicator of solvency 1, calculated as a percentage ratio between the equity level 1 and net exposure (total assets and off- balance sheet items, weighted according to their degree of risk), an indicator whose minimum is 12%.

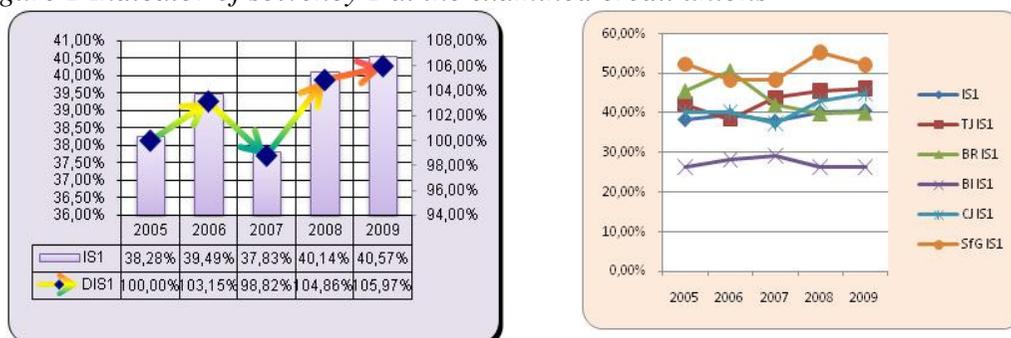

Formula	Own funds/[net assets (after deduction of liabilities AB) + off balance sheet items, converted to equivalent credit depending on their degree of credit risk processing] weighted according to their degree of credit risk		
Periodicity	monthly		
Development limits	>15%	Well capitalized	(rating 1)
	12-14,9%	Adequately capitalized	(rating 2)
	8-11,9%	Undercapitalized	(rating 3)
	5- 7,9%	Significantly undercapitalized	(rating 4)
	< 5%	Major undercapitalized	(rating 5)

Table 1 Evolution of the solvency ratio at the credit unions examined

Indicator of solvency 1 (SI1)=OF*100/NE		2005	2006	2007	2008	2009
Own funds level 1	OF	8.815.052	10.823.266	22.245.640	28.071.974	28.287.224

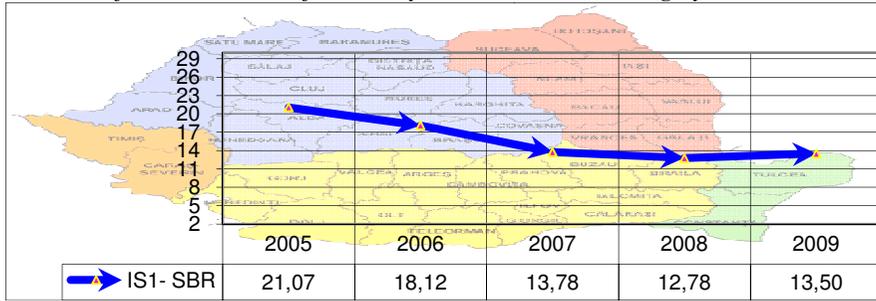

Figure 1 Indicator of solvency 1 at the examined credit unions

Source: own illustration based on the aggregated financial statements

From the graphic above is noted that the indicator of solvency 1 throughout the period under review stood at a level exceeding 37% and 12% upper limit, something which highlights the state of solvency of credit cooperatives analyzed. It is also higher than the average recorded in the banking system in Romania.

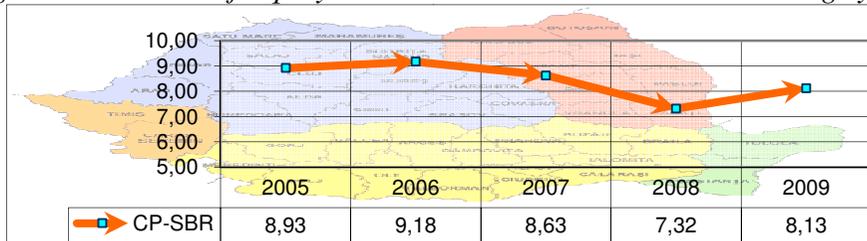

Figure 4 Equity Rates at credit unions examined

Source: own illustration based on the aggregated financial statements

Equity rate evolved increased from 29.18% in 2005 to 32.33% in June 2009 because the assets increased faster than the equity.

Figure 5 Evolution of Equity rate indicator in the romanian banking system

Source: NBR Periodical publications

The indicator in the banking system in Romania reached the 8.13 level in June 2009.

The ratio of equity capital

Formula	Equity/ Capital		
Periodicity	monthly		
Development limits	> 150%	well-capitalized	(rating 1)
	150 - 100,0%	adequately capitalized	(rating 2)
	80 - 99,9%	undercapitalized	(rating 3)
	50 - 79,9%	significantly undercapitalized	(rating 4)
	< 50%	major undercapitalized	(rating 5)

Defining capital ratings: related adequacy

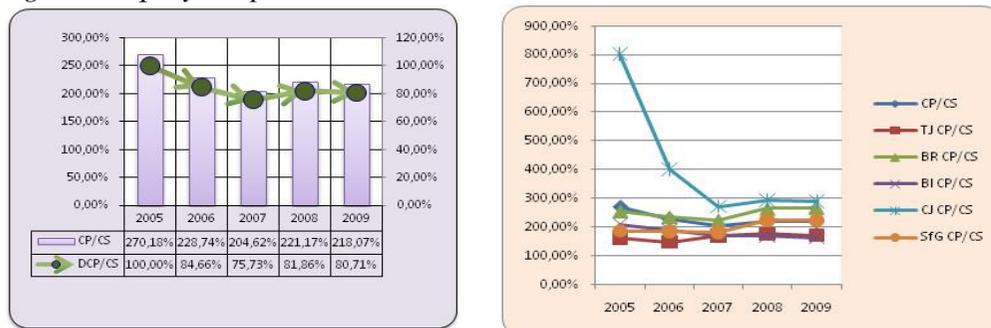

Rating 1: indicates a strong level of capital compared to the bank's risk profile.
 Rating 2: indicates a satisfactory level of capital compared to the bank's risk profile.
 Rating 3: shows a less satisfactory level of capital that can not fully support the bank's risk profile. Rating indicate the need for improvement even if the capital exceeds the minimum required by regulations.
 Rating 4: indicates a deficiency of capital, the bank's viability could be threatened. In this case, shareholders may request the assistance or financial support from external institutions.
 Rating 5: indicates a critical deficiency of capital, threatening the viability of the bank. It requires immediate financial aid of shareholders or an external funding agency.

Table 4 Evolution of the ratio of equity and capital to credit unions examined

Equity / Capital (>100%)		2005	2006	2007	2008	2009
Equity	E	7.966.648	9.996.581	21.597.200	27.528.455	27.577.437
Equity	C	2.948.630	4.370.190	10.555.010	12.447.020	12.646.170
Equity / Capital	E/C	270,18%	228,74%	204,62%	221,17%	218,07%
Dinamyc of Equity / Capital	D E/C	100,00%	84,66%	75,73%	81,86%	80,71%

Source: Own calculations based on the aggregated financial statements

Figure 6 Equity /Capital in credit unions examined

Source: own illustration based on the aggregated financial statements

The indicator fell during 2005-June 2009 from 270.18% to 218.07% because the equity increased faster than the capital.

A bank may be considered:

Well capitalized (rating 1) if it meets the following conditions:

- solvency ratio 1 is 15% or more;
- solvency ratio 2 is 10% or more;
- Equity ratio (leverage effect) is 6% or more;
- It is not in danger of not fitting within the terms of any legislation aimed at maintaining a specific level of capital.

Adequately capitalized (rating 2) if it meets the following conditions:

- solvency ratio 1 is 12% or more,

- solvency ratio² is 8% or greater;
- Equity ratio (leverage effect) is 4% or higher.

Undercapitalized (rating 3) if:

- solvency ratio 1 is below 12% and / or
- solvency ratio 2 is below 8% and / or
- Equity ratio (leverage effect) is less than 4%.

Significantly undercapitalized (rating 4) if:

- solvency ratio 1 is below 8% and / or
- solvency ratio² is below 6% and / or
- Equity ratio (leverage) is less than 3%.

Major undercapitalized (rating 5) if:

- solvency ratio 1 is below 5% and / or
- solvency ratio 2 is below 4% and / or
- Equity ratio (leverage) is less than 2%.

Conclusions

A bank is expected to maintain adequate capital compared with the nature and extent of risk, and management's ability to identify, measure and control these risks.

To determine the adequacy of capital is taken into account the effect of credit risk, market and other risks to the financial condition of the bank. Types and size of risk in bank activity, determine whether the capital should be above the minimum level required by regulations to cope with unintended consequences.

Two issues are covered by this study: 1) critical analysis and systematization of equity controversies and 2) attempts of finding technical solutions for measuring fiscal inequality, closely related to the redistributive role of income tax.

Keywords: tax equity, income inequality, redistribution

JEL Clasification: D31, H22, H23, H24, H5

1. Tax Equity controversies

Construction of a rational tax system has proved to be a step as difficult as it is delicate. The main reason is that its foundation principles and demands are often contradictory and extremely difficult to harmonize: moral and ethical demands of equity and tax justice, tax efficiency and technical principles of social policy and fiscal policy.

Principle that has been given special attention over time is that of fairness, ethical principle par excellence. "Equity should be the rule and taxation objective [...] since we were all created equal. But fairness does not mean that all individuals should be charged as [...] it implies that any tax act to be done correctly, taking into account a particular context or situation." ⁹²⁷(Henry George, 1881)

Achieving ethical goals is very difficult to accomplish. Murray Rothbard pointed out that in this respect "Our conclusions are two:⁹²⁸ economic science can not justify any principle of fair taxation and that nobody has managed to establish such a principle and (2) neutral tax, which seems to many an achievable ideal, logically proved unobtainable. Economists should abandon their quest for fair and neutral tax. "

However the public debate related to finding the optimal tax system both socially and economically, is becoming increasingly heated. The idea of fairness in taxation was perceived differently from author to author and from one era to another. So over the last century have crystallized three major normative theories that have attempted to define an ideal tax system and fairness of each of these three cases is seen differently. The first theory on chronological order of their appearance, Equitable Taxation theory, has its origins in the writings of Henry Simons (1938), a recognized advocate of classical liberalism. The role of the State was to create equity through redistribution. Equity is achieved mainly horizontally, by applying the same rates to the same income. Taxation which is solely aiming the fiscal equity, is disregarding efficiency

⁹²⁷ Henry, George, The Common Sense of Taxation, The North American Review, iulie, 1881, Volumul 130, p.296

⁹²⁸ Marinescu, Cosmin, "[Mitul criteriului eficienței în știința economică](#)", Revista Analiză și Prospectivă Economică, Ed. ASE, nr. 1-2/2005, p. 49-53

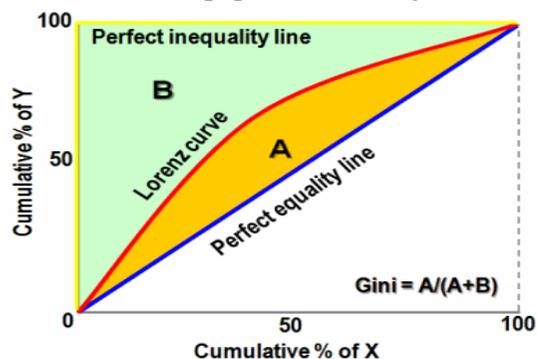

objectives. The second theory was the theory of Optimum Taxation, based on the doctrine of sacrifice and was developed by the classical school. In *The Principles of Political Economy* (1891) John Stuart Mill states that the fairness of taxation is that each taxpayer bears the same burden and the same sacrifice. Modern welfare economics (Pigou), interpreted the sacrifice as a utility loss, claiming that in order to equalize marginal utilities to minimize the sacrifice aggregate caused by taxation. Later, Frank Ramsey (1927), James Mirrless (1971), Peter Diamond (1971) also reiterated the idea that the tax system should involve the smallest sacrifice, but define sacrifice as a reduction in social welfare, and not as simply individual utility loss. Exchange Theory of taxation, the most recent theory, is looking for a tax system as close to perfect. The idea comes from the old tax theory of voluntary exchange Knut Wicksell's (1896) and the works of James Buchanan (1976-1980). This theory involves narrow, multiple elastic tax bases. Regarding tax rates are recommended fair rules to limit taxation by discrimination. From the findings above it appears that the three approaches have very different views on the fiscal construction, how tax is levied and how the idea of fairness can be applied in the system. Regarding their applicability, can be said that all three approaches were used as starting points to build different tax systems. Thus, the theory of fair taxation exercised most pronounced impact on the systems of USA, Sweden and Ireland. Optimal tax theory has exercised a less visible effect in recent years. Theory of tax exchange had a minimal effect at least until now the current tax system; it is visible only as theoretical support for constitutional changes to limit the power of local or state tax in the U.S. So equity in taxation is an easy to pronounce, but difficult to accomplish in practice, and neutralization of taxes is absolutely obvious conflict with their redistributive role and their quality of fiscal levers.

2. Indices of income redistribution through taxes

In developed countries, income tax has long been regarded as the main instrument for redistributing income and wealth. To measure fiscal equity, we use several indices., from wich the most commonly used is the Gini index.

2.1 The Gini Index

The difference between the Gini index for the distribution of income before tax and Gini index after taxation, is an indicator that measures the impact of such taxation. Gini Coefficient is a measure of statistical dispersion, first to be drawn up by the italian statistician Corrado Gini ("*Variability and change*", 1912). It is frequently used as a measure of income or wealth inequality. Gini coefficient is usually defined mathematically based on the Lorenz curve, each portion of the y-axis represents the proportion of total incomes simultaneously obtained by the bottom x% of the population. 45 degree line represents perfect equality of income.

Gini coefficient can be calculated as the ratio between the area that lies between the line of equality and the Lorenz curve (marked "A" in diagram) and total area under the equality line

(marked "A" and "B" in diagram), for example $G = A / (A + B)$. Gini coefficient can vary between 0 and 1, is sometimes multiplied by 100. A low Gini coefficient indicates more equal distribution, corresponding to a 0 is perfect equality, while the Gini coefficient indicates more unequal distribution, the corresponding value of 1 is maximum inequality.

Countries	1995	1996	1997	1998	1999	2000	2001	2002	2003	2004	2005
BG				26	26	25	26	26	24	26	
FR	29	29	29	28	29	28	27	27	27	28	28
DE	29	27	25	25	25	25					28
HU						23	23	24	27		28
PL					28	30	30				36
RO				28	29		30	30	30	31	31
UK	32	32	30	32	32	32	31	35	34		
EU-25									29	30	31

[Source of this data: [Eurostat](#)]

In the table from above there are presented the values taken by the Gini index in some of the European countries, between 1995 and 2005.

While the developed European countries and Canada tends to have Gini indices between 24 and 36, the Gini index of the United States and Mexico are over 40, indicating that in the USA and Mexico inequality is high. In 2005, the Gini index for EU was estimated at 31, and in Romania grows from 1998 until 2005 at 28, 31, indicating a slight increase of tax inequity. The introduction of 16% tax, have produced, without doubt, an even more increase of the index. (32 in 2008-103 place in the world).

2.2 The Suits Index

The Suits⁹²⁹ index is a measure of the Suits collective progressiveness, bearing the name of the economist Daniel b. Suits. It is often used in the analysis of fiscal policy in order to measure the degree of progressiveness, or changes under the arrangements for alternative tax. Similar to the Gini coefficient, Suits index is calculated by comparing the area below the Lorenz curve to the area under a proportional line. For a progressive tax, the index is positive, a [proportional tax](#) has a Suits index of zero, and a [regressive tax](#) has a negative Suits index.

However, almost all of the income tax systems allow for some amount of income to be earned without tax (an [exemption](#) amount) to avoid collecting tax from very low income units. Also, most of the income tax systems provide for higher marginal tax rates at higher incomes. These effects are combined to make income taxes generally progressive, and therefore have a positive Suits index. A tax that the richest people pay the whole tax has a Suits index of 1, and a tax where the poorest person pays everything, has a Suits index of -1.

⁹²⁹ John E. Anderson, Atrayee Ghosh Roy, Paul A. Shoemaker "Confidence Intervals for the Suits Index" National Tax Journal. 2003-03

The Suits index has the useful property that the total Suits index of a group of taxes or policies is the revenue-weighted sum of the individual indexes. The Suits index is also related closely to the Gini coefficient. While a Gini coefficient of zero means that all persons receive the same income or benefit as a per capita value, a Suits index of zero means that each person pays the same tax as a percentage of income.

2.3 The Hoover Index

Hoover index is the easiest to calculate from all measures of inequality, namely: the proportion of all income which would have to be redistributed to achieve a state of perfect equality (taken from the richer half of the population and offered to the poorest half). Hoover index varies between 0 and 1 (0% and 100%), where 0 (zero) indicates perfect equality and 1 (100%) indicates maximum inequality.

In a world of perfect equality, no part of resources need to be redistributed to achieve equal distribution, to have an Hoover index equal to 0 (zero). In a world in which all income was received only by one family, almost 100% of this revenue should be redistributed to achieve equality.

2.4 The Theil Index

Theil index is a measure of entropy. That for any distribution of resources and with reference to information theory, "maximum entropy" occurs once income earners can not be distinguished by their resources, ie when there is perfect equality. The individuals can be distinguished by their income resources. The more distinguished they are, the lower „actual entropy” of a system consisting of current income and income earners. Also, based on information theory, entropy difference between these two may be called "surplus". It acts as a negative entropy.

A Theil index of 0 indicates perfect equality. A Theil index of 1 indicates that the distributional entropy of the system under investigation is almost similar to a system with an 82:18 distribution. This is slightly more unequal than the inequality in a system to which the "80:20 [Pareto principle](#)" applies.

There are three variants of the Theil index. When applied to distributions of income, Theil index first refers to systems in which revenues are distributed stochastically to income earners, while the second Theil index refers to systems within which the earners are stochastically distributed to incomes. Third Theil index is the arithmetic mean of the two mentioned above. Interestingly, the third formula of the Theil index has some similarities with Hoover index.

Conclusions:

There are two forms of tax equity: vertical and horizontal equity⁹³⁰. Vertical equity – „The degree to which taxpayers with higher ability to pay in fact pay more in taxes”. In this case progressivity is the solution agreed in developed countries. Horizontal equity – „The degree to which taxpayers in identical circumstances pay the same taxes”, the revenue neutrality with respect to the income origin being more appreciated than fiscal discriminations.

Based on the indicators presented were designed several models for calculating the equity income taxation, analysis and measurement horizontal and vertical equity, the degree of progression of income taxation system, which will be topics of future research, with the base given the situation in Romania.

PREMISES FOR A MODEL OF DECISION – MAKING ON THE FINANCING OF A PROJECT

Tulai Constantin

“Babes-Bolyai” University

Popovici Ioana

“Babes-Bolyai” University

The classical theory of finance is based on the premises of rationality and maximizing profits that accompany economic decision-making. Complementarily, the modern theory of behavioral finance studies the effect of emotional and psychological factors of decision-maker on the choice of financing sources for economic activities. In opposition with the classical perspective, the contemporary theory of finance brings up to the stage various aspects of decision making, including elements of strategic behavior towards risk. All these contradictory elements are used as premises for modeling the decision making process of financing a project.

Keywords: decision - making, behavioral finance, strategic behavior.

JEL Classification: D8; C 70; D03.

1.Introduction

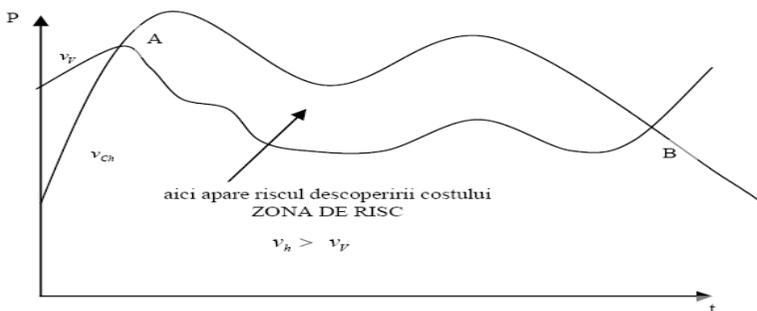

This paper presents a decision analysis model on financing alternatives that may be used to finance a particular project. The concept of project involves a number of defining elements that distinguish it from any other activity. Firstly, a project involves tracking a series of objectives to achieve a specific purpose. It also implies going through several activities ordered in time and space, as a process. The notion of project differs from that of a process in the sense that the objectives pursued by the project involve achieving a result which means the ending of the project, while in a process each output is a new entry for another stage without implying the existence of a certain limit point.

The present research offers a new approach of the financial risk in funding a project. In terms of project management, the required project resources, human, material and money are accounted separately at project level and quantified in monetary project budget. In this context, there will be analyzed the generated cash flows within the project.

The classical methods used to measuring⁹³¹ risk by statistical probabilities of occurrence for a risky event, the economic model described in this paper brings an innovative element. This refers to a systemic vision of risk, studying the cumulative effect of factors that lead to specific risks in the building of the project. The model introduces the time factor in the analysis because of its influence to the financial balance between revenue and expenditure in the budget of the project is due to timing of receipts and payments over time. Time factor entered into the equation leads to indicators such as the velocity of cost and revenue whose temporal evolution can generate the emergence of systemic imbalances in the financial equilibrium of the project leading to risk. The model examines the risk of not being able to cover the project cost from the revenue generated in the project. Starting from the premises that a higher level of velocity of cost and revenue can lead to the occurrence of risk and depending on the duration of exposure to this risk the project can approach financial collapse. The figure below shows how velocity of cost and revenue leads to risk represented by the bounded area between the two velocity curves.

Chart.1.Representation of velocity variation of revenue and cost within the budget of a project.

⁹³¹ Kolmogorov N., Fomin S., (1970), Introductory real analysis, Dover Publications, New York,p.34

Source: Own approach

The model provides decision support needed by any financial manager in selecting the most appropriate financial sources to run a certain investments made through a project. Model analysis implies identifying "risky areas". These are the places where risk can occur due higher levels of revenue velocity greater than those of cost generated by the financing sources used. The model analysis implies studying the behavior of risk into four scenarios. Varying the funding sources and thus the velocity of cost but keeping the revenue levels the same throughout the scenarios implies studying the variation of risk levels due to financing. Alternative funding sources, available⁹³² are described in the table below:

Table 1. Funding sources used in the model.

TYPE OF FINANCING	DEFINITION
Investment funds (equity)	Investors are individuals who have cash they want to invest in companies with a high risk profile through the purchase of stocks or shares in a company with the purpose of exercising control over it.
Bank loan	Bank loans are repayable sources of financing to companies in exchange for the payment of an interest (cost).
Grant	Grants are offered to enterprises by public or private institutions on a project basis or a business plan.
Public-Private Partnership	A form of partnership between public institutions and private companies to financing public utility projects.
Self-financing	Using revenue generated by the project to cover the necessary operating and financial costs.

Source: own approach

Throughout the scenarios used to test the model, the revenue generating capacity of a given project will be considered to be the same along the scenarios. The variable elements of the analysis will be the funding available to finance a project. The role of the model is to provide an informational tool for making decisions regarding the financing sources of an investment project.

2. Model description

The model is defined through several steps. The first step in building the analysis of the model refers to defining the notions of velocity of revenue and cost. The second step in the model refers to building function $\varphi(t)$, as the difference between the velocity of cost of funding accessed and other operating expenses of the project concerned and the velocity of revenue generated from the investment made through the project. The notions of velocity of cost and revenue are defined as

⁹³² Tulai Constantin, (2003), *Finanțele publice și fiscalitatea*, Ed. Casa Cărții de Știință, Cluj Napoca, p.23

follows: $v_v = \frac{\Delta V}{\Delta t}$, $v_{Ch} = \frac{\Delta Ch}{\Delta t}$, where: v_v is the velocity of revenue generated from the investment realized in the project, v_{Ch} is the velocity of cost generating from operating and financing activities. Δt is the period of time between two reimbursing installments, which is considered to be of 1 year.

1. The notions of revenue (V) and cost (Ch) are described in the budget equilibrium equation described below:

$$Cf + Chf = V$$

$$Cf = S_0 + cf$$

deriving the formula we can obtain the dynamic equilibrium equation as follows:

$$\Delta Cf + \Delta Chf = \Delta V,$$

$$\Delta Chf = 0$$

The analysis of the model implies the following premises:

- the revenue generated by the investment made through the project financed stays the same through the scenarios but the v_v is the velocity of revenue generated from the investment isn't the same because of the different periods of time between the instalments in various types of financing.
- the cost of operating investment made is held constant throughout the analysis,
- these elements are possible due to the fact that the analysis purpose refers to comparing the possible financing sources for the project in order to select the financial structure based on the criteria of risk, as tackled by this paper.

