THE ANALYSE OF THE REGULATIONS AT THE EUROPEAN LEVEL REGARDING CARTELS. CASE SUDY: CARTEL BETWEEN THE COMPANIES CHIQUITA AND PACIFIC

Berinde Mihai
University of Oradea Faculty of Economics

Fora Andreea - Florina
University of Oradea Faculty of Economics

The present paper tries to make an analyse of the policy in the field of competition, at the level of the European Union, more exactly the policy applied on cartels. It is important to know the regulations regarding cartels, especially the way in which procedures are done in the case of a cartel. Cartels have a negative impact on competition and consumers, and that's why it is extremely important that they are discovered on time and after that, by using correction measures to try to recuperate the created damage.

The used research method is the analyze of the legislation in force regarding cartels and the study of the existing literature in this field, and in order to give an example of the procedures in the case of a cartel, we analyzed the cartel between two companies Chiquita and Pacific. It is extremely important for these regulations to be known, and in order to discourage such practices, the European Committee has thought of a series of advantages for the companies that give information and evidence regarding the existence of a cartel. Among these advantages we could mention immunity to fine, that permits the company to be absolved of all its fines.

The paper presents schematically the legislation that forbids anti-competitive practices, at the level of the European Union, and after that the applied procedure when a law violation is discovered. The modality in which the procedures are applied, in the case of suspecting a cartel, have been presented step by step, and after that, the case study does not exist only to give an example of procedures, but also to present the applied methods, in the case of success in proving the existence of a cartel.

The importance of competition policy at a European level cannot be denied because of the fact that only by implementing of a proper policy in this field, an economy can develop further.

Keywords: cartels, competition policy, European legislation, fine, immunity from fines
JEL: F51, K21, L13, L66

1. Regulations regarding cartels

At the level of the European Union the policy regarding competition between cartels is regulated by Article 101 of the *European Union's Functioning Treaty*, that has replaced Article 81 from the European Community Treaty. The European Law System forbids any agreement between companies that can affect trade between the European Union's member countries. Article 101 from the *European Union's Functioning Treaty* refers to the prohibition of some aspects, such as: direct or indirect settle of purchase or sale prices, markets' sharing, output control or trade control, and unequal conditions for commercial partners that provide similar services (European Committee).

The policy applied to cartels is based on economic principles, exactly like the legislation that regulates the policy regarding competition.

Because there is a difficulty in proving the existence of a cartel, by the fact that this is a secret agreement between two or more companies, at the level of the European Union there is a possibility that a company to benefit from fine immunity when it gives information about the cartel it is included in.

The fine immunity is given to companies based on some strictly regulated conditions. This immunity must be perceived as a reward given to companies that provide useful information to the Committee during the investigation. A company can get immunity, if it voluntary offers the Committee useful information regarding the existence of an agreement between companies, and this information can be the starting point of the investigation. Immunity cannot be granted if the request for clemency comes after the beginning moment of the investigation or if the Committee has information regarding the alleged agreement.

If the conditions for fine immunity granting are not met anymore, the companies can benefit of a reduction in the amount of the fines. In order to benefit of a reduction in the amount of the fines, the companies have to give the Committee information that bring an extra value during the investigation. In a cartel, if more companies wish to benefit of such a reduction, they have to obey the following rules: the first company that brings significant information will benefit of a fine reduction, reduction that can be up to 50%, the second company that brings significant information will benefit of a reduction between 20% and 30%, and the companies that bring information after, will benefit of a reduction of maximum 20% from the given fine.

2. How to conduct the proceedings in the case of a cartel

To start an investigation in the case of a cartel can be done if there are some complaints made by: companies, physical or juridical persons, member states of the European Union or European Committee can dispose to start an investigation, based on information gathered during the years. Before the investigation begins, there is an initial evaluation, which has as a goal, the analyse if the information of the European Committee is enough, or there is a need of gathering more data. When the investigation is started, the companies and their field of activity is established. The decision to start the investigation is made public only after informing the company in writing as well as orally. The notification of the company is done in the language of the country where the company has its headquarters, but it can be done in any other language officially acknowledged in the European Union.

After the beginning of the investigation the European Committee has the right to ask for any kind of information that is considered to be necessary of the solving of the case. This information will not be asked only from the companies implied in the investigation, but also from other companies that can provide useful information in the case. The Court of Justice of the European Union recognizes the right of a company not to contribute at its own incrimination. Thus, when a company invokes this right, more exactly its refuse to give information that could incriminate it, the company has to notify this to the General Direction for Competition. The dead line for information request is clearly settled and it permits to answer in due time. The companies can ask for the information given to be strictly confidential. During the investigation, the General Direction for Competition can ask from the parties involved, but also to others, to take part at different meetings that have want to clarify some aspects. During these meetings, the persons involved in the investigation give declarations.

During the stage of investigation, there can be inspections done at the headquarters of the companies. During the investigations, the European Committee can exchange information with the national authorities of competition.

Also there are meetings organised in order to analyse the current situations, meetings that have the role of maintaining the transparency between the general Directions for Competition and the involved parties. During these meetings, the involved parties are given the chance to clearly present their point of view. They are presided by the leaders of the General Direction for Competition and take place immediately after the beginning of the investigation when the investigation has reached an advanced level.

After the investigation, the following decisions can be taken: forbidding one or more problems identified at the beginning of the investigation, on the reason that they are contrary to Article 101

from the *European Union's Functioning Treaty*, or the finishing of the investigation on the reason that the accusations are not founded. Before taking a final decision, in the case of not finishing the investigation, the involved parties have the right to be heard. After the hearings, the Committee will say its objections and the intention of giving or not giving a fine will be mentioned. This stage of the investigation can end with the decision of closing the case, if the communicated objections are considered to be unfounded, or a decision can be adopted as a consequence of breaking the competition norms.

Voluntarily, the companies can propose the Committee some commitments that can answer to problems identified in the field of competition. Before these commitments are obligatory, a decision is taken regarding some market test to see if the measures applied are efficient. The committee can consider that besides these commitments the introduction of some corrective measures and fines are proper. The fine for each company can reach up to 10% from the turnover of the company, depending on the seriousness of the facts. The decisions are adopted by the Committee, the implied parties are informed, and after a short period of time, the decisions are published. The abstract of the decision is published in the Official Journal of the European Union.

3. Case Study: the Cartel between Chiquita Company and Pacific Company

The cartel between Chiquita Company and Pacific Company has been called *Exotic Fruits*, having the number 39.482. the companies that have been investigated were, on one hand: Chiquita Brands International, Inc. From the U.S.A., *Chiquita Banana Company BV* from Belgium, Holland and Luxemburg and *Chiquita Italia SpA* from Italy, and these companies being collectively called Chiqhita,; and on the other hand, the companies: *FSL Holdings NV* and *Leon Van Parys NV* from Belgium and *Pacific Fruit Company Italy SpA* from Italy, these companies being collectively called *Pacific* (European Committee). These two companies have been subject to one investigation, also for violeting Article 101 from the *European Union's Functioning Treaty*, and with the Committee's decision in 2008, the existence of a cartel between the two companies has been proven, establishing the price for bananas on the North European market.

In this case, the subject of the research has been the price establishing for ripe and unripe bananas on the South European market. In 2007, the Committee has got a series of documents that have been gathered by the Italian police, when making an inspection at the headquarters of the Pacific company, After that, some other inspections have been done at the headquarters of other significant importers of bananas from Spain and Italy. In December 2009, the Committee has communicated the objections to this case. After this communication, all the involved companies have presented, in writing, their point of view, regarding the objections made against them.

In June 2010 the hearings took place, where all the involved parties were present. We have to mention the fact that, Chiquita Company, in 2005, submitted an application for fine immunity. Of course, this application was approved on the condition that the company gave all the necessary information during the investigation. The application was submitted in order to be given a fine immunity in the case of the cartel regarding the price establishing of the bananas on the North European market. This application was also acknowledged in the present case, the only imposed condition being to cooperate exactly like in the first case. Thus, after the investigation, it was clear that during eight months, July 2004-April 2005, the two companies, Chiquita and Pacific coordinated their strategy regarding the price for selling ripe and unripe bananas on the Portugal, Italian, and Greek markets. During this period, the two companies exchanged information regarding the future price strategies, applied on the three markets.

The cartel could be proved on the basis of the documents found at the headquarters of Pacific Company, after the unannounced inspection and of the information brought by Chiquita

Company. These two companies are among the largest providers of bananas on the European market.

The decision adopted by the committee, on the 12 October 2011 could be summarized as follows: a secret agreement between the two companies could be proved, agreement regarding the price establishing for bananas, for a period of eight months and 12 days; the significant market was Greece, Portugal and Italian; and as corrective measures regarding the above mentioned violation, there were some fines given. The amount of the fine was established according to the sales done in Portugal, Italy, and Greece, during eight months. Thus, as a consequence of the final decision, the Pacific Company was given a fine of 8.919.000 Euro, and Chiquita Company has benefited of the clemency policy, thus being exempt from the payment of any fine.

4. Conclusions

The importance of a policy in the field of competition, at a European level, cannot be neglected, because only by implementing of an adequate policy in this field, an economy can develop.

At a European level, the policy in the field of competition is focused on: cartels, abuse of dominant position, economical concentrations and state aid. Regarding cartels, the regulations and proceedings are clearly established. The particularity in the case of a cartel is that it is rather difficult to be identified, being by definition a secret agreement between two or more companies and that aims the coordination of the market prices, thus influencing both competition and consumers.

During the years, the European Committee has been confronted with different kinds of cartels that activated in different sectors. All these cartels have been punished by applying corrective measures. The extent of these measures was established according to the damage and according to the period of the cartel's existence.

In the table below (Table no.1) we can observe the amount of the fines applied to cartels in the European Union, between 2006-2012. Analysing this table, we notice the fact that in 2007, the fines had the highest value, a total of approximately 3.338 millions of Euro, and the smallest value was recorded in 2011, totalling 614 millions of Euro. We cannot take into consideration 2012 because only three months were taken into consideration.

Table no.1 Fines applied to cartels between 2006-2012

Year	Amount in €
2006	1.846.385.500
2007	3.338.427.700
2008	2.263.279.900
2009	1.540.651.400
2010	2.868.676.432
2011	614.053.000
2012*	255.258.000
Total	**12.726.731.932**

Source: adapted on information found at http://ec.europa.eu/competition/cartels/statistics/statistics.pdf
          * March 2012

According to the statistics, beginning with 2006 up to present, during these seven years, on the European level, there were fines given valuing approximately 12.727 millions of Euro, because of Article 101 violation, from the *European Union's Functioning Treaty* (once Article 81 in the *Treaty of the European Community*).

In order to emphasize more clearly the evolution of the fines applied to cartels in the European Union, in the period 2006-March 2012, we can analyse the chart below (Chart no.1). We can

notice the fact that during seven years, the maximum points were reached in 2007 and in 2010. The period between 2007-2009 registering a decrease of the fines applied to cartels.
Chart no.1. The evolution of the fines' value, applied to cartels between 2006-2012
Source: made by the author based on data from http://ec.europa.eu/competition/cartels/statistics/statistics.pdf
* March 2012

In order to see also an evolution of the cartel cases, acknowledged by the European Committee, the table below can be analysed (Table no.2). During the analysed period, we notice that, in 2007 there were discovered and punished, most cases of cartel, that is 8, and in 2011, the fewest cases, that is 4. Until March, the current year, two cases of cartel were acknowledged.

Table no.2 The number of cartel cases acknowledged by the European Committee, during 2006-2012

Year	No. cases
2006	7
2007	8
2008	7
2009	6
2010	7
2011	4
2012*	2
Total	**41**

Source: adapted based on the data from http://ec.europa.eu/competition/cartels/statistics/statistics.pdf
*March 2012

Thus, in order to diminish the cases of cartel registered at a European level, it is extremely important that the legislation in the field of competition should be strictly applied.

ROMANIA'S EU ACCESSION. GAINS AND LOSSES (I)

Caba Stefan
University of Oradea Faculty of Economics

EU accession has brought, as expected, many changes in economic, social and cultural domains. An important chapter is the trade dynamics and how this dynamic has been modified over time by changes in the legal status of Romania's relations with certain trading partners. In this paper we present data on trade with countries with which Romania has concluded trade agreements before accession. Data presentation and analysis continues in "Romania's EU accession. Gains and losses (II)".
Keywords: bilateral agreement, comparative advantage, international trade, EU accession, EU integration.
JEL Classification: F13, F14, F15.

Introduction

As a result of national will and political interests, the accession process and then, the integration of Romania into the EU is too often regarded as controversial. If the accession and integration option is not contested, how governments have managed this process is considered unprofessional. EU had fulfill its role of providing training support for accession and quickly integration, but governments did not know or did not want to get maximum profit for the citizens. Five years after accession Romania does not yet feel the benefits of EU membership. Many of the actions taken by representatives of political and administrative power are, though, against national interest and appear to show resistance to the EU's democratic institutional system. An important factor, among others, is the opening to the biggest economic market. If the governments knew and wanted to take advantage of Romania's foreign trade this would have grown strong with January 1, 2007. This in fact happened but not in the desired direction: trade volume increased, but trade deficit with the EU also increased. This supports the idea that in the economic relations with a majority of partners, comparative advantage is on their part and not Romania's one. Romania's main comparative advantajes are cheap labor and low price of exported natural resources. Neither of these two components do not contribute to economic development in Romania but to its devaluation. To justify these assertions we will analyze (in part (I) and part (II)) commercial advantages or disadvantages of EU accession by studying the dynamics of commercial balance with countries with which Romania has changed, during time, the legal status.

Romania before 2007

Romania has concluded trade agreements wich, with the accession, were closed. The main agreements were concluded with the CEFTA, EFTA and that bilateral agreements with Albania (2004), Bosnia (2004), Israel (2001), Macedonia (2004), Moldova (1995), Slovenia (2004) and Turkey (1998).

We present statistics on trade with these countries with highlighting, if any, the effects of termination of these contracts, on the one hand, and the accession, on the other hand, on the volume of these exchanges. Note that data for 2010 are provisional and those for 2011 are obtained by interpolating the data for the period January-October 2011 (according to INS (Institutul National de Statistică) monthly statistical bulletin issued).

First we present data on those CEFTA countries which joined the EU before Romania. It's about Czechoslovakia (Czech Republic and Slovakia) (1992, 2004), Poland (1992, 2004), Slovenia (1996, 2004) and Hungary (1992, 2004). Since the effective separation of Czechoslovakia took

place on January 1, 1993 to 1991 and 1992 data were mentioned on the behalf of Czech Republic. Dates in the brackets represent the year when the country joined CEFTA, and the year when the country joined the EU and therefore the output of the CEFTA.

We are not doing here an analysis, because we return in Part II, but already seen a steady growth of trade volume with these countries.

Table 1. Romania's trade with selected CEFTA countries during 1991-2011

	Imports (thousand euros)					Exports (thousand euros)				
	Czech Republic	Poland	Slovakia	Slovenia	Hungary	Czech Republic	Poland	Slovakia	Slovenia	Hungary

A first conclusion following the analysis of the graph showing trade with CEFTA countries mentioned is that the inclusion of Romania, in 1997, in to the Central European Free Trade Agreement has led to a growing trade deficit with these countries, the deficit widened in 2004, year that all states accessed EU. Moreover, following the accession to the EU, trade deficit rises sharply with values 2-3 times higher than the previous. Things were changed in 2008-2009, but not to the values of the period 1991-2000. It is important to note, and we return to this issue in analyzing the advantages and disadvantages of accession (from trade point of view), that deficit reduction is mainly based on the growth of value of exports to these countries.

An interesting development is the dynamic trade with EFTA signatory states (Norway, Switzerland, Iceland and Lichtenstein).

Table 2. Trade between Romania and EFTA Member States during 1991-2011

	Imports (thousand euros)				Exports (thousand euros)

If, regarding Iceland and Lichtenstein, trade does not record (in absolute values) significant changes (even if the relative values can vary over 15 times) regarding Switzerland and Norway a mirroring behavior is observed. This suggests that European free trade association has a lesser role in the individual Member States trade with other countries and probably more influenced relationships between EFTA.

Another category is the Romanian relations, before and after accession, with the states with which our country had concluded bilateral agreements. It is, as mentioned earlier, Albania (2004), Bosnia (2004), Israel (2001), Macedonia (2004), Moldova (1995), Slovenia (2004) and Turkey (1998).

ROMANIA'S EU ACCESSION. GAINS AND LOSSES (II)

Caba Stefan
University of Oradea Faculty of Economics

This paper is a continuation of "Romania's EU accession. Gains and losses (I)" where we have been presented statistics on Romania's trade with major trading partners to whom, before, or after EU accession, the legal status has changed. In this paper we try to identify the benefits and costs of accession to the EU in terms of trade. In the first part we analyze the dynamics of trade with new partners, resulting from the accession. The last part is devoted to conclusions. The main idea that emerges from this work is that, unfortunately, Romania governors, did not know to take advantage of the opening to the biggest economic market although the financial and institutional support offered by the EU.

Romanian trade agreements after 2007

With the accession to EU Romania was bound to abandon its trade agreements, instead became part of the union agreements with third countries or regions. In this paper we try to identify any correlations and, obviously, the effects that these legal changes over Romania's trade. For this we analyze the dynamics of trade with the signatory states of the Euro-Mediterranean Association Agreement with the EU, and the trade dynamics with South Africa, Chile and Mexico. These are countries with which Romania has not concluded bilateral agreements before accession. Obviously, this analysis does not include all countries in the category with which Romania has not concluded trade agreements until accession; to name, as an example, EU agreement with ACP countries. In the latter case, however, for example, Member States are to 79 (of which 78 have signed the Cotonou Agreement), and an analysis of trade relations between Romania and each of them exceeds the objectives of this paper.

Table 1. The dynamics of trade balance between Romania and the main countries involved in regional agreements with the EU (thousand euros)

Figure 1.
Source: Graphic made by author based on data in Table 1.

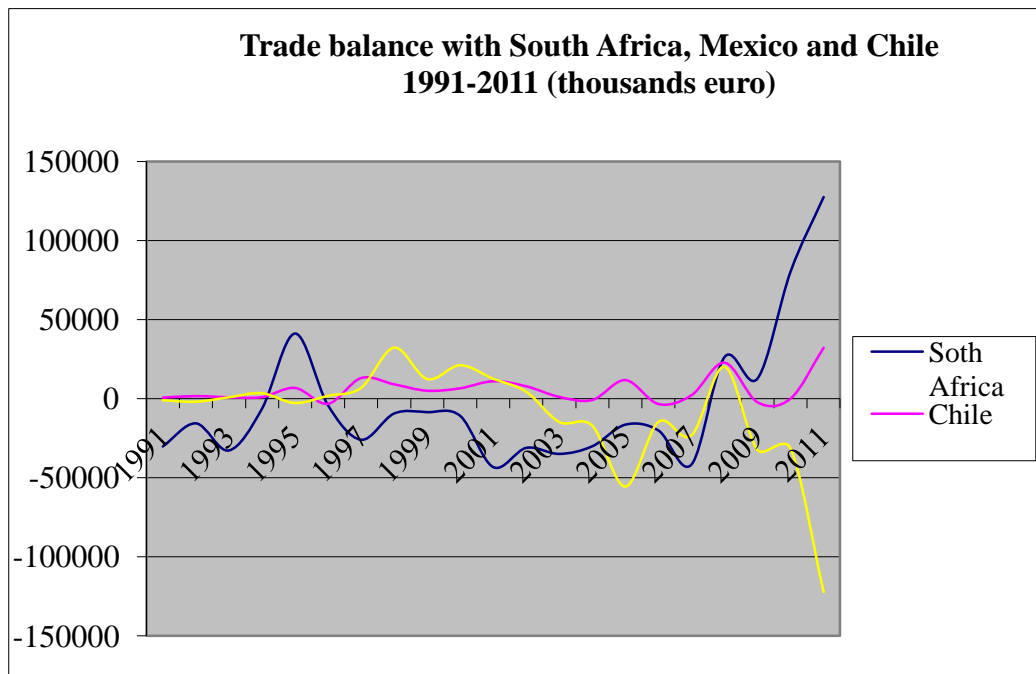
After analyzing the trade balance Euro-Mediterranean countries, that are parts of the agreement with the EU, an increase, beginning with the 2000-2003 period, is seeing but it does not contribute significantly to analysis efficiency. However, after 2007, it seems that there is a sharp rise in trade surplus.


Figure 2.
Source: Graphic made by author based on data in Table 1.

Trade balance with South Africa and Chile is growing after 2009, which seems to be a correlation with the date of accession. However, supporting the EU's willingness to develop trade relations with South American countries, including the reduction or withdrawal of reciprocal custom duties, an increase of trade deficit with Mexico is observed. Mean time low level of trade surplus with Chile is maintained.

Commercial advantages and disadvantages of Romania accession to the EU
We will analyze, based on data presented in the previous paragraph, the dynamic changes in trade, separate for each partner.
a) CEFTA countries
First we will review trade with CEFTA member states that joined the EU, and therefore exit CEFTA, before Romania. We try to identify if the two time points 2004 (exiting CEFTA) and 2007 (Romania accession) has caused or not, fluctuations in the level of trade.
Charts, which are dynamic trade with the Czech Republic, Poland, Slovakia, Slovenia and Hungary, have obvious similarities. Remember, first, that in 1997, when Romania became a member, all these countries were already in CEFTA (Slovenia in 1996, the rest of 1992). In addition, all states listed have become EU members in 2004.
What stands out in these graphs are the two time points (1997 and 2007) which marks an increase of trade but, unfortunately, at the same time with Romania's trade deficit with all five states. This underlines that CEFTA membership, and then the EU membership caused an increase in trade with other Member States, which is natural situation because both moments generated legal status changes and reduction or elimination of customs duties.
The negative trade balance, unfavorable to Romania, increased after 2007, and can only be explained by low competitiveness of Romanian products compared with those of the five countries analyzed. This fact underlines the need for increased integration and obliges governments to identify and implement measures to justify efforts for accession.

b) EFTA countries

A second category of countries analysed is the signatory countries of EFTA. We recall that in 1993 Romania ratified the accession to EFTA agreement. The agreement is, in many aspects, similar to the European Agreement.

Analysis of trade with EFTA Contracting States has a special character determined, on the one hand, by the status of nonUE states and, on the other hand, by the low level of trade with Iceland and Lichstenstein. Perhaps the most important observation is that, although Romania has concluded trade agreements with EFTA since 1993, the year seems to mark a fact boost trade, the highest increases occurring in the periods before and after accession of Romania to the EU.

This rather suggests a trade connection between the EU and EFTA and not between EFTA and Romania. Unfortunately in this case also increasing trade relations implied rising of the trade deficit. This dynamic is justified by the fact that Romania and the EFTA agreement had provisions similar to the Europe Agreement.

c). Countries with which Romania has concluded bilateral agreements

A more interesting is that trade with countries with which Romania has signed agreements before 2007. We emphasize that we not do, in this paragraph, referrings to agreements before 1989.

The evolution of trade with Albania has experienced a pronounced upward trend since 2005 which suggests that there is a direct connection with the signing of bilateral agreement (2004) but not with Romania's EU accession. When analzsing trade relations with Albania we should kept in mind the effects of social tensions in the area have had on this country. However, the trade is very low compared with major trading partners which affects less any assumptions about the influence of accession.

Data for Bosnia and Herzegovina are strongly influenced by the wars of 1995 and the changes to the socio-political-administrative associated with these wars. Signing the agreement (in 2004) seems to have led to a sharp increase followed by a positive trade balance in 2007 and a sharp drop timid return after 2008.

Agreement with Israel was signed in 2001 and apparently had a major, but short, effect on trading in the pre-accession period. More important is to note that, after 2007, there is a growing trade balance, which tend to put him on account of Romania's EU accession.

The graph suggest a strong positive effect of the bilateral agreement (signed in 2004) on trade between Romania and Macedonia. As for Albania and Bosnia and Herzegovina should be noted that the wars in the region strongly affected the foreign trade of these countries.

Trade agreement with Moldova was signed in 1995. As shown in graph trade know a positive trend thereafter. EU accession seems to have not caused significant changes in trade relations.

Trade agreement with Turkey was signed in 1998 and, according to INS, had a positive effect for Romania at least for the next two years (1999, 2000). Note that elimination from 1 January 2002 of customs duties on industrial products of Turkish origin caused a steep increase in imports. Fortunately exports grew at the same time, thus avoiding (except in 2008) the trade deficit. 2008 marked the beginning of a trade deficit (based on increased imports from Turkey), but 2010 has led to a positive return generated by an increase of Romanian exports.

d) New partners as a result of Romania integration in EU

d1) Euro mediteranean countries

Except for Tunisia, where the year 2010 marks a decline in exports in all other cases, the year 2007 marked a significant increase in trade volume, together with a positive trade balance. The explanation may be the same as in trade with CEFTA partners with former difference, essential in fact that, in the latter case, Romania has more competitiveness. Unfortunately trade surplus recorded values with the Euro-Mediterranean countries is far from commercial shortfall relationship with former CEFTA member states.

d2) Africa, Chile, Mexic

Commercial relations with South Africa, Chile and Mexico marks, as expected, changes in the before and after accession periods. Even if in the relationship with Mexico, Romania is knows trade deficit, all trade with the three countries generates a trade surplus, which supports the idea that membership was a good solution for Romania.

Conclusions

We emphasize, from the beginning, that we analyze the EU accession only from commercial component point of view. Only mention that Romania, as a candidate for EU membership, has benefited over time, substantial financial and institutional aid from the EU.

All the actions taken by the EU had intended to prepare Romania for membership, a status that brought, among others, another level of commercial competition within the EU, on the one hand, and a different position in relation to third countries. We refer here to the transition from a preferences beneficiary country to a donor one.

It identifies two main components (commercial) of accession. On the one hand, the adoption of common customs tariff and common commercial policy and, on the other hand, the elimination of customs duties on intra-EU imports.

The elimination of customs duties on industrial products has gradually evolved and ended in late 2001. From 1 January 2002 suppression duties on imports of industrial products were extended to signatory countries of EFTA and Turkey. These actions have caused, among other things, an increase of trade deficit. As mentioned in previously published work (Caba 2010: 52) mutual reduction or elimination of tariffs tend to generate trade surplus to the country with most, or most important comparative advantages. Unfortunately for Romania, the comparative advantage in dealing with a large number of trading partners is the cheaper labor and less by the higher productivity or increased competitiveness generated be work quality. This advantage, however, is fleeting and, moreover, is affected by the low cost of labor in the Far East.

Romania and, in this case, Romanian companies should take advantage of free access to the largest global economic market (over 500 million inhabitants). This openness is, however, for the moment, rather a disadvantage. As long as it does not reach higher values of competitiveness and productivity and meanwhile trade is based on export of natural riches and the cheapness of labor Romania will be condemned to laggard positions among EU members. Government policies should be directed to supporting productive industry and to develop export opportunities.

If in terms of exports and imports extra-EU common commercial policy is very little influenced by the decisions of the Romanian political body, intra-Community trade, which represents most of Romania's total trade can be influenced, both in volume and the structure, only by the degree of industrial development that determine the competitiveness of Romanian products to export.

From our perspective the EU has done its duty of support, including financial, Romania accession and integrations process. A simple analysis of data provided by the former Ministry of European integration shows a calculated net benefit of over 18 billion resulting difference between the grants made available to Romania and its contributions to 2013 inclusive.

A STUDY ON FINANCIAL DERIVATIVE WORLDWIDE TRANSACTIONS – FUTURES CONTRACTS

Ciobanu Gheorghe
Babeș-Bolyai University, Cluj-Napoca Faculty of Economics and Business Administration

Sechel Ioana-Cristina
Babeș-Bolyai University, Cluj-Napoca Faculty of Economics and Business Administration

Financial products and financial derivatives transactions are on front page in the profile publications, because they have generated huge gains for a small part of market participants, and losses as well, sometimes followed by collapse even on the international financial institutions. Very common we can find in specialized media the hypothesis that the global instability was caused by derivative contracts and by the magnitude of these transactions, from the years preceding the crisis. Since they appeared in order to protect investors against various risks, we believe that the approach must have via derivative products is the ethical one. It is true that derivatives trades have grown very rapidly and have expanded from the commercial field (commodity derivatives) to the capital market, but this was because the demand for such products was very high. Basically, the demand for financial derivatives products has validated their existence in the market.

Derivative financial products are used by traders of financial intermediation companies, dealers, brokers, individual investors and corporations or governments. Precisely because of this large spectrum of users of financial derivatives, we can ask whether they should be used only by specialists in derivatives trading. Taken literally, the term derivative refers to a new product resulting from the modification of an existing product, but has different properties from the original product and from which it was derived (Business Dictionary 2012). But financially speaking, a derivative is a financial contract between two or more parts that comes from the future value of n reference asset (Reuters 2001, 17). Of course, in literature there are many definitions of the concept of financial derivative. If we were to build our own simple definition, we define financial derivatives as financial contracts based on an underlying asset whose price on the spot market determines its price. This is a very simple statement, but true.

Regarding the main categories of derivatives market, the literature (Popa 1994, 62) (Bako 2006, 65) refers to four such categories: forward markets, futures markets, options market and swap markets. We chose as a subject for this article the futures market, worldwide. The latest data available at this time refer to 2010 statistics; in this area the data for 2011 are not available yet.

Keywords: futures, commodity futures contracts, currency futures contracts, interest rate futures contracts, stock index futures.

Futures market has suffered constant changes since the 1980s, both in Europe and especially in the United States. The stock exchange markets that offer derivatives for trading, namely futures products have diversified its range, there underlying assets are the most various traded futures. The most traded future contracts worldwide have as an underlying asset currencies, interest rates or indexes. Traditional futures markets, commodities markets have declined in the last 20 years

due to extremely rapid development of markets where futures are traded mainly with the underlying financial assets.

1.Commodity future contracts and energy products

Commodity futures contracts are among the oldest derivatives and are the base for financial futures development. The goods most traded on the Chicago Stock Exchange are:

- Cereals and oilseeds: corn, wheat, soybean, soybean oil, crude palm oil, oats, rough rice.
- Livestock: live cattle, lean hogs.
- Frequently consumed products: Milk category 3 and 4, milk powder, whey, butter.
- Wood products: variable length timber, resin (cellulose).
- Other agricultural products: Cocoa, Coffee, Cotton.
- Precious metals: Gold, Silver, Platinum.
- Ferrous metals: Steel.
- Other metals: Copper, Uranium.

From the category of energy products traded on the Chicago Stock Exchange, we can mention: coal, refined products: heating oil , gasoline (various types), marine oil, electricity, natural gas, ethanol, light sweet oil, brent oil (name of two different types of oil extraction due to their area of extraction).

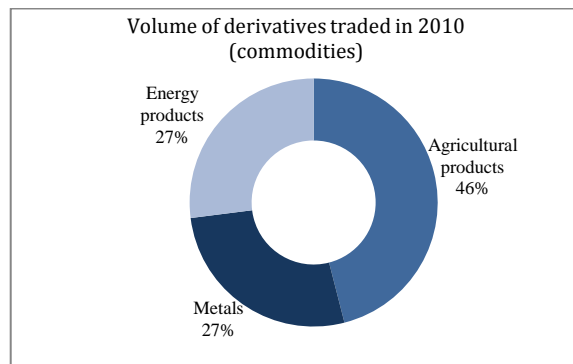
Worldwide, the volume of derivatives traded with the goods underlying asset, in 2010, can be presented as follows:


Figure no 1. Volume of derivatives traded in 2010 (commodities)
Source: made by author by data provided by the World Federation of Exchanges.

World Federation of Exchanges has made in 2011 a study conducted on the world market of derivatives of all types, and classified the exchanges that trade derivatives according to the volume traded in 2010 in comparison with the volume traded in 2009.

On the first position as increased trading volumes in 2010 compared to 2009 we find EUREX (337%). EUREX is one of the most representative markets for derivatives worldwide. This was the first market where investors could trade derivatives on gas emission allowances with greenhouse effect (CO_2). The great advantage of this market, managed by Deutsche Bourse AG and SIX Swiss Exchange, has been buying ISE (International Securities Exchange) in 2007, this system offers a wide variety of electronic trading platforms and access to many international stock exchanges. Volume traded with derivatives increased on average by 34% in all markets.
Figure no 2. Geographical distribution of transactions with derivatives trading volume in 2010/2009
Source: made by author by data provided by the World Federation of Exchanges.

As shown in figure number 2 above, the most commercial derivatives were traded in the Asia-Pacific. Stock exchanges in this area increased in trading volumes (36% higher in 2010 compared to 2009), given that 87% of total volume traded in this region of the world has been determined by China. The volume of commodities derivatives traded at Shanghai Stock Exchange in 2010 increased by 43% compared to 2009, while on the stock market in Zhengzhou were traded with 118% more transactions in 2010 compared to 2009.

Chicago Stock Exchange (CME Group) dominates the trading with commodities derivatives in America, across all segments, as follows: agricultural products, energy products and metals. The number of derivative contracts traded in 2010 was 35% higher than traded during 2009. This because of the possibility created by stock exchanges for investors to trade using trading platforms such as CME, CBOT and NYMEX.

2.Currency future contracts
Currency futures contracts require standardization of most elements (Ciobanu 1997, 204), the margin that has to be submitted is very small, hence the possibility of employment in high value transactions. However, a small margin for the transactions engaged, can bring huge profits, but this mechanism can generate losses as well. Most times, transactions with the future contracts with underlying asset on currencies, are made for speculative purposes or for a foreign exchange risk coverage.

Derivative transactions with underlying asset on currencies saw a remarkable increase in 2010 in their volume compared to 2009. Worldwide, the increase was 142% for stock exchange markets taken in the analysis of World Federation of Exchanges. Thus, in the top of stock exchanges with the highest growth of derivatives trading volumes on currency futures, there is Osaka Securities Exchange with a volume increase of 684% in 2010 compared to 2009, MCX-SX (MCX Stock Exchange Ltd India) with an increase of 294% or National Stock Exchange of India with an increase of 218%. At CME Group, the volume of transactions increased by 45%.

The volume of transactions with derivative contracts with underlying asset on currencies declined by 11% in 2010 at NYSE Liffe, compared to 2009.