2. There is the function $\varphi(t)$ of recovering the cost from the revenue from the projects' budget as the difference between velocity of revenue and project cost, as follows: $\varphi(t) = v_v(t) - v_{Ch}(t)$.

The function can be defined at each point in time t chosen to coincide with the time of each installment repayment of the funding accessed. There are three possible values that the function $\varphi(t)$ is able to take:

- a) $\varphi(t) > 0 \Rightarrow v_v(t) - v_{Ch}(t) > 0$, in this case we have a full "covering" of the costs from the revenues generated by the project, at time t , chosen as a reference.
- b) $\varphi(t) = 0 \Rightarrow v_v(t) - v_{Ch}(t) = 0$, in this case we have a balance between the revenue and cost at the budget of the project, when the project is at the breakeven point.
- c) $\varphi(t) < 0 \Rightarrow v_v(t) - v_{Ch}(t) < 0$, in this case the project revenues are not enough to cover the costs required for the project. This situation should be temporary as the project financial balance depends on the period of time that this situation prevails, in order to prevent a financial collapse of the project.

3. The next step in the model analysis refers to the defining of the function of risk $R(t)$ as the graphical area between the curves generated by velocity of cost and revenue generated by the project. There is a proportionality relation between the area of the function $R(t)$ and the dimension of risk of not being able to cover the projects' cost from the revenues generated. We are able to formulate the risk function $R(t)$ depending on the factor of time:

$$R(t) = \int_0^t [v_v(t) - v_{Ch}(t)] dt = \int_0^t \varphi(t) dt = \sum_0^t \varphi(t) \Delta t \wedge \Delta t^* = t_1 - t_0 = 1$$

$$R(t) = \sum_0^t \varphi(t) = \sum_0^t [v_v(t) - v_{Ch}(t)]. \text{ Where the indicators have been described beforehand.}$$

3.The decision function is defined as follows: $F(x) = \begin{cases} 1 \Leftrightarrow R(t) \geq 0 \\ -1 \Leftrightarrow R(t) < 0 \end{cases}$ where $F(x) = 1$, the

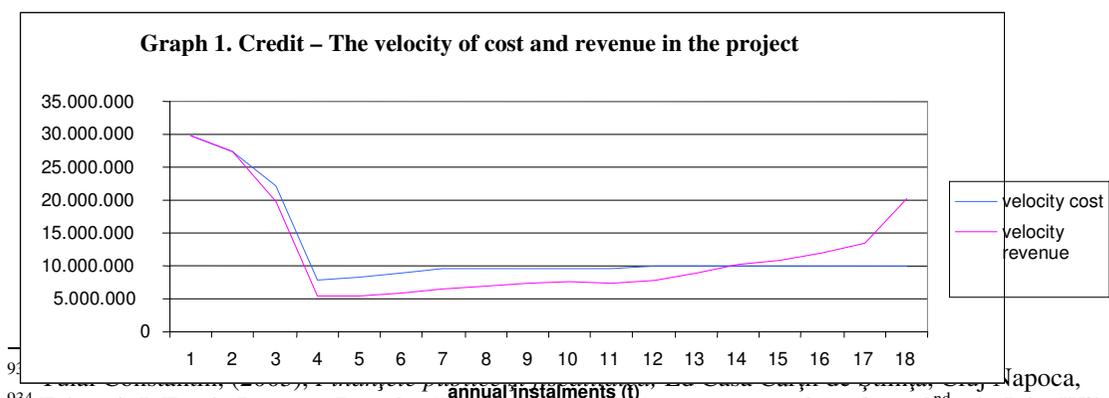

subject will select this type of funding, $F(x) = -1$, the subject will not choose the funding,

3. Scenario analysis

Model testing will be done by simulating four scenarios for scientific validation. The experiment will be done by simulation. The analysis of the model described above will be achieved by using four scenarios related to four combinations of project financing⁹³³:

Table 2. No.1 Scenario assumptions.
Credit financing is used for the investment in the project that runs over 18 periods (years), Cost of financing refers to the annual installments of loan repayment and interest payments since the third year of the operating of investment.
No.2.Scenario assumptions
Credit financing is used in combination with equity, for the project that runs over 18 periods (years). Equity loan will be repaid together with the rate of return required by investors ⁹³⁴ in two different installments, in the 7th and 9th year respectively. Cost of financing refers to repayment in annual installments and interest on loan, from the 7th year after accessing credit to finance repayment of the loan in the form of equity;
No. 3. Scenario assumptions
Public-private partnerships are used for financing the investment projects that are conducted in partnership with the state, over 18 years. To finance the investment through a bank loan to be repaid together with the cost from the 3rd year. Cost of financing refers to the annual installments of loan principal and interest rate repayments and pay a fee ⁹³⁵ for the provision of public service concession, since 3rd year.
No. 4.Scenario assumptions.
Grant funding is used for the investment in the project that runs over 18 periods (years). The investment is financed by bank credit to be repaid together with the cost from the 3rd year. Since the 4th, over 10 years, the annual grant will reimburse the expenditure on investment in 80% of the total value of the investment ⁹³⁶ . Cost of financing refers to paying the annual installments of loan repayment and interest rate, since the 3rd year.

4. Conclusions

The scenario analysis shows that there are parts of the graph where revenue is above the curve of cost and the type of financing reflects a favorable situation for a minimum risk. There are areas on the graphs of risk where the velocity of cost is higher than the velocity of revenue indicating a higher level of risk. Depending on the length of time that this situation is maintained the risk of not being able to cover the cost in the project by the revenue generated by using such financing and there is the possibility of a financial collapse in the state of financial balance of the project.

SUBSECTION: BANKING

THE PARTICULARITIES OF THE MONETARY POLICY TRANSMISSION MECHANISM IN ROMANIA

Apostoaie Constantin Marius

“Alexandru Ioan Cuza” University of Iasi

Faculty of Economics and Business Administration

Roman Angela

“Alexandru Ioan Cuza” University of Iasi

Faculty of Economics and Business Administration

The process of transmitting monetary policy impulses to the real economy presents a series of particularities from one country to another, mainly because of the diversity of financial systems. Thereby, the functionality of various monetary policy transmission channels is significantly influenced by the specific features of each country's financial system.

The objective of this paper is to highlight some of the key features of the monetary policy transmission mechanism in Romania, taking into consideration the dominant role of the banking sector in the national financial system.

Key words: monetary policy, transmission mechanism, interest rate channel, credit channel

JEL code classification: E51, E52, E58, G21

1. Introduction

Although economists don't agree about how monetary policy conducted by a central bank affects the economy (their views diverge in terms of the specific channels through which monetary policy works) an understanding of the transmission process is essential to the appropriate design and implementation of such a monetary policy.

Monetary policy compresses the rules and various actions adapted by a central bank in order to achieve its objective(s). These actions, when undertaken by the bank, set into motion a series of effects (consequences). It is generally assumed that monetary policy effects start with changes in financial market conditions, work through changes in firms and private household spending, and eventually exert, via demand and supply, effects on the economy's price level. The path of consequences a change in the economy's stock of money triggers in terms of real magnitudes is known as *transmission mechanism*.

The empirical studies of monetary policy transmission mechanisms focus upon two major aspects: 1) identification of the effects of monetary policy shocks and 2) identification of those channels through which changes in monetary policy stances reflect on the economy. The first aspect deals with attempts to identify the exogenous monetary policy shocks and their subsequent effects on macroeconomic variables, whereas the second aims at investigating which channels in particular are at work. Through various channels of the transmission mechanism the central banks affect different variables and different markets, and at various speeds and intensities. Identifying these channels is important and attracts a lot of attention from economists, policy makers and investors alike, because they determine the most effective set of policy instruments, the timing of policy changes, and hence the main restrictions that central banks face in making their decisions.

In Romania, the monetary transmission channels were subjects for some papers. Pelinescu (2001) revealed some circumstances such as weak competition, soft budgetary constraints and lax corporate governance that lead to a short transmission period of the mechanism in the Romanian economy. Popa et al. analysed the impact of inflation targeting regime on the monetary transmission channels and Antohi, Udrea and Braun (2003) established an econometric model of the monetary policy transmission mechanism for the period October 1999 – May 2002.

The paper is organized as follows. The second section of the paper consists in a survey of the literature regarding the monetary policy transmission channels. In the third section we present some key features of the monetary policy transmission mechanism in Romania highlighting the role of the banking sector in transmitting the monetary policy impulses to the real economy. The final section focuses upon some main conclusions and key aspects of the paper.

2. Literature review regarding the monetary policy transmission channels

Monetary policy decisions are transmitted through the economy in a variety of ways and that eventually reflect upon the evolution of prices and output. The monetary transmission mechanism is a combination of all the economic channels through which, over a certain period of time, monetary policy affects the economy.

Mishkin (1995) identifies four channels of monetary policy transmission (in the context of the US experience): interest rate channel, credit channel (balance-sheet channel and bank-lending channel), the exchange rate channel and other asset prices channel.

A transmission channel is the *interest rate channel*, the traditional mechanism and the one often regarded as the “main channel of monetary policy transmission”, a position taken by Taylor (1995), but strongly disputed by Bernanke and Gertler (1995). On the one hand Taylor emphasizes the importance of financial prices (like interest rate) as opposed to financial quantities in the transmission process and argues that there is strong empirical evidence for substantial interest rate effects on consumer and investment spending. On the other hand Bernanke and Gertler emphasize the importance of the financial market quantities: credits.

The *credit channel*, according to the “credit view”, implies that monetary policy affects the real economy by shifting the supply schedule of credit. The credit view is composed of two different views, namely the “lending view” and the “balance-sheet view”. Kashyap and Stein (1994) trace the origins of thought on the bank lending channel back to Roosa (1951) and also highlight Blinder and Stiglitz’s (1983) resurrection of the loanable funds theory and Bernanke and Blinder’s (1988) extension of the IS-LM model as two approaches that account for this additional source of monetary non-neutrality.

According to Kashyap, Stein, and Wilcox (1993) and Kashyap and Stein (1994) the narrow credit channel or the narrow bank lending channel refers to that situation in which small banks are more limited than large banks in their ability to find alternative funding sources when monetary policy is tight and are, therefore, less able to make loans. The second channel formalized by Bernanke and Gertler (1989), referred to as the balance-sheet mechanism or broad credit channel, can exist because tighter monetary policy causes firms’ interest payments to rise at a time when revenues are falling, weakening firms’ balance sheets and limiting their ability to grow and spend. Policymakers at times have also resorted to more direct actions to limit bank credit “availability”, such as credit controls or jawboning (Romer and Romer, 1993). There is abundant evidence on the empirical relationship between monetary policy, bank loans and economic activity but in most of the studies the general conclusion is that tight monetary policy leads to a drop in bank credit, which has large negative impact on economic activity.

After discussing about the interest rate there is no reason to focus on only one it as a channel of monetary transmission, because monetary policy can also have important effects on the prices of bonds, equity, real estate and foreign exchange. Given the fact that there are special features of the transmission of monetary policy through the exchange rate, we will discuss about equity, bonds, and real estate as a single group, asset price channel. The additional *asset price channels* are highlighted by Tobin’s (1969) *q*-theory of investment and Ando and Modigliani’s (1963) life-cycle theory of consumption.

The *exchange rate channel* plays an important role particularly in open economies and also in developing countries with only rudimentary markets for bonds, equities and real estates (Kamin et al., 1998). This channel works through both aggregate demand and aggregate supply effects.

The literature identifies also a fifth channel, separate from the others, based on private sector expectations about the future stance of monetary policy and, more generally, about all future-related variables. This *expectations channel* implies that all variables that have intertemporal implications, and are therefore determined in a forward-looking way, are affected by agents' beliefs about future shocks to the economy and how the central bank will react to them. The specific mechanisms for the expectations channel are intertemporal versions of the static interest rate, asset price, exchange rate, and monetary and credit mechanisms.

3. The role of the banking sector in the monetary policy transmission mechanism in Romania

Not all economies react in the same way to changes in monetary policy. The choice of transmission mechanisms and their effectiveness in the conduct of monetary policy depend on the specific features of the economy in question. For purposes of illustration, Loayza & Schmidt-Hebbel (2002) divided the monetary transmission into two steps.

According to the authors, the first step consists in the fact that policy instrument affects various asset markets and prices, and the second step, when these changes affect spending decisions by firms and households. Each step is affected by the economy's specific features, and in particular its stage of financial development and openness to international trade and capital. The effect that changes in market prices can have on aggregate demand is also determined by the solvency and liquidity of firms and households.

Romania is not an exception. In order to estimate the effectiveness of a certain transmission channel we have to analyse several characteristics of the Romanian financial system: whether it is based primarily on banks or comprises a variety of financial institutions, whether it is run publicly or privately, and whether it offers a large range of financial products. These characteristics in turn affect the effectiveness of NBRs' monetary policy.

According to the specialised literature in the field⁹³⁷, an important role in transmitting the monetary policy impulses to the real economy has the structure of the financial system. In Romania, taking into consideration the particularities of the financial system (bank-based system), the transmission of monetary policy impulses is carried out mainly by the lending channel and the interest rate channel.

Monetary policy measures adopted by the NBR are transmitted to the economy also by the exchange rate channel and the expectation channel. However, in this paper we consider only the bank lending and interest rate channels, which have a considerably greater importance given the prevalence of the banking sector in the national financial system.

In the period until 2000, the credit channel and the interest rate channel were almost inactive, therefore the monetary policy transmission mechanism had a low efficiency. The possibilities of the NBR to influence the real economy have been reduced, due mainly to the banking system that was dominated by a few banks, which did not depend on resources drawn from central bank, the budget deficits that were financed by the banking sector and the volume of bank loans that presented low levels.

After 2000, in the context of the reforms undertaken in the Romanian economy, the restrictive monetary policy pursued by the central bank had positive results. The disinflation process and increasing competition among banks led credit institutions to reduce active and passive interest rates for operations in lei, as well as the margin between them. Also, 2000 marks the beginning of the recovery process of financial intermediation and the connections between financial variables and the real economy⁹³⁸.

The developments in the financial system of the Romanian economy after 2000 contributed to the

⁹³⁷ Cecchetti, Stephan G. (2009), „Legal Structure, Financial Structure, and The Monetary Policy Transmission Mechanism”, *Working Papers*, No. 7151, June, 1999, at www.nber.org/papers/w7151.pdf?new_window=1

⁹³⁸ Antohi, D., Udrea, I. & Braun, H. (2003), “Monetary Policy Transmission in Romania”. *National Bank of Romania, Occasional Papers*, No. 3, p. 9, at <http://www.bnr.ro/PublicationDocuments.aspx?icid=6786>

efficiency in transmitting the monetary policy impulses to the real economy.

The Romanian financial system is dominated by the banking sector (see data in Table 1) so that the transmission of monetary policy impulses is more sensitive to its features and how it functions. Therefore, the changes occurred in the Romanian banking sector in the period after 2000, led to significant changes in the transmission of monetary policy decisions on the real economy.

Table 1. *Romanian' financial system characteristics during the period 2000 – 2009*

Indicators	2000	2002	2005	2006	2007	2008	2009
The share of bank assets per total financial system assets	20,4	86,35	83,7	83,8	82,16	82,76	...
The share of bank assets to GDP	30,6	31,9	44,76	50,6	61,5	62,4	67,30
Market concentration (top five banks in the system / total assets, in percent)	65,5	62,8	58,8	60,3	56,4	54,4	54
Share of assets held by banks with private capital per total assets of the banking system	53,9	59,6	94	94,5	94,5	94,7	92,7
Share of assets held by foreign-owned banks per total banking system assets	50,9	56,4	62,2	88,6	87,8	88,3	85,3
Market capitalization to GDP (%)	3,8	6,05	19,52	21,28	27,3	11,23	18,81

Source: NBR - Annual Reports, 2000-2006, Report on financial stability, 2008, 2009; <http://www.bnr.ro/Indicatori-agregati-privind-institutiile-de-credit-3368.aspx> and data processed.

As we can see in Table 1 there is a predominance of private ownership in the banking sector. This improved the monetary policy transmission mechanism. Also significant is the presence of the foreign private capital in the banking sector, which has positive effects, translated into better corporate governance in the banking sector, increase efficiency and strengthen risk management of banking sector stability. However, the presence of foreign banks may reduce the efficiency of transmission of monetary policy decisions because they have better access to external financing, being less dependent on attracting domestic resources. Also, given the current crises in international financial markets, foreign capital can transmit by contagion, some of the risk to the national financial system. Another feature of the Romanian banking sector with influence on the monetary policy transmission mechanism is the degree of concentration. This feature determines that the impact of monetary policy decisions are perceived and transmitted uneven in the economy. An important aspect that indicates the progress of the Romanian banking sector is the significant increase of non-government credit share in GDP (from 9.3% in 2000 to 39.3% in 2008), showing a positive change in the attitude of the credit institutions to the real economy and the return to the traditional function of financial intermediation. Restoring the financial intermediation process and unlocking of the credit lending channel, after 2000, were caused by changes in the supply and demand offers.

Simultaneously with the reinvigorating of the credit channel, in the context of the recovery process of financial intermediation, a revival of interest rate channel was noticed too, these two components of the monetary transmission mechanism being interconnected. In comparison with the period until 2000, when the elasticity coefficient of the demand for loans and deposits with the interest rate was low, in recent years the interest rate channel proves to be quite efficient, in the context of the relationship central bank – commercial banks but also in the context commercial banks – customers.

The main tool that we can use to highlight the impact of monetary policy decisions on the real economy and thus, on prices, through the banking system is NBRs main instrument of monetary policy, i.e. the monetary policy interest rate. This has a direct impact on the interbank interest

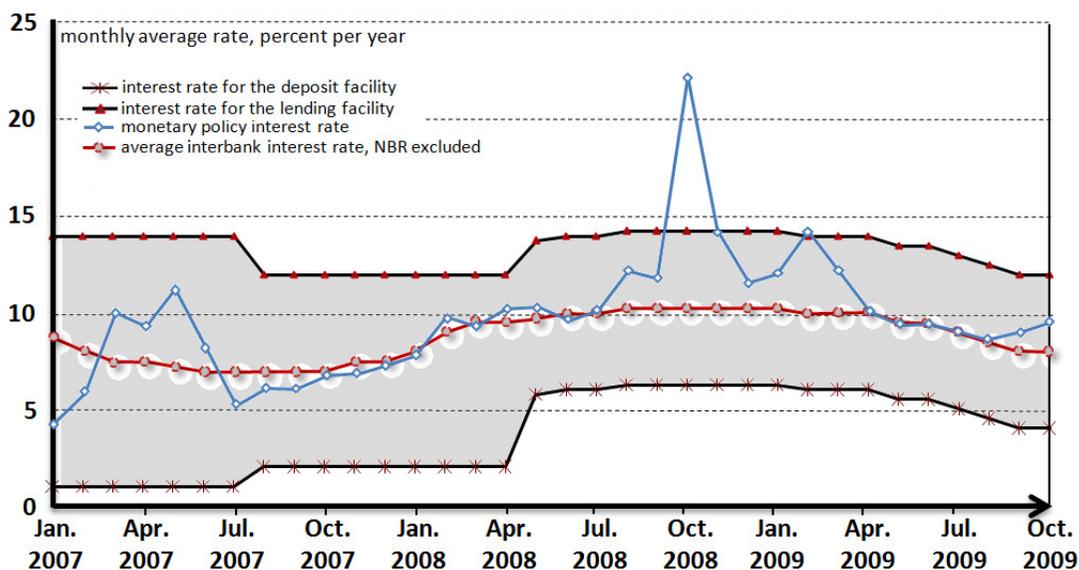

rates because through monetary policy operations, the central bank has the ability to influence the volume of market liquidity. In turn, changes in the interbank interest rate affect the interest rates used by banks on deposits and loans, which have an impact on consumer decisions, investments, savings and therefore ultimately, on the aggregate demand in the economy.

In order to improve the signal role of the monetary policy interest rate and increase the efficiency of the transmission mechanism, in May 2008, the central bank decided to reduce the due date of the key instrument of monetary policy (the standard operations of deposits, whose maturity has been reduced from two weeks to one week) and to narrow the amplitude of the corridor formed by the interest rates on standing facilities to a value of ± 4 percentage points (see Figure 1).

Changes in the monetary policy interest rate are transmitted to the real economy after a certain period of time, as a result of gradual adjustments of bank interest rates.

Furthermore, the transmission of monetary impulses is uncertain and there may be circumstances in which the interbank interest rate does not react to the signal of the monetary policy interest rate. According to Figure 1, one can notice that in certain periods of time there is a significant gap between these two interest rates. For example, in October 2008, in the context of the current international crisis, there were significant malfunctions on the interbank market, reflected by the amplitude of the gap between the interbank interest rate and the monetary policy interest rate. The increased disbelief and the risk aversion of the credit institutions resulted in a significant decrease in the interbank market transactions so that the monthly average interbank rate reached a level of 23%, well above the monetary policy interest rate of 10.25%. In this context, the central bank, considering that it is the case of an unrealistic growth, granted the possibility to temporarily suspend publication of the interbank market indices (ROBID / ROBOR), when the quotations for participants' deposits (ROBOR) to the calculation of the average interest rates interbank exceeds the interest rate on lending facility by more than 25% (BNR, 2008).

Figure 1. *The evolution of the monetary policy interest rate and the interbank interest rate, in the corridor formed by the interest rate for the deposit and credit facilities, in Romania, January 2007 – October 2009*

Source: processed data from the site www.bnr.ro

In February 2009, in the context of a reduction in the economic growth rate and in lending activity, given the current international crisis, NBR started to relax the monetary policy, as shown by the reduction of the monetary policy interest rate and the Reserve Requirements. Nevertheless, the reactions of the bank interest rates to the monetary policy impulses are slow and limited in

size due to the high degree of cautious of the credit institutions, but also to people and traders' reluctance to borrow.

Conclusions

Monetary policy decisions have an impact on the real economy through several channels, whose importance varies from one country to another, mainly depending on the specifics of each economy, on the financial system structure and the existing legal framework.

In Romania, taking into consideration the particularities of the financial system (bank-based system), the transmission of monetary policy impulses to the real economy is carried out mainly by the lending channel and the interest rate channel.

In the period after 2000, the efficiency of the transmission of monetary policy decisions on the real economy via the lending channel and the interest rate channel has increased, due to the positive developments of the national economy in general and of the banking system in particular.

In the context of the current turmoil, the significant contraction of supply and demand for bank loans, due to deteriorating macroeconomic indicators and uncertainty about the prospects of national economies, leads to difficulties in transmitting monetary policy decisions, as shown by the week and small-scale reaction of bank interest rates. Thus, the activity of the National Bank of Romania is not an easy one, if we consider the fact that through the operational framework of the monetary policy, the central bank wishes, on the one hand, to achieve its primary objective (price stability) and, on the other hand, to renew the activity of bank lending, which was significantly influenced by the current crisis.

THE ROMANIAN BANKING COMPETITION AND THE ACCESSION TO EU

Căpraru Bogdan

„Al. I. Cuza” University of Iasi, Faculty of Economics and Business Administration

In this study we try to assess banking competition in the Romania for 2001 – 2008, taking into account the evolution of market share of the top five, Herfindahl-Hirschman Index (HHI), performances indicators like ROA and ROE and evolutions of deposit and loans rates. We observed that the competition in the Romanian banking system increases continuously in the last years. The main factors which have influenced this process were: the privatization of the majority of state capital banks and the perspective of accession of our country in the EU. In the period assessed, there are two approaches: in the first period banks have had very good performances due to their market share in a low competitive banking environment and after the privatization of some state capital banks, the leader of the market lost market share in the favor of other bank with greater performances.

Keywords: bank competition, the Structure-Conduct-Performance Hypothesis, Efficient Structure Hypothesis, banking system, European integration

JEL code: G21; L11

Introduction

The competition in the Romanian banking system has been growing continuously in the last years. Romania has passed a period of transition to the market based economy from the beginning of the '90. Thus, the Romanian banking system had a period of transition, from a “monobank” banking system, with few specialized institutions to a modern one, based on market economy principles.

In this study we try to assess banking competition in the Romania for 2001 – 2008, underling the main factors which has influenced this phenomenon.

Measuring banking competition

In the literature, there are some empirical approaches concerning the evaluation of the competition, the most known being „the Structure-Conduct-Performance Hypothesis” (SCP) and the „Efficient Structure Hypothesis” (ESH). The first approach, SCP, supposes that higher concentration in the banking market causes less competitive bank conduct and leads to higher bank profitability. The SCP model is originally developed by Bain (1956). The second approach, ESH, developed by Demsetz (1973) and Peltzmann (1977) suggests that the superior performance of the market leaders determines the market structure, implying that higher efficiency produces both higher concentration and greater profitability.

The most common measures of concentration are the Herfindahl-Hirschman Index (HHI) and the n-bank concentration ratio (CR_n). The HHI is defined as the sum of squared market share of the banks in the market. The upper bound of the HHI is 10.000, which indicates a monopoly, and the lower bound is 0 in the situation of an infinite number of banks. A market with a result of less than 1.000 is a competitive marketplace, a result of 1.000 – 1.800 indicates a moderately concentrated marketplace and a result of 1.800 or greater indicates a concentrated marketplace. The n-bank concentration ratio (CR_n) is calculated as the percentage of the market controlled by the top n banks in the market, usually the first three or five banks, and the measure takes the share of deposit, loans or assets.

The profit is measured either by ROA or by ROE and the price of bank product is measure by the value of interest rates or commissions.

The evolution of competition in Romanian banking system 2001 - 2008

The accession to the European Union implies the entering in “the single” European market and the existence of the single banking license. In this context, foreign banks can enter more easily the territory of a member country, which can determine the expansion of competition in the local banking activity. The methods to enter the banking market can be diverse: open branches or subsidiaries; equity investment in the local banks; mergers or acquisitions of local banks.

After the accession of our country to the EU and the liberalization of the service market, a number of 190 foreign institutions have expressed their intention to have direct banking activities on the Romanian territory, out of which 174 are banking institutions, 3 are non-banking financial institutions and 13 e-money providers (NBR, 2008).

Millennium Bank, as this is the name of the local branch of the Portuguese Millenium BCP, is the first example of greenfield investment on the banking market after many years of acquisitions. Millennium Bank started its activity on the Romanian market on October 11, 2007, by simultaneously opening 39 branches in Bucharest and in other eight cities of the country.

Before 2007, there was some foreign entrances in the Romanian banking system after the privatizations of certain Romanian state banks, such as: Banca Română pentru Dezvoltare (BRD-GSG) bought by Société Générale and Bancpost in 1999, bought by a consortium formed by General Electric Capital Corporation (35%) and Banco Portugues de Investimento (10%); Banca Agricolă bought in 2001 by Raiffeisen Bank and Banca Comercială Română whose privatization process last between 2003 and 2006, when Erste Bank took the biggest bank of Romania. Also OTP Hungary overtook RoBank in 2004, the first acquisition of a bank with private capital in Romania.

As we can see in the Table 1, the concentration of the Romanian banking system has been decreasing continuously from 2001 to 2008. This means that the competition in the Romanian banking system has increased yearly, especially due to diminishing of the state capital and entering of foreign capital.

Also the performances indicators declined, being closer to the average value of this indicator. At end-2008, the key profitability indicators (ROA – return on assets and ROE – return on equity) showed a significantly higher level (1,56% and 17,04%) compared to that reported at end-2007 (1.01% and 9.43%). This development was due mainly to the sale of participating interests held by four banks in the equity capital of an insurance company, on the one hand, and to the higher net interest income, on the other.

Table 1. Bank concentration and profitability in the Romanian banking system (2005 – 2008)

	Dec. 2001	Dec. 2002	Dec. 2003	Dec. 2004	Dec. 2005	Dec. 2006	Dec. 2007	Dec. 2008
Number of banks	41	39	39	40	40	39	42	43
Market share of the top five banks in total assets (%)	66,1	62,8	63,9	59,2	58,8	60,3	56,3	54,4
Market share of the top five banks in total loans (%)	59,78	56,2	57,1	55,7	61,1	57,1	63,5	53,5
Market share of the top five banks in total deposits (%)	66,12	63,0	64,9	59,5	57,0	60,0	58,3	54,1

Source: NBR, banks, Piața financiară

The leader of the market was continuously Banca Comercială Română (BCR), which was the biggest state bank until 2006, when the process of privatization was completed and it was bought by Erste Bank. In 2001 BCR owned about one third of the market in total assets, loans, deposits, equity and profits. Also, the ROA and ROE accounted a value over the average of the market. Even if his market share decreased during the period of 2001 – 2008, the evolution of performances indicators had a sinuous evolution. Between 2001 and 2006 these indicators decreased, but after 2006, the year of privatization, the profitability of the bank started increasing. In 2007 BCR lost his position in the share of market in total of profits in the favor of the next competitor BRD-GSG.

Tabel 2. Bank concentration and profitability of the leader of the Romanian banking system (2005 – 2008)

	2001	2002	2003	2004	2005	2006	2007	2008
Leader of the market	BCR	BCR	BCR	BCR	BCR	BCR	BCR	BCR
Market share in total assets (%)	31,27	31,51	29,42	26,30	25,7	26,2	23,8	20,4
Market share in total loans (%)	28,78	28,65	27,21	25,32	26,4	26,6	23,5	22,7
Market share in total deposits (%)	31,61	32,82	31,99	27,81	26,4	23,9	20,5	20,4
Market share in total profits (%)	42,75	43,02	35,49	34,28	35,15	33,3	18,0*	41,7

ROE	24,22	20,93	16,6	18,6	16,9	18,8	20,6	38,2

* the leader was BRD with 33,5%

Source: NBR, banks, Piața financiară

The second competitor of the market in this period was BRD – GSG, the rest of the positions in top 5 changing in every year. In the period 2003 - 2007 the third competitor was Raiffeisen Bank, which has lost his position in 2008 in favor of Volksbank. BRD – GSG had a relative constant market share in contrast with the first competitor, which has lost market share continuously. Even if some banks was in the top 5, their deposit market share was very low, because their low interest in attracting deposits from Romanian market, in the context of receiving funds from their parent undertakings (e.g. HVB, Volksbank).

Table 3. Bank concentration and performances of the top five banks in total assets (2005 – 2008)

Year	Banks (first 5)	Market share of the top five banks in total assets (%)	Market share in total loans of the top five banks in total assets (%)	Market share in total deposits of the top five banks in total deposits (%)	ROE
2001	BCR	31,27	28,78	31,61	24,22

* June 2005; ** September 2007

Source: banks, Piața financiară

As we can see, the first competitor BCR had lower performances like the other from top 5. Its performances were improved after the privatization in 2006, being more and more close to BRD, in the first position regarding ROE in the period 2001 - 2008. CEC another state capital bank in the system has lost position continuously and in 2005 it was out of top 5.

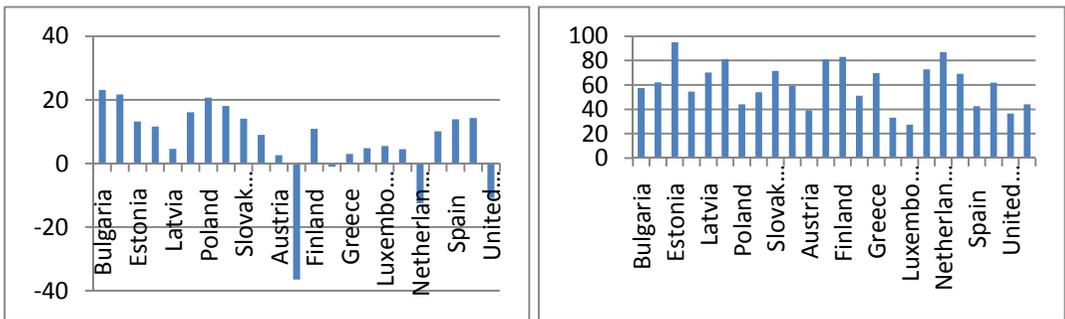

Even though competition in the banking system is continuously increasing the Romanian banking system proves to be concentrated. In 2008, the first 5 banks in Romania according to the value of their assets held 54,4% from the aggregate balance sheet assets, 53,5% from the total of offered loans, 54,1% from the attracted deposits and 51,4% from the equity of Romanian commercial banks, a letdown in comparison with December 2007.

Starting with 2006, the value of Herfindahl-Hirschmann index entered a slightly downward path, still posting a moderate concentration. In 2008 its value came below 1.000, indicating moderate to low concentration and a moderate to high competition.

These indicators demonstrate an improving in bank competition in the Romanian banking system as a consequence of entering in the European single market.

Also we can mention that the value of ROE and market share of the first five banks in total assets is comparable with the European average.

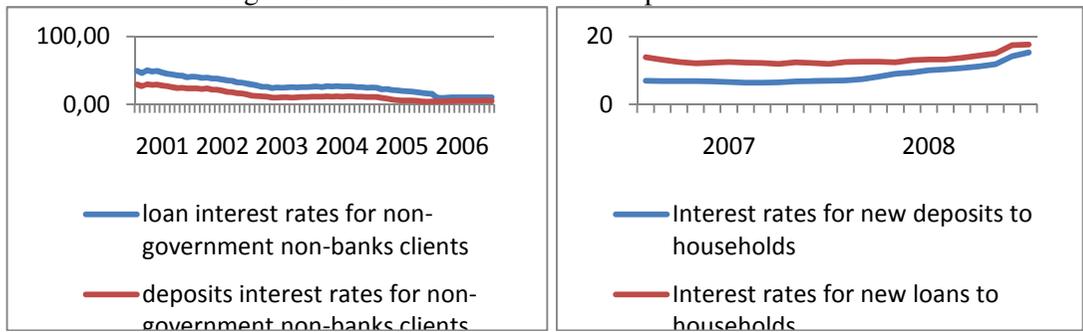

Figure 1. Return on equity (ROE) and concentration ration for the first five banks in total assets in EU, 2008

Source: FMI Global Financial Stability Report, October 2009

As we can see in the next figures, the evolution of deposits and loans interest rates proof a continuously decreases excepting the end of 2008, when the first signs of the financial crises could be found. The spread between deposits and loans rates became more and more tighten. This evolutions proof again the increasing of competition.

Figure 2. Evolutions of loans and deposits interest rates

Source: NBR Monthly Reports 2006-2008

Conclusions

The competition in the Romanian banking system increases continuously in the last years. The main factors which have influenced this process were: the privatization of the majority of state capital banks and the perspective of accession of our country in the EU. In the first period of transition of Romanian economy banks have had very good performances due to their market share in a low competitive banking environment. After the privatization of some state capital banks, the leader of the market lost market share in the favor of other bank with greater performances. Also, the privatization of BCR determined grater performances for it starting with the year 2006. BRD, the second competitor maintained his market share and performances in all this period. As a fact of improving competition we can see a trend of tightening of the spread between deposits and loans rates, and one of loan rates decreasing (excepting the period of the beginning of the actual financial crises in the end of 2008).

E-banking is a fully automatic service for traditionally banking customer’s products based on information technology platforms. E-banking services provide customer access to accounts, the ability to move their money between different accounts or making payments via e-channels.

The advantages generated by this services have determined an accelerate developing of this industry over the entire world. This paper examines some of the advantages of electronic banking products together with the characteristic management issues generated by the implementation of this new channel for financial services delivery.

Keywords: Electronic banking, Internet banking, Home Banking, Mobile Banking.

JELL Clasification: G21

1.Introduction

Many specialized works define e-banking as a modern fully automatic service which delivers traditional banking products to customers with the help of information technology platforms and interactive communication channels.

2. Body of paper

Other works define e-banking as the automatic supply of new and traditional banking products and services directly to customers, using interactive channels of electronic communication. E-banking includes systems which allow customers, whether individuals or corporations, to access accounts, to close deals or obtain information about products and services through a public or private network, including Internet.

E-banking relies heavily on information and communication technology (ICT) to achieve its promise for 24 hours availability, low error rates and quicker delivery of financial services

Initially, e-banking was limited to phone banking operations and remote banking, but the range of services has increased thanks to the technological advances, the spread of online banking has coincided with the spread of high-speed broad and connections and the increasing maturation of the internet user population

One important factor in e-banking growth is that banks have discovered the benefits of e-banking and have become keener to offer it as an option to costumers.

Today, customers can use Internet Banking or Mobile Banking services. Remote banking consists of electronic transactions between customers and their bank. These transactions are operated through a closed communication network using specific software provided by the bank. By these means, clients establish relations with their bank without being physically present in its premises. E-banking allows customers to access banking services through alternative distribution channels which focus on the customers' operational needs. These non-conventional channels use "electronic currency" and offer advantages which have made customers as well as banks use them increasingly:

- permanent technological innovation;
- fast and cheap communication with the existing clients;
- lower processing cost than conventional channels;
- serving a greater number of customers through the same physical infrastructure of bank branches;
- increased expectations from an ever increasing number of customers who are also better educated with respect to the use of these channels, in most cases;
- possible introduction of new commissionable services;
- identifying profitable clients and categories of clients;
- customized offers for an ever increasing number of clients selected from the data bases.

Technological advances lead to the development and implementation of new services [1] which complete the range of traditional ones. These new services are described below.

TELES Services allow customers to access the bank database and to do various operations through virtual bank branches. These services can be:

- Simple, allowing customers only to get information about their account status, or
- Complex, allowing customers to get information about their account status, to make payments or transfers between accounts, and to ask bank forms.

PHONE BANKING services use a rented telephone line (dedicated line), a connection convention signed by the customer, a password only known by the client and a personal code allowing access to the data.

HOME BANKING services allow access to the bank accounts through a software module which is installed on the customer's PC and accesses the server connected to the bank's database. Access is possible thanks to a customer code, a password only known by the customer and an electronic signature. There are several security levels (customers' access to the application, access to the server and access to payments). Customers can check their accounts, do bank transfers, and obtain financial and banking information (exchange rates, interest rates, etc.). Home banking is powerful software located in one or more computers at the customers' headquarters. As authorized users, customers access a Multicash server connected to the bank's databases. From the customers' point of view, the advantages of home banking are:

- comfort: access to the bank 24 hours a days, 7 days a week, without depending on the bank's schedule;
- flexibility: adaptability to the client's needs;
- accessibility: at present, customers can access bank servers by dial-up connection or through the web; bank statements are easy to access;
- safety: transactions are made in the best safety conditions;
- low costs: in order to reduce the number of clients who go to the bank desks, there are fee reductions (10-50% of the ordinary fees) for the electronic payments;
- time saving and reduced expenses (no more transportation to and from the bank building);
- free installation, training and technical assistance;
- interoperability: it is possible to import and export databases for a more efficient management of the customers' own accounting applications;

The disadvantages are:

- additional costs (subscription and connection to the server);
- dependence on the computer where the client software has been installed;
- offline connection with the bank; data can only be updated upon connection to the bank server; data are only updated once a day or every hour.
- an expert must go install and configure the client module;

INTERNET BANKING services allow customers to access their accounts online. Customers connect to a bank portal and thus can check their accounts and do bank transfers from any computer connected to the Internet. For authentication, a customer code and a password are provided.

Internet technology can make significant contribution to a company's value chain, provides a powerful platform for corporations to market and advertise their products and services.

It is important also to mention some of the problems of internet medium: overload, security & privacy problems, rapid technology change, high initially cost and uncertainly about information reliability.

Internet banking is a service which concerns individual and companies who are customers of a certain bank and have access to the Internet. This service allows them to access their bank accounts through a web browser connected to the site of the bank. As there is no need for special software, the only costs customers pay are the Internet connection and the fees.

In order to insure a high level of security, this service is developed on an infrastructure complying with the international information security standards. From the moment the authorized client is connected, any data exchange takes place under a secured protocol, SSL3, which uses a 128 bytes encryption key (the most powerful available for the time being) and a DES algorithm. Moreover, as this service can be provided and guaranteed by VeriSign, clients can easily recognize and check the authenticity of the site.

Currently, there are many Internet banking solutions on the market. They have been usually developed by specialized software companies or in house, due to the specificity for the data security. This service is provided to individuals, physical persons, and small and medium enterprises.

Internet banking is used for the following operations:

- checking bank statements (remainder, history, transactions for all the accounts);
- issuing payment authorizations in any foreign currency (between banks or within the same bank);
- remainder transfers from the current account to the card accounts of the same individual;
- creating and annulling deposits;
- daily information about currency exchanges and interest rates;
- currency exchange and currency exchange negotiations
- securing transaction by an encryption key;
- modularity: use of various customer profiles and limitation of the operation in compliance with the bank policy;
- possibility to pay local taxes and duties (at banks which have implemented the e-Tax service)

Customers have the following advantages:

- comfort – access to the bank 24 hours a days, 7 days a week, without depending on the bank's schedule;
- low costs – in order to reduce the number of clients who go to the bank desks, there are fee reductions (10-50% of the ordinary fees) for the electronic payments;
- time saving and reduced expenses (no more transportation to and from the bank)

building);

- safety – transactions take place in the best security conditions as customers use a user name, a password, and an encrypted channel;
- accessibility – online connection with the bank from any Internet connected computer; simple and ergonomic menu leading the client directly to the operation he/she wants to perform;

One disadvantage concerns the additional costs of subscription and Internet connection.

MOBILE BANKING services can be described as the newest services in electronic banking. They are performed using mobile phones or other mobile devices. Mobile banking services are provided through a convention of connection to these services. Access to the database is made through a password and a customer code. Customers can check their balance and make adjustments between accounts.

The potential for providing mobile banking services may be far greater than services through typical desktop access, as there are several times more mobile phone users than online PC users.

There are two main types of technology available for use in mobile banking: WAP (Wireless Application Protocol) and WIG (Wireless Internet Gateway).

The first one is an application environment and set of communication protocols for wireless devices built to enable manufacturer, vendor and platform independent access to the internet and advanced telephony services.

The other one (WIG) is a SMS-based service in which a menu of banking services options is downloaded from the bank to the phone. This enables the user to browse to all bank services options and through their accounts and to conduct specific tasks.

The main problems in developing mobile banking are:

- internet connectivity costs;
- difficult user interface;;
- lack of awareness amongst customers;
- limitation in functionality of mobile devices;
- accessibility issues;
- security concerns;
- organizational changes;
- small number of choices;
- technology overload;

Mobile-banking can be defined also as an account management tool which can be accessed through the mobile phone. This modern service appeared on the market as an alternative to electronic banking and internet banking services and it facilitates access to accounts and banking operations through the mobile phone. This service can be easily used whether in the home country or abroad. If a client is abroad and wants to access his/her bank account, that can be done through the mobile phone operator. The bank is accessed by Internet (through the WAP service which allows reading Internet pages directly on the mobile phone display) or by SMS through the local operators.

Mobile banking is a fast, secure and efficient service. It offers up-to-date information on the status of the clients' bank accounts, whatever the location of clients or the schedule of the bank.

From the customers' perspective, mobile banking presents the following advantages and disadvantages:

- access to the bank 24 hours a day, 7 days a week, through the mobile phone;
- smaller fees for electronic payments than for traditional payments;
- reduced transportation costs and time saving;
- offline link to the bank;
- Additional costs for the subscription and the connection to a GSM provider.

CALL CENTER services are provided by a team which performs a homogeneous set of interactions with customers according to procedures under control. Customers can benefit from technical assistance by experts and can check and make transfer between accounts.

A rapid development of e-banking requires the increase of the customers' base by attracting new categories of clients with a new behavior and which are very open to the latest technological advances. At present, there is an increased competition in the banking system because of many banks

with small territorial network entering the market and offering new products competing with traditional ones.

For the future it is expected to have a decrease in the banks' operational costs by reducing the volume of "traditional" operations, customers' transactions costs (in 2003, in the US, a transaction operated at the bank's desk would cost almost 1\$, while the same transaction operated online would cost 0,1 \$), and the number of operations requiring the customers' presence in the bank's buildings.

The Call-Center is an assistance tool for the bank accounts management through the phone. In the broad sense, a call-center is a functional entity that exists within a company and is able to communicate by phone and electronically in real time.

E-banking management problematic issues

The implementation of e-banking services is far from being well known and is encountering a numerous difficulties and barriers

The Internet as the unique channel for services delivery is totally different from the classic branches network or telephone banking. That's way it brings up its own challenges that require unique and innovative solutions.

The most common problematic issues in e-banking implementation and management include:

- Traditional structures that are unable to respond to the agility required for the e-banking;
- Resistance from the employees;
- Legacy systems;
- Security issues;
- Regulatory issues which are more complex than traditional ones;
- Project management problems

Further more it is necessary to identify the technology related problems like:

- IT and Telecommunication issues;
- Capacity (or scalability) problems;
- Availability and System Integration;
- Operational Functionality of Web Site Design;

together with management problems like:

- Regulatory issues;
- Information Management;
- Outsourcing problems ;
- Security;
- Loss of Personal Relationship;
- Organizational structure and resistance;
- Trust issues;
- Acceptance issues;
- Clash with other service delivery channels;
- Change Management issues;
- Ethical issues.

3. Conclusion

Organizations that have successfully adopted e-banking demonstrate that a combination of a strong customer focus, performance measures and strategic planning process can be easily incorporated. All these organizations are able to measure the quality of their services and products and become flexible enough to quickly respond to their customer request and market changes

MONETARY STABILITY VERSUS FINANCIAL STABILITY IN ADJUSTING THE REAL ECONOMY

Boldea Bogdan

Gheorghe Roxana Maria

Ivanovici Daniela Cecilia

Strezariu Iulia Ana-Maria

Universitatea de Vest din Timișoara

Facultatea de Economie și de Administrare a Afacerilor

Nowadays, in the economic theory and practice, there's commonly held idea that the primary objective of monetary policy should be price stability. However, the possibility of achieving this goal depends on the development and stability of the financial system. Even though financial stability represents a prerequisite for reaching the objective of price stability, the relationship manifests itself in reverse also.

In the long term, the two objectives support and reinforce each other, but in the short term, there may occur certain incompatibilities, thus resulting in the central bank's dilemma of abandoning one in favor of the other.

This paper aims to investigate precisely the circumstances in which the policies pursued to ensure price stability can cause or worsen financial stability.

Keywords: price stability, financial stability, central bank, monetary policy, National Bank of Romania

JEL Classification: E31, E52, E58, G01

Modern economies must cope with the challenge of achieving financial stability, given that the globalizing financial environment is becoming more complex due to globalization, to the intersection of the monetary and financial market, and to the financial industry innovativeness. Although this evolution of the markets encourages more efficient allocation of global capital resources, allowing the ways of financing to adapt more quickly to the needs of the real economy, “the financial sector is not exempt from tensions and destabilizing movements, which generate risks not only for the players of the financial sector, but also for the economy as a whole”.

Thus, most of contemporary economists have reached consensus on the importance of the central banks (CB) in ensuring financial stability. Missing this goal may cancel the monetary authority performances in achieving its ultimate objective priority – price stability.

Through the years, the CB activity has oriented its monetary policy on various objectives. In the 70s – 80s, the CB were particularly concerned with stimulating the economic growth, their main role being that of providing liquidity and monetary supply expansion through bank refinancing (active monetary policy). Since the early 80s, CB have focused on the objective concerning price stability (the new monetary policy), and currently, financial stability has become again an important objective in the economic decision making process, mainly due to the liberalization of capital flows and to the emergence of economic and financial crises.

Therefore, in our opinion, financial stability is no fresh news to economy, but a retrieval of a traditional issue.

It is required a delimitation of the two concepts – “price stability” and “financial stability” – taking into account the existence of multiple definitions concerning the first concept and the lack of universally accepted definitions for the second one.

After analyzing some definitions from the specialty literature for clarifying the two concepts, we considered the ECB's⁹⁴¹ vision relevant with respect to price stability and the paper "Financial Stability", in what concerns the definition given to financial stability⁹⁴².

The ECB's vision concerning price stability is the following: 'price stability is defined as the state of economy when the general price level is stable in the strict sense or when the inflation rate is sufficiently low and stable, so that considerations related to the nominal dimension of transactions cease to constitute a relevant factor for the economic decisions'.

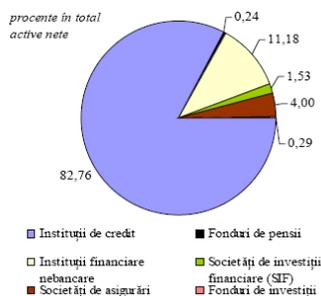

In Romania, price stability represents the objective of the National Bank of Romania's strategy: direct inflation targeting. The aim of this strategy is reaching the optimal level of inflation, which can contribute to sustainable economic growth, macroeconomic stability, and last but not least, to ensuring a high level of social welfare.

Unlike price stability, there is no universally valid definition of financial stability. The following genus-differentia definition of 'financial stability' better satisfies the requirements of formal logics: "financial stability is the feature of the financial system which subsists in its capacity of absorbing the financial imbalances that occur endogenously or due to exogenous, significant and unanticipated event, thus facilitating the achievement of economic performances".

Authors such as J. Chant refer to this concept starting from the opposite term: 'financial instability'. "Financial instability refers to the financial markets, conditions which affect or threaten to affect the economic performances through their impact over the financial system".