As shown in the figure number 3, most currencies derivatives were traded in Asia-Pacific. The stock exchanges in this area recorded increases in trading volumes on average 216% higher in 2010 compared to 2009. Volume traded on currency derivatives on Osaka Exchange, has

increased 684% in 2010 compared to 2009, while on the MCX – SX stock exchanged were traded with 294% more transactions in 2010 compared in 2009.
Figure no 3. Geographical distribution of transactions with currency derivatives in 2010/2009
Source: made by author by data provided by the World Federation of Exchanges.

3. Interest rate future contracts

Interest rate futures are commitments to deliver or to receive at a fixed maturity, a financial asset with an interest fixed at the start of operation (Ciobanu 1997, 206). The purpose of the futures contract in this case is the interest produced by the asset, the buyer will actually buy the interest that the asset will produce in the future. This interest will have a fixed rate at the signing of the contract.

Regarding trading derivative products with underlying asset on interest rates, there has been an increase on their volume by 29% in 2010 compared to 2009, worldwide after two consecutive years of decline. Since 2009, trading interest rate derivatives has evolved in the context of the practice of monetary policy interest of almost 0% by several major central banks around the world. But from 2011 the European Central Bank changed its interest rate and increased it from 1% to 1.25% in April 2011, the same action have been adopted by other specialized banks, the perspective of gains for investors using derivatives on interest rates, was almost obvious. Thus, the first months of 2011 have brought increased trading volumes on these instruments.

Regarding the distribution of derivative transactions on interest rates, in 2010, 40% of them have been concluded with futures contracts based on short-term interest rates (STIR futures), 39% with futures based on long term interest rates (LTRI futures), 16% with options contracts based on short-term interest rates (STRI options) and 5% were concluded with options contracts based on long-term interest rates (LTRI options).

From the regional point of view, the most futures and options on short-term interest rates were traded in America (about 1170 million contracts in 2010) while in Europe, Africa and in the Middle East was traded a number of 578 million such contracts in 2010. The fewer contracts based on short-term interest rates have been traded in the Asia-Pacific (24 million contracts in 2010). Most futures contracts and options on long-term interest rates have been traded throughout the Americas (696 million contracts in 2010), while in Europe, Africa and Middle East were traded 612 million contracts. In contrast stands the Asia-Pacific zone, with a volume of 99 million contracts.

In the category of interest rate derivatives and offered for trading by EUREX (Eurex 2010, 110), we can mention:

- Futures on fixed interest rates: they are debt securities issued by Germany, Italy and Switzerland, whose value / contract is 100.000 euro or 100.000 Swiss francs.
- Contracts for fixed interest rate options.
- EONIA futures (Euro Over Night Index Average): These are futures contracts based on the average effective overnight reference rate for the euro. This rate is calculated by the European Central Bank for a period of one calendar month. The contract is 3 million euro.
- EURIBOR Futures: are future contracts that are based on EURIBOR for 3 months deposits. The value of such a contract is 1 million euro.
- Options on Futures EURIBOR futures.
Figure no 5. Geographical distribution of volume transactions with stock index future contracts in 2010/2009.
Source: made by author by data provided by the World Federation of Exchanges.

In Asia we can find five stock exchanges in a ranking of the highest trading volume in stock index futures contracts as follows: Hong Kong Exchange, Korea Exchange, National Stock Exchange of India, Osaka SE and Singapore Exchange.

In the Europe, Africa and the Middle East we can distinguish tree stock exchanges in trading such instruments: EUREX, RTS and NYSE Liffe. In fact, this area records also the highest growth on the volumes traded in 2010, with 15.18% higher than in 2009.

4.Conclusions

Derivatives traded volumes has grown globally in an impressive mode, especially in the last 12 years when their volume was approximately 10 times higher than 1998-2000. The period of the financial derivatives transactions boom was situated between 2003 and 2007 when most of the capital markets were increasing. During this period the growth of derivative products traded was higher than the volume traded on spot markets, worldwide. The years 2008 and 2009 brought with the crisis a decline in volumes of traded derivative products, globally. However, 2010 was noteworthy, the increase was 25% compared to 2009. With this increase of trading volume it returned to pre-crisis level. The major reasons for this increase relates to better market conditions in 2010, trading infrastructure development, etc.

If we analyze the derivative contracts traded by different regions, there is an impressive increase in trading volumes in the Asia-Pacific (+36%), especially in the KOSPI (Korea Composite Stock Price Index) on the options. In the America, traded volumes of such products in 2010 increased by approximately 35% in 2010 compared to 2009, and in the Europe, Africa and the Middle East, the increase was about 21%.

The main attribute of increased derivatives trading volumes on the one hand is the increasing of global liquidity and on the other hand it ensures a fair distribution of risk between the various participants at the transaction. We could say that much of the derivatives market participant expectations palette was satisfied with the financial instruments provided, but certainly there is enough space remained for new products and new innovations in this field.

LITTERATURE REVIEW OF THE EVOLUTION OF COMPETITIVENESS CONCEPT

Haţegan D.B. Anca
University of Oradea
Faculty of Economic Sciences

The concept of competitiveness can be reported – considering the level of disscution – to a product, firm, industry or sector, region, nation, commercial block or to a global aspect and there is a close connection or relationship between all these levels of competitiveness. Firstly, the quality of a certain product or service determines a firms possibilities to survive the competition. On the other hand, a firms economic performance is connected to the performance of a certain sector, region or nation in an international scale. Competitiveness is a concept that can be used in a comparative sense or analysis. Due to the globalization and liberalization process, the boundaries between the domestic and international markets fainted, conducting to disappearing of the distinction between national and international competitiveness
Despite the complexity and notoriety surrounding the concept of competitiveness, this article is trying to gather as much information as possible regarding this notion, presenting it from different perspectives, at micro and macro level, reviewing the theoretical literature background: the classical, neoclassical, Keynesian theories, the development economics theory, the new growth theory, the new trade theory and all their implications on the evolution and development of the concept of competitiveness , but also the empirical literature such as IMD's World Competitiveness Index, WEF's Global Competitiveness Report, OCDE's New Economy Report and UK Government's Productivity and Competitiveness Indicators.

Key words: international competitiveness, national competitiveness, regional competitiveness, firm competitiveness, evolution of competitiveness

JEL codes: F23

Introduction

Lately, the concept of competitiveness has been oftenly used, and sometimes quite abusive. The rising questions and the derived concepts are essential, also being the central question of all researchers: a better understanding of the problems of wealth and its distribution. In the present context, of European integration process, the challenges faced by the member states are related to applying the Lisbon Agenda objectives and transforming the European Union in the most competitive and dynamic economy, based on knowledge, at international level, that should generate a sustainable economic growth, more jobs and social cohesion. That is why it is very important to understand the concept of competitiveness under all ita various forms, both at micro and macro level.

Stephane Garelli begins his latest work, *Top class competitors. How nations, firms and individuals succeed in the new world of competitiveness,* with a very interesting observation related to the notoriety and the excessive usage of this concept, stating that a simple Google search of the word competitiveness, generates more than 35 million entries (Stephane Garelli 2006:XV).

Although this concept is excessively used, its definition still remains ambiguous. That is why this article tries to cover as much as possible the economic literature. The competitiveness's main objective is represented by the growth of the prosperity level of a nation and of the individuals. At a national level, the source of competitiveness is represented by the firms operating on it's territory, stating that this is the place where the economic value added takes place. The role of state in this case, is to ensure a sustainable flow of economic wealth from firm to its citizens, meaning direct revenues or benefits resulted from the services offered by the state and the infrastructure. Overall, the nations prosperity level results from the interaction of three forces: the competitiveness of firms, the competitiveness of individual and the competitiveness of nation.

The micro and macro perspective of competitiveness

At micro level, the understanding of the concept of competitiveness refers to a firm's ability to compete, to grow and to be profitable. At this level, the competitiveness consists in a firms capacity to produce in a profitably manner goods that should correspond to an open market requirements.

Comparatively, at a macro level, the concept of competitiveness is more vaguely defined and much more controversed. Despite the fact that improving a nations competitiveness or a region's competitiveness is the central purpose of every economic policy, the lack of a clear unanimously accepted definition represents a source of constant controversy, the main argument being that it is quite dangerous to construct an economic policy around such an amorphous and interpretable concept.

Paul Krugman describes national competitiveness as being a "dangerous obsession", that rises three important issues: firstly, this concept is very confusing, and the analogy between the firm and the nation is incorrect. This point of view is accepted by the supporters of the concept of macroeconomic competitiveness, that could be illustrated by the following definitions: "A nation's competitiveness is represented by the degree to which into a free market economy this can produce goods and services that meet the requirements of the international market, simulating in the same time a real growth of the citizens incomes. At national level, competitiveness is based on economic performance and on a economy's ability to transform the results generated by the productive activities in raising the incomes. Competitiveness is oftenly associated to rising the living standards and rising the employment opportunities and also in a nation's ability to maintain its responsabilities at international level. It is not just a measure of a nation's ability to sell its goods at international level and to maintain a commercial equilibrium (The Report of the President's Commission on Competitiveness , 1984).

OECD defines competitiveness as being the degree to which a state may produce goods and services that should pass the test of international competition and in the same time to maintain and develop its incomes al national level, in the conditions of market liberalisation (*OECD Programme on technology and the Economy, 1992*).

In the European Competitiveness Report, an economy is competitive if its population can benefit over higher living standards and a better employment degree, in a sustainable perspective (European Competitiveness Report, 2000).

The above definitions have some common features regarding the macroeconomic perspective of competitiveness: the performance is expressed in improving the living standards and the real incomes; the liberalisation condition of markets for the goods and services produced by the nation in charge, and on short term, competitiveness dhould not generate imbalances.

In this context it is important to introduce the concept of regional competitiveness, a term that is not used that often and is defined less. Trying to define this concept, the European Commission states that this definition should encompass certain elements, despite the fact that there are competitive firms and less competitive firms at regional level, there are common features in these regions, that affect the competitiveness of the firms localised in these regions. So, for being competitive, a region must ensure the growth of incomes and of the living standards, the quantity and also the quality of jobs, in the terms of international competition.

In other words, regional competitiveness represents an economy's ability to optimize its local resources, to compete and prosper on international and national markets and to adapt to the changes present on these markets.

Theoretical background and the evolution of competitiveness

This section presents the theoretical aspects of economic literature and their implications on the evolution of the concept of competitiveness. Every one of the schools of thought had important effects on the notion of competitiveness, even if we refer to international, national, regional or

firm competitiveness. This part of the article is concentrated on the economic doctrines, presenting the ideas of classical theory, neoclassical theory, Keynesian theory, development economics theories, new growth theory and new trade theory, from the perspective of the concept of competitiveness.

According to classical economic theory, the specialisation under the form of "work force division" developed by Adam Smith generates scale economies and differences of productivity between nations. For Adam Smith, the capital investments and trade ensures the specialisation and result in rising the productivity and the output. With respect to trade, Adam Smith demonstrated that the benefits of trade appear when the autarhic regime changes into free trade, and the nations involved have an absolute advantage in the production of some goods. So, trade means differences of productivity.

David Ricardo demonstrated that the benefits from trade result when the nations specialise in the production of goods for which they have a comparative advantage for. In the model developed by Ricardo, the production technology differences between industries and nation lead to employment productivity differences.

The implications of classical economic theories on the concept of competitiveness are the following:
-    Every nation plays a certain role in the division of the work force based on the comparative advantage. If the technology and productivity are the same for each nation, the trade would be pointless.
-    Even if a state is more productive than the other in producing a certain good, it could register a decline of this industry in the terms of free trade.

The neoclassical economic theory offers the conditions of a world based on perfect competition. The Hecksher – Ohlin model is based on the Ricardian model, comprising other two production factors, work and capital and it assumes that the technology is the same and the comparative advantages are due to the differences generated by the abundency of production factors.

The implications of neoclassical economic theories on the concept of competitiveness are the following:
-    Every nation has its own role in the labour division, based on the relative proportions of the production factors. If the proportion is the same, then the trade would be useless;
-    The equalisation of factor prices implies a certain degree of convergence of incomes derived from capital and labour;
-    In the conditions of perfect competition, the competitiveness concept is not sustainable on long term.

While the classical economists considered capital and labour two independent production factors, the Keynesian theory states that they are complementary. The Keynesian theory is based on the dynamics of the demand and on the degree of employment, and it focuses on expectations because they influence investments and the consume behaviour. Even if Keynesian theory and policy are categorised as being part of the macroeconomic perspective, they have important repercussions on the regional analysis.

The implications of Keynesian theory on the concept of competitiveness are the following:
-    The state may interfere successfully whenever;
-    The imperfect markets allow the existence of regional disparities;
-    The regional convergence may be acquired through economic policies,
-    The intensity of capital leads to economic and productivity growth.

The development economics theories represented the subject of endless contradictory discussions. The most important subjects are the efficiency of state aids, the trade liberalisation, the foreign direct investments. Some of the concepts appeared from the development economics, some of them being very relevant for the regional competitiveness.

The implications of development economics theories on the concept of competitiveness are the following:
- Thye central regions that have a productive advantage will maintain their positions ahead of the peripheric regions;
- The economic policies should consider the state of development of every region,
- The economic policies should promote the 'multiplication effects' of FDI.

The main aspect developed by the endogenous growth theory is the fact that the accumulation of knowledge generates an increase of incomes. Knowledge and know – how are not disseminated instantly, they must be obtained.

The implications of endogenous growth theories on the concept of competitiveness are the following:
- The technological and human capital improvements represent the engines of growth;
- Free trade is a determinat of growth and technological development
- The R&D investments are very important.

The new theories of trade are based on the economies of scale and product differentiation, as being the most important explanations for the trade models between nations.

The implications of new trade theories on the concept of competitiveness are the following:
- The labour specialisation is necessary,
- The investments intensify the economies of scale.

For understanding the concept of competitiveness, there are necessary some insights developed from the urban theories, the new institutional theories and the Schumpeterian theory.

In the urban theory, Jane Jacobs considers that the cities are the main factors of wealth.

A different perspective is offered by the 'transaction cost" theory, that states that a firms dimension must be explained by the transaction costs.

The most important theory is the cluster theory developed by Michael Porter, and according to which to be competitive, a firm must constantly improve its operational efficiency and geographic clusters stimulate a firms necessity to be competitive.

The Scumpeterian theory states that the role of the entrepreneur is the most important on economic growth.

The empirical literature
In the research conducted on the concept of competitiveness, there were found certain difficulties like: the linear and causal relations and the quality and quantity of the data available. This research lead to classifying the evaluation and measuring models of competitiveness in three categories:
- National competitiveness;
- Regional competitiveness
- Firm competitiveness.

From the national competitiveness point of view the most important sources of measurement are developed by:
- World Competitiveness Yearbook, IMD;
- Global Competitiveness Report, WEF;
- New Economy Report, OECD
- DTI competitiveness indicators.

From the regional competitiveness point of view the studies are focused on the following studies, developed by:
- Second Report on Economic and Social Cohesion, European Commission;
- Compeating with the world, Barclays Bank PLC;
- Regional Competitiveness Index, DTI of UK
- Regional Investment Climate Study, ECORYS-NEI

From the firm competitiveness point of view, the economic literature shows that the main determinat factors of competitiveness are the entrepreneurship and the investments.

Conclusions

Overall, the economic literature demonstrates that the competitiveness concept is very complex, difficult and amorpheous.

There is still not a common view with respect to the concept of competitiveness, the common features being the following: its deffinition must comprise the ability of selling on the international markets and the effective competition at a global level.

Despite the confusions surounding the deffinition of the competitiveness concept, the economic literature shows some of the important aspects:
- There is no theoretical perspective complex enough to define the term;
- Competitiveness means qualitative and quantitative factors and conditions;
- Competitiveness has several dimenssions: national, regional and local;
- Competitiveness is explained by composite factors.

POSSIBLE TRADE EFFECTS OF THE NEXT EUROPEAN UNION ENLARGEMENT

Nedelescu-Ionescu Daniela
Academia de Studii Economice din București

Rujan Ovidiu
Academia de Studii Economice din București

The European Union next enlargement will constitute a significant qualitative change in the structure of the current Union, as the accession of the Western Balkan countries and of Turkey in particular will bring a brand new set of economic problems. It is expected that this enlargement to have a considerable effect for the new entrants, as well as for the European Union as a whole. Considering some of the aspects raised by a new extension, this article aims to observe the trade impact of a new enlargement with the membership of the Western Balkan countries and Turkey, as this new growth is expected to have a considerable effect for the new entrants and for the European Union as a whole.

This study is based on the compare of the potential trade creation effects with the trade diversion effects resulting from the removal of trade restrictions for Western Balkan countries and Turkey and the European Union, by using the revealed comparative advantage index.

The analyze objective was to estimate the degree of trade creation and trade diversion outcome on the EU countries when Western Balkan countries and Turkey are included into the Union market.

The obtained results suggest that the export structures differ significantly among Western Balkan countries and Turkey and the European Union. Based on the revealed comparative advantage indexes, the authors would expect an intra-regional trade creation effect, but also we expect a risk for the Eastern European countries trade with European Union, especially as a result of Turkey's accession into the European markets without any trade barriers.

As far as trade creation and trade diversion effects are concerned, they observed that Western Balkan countries and Turkey, probably, do not change the European Union position significantly because of their lower trade volume comparing with the one of the EU-27.