In the broad sense, financial stability implies that the financial system must be "able of attracting and placing funds efficiently and of withstanding shocks without hurting the real economy", while in the restricted sense, specific to the banking sector, financial stability relates to the situation characterized by a lack of banking crises and the existence of a certain level of assets price stability, including the interest rates.

Thus, the concept of 'financial stability' appears as a feature of the financial system, which includes the financial market, financial institutions and their related infrastructure. As a consequence of the many links among these components (markets, institutions and infrastructure), any imbalance in either of the elements may affect the others, thus compromising the stability of the whole system. However, if the system works well enough to perform its core functions, even when one of the components faces problems, they do not necessarily constitute a threat to overall stability. This means that it is not mandatory for all the elements to operate at / near maximum at any time.

A stable financial system has the capacity to limit or to solve imbalances, partly through self-control mechanisms, before leading to crises (in which case, financial stability and monetary stability are achieved simultaneously). Therefore, we must speak of both global perspective and a systemic one, in measuring the soundness of the financial system.

⁹⁴¹ European Central Bank.

⁹⁴² In our paper, we will refer to the two concepts considering these definitions, as they are the most adequate, in our opinion.

When it comes to Romania, we must highlight the fact that it still shows the features of an emerging financial market. In 2008, financial and non-bank financial institutions continued to hold the largest share of total financial assets, being in slight increase up to 93,9%, while the insurance and capital markets account for only 6,1% of total net assets.

Consequently, the impact over the stability of the entire financial system, caused by failures in the banking sector, would be much higher than if it were provoked by problems of any of the components of the financial sector (Chart 1 – Structure of the financial system in Romania), so they must be efficiently supervised.

Bank supervision plays a very important part in ensuring both financial and monetary stability because the banking sector is the main transmission channel of monetary policy. Therefore, if it recorded imbalances (liquidity deficit or surplus), it would be very difficult for the CB to fulfill their objectives.

In our view, bank regulation and supervision is vital in maintaining price stability because the micro and macro-prudential information obtained by practicing this function may be successfully used in preventing or managing crises which could negatively affect the main objective of the CB, taken into account the repercussions on the real economy.

Usually, financial stability does not represent an explicit objective for modern central banks, but they begin to show a particular interest in achieving their main objective: to ensure currency stability. Monetary policy can not be fully effective unless it is based on foreseeable transmission mechanisms, which implies a sufficiently stable financial environment. Mutually, price stability is a necessary condition in ensuring financial stability, but not sufficient. In our opinion, there are certain circumstances when some unpredictable transmission mechanisms may also have a high efficiency.

A well-functioning financial system allows an economy to exploit the full potential of growth because it provides the necessary funds for investment opportunities at minimal costs. Also, a stable financial system facilitates the economic performances improvement and contributes in correcting imbalances that affect the economy. However, this concept should be perceived dynamically. This means that resources must be permanently mobilized, and once stability is reached, a more lax policy should not be adopted, instead, it should be operated with different levers to maintain stability, because the financial system is in a permanent qualitative change.

But still, could the policies pursued to achieve monetary stability (restrictive policies), cause or even worsen financial instability, in certain circumstances? The answer to this question, somehow rhetorical, is the objective of this research.

Regarding the relationship between price stability and financial stability, in the literature there were formulated two approaches: *the conventional approach* – according to which, the two types of stability support and reinforce each other, in the long term - and the *"new environment" hypothesis* – which holds the idea that along with controlling inflation at low levels, a new economic environment is developed and financial stability is not guaranteed anymore.

We subscribe to the idea that the two objectives are compatible in the long term, but in what concerns concrete monetary policy, short term outlook is targeted, in detriment of the former. Such conflicts may arise between the two concepts within the meaning of disclaiming one for another.

The interest rate monetary policy is one of the main tools used by CB to ensure financial stability. To illustrate, in an economic scenario with two variables - high inflation and fragile banking system – in order to combat high levels of inflation CB may increase the nominal rate of reference interest rate, thus causing higher instability of the banking system.

Therefore, we can talk about an incompatibility between the policies pursued in the short term to ensure price stability, respectively financial stability. Interest rate variations induced by CB in the monetary market triggers a series of mechanisms, having a strong influence on the population and enterprises decisions of consumption, savings and investment.

In *caeteribus paribus* terms, a higher interest rate will lead to a contraction in the consumer and investment credit in what concerns the population, respectively the businesses, thus affecting the already installed fragility of the banking system. Also, the population will be encouraged to save, in detriment of investing, these chain effects, finally, having an impact on other real economy variables, like production and correlative volume of imports and exports.

On the one hand, from the households' point of view, an increase in real interest rates above the growth of differential inflation rate increases the attractiveness of saving because the efficiency is higher in terms of future consumption, resulting therefore in lower current consumption. Furthermore, regarding an enterprise, a higher rate of interest will have inhibitory effect on investments because there will be fewer investment projects available to provide sufficient performance to cover the increased costs of capital.

The connection between monetary policy and bank stability does not inhere exclusively in the level and volatility of interest rates. A more general tension is that the cyclical effects of monetary policy and bank regulation push in opposite directions. Monetary policy tends to move in countercyclical fashion: in the event of an economic slowdown, the central bank may expand the money supply and provide more funds to speed up the economy's recovery. However, the effects of bank regulation—especially prudential regulation, such as capital adequacy requirements—are procyclical, requiring a contraction of banking activity when the economy slows. For example, during a recession, a bank regulator might require an increase in loan-loss reserves and an improvement in the quality of banks' lending portfolios.

A second argument of the incompatibility between monetary policy and financial stability is reflected in the literature of ideas set out by various authors who disagree with CB involvement in regulatory and supervisory activities. The supported idea is establishing a Single Supervisory Authority (SSA), responsible for the stock exchange, insurance sector and banking supervision, thus absolving CB from regulatory and supervisory function of the banking sector.

The main argument used by the authors in question is the possible conflict that may arise between the objective of financial stability (achieved mainly through this function) and the objective of monetary policy, for instance, in a crisis, when CB should not be concerned only with the inflation targeting, but with ensuring the stability of the financial and banking system by/through injecting cash in order to rescue financial institutions which are in difficulty (it will choose "the least bad").

We consider that a SSA is justified if the stock market would be developed or it would be difficult to define each financial sector's activities, and not based on the incompatibility theory between banking supervision and the objective of monetary policy. In Romania, the supervision unification is not appropriate now, given that the Romanian financial system is characterized by a low degree of intermediation, insurance and financial investment are underdeveloped, the banking sector having a significant weight.

Although, in the short term, a compromise between monetary stability and financial stability can be reached, we consider necessary to keep the banking supervisory function as an attribute of CB, because macroeconomic forecasts can be improved when based on confidential information obtained from prudential controls on credit institutions.

A third argument of the incompatibility between monetary stability and financial stability, identified in the literature, is the very complexity of the two objectives. If price stability is the main goal of many modern CB, it can be well defined, achieved and maintained over time, financial stability is more complex, both by the different opinions on its definition, and by the many ways of achieving it, as by the importance that some authors assign to this concept in light of the economic context. Financial stability depends both on endogenous factors, such as: real economy movement, relations with foreign countries, operational risk, domino effect, etc., and exogenous factors: macroeconomic disturbances, natural disasters, large business failures.

Since August 2005 NBR's attention has focused, in particular, on the objective of price stability, due to increased inflation expectations and national currency appreciation caused by massive capital inflows (direct investments, portfolio investments, return of labor incomes). Between 2005-2007, NBR fulfilled the net debtor position towards the banking system when increases of the interest rate, needed to bring expectations in line with the inflation target, were attracting more foreign capital, and appreciating the national currency unsustainably ("Tosovsky dilemma").

From the onset of the financial crises in July 2007, NBR aims to be a net creditor of the banking system, foreign capital inflows being significantly attenuated. The reduction of external funding led to national currency depreciation, which increases inflation and requires a relatively high nominal interest rate. Due to the exponential growth in consumer credit recorded in the period 2005-2008, the main affected by the depreciation of the national currency are the borrowers in euro and currencies, who do not register a debt service as good as the previous, thereby assist in increasing the vulnerability of the financial system. Although it is necessary increasing the interest rate, this may decelerate economic growth and, moreover, could lead to the augmentation of contracted credit costs and also of the possibility of converting them in nonperforming loans, with the risk of destabilizing the financial sector. Under these conditions, the compromise between the monetary policy objectives (price stability and financial stability) appears.

In modern economies, a low and stable inflation level leads to a new economic environment in which financial stability is not guaranteed and so the reconsideration of the relationship between price stability and financial stability is strictly required. So, there can be identified a fourth argument for the incompatibility of the two objectives, namely: the "new environment" hypothesis.

The cases of Asian countries during 1997-1998 were relevant in this direction. In the period preceding the onset of a financial crisis, these economies had experienced significant imbalances, despite the existence of a relatively high degree of price stability. The same situation/case is observed with current financial and economic crisis in which CB were forced to inject a considerable amount of cash to maintain financial systems in operation. So, CB are no longer able to ensure both price stability and financial stability, in the event that their implementation requires contradictory measures.

Analyzing the case of Romania, we can affirm that maintaining financial stability has a particular importance to price stability, being primary considered regarding an alert process of disinflation. During 2000-2007, financial instability had been avoided through a proper dose of the disinflation rate, thus recording an average rate of disinflation of 5.8% per year, while maintaining financial system stability, which shows that, although both objectives, on short term, can be in contradiction, on the long term, they sustain and highlight each other (conventional approach). Failure in maintaining financial stability can only lead to an inflation growth.

The long term objective of monetary policy should be to achieve a low and stable inflation which helps long-term sustainable growth. Accordingly, low and stable inflation represents a goal in itself and also a way of achieving sustainable economic growth. The effectiveness of monetary policy in achieving this objective is limited by the level of financial stability.

As shown above, we can affirm that if financial stability is a condition for achieving the objective of price stability, the dependency relationship between them manifests also in reverse.

At the end of 2005, NBR adopted a series of "unorthodox" measures in order to limit the magnitude of the inflows impact on price stability and financial stability, such as: "cooling" - government credit growth which mitigates the phenomenon of overheating, that contributes to the reduction of inflationary pressures and limits external imbalances; reducing the growth rate of foreign currency component which prevents the increase of banks vulnerability to currency exchange rate fluctuations, that ensures the avoidance of an augmentation in the nonperforming loans volume.

The “unorthodox” measures which NBR adopted in 2005 and 2006 were primarily effective in the short term, ensuring reconciliation between financial and price stability. Since 2007, with Romania’s accession to EU, NBR has gradually dropped these restrictive measures which aimed especially the credit restriction.

But why were these measures so important? If NBR had not tried to restrict foreign currency loans, based on excessive appreciation of the national currency due to massive inflows of speculative capital, the population would have been tempted to overborrow in foreign currency. Since 2004 until August 2007, NBR has made relatively large purchases of foreign currency, being criticized that it had not left the course to appreciate in line with market requirements.

Often, high volatility of the exchange rate is associated with large current account deficits which are dangerous due to major implications primarily for monetary stability and generally for macroeconomic stability. Therefore, NBR adopts a floating current which allows CB interventions on the foreign exchange market, but without imposing them. It also reduces the possibility of speculative attacks on national currency, which intensified along with the liberalization of capital account.

The fact that CB does not assume a strict commitment rate and allows the market to set the exchange rate, represents both an advantage for financial system stability and a precondition of accession to ERM II.

In conclusion, we sustain the view according to which the policies designed to ensure price stability and financial stability have different intensities effects on the real economy, even if they can be implemented using similar tools by CB. Also, in our opinion, it is necessary to keep the regulatory and prudential supervisory function of the banking sector as an attribute of CB, because in this way micro- and macro-prudential information are obtained, information which contributes to the increase of monetary policy effectiveness.

We consider the arguments presented above as a reflection of the potential conflicts that may arise in the short term and/or very short term, between the two objectives, in the context of abandoning one for the other and not as a total incompatibility between them. Furthermore, we believe that, on the long term, the two objectives are interrelated, mutually sustaining and highlighting.

Analyzing the relationship between monetary stability and financial stability, we can affirm that there is a two-way link between them. Therefore, we believe that even if, in the long term, the primary objective of CB is, in general, price stability, they must pay attention also at financial stability. Otherwise, even if there is a progress regarding disinflation, their sustainability is not ensured in the context of an unstable financial system. Failure in maintaining financial stability can only lead to an inflation growth.

POSSIBILITIES OF IMPROVING THE METHODS AND TECHNIQUES USED IN THE SURVEILLANCE OF CREDIT RISK MANAGEMENT

Bolocan Mihail-Dragos

“Babeş-Bolyai” University Cluj-Napoca

Balogh Peter

“Babeş-Bolyai” University Cluj-Napoca,

Through their daily activities, credit institutions are subject to various risks which could affect both the bank and the whole banking system, national and transnational. The activity field of the banks, marked by volatility, by the internationalization and liberalization of the financial markets, is in a continuous change. The contagion effect, as it has been proved by the spread of the financial crisis' effects, determines the surveillance authorities to pay increased attention to the financial risks and implicitly to the systemic risk.

In this study, to start with, there shall be presented some aspects regarding the banking rating systems used by the surveillance authorities and then some ways of improving the models of managing credit risk in banks. In the end, there will be demonstrated that the risk profile of the banking institution has a determining role in the management of the credit portfolio.

Key words: banking system, banking risk, surveillance, rating systems, credit portfolio, investment.

Cod JEL: G32

1.Introduction

By promoting the new agreement (Basel II), it is intended to improve the surveillance methods of the credit risk, as well as to develop a methodology for each banking institution for the measurement and management of the banking risk, to increase discipline on the financial markets, but also to offer some stimulents for the banks that implement the best practices in this domain. Thus, it is intended to reach a convergence between the reglemented capital (established by the national banks) and the economic capital [1]. Establishing the reglemented capital on the basis of the assumed risk level by each bank will allow these to manage their resources better (Maniu, 2006).

The integration of the financial markets and infrastructures in the European Union, together with the growing number of big and complex financial groups, which have cross-border operations, contributes to the efficiency and stability of the financial system of the European Union. At the same time, the financial/monetary integration increases the possibility of cross-border and cross-regional contamination and it consequently amplifies the possibility of a systemic crisis which could affect one or several state members. The financial stability is, consequently, a common preoccupation for all “euro states” and it must be protected through an open collaboration.

In order to limit the economic impact of a systemic cross-border financial crisis, there must be allowed a response at the appropriate and efficient moment. In-time preparation for a crisis is necessary, allowing sufficient flexibility in order to solve the specific circumstances of each potential crisis. Consequently, it is important that at the level of the European Union there are common principles, procedures and agreements regarding the cooperation between the authorities responsible for maintaining the financial stability.

2.The banking rating systems used by the surveillance authorities.

The main objective of the surveillance system is represented by the identification in an incipient stage of those banks considered inefficient, according to the evaluation criteria of the financial and operational aspects established by the monetary authority or by the manifestation of adverse trends, requiring special surveillance.

Credit risk is one of the most important risks encountered in the activity of a banking institution and it expresses the possibility that the debtors or the title issuers cannot accomplish obligations in time, as a result of the degradation of their financial situation which can be determined by the lending conditions or by the general economic situation.

In the surveillance activity, surveillance authorities generally use a top-to-bottom approach, starting from the financial reports which give a lead and reaching the particular, stressing the identification quantification, management and control of risks, all these by the help of some instruments called *early warning systems* [2]. The best known bank surveillance system is CAMEL [3], model used in The United States of America. Federal Reserve Bank evaluates credit institutions based on some events, limits etc., included in the CAMEL system. SEER Risk Bank Model (System for Estimating Examination Ratings) utilized by FED established the possibility of banking bankruptcy or severe sub-capitalization by the means of a probit-like regression. Part of the same category of early identification instruments of the credit institutions whose performance degrades is the SCOR model (Statistical Camels Off-site Rating) utilized by FDIC.

The Banking Commission in France utilizes the SAABA system based on historical data in order to evaluate possible losses at the credit portfolio level for the following three years. The diagnostic element and the alert mechanism are based on the indicator's solvability level and on the shareholding's quality.

The Bank of Italy (BdI) estimated a survival function of the credit Italian institutions by using the Cox Proportional Hazards model. This quantifies the probabilities of the appearance of some severe difficulty states at the level of the Italian banks during a period of two years. In this respect, the severe difficulty state is evaluated on the basis of bankruptcy events in the juridical sense, of the overtake of a credit institution by a stronger one from the financial point of view and in which the banking rating system (PATROL) [4] classifies the credit institution into category 4 or 5.

The new concept introduced by The Basel II Agreement is represented by the risk-based analysis [5] of banks, which presupposes a permanent analytical revision of the bank's activity, thus ensuring the maintenance of stability and trust in the financial system. This approach presupposes the extension of instruments used by the traditional banking analysis, these being starting points for anticipating risks and forming simulations, their change offering in time a dynamic image of the bank's performances. On the other hand, the financial indicators (referring to the structure of the balance, profitability, market risk and credit risk, liquidity or exchange rates) are the object of the banking surveillance, each bank having the obligation to calculate these indicators.

Taking into account the requirements of the Basel II Agreement, the elements which can be developed in the rating systems refer, in our opinion, to:

- completing the quality marking modality of the shareholding by individual ratings for each shareholder [6], among which we can mention the shareholders' financial situation, the type of shareholder, the type of reports with the credit institution etc.;

- quantifying the sensibility to the market risk;

 - measuring the credit risk by using the verified databases received from the credit

- institutions regarding credit types, activity domain, data obtained from the Banking Risk Authority (BRA) and from the Payment Incident Authority (PIA) verified by macroeconomic elements regarding the activity sectors where credit institution have investments with a considerable concentration.

3.Possibilities of improving the models of managing credit risk in banks.

For the management of a credit portfolio there are several models [7], each stressing different aspects (entrances). Thus, on the one hand, the stressed items are the historical data of the counterparty (SD, debtor's rating, non-reimbursement incidents, frequency etc.), among which we mention the CreditRisk+ or CreditMetrics models and, on the other hand, models of credit portfolio management which also take into consideration the macroeconomic indicators (CreditPortfolioView or PortofolioManager), thus positioning the counterparties in a more realistic context regarding the non-reimbursement probability.

There certainly is an impressive number of models for the management of a credit portfolio but, in our opinion, the great challenge is represented by the identification of minimal elements that must be included in composing that model by the credit institution.

In elaborating models there are some principles which have to be taken into consideration [8] (according to the recommendations of the Basel Committee):

- credit institutions must not forget that the main responsibility in the formation process is theirs;
- the model must have real predictive abilities for the risk estimations of a bank and the analysis of the way in which these are utilized in the relevant activities of the credit institutions;
- there is no universal elaboration method for these, only minimal elements that have to be introduced;
- they must comprise of both qualitative and quantitative elements;
- the process and the results must undergo independent reviews.

It is recommended for each credit institution that the entire credit risk exposure is monitored by limits and a reporting system.

In the best known scoring methodologies, the credit risk value is calculated by the method of a scoring equation:

$$Y = w_0 + w_1 X_1 + w_2 X_2 + \dots + w_n X_n, \text{ where:}$$

X_1, X_2, \dots, X_n – entrance variables of the model (in case the scoring is meant to measure the credit risk of a company, these variables usually represent indicators calculated based on the data from the financial situations)

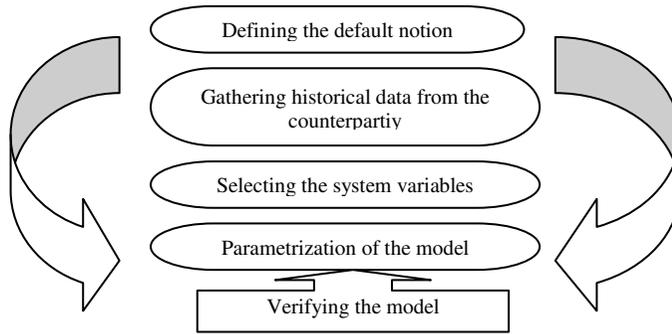

$w_0, w_1, w_2, \dots, w_n$ – interception coefficient and constant which describe the balance of the model's particular variables, the so-called *weights* (balances)

Y – the number that describes the stability/state of the entity's credit under verification and it depends on the determination of the Y bigger model, meaning a weaker evaluation of the credit; nevertheless, the relationship can also be the other way round.

The formation process of a scoring model consists of the following stages:

1. Defining the case of the neglect of duties.
2. Gathering historical data from the counterparties.
3. Selecting the variables X_1, X_2, \dots, X_n .
4. Evaluating, on the basis of historical data of the parameters $w_0, w_1, w_2, \dots, w_n$.
5. Verifying the model taking into account the forecasted accuracy.

The formation process of a scoring model

Source: created by the authors

In case a credit institution selects a *logit model* these explicative independent variables X_1, X_2, \dots, X_n with which the state of the Y entity can be modelled, the so-called dependent variables. In the scoring based on logistic regression, the state of the Y entity has the following interpretation:

$$Y = P(\text{default} \mid X_1, X_2, \dots, X_n),$$

and thus Y reflects the probability of neglect during a prolonged period, starting with the rapport date at which the variables X_1, X_2, \dots, X_n were calculated. Through such an interpretation Y , by X_1, X_2, \dots, X_n , on the basis of the linear regression and consequently the attempt to build the regression of the formula $Y = w_0 + w_1X_1 + w_2X_2 + \dots + w_nX_n$ encounters problems of a fundamental nature: Y probably belongs to the row $[0,1]$, and to the linear combination $Y = w_0 + w_1X_1 + w_2X_2 + \dots + w_nX_n$ and it can take any values $(-\infty, \infty)$.

In the models formed by the logit methodology, the Y result certainly represents a function of the default probability, during a future period, for example an year from the result calculation. Thus, through a good model calibration, the more ample the function of the neglect definition utilized for the calibration of the model, the greater Y exit results.

The evaluation and estimation systems of the credit risk implemented in the financial (banking) institutions attempt to quantify the losses that might appear as a result of the counterparty's default (payment inability). Credit risk factors are generally specific to each company, but they must also include a series of macroeconomic variables which reflect the state of the economy and the specific branches.

4.The risk profile of the banking institution –determining factor in the credit portfolio management.

In the demarches regarding the utilization of a work methodology, in order to elaborate some credit risk management models, there must be taken into consideration two items. Firstly, specialty literature should be consulted, including the requests expressed by laws, regulations, work procedures, and then there must be taken into consideration the peculiarity of each banking institution's activity. Thus, the conceptual models used for the marking system regarding the identification of credit risk to which the counterparty exposes itself before offering the credit, respectively assuming the payment engagement, must take into consideration, on the one hand, the creditor's experience in the process of offering credits and, on the other hand, the automated models of previewing the non-reimbursement possibility of the assumed engagement, this being realized by sophisticated models, estimation statistics of the counterparty's behaviour during the engagement.

The elaborated models should preferably comprise both rating and statistic elements, in the form of mathematical models, well established. The scoring function [9], which is an important step in the formation of the rating system, does not necessarily presuppose determining the non-

reimbursement probability for each counterparty, only the transfer of the risk characteristics considered relevant, in a small amount, represented by a value called score. As a result of the interconnection and classification of the scoring models, the counterparties will be included in the marking classes.

Thus, after the analysis of a hazardous sample of the clients' portfolio of a credit institution for which the balance data were available in December 2008, financial indicator like gross/nett margins, "equity ratio", "debt-equity ratio", the rapport between the operational expenses and incomes, EBIT (EBITDA), ROE, but also date referring to the debtors' behaviour as client of the banking institution (ex. debt service), together with a set of standard financial indicators (solvability, debt degree, current rate, economic profitability) which are compulsorily calculated for each client by the credit institution, there has been noticed different behaviour as regards reimbursement ability, especially if the debtor belongs or not to a different activity sector.

The econometric model of the logit type on the basis of which we estimate the probability of non-reimbursement of companies from the existing sample has the following formula:

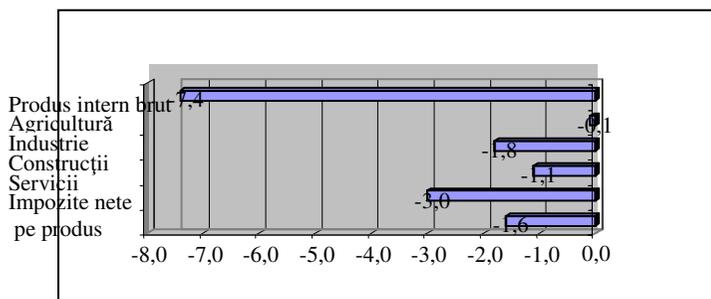

$$\log \frac{p}{1-p} = ct + \sum_i \beta_i \cdot Indicator_{Microfinan} + \sum_j \beta_j \cdot Aspect_{macroeconomic}$$

For each activity domain of the debtors in the sample there has been built a "dummy" variable, thus observing that the most important sector as representation in the sample is the services one and the least represented is the agricultural-fishing one.

In any regression we have estimates during the analyses; we have started from a specification that includes the variables for each client calculated by the credit institution: solvability, debt degree, current rate, economic profitability. In regression there were taken into consideration the linear correlations between certain indicators like the economic profitability and the debt degree, where the correlation of 97% is negative. This implies that from the two variables there must be included only one in the logistic regression and there was an option for the variable debt degree. This variable is also negatively correlated, in a proportion of approximately 98% with the variable „equity ratio”, which determines us to eliminate from the regression specification also this last mentioned variable.

As a result of the analyses there has been noticed that a company from the services sector has a non-reimbursement probability greater with 6,5 percentage points than a company in any other sector, if both companies are characterized by the same solvability and market quality. This result does not seem surprising at all for the analysis of a clients' portfolio at the end of the year 2008, a raised macroeconomic risk of the services sector compared to the other sectors. Practically, the logistic regression catches the beginning of a phenomenon latter confirmed by the macroeconomic evidences, an example being the below graphic.

The contribution of the main activity branches to the decrease of PIB during 1.I.-30.IX.2009 compared to the period 1.I.-30.IX.2008

Source: *Rapports National Statistics and the National Bank, own adaptation.*

5. Conclusions

When defining a neglect of obligations, the banking institution that forms the analysis model of the credit risk, both ex-ante and post-factum, there must exist the possibility of answering to the following question: “Which of these credit institutions wouldn’t have given a credit/wouldn’t have made that investment, had it previously known that this situation might arise?”

Extremely important in the analysis of the credit risk is determining the *default*. This presupposes the extension of the definition, for the purpose of the credit risk management, thus being subordinated to the profile of aversion towards risk of that credit institution. It is wrongly stressed the fact that the way of defining a neglect of an obligation is limited by the quality of historical data utilized in forming the model. The too detailed definition can be useful at a certain stage, as it might similarly be impossible to determine the moment whether the neglect manifested itself in the past for too many counterparties.

An individual element from CPP or BS has little importance taken singularly. A rate, on the contrary, taken as a rapport/combination between two or more elements can bring about important clues, especially if it is compared to the similar one of industry, of competitors. In Romania, such references, databases are almost absent, and the instability registered so far determines many analysts to regard this demarche without much trust. Nevertheless, this way is the only valid reference point, although it has imperfections or its realization brings about inherent implementation difficulties.

Comparisons with the industrial standards (benchmarks) are important so that all societies are influenced, to a greater or smaller degree, by the economic expansion or recession (contraction). It is unlikely that a growth of sales, profits intervenes when the economy (a certain sector) is on a descendent road. Similarly, there can’t appear a growth of activity, business volume, although it might seem attractive if it is under the industry’ average, of the main counter-candidates, this meaning loss of competitiveness and market share.

In order to overcome the eventual “contracted” degradations right from the start and which now are part of the credit portfolio, banks must conceive and implement *alarming policies*, more precisely minimum and maximum limits which offer to the board of the credit institution a continuous feedback upon the efficiency of the control process of the quality of credits, investments, so that those with problems are detected and amended (as much as possible) in time.

Notes

1. The notion of *economic stresses* the fact that measuring risk is done in the conditions of the economic realities and not based on accounting or settlement rules.

2. Moinescu, Bogdan (2007) “Sistem de previziune a evenimentelor de deteriorare a ratingului CAAMPL”, Caiete de studii, Banca Națională a României.

3. Acronym formed out of elements included in the verification process of the security and solidity of credit institutions: solvability, assets' quality, management quality, the quality of incomes and liquidity.
4. Adapting the capital, profitability, credit risk, organization, liquidity.
5. *Organization's pure risk* – utilized for the first time in 1956 by Russel Gallanger *Risk Management: A new Phase of Cost Control*, Harvard Business Review.
6. Banking rating methodologies utilized by the surveillance authorities especially represent expert systems which furnish evaluations only for the period during which the evaluation is being made, without offering signals regarding future evolutions. The ex post results must be completed based on the information furnished by the prediction instruments whose utilization offers more time for the surveillance authority to take the necessary measures.
7. A description of the formation of the scoring models based on the linear regression is presented by R. A. Johnson, D. W. Wichern, *Applied Multivariate Statistical Analysis*, 2002, Prentice-Hall or L. C. Thomas, D. B. Edelman, J. N. Cook, *Credit Scoring and Its Applications*, 2002, SIAM
8. www.bis.org.
9. The scoring function is a statistical or heuristic (subjective) method which offers the possibility to organize counterparties according to the risk level, level established either by the credit analyst (by verifying the counterparty's characteristics considered relevant, based on a manual or evaluation form conceived by the institution) or automatically calculated by the help of a statistical model (created on the basis of an initial data set which comprises interest characteristics and the registered events of non-reimbursement) or as a combination of the two.

CENTRAL AND EASTERN EUROPEAN COUNTRIES IN EUROPEAN UNION – IMPACT OF FOREIGN DIRECT INVESTMENTS

Apolzan Carmen

West University, Timișoara , Romania

Faculty of Economics and Business Administration

Economic integration refers to trade unification between different states , and one of its most important aspects is liberalisation of capital movement. In this paper is presented a brief evolution of economic integration cases focusing on one of the most integrated economies – European Union. We concentrate on the participation of foreign investors in different economies and their impact, taking the example of Central and Eastern European Countries and their markets. Also , the level of influence that direct investments in capital markets entails on the Stock Exchange evolution is presented for the case of Romania .

Keywords: European Union, foreign direct investments, capital markets, CEEC

JEL classification: E20, E22, E44

1. Introduction

Economic integration refers to trade unification between different states by the partial or full abolishing of customs tariffs on trade taking place within the borders of each state. This is meant in turn to lead to lower prices for distributors and consumers (as no customs duties are paid within the integrated area) and the goal is to increase trade. The trade stimulation effects intended by means of economic integration are part of the contemporary economic [Theory of the Second Best](#): where, in theory, the best option is [free trade](#), with [free competition](#) and no [trade barriers](#) whatsoever. Free trade is treated as an idealistic option, and although realized within certain developed states, economic integration has been thought of as the "second b". The framework of the theory of economic integration was laid out by [Jacob Viner](#) (1950) who defined the [trade creation](#) and [trade diversion](#) effects, the terms introduced for the change of interregional flow of goods caused by changes in customs tariffs due to the creation of an economic union. He considered trade flows between two states prior and after their unification, and compared them with the rest of the world. His findings became and still are the foundation of the theory of economic integration.

The basics of the theory were summarized by the [Hungarian economist Béla Balassa](#) in the 1960s. As economic integration increases, the barriers of trade between markets diminish. Balassa believed that supranational common markets, with their free movement of economic factors across national borders, naturally generate demand for further integration, not only economically (via monetary unions) but also politically—and, thus, that economic communities naturally evolve into political unions over time.

The dynamic part of international economic integration theory, such as the dynamics of [trade creation](#) and [trade diversion](#) effects, the [Pareto efficiency](#) of factors (labor, capital) and value added, mathematically was introduced by Ravshanbek Dalimov. This provided an interdisciplinary approach to the previously static theory of international economic integration, showing what effects take place due to economic integration, as well as enabling the results of the non-linear sciences to be applied to the dynamics of international economic integration.

2. Recent examples of economic integration

The experience of economic integration, as currently understood, starts with the creation of the [Union of South Africa](#) (1910), which was further implemented in the Belgium-Luxemburg economic union, [Benelux](#) (1944), and the [European Coal and Steel Community](#) (1951).

Economist [Fritz Machlup](#) traces the origin of the term 'economic integration' to a group of five economists writing in the 1940s, including [Wilhelm Röpke](#), [Ludwig von Mises](#) and [Friedrich von Hayek](#). Economic integration was a foundational plank of US foreign policy after World War II.

The [USA](#) is also economically and politically integrated, as it has unified 50 different states (the US states), but the current political and economic structure was achieved via civil war, and not by steady peaceful development according to the stages of economic integration.

An example of recent unprecedented development of economic integration is the formation of the East Asian Free Trade Area (EAFTA): [ASEAN](#) has proposed that Japan (along with India and China) join EAFTA, and at first Japan declined to do so. China's consent to enter EAFTA has forced Japan to sign on, since otherwise Japanese goods would become cost-inefficient (more expensive) and hence lose competitiveness both regionally and globally.

Probably one of the most integrated economies today, between independent nations, is the [European Union](#) and its [euro zone](#). The **European Union (EU)** is an [economic](#) and political union of 27 [member states](#), located primarily in [Europe](#). Committed to [regional integration](#), the EU was established by the [Treaty of Maastricht](#) on 1 November 1993 upon the foundations of the [European Communities](#).

The EU has developed a [single market](#) through a standardised system of laws which apply in all member states, ensuring the [free movement of people, goods, services, and capital](#). It maintains common policies on trade, [agriculture](#), [fisheries](#) and [regional development](#). Sixteen member states have adopted a common currency, the [euro](#), constituting the [Eurozone](#). The EU has developed a limited role in foreign policy, having representation at the [World Trade Organization](#), [G8](#), [G-20 major economies](#) and at the [United Nations](#). It enacts legislation in justice and [home affairs](#), including the abolition of passport controls by the [Schengen Agreement](#) between [22 EU and 3 non-EU states](#).

The WTO is one of the engines of international economic integration, as it has been pushing the states around the world towards decreasing the tariffs: their average level sharply dropped from 45-50% in 1950s to 4-5% in 2000. Global economic integration de-facto will be in place when the level of tariffs equals 1-2%. Due to rapid development of the worldwide web the global competition pushes traders and the states worldwide to gradually decrease tariffs. The driving forces of trade which seeks maximization of profits and extra-cutting the costs may seem as being independent, but they all simultaneously push towards one same goal - global economic integration.

3. Foreign Investments in Central and Eastern European Countries after joining European Union

After the end of the traditionally not very intensive external relations between CEECs and EU before 1989/90, CEECs started to seek for stronger economic integration into the Western markets, terminating their rather strong orientation towards Russia. In addition to Trade and Cooperation Agreements with the EU, far-reaching Association Agreements, the so-called Europe Agreements (EAs), started to get into force. The first of the so far ten EAs with CEE countries have been signed at the beginning of the 1990s.

The integration of CEE countries into the European Union accelerated the integration of CEE capital markets into the international and European capital markets. The major economic factors behind this integration of capital markets are improved possibilities for risk diversification and for future returns which the CEE capital markets could offer to international investors.

International mobility of capital is extremely important for transition countries. Due to the general lack of domestic savings in these countries, capital inflows are necessary for complementing the finance of domestic investments and thus for growth and employment, influencing the macroeconomic situation. For Estonia 26.4% of gross fixed capital formation has been financed by foreign direct investment in 1994 to 1998; a huge amount of foreign finance of domestic investments can also be found in Hungary (25.2%), Poland (16.6%) as well as in the Czech Republic (11.2%). The extent of capital inflows simultaneously depends on the progress in the process of transition. However, the import of large amounts of foreign capital increases a country's vulnerability to the fluctuation of capital inflows and its dependence on international markets and investors or foreign governments. This vulnerability decreases if short-term capital inflows are not denominated in foreign currency as well as if the majority of capital inflows is not (more) short-term FPI, but FDI -which in the case of transition economies seems to be closely linked to the success in the process of privatisation. Simultaneously, FDI inflows do not substitute but complement for domestic investment. In addition, the diversification of investment-related risks as well as the improvement of international trade conditions can be achieved by sound and prudent capital outflows.

In 2008, inward FDI flows in analyzed countries- Bulgaria, Czech Republic, Hungary, Poland, Romania, Slovakia, Slovenia, reached a new record high, despite the global financial and economic crisis. The growth rate of inflows was high, especially in the first half of 2008. However, with the crisis deeply affecting several countries by late 2008, initial hopes that the region would prove relatively immune to the global turmoil evaporated. Inward FDI flows to the group in 2008 were unevenly distributed, four countries together accounted for the lion's share (77%) of the group's total inflows: Poland (\$16.5 billion), Romania (\$13.3 billion), the Czech Republic (\$10.7 billion) and Bulgaria (\$9.2 billion). As many companies scaled back or suspended their expansion plans due to the global financial crisis, FDI inflows into Poland and Bulgaria declined considerably in the end of 2008, but in the Czech Republic and Hungary they did not change significantly, despite increasing macroeconomic problems in both countries. For many years the automotive industry has been the key driver of strong FDI inflows to the new EU member countries, but the decline in euroarea car sales that began in the last quarter of 2008 has revealed the region's vulnerability on account of its heavy reliance on the industry.

Outward FDI from the region slow down in 2009. However some Russian TNCs with large cash reserves, but which are new to foreign expansion, expanded in early 2009 despite the financial crisis. For example, Surgutneftgaz bought 21.2% shares in the National Hungarian Oil Company, MOL, from the Austrian National Oil Company OMV for \$1.4 billion, marking the first major acquisition abroad by that Russian company.

4. Impact of foreign investments on Romanian Capital Markets

Taking into consideration the evolution of capital markets after integration in European Union, we must emphasize two factors that have influenced the growth of securities markets in the CEECs: the early development of a government debt market, and the method of privatisation chosen. Stock markets are generally more developed in countries where privatisation has been organised through the use of vouchers, such as the Czech and Slovak Republics. In the latter countries market infrastructure and regulation has been put in place after a rudimentary securities market had already developed (ex-post), in response to the needs of market participants. In other countries, such as Poland and Romania, the opposite was the case: privatisation occurred more gradually and through initial public offerings, after the necessary regulation had been put in place. In this ex-ante approach, with an emphasis on high fiduciary and disclosure standards, capital markets developed more gradually

However, not only privatisation played a crucial role. Also, the development of secondary markets in government securities was important, even if the primary purpose for policy makers has been the satisfaction of the government's borrowing needs. Secondary public debt markets provide liquidity to investors, incentives for financial market development and support interest rate liberalisation. In Hungary, for example, the existence of a liquid government securities market has contributed significantly to the growth of a wider securities market, and is considered as an important achievement in Hungarian financial sector reform.

In Romania, privatization of industry was pursued with the 1992 transfer of 30% of the shares of some 6,000 state-owned enterprises to five private ownership funds, in which each adult citizen received certificates of ownership. The remaining 70% ownership of the enterprises was transferred to a state ownership fund, with a mandate to sell off its shares at the rate of at least 10% per year. The privatization law also called for direct sale of some 30 specially selected enterprises and the sale of "assets" (commercially viable component units) of larger enterprises.

Financial and technical assistance continued to flow in from the U.S., European Union, other industrial nations, and international financial institutions facilitating Romania's reintegration into the world economy. The International Monetary Fund (IMF), World Bank (IBRD), the European Bank for Reconstruction and Development (EBRD), and the U.S. Agency for International Development (USAID) all had programs and resident representatives in Romania. Romania also attracted foreign direct investment, which in 2008 rose to \$72 billion.

Romania signed an Association Agreement with the EU in 1992 and a free trade agreement with the European Free Trade Association (EFTA) in 1993, codifying Romania's access to European markets and creating the basic framework for further economic integration. At the Helsinki Summit in December 1999, the European Union invited Romania to formally begin accession negotiations. In 2002, the target date of 2007 was set for Romania, along with Bulgaria, for its accession efforts. This was confirmed in 2003 at the Thessaloniki Summit and then in early 2005 Romania and Bulgaria signed the adherence treaty to EU. They formally joined the EU on January 1, 2007.

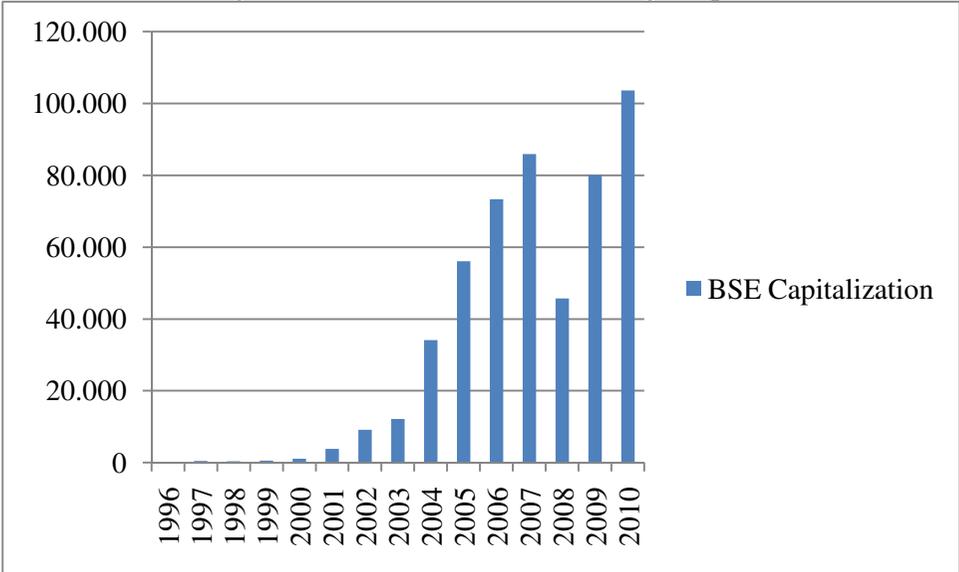

Growth in 2000-07 was supported by exports to the EU, primarily to Italy and Germany, and a strong recovery of foreign and domestic investment. Domestic demand is playing an ever more important role in underpinning growth as interest rates drop and the availability of credit cards and mortgages increases. Current account deficits of around 2% of GDP are beginning to decline as demand for Romanian products in the European Union increases. Recent accession to the EU gives further impetus and direction to structural reform.

In Romania, the main regulated Stock Exchange is the Bucharest Stock Exchange. After a break for 5 decades, the Bucharest Stock Exchange was reestablished in 1995, first trading day is November 20, 1995, days that were traded 905 shares of 6 companies listed. Since reopening, the exchange has seen a continuous development. An important moment in the evolution of this scholarship is the merger with RASDAQ Exchange in 2004. Thus, in 2007 a total capitalization of the Bucharest Stock Exchange approached the threshold of \$ 12 billion and represent over 17% of GDP, thereby decreasing the gap with the stock market the most advanced Central and Eastern Europe.

According to S & P, Romanian Stock Market registered a 69.7% annualized growth in the period before EU integration, 2002-2006. During this period, Romania has the highest return on capital markets, other countries located around the same level of 60% as Bulgaria, Kenya and Ukraine. After Romania's EU integration, Romanian capital market saw an annual increase of 15 to 25% in 2007.

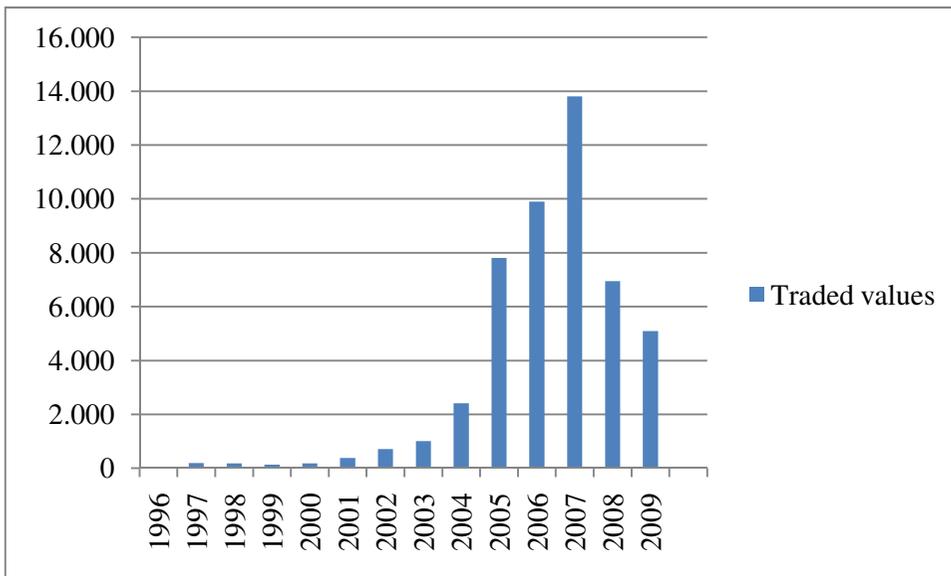

In October 2008 financial crisis caused the stock minimum both in developed markets and emerging ones. In 2008, accounted for BSE and to all participants on the domestic stock market one of the most difficult periods in modern history of capital market in Romania. After nearly a decade in which major indicators and indices of BSE have described an ascending trend, pronounced and sustained in recent years associated effects of accession of Romania to the European Union, 2008 was marked by the abrupt reversal of the upward trend of quotations and sensitive reduction of the overall stock market liquidity.

Figure no. 1 Bucharest Stock Exchange Capitalization

Source: Bucharest Stock Exchange

Figure no. 2 Traded values on Bucharest Stock Exchange

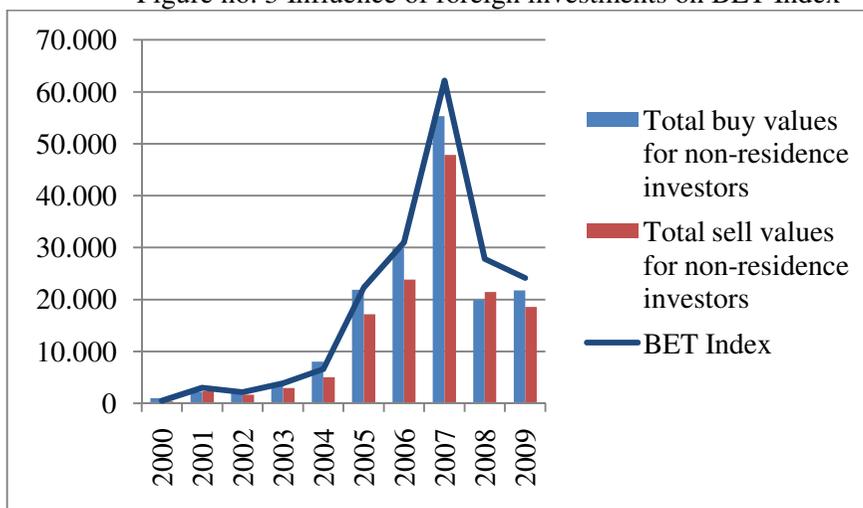

Source: Bucharest Stock Exchange

One of the most important element to influence market evolution is the foreign investors' behaviour. Starting with 2004 foreign investors are more and more attracted by Romanian capital market since it proved to bring great returns and more stability in the perspective of a future integration in EU. Romanian capital market developments have naturally reflected in the investment funds with exposure in this market. For example, East Capital Balkan Fund-fund with the largest exposure on the Romanian market of all funds managed by East Capital (12.1% in Romania) - had a dramatic increase of 239.6% during 2004 to 2007.

Analyzing the correlation between foreign investments and BSE - BET Index evolution, one can easily distinguish a strong bond between the two variables. Year 2008 proved the main vulnerabilities of this market against retiring of foreign institutional investors that caused a drop of 55% of BET Index.

5. Conclusions

Economic integration refers to trade unification between different states by the partial or full abolishing of customs tariffs on trade taking place within the borders of each state. One of the most developed form of integration is European Union, Central and Eastern European countries taking the first steps to integration in 1993. Evidence prove that accession in EU comes with important foreign investments, situation that creates great benefits for an economy. Large amounts of inward FDI constituted the engine for a quick development in CEEC's economies. The recent crisis showed that large exposures that Central and Eastern European Countries have towards foreign investors can cause great turmoil once these funds exit the economy.

EMPIRICAL EVIDENCE ON THE RELATIONSHIP BETWEEN MERGERS & ACQUISITIONS AND THE ROMANIAN STOCK MARKET

Based on empirical studies and theoretical evidence, the paper investigates the relationship between mergers and acquisitions in Romania and Romanian stock market, described by the BET and BET-C indexes. By using the Granger causality test for the number of mergers and acquisitions, the research results suggest that, for the market and period considered, one way and both ways relationships are present.

Keywords: Mergers, Acquisitions, Granger Causality, Stock Market Index

JEL code: G34; G30.

Introduction

An important issue which regards mergers and acquisitions activities (M&A) and the stock market is whether M&A can be used as a predictor for the stock market performance or whether the stock market exerts an influence over the M&A market, and which one influences the other in a more significant manner. The practical relevance of the matter is determined by the fact that stock market performance can be used as a determinant factor for mergers and acquisitions and vice-versa. While the issue remains open for discussion, there are many previous studies that use a variety of approaches in order to determine the before mentioned relationships.

In one of the earliest relevant studies on the issue, Nelson (1959) used quarterly data to investigate the relationship between merger activity, stock market prices and industrial production over the period 1895-1956. By using simple regression analysis, he found that there was a positive and significant relationship between merger activity and stock market prices between 1895 and 1920 and 1895 and 1956.