Keywords: EU enlargement, trade creation (TC), trade diversion (TD), revealed comparative advantage (RCA), economic integration

JEL Codes: F10, F15, F17.

Introduction

The EU next enlargement will constitute a significant qualitative change in the composition of the EU, as the accession of the Western Balkan countries and of Turkey in particular will bring a brand new set of economic problems.

It is expected that this enlargement to have a considerable effect for the new entrants and for the EU as a whole.

Focusing on the Western Balkan countries and Turkey, the purpose of this paper is to investigate the potential trade creation (TC) and trade diversion (TD) effects of economic integration for these countries and for the EU. The analysis is based upon an approach found in the literature acknowledged as the Revealed Comparative Advantage (RCA) index discussed below.

Previous research

The initial academic contribution to the understanding of customs union was made by the Chicago School economist Jacob Viner (Viner:1950)[1], who showed how welfare gains or losses may result from either TC or TD. His study became the foundation of the theory of international economic integration. Study's theoretical framework suggests that the benefits of TC to member states of joining a regional bloc like the EU may be small and possibly exceeded by the negative effects of TD. TC, as a result of forming a customs union, takes place as a result of shifting the imports from higher cost source to a lower cost source, while TD takes place when imports from a lower cost source are altered to a higher cost source. In his study Viner considered two states, comparing their trade flows with the rest of the world after they eliminate customs tariffs on inner border of their union, and describing the redirection of the trade flows by TC and TD.

Later on some other studies on customs union theory about static and dynamic effects were provided by Lipsey (Lipsey:1957)[2], Balassa (Balassa:1961)[3], Baldwin (Baldwin:1992)[4], Huang and Tu (Huand and Tu:1994)[5], Krueger (Krueger:1999)[6], Karakaya and Ozgen (Karakaya and Ozgen: 2002)[7].

Methodology

This article adopts Karakaya and Ozgen (Karakaya and Ozgen: 2002)[8] approach, by comparing the TC effects with the TD effects resulting from the removal of trade restrictions for Western Balkan countries and Turkey and the EU as a whole.

The RCA index measures the comparative advantage of every industry within all countries. The more dispersed the distribution of comparative advantages among the member countries, the better will be the possibility of these countries balancing each other's industrial production. Therefore, all other things being constant, if the variance of the RCAs of the member countries in one industry is large, the TC effects in that industry should also be large. Furthermore, a large difference in the RCAs of member and non member countries would suggest larger TD effects, since imports originating from non member countries would be replaced by imports from the member countries. Thus, viability or potential of this grouping depends on the net difference between TC and TD. As mentioned before, the dispersion of RCA's among the member countries are used to measure the magnitude of TC and the difference in RCA's between the selected group and the rest of the world is used to determine the magnitude of TD.

The relationship between the RCA index and TC/TD

As said above, the TC represents a shift in production from higher cost domestic producers to cheaper producers in the partner country, and is equivalent to an increase in intra-regional trade.

In contrast, the TD represents a shift from lower cost producers in the non member countries to higher cost producers within the group, due to inequitable trade policies against non member countries, and is equivalent to a decrease in inter-regional trade.

RCA represents the index used for calculating the relative advantage or disadvantage of a certain country in a certain class of goods or services as evidenced by trade flows. It is based on the Ricardian comparative advantage concept and introduced by Balassa (Balassa:1965)[9].

A country is said to have a revealed comparative advantage in good *i* if its export share of good *i* is higher than the world average, i.e. the RCA index of good *i* for that country exceeds one.

On the contrary, a country is said to have a revealed comparative disadvantage in good *i*, if the corresponding RCA index is less than one.

As per Karakaya and Ozgen[10] the above concept may be restated as follows:

- Agree that
    X^i_k indicates the value of exports of good *i* from country or region *k*.
- Consequently
    $X_k = \Sigma_i X^i_k$ represents the total export value of country or region k
    and
    $S^i_k = X^i_k / X_k$ represents the share of commodity group *i* in the total exports for country or region *k*.
- Thus
    $X^i = \Sigma_k X^i_k$ would be the total exports of good *i* in the world
    and
    $X = \Sigma_i X_i$ represents total exports in the world.
- Then
    $S^i = X^i / X$ shows the *i*-th commodity group's share of the world exports,
    and the RCA index may be obtained by the formula
    $RCA^i_k = S^i_k / S^i$
- Interpretation
- if $RCA^i_k > 1$ country or region *k* has a revealed comparative advantage in good *i*, if $RCA^i_k < 1$ country or region k has a revealed comparative disadvantage in good *i*, additionally, the larger the deviation of the RCA index from 1, the higher comparative advantage or disadvantage.

The data for each country's export share of given commodity group, S^i_k were drown from the World Trade Organization statistics[11]. With S^i_k and by making use of total export value of a country, X_k, from World Trade Organization statistics, we calculated the share of the same grouping in total world exports, since $X^i_k = X_k \cdot S^i_k$.

Table 1 provides the export share of each commodity group in Western Balkan countries, Turkey and EU countries. It also presents the share of each commodity group in the total exports of the world.

Table 1: Commodity Trade Shares for Western Balkan countries, Turkey, EU-27, and World [% from the total merchandise exports]

Year	Agricultural products exports	Fuels and mining products	Iron and steel exports	Chemicals exports	Machinery and transport equipment	Textiles and clothing export	Other exports	Total merchandise exports	Country or Group of countries

data source: World Trade Organization Statistics[12]

With the data from Table 1 were obtained the ratio $X^i_{k\ country} / X_{k\ world}$ based on which were calculated the RCA indices using the report $X^i_{k\ country} / X_{k\ world} : X^i_{k\ country} / X_{k\ EU-27}$.

The data from Table 1 show that there is a high difference in the export structures of the Western Balkan countries, comparing with Turkey, or EU-27. Due to this different export structures among the EU-27, the Western Balkan countries, and Turkey, we would expect to find a significant trade creation effect after integration, if the trade barriers within the union will be completely removed.

These findings are also supported by RCA indices for the concerned countries and groups of countries. As noted before, an RCA^i_k that is higher than 1 implies a revealed comparative advantage of good *i* for country or region *k*.

Table 2 shows the RCA indices, obtained after performing the calculations, for the countries and groups of countries quoted in the Table 1, related to the commodity groups mentioned in the same table.

Data source: data obtained after performing the RCAs calculations

The RCA indices obtained from the last four years give us an idea about the potential TC or TD if the Western Balkan countries and Turkey are joining EU.

Results
As noted before, a difference in export structures leads to trade creation.

Table 2 shows that the RCA indices which are greater than value 1 are: for Croatia agricultural products, fuels and mining products, textiles and clothing; for FYI Macedonia agricultural products, iron and steel, textiles and clothing; for Montenegro agricultural products, fuels and mining products, iron and steel; for Serbia agricultural products, fuels and mining products, iron and steel, textiles and clothing; and for Turkey iron and steel, textiles and clothing.

Table 3 shows us clearly which countries have a revealed comparative advantage for the analyzed commodity groups, since the RCA indices for these goods are greater than one.

Table 3: TC and TD for Western Balkan countries and Turkey during 2007-2010

Years	Agricultural products	Fuels and mining products	Iron and steel	Chemicals	Machinery and transport equipment	Textiles and clothing	RCA for each Country or Group of countries

2009	TC	TC	TC	TD	TD	TC	
2010	TC	TC	TC	TD	TD	TC	
2007	TD	TD	TC	TD	TD	TC	
2008	TD	TD	TC	TD	TD	TC	RCA Turkey
2009	TD	TD	TC	TD	TD	TC	
2010	TC	TD	TC	TD	TD	TC	

As for Croatia commodity groups 'Agricultural products', 'Fuels and mining products' and 'Textiles and clothing' have a revealed comparative advantage, if this country join EU, while for 'Iron and steel', 'Chemicals' and 'Machinery and transport equipment' this country has a comparative disadvantage.

For FYI Macedonia commodity groups 'Agricultural products', 'Iron and steel' and 'Textiles and clothing' have a revealed comparative advantage if this country join EU.

For Montenegro commodity groups 'Agricultural products', 'Fuels and mining products' and 'Iron and steel' have a revealed comparative advantage if this country join EU.

For Serbia commodity groups 'Agricultural products', 'Fuels and mining products', 'Iron and steel' and 'Textiles and clothing' have a revealed comparative advantage if this country join EU.

For Turkey: commodity groups 'Iron and steel' and 'Textiles and clothing' have a revealed comparative advantage if this country join EU.

Having said that, it can be expected that a sizeable intra European TC effect, as a result of next EU enlargement, would appear.

Conclusions

The aim of this paper was to estimate the degree of TC and TD effects on the EU countries when Western Balkan countries and Turkey are included into the EU market.

By using RCA index to examine TC and TD effects it was found that the export structures are substantially different among Western Balkan countries, Turkey and EU-27.

As far as trade creation and trade diversion effects are concerned, we observed that Western Balkan countries and Turkey, probably, do not change the EU position significantly because of their lower trade volume comparing with the one of EU.

The results here reflects static changes and future analysis should focus on more dynamic effects of Western Balkan countries and Turkey accession, like scale economies, increases in bargaining power, increases in competition etc, factors which are usually of much concern to member countries.

ROMANIA'S SPECIALIZATION IN TRADE TOWARDS EU-27-A REVEALED COMPARATIVE ADVANTAGE APPROACH

Popa Angela Cristina
Academy of Economic Studies ofBucharest, Faculty of International Business Economic

"International competitiveness" is a complex topic which raised over time many questions and theories on key factors that underpin it and is still subject to wide debate. Such analysis proves to be necessary under the new requirements raised by the participation of Romanian organizations in the European and global competitive environment in which competiting for new markets can be a platform of economic recovery.

As companies compete for markets and resources, national economies compete with each other to achieve performance in a specific activity: for example, we can say that Romania has become less competitive in clothing production, and competitive in cars production. But it makes sense to say that "Romania has become more or less competitive as the economy?".

The answer is no."Competitiveness" is a meaningless word when referring to national economies. Deniying Romanian competitiveness in a particular industry does not mean that Romania's economy is less competitive. The decline in these industries may be a manifestation of their change in production factors endowment or necessary reallocation these factors from old activities with comparative advantage to new ones.

This paper aims to examine the structural competitiveness of Romania vis-a-vis EU-27. Empirical analysis is based on Revealed Comparative Advantage (RCA), an indicator often used in international trade analysis. Section II reviews the empirical literature on the comparative advantage and the competitiveness of Romania, highlighting various theories and approaches, alternative measures of RCA indices are presented in the section III, section IV reports empirical results and the final section draws some conclusions based on the findings.

In 2009, in terms of orientation of the foreign investors towards the economic sectors, according to NACE Rev. 2 Classification, the direct foreign investments were directed mainly to Manufactured goods (31,1% of total), within its best represented branches: oil, chemicals, rubber and plastic processing (6,3% of total), metallurgy (5,2%), transport industry (4,7%), food, beverage and tobacco industry (4,1%) and cement, glass, ceramic(3,3%), some of the sections having low weight to the potential, such as textiles, clothing and leather (1.4%), decreasing their attractiveness due to the convergence of non-tradable goods prices towards Eurozone prices, according to the Balassa-Samuelosn effect. Development of sections refering to intensive technology products should be a priority in the economic transformation of the countries converging to Euro Zone, especially Romania.These sections are: XVI: „Machinery and mechanical appliances;electrical equipment; sound and image recorders and reproducers" and XVIII „Optical, photographic, cinematographic, medical or surgical instruments and apparatus and similar; clocks and watches; musical instruments; parts and accessories thereof". An increase in exports of these products may have beneficial effects on trade balance, balancing it by reducing the imports of these goods.

I. Introduction

"International competitiveness" is a complex topic of global concern which raised over time many questions and theorieson key factors that underpin it.Such analysis proves to be necessary under the new requirements raised by the participation of Romanian organizations in the European and global competitive environment in which competiting for new markets can represent a platform of economic recovery. The popularity of the concept of "competitiveness" is in continuous growth, as researchers, politicians and business man try to assign different definitions and meanings, according to the field in which they perform.For members of government, competitiveness is a positive balance of trade. For some economists, competitiveness represents a low unit labor cost adjusted according to exchange rates. Increasing international competitiveness is an economic policy priority for all nations of the world knowing that between prosperity of a nation and its degree of international competitiveness there is a strong interconnection. Undoubtedly, economic growth - reflected by an upward trend of the main economic indicators (GNP per capita, production per capita, the export value per capita, etc.) - is a necessary condition for increasing wealth. As companies compete for markets and resources, national economies compete with each other to achieve performance in a specific activity: for example, we can say that Romania has become less competitive in clothing production, and competitive in cars production. But it makes sense to say that "Romania has become more or less competitive as the economy?".

The answer is no. "Competitiveness" is a meaningless word when referring to national economies. Deniying Romanian competitiveness in a particular industry does not mean that Romania's economy is less competitive.The decline in these industries may be a manifestation of their change in production factors endowment or necessary reallocation these factors from old activities with comparative advantage to new ones. In a desirable context, with perfect balance, optimal resource allocation counts, not the rise or decline in specific activities.Relevant examples in this respect is Switzerland, though endowed with natural and a spectacular mountain landscape, it continues to dominate the watch industry and obtain a huge profit for almost 100 years, and Finland which maintains its leading position in mobile phones. This contradicts the theory of free trade which asserts that free trade automatically diverts nations towards industries for which they are best prepared.

This paper aims to examine the structural competitiveness of Romania vis-a-vis EU-27. Empirical analysis is based on Revealed Comparative Advantage (RCA), an indicator often used in international tradeanalysis.The plan of the paper is as follows. The following section reviews the empirical literature on thecomparative advantage and the competitiveness of Romania. Alternative measures of RCA indices are presented in the Section III. Section IV reports empirical results and the final section draws some conclusionsbased on the findings.

II. Literature review

A way to highlight a country's degree of specialization in different goods, services or industries industries, it is the determination of revealed comparative advantage index (RCA). (Cristureanu, 2004; Cojanu, 2007).In the theories of international trade, comparative advantage is an important concept for explaining pattern of trade. David Ricardo (1817) firstly introduces the concept of comparative advantage with very strict assumptions. Countries exploit technological differences is then well recognized as the Ricardian model. In the modern theories of international trade such strict assumptions are replaced with the more realistic ones. Heckscher (1919) and Ohlin (1933) examine the effect of different factor endowments on international trade. Their model, which is well known as the Heckscher-Ohlin (HO) model, concludes that a country will export commodity

uses the abundant factor of production, while it will import commodity uses the scarce factor of production.

So far, the dynamic theory of comparative advantage has put greater attention on the changes in supply (production) side. This is related to how specific determinants affect the output (economic) growth and, in turn, comparative advantage. Redding (2004) finds that comparative advantage is endogenously determined by the past technological changes and innovation. To justify national policies to stimulate and support industries that have comparative advantage, it appears as a reality "ex ante", which provides reliable performance. But this theory is contradicted by the reality of market dynamics which states that comparative advantage is either gained or lost.În schimb, ţările care, în lipsa unei teorii mai bune a competitivităţii, mai utilizează în proiectarea politicilor lor teoria avantajelor comparative, riscă să neglijeze o gamă largă de opţiuni politice privind creşterea eficienţei şi promovării creşterii care ţin cont de prezenţa (pervasiveness) eşecurilor de piaţă în economiile moderne (Stiglitz, 1989a).

The dynamics of comparative advantage might be also caused by the role of input trade (Jones, 2000), the friction in international trade and investment flows due to geography, institutions, transport, and information cost (Venables, 2001), the transmission of knowledge across borders (Grossman and Helpman, 1991), the technological differences across border (Trefler, 1995), and the monopolistic competition in differentiated products with increasing return to scale (Krugman, 1979). Indeed, many applied economists, e.g. Liesner (1958), Kanamori (1964), Balassa (1965), Donges and Riedel (1977), Bowen (1983), Vollrath (1991), Dalum et al. (1998) and Laursen (1998), among others, have tried to make various empirical measures to "reveal" countries' comparative advantage. Also, countries may very much differ in the quantity of products they export through the export prices of similar goods [Schott (2002), Hummels and Klenow (2002)]. The Balassa index has been subject to several critiques, leading some authors to propose several modified versions. For instance, Laursen (1998) suggests a transformation that produces a symmetric outcome, ranging from -1 to 1 and with a threshold of 0; Proudman and Redding (1997, 2000) suggest a transformation that results in a constant mean across the different sectors for a given country. Nevertheless, the popularity of the original index remains in place and the traditional Balassa index has been used extensively in the literature. As in the Proudman and Redding (1997, 2000) contribution, the product specialization index suggested here has a clear and well-defined link with the original Balassa index. In his study, entitled „Convergence of the Export Structure of Romania, Croatia, Serbia and Bosnia-Herzegovina to the Structure of Import Demand in Developed Countries" (2010), Goran Nikolić is analyzing the export structures of observed transitional countries (Romania, Croatia, Serbia and Bosnia-Herzegovina) with the import structure of developed economies (EU) to examine if there is convergence, and the level of that convergence. The study points out that in Romania, between 2000 and 2009 was registered a poor, but significant convergence, due to the share of 20.1% of goods belonging to sections 0- Food and live animals and 6-Manufactured Foods Classified by Material (especially the early stage of processing of goods, especially products), in total exports. In Romania, the share of 47,9% of the sections 7-Machinery, Transport Equipment and 5-Chemical Products was very high, mainly due to the numerous subdivisions 78-Road Vehicles and 77-Electrical Machinery, which includes the production of motor vehicles and electrical machines, intensified after 2000 along with increasing of foreign direct investment flows. The main difference between the export structures of developing countries considered in the study and trade structures of the EU27 remains the technology intensive products.