In more recent studies, Clarke and Ioannidis (1996) investigated the relationship between merger activity and the stock market by using two measures of merger activity (number and value) in the UK, with quarterly data from January 1971 to April 1993, on one side, and the London Stock Market Index, on the other side. In their case, the Granger causality test shows that “real” stock market prices “Granger cause” both numbers and real values of mergers.

Another milestone study was developed by Sharma and Mathur (1989), in which the results of the study, based on the Granger test for causality, indicated very strong causality going from stock market prices to merger activities. They also found that increases in stock market prices lead to increases in the number of mergers being completed.

Other studies have produced contrary results to the ones previously mentioned. Geroski (1984) looked at the relationship between mergers and the stock market index and found no link between mergers and stock prices. He also found that correlations between the

variables considered were unstable. Guerard (1989) found no evidence of “Granger causality” running from stock prices or industrial production to mergers in US data during 1895-1964.

A highly relevant study regarding emerging markets made by Harvey (1995) shows that these markets are characterized by high returns and high risks. When he analyzed the predictability of emergent markets, he concluded that they are more likely than developed markets to respond to local information. The results are relevant for this paper due to the fact that the mergers and acquisitions market is a carrier for high volume of information that may be used by investors.

Based on previous empirical studies and theoretical evidence, in this paper we investigate the relationship between **mergers and acquisitions in Romania** and the **Romanian stock market described by the BET and BET-C indexes**.

1. Data

To prove the relationship between mergers and acquisitions and the stock market we used quarterly and semestrial data on the number of mergers and acquisitions in Romania from January 2000 to December 2009. The BET and BET-C indexes were chosen as the measure of stock market performance resulting in the usage of six indicators as follows:

MA_QUART	Quarterly Number of M&As
MA_SEM	Semestrial Number of M&As
BET_QUART	Quarterly BSE index of the most liquid 10companies
BETC_QUART	Quarterly BSE index of all listed companies
BET_SEM	Semestrial BSE index of the most liquid 10companies
BETC_SEM	Semestrial BSE index of all listed companies

Augmented Dickey-Fuller Unit Root Tests were performed for all data series in order to check the stationarity condition and the first difference was used to stationarise the number of mergers and acquisitions series both for quarterly and semestrial data.

2. Methodology and Results

To test whether stock market activity is a useful predictor of mergers or vice-versa, we used the Granger causality approach (Granger, 1969; Sims, 1972). The basic idea behind this is that “cause cannot come after effect” and that “correlation is not the equivalent of causality”. If in a set of two covariance stationary variables, the lagged values of variable “x” affect variable “y”, then “x” can be used to predict “y”, i.e. “x” “Granger causes” “y”. The approach to the question of whether “x” causes “y” is to see how much of the current “y” can be explained by past values of “x” and then to see whether adding lagged values of “x” can improve the explanation of “y”. “Y” is said to be Granger-caused by “x” if “x” helps in the prediction of “y” or, equivalently, if the coefficients on the lagged values of “x” are statistically significant.

For the optimum lag length, being the shortest lag for which no autocorrelation is found in either of the equations entering the VAR, we have tested all instances for which Granger causality tests will be performed using the following lag length criteria: Sequential modified LR statistic test (each test at 5% level), Final prediction error, Akaike information criterion, Schwarz information criterion and Hannah-Quinn information criterion. The following optimum lag lengths have resulted:

Series	Optimum lags
MA_QUART	1
MA_SEM	1
BET_QUART	1
BETC_QUART	1
BET_SEM	1
BETC_SEM	1

We first test for “Granger causality” between the number of mergers and acquisitions on a quarterly basis and the BET stock market index. The first results show that the hypothesis of “non-causality” from quarterly stock market returns to quarterly number of acquisitions was rejected at 5% level of significance. We were not able to reject the complementary hypothesis that acquisitions do not “Granger cause” stock market prices.

Table 1:

Causality between the quarterly number of mergers and acquisitions and BET stock market index from January 2000 until December 2009

Lags: 1			
Null Hypothesis:	Obs	F-Statistic	Probability
MA_QUART_D1 does not Granger Cause BET_QUART	38	0.24538	0.62345
BET_QUART does not Granger Cause MA_QUART_D1		6.16241	0.01799

The same conclusion is drawn when examining the causality relationship between the number of acquisitions and BET-C stock market index. For the considered lags, the hypothesis of “non-causality” from stock market performance to mergers and acquisitions was rejected at 5% level of significance. We were not able to reject the complementary hypothesis that acquisitions do not “Granger cause” stock market prices.

Table 2:

Causality between the quarterly number of mergers and acquisitions and BET-C stock market index from January 2000 until December2009

Lags: 1			
Null Hypothesis:	Obs	F-Statistic	Probability
MA_QUART_D1 does not Granger Cause BETC_QUART	38	0.00048	0.98264
BETC_QUART does not Granger Cause MA_QUART_D1		5.28758	0.02756

As a sum up, we can clearly state that, for the considered time period, market and data frequency evidence of one way causality between the stock market and acquisitions was discovered. This means that a growing market represents a sufficient incentive to attract companies to make acquisitions on the considered market. The same cannot be said vice-versa, meaning that the volume of mergers and acquisitions does not exercise influence on the stock market.

*Table 3:
Causality between the number of mergers and acquisitions and BET stock market index from
January 2000 until December 2009 on a semestrial basis*

Lags: 1			
Null Hypothesis:	Obs	F-Statistic	Probability
MA_SEM_D1 does not Granger Cause BET_SEM	18	8.02696	0.01259
BET_SEM does not Granger Cause MA_SEM_D1		3.45516	0.08279

The findings presented Table 3 show that, for a 10% level of significance, the hypothesis for non causality can be rejected in the case of the stock market index “does not Granger cause” the number of acquisitions. In contradiction with the observed results, in the case of quarterly data, the number of mergers and acquisitions on a semestrial basis “Granger causes” the BET index.

*Table 4:
Causality between the number of acquisitions and BET-C stock market index from January 2000
until December 2009*

Lags: 1			
Null Hypothesis:	Obs	F-Statistic	Probability
MA_SEM_D1 does not Granger Cause BETC_SEM	18	3.72740	0.07265
BETC_SEM does not Granger Cause MA_SEM_D1		3.96562	0.06497

The conclusion resulting when examining the causality relationship between the number of acquisitions and BET-C market index in a semestrial frequency is that, for the considered lags, the hypothesis of “non-causality” from stock market returns to acquisitions was not rejected at 10% level of significance. We were also able to reject the complementary hypothesis that acquisitions do not “Granger cause” the BET-C stock market index.

Bellow we provide a sum up of the results regarding the causality findings between the number of mergers and acquisitions and the Romanian stock market:

*Table 5:
Sum up of the Granger causality tests*

Instance	Significance	Lags
Number of M&As “Granger cause” the:		
Quarterly BET index	Not significant	1
Quarterly BET-C index	Not significant	1
Semestrial BET index	Significant at 5%	1
Semestrial BET-C index	Significant at 10%	1
Number of M&As is “Granger caused” by the:		
Quarterly BET index	Significant at 5%	1
Quarterly BET-C index	Significant at 5%	1
Semestrial BET index	Significant at 10%	1
Semestrial BET-C index	Significant at 10%	1

3. Conclusions

The results found in this paper are consistent with the findings of Clarke and Ioannidis (1996) and Sharma and Mathur (1989), in the way that stock market prices “Granger cause” acquisitions.

The first results show that the number mergers and acquisitions are “Granger caused” by stock market prices represented by the BET and BET-C indexes, adding to the theory that CEOs’ decisions to merge with or acquire companies are strongly influenced by the respective stock market evolution, driven by the perspective of high future market capitalisation.

In the case of semestrial data regarding the causality relation between the number of mergers and acquisitions, two way causality was found for the BET index and BET-C index. Even though the semestrial frequency data results have less statistical significance than in the case of quarterly frequency data results, proof is still found that the stock market “Granger causes” acquisitions and strong proof is found that the volume of mergers and acquisitions “Granger causes” stock market prices.

Overall results indicate that a solid or unstable stock market does indeed encourage or, respectively, discourage CEOs to initiate costly merger and acquisition transactions. Even though the market may act as a safety net in case of failed mergers and acquisitions, the success of such actions cannot be fully ensured by a growing market, thus a high volume of mergers and acquisitions fail even during favourable market periods. The results of this paper also indicate that informational content provided by M&A activity can be used as a predictor for the stock market performance.

THE PERSPECTIVES OF EURO INTEGRATION IN ROMANIA, IN THE UNCERTAINTY CONTEXT AROUND THE FOREIGN MARKETS

Ciobanu (Sireteanu) Elena
„Alexandru Ioan Cuza” University of Iași
Faculty of Economics and Business Administration
Doctoral School of Economics

This paper has the object to analyze to what extent Romania fulfils the Maastricht criteria in comparison to some countries which are candidate members from Central Europe, in the today's unfavorable context which has been achieved under the actual global financial and economic crisis and with an important impact on the disfunctionalities which appeared in the emergent economies and also in those from the Euro Zone. Romania's modernization towards the European Monetary Union is a complex and hard process which contains real and coherent economical policies pointed towards the accelerated diminution of the economic development differences and that is why a quick adoption of Euro, at this moment it is not an alternative.

Keywords: nominal convergence, real convergence, global crisi, exchange rate mechanism II, euro area

JEL classification: F33, F36

Introduction

Since it is known, starting from the 1st of January 2007, Romania is a member state of the European Union, with a status of “state with derogation”, because at the time of joining it did not comply with all the criteria demanded by the European Monetary Union (EMU), stated by the Maastricht Treaty. However, though the new members bind to join the Euro Zone as soon as they fulfill all the nominal convergence criteria, these cannot choose the way out from the euro zone, a possibility which is approved for any of the actual members of the E.U (Denmark and U.K). Sweden also has not achieved permanent derogation, but it postpones the adoption of the euro currency because it does not fulfill all conditions imposed by the treaty.

The joining of the European Union and also the entrance in the euro zone can be seen as stages in the process of acceleration and diminution of the gaps in the economical development. Also, the adoption of an unique euro currency represents the finality of a complex process of convergence, not the beginning of one, in particular, it does not eliminate the necessity of solving the macro economical unbalances which exist between the countries.

The broach of the participation in the ERM II⁹⁴³ represents a very important component for the trajectory of the Romanian economy towards the integration in the EMU. That is why, the moment of integration in the ERM II must be chosen so that a two year term for the participation in this exchange currency mechanism must be sufficient for the satisfaction of all nominal convergence criteria, before the adoption of Euro in Romania.

The fulfillment of all nominal criteria for the entrance in the euro zone must not determine a decrease of the importance granted to the real convergence process. However, without the recording of major progress in the real convergence domain, the sustainability of the nominal convergence is being severely affected. Regarding the existence of some relations between the nominal convergence and the real one, also between the community's institutions and national authorities from the E.U. countries, we could say that there is a consensus, meaning that the two

⁹⁴³ Exchange Rate Mechanism II.

processes must be realized in the same time, as some authors sustain⁹⁴⁴ “the nominal convergence and the real convergence are two sides of the same coin, and must be realized simultaneous” The practice demonstrates that, the national authorities from the E.U member countries have been concerned on the realization of the nominal convergence, for the fulfillment of the conditions imposed for the E.U. joining, being in its essence a practical decision.

The process of nominal convergence

The Maastricht Treaty brings in front of the candidate states a series of criteria, extremely precise and strict economical objectives, whose accomplishment fallows actually the nominal convergence for the introduction of the euro, and these must be totally respected and in a sustainable manner.

The Treaty does not contain a strict calendar for the adoption of the euro currency; this process is left at the latitude of each country in consulting with the European Commission and the Central European Bank.

Table no.1 contains the principal indicators of nominal convergence established by the Treaty and the way in which these criteria will be achieved by Romania in the period before and after the joining of the E.U.

Romania has continued the process of disinflation also after the joining of the E.U., with interruption of this tendency in 2008, where we can see an increase than the year 2007, with 3.01 procentual points, a situation determined at first by the numerous heterogeneous factors and also by those exogenous (the increase of international prices for the manufacture materials and for the fuel).

The dynamic of the inflation rate between 2006-2009, reflects in terms of nominal convergence indicators, a surpass of the nominal criteria with 3.85 procentual points for the year 2009.

Regarding the criteria of interest rates on long term, this was far from the reference criteria in 2008, and also in 2009, on the background of financial turbulences which have marked the increase of aversion towards the risk from the financial investors.

Between 2006-2008, the variation of the exchange rate for the national currency in comparison with the euro has not been excelling the standard band of $\pm 15\%$ from the reference level. But, starting from the 4th trimester of 2008, the crisis global effects have been reflected also on the financial market, and the reevaluation in an ascendant level of the associated risk for Romania has conducted to a depreciation tendency for the RON which has been accentuating during 2009, passing 18% percent.

Regarding the importance of the consolidated budget deficit in GDP, this has been situated between 2006-2007 under the level established through the Maastricht Treaty. The increase of the public costs and the powerful decrease of the GDP's dynamic, starting with the 4th trimester from 2008, have influenced in an unfavorable way the balance between the budget deficit and the GDP, in 2008 and also in 2009, overtaking significantly the value of 3% from the reference criteria. As a consequence of these financial inadequate evolutions, from October 2009, Romania has been put under the procedure of excessive deficit. On all the period being analyzed, the public debt of Romania continued to register net levels inferior than the Treaty's⁹⁴⁵ concerted stipulated limit.

Enciclopedică, București 2005, p.6.

⁹⁴⁵ According to estimates made by the IMF, during the evaluation mission from trim. I. of 2010, Romania, in 2010 can afford a level of public debt exceeding 35% of GDP.

Table no. 1 Nominal convergence indicators for Romania in 2006-2009

Nominal Convergence Indicators	Maastricht Criteria	Romania			
		2006	2007	2008	2009
Inflation rate (HICP) (percent, annual average)	<1.5 pp above the three best performing Member States 4.0 percent for 2008 1.6 percent for 2009	6,56	4,84	7,85	5,6
Long- term interest rates (percent, per annum)	<2pp above the three best performing Member States 6.2 percent for 2008 5.3 percent for 2009	6,51	6,7	7,7	9,7
Exchange rate (vs. euro)	+/- 15 percent	+6,4/ -9,1	+11,0/ -6,4	+9,7/ -14,6	+1,6/ -18,2
General government deficit (percent of GDP)	Below 3 percent	-1,9	-3,2	-5,4	-7,9
Government debt (percent of GDP)	Below 60 percent	12,4	12,6	13,6	21,0

(HICP) – Harmonized index of consumer prices according to Eurostat methodology

Source: revised after ECB, Convergence Report, May 2008, NBR, Monthly bulletin, December 2009 and www.bnr.ro

As well as it have been presented before, neither the inflation rate, nor the level of interest, the exchange rate or the budget's deficit are not at the moment at an European level, only one criteria from all of these five is under the reference level of values, but bringing them in tolerable limits is quite hard.

In comparison with the other Central-European countries, which are candidates for the EMU, Romania's performances registered in the convergence process are weaker than those of the others, as well as it can be observed in the table no.2.

On March 24, 2010, the European Commission assessed the convergence programs for the period 2009 -2012 in the Czech Republic, Poland, Romania and Hungary. Evaluated programs showed a debt to GDP below 60% over the period 2009 -2012, concerning the Czech Republic, Poland and Romania.

Regarding Romania, according to the recommendations of the E.U. Council, it aims at reducing the public deficit from 7.9% of GDP to 3% of GDP in 2012. Planned fiscal adjustment is concentrated in the early period (2010 to 2011).

European Commission underlines that Romania's convergence program details not sufficient consolidation measures to be taken in 2011 and 2012, however, it is expected in the medium term the budgetary framework from 2011 to 2013 to include more information.

Following the fiscal developments in the period 2008 - 2009, in the above table, we see that in most euro area countries, fiscal positions have seen a marked deterioration. Thus, the end of 2009 was the highest since the establishment of EMU budgetary deterioration, when 14 of the 16 Euro Zone countries have seen share of GDP public deficit higher than the 3% level. Finland and Luxembourg were the only countries where the government deficit has remained within the limits set by the Stability and Growth Pact. Most inappropriate developments have been recorded on three countries: Greece (-12.7% of GDP), Ireland (-11.7% of GDP) and Spain (11.4% of GDP).

Table no.2 The way of fulfilling the Maastricht Treaty Criteria, 2008

	HICP	Long-term	Exchange	General	General	Nr.
--	------	-----------	----------	---------	---------	-----

	(percent annual average)	interest rate (percent per annum)	rate vis-à-vis euro	government surplus (+) or deficit (percent of GDP)	government debt (percent per annum)	Fulfilled criteria
<i>Criterion</i>	4,1	<6,24	+/-15	-3	<60	5
<i>Czech Republic</i>	6,3	4,6	+20,9/ -3,5	2,1	30,0	3
<i>Hungary</i>	6,1	8,2	+11,3/ -10,6	3,8	72,9	1

Source: ECB, Monthly Bulletin, March 2010, p. 84

Most Euro Area countries are subject to excessive deficit procedures (13 Countries), except Cyprus, Finland and Luxembourg and which will initiate the process of fiscal consolidation starting from 2010 / 2011, according to the recommendations of the excessive deficit procedures. A similar situation is found in the case of the indicator which reflects the share of public debt to GDP, across the Euro Zone, which increased from 69.4% in 2008 to 78.7% in 2009. Looking at the individual level, we find that in 2009, only six Euro Zone countries - Cyprus, Luxembourg, Spain, Slovenia, Slovakia and Finland - have recorded levels of public debt below 60% of GDP.

With a debt of 113.4% of GDP and a budget deficit of 12.7% of GDP, Greece is in the worst situation, with great difficulty to meet deadlines. It is not the only country causing concern in the Euro Zone, there are also some others (Ireland, Spain, Italy).

Adverse fiscal developments were caused, in general by many factors: (i) the financial crisis and economic downturn have led both to decreased tax revenues and increased social spending and structural costs, (ii) the adoption by the central government from Euro Zone of consistent packages of tax incentives, (iii) many countries have adopted comprehensive measures to stabilize the financial sectors, which influenced the public debt ratio in 2009. According to the stability programs 2010-2012 submitted by Euro Zone countries, the European Commission shows that most countries are now subject to excessive deficit procedures which were designed to reduce the public deficit ratio to GDP below 3%, by 2012, while the share of public debt to GDP euro area is projected to rise further to 87.3% in 2012.

Those described above, show that public budgets of big countries in Europe have deteriorated and remain without prospects for the next period, and funding imbalances in the future Member States would be very difficult.

Real convergence process

The Maastricht Treaty does not explicitly mention the real convergence criteria, but are equally important for the euro currency.

The assessment of the opportunities into the Euro Zone is considering and analyzing indicators such as: GDP per inhabitant, the structure of the national economy branches (% of GDP), the openness of the economy, foreign trade and its degree of integration into EU and the costs of labor.

GDP per inhabitant expressed in purchasing power standard, rose in a sustained process of catching up to the euro area externally, reaching in 2008 to a level about 40 % of GDP per person for the Euro Zone. All these developments occurred as a result of sectorial structure of economic convergence. The openness of the Romanian economy has continued during 2002 - 2008 around 75%, while the EU is the main trading partner, but in the year 2009, the indicator fell to 68% mitigation fund export controls. Also, in terms of Romanian financial system development, it is highly integrated into the European Union, however, there are indirect financial intermediations to levels lower than the Euro Zone.

Projections for euro adoption

The euro currency adoption requires participation for at least 2 years in ERM II mechanism (Exchange Rate Mechanism II).

This mechanism performs a dual role, representing the same exchange rate arrangement for the currency of the candidate countries integration into the EMU and a nominal criterion for accepting the Euro Zone. The first situation involves keeping an ERM II standard fluctuation band against the euro of $\pm 15\%$. Nominal convergence criteria for euro area entry were presented in Table 1. To establish a coherent timetable for adopting the single currency, there have been made two fundamental decisions related to the entry into the ERM II mechanism and duration of participation in this mechanism.

The European Central Bank recommended that the entry into the ERM II mechanism should be made after that country's EU accession and participation in ERM II period would not be exceeding the mandatory period of 2 years. This implies that the countries have enhanced macroeconomic stability at the time of entry into the mechanism. It is also an important achievement of a sustainable manner of nominal convergence criteria.

For Romania, the euro involves three steps:

- the period before entry into the Exchange Rate Mechanism II, which requires consolidation of disinflation, financial market development and convergence of long-term domestic interest

rates, the relative stability of the RON exchange rate around the long-term equilibrium level and deepening structural reforms;

- the second step towards the entry into ERM II is planned for 2012. Time was chosen taking into account the need for meeting the nominal convergence criteria while achieving significant progress in the process of real convergence;
- entry into the Euro Zone was expected by the year 2015.

Since that time, Romania will participate in the mechanisms of coordination of economic policies of the euro area, and should comply with the Stability and Growth Pact, which is related mainly to finance public health. Also, Romania will adopt the common monetary policy of the European Central Bank and will need to have mechanisms for automatically balancing the economy and increase the speed of reaction of fiscal policy to symmetric/asymmetric shocks which will be confronted with the domestic economy.

Conclusions

The euro in 2015 should be one of strategic targets for Romania. In these circumstances the provisions Convergence Programme for Romania's accession to the Euro Zone would be a possible correlation between the achievement of nominal convergence and real convergence. But without consolidating disinflation, increasing the competitiveness of Romanian exports, and increase predictability and performance of medium-term fiscal policy, also increased absorption of EU funds and strengthen structural reforms, the euro will become a target of increasingly distance.

In this context, National Bank of Romania (NBR) also insists for the 2014-2015 calendar, when Romania should be very well prepared for the adoption of Euro, otherwise we are assuming major risks.

CAUSES AND CONSEQUENCES OF MASSIVE CAPITAL FLOWS

Coroiu Sorina Ioana

University of Oradea, Faculty of Economics

Sabău Popa Claudia Diana

University of Oradea, Faculty of Economics

At this stage of global economic crisis that traverse, it was observed that massive capital flows have major impacts on economies. Therefore, it is important to analyze the factors behind the attraction of these massive capital flows, and the main consequences that followed.

Keywords: Massive capital flows, crises, causes, consequences.

JELL Classification: F21, F34, E52, E58.

In the current economic crisis, massive capital flows' analysis is very important because some authors in the literature, Reinhart and Reinhart (2008) - believe that there may be links between capital inflows and sovereign debt crises, exchange rates, inflation and the banking system. Between 1975-1982, there were concomitant capital inflows, followed by the debt crisis. Capital inflows reappeared during 1990-1993, followed by an emerging markets debt restructuring. Since 2002, many countries faced with capital inflows. End this cycle coincided with the financial crisis started in the second part of the year 2007. Massive capital inflows recorded by the current global crisis occurrence, were due to several factors, including: financial globalization, the existence of an abundant liquidity in developed economies, economic development perspective of that country, following the accession to an economic union.

Globalization phenomenon is one of the main reason that caused financial globalization and capital movement. Falling communication costs, strong competition, and rising costs in domestic markets, led firms in industrial countries to produce abroad to increase their efficiency and profits. This not only triggered FDI, but also changed its nature in comparison to the 1970s and early 1980s. In those years, FDI was mainly driven by resource extraction and import substitution, whereas the progressive globalization of production has led to a high proportion of current FDI being characterized as efficiency-seeking investments.

The second development in the financial structure of industrial countries that increased capital flows to emerging markets was the growing importance of institutional investors. These investors found themselves more willing and able to invest abroad because of higher long-term expected rates of return in developing countries and to wider opportunities of risk diversification.

Until the first signs of the current crisis, there was abundant liquidity in developed economies. The liquidity has to keep interest rates at low levels and volatility in financial markets lower. However, economic growth in developed countries has slowed in recent year, investors in these markets have seen lower profits, so they began to seek new opportunities for profits. Increasingly, investors began to look favorably emerging economies and capital inflows continued. Reinhart and Reinhart (2008) analyzed 181 countries, from 1980 to 2008, and noted that the maximum duration of the cycle of capital inflows was 3 years for more than 50 countries, for 4 years for more than 30 countries and almost 5 years to 20 countries.

Capital inflows have occurred both in low-income countries and middle-income or large income countries, members of the OECD. For example, capital inflows have been relatively high in the U.S. in the period 2002-2007, the United Kingdom and France between 2005 and 2007, in Spain between 2004 and 2007.

In Romania, these inflows were higher in the period 2004-2008. Romania was an attractive location for foreign investors due to cheap labor, facilities given by authorities, and so on. Another factor behind the increase in capital inflows in a given country was that country's

economic development perspective, the accession to an economic union: the European Union, NAFTA. The premise was that an economic union membership has more security, limited exchange rate fluctuations, reduce capital costs by reducing risk spreads, stock prices are maintained at satisfactory levels.