Some economists argue that the nature of international trade is in a continuous change (Grossman and Rossi-Hansberg 2006, 2008, Blinder 2006, 2009, Hanson, Mataloni and Slaughter 2005). Instead of simply creating more trade in goods, global integration is increasingly marked by "trade in tasks" (Grossman and Rossi-Hansberg 2006), meaning more trade of intermediate goods and services due to the widespread emergence of offshoring. Other economists bring into

discussion the public choice theory. Oates and Schwab (1988) stated that governments can set "weak" or "strong" standards and by employing public choice theory, government officials may want to impose weak environmental standards in order to attract capital investment.

III. Methodology

A way to highlight a country's degree of specialization in a particular product or industry, is the determination of Comparative Advantage Index (CAI). CAI compares the share of production / exports of a country for a specific product / industry in it's total production / export with the share in production / world exports (or a group of countries) of that product / industry. Before Balassa introduced his famous index of comparative advantage in 1965, Liesner (1958) was the one who contributed to the empirical literature of AC. In this sense, Liesner (1958) developed the first empirical study in the area of CA. The simple measure proposed by Liesner for calculating CA was:

$$RCA_1 = \frac{X_{ij}}{X_{nj}} \quad (1)$$

where x represents exports, i is a country, j is a commodity (or industry), and n is a set of countries (e.g. the EU). An advanced formula of the CA was later presented by Balassa (1965) and was widely accepted in the literature:

$$RCA_2 = \frac{X_{ij}/X_{it}}{X_{nj}/X_{nt}} = \frac{X_{ij}/X_{nj}}{X_{it}/X_{nt}} \quad (2)$$

where x represents exports, i is a country, j is a commodity (or industry), t is a set of commodities (or industries) and n is a set of countries. RCA_2 measures a country's exports of a commodity (or industry) relative to its total exports and to the corresponding exports of a set of countries, e.g. the EU. Comparative advantage is "revealed" if $RCA_2 > 1$. If RCA_2 is less than unity, it is said that the country has a comparative disadvantage in that good/industry. But RCA_2 index is considered to be biased because of omission of imports, especially when the country has an important dimension (Greenaway and Milner, 1993). An alternative RCA index (RCA_3 in equation 3) is calculated only to make reference to country's own trade performance. This type of measuring country's comparative advantage also allows the simultaneous calculation of exports and imports of a good or industry:

$$RCA_3 = \frac{(X_{ij} - M_{ij})}{(X_{ij} + M_{ij})} \quad (3)$$

In the case of ecuation 3, index ratio ranges from -1 ($X_{ij} = 0$ and revealed comparative disadvantage) to +1 ($M_{ij} = 0$ and revealed comparative advantage). However,, regarding RCA_3, exists ambiguity around zero value (Greenaway and Milner, 1993). You can get another version of the Balassa RCA (1965) derived the following equation:

$$RCA_4 = \frac{X_{ij}/X_{it}}{M_{ij}/M_{it}} = \frac{X_{ij}/M_{ij}}{X_{it}/M_{it}} \quad (4)$$

where X and M are exports and respectively imports, i is a country, j is a product (or industry), t is a set of commodities (or industries). A similar version of equation 4 derived from Balassa (1965) is as follows:

$$RCA_5 = ln \left[\frac{(X_{ij}/X_{it})}{(M_{ij}/M_{it})} * 100 \right] \quad (5)$$

The RCA_3, RCA_4 , RCA_5 indices point out the bilateral competitiveness between Romania and EU. In our study, we will concentrate only on bilateral competitiveness.

To analyze the Revealed Comparative Advantage for Romania using Balassas alternative measures of RCA, I used Combined Nomenclature (CN) which is the European Community's classification of goods, which meets requirements in terms of external trade statistics (both intra– and extra–Community) covering Romania's exports and imports on bilateral level with the EU-27 for the period 2007-2009 from the Romanian National Institute of Statistics.

IV. Results and main findings

The followings are the basic points and outcomes on our alternative RCA calculations. The following classifications are based on the common characteristics of commoditygroups, and are taken into account RCA_3 , RCA_4 , RCA_5 indices.

Table 1: Outcomes based on the common characteristics of commodity groups

CN Code	Sectors with RCA in all (three) indices (Section)
01	• live animals
27	• mineral fuels and oils;bituminous substances; mineral waxes
31	• fertilizers
42	• leather goods
44	• wood, charcoal and articles of wood
61	• knitted or crocheted clothingand accessories
62	• not knitted or crocheted clothing and accessories
64	• footwear and parts thereof
76	• aluminium and articles thereof
86	• railways or tramway locomotivesand rolling-stock
89	• ships, boats and floating structures
94	• furniture; lighting fittings and other similararticles; prefabricated buildings

Table 2: Outcomes based on the common characteristics of commodity groups

Sectors with "increasing" RCA in time period (year-by-year) Romania vis-à-vis the EU market		Sectors with "decreasing" RCA in time period year-by-year observation Romania vis-à-vis the EU market	
CN Code	Section	CN Code	Section
44	• wood, charcoal and articles of wood	01	• live animals
94	• furniture; lighting fittings and other similar articles; prefabricated buildings	31	• fertilizers
		42	• leather goods
		61	• knitted or crocheted clothingand accessories
		62	• not knitted or crocheted clothing and accessories
		64	• footwear and parts thereof

V. Conclusions

Romania has the 11th largest economy in the European Union by total nominal GDP and the 8th largest based on purchasing power parity (PPP). With annual GDP growth rates consistently above 6%, Romania was one of the fastest growing markets in the European Union (EU) until 2009. The country has also been referred as a "Tiger" given its rapid development and high

economic growth rates and compensates the structural gaps with a high commercial integration with the rest of the EU-27 countries, while 2009-2010 registered a slight decrease.

Given that about half of Romania's trade with EU-27 is done with the core of the euro area(Germany, France and Italy), then their macroeconomic developments will decisively influencethe industrial activity and exports of the Romanian economy. Economic shocks that will affectthese economies will be transmitted through trade in the Romanian economy and these willbecome more symmetrical.In 2009, in terms of orientation of the foreign investors towards the economic sectors, according to NACE Rev. 2 Classification, the direct foreign investments were directed mainly to *Manufactured goods* (31,1% of total), within its best represented branches: *oil, chemicals, rubber and plastic processing* (6,3% of total), *metallurgy* (5,2%), *transport industry* (4,7%), *food, beverage and tobacco industry* (4,1%) and *cement, glass, ceramic*(3,3%). There are areas with a low weight to the potential, such as textiles, clothing and leather (1.4%), decreasing their attractiveness due to the convergence of non-tradable goods prices towards Eurozone prices, according to the Balassa-Samuelosn effect.Development of sections refering to intensive technology products should be a priority in the economic transformation of the countries converging to Euro Zone, especially Romania. These sections are: XVI: „*Machinery and mechanical appliances;electrical equipment; sound and image recorders and reproducers*" and XVIII „*Optical, photographic, cinematographic, medical or surgical instruments and apparatus and similar; clocks and watches; musical instruments; parts and accessories thereof*". An increase in exports of these products may have beneficial effects on trade balance, balancing it by reducing the imports of these goods.

ATTRACTIVENESS OF PUBLIC POLICIES FOR FDI IN CENTRAL AND EASTERN EUROPEAN COUNTRIES

Popovici Oana Cristina
Bucharest Academy of Economic Studies, Faculty of International Business and Economics

Călin Adrian Cantemir
Bucharest Academy of Economic Studies, Faculty of International Business and Economics

The paper builds on the burning issue of the attractiveness of the location for foreign direct investments (FDI), assuming its positive and substantial economic impact on the development of the host country. The location decision for FDI in Central and Eastern European (CEE) countries is investigated based on the attractiveness framework designed by policy makers: infrastructure endowment, institutions' quality, labour market conditions and level of taxation. The analysis assesses the FDI inflows in a country in three years: 2004, 2007 and 2010. Thus the FDI evolution relative to public policies attractiveness is seized starting with the European Union (EU) integration and after the crisis started. The paper follows the literature on the determinants of the FDI related to the L (location) factor described in the eclectic paradigm of Dunning (the OLI model), but focuses on the role of public policies in attracting FDI and captures two of the recent major turning points faced by the CEE countries, scarcely tackled in the literature: the EU integration and the recent economic crisis.
We compute a public policy index, constructed as a composite measure, based on the four pillars mentioned above, in order to test the public policies attractiveness in the CEE countries. Moreover, we develop an attractiveness matrix starting from the public policy index, and we rank the most attractive countries for FDI in the three years. We analyze the matrix based on the FDI inflows per capita.
We found a positive relation between the increase in the public policies attractiveness and the inward FDI. The increase of the FDI per capita since the EU accession year is, at least partially, due to the increasing attractiveness of the public policies. The crises worsened the CEE countries' attractiveness. Still, the winners in the race for FDI remained those countries that improved the infrastructure, the institutions' quality and the labor market conditions. Therefore, short and medium term policy directions can be emphasized. Infrastructure and institutions' quality can be improved for further attracting FDI during rough budgetary constraints. The literature is enriched with the empirical analysis of the FDI determinants in the recent years. Our paper takes into account the major events faced by the CEE countries in the last years and checks for potential methods of attracting FDI even during difficult economic conditions.

Keywords: foreign direct investments, public policy, Central and Eastern Europe countries, attractiveness matrix

I. Introduction

There is a wide literature on the positive and substantial economic impact of FDI on the development of both the host and the home country of FDI. In times when the economic stability is endangered and growth remains under pressure, foreign investments are the gate to a healthy economic development. Enhancing attractiveness for FDI became a priority on the national agenda, especially as the crisis tested the strength of the traditional determinants of FDI and

enhanced the occurrence of new opportunities. For the CEE countries, relying only on the market size and low wages is no more an option.

The signal of entering in a new era of FDI determinants was drawn years ago. In the attempt to determine the decisive factors for attracting FDI, a number of studies have illustrated the growing importance of political factors, especially the institutional determinants in the host country. Other papers developed at the beginning of this decade revealed that the factors influencing the attractiveness of a region, particularly for the East European countries, are no longer the natural resource endowments, but the created resources, such as the quality of infrastructure and institutions. Goodspeed, Martinez-Vazquez and Zhang points out that in order to be more effective in attracting FDI, government officials in developing countries should pay more attention to policy programs aimed at improving governance institutions and public infrastructure (Goodspeed, Martinez-Vazquez and Zhang 2009: 22). The taxation is important for FDI choices, but only after more fundamental institutional governance issues are addressed and public infrastructure is developed. The countries, especially those in CEE, started to tackle the public policy instruments in order to attract more FDI: to improve the infrastructure, to reduce the administrative burden and to increase the efficiency of institutions, to make more flexible the labor market and, where possible, to address the taxation and the cost level for companies. The EU adhesion facilitated their approach and the results corresponded to the expectations, but the crisis hampered the FDI inflows.

The aim of this paper is to analyze the impact of infrastructure, of institutions' quality, of labor market and of taxes on CEE strategies for attracting FDI since the EU adhesion year and during the crisis; it also aims to determine if there is room for further improvements on the public policies side. As all these factors are under the immediate control of the public officials, the paper's objective is to assess the state's role in attracting FDI. The study employs a composite index to rank the most attractive countries for FDI, as regard the public policy framework.

II. Literature review

Dunning eclectic paradigm or the OLI model sets the basic framework for the analysis of the FDI determinants. This paper focuses mainly on the L (location) factor, explaining where a multinational company will locate its activity.

Some FDI theories point out the companies' behavior of searching attractive environments. The theory of international production states that a firm decision to initiate foreign production depends on the specific attractions in its own country compared to the resources and benefits involved by locating in another country (Morgan and Katsikeas, 1997). Therefore, the foreign government actions significantly affect the attractiveness of a country. In describing the public policy actions for attracting FDI, the studies focus on the infrastructure, good governance, level of taxation and labor market (Bellak, Leibrecht and Liebensteiner, 2010: 38; Goodspeed, Martinez-Vazquez and Zhang, 2009: 5; Bellak, Leibrecht and Stehrer, 2008: 1). Groh and Wich compute a comprehensive composite measure to determine a host country's attractiveness for FDI and take into account the labor costs, the quality and endowment of infrastructure and the quality of the legal system (Groh and Wich, 2009: 7).

We assist today at a "caravan capitalism". For the transitional economies in CEE, the level of wages was one of the most important factors affecting the investment decision. The re-location of labor–intensive activities in countries with low wages was and remains a common trend nowadays. This evolution is captured by the literature. Benacek, Gronicki, Holland and Sass survey the literature until 2000 and found that the CEE countries were targeted for investments due to their favorable combination of low wages and relatively skilled workforce (Benacek, Gronicki, Holland and Sass, 2000: 15). Since then, other studies revealed the same results. Botric and Skuflic signal that labor costs, represented by wages, are still important for foreign investors (Botric and Skuflic, 2006: 20). The labor market costs, expressed as the compensation of

employees per total hours worked, discourage FDI (Bellak, Leibrecht and Stehrer, 2008: 11). Also for assessing the attractiveness of the labor market, several proxies are used to express skilled workforce, such as the average years of schooling or the number of technical workers (Benacek, Gronicki. Holland and Sass, 2000:4).

In assessing the impact of institutions on FDI, one indicator is the freedom of FDI as calculated by the Heritage Foundation. The indicator captures the legal barriers to inward FDI, namely the restrictions on FDI limiting the inflow of capital and thus hampering the economic freedom. The econometric results show that more restrictions are equivalent to a reduced level of foreign investment (Bellak, Leibrecht and Stehrer, 2008: 11). A relevant proxy in the literature for measuring good governance is the corruption level, as provided by "Corruption Perception Index" from Transparency International (Goodspeed, Martinez-Vazquez and Zhang, 2009: 6).

The infrastructure endowment is a precondition for firms to conduct their businesses in a foreign country. A larger infrastructure endowment, including both transport infrastructure and Information and Communications Technology (ICT) is generally considered to have a positive impact on FDI. The countries on the top positions for FDI attractiveness are those with a better infrastructure for ICT (Botric and Skuflic, 2006: 20; Goodspeed, Martinez-Vazquez and Zhang, 2009: 6). A positive result is obtained between FDI and ICT-infrastructure, measured as the sum of telephone mainlines, mobile phone subscribers, internet connections and personal computers per 1000 inhabitants (Bellak, Leibrecht and Stehrer, 2008: 11). Other results indicate that information and telecommunication infrastructure, followed by the transport infrastructure, are of a special significance in attracting FDI (Bellack, Leibrecht and Damijan, 2009).

At the same time, econometric studies of the past 15 years show that both the level and location of FDI are highly sensitive to the treatment of taxes (Gordon and Hines, 2002: 42-49). Bénassy-Quéré, Fontagné and Lahrèche-Révil indicate that high relative corporate taxation discourage FDI inflows and maintain a significant role in the attractiveness of a country (Bénassy-Quéré, Fontagné and Lahrèche-Révil, 2003). Anastassopoulos takes into account the effect of the corporate tax rate on profit and find a negative and statistically significant impact on FDI (Anastassopoulos, 2007: 45). Among the most problematic factors for doing business in the CEE countries are tax rates and tax regulations, accompanied by the inefficient government bureaucracy or corruption (the Global Competitiveness Report 2010-2011).

III. Methodology

The present study assesses the attractiveness of 10 CEE countries (Bulgaria – BG, the Czech Republic – CZ, Estonia – EE, Latvia – LV, Lithuania – LT, Hungary – HU, Poland – PL, Romania – RO, Slovakia – SK and Slovenia – SI) based on the public policy approach in the EU accession year (2004 or 2007) and in 2010. The analysis allows the taking into account of the impact of both EU integration and crisis in evaluating the countries' evolution.

The attractiveness matrix is constructed based on the public policy attractiveness index, which aggregates four sub-indices, identified as key-drivers for this study, representing the institutions' quality, the infrastructure endowment, the labor market conditions and the taxation level. This approach allows a deeper analysis of the strengths and weaknesses of the policies carried out by the governments. Each sub-index consists of relevant proxies identified in the literature for reflecting the above mentioned key drivers.

The infrastructure index (II) is proxied by the number of main telephone lines per 1000 inhabitants and the level of internet access of households as percent of the total population, both provided by Eurostat. For the first variable, we use the last data available for 2009.

The institutions' quality index (IQI) is a measure of the accuracy and efficiency of public administration. For assessing the institutions' quality, we use the Corruption Perception Index developed by Transparency International, which measures the perceived levels of public sector

corruption, and the investment freedom index obtained from the Heritage Foundation's Index of Economic Freedom. This index evaluates the restrictions typically imposed on investments.

The index expressing the labor market conditions (ILM) is measured using the labor cost index and the tertiary education graduates which allows for checking the degree of labor force qualification. The labor cost index indicate the short-term development of the total cost affecting the employer (including gross wages and salaries, employers social contributions and other taxes connected to employment), on an hourly basis, for employing the labor force. The tertiary education graduates per 1000 of population aged 20-29 allows for checking the degree of qualification for the labor force. For this variable, last data is available until 2009. All necessary data are provided by Eurostat.