The World Bank (1997) noticed that Capital Flows suggesting Several trends have been driven by more than external factors. Fundamentals Affect the Long-term rates of return to investors. Fundamentals countries with the strongest (high investment-to-GDP ratio, low inflation, real exchange rates and low variability) have received the largest flows as percentage of GDP. Whereas countries with very poor fundamentals have attracted private flows. FDI is one of the largest component of private flows, but, although sensitive to macroeconomic fundamentals, it is note explained by global interest rates. Portfolio flows is more sensitive to interest rates. Still, they have shown year upward trend since 1992-93 despite the increase in global interest rates. Nevertheless, the role of foreign factors cannot be ignored.

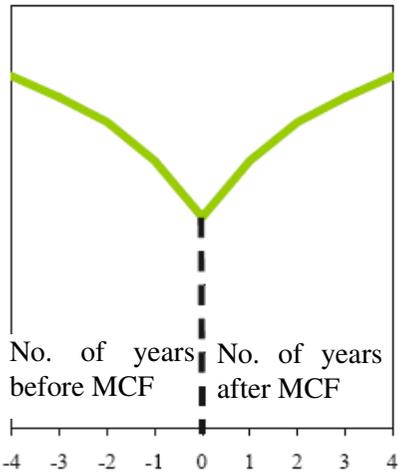

A breakdown of sources of capital inflows in the countries of Central and Eastern Europe (CEE) is provided by Lane and Milesi-Ferretti (Isarescu, 2009). In total foreign direct investment in Central and Eastern Europe, the euro zone countries had a share of 73% -95%. In 2004, in most CEE countries, over 50% of total portfolio investment in the stock market came from the euro area, which was the main source for foreign assets of the banking systems of CEE and long-term investments that create debt.

In general, relatively high capital markets became relatively small and shallow. The discrepancy between financial depth and volume of emerging economies in capital inflows led to appreciation of currencies. To prevent the excessive appreciation of currencies, the reserves have strengthened. This was more intense in countries that export energy resources. Also, to prevent massive capital inflows, the authorities raised the reserve requirement, imposition of taxes on financial transactions and other administrative restrictions. However, positive developments have dimmed prices real need for structural adjustment, which were postponed. This was probably the most important implication for these economies since the long term, structural adjustment delay adversely affects external competitiveness.

All episodes of inflows or sudden stop of capital have common characteristics, even though they showed different features depending on the country or time period analyzed. These characteristics refer to the dynamic indicators such as GDP, real exchange rate, inflation and current account, both before and after an episode of capital inflows. Using the results presented in literature - Reinhart and Reinhart (2008), Isarescu (2009), one can identify certain patterns of dynamic indicators mentioned, 4 years before concluding episode of capital inflows and 4 years after this time.

The graph in Figure 1 presents the evolution of current account deficit before and after the episode of large capital inputs (denoted by zero on the horizontal axis). Note that during the episode of capital inflows, it has been a deterioration in current account adjustment, beginning to previous levels. V-shape of the current account evolution is sharper for small and medium-income countries.

Fig. 1. The evolution of current account deficit (% in GDP)

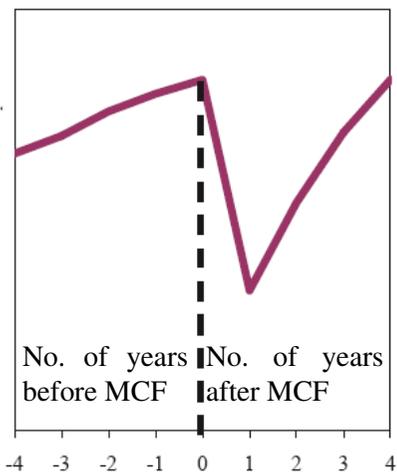

0 = Moment of massive capital flows (MCF)

Source: Isarescu, 2009

Generally, there is a directly proportional relationship between inflows and GDP. During the period of capital inflows, GDP recorded a relatively high growth, and decreases sharply in concluding episode, then again there is a noticeable trend. In other words, after completion of large capital inflows, GDP has a V-shaped trajectory (Fig. 2).

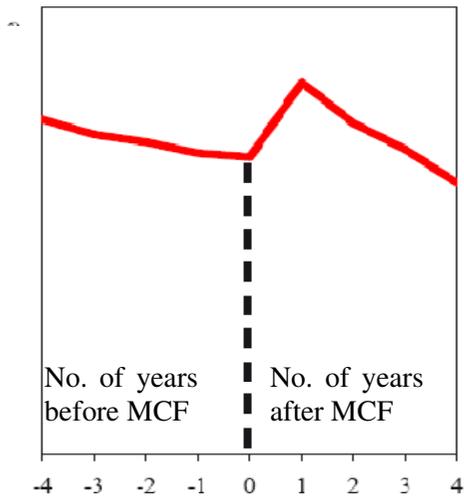

Fig.2. The evolution of GDP (%)

Source: Isarescu, 2009

It has been difficult to identify a trend of inflation, because the data presented in literature are varied, because monetary policy plays an important role. Isarescu (2009) believes that the end of the cycle of capital inflows followed by a short-term inflationary spurt, mainly due to exchange rate channel. In subsequent years, however, inflation is at levels more or less similar to those before the end of episode than capital inputs.

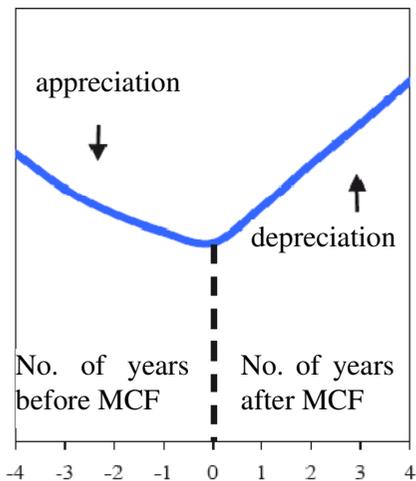

Fig. 3. Inflation rate evolution (%)

Source: Isarescu, 2009

Figure 4 presents the evolution of the exchange rate. If capital inflows last few years, real appreciation of each year tends to be significant, so the cumulative assessment is also significant, leading to downward slope of this graph. Literature shows that in most cases, real depreciation occurs through nominal depreciation of the currency. In the graphic we see that real depreciation is driven by falling prices only after the first year of the end episode.

Fig. 4. Exchange rate evolution (%)

Source: Isarescu, 2009

We have seen that massive capital flows have significant consequences, therefore, the control of the volume is necessary. The biggest challenge after the financial crisis, is to direct capital flows and avoid recurrence of imbalances, that have accelerated the decline in savings.

HAVE THE RECENT CRISIS AFFECTED FOREIGN BANKS' POSITIONS IN CENTRAL AND EASTERN EUROPE? (I – GENERAL OVERVIEW)

Bădulescu Daniel

University of Oradea

“Lucian Blaga” University of Sibiu

Faculty of Economic Sciences

The aim of this paper is to investigate the extension to what foreign banks reacted during recent crisis in supporting their subsidiaries and thus the host economies. The analysis focuses on a brief theoretical overview and an analysis in terms of foreign claims regarding selected Central and Eastern European countries. We are also interested in finding if the entry mode (acquisition of a existing local bank, greenfield investment, non-resident office) did matter in this issue.

Key words: foreign banks, Central and Eastern Europe, economic crisis

JEL Classification: E5, G21

1. Introduction

Foreign direct investments in Central and Eastern European banks have increased considerable in constant high ratio, being considered, by many deciders, as a solution or a panacea for current and structural problems of host countries. Only in a decade, the structure of banking systems of each country of Central and Eastern Europe has dramatically changed, the ratio of foreign capital reached unusual levels, even for west European countries, where the foreign banks came from⁹⁴⁶. For example, at the end of 2008, excepting Slovenia, these figures were between 50-70 % for Poland and Hungary, between 75-90 % for Bulgaria and Romania or even over 90% in Czech Republic, Slovakia, Estonia⁹⁴⁷ etc. (see Table 1).

Table 1. Foreign capital in banking sector of CEE countries (share in total assets, %)

Country	2003	2004	2005	2006	2007	2008
Bulgaria	81	80	80	80	75	84
Czech Republic	95	89	94	97	97	97
Poland	72	60	70	68	67	68
Romania	59	63	68	66	89	89
Slovakia	96	96	98	99	96	96
Slovenia	38	38	39	41	29	30

⁹⁴⁶ For example, the share of state owned banks in many western European countries was at a high level until the middle of '90, and the foreign capital in banking system of several countries, as Germany, France, Sweden was under 15%. More of that, during of privatisation process, many significant voices asked a privatisation in favor of a national entity, see Gardner, Ed. și Molyneux, P., *Changes in Western European Banking*, London, Unwin Hyman, 1990, *Consolidation and diversification in the euro area banking sector*, ECB's Monthly Bulletin, May 2005; Daniel Bădulescu, *Globalizarea și bancile. This implication was unanimously seen to have a great achievement, mostly because it introduced stability, new management, financial and human capital, improved risk assessments etc. The foreign banks were capable to give considerable advantages in term of resources and costs: facing slim margins in their home markets, they could borrow consistent loans in host countries with significant margins but advantageous for local clients comparing with the cost of the same loan in national currency. But this trend has turned, the great liquidity flows that have financed the emerging economies and consistent growth rates are a thing of past; the Institute of International Finance, an international standard setting body formed by 375 global banks, estimates that, contrary to previous years, outflows from the region to banks will actually exceed inflows by EUR 27.2 billion. Only two years ago, at the height of western capital inflows, western banks poured EUR 217 billion more in the region than they withdrew from there⁹⁴⁸. The reality of past years is unfortunately dominated by global economic and financial crisis, which strongly affected the economy of this area and consequently, the banks. The purpose of this paper is to see if, in these conditions, the behaviour of foreign bank subsidiaries is to leave, to abandon the existing position in host countries, or to continuing the financial intermediation, in the emerging economies.

2. Have parent banks sustained their subsidiaries during crisis time?

The subject of foreign bank subsidiaries behaviour on host markets and the analysis of their actions under crisis impact is not new and not direct related to these recent developments in Central and Eastern European countries. In the 70s, the issue was studied by several scholars, first on Latin America markets, then on Central Europe or Asia⁹⁴⁹. Taking into consideration that

economic activity, including banking, tends to be pro cyclic, especially in crisis periods⁹⁵⁰, it is important to notice if this cyclical evolution is more obvious in banks subsidiary activities comparing with local banks, and if, overlapped on the general contraction due to crisis effects, their behaviour is more stable or not for the host countries.

On the other hand, we have to understand that the implication degree of banks subsidiaries and branches on host markets isn't a local decision, but of the parents banks'. In the case that a parent bank decides to reallocate the capital between branches on different markets and countries - on expected opportunity investment basis - , this will lead to instability on subsidiaries position. It was noticed⁹⁵¹ that parent banks preferred to support the subsidiaries evolution, to accept a longest period for consolidation on emergent markets and, in this way, the appeal on parent bank resources to overpass the temporary difficulties means a contribution to the stability of the system in the host country or a region.

According to Morgan's et. al. models or Holstrom and Tirole⁹⁵², the multinational banks are capital constraint institutions and risk neutral, the decision in reallocating the capital being taken on the basis of two determinants – internal financial constraint (or internal market) and shocks in real economy, specific for the country where they are implanted. In the first case the things are more clear, this reallocation is made due to an analysis of internal process (different performances between markets, products, units etc., perceived opportunities, even internal fraud or financial losses in subsidiaries or head office), the shocks on real economy are more complex. That means, from parent bank point of view, changes in opportunities generated by economic and political transformation, crisis occurred in host countries, but not directly related with the subsidiaries activity.

The parent bank's possibility to reallocate the resources in internal network is interpreted by De Hass and Lelyveld⁹⁵³ as a capacity to ensure an effective support to the subsidiaries and this will lead to two effects: *the support effect* – the support of the own units even in less expected performance and, *the substitution effect* – the reallocation of the capital between own units as a reaction on the real economy shocks which modifying the profitability in the host countries.

Analysing a variate and complex database – which comprises 45 multinational banks from 18 home countries with 194 subsidiaries across 46 countries, with most parent banks (83 %) and subsidiaries (73 %) are based in Europe, 14 % of all parent banks and subsidiaries are based in North America, 5% from Latin America, the rest from Africa and Asia (this regions still have limitations on majority foreign bank ownership) – the authors argue that the support effect is very strong, the parent banks are interested to reallocate the capital in favour of those subsidiaries faster growing and generating more return to the group, facts verified for all Central and Eastern European countries, including Romania, in pre-crisis period. Regarding the substitution effect, they appreciate it as quite weak, because the subsidiary has the alternative to seek resources for lending activity in local currency and can relative compensate the scarcity of resources supplied by parent bank. But this policy can expose the subsidiaries at various risks and generate a pro-cyclic effect like local home based banks. The support of parent bank is more necessary as this parent bank is a strong bank, able to obtain enough resources, stable and at low costs. The authors show that the substitution effect is more powerful in the case of non-resident offices acting on host countries market, and for green-field subsidiaries.

Likewise the way used to analyse and measure the modalities and forms of penetration of foreign banks on emerging markets, in our approach we shall pursue two aspects: first, the cross border

⁹⁵⁰ De Hass, Ralph (2009). *In defend of foreign banks*, <http://voxeu.org/index.php?q=node/3609>

⁹⁵¹ idem

⁹⁵² Morgan D., Rime, B, Strahan, P.E. (2004). "Bank integration and state business volatility", *Quarterly Journal of Economics* 119; Holstrom, B., Tirole, J. (1997), "Financial intermediation, loanable funds and the real sector", *Quarterly Journal of Economics* CXII

⁹⁵³ de Haas, R., van Lelyveld, I., *Internal Capital Markets and Lending by Multinational Bank Subsidiaries*, MPRA Paper no. 16164, february 2009, <http://mpra.ub.uni-muenchen.de/13164/>

activities of the banks, and second, the non-resident branches locally implanted in host countries, i.e. the distinction between cross border claims granted by foreign banks and local lending activities, by the subsidiaries of foreign banks.

Conceptually, we understand a foreign financial institution as a legally incorporated organisation in a foreign institution in which a significant part of the owner has a foreign origin. Consequently, the foreign banks in Central and Eastern Europe can be defined as banking organisations legally incorporated in a foreign institution or in a organization with a significant foreign part of the ownership. First part of the definition is referring to various organisation forms, from representative offices to branches (foreign entities, directly dependant from parent bank). The second part of the definitions is referring at banking institutions with foreign ownership (individual or legal persons) but, legally registered as internal (domestic) entities. The only difference between this institution and others is that an important part or all owners are from outside the host country. Most often, the foreign representative, office, branch etc. is focused on corporate lending, international trade financing or private banking-wealth management, and less on retail activities, being used by parent banks in order to support the home client's activities from original countries in host countries⁹⁵⁴.

The presence of the foreign banks in a country can be evaluated through several indicators: some of low complexity- as the number of foreign banks (both subsidiaries and representative offices) comparing with local banks, and the share of the foreign banks assets in total banking system assets, but other indicators, more complex, based on Bank of International Settlements (BIS)⁹⁵⁵ regarding consolidated claims of international banks, and BankScope database⁹⁵⁶, regarding credits granted both by foreign banks subsidiaries and by local banks in host countries in Central and East Europe. In this last situation, we consider the total amount of the credit granted by banks with head office based on a reporting BIS country- cross border claims and credit granted by implanted subsidiaries, and sectoral distribution of the claims from reporting BIS countries. We can add in our analysis the evolution of the real cross border credit from subsidiaries of foreign banks (BIS reporting or non reporting banks) and the internal credit (granted by home based local banks)⁹⁵⁷.

These measures will allow us to analyse if the loans and deposits made by the subsidiaries implanted in the host country, and both the cross-border credit, suffered or not considerable changes in this period and if they reveal the stability and support of the host economies or these banks abandon these countries, confirming the fears related to the opportunism of this kind of investments and their instability in difficult times.

In Table 2 we present data regarding two different moments: September 30, 2007 – before the crisis starts in Central and Eastern Europe, and two years later, September 30, 2009, the most recent period with available information in BIS statistics. We took into analysis several selected Central and Eastern European countries, covering a large variety of situations, experiences and development levels.

⁹⁵⁴ see Daniel Bădulescu, op. cit. and Konopielko, L., “Foreign Banks Entry into Central and Eastern European Markets: Motives and Activities”, in *Post-Communist Economies*, vol. 11, no. 4/1999, pp. 463-485

⁹⁵⁵ www.bis.org

⁹⁵⁶ Database covering 24000 commercial banks (consolidated and non-consolidated balance sheets, financial situations etc.), i.e. more than 80% of the international banking activity in the world:

<http://www.bvdep.com/BANKSCOPE.html>

⁹⁵⁷ The appeal to these studies for the case of Romania or other Central and Eastern European countries is motivated by the fact that BIS reporting banks cover 95% of the total bank assets and the number and importance of non-BIS reporting foreign banks is insignificant, not influencing the accuracy of reports and analysis

Source: own calculation based on BIS data, different years

The analysis of the data allows us to draw the following conclusions:

- All countries experience increase in total foreign claims, in different proportions, from 3% in the case of Romania to 32% in the case of Poland and even 62% for Bulgaria;
- Cross-border claims have different developments, while the flows are still high for Bulgaria (+65%) and Poland (+34%), they are much lower in the case of Czech Republic, Slovenia (+15%, respectively +16%) and even decreases for Romania and Slovakia (-2%, respectively -16%);
- On sectoral basis, there are reported similar developments, regarding both the graduate withdrawal of cross-border flows dedicated to bank units from the analysed countries (varying from - 46% in the case of Czech Republic, -44% in the case of Slovakia and -34% in the case of Romania, but only -10% in the case of Poland) but even growth of the flows designated for the public sector and respectively for the private non-bank sector in most of the analysed countries. We notice significant differences from sector to sector and from country to country. An exception is Romania, which experiences a stagnation regarding the consolidated cross-border claims in all currencies and local claims in non local currencies dedicated to the non-bank private sector.

3. Preliminary conclusions

The evidence presented above suggests different level of involvement of foreign banks in emergent economy, they attempted to maintain previous position, even affected by crisis. In the second part of the paper we will focused on some developments in the Romanian case.

HAVE THE RECENT CRISIS AFFECTED FOREIGN BANKS' POSITIONS IN CENTRAL AND EASTERN EUROPE? (II – FOCUS ON ROMANIA)

Bădulescu Daniel
University of Oradea
Faculty of Economic Sciences

The aim of this paper is to investigate the extension to what foreign banks reacted during recent crisis in supporting their Romanian subsidiaries and thus the local economy. The analysis focuses on the interpretation of foreign claims broken by maturity, sector, local versus foreign denomination currency, and liabilities. The data were completed with a brief analysis of internal credit (governmental and non-governmental) and finally with an analysis of the behavior of foreign banks located in Romania on the basis of the parent bank's country of origin.

Key words: foreign banks, economic crisis, Romania

JEL Classification: E5, G21

1. Introduction

Following the methodology and approach developed in the first part of the paper, we will try to extend the research on foreign banks' behaviour regarding the support they provided to their subsidiaries their during crisis time, in the case of Romania. We are interested an evolutive, sectoral perspective, combining data regarding the evolutions of total foreign claims, internal credit (governmental and non-governmental) and liabilities. Finally, we are interested to find out if the banks originated in certain countries had a more unstable action comparing with others.

2. The analysis of foreign claims

Starting with the general findings about the evolution of foreign claims in several selected Central and Eastern European countries, we have to further develop the analysis by taking into consideration the developments of foreign claims, on a quarter basis, since Q4 2005 to the most recent available data. Table 1 summarises the data by maturities, sectors and claim type.

This information related to Romanian banking system shows that the indicators on foreign banks – both on cross border credit and on local credit grant by implanted banks – show a significant increase in the third quarter of 2009 comparing with December 2005, but considerably inferior to the amount registered in the maximum periods (end of 2007 until September 2008). Decreases go from 9-10% for total external credit to 39% for cross border credit.

3. Internal credit developments

Based on the National Bank of Romania data for 2009⁹⁵⁸, we can notice that in 2009 the increase of total credit was mainly represented by the government credit (increasing with more than 1,7 times in 2009 versus 2008 and 3,9 ori comparing with 2007), and less on non-government credit (only 1% in 2009 comparing with 2008) – see Chart 2.

Source: NBR, Monthly bulletin January 2010

Analysing this data together with the data regarding foreign banks' involvement, we can draw the following conclusions:

- Both foreign and domestic banks demonstrated a much reduced interest – comparing with the pre-crisis period – in financing the real economy; they all reported a greater preference in government financing;
- The foreign claims – either referring to cross-border credit or to locally granted credit supplied by the Romanian located subsidiaries of the foreign banks, followed the same pattern; the interest and involvement in the Romanian economy were achieved especially by the financing supplied for the government (in local currency or foreign currency) in the same time with an effective withdrawal from the real economy or population financing;
- The withdrawal of Romanian located foreign banks is confirmed also by the consistent decrease of cross-border credit granted to the Romanian bank sector (decreasing by more than 34%), comprising here the greatest part of the credit supply by parent banks to their own subsidiaries locally implanted in Romania;
- Within the total claims of foreign banks on Romania, the most significant decrease is registered in the case of lending provided in local currency by the subsidiaries of the foreign banks located in Romania, fact indicating a reducing involvement in the Romanian economy and a pro-cyclical action.

In the better possible case, accepting with honest-mindedness the foreign banks' representants statements about their maintained interes regarding the Romanian economy⁹⁵⁹, this fact can be seen as a consequence of the capital re-allocation decisions according to the market oppotunities in risk-aversion conditions.

It worths mentioning that the developments could be much more dramatic then the effective ones, in the absence of international support provided by the EU and the IMF. As Mugur Isarescu, the NBR Governor stated, "the import of credibility from the EU and the IMF determined some private financing not to reduce themselves or to reduce less; this financing positively reflected itself in several directions: relatively larger investment comparing with the situation ob absence of these agreements (with EU and IMF – n.n.); diminishing the depreciation and temperating the foreign exchange rate volatility of the romanian leu relative to euro and other currencies; the Wien agreement on the banks engagement to renew the existing finance lines and to maintain capital adecquation ratios to secure levels"⁹⁶⁰.

4. The liabilities' perspective

Foreign banks' involvement in the economy of developping countries has to be completed with the analysis of local liabilities denominated in local currency. Even the relevance of this indicator seams reduced compared with the measure of credit granted (to bank sector, non-bank private sector, public sector in the host country), it reveals it's importance through several issues.

On one hand, an important issue is the way in which the capital entried the host country⁹⁶¹. Where the entrance was achieved by cross-border granted international claims – the involvement in deposit collection is very low and insignificant. In the case of greenfield involvement, the resources' collection from that country's residents – especially in local currency – is limited especially by the network size, type of clients etc. Finally, if the foreign capital entry is achieved by the acquisition of a existing local bank, often with an important market share in the host economy, it is highly possible that the dimensions, size and expertise of the network, and the contact with the local clients rise the availability and willingness of the new entities to continue their involvement also in resource and deposits collection, in local or foreign currency, at the same time with the appeal to the cheaper, foreign currency resources supplied by their parent bank.

On the other hand, the relevance of this measure is shown by the different way in which the foreign banks' subsidiaries approach the effects of the crisis. Starting from de Hass and Lelyveld findings, we can state that the extension and measure in wich a foreign bank involves in resource collection and lending in local currency can generate two possible developments:

- Increasing it's relative independance toward their parent bank regarding the resource supply and thus valorising more rapidly and more effective the growing opportunities in the local market, exceeding the estimations at the time of implantation;
- On other hand, in crisis times, and in the case when parent bank has not a high financial power and/or experiences difficulties on their home market, the parent bank's support to

⁹⁵⁹ Parent groups of the main 9 banks with foreign capital signed in August 2009, bilateral letters of engagement to maintain the exposure level on Romanian market and the solvency ratio to over 10%. The banks signing the agreement – Erste Bank, Raiffeisen International, Eurobank EFG, National Bank of Greece, Societe Generale, Alpha Bank, Volksbank, Piraeus Bank and UniCredit – counted for about 70% of the Romanian banking market

⁹⁶⁰ Isarescu Mugur (2009), *Finantarea dezechilibrului extern si ajustarea macroeconomica in conditiile crizei financiare. Cazul Romaniei*, NBR

⁹⁶¹ see Grubel, H., *A Theory of Multinational Banking*, Banca Nazionale del Lavoro Quarterly Review, nr. 123/1977 Konopielko, L., *Foreign Banks Entry into Central and East European Markets: Motives and Activities*, în "Post-Communist Economies", vol. 11, nr. 4/1999, apud: Badulescu, D. (2007), *Globalizarea si bancile. Cu o privire specială asupra Europei Centrale și de Est și asupra României*, Editura Economica, Bucuresti

its subsidiaries reduces. As a consequence, these subsidiaries masivly involved on the local market through lending and deposits will behave more as a domestic bank, acting pro-cyclicly and suffering the majority of the crisis' effects on the host market. In other words, the consistent support of the parent bank – possible if this parent banks is a powerful multinational bank – is decisive in maintaining the subsidiary as a bank less affected but the crisis in the host country; in a more general approach, this fact justifies the statements regarding the positive effects of foreign banks involvement on the developing countries in the case of entry of powerful banks, originated from developed economies.