The taxation index (IT) measures the fiscal burden borne by the investors. We firstly use the statutory level of the corporate income tax rate because it affects directly the profits generated from conducting a business. Data can be found in the Annual report of the Romanian Fiscal Council and in the study of Mintz and Weichenrieder (2010). The second proxy used is the value added tax (VAT) level, as it represents an important tool for economic and fiscal policy and it is a cost incurred by all the economic agents. The European Commission documents provide all the data needed.

The first step is to establish a common basis for data evaluation, as the actual data are differently expressed. This is done for each variable, by establishing the ratio of the value recorded by each country in the value of the best performing country. We use equal weighting for computing the sub indexes, as there is no significant difference as compared to the results obtained from factor analyses (Groh and Wich, 2009: 13). The public policy attractiveness index (IPPA) is also computed as weighted average, based on the equation:

IPPA = (II + IQI + ILM + IT) x 0.25   (1)

Finally, in order to evaluate the ranking accuracy, the results will be compared with the inward FDI flows in USD at current prices and current exchange rates per capita in 2004, 2007 and 2012, as obtained from the United Nations Conference on Trade and Development (UNCTAD).

IV. Results

The attractiveness matrix (Table no. 1) is created by ranking the countries according to the results obtained in the three years, from the most attractive (the country with the highest score) to the least attractive (the country with the lowest score).

Table no. 1. Public policy attractiveness matrix

	Rank/ Year	1	2	3	4	5	6	7	8	9	10
Attractiveness Index	2004	PL 0.73	LV 0.72	LT 0.71	EE 0.71	SK 0.68	HU 0.62	SI 0.59	CZ 0.58	BG 0.57	RO 0.53

Source: Authors' work

According to the results, all governments carried out policies for enhancing attractiveness in their countries since their EU accession. The intermediate results show that the infrastructure endowment improved the most.

Poland ranks first in 2010 and maintains its leader position since EU accession (2004). Slovenia improved the most its public policy attractiveness, by 0.17 points during the 6 years of its accession. The ranking obtained in 2007 allows checking for the impact of the crisis. If the ranking is almost the same in 2004 and 2007, as a consequence of the crisis, 2010 saw a total

turmoil and rearrangement of the ranking. Again, Poland leads the race of attractiveness, continuously improving its score. The result obtained can be correlated with the fine route of Poland during crisis. Still, most of the other countries worsened their score, mainly due to a rise in the taxation level (Estonia and Latvia) and the quality of institutions (Bulgaria and Slovakia). The winners relied on improvements mainly regarding the infrastructure endowments (the Czech Republic, Lithuania, Poland, Romania, Slovenia), institution quality (Poland and Romania again) and labor market conditions (Slovenia), according to the evolution of sub-indexes (Table no. 2).

Table no. 2. Evolution of sub-indexes

Source: Authors' work

In order to assess the accuracy of the public policy ranking, we compared it with the ranking provided by the inward FDI flows per capita (Table no. 3), a measure for evaluating the FDI inflows, given the different size of the analyzed countries. The first observation is that the two rankings are not perfectly corresponding, pointing that there are other stronger determinants influencing the FDI, such as the macroeconomic and political stability. At the same time, it must be signaled that it is difficult to measure the fiscal facilities or state aids offered by the governments to the foreign investors. In this respect, the pillar on taxation lacks information.
Still, each improvement in the attractiveness score is followed by a higher FDI per capita in 2007, the year before the crisis. This time, as the FDI level is lower due to the crisis, we will compare the countries' change of position in the ranking. Therefore, comparing 2007 with 2010, a worsening of the attractiveness score is followed by a worsening in the FDI per capita ranking in the case of Slovakia, Latvia and Bulgaria. The sole exception is Hungary and Estonia. Similarly, an increase in the ranking is observed for Lithuania, Slovenia, the Czech Republic and Romania, that also improved their attractiveness score. Poland maintained its first place in the FDI inflows ranking, as a result of its attractiveness increase.

Table no. 3. Inward FDI inflow rankings

	Rank/ Year	1	2	3	4	5	6	7	8	9	10
Inward FDI inflows	2004	EE 710,11	SK 560,02	CZ 487,62	BG 436,13	HU 421,92	SI 413,38	PL 337,25	RO 294,60	LV 274,48	LT 225,43

V. Conclusions

84

In the present paper we have examined the impact of one country's public policies in the areas of infrastructure, institutions' quality, labor market and taxation on the FDI attractiveness. The study has examined the role of the state in creating the appropriate framework for attracting FDI. We have found that the public policies show an obvious impact on FDI, as market forces cannot substitute for the role of governments in this area. Thus, the governments in all countries must keep an eye open and pay more attention to measures aimed at improving institutions' efficiency and infrastructure in order to build sustainable basis for further attracting FDI and increasing their performance by climbing up on the value chain.

Compared with other studies in the literature, our empirical analysis takes into account the major events faced by the CEE countries in the last years. The paper adds to the literature by assessing the impact of the public policies on FDI during the crisis. The role of the governments in attracting FDI was tested during the crisis. Our main result, in accordance with the literature, is that public policies continue to influence FDI. Still, the sharp decrease in FDI inflows during the crisis was mainly determined by the investors' lack of confidence in the national economies or in the financial system.

Moreover, we have evaluated the evolution of the public policies since the year of the EU accession. A positive relation was found between the increase of the public policies attractiveness and the inward FDI.

The results underline the fact that the CEE countries have a powerful policy instrument at hand to increase FDI inflows. Some short and medium term policy issues can be emphasized. The FDI inflows rise where the local capabilities are strengthened and new capabilities are created. The economic and financial crisis has pointed out that the created resources are at least as important as the natural endowments. In the midst of the crisis, most countries seized the opportunity to improve public policies in order to attract FDI. There is room for improvements especially in the infrastructure and institutions' quality on the short run. The two areas offer in times of crisis valuable maneuvering space for attracting investors.

GLOBAL ECONOMIC GOVERNANCE AND STATES: STILL IMPORTANT AS LEADERS?

Sterian Maria-Gabriela
Universitatea Româno-Americană Facultatea de Studii Economice Europene

The importance of countries as actors in international economy is the basis of global economic governance. Though the world has increasingly become more integrated in terms of economics, it continues to be politically fragmented in independent states, which follow their own interests. In general, the countries choose the organizations which serve best their interests. But they seek also to achieve their goals through building coalitions with other states, seeking to solve problems of mutual interest directly and in a pragmatic way. Global economic governance requires the development of agreements and coalitions of states or groups of states and, also, the creation of ad-hoc multilateralism, which has to deal, in particular, with peace and security problems.

Introduction

Regional and global hegemonic powers have created interstate business organizations to strengthen their dominance and influence worldwide. As international relations critics say, the various models of economic governance are created for the rich and powerful ones, with privileges in a discriminatory manner for some countries than others. Decision-making process of the five permanent members of the United Nations Security Council gives them the power to influence others' opinions, like the International Monetary Fund and World Bank (Karns, Mingst, 2010).

The rich countries use their financial resources to influence international organizations, and decisions are not always taken in the distribution of wealth for everyone, of multilateral diplomacy to build coalitions among the less favored ones. Not all the states have a say in solving global and regional problems. The conventional image of power belongs to the powerful states or to the most powerful one, that dominates its neighbors and the smaller ones are reduced to the status of dependent states in the international system (Palan et al, 2007). But in an increasingly interconnected world, everyone has the power to be a modeler. Even without a global government, we can achieve better global governance (Friedman, 2008).

The importance of countries in global governance

International organizations and the mechanisms serving personal interests are involved in solving the practical problems between states, like the coordination of telecommunication and transportation infrastructure. But states can depend on these things when it comes to providing goods or health protection. The genius of the nation-states resides in their ability to provide a new collective identity for a growing number of free and autonomous agents that make up the world of private property relations in self-regulatory markets (Rifkin, 2006).

One of the main issues for debates when it comes to this type of relationship is the sovereignty. Sovereignty is the basis of the state's power supremacy within the country itself, exclusive control over the territory and power independence from other states, concept that is analyzed and criticized for centuries. Over time, sovereignty was limited by international agreements. The

world order is based on sovereignty, but the concept itself dates from the time when there were rulers and ruled (Soros, 2007).

Increased sovereignty is taken as assessing responsibility, including environmental or human health and not only the geographical territory. But the state has become an unnatural unit, sometimes dysfunctional in organizing the human activity and business management in a world without borders (Ohmae, 1995). After creating regional economic groups, states can no longer be considered the most effective and functional entities for growth. And the growing internationalization of production, trade and finance, combined with the increasingly global nature of economic and environmental issues rise the question related to the functional capacity of the states. No matter how different and incompatible are the social issues, one of the most important task of the states is to create consistency in its policies (Gilpin, 1987).

When it comes to international organizations, a key question is whether states are willing to give some of their sovereignty to supranational institutions. Some studies show that only a small number of organizations have decision-making power and states are willing to delegate this authority legally speaking: European Court of Justice, European Central Bank or the mechanism of dispute resolution under World Trade Organization.

The various international forums provide the possibility to choose exactly where to discuss each problem and what mechanisms they need in taking a decision. Although certain thing belongs logically to certain specialized organizations, the correlation between problems in question is difficult to take into consideration when it comes to choose a specialization for a certain institution. For example, issues related to the rights for workers or international investments can be addressed using the norms provided by WTO or EU, and in environmental problems they can contact the World Bank or the Commission on Sustainable Development.

Some countries learn how to use the situations in their advantage and others develop by using a more holistic approach on their policies and institutions (Palan et al, 2007). The growing trend toward regional integration is almost at universal level, so we have a more pronounced integration in economic activities in a number of specific regional agreements (Gilpin, 2004). Regionalism is considered the economic strategy followed by countries in order to improve and enhance their competitiveness on global markets, and as a response to changing global economic environment, which undermines the tradition preeminence of the nation-state. Regionalism is not only an instrument for improving competition in the global game; its attraction is done by the fact that is a competitive strategy and an instrument of regional and global economic governance.

The growing number of the groups of states provides another important element of global governance. At the moment, the most important group seems to be G20, a coalition of finance ministers and the governors of central banks, whose purpose is to promote informal dialogue between developed and emerging countries. G20 includes 19 states and the EU, the IMF and World Bank as ex officio participants and represents about 90% of world gross product, 80% of world trade and 2/3 of global population. Until the beginning of the economic crises in 2008, the G20 was not so well known outside the WTO negotiations, where Brazil, Russia, India and China were using group policies to accelerate the economic reforms in developing countries. But with the crisis, the G20 held its first international summit and has engaged in finding and coordinating responses to global problems.

The strategic choices of countries

The states have to deal with choosing the best types of policies and strategies in line with global economic governance (Karns, Mingst, 2010). A strategy can be defined as a calculated and deliberated application in order to reach a specific policy. The debates and controversies concerning the appropriateness and effectiveness of these strategies offer interesting perspectives. The countries implement several strategies at once and they are not always complementary, but also contradictory and inconsistent.

A state can choose a strategy as a subject to the following factors: it must be based on a historical compromise, successful strategies are copied, selecting a strategy is based on the degree of development everyone state has. State strategies are tools for national restructuring and they do not only provide macroeconomic conditions in which certain business thrive, but they also create specific institutions, which manage and promote the expansion of social, economic and political values (Sklar, 1990).

The structure of the international system, especially its anarchic nature, helps in explaining the strategies chosen by states. The theory of hegemonic stability has dominated the world in '80s and '90s, explaining whether international organizations are being created or not, a decisive factor in taking a position (Keohane, 1984). The United States and the Western powers were dictating the regulation of the global economy, and the power distribution between states offered explanations of a certain type of strategy choice from the multitude of policy instruments and decisions taken at international forums. The immediate interest of the hegemony is market creation and ensuring a stable supply of raw materials (Williams, 1972).

Hegemony is controversial as an option in foreign policy, accessible to a just a few selected countries. It may take the form of a strong state, but the picture is more complicated; it is exercised in a constellation of social and political forces for a historical block (Gill, 1994). Hegemony is domination and power and is less a strategy for economic competitiveness since it proved to be costly in the long term (Palan et al, 2007). Hegemonic strategy dominates all other possible state strategies (Calleo, 1982).

Domestic policies play a key role in drawing a state strategy, international commitments and attitudes toward global governance. Understanding the fact why states choose to cooperate at multilateral level and their susceptibility toward global governance can depend on the domestic dynamics of the already adopted policies, rather than on the interactions between states, international organizations and NGOs. Great powers have included economic regionalism in the strategies they choose to increase their relative gains and protect themselves against external threats to their economic welfare and national security, but also to reap the benefits of an expanding global economy (Gilpin, 2004).

Countries and global economic governance

As the dominant hegemonic power after World War II, the United States played a critical role in shaping the structure of the postwar international system, including the creation of many international organizations like the United Nations, the institutions that emerged from the Bretton Woods system, NATO and GATT. The fact that this system is marked by the existence of international institutions and the promotion of international law is the result of the U.S. preferences, which gave birth to rules and regulations compatible with its own interests.

The U.S. unilateralism was often a threat to the global peace, and its increasing power makes United Nations to take decisions that ignore the less developed countries (Ikenberry, 2003). In response to these unilateral decisions, other countries have shown frustration and the desire to participate in global economic governance without the U.S. The researches have shown that anti-American sentiment may lead to the inability of international organizations to take any legitimate global decisions (Johnson, 2007).

American exceptionalism is based on the belief that American values and norms are universal, and the U.S. has the responsibility to promote them and use the international organizations as the main instruments of their development (Luck, 1999). But the U.S. hegemonic position is used incorrectly (Calleo, 1982), and the main challenge to the American leadership is to identify problems they can still solve alone, namely those it can solve with the help of its partners (Friedman, 2008).

The U.S. has easily embraced the multilateralism of the international financial institutions, because it had an immense power over their voting decisions by controlling both the IMF and the

World Bank and having well-trained scientists from educational system within them. The Americans have the power to act alone, but by taking unilateral actions they risk undermining the multilateral system, a system that is almost entirely consistent with U.S. interests (Friedman, 2008).

When a hegemonic power fails to act within its borders, the credibility of the established institutions and norms fail as well (Cronin, 2001). The international institutions, dominated for long time by the American money and ideas, were considered as influential vehicles of the U.S. and emerging economies, like China, Russia, India, Brazil, Saudi Arabia and South Korea, not only they do not longer need them, but are taking more and more the position of a direct competition with them (Zakaria, 2009). But the U.S. is no longer the only power in global governance. Other powerful states appeared on the arena of international relations and their weight considerably in global decision-making process.

The political ambitions of the Latin America depend entirely on Brazil, which is encouraged by the mythical similarities with the U.S. and is trying to become the vanguard of the Latin diplomacy (Khan, 2008). Brazil's global leadership is recently, the state is in this position due to its strong economy based on agriculture, mining and processing industry, and also its political stability since the early '90s. Brazil supports Pan-Americanism, but has adopted an independent position in the era of globalization, building MERCOSUR and resisting the U.S. desire to create a Free Trade Area of the Americas. To improve its global image, it has become a major contributor to the peace missions under United Nations and to assist technically the South-South agreements, especially in tropical agriculture, energy and transportation projects in southern African countries (Karns, Mingst, 2010). It is not just another South American country, but the continent's essential geographical key factor (Khan, 2008). Brazil took the lead of G20 with China, India, Russia and South Africa, showing diplomatic maturity in international trade arena. Emerging strategic alliance between them is illustrated by the fact that U.S. has unconditional allies on the geopolitical market, and the developing countries can effectively work together in finding a balance and redrawing the global economic governance.

During the Cold War, Russia has held the role of hegemonic power in the bipolar struggle for supremacy with the U.S. He created two multilateral organizations as response to the ones created by the American side: the Warsaw Pact in opposition to NATO and the Council for Mutual Economic Assistance in opposition to the Marshall Plan. In both of them, it dictated the operating policies and programs, being a coercive military power in order to maintain its domination. After the fall of the Soviet Union, the Russian power has been economically weakened, but still having strong influence in the United Nations. Its weakness is an imminent threat to the world stability (Friedman, 2008). After extended its multilateralism in international forums, such as OSCE and G8 and has developed a partnership with NATO, Russia has shown increasing nationalist tendencies. Instead of joining the global economic system, Russia prefers to be a regional power and provide a distinct alternative to the economic and political institutions (Karns, Mingst, 2010). But its transition is uncertain and even it has eliminated the central planning, still having an opaque communist culture, which lacks flexibility and transparency (Friedman, 2008).

Nowhere in the world there lies so provocative such a depopulated state as Russia with such a populated one as China. A huge demographic imbalance and China's growing needs for resources lead to the question: can Russia continue in its actual shape? Russia is the state whose map will change in the near future: while Europe absorb its former influence spheres in the West, China swallow it to the East; without Russia, the Western world do not have access to the headquarters of power in the Eastern part of the continent. If the West is not successful in addressing Russia, then China will be victorious (Khana, 2008).