Different from the evolution of the indicators analysed in table 2 and 3, the information in Chart 3 shows a similar evolution of local liabilities for all analysed countries; the difference only comes from the lag of starting the crisis or the amplitude of decrease for each country:

- All countries experienced considerable decreases of these liabilities, from -49% in the case of Poland and -42% in Hungary (Q1 2009 versus Q2 2008), -25% – -30 % in the case of Czech Republic, Romania, Bulgaria, or considerably lower in the case of Slovenia (where the foreign capital presence is much less than in other countries cases).
- Even the moment of the decreasing is de-phased in time, it occurs abruptly, and the recover is usually slow; at the moment September 2009, the indicator haven't reach the pre-crisis levels in no country.
- Finally, as a general explanation, confirming the pro-cyclical affection of foreign banks' subsidiaries, is the fact that reducing the amounts of these attracted funds is due to the effects of the profound crisis which affected the real economy, population and firms, government institutions refering to a more extent to the existing liabilities as the access to finance is more and more restrictive and the associated risks higher.

5. Final Conclusions

We can state that the support and involvement of the foreign banks in Romanian economy is moderate, under certain conditions and selective, explained by:

- a. Over 55% of the foreign capital in Romanian banking system comes from countries very affected by the global financial crisis, as Greece, or from relative consolidated banks but very exposed on Central and Eastern European market (Austria).
- b. Decreasing in total claims on Romania was more pronounced from the country consistently involved in Romanian banking system (Austria -11%, France -11.4%, Netherlands -9.7%, comparing with an average at 9.23%)
- c. The scale of crisis shock on Romanian economy

Source: own calculation based on BIS data, different years

For all Central and Eastern European countries, the global financial crisis is a real, effective test proving the support form multinational banks for their subsidiaries. We can noticed that this involvement has different degrees and extension, explained both by internal particularities of the banks (financial power, complexity and dimension of the abroad networks) and by the particularities of host country economy (crisis effects, economic policy and performance, support from international organizations as IMF, EU etc.).

BEHAVIORAL BIASES IN TRADING SECURITIES

Dedu Vasile

The Bucharest Academy of Economic Studies

Turcan Radu

University of Oradea

Turcan Ciprian

The Bucharest Academy of Economic Studies

The main thesis of this paper represents the importance and the effects that human behavior has over capital markets. It is important to see the link between the asset valuation and investor sentiment that motivate to pay for an asset a certain prices over/below the intrinsic value. The main behavioral aspects discussed are emotional factors such as: fear of regret, overconfidence, perseverance, loss aversion, heuristic biases, misinformation and thinking errors, herding and their consequences.

Keywords: Behavioral finance, Investor psychology, Irrationality, market efficiency, Behavioral biases, limits to arbitrage.

JEL Classification: G11, G12, G14, D81

“Wall Street never changes, the pockets change, the suckers change, the stocks change, but Wall Street never changes, because the human nature never changes”.

- Jesse Livermore.

Much of the academic finance theory is based on the assumption that individuals act rationally and consider all available information in the decision-making process. But, the researchers have discovered in the markets, many irrational behavior and errors in judgment. Individuals consider the stock market as a person: with its own moods, sometimes it can be ornery or exuberant, may overreact and make amends next day, and so on.

Academic finance, the conventional part of the finance literature, is built on the arbitrage principles of Miller & Modigliani, the portfolio construction of Harry Markowitz, CAPM theory of Lintner and Sharpe, Black-Scholes, and Merton theories. The hypothesis that actual prices reflect fundamental values is the Efficient Markets Hypothesis (EMH). EMH was made famous by Eugene Fama (1970) and affirmed that no trader could “beat the market”, because under this hypothesis, “prices are right”, set by agents that understands Bayes’ Law and no investment strategy can earn better average returns than are warranted for its risk – there is “no free lunch”. The theory of “random walk” in asset prices that knowledge of the series of the past stock prices cannot be used to obtain higher return than a buy and hold strategy.

Behavioral finance that is, finance from a broader science perspective including sociology and psychology, is a new approach to financial markets, in response to the difficulties faced by the academic finance, until a few decades considered to be proved beyond doubt. Behavioral finance deals with understanding and explaining how rational and irrational traders interact, how may affect irrationality the assets prices. “Limits to arbitrage”⁹⁶², form one of the two buildings blocks of behavioral finance. Psychology is the second building block of behavioral finance (people’s beliefs and people’s preferences). From the end of the 70s many studies revealed theoretical and empirical challenges to the efficient market hypothesis, (**limits of arbitrage**), studies that

⁹⁶² Barberis, Nicholas & Thaler, Richard, 2003. "A survey of behavioral finance," Handbook of the Economics of Finance, in: G.M. Constantinides & M. Harris & R. M. Stulz (ed.), Handbook of the Economics of Finance, edition 1, volume 1, chapter 18, pages 1053-1128 Elsevier.

evidence inefficiency consistent with the strong and semi-strong form of the efficient market hypothesis: excess volatility, fundamental risk, noise trader risk, implementation costs, index inclusions, Price Earnings Ratio effects, Book to Value Ratio effects, liquidity effect, stock repurchases, mergers, momentum. The presence of occurring anomalies in academic finance, was a sound contributor in developing of behavioral finance.

Practically, behavioral finance studies mainly two aspects: *cognitive psychology* and *the limits of arbitrage*. Psychologists discovered many patterns, *cognitive biases* regarding people behave:

Overconfidence and wishful thinking

Overconfidence in decision-making process manifests in a number of ways. One of them might be the too little diversification, because of a tendency to invest too much in something what one is familiar with (a chemist or a doctor may invest rather in pharmaceuticals industry, a banker may invest particularly in financial companies, a real estate agent the real estate companies or some of the investors may invest very much in the company they work for - Enron. One study, by Olson and Cox (2001), has shown that individuals with similar training, professional experience and information, formulate distinctive judgments regarding their risk perception and their reaction to risk. On average, the study has shown that men have lower returns than women, because they trade more actively. Woman professional investors, have a tendency to focus on risk reduction more than male investors in portfolio management.

Prospect Theory and Loss aversion

Prospect theory⁹⁶³ was developed by Daniel Kahneman, professor at Princeton University's Department of Psychology, and Amos Tversky in 1979 as a psychologically realistic alternative to expected utility theory. The theory describes how people make choices in situations where they have to decide between alternatives that involve risk, decision processes consisting of two stages, editing and evaluation. Prospect theory may also explain some illogical financial behaviors, such as the disposition effect, with refers to the tendency of people to save money in bank to earn interest, who refuse to work extra-time because they don't want to pay extra taxes. Many academic experiments demonstrated that a loss bothers investors twice as much in absolute term than a pleasure from an equal profit. Because of the **loss aversion**, investors refuse to sell at a loss. There is an ego in each of us. No one likes to admit that he is wrong so, instead of taking a small loss, investors tend to wait too much for the reversal of the stock and the loss may rise even more. Often could be more profitable taking the small loss (right after the mistake was first realized), and reinvest properly the money than hoping too much to get to breakeven with a losing position. "They say you never grow poor taking profits. No, you don't. But neither do you grow rich taking a four-point profit in a bull market"⁹⁶⁴.

Anchoring

The concept of anchoring refers to the tendency to attach or "anchor" the thoughts to a reference point. The most frequent anchor is a past event or trend. For instance, some investors could tend to invest heavily in the stocks of companies that have fallen "too much" in a "two short" period of time, regardless of the fundamental matters. Investors anchor on the recent "high" and consider that the price drop provides an opportunity to buy the stock at a discount. "This semi sucker is the type that thinks he has cut his wisdom teeth because he loves to buy on declines. He waits for them. He measures his bargains by the number of points it has sold off from the top."⁹⁶⁵ Anchoring on historical price could harm much the investor's portfolios.

Belief perseverance

⁹⁶³ http://en.wikipedia.org/wiki/Prospect_theory

⁹⁶⁴ Jesse Livermore, Ch 4, Reminiscence of a Stock Operator

⁹⁶⁵ Jesse Livermore, Ch 5, Reminiscence of a Stock Operator

Once people have formed an opinion, they cling to it too tightly and for too long. They rather search for the news and analysis that confirm their beliefs than for the ones that may contradict their beliefs. People tend to misinterpret evidence that goes against their hypothesis as actually being in their favor. “One of the most helpful things that anybody can learn is to give up, trying to catch the last eighth or the first. These two are the most expensive eights in the world. They have cost stock traders, in the aggregate, enough millions of dollars to build a concrete highway across the continent”. “A speculator must concern himself with making money out of the market and not insisting that the tape must agree with him. Never argue with it or ask it for reasons or explanations” – Jesse Livermore. “When you begin to believe that a stock can only go in one direction, that is when you will have your head handed to you” – Dan Zanger

Framing

Framing refers to the format in which a situation or choice is presented (for instance, the same question, presented in two distinct but equal means, could extract identical or different response). An example of frame could be saying “there is 50% chance of success” instead of “50% chance to fail” – the famous half-full or half-empty glass. Mental frames are often linked to the language used, to stress the positive or negative aspects with adequate words and the consequences could be deciding with blinders. Framing can have different origins: personal cognitive bias – occasional or a habit (internal framing), or outside misinformation (external framing) done involuntarily (because of the incompetence of the author), or voluntarily by the “informer”: in order to manipulate the auditor.

Representativeness

Investors can make judgments based on stereotypes. They make assumptions based on information that has no bearing on reality. For instance, if a company with a history of releasing poor results will be perceived as a lousy company, and will get poor results in the future, even if lately the improvements are visible. Representativeness leads to the “sample size neglect” bias: a small sample can be just as representative as a large one. Investors tend to believe that a money manager with outstanding record for a few years will have outstanding results in the future – so called “hot hand” phenomenon. Rabin (2002)⁹⁶⁶ calls this the “law of small numbers”, the belief that even small samples will reflect the properties of the parent population, and could lead to a “gambler’s fallacy” effect when investors do not know the data-generating process (odds) in advance.

Gambler’s fallacy effect

In the gambler’s fallacy, a person erroneously believes that the onset of a certain random event is less likely to happen following an event or a series of events. This judgment is incorrect. A very common example can be found with people’s relationship with slot machines⁹⁶⁷. Most of these people believe that every losing pull will bring them that much closer to the jackpot. Related to investing decision-process, investors tend to liquidate a position after it has gone up in a series of subsequent trading sessions, because they don’t believe that is likely to continue going up and vice versa (maintaining a stock that “has fallen too much” and further declines are “improbable”). Jesse Livermore said something very important about gambling in the stock market: “Don’t trade when the market isn’t acting right! ...When prices drift up and down without trend, like a ship without a rudder, and few positive indications develop, the percentage of losing trades is apt to be high. When this condition continues it is well to hold off until the character of the market changes”...“When I couldn’t play according to my system, which was based on study and experience, I went in and gambled. I hoped to win, instead of knowing that I ought to win on

⁹⁶⁶ Rabin, M (2002), “Inference by believers in the law of small numbers”, Quarterly Journal of Economics 117:775-816

⁹⁶⁷ Phung, A., Behavioral Finance : http://www.investopedia.com/university/behavioral_finance/default.com

form”. ... “There is the plain fool, who does the wrong thing at all times everywhere, but there is the Wall Street fool who thinks he must trade all the time. No man can always have adequate reasons for buying or selling stocks daily – or sufficient knowledge to make his play an intelligent play”.⁹⁶⁸.

Forecasting errors:

It is quite usual that on tops many people to see that stocks prices may never fall and on the bottoms that the stock market may never recorded. The same thing could be seen with the oil prices: when oil was near 150\$ / Barrel many researchers and analysts predicted that there will be shortages of oil and the price will rise even more than 250\$/ Barrel in the near future term. But it went less than 50\$ in less than 12 months after those

”predictions”. When was reaching less than 40\$, many analysts forecasted that it could go even lower the price because of the world recession and the dumping global demand for oil – they were targeting the oil barrel price somewhere less than 25\$/barrel. Of course, that it did not happen that and the reversal to 80\$/ Barrel has begun. An interesting sample of excessive pessimism during the reversals, could be the following: *“But in November of 1974, I was newly married, and my husband and I decided that we should start saving. So we went to a broker and told him we wanted to buy some new shares. I still remember what he said: <<I really don’t think this is a good idea, a nice young couple like you – you really shouldn’t be putting your money into something as risky as stocks”. “That’s how you can tell it’s a bottom”, added Allyn. “They don’t even want to sell you the stuff”.*

Conservatism

“A conservatism bias means that investors are too slow (too conservative) in updating their beliefs in response to recent evidence. Such a bias would give rise to momentum in stock market returns”- Bodie, Kane and Marcurs (2005). Investors tend to under react and delay the needed changes in their portfolio composition when the markets situation imposes, and financial analysts often adjust too slowly their previous estimates when new information should make them reanalyze the situation and prospects. The main causes could be: the inertia a quasi physical bias (neglecting, laziness, indifference, comfort found in keeping habits), emotional biases (self doubt, instinctive fear and mind paralysis, loss aversion, commitment, nostalgia, overconfidence, pride, ego), or cognitive biases (mental anchoring on an old reference or cognitive dissonance, like denial of reality).

The influence of worry

Worrying is a lasting concern with a past or an upcoming event. Investors feel fear (worry about uncertainties) and anxiety (the gut level feeling that accompanies uncertainty). In The Journal’s Intelligent Investor column of September 30, 2008⁹⁶⁹, Jason Zweig, considered some of the arguments referring that investors hate uncertainty: <<“Investors hate uncertainty.” Well, that’s just tough. Uncertainty is all investors ever have gotten, or ever will get, from the moment barley and sesame first began trading in ancient Mesopotamia to the last trade that will ever take place on Planet Earth. *If tomorrow were ever knowable with absolute certainty, who would take the other side of a trade today?* The financial future is no more uncertain now than it used to be; in fact, it’s far less uncertain than it was in the summer of 2007, when the Dow shot above 14000, the future seemed bright, and utterly no one foresaw the disaster that would befall the financial system. The absolute certainty of blue skies ahead was an illusion then, and the notion that we all know that worse misery lies in store is an illusion now. The only true certainty is surprise.>> . “People tend to underestimate low probability events when they haven’t happened recently, and

⁹⁶⁸ ⁹⁶⁸ Jesse Livermore, Reminiscence of a Stock Operator

⁹⁶⁹ Zweig, Jason – “The Depression of 2008? Don’t Count on it”, The Intelligent Investor Column, Wall Street Journal, 30. Sep. 2008 – <http://online.wsj.com/article/SB122272238714287459.html>

overestimate them when they have” – W. Buffett. “I don’t know whether I make myself plain, but I never lose my temper over the stock market. I never argue with the tape. Getting sore at the market doesn’t get you anywhere”. – Jesse Livermore

Mental accounting

Mental accounting refers to the tendency for people to separate their money into separate accounts based on a variety of subjective criteria, like the source of money and intent for each account. Investors divide their investments between a safe investment portfolio and a speculative portfolio in order to prevent the negative returns that speculative investments may have from affecting the entire portfolio. The problem is that the investor’s net wealth will be no different that if he had held one larger portfolio, because the money is fungible, regardless of its origins or intended use. It is just like having savings for a car, for a holiday while not paying the debts for the credit card, sometimes it makes more sense to liquidate the savings in order to pay off debt. Investors who tend to write – keep a journal of every transaction for a period of time, with individual profit or loss, tend to be more attentive with risks. Avoids gambling.

Confirmation and Hindsight Bias

In investing, confirmation bias suggests that an investor would rather look for the information that confirms his beliefs and ideas, rather for the one that contradicts it, even if all the information is against his beliefs, leaving investors with a false picture of the situation. Hindsight bias refers to situation where an investor believes (after the fact), that a past event was predictable and completely obvious, whereas in fact, the event could not have been reasonably predicted. The bias is very common after the bubbles burst. (Dot.com bubbles, South Sea bubble of 1711, Tulip bubble, the recent financial and economic crisis (2007), Crude oil price bubble (2008-2009). If the formation of an asset bubble had been obvious, it probably wouldn’t have escalated and burst like that. One of the old Wall-Street sayings is: “A bullish market is born amid pessimism, grows up under skepticism, matures with optimism and dies with euphoria”.

The role of affects – feelings

One of the major mistakes in investing, is falling in love with a stock. Investors are human, and humans don’t like to admit that are wrong. It happens to everyone. Never fall in love with a losing position and use a stop-loss order to protect against excessive losses. Some of the Wall-Street sayings are: “The market doesn’t know whether you’re long or short and it couldn’t care less”; “The more you lose in a trade, the less objective you become. EXITING A LOSING TRADE, clears your head and restores your objectivity”. One day, Marty Schwartz was asked: “Why do most traders lose money? Because they would rather lose money than admit they’re wrong. What is the ultimate rationalization of a trader in a losing position? “I’ll get out when I’m even”. Why is getting out even so important? Because it protects the ego. I became a winning trader when I was able to say, “*The hell with my ego, making money is more important*”. “I made a big mistake in not selling several of our larger holdings during The Great Bubble. If these stocks are fully priced now, you may wonder what I was thinking four years ago, when their intrinsic value was lower and their prices far higher. So do I” – Warren Buffett, 2003, Berkshire Hathaway annual report.

Herd Behavior

Herd behavior, refers to the tendency of people to mimic actions (rational or irrational), of a larger group. Some of the reasons for creating the herd effect could be: the social pressure of conformity (Dot.com bubble, maybe the most infamous financial event – bursting the internet bubble) – people are very sociable and have a natural instinct to be accepted by the group, rather than named to be as an outcast (following a group is an ideal way of becoming one of them). The second reason could be the common sense that “such a large group cannot be wrong”, “they must

know something that you don't". It happens to novices very often to follow the herd. Even professionals tend to follow the crowds, because if the strategy works, their clients will be happy, if not, he could justify his bad investment decision by pointing out just how many other investors were led astray. It is a good strategy to follow the herd, if you enter in the positions right at the beginning of trend. "When the market gets greedy, I get nervous; when the market gets nervous, I get greedy" – Warren Buffett. "By 1929, it seemed as though everyone, in all walks of life, and not just businessmen, was interested in the stock market. People took out second mortgages on their home and housewives sneaked money from household expenses to play the market. Some people invested everything they had in the market in the belief that there was no way they could NOT become rich"⁹⁷⁰.

Conclusions

The greatest critique of behavioral finance is that it is not considered an actual science, like the quantitative finance. It is too general. It is not possible to calculate and quantify exactly behavioral factors neither for one person nor for a crowd. Behavioral finance should be regarded as a useful toolkit when trading because it could give a competitive advantage in trading and a better knowledge of it. As Jesse Livermore said, it is very important to learn from our mistakes and understand the market in a better way: "*It wasn't anything to be proud of, when you think I had been broke three times in less than two years. And as I told you, being broke is a very efficient educational agency. It is literally true, that millions come easier to a trader after he know how to trade, than hundred did in the days of his ignorance*" – Jesse Livermore.⁹⁷¹

⁹⁷¹ **Jesse Livermore** (1877 - 1940), also known as the **Boy Plunger**, was an early 20th century stock trader. During his lifetime, Livermore gained and lost several multi-million dollar fortunes. Most notably, he was worth \$3 million and \$100 million after the 1907 and 1929 market crashes, respectively. He subsequently lost both fortunes. Apart from his success as a securities speculator, Livermore left traders an outstanding working philosophy for trading. – Source: http://en.wikipedia.org/wiki/Jesse_Lauriston_Livermore

NEUROFINANCE – GETTING AN INSIGHT INTO THE TRADER’S MIND

Dedu Vasile

The Bucharest Academy of Economic Studies

The Bucharest Academy of Economic Studies

Much of the academic finance theory is based on the assumption that individuals act rationally and behavioral finance treats investors’ choice based by behavioral biases. In contrast, neurofinance (as a blending of psychology, neurology and finance) attempts to understand behavior by examining the physiological processes in the human brain when exposed to financial risk. Scientists map the mind to learn how fear and greed drive the financial markets. The paper, will briefly present why neurofinance is important and how will be able to provide in the near future a number of effective tools for improved financial decision making.

Keywords: Emotions, Behavioral finance, Neurofinance, Brain, Risk taking, Affect, Beliefs, Dopamine, fMRI

Jel Classification: D03, D81, D83,D84, D87, G11

Much of the *academic finance* is based on the assumption that individuals act rationally, consider all available information in the decision-making process and the expected utility theory represents the model for choice under certainty. In fact, when it comes to financial decisions, investors may not always be as rational as we think.

A new field of finance, called *behavioral finance* examines why some traders achieve phenomenal success while others gamble away fortunes. Behavioral finance that is, finance from a broader science perspective including sociology and psychology, represents a new approach to financial markets, in response to the difficulties faced by the academic finance. Behavioral finance attempts to understand and explain how emotions influence investing decisions. Humans differ very much with respect to concepts such as risk aversion, time preference and tastes. “Limits to arbitrage”, form one of the two building blocks of behavioral finance. Psychology (behavioral biases) is the second building block of behavioral finance (people’s beliefs and people’s preferences). "Extraordinary Popular Delusions and the Madness of Crowds," written by **Charles Mackay** in **1841**, remains a Wall Street classic to this day. He shows how otherwise intelligent people sometimes succumb to mass idiocy. Mackay examined the history of alchemy, witch hunts, fortunetelling and speculative frenzies such as the *mania over tulips* that gripped Holland in the early 17th century, when the flower bulbs *traded at a higher price than gold*. Keynes coined a colorful term for one of the vital ingredients of economic prosperity, the naive optimism that prompts people to cast aside their fears despite all experience: "animal spirits."⁹⁷² The explanation that human beings are irrational about money lies in the human brain and its multi-billion neuronal connections. Recently, behavioral economists have leveraged the findings from psychology and neurology developing new fields like *neuroeconomics*⁹⁷³ and *neurofinance*, in order to understand how people make economic decisions. By looking inside the brain, we may have a more realistic model of decision-making, and we’ll be able to explain in a better way (compared to the standard model) a wide range of individual economic behaviors and their effects translated into aggregate market phenomena. Neurofinance is a new science that

⁹⁷³ Neuroeconomics is an emerging transdisciplinary field that uses neuroscientific measurement techniques to identify the neural substrates associated with economic decisions” – **Zak, J. Paul** “*Philosophical Transactions: Biological Sciences*, Vol. 359, No. 1451, Law and the Brain (Nov. 29, 2004), pp. 1737-1748

analyzes financial markets by applying neurotechnology to trading behaviors⁹⁷⁴. The main objectives are: improving trading results and a better understanding of financial markets, by identifying which physiological traits affect trading behavior, correlating these traits (that occur in our brain and hormonal activity) with trading success or failure and developing tools, technology and training methods to improve trading performance. The main difference between neurofinance and neuroeconomics, though they use many similar techniques, is that neurofinance focuses more narrowly on trading and financial markets.

Decision-making process is fundamentally integrative, melding the complex cognitive processes through which causal relations between actions and consequences are encoded, retrieved and maintained in working memory, with the motivational processes that determine the value, or utility, of actions or sequences of actions. It is important to recognize the interaction of the cognitive, motivational and behavioral processes engaged during the course of specific decisions that cannot be reified to a single specialized circuit, cell type or intracellular process⁹⁷⁵. They are better understood at a systemic level. Brian Knutson was wondering *why some of the traders get rich while others walk away losers*. The answer may lie somewhere in the approximately 60000 miles of neural wiring inside our brains. What lies behind a successful trader? There has to be something more than simply guts, self confidence to take a loss and move on, or understanding risk and reward at a simply and intuitive level. May neurofinance be able to understand the brain's electrochemistry of a successful trader? Why some of them gamble away fortunes on losing investments, averaging down or doubling when logic tells them to stay out, or letting winning positions ride when rational persons would cash out? Why smart guys like Paul Tudor Jones, Richard Dennis, Victor Sperandeo, Stanley Druckenmiller, Ed Seykota, Jesse Livermore, Bernard Baruch, Warren Buffett and so many others made multimillion and even billion-fortunes in trading securities? How come George Soros became known as "the Man Who Broke the Bank of England" after he made \$US 1 billion profit during the 1992 Black Wednesday UK currency crisis? What is that makes them so special?