Along with China, India is one of the most populated states, with a significant economic growth in the last decade and one of the declared nuclear powers. The backbone of its economic

development is the private sector, and the economic growth has nothing in common with the governmental activity, but exists despite it (Zakaria, 2009). Its foreign policy has incorporated significant elements of multilateralism and, also, unilateralism. India is an active participant in peacekeeping missions led by the United Nation and helps the poorest countries, providing diplomatic support in the redistribution of preferences to the disadvantaged areas (Cooper, Fues, 2008). India has refused to be part of treaties and other agreements that would emphasize its role as a powerful state, but is still an active member in ASEAN or APEC. It faces an interesting domestic paradox: although the society is open, energetic and ready to take its place in the world, the ruling class is hesitant, weak and suspicious in front of the changing realities around them (Zakaria, 2009).

China's role in the international arena has changed along with the transformation from a self-imposed isolation to the opening toward the global system. The awakening China is reshaping the economic and political landscape, being modeled by the rising world (Zakaria, 2009). As one of the most populous states in the world, as a nuclear power, as the largest borrower for the World Bank, as the largest aid donor to Africa and having the highest carbon dioxide emissions, China is a key player at global level (Kent, 2007). Its relations with the world are practical, reflecting the context of its interests and it declares itself as being a developing country, even if it is one of the major economic powers that redefine the global economic order. Multilateralism has become the center of its foreign policy. After avoiding multilateral agreements for a long time, China has recently come into many as possible. Since the mid-'90s, it has proved unprecedented actions toward multilateralism in Southeast Asia, is an active member of ASEAN and it is taking the responsibility in solving regional and global problems.

Since 2000, China has shown self-confidence due to its economic growth, international experience and perception of U.S. vulnerability. In fact, its multilateralism contrasts sharply with the American unilateralism in a time when multilateral actions and consensual decisions are needed. Although he agreed to cede some sovereignty just like the U.S. and other important states did, China was selective in responding to challenges. It moved slowly in taking decisions regarding trade liberalization and implementation of the imposed standards by international organization (Karns, Mingst, 2010).

China's multilateralism is one with regional and global prerogatives and has become a convenient way to move in the direction of being a world superpower, to extend its influence, to promote multi-polarity and to assume proper responsibility in global decision-making process (Wu, Lansdowne, 2008). This way of thinking has contributed to the increasing interdependence, compromises in achieving targets and to embrace the institutionalized forms of cooperation not only to continue its growth, but also to address the arising challenges of globalization process. But, in reality, the globalized world pushes America and China into an alliance hard to materialize geopolitically speaking; for over three decades, China's foreign policy was geared towards satisfying the U.S., and the economic relationship is one of mutual dependency: China needs the U.S. market to sell its product, U.S. needs China to finance its debt (Zakaria, 2009).

Conclusions

The study of global economic governance allows the understanding of the complex interactions between states and other important international actors. Systemic shocks or rapid changes at the regional and global level in the distribution of power contribute to choosing a state strategy. Cold War, oil crises, financial and economic crises are just a few examples of systemic changes that contribute to taking a strategic position. In such cases, states may be willing to cede more of their authority to the new governance structures or to the ones already in place in order to protect themselves against side effects.

Groups and coalitions provide a certain coherence and order in the world of over 192 countries, with an extremely busy agenda of issues to be solved in no time. They put these issues on the

table and engage in negotiations with compromises in order to reach consensus. The countries remain active participants in the new global economy.

RESEARCH ON THE IMPACT OF ICTS ON THE LOCATION AND SPATIAL DEVELOPMENT OF FIRMS

Schwartz Andrei
The West University of Timişoara Faculty of Economics and Business Administration

This article resulted out of primary data produced on the basis of PhD level research of the use of information and communication technologies (ICTs) in, primarily, professional services firms located in Romania and the broader European spectrum. We have aimed at seeing whether ICTs produce a spatial effect on firms (such as their launching of new offices or hiring of remote workers, in places where the firm does not have branches. Among the chief conclusions of this paper, we have highlighted the idea of how companies should be encouraged to conceptualize the ease with which they can locate their branches wherever so as to capitalize on two aspects: a broader market for their services and products as well as tapping into reservoirs of talent in lower cost countries .

I. Introduction

With gasoline prices skyrocketing around the world as a result of both increased demand and the instability of autocracies and teocracies in most OPEC countries, as well as with the added stimulus of having a reliable tellecomunications network connecting most countries, many firms as well as their employees started looking, with the start of the latest financial crisis, into other, more modern, ways of working. One oif the reasons was obvisouly reducing costs in their operation. Another was simply, doing things smarter and in a more efficient way.

Alternatives started then being implemented, such as transit subsidies, carpooling with other colleagues or other means through which the employees would commute to the company's HQ. The one other major new idea which was researched and implemented starting in the USA (either through careful strategy and planing or through the natural course of action of using the ICTs): telecommuting or telework (the later is the EU preffered term for the subject).

The proliferation of high-speed, broadband Internet connectivity and the existance of smartphones also occurred during the later half of the first decade of the 21st century, all this helped telework become a well accepted and, by many employees, desired way of working for many companies and individuals worldwide.

And last, but surely not the least, people started appreciating more and more a better balance between personal life and working time. All this could be facilitated via flexible-time, remote working.

II. Research methodology

We wanted to research some of the hypotheses presented in our introduction and the way we chose to do it was via applying a questionnaire. We have mostly used quantitative tools and data, to add volume to the perceptions which already resulted through some 1 on 1 interviews with managing directors of companies – that being the bulk of the qualitative information.

We've sent invitation letters for the questionnaire to over 950 individuals through the business network LinkedIn (www.linkedin.com). The response rate was surprisingly good for such a research project (close to 10%).

Other invites we've sent via the Timiş County Chamber of Commerce, Industry and Agriculture have been left unanswered, to our great disappointment and, thus, presenting complications and implications for our study and conclusions (and limitations we have tried to overcome).

We've presented some identifying data on the sample population we've researched in the tables below (Tables 1 through 3).

Table 1. Size of company - number of employees

Size of company	Percentage
0-10	22%
10-50	14%
50-300	22%
300-1000	11%
>1000	32%

Made by the author

Close to 60% of the respondents (adding up 22%+ 14%+22%) come from firms with less than 300 employees, making this sample population relevant, primarily for SMEs (Small and medium enterprises).

Table 2. Activity domain of the company

Industry	Percentage
Translation services	5%
IT/High-tech/software	30%
Design/Digital	2%
Marketing/PR/Communications	12%
NGOs	5%
Telecommunications	5%
Banking and finance; insurance	8%
Other professional services	33%

Made by the author

We can see that the majority of the firms represented in our study are in the tertiary area of the economy, being service providing firms.
In table 3 we have presented the geographical spread of respondents. Instead of presenting each country, we have highlighted the continents they represent.

Table 3.Location of respondents

Continent	Percentage
Europe	78.1%
Asia	9.6%
America	12.3%

Made by the author

Amongst countries, Romania is, obviously, the best represented territory, accounting for 29% of respondents.

III. The results of the research

Moving into the depth of our testing of the original hypotheses, we've directed at our respondents questions meant to reveal practices and perceptions related to the use of ICTs and their impact on location strategies.

We have highlighted a few questions and the statistics built upon the answers to these in the tables below.

Table 4. Do you have colleagues working (constantly) away from firm's headquarters (offices)? *
(those working from home, teleworking/remote-working)

Option	Percentage
Yes	74%
No	16%
No, but the firm takes this option into consideration	10%

Made by the author

We can notice how a large majority of companies have employees who work, with a certain degree of regularity we have not gotten into researching now, sometimes, away from company headquarters or offices.

Another question worth presenting conclusions for is about the means of communication (Table 5). We have looked at how the past few years have seen a shift from the fixed-line phone and fax model of communication of firms with their branches/offices and business partners (clients, suppliers, the Administration) to a much more diversified way of keeping in touch. Mobile phones are used by 77% of those polled in their business communication, versus only 18% still using regular/snail mail or the 27% who still operate a faxing machine. A tremendous change compared to 5-10 years ago; one which could favor flexible location strategies and teleworking.

Table 5. Communication with other branches and with customers is achieved through:
(* multiple choices allowed, hence the total being over 100%)

Means of communication	Percentage
Traditional phone systems - fixed lines (ex: Romtelecom, ATT, France Telecom)	73%
Mobile phone lines (ex: Vodafone, Orange, O2)	77%
Internet based phone/ VoIP (ex: Skype, Viber)	55%
Email	96%
Fax	27%
Regular/snail mail	18%
Text messages (SMS)	15%
Other	12%

Made by the author

Eurostat (2012), through (Table 6) provides reference statistics (vis-à-vis data in Table 4 and Table 5) on a much larger target population; this data can be used to verify the relevancy of the results of our PhD level research.

Table 6. Percentage of persons employed working part of their time away from enterprise premises and accessing enterprise's IT systems from there

GEO/TIME	2003	2004	2005	2006
European Union (27 countries)	:	35	44	47
European Union (25 countries)	:	37	44	48
European Union (15 countries)	22	42	50	53
Euro area	19	41	44	47
Belgium	58	52	58	62
Bulgaria	:	22	19	26

Czech Republic	10	7	10	27
Denmark	69	75	77	80
Germany (including former GDR from 1991)	5	48	54	61
Estonia	:	35	34	39
Ireland	42	40	35	35
Greece	34	27	29	42
Spain	25	28	27	31
Italy	29	28	33	20
Cyprus	:	33	37	39

Norway	62	67	66	77

Source: Eurostat, 2012 (Last update 06.03.12
Extracted on 23.03.12)

We have identified a few trends in our research. People seem to, generally, be quite happy with the option of working from home for their companies, if this option does not cost them dearly in their pay slip at the end of each month. The proportion in this area is a telling 2:1.

Table 7. If you were offered a choice between the two options below which would you choose?

Choice	Percentage
Bigger salary (flexibility about the location from where you work is not so important)	64%
Flexibility in working from home (you would give up on a higher salary)	36%

We have presented the results of our question on the main benefits of technology in day to day work (Table 8).

Table 8. Main benefits of the Information and Communications Technologies (ICTs) in your company's activity are: (* multiple choice)

Benefit	Percentage
Provides a better quality of work	71%
Work becomes faster	89%
It offers all employees, regardless of location, easy access to common data (eg. via the Intranet, Google docs)	84%
The possibility of reducing the number of employees	22%
Greater job satisfaction for employees	33%
Makes the company a more attractive employer	40%
A policy to protect the environment more effectively (lower consumption of paper, fewer visits to customers by car/airplane)	53%
Being able to work away from firm offices	71%

A large portion of the population polled (71%) tells us that flexibility vis-à-vis location is indeed one of the benefits. 84% also tell us that easy access to centralized data, from any point in the world (connected to the Internet/phone line) is another of the clear pluses which come to mind when analyzing the role of technology.

One final question and its results are presented below (table 9).

Table 9. "In your opinion, the contribution of the existence of the IT/Telecommunications/Internet infrastructure to the company's development is:"

<20%	4%
20-40%	20%
40-60%	28%
60-80%	30%
80-100%	19%

The highest numbers of respondents (30% and 28%) believe that the contribution of ICTs to the development of the companies they work for is very significant (estimated at between 40 and 80%). Only 3% of those polled believe that the ICTs contribution is relatively insignificant (0-20%).

IV. Conclusions

This article presents a small excerpt of the data which we gathered and analyzed. Some of the conclusions on the linkages between the different variables have been checked through applying a regression. In its 7th iteration, the results are (Table 9):

Table 9. Regression – the influencing factors

Regression Statistics			
Multiple R	0.48726		
R Square	0.237422		
Adjusted R Square	0.199294		
Standard Error	0.614296		
	Coefficients	Standard	t

		Error	Stat
Intercept	1.760587	0.291572	6.03
(x1) Location of firm branches	-0.10328	0.07562	-1.36
(x5) Employees working remotely/ teleworking, etc.	0.235006	0.094582	2.48
(x7) Proportion of clients attracted through the Internet	0.22098	0.06623	3.33
(x8)Number of employees:	0.204219	0.059157	3.45

One thing we can see is that many companies already use multiple locations in their activity, whether for research, production or sales activity. The use of the Internet as well as other ICT related tools can help firms expand, without the need for opening physical branches and offices. Sales can be achieved via localized websites and employees can be hired in countries the firm has never set foot in or in which they could not open a branch due to costs, legislation or other entry barriers. Companies in the UK who could not hire Romanian employees in the British Isles, due to employment barriers for these nationals, are, nevertheless, capable of contracting their services (as companies providing services, instead of the traditional role of full-time employee) via the Internet.

More firms should be encouraged by the Chambers of Commerce or national and local authorities to conceptualize the ease with which they can develop and locate their facilities anywhere (for example in lower cost regions or countries), capitalizing on the existence of the Internet and the ease with which branches can communicate and use the same set of information in real-time.

More firms should also understand that by offering (some of) their employees the opportunity of working remotely (from home or otherwise), they can benefit from higher productivity and ensure higher employee loyalty, which translates in higher returns on the hiring and training effort - one of the major business related costs. The office-centric working model is of the past, with the exception of certain industries (manufacturing, sensitive information, etc.) and functions (those which require daily interaction with clients, suppliers, other parties).

CONSIDERATIONS UPON ROMANIA'S MANUFACTURING COMPETITIVENESS IN THE EUROPEAN CONTEXT

Vasilescu Felician
Academy of Economic Studies

Luțan Iustina
Academy of Economic Studies

Rujan Ovidiu
Academy of Economic Studies

Manufacturing structure is essential to ensure the dynamic equilibrium of the whole economy. In fact, this industry is the one that disseminates through the organization and conduct of business as well as by the products delivered, elements of technological progress and new, modern work methods, with significant economic effects. Today in the Romanian industry, an urgent matter is material and energy cost savings thus increasing the value added. According to the economic development, within the industrial structural changes, usually occur the following main trends: the declining share of production from mining industry, while increasing the intermediate and final production, the declining share of industries with labor intensive and reduced complexity and diminishing, starting from a certain development level, of the share of industries with intensive natural resources deficits, especially energy resources, increasing the branches characterized by intensive and highly skilled labor, priority development of branches based on inventions vastly incorporating R&D, etc.. Some of those trends are increasingly emphasized by research, technological transfer and international trade, processes that enhance the interdependence between and within national economies. Labor-intensive industries reduce their share in total industry in developed countries. Demand for products manufactured by these industrial branches begins gradually to be met by developing countries. Production based mostly on the traditional technologies, easily transferable, is moving gradually from more developed countries to least developed ones. In contrast, in the industrialized countries are rapidly developing those industries incorporating important R&D results. These processes had been the subject for several specific research.
Although labor productivity decisively influence GDP per capita during long periods of time, the correlation between GDP annual growth rate and labor productivity growth rate differs between countries.
GDP per capita is strongly and positively correlated in most countries with labor productivity per capita relative to production and income per capita relative to consumption.
Keywords: Labor intensive industries, Energy intensity, Value added in manufacturing, Highly skilled labor, Capital intensive goods.
JEL Codes: F14 - Country and Industry Studies of Trade, F15 - Economic Integration

Introduction

Concept of economic structure and specialization in production of a nation has been dominated by Ricardian doctrine of comparative cost. (Krugman, Obstfeld and Melitz 2012: 25-26). Hence the need for countries in production specialization, considering the available resources and international trade advantage, as well as the possibility of a fair distribution of benefits resulted from international trade exchanges for all countries participating in the international division of labor, due to competition that occurs in world economy. It was concluded that this theory was based upon unacceptable and unverifiable assumptions, such as, for example, the fact that quantity and quality of production factors are immobile within the international relations, etc. and

considered a single production factor: labor. J. Viner, noted that such a simplification raised a barrier to exploring the consequences that differences between regions and countries have upon the production factors endowment.(Viner 1957: 19).The matter concerning the production factors endowment of a national economy in analyzing the production and foreign trade structure, has become a fundamental issue of economic research, first ones to tackle this were the Swedish E. Heckscher and B. Ohlin.(Ohlin 1967: 43-57; Krugman, Obstfeld and Melitz 2012: 97-99).According to their theory, the geographical distribution of the production factors is particularly important, influencing the specialization in production and development.

Previous research

In general, the inequity specialization is obvious for those countries to export only goods characterized by intensive unskilled labor and low productivity level for importing goods intensive in highly qualified labor and a higher productivity level.Emphasizing the independence of the industrial structures relative to natural sources is accompanied by increasing national dependency towards the world market. So, the dependence gradually moves from the national economy to the world economy through foreign trade. This tendency results from the development path in a large number of countries, for which the satisfaction degree for natural resources demand from own production decreased significantly. Within the development stage in which the tertiary sector starts to grow, the industries with high consumption of natural resources gradually reduce their weight, for capital-intensive ones and especially those that encounter highly skilled labor and apply the latest R&D results.

Methodology

G. Fels and F. Weiss point out that there are some characteristics of these structures, relative to the development stages mentioned: gradually moving, in accordance with the economic development, from labor intensive industries to large consuming natural resources and hence to the standard goods producing industries, where in general, production technologies are well known and easily accessible(Fels and Weiss 1977: 32; Trefler 2005:21-29;Eicher, Mutti and Turnovsky 2009:88 – 98).Labor-intensive industries reduce their share in total industry in developed countries. Demand for products manufactured by these industrial branches begins gradually to be met by developing countries. Production based mostly on the traditional technologies, easily transferable, is moving gradually from more developed countries to least developed ones. In contrast, in the industrialized countries are rapidly developing those industries incorporating important R&D results(Bowen, Leamer and Sveikauskas 1987: 791–809).These processes had been the subject for several specific research.Although labor productivity decisively influence GDP per capitaduring long periods of time, the correlation between GDP annual growth rate and labor productivity growth rate differs between countries. In the developed ones the association is stressed positive, productivity being the main engine of growth. In the less industrialized countries the mentioned correlation is weaker, suggesting that other factors determine the economic performance of a country in a given year. (Srebotnjak,Hizsnyik and Toth 2011:2). GDP per capita is strongly and positively correlated in most countries with labor productivity per capita relative to production and income per capita relative to consumption.

Results

Negative correlation between GDP per capita and energy intensity is apparently valid in most countries, highlighting the fact that economies, as they become richer use less energy to produce one unit of GDP.(Srebotnjak,Hizsnyik and Toth 2011:5). Compared with other EU countries, Romania registers a modest performance. As regards the value added in manufacturing, the country is ranked 18, as outlined in Fig. No 1.

Fig. No. 1: EUmembercountriesvalue added in manufacturing, 2007

06.03.2012

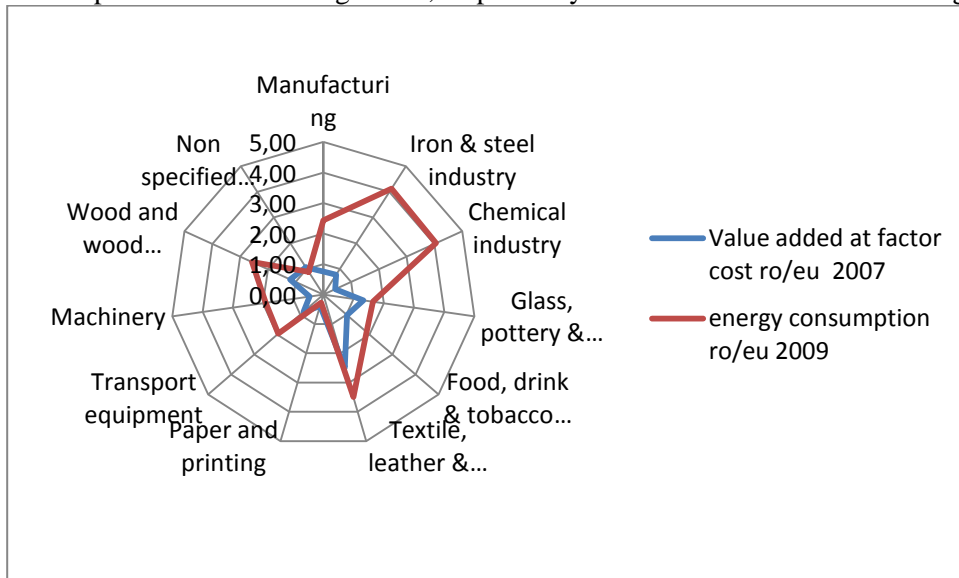
Another interesting comparisonistheRomania's position in theEU27 regarding the energy consumptionofmanufacturing sector, respectively the value added as shown in Fig. No. 3.


Fig. No. 3: Comparison between Romania and EU27 regarding the value added and energy consumptionofmanufacturing sector branches.
Source: EUROSTAT, Annual detailed enterprise statistics on manufacturing (NACE Rev.1.1 D), 06.03.2012 and Energy balance sheets 2009-2010,2012 edition

Conclusions

Only for a limited share, the supply of production factors can be adapted to different industries demand. In each region or country, the exported goods relatively contain in larger quantities the cheap factors, while imported goods incorporate scarce and expensive resources for the importing country. Romania exports particularly labor-intensive goods and imports capital intensive goods, hence the labor productivity aspect in general and especially in export industries being vital. Compared with other EU countries, Romania registers a modest performance. As regards the value added in manufacturing, the country is ranked 18. Comparison regarding the position of different branches within the Romanian manufacturing industry and EU27 highlights divergence,and the share of this industry in Romania and in the corresponding industries at EU27 level is almost insignificant. The Romania's position in the EU27 regarding the energy consumption of manufacturing sector, and the position regarding the value added are obviously divergent

THE EFFECTS OF FOREIGN DIRECT INVESTMENTS ON EMPLOYMENT IN CENTRAL AND EASTERN EUROPE. FOCUS ON ROMANIA AND POLAND

Vintila Denisia
The Academy of Economic Studies, Faculty of International Business and Economics

Popescu Raluca Georgiana
The Academy of Economic Studies, Faculty of International Business and Economics

Central and Eastern Europe has become a player on the international market of foreign direct investment (FDI) with the fall of communism in 1990. Liberalization of markets has brought both advantages and disadvantages to new states in transition. Despite modest values of FDI received, the share of the region in total global FDI is increasing. Any type of investment, foreign or domestic one, is considered crucial as it generates employment and contributes to the economic growth .This paper tries to provide an analysis of the effects of FDI on the labor force of this region, and specifically in Romania and Poland. We analyzed the quantitative effect on the labor force, more precisely the effect on the employment. Foreign subsidiaries hold an important part of the occupied population, although the number of foreign firms is lower than the domestic ones. Despite the destruction of jobs in the early transition in the process of restructuring, foreign subsidiaries, both directly and indirectly create jobs and usually at a higher rate than the domestic companies manage to do. During the recent financial crisis, foreign subsidiaries proved to be more resilient and the cut off jobs was lower than in domestic firms.

I.Introduction

Central and Eastern Europe has began to show interest to foreign investors with the fall of communism. Starting the transition process has led to major restructuring in all countries of the region and foreign investors have tried to take advantage of the opportunities. Although there was a fear at first because of uncertainty that these states presented, over time Central and Eastern Europe has become one of the favorite regions of foreign investors.

Many multinational companies decided to invest and relocate a large part of their activities to these countries. According to Ernst and Young's survey from 2010, in 2008 the CEE region was considered as attractive as the states of North America and West Europe being in top 3 among the investors' preferences. Among the strengths of Central and Eastern Europe we find: cheap labor and highly qualified labor force, membership to the single European market or proximity to it, large markets (Russia, Ukraine, Poland or Romania).

 Not only foreign investors have taken advantages from realizing FDI in this area, but there are many benefits to host countries too. One of the most important effects is the one on the labor force. In particular, for this region this impact is particularly important because of the major features that characterize this region: the transition period and the creation of the private sector.

Workforce is an important problem also in the European Union, due to the existence of regional disparities which is manifested most in the transition states (Jurajda and Terrell, 2006).

This article presents an analysis of the effects of FDI on the employment in Central and Eastern Europe(CEEC), and tune the effect for two states: Poland and Romania. The impact of FDI on the employment can be analyzed from several points of view: quantitative (number of jobs created), qualitative (productivity, training) , direct effects and indirect effects. This analysis will

focus on the quantitative effect of the employment, namely an analysis of job creation/ destruction realized by foreign investors.

The paper is split in 3 parts: the first one presents the evolution of FDI in CEECs, while the second one analysis the effects on the employment, the last part focusing on Romania and Poland.

II. The growing importance of FDI for CEEC

In the first years of transition, CEE countries didn't attract many foreign investors, who had many fears regarding the changes these countries were passing through. Repatriation of profits from the region was an important reason of concern for all investors, and the lack of currency convertibility just added more reasons to choose carefully the host country for your investment. (Gray and Jarosz, 1993). Although FDI is increasing year by year, though their value was quite low in the first decade of transition. Countries of Central and Eastern were characterized by a poor economy, hyperinflation, low productivity, infrastructure virtually nonexistent, and often unclear legal situation (UNCTAD 1994).

Since the early years of transition, investors to Central and Eastern Europe have shown a preference for a small group of countries, probably those in which economic reforms were accomplishing their goals best. Hungary, Poland, Czech Republic and Slovakia were the favorite destinations of foreign investors, the four creating also the Visegrad group.

 Thus, in the early transition, countries of Central and Eastern Europe, according to the FDI received can be divided into three categories:

 - Visegrad-countries: Czech Republic, Hungary, Poland, which recorded the most part of the FDI stock (69%) (these are almost industrialized countries and have strong ties to Western Europe)

 - Second wave: Bulgaria, Estonia, Romania, the Russian Federation, Slovakia, Slovenia, Ukraine and the Federal Republic of Yugoslavia which have about 29% of FDI stock

- Countries for which FDI negligible: Albania, Belarus, Latvia, Lithuania, the Republic of Moldova, 2% of the stock area. (UNCTAD, 1995).

 Between 1990 and 2001, CEEC have attracted 166.5 billion U.S. dollars, or 2.7% of total FDI. Accounting for 46% of the total population of Europe, CEE attracts only 5.7% of FDI, or per capita less than Spain. The largest stock of FDI in 2001 was in Poland, followed by Czech Republic and Hungary, while the highest stock per capita is found in the Czech Republic, Hungary and Estonia. (UNCTAD, 2001). Even if reported at global level, the stock is extremely low, yet the rate at which it increased in 10 years is impressive and the outlook is optimistic.

 The first part of the transition process was characterized by an increase in privatization –related FDI. The challenge of the last decade was to attract greenfield FDI (Picciotto, 2003) The starting of the new millennium brings changes in the evolution and structure of FDI. 9 countries will become EU members, which means they met the criteria required by the European Union. This status gives credibility in front of foreign investors. Starting with 2004, we may notice an increase in the volume of FDI attracted by the region, but the highest FDI values are not reached in 2007 as happened at global level, but in 2008, when the crisis outbreak (figure 1). The negative effects of the crisis are felt in the next year, when we see a decrease of about 50% of the foreign investments attracted compared to 2008.

Between 1995-2004 FDI stock of the 10 new EU member states grew twice as fast than the world stock did. The highest stock is found in Poland, with 61 billion dollars, followed by Hungary and Czech Republic. The three countries accumulated 75% of FDI stock of the new EU member countries in 2004(UNCTAD, 2005). At individual level there are significant changes in the 20 years that past. The domination of the three countries: Poland, Hungary and Czech Republic is declining. Poland takes the leading place of FDI inflows in 1996, and keeps it until 2001, when records its first decline.In 2000, the FDI inflows in Poland were representing 34% of total FDI

directed to the region. Although the relative values decrease by 38% FDI in 2001, in absolute terms, they received the highest value. In 2002, however, lost for the first time since 1995 the leading position to Czech Republic si, but recovered the leadership in 2003 and never lost again this position so far. The share of FDI attracted by Poland in total FDI of the region has decreased in the last decade, with values between 12-15 % excepting for 2008, when only 8% of FDI of the region were recorded by Poland.

Figura 1- Trend of FDI in Central and Eastern Countris(mln euro)
Source: created by author(WIIW database)

Romania recorded modest values of FDI in the first decade of transition, recording a peak in 1995 and another one in 2000. The strong launch of privatization programs in 1997, brought some huge increases of FDI inflows between 2001 and 2003, period when took place the most important privatizations (Hunya, 2004). The macroeconomic stability, after 10 years of turbulent movements, and the possibility of joining the EU rose the attractiveness of Romania to foreign investors. Thus, since 2006, Romania has become the second host country after Poland, drawing that year about 11% of total FDI attracted by the region. The peak was reached in 2008, but immediately, next year, a decline of 60% was recorded due the outbreak of the financial crisis.

III. FDI and the impact on employment

For the former communist states, which until 1990 had only state-owned property, there was no unemployment problems, as well as there was no concept of efficiency. The transition process automatically led to the restructuring of enterprises and therefore of the workforce. Thus, countries have moved from no unemployment problem that didn't artificially exist to the cut off jobs and implicitly to unemployment. The new private sector created was not able to cover reductions of state sector and therefore negative effects were felt in the labor force.

Workforce is an important problem in the European Union too, due to the existence of regional disparities , which manifest most in the transition states (Jurajda and Terrell, 2006)

In 2006 global foreign subsidiaries had 73 million employees, ie 3% of total employment worldwide. A good part of this workforce is found in the states in transition as production of labor-intensive products is outsourced to these countries (OECD, 2008). Generally, capital intensive activities remain in the home country, while the labor intensive activities are moving to states that benefit from a reduced labor cost. (Konings, 2004).

Also the method of privatization is important in determining the effect on employment.

Voucher and insider privatizations offered the most benefits for labor, but there were negative effects by slowing the restructuring. (Radosevic et al, 2003). In 1998, Romania recorded about 25% of all privatizations in the form voucher (unlike Poland which percentage was below 6%), which along with the unemployment rate (high in Poland and much lower in Romania) can support the above statement. Taking into account that privatization through vouchers lead to a

faster distribution of shares, some countries (Romania, Czech Republic and Bulgaria) have opted for this form of privatization, which led to a greater social equity (Kalotay and Hunya, 2000) .

Konings (2004), quoting on Blanchard (1997) presents the two extremes of the transition :

1) the fall of the state sector with "sluggish" growth of the private sector are the main forces carrying out the transition process. The growth and development of the private sector is not sufficient to cover layoffs made by the state, which leads to high unemployment rates and thus slow the process of restructuring.

 2) the rapid growth of the private sector is the main driving force of transition, feature characterized by absorbing the dismissed labor force of the state sector.

Creation and destruction activities of workforce in CEE have been and are critically important (Konings, 2004). For Poland, creation and job destruction decreased in 1994 and became almost equal in 1997. During this time, the evolution of the same indicators in Romania, decreased modestly, and the net value is negative, job destruction was clearly superior to job creation in 1997. (Konings, 2004).Divided by type of ownership is seen that a strong discrepancy between the labor rate in the state sector and the one in foreign / private sector. For Romania and Poland, the foreign sector is by far the one that creates jobs. (Konings, 2004).

The effects on employment were divided by Hunya and Geishecker(2005) into two categories: direct effects and indirect effects.

1)Direct effects: - *Destruction of jobs due to restructuring of state enterprises* (Hunya and Geishecker, 2005).

This was the first direct effect felt by countries in transition. Making acquisitions through privatization in the early years of transition was equivalent to the layoff of the workforce. But the alternative may lead to larger cuts in jobs (Meyer, 2003). Delaying privatization can lead only to a delay in the restructuring of the companies and, therefore, delay in redundancies and streamlining enterprises. At first, states have tried to provide incentives in terms of maintaining employment by making contacts and guarantees asking to maintain the number of jobs, in exchange for lower prices. But these practices have proved to be inefficient (Radosevic et al, 2003) For example, Poland has lost 40,000 jobs as a result of the privatization of the national telecommunications company TPSA by France Telecom (Lewis 2005 in Dufaux 2010). And despite many years have passed since the start of the restructuring, the number of jobs lost have not been recovered, at least not entirely. (Dufaux 2010)

Effects of destruction of jobs have been observed especially in the early days of transition and as the transition process has evolved, they reduced. Job cuts, absolutely necessary in restructuring is compensated by the foreign investors through the financial resources and especially the managerial one, that they provide and that do not exist at domestic level.. This will lead to streamline the company and soon create new jobs (both directly and indirectly) through the backwards and upwards links that foreign branch has in the global production network. (Meyer, 2003). Analyzing the unemployment we may notice an increase iof this indicator for the former communist states during 1991-2000, ie in the first stage of transition. This is a direct cause of restructuring enterprises leading to job cuts and unemployment. For Hungary the unemployment rate has a tendency of decline, possibly due to completion of the privatization process and high economic performances that have contributed to mitigate the negative effects of transition. Romania kept unemployment rates low in early years due to delay of the restructuring process and achieve double-digit unemployment rates, even in 1998, the year privatization process started an upward trend. For Poland high unemployment during the first phase of transition was one of macroeconomic problems most severe. In the second decade of transition, unemployment is reduced in most countries of Central and Eastern Europe, including Poland (even if a reduction of this indicator was achieved much later compared to other states)

- *Job creation through greenfield investments* (Hunya and Geishecker, 2005)

FDI through acquisitions and mergers have mainly contributed to the transformation of state companies and creation in the host countries of the private sector. FDI as greenfield investments have a significant impact on jobs. If for the first category there was a reduction of jobs, the latter contributed to their increase.

Greenfield FDI is targeted by all states and in terms of job creation they are preferable to acquisitions. For ex-communist Europe, this type of investments was difficult to attract in the early years of transition, considering the non-existent private sector and the need to create it by privatizing state enterprises, the lack of regulations, the technological gap ecc. Foreign firms, had also their fears and had no knowledge of local business, so they preferred initial penetration of eastern markets through acquisitions.

2) Indirect effects (Hunya and Geishecker, 2005)

- *Loss of jobs for local suppliers*, once the takeover took place, due to faulty with them and pointing to the parent company's traditional suppliers

- *Loss of employment through the creation of subsidiaries* by large and technologically advanced foreign firms;

- *Job creation by creating new links with local suppliers*: if at first foreign subsidiary will import the necessary materials, as local suppliers will become competitive, foreign branches will focus on the latter

IV. An analysis of the evolution of employment in Romania and Poland

For Poland the first decade of transition has not been very good, the manufacturing sector has lost many jobs in both local and foreign companies. (Hunya and Geishecker, 2005) Romania, was just beginning massive restructuring that led to a loss of jobs, leading foreigners to recover only half of the jobs lost locally. (Hunya and Geishecker, 2005). In the second half of 2000s the situation has changed. In Romania the number of foreign subsidiaries dropped from 30,407 in 2003 to 25,835 in 2009. Meanwhile the number of employed people reached 916,869 people or about 24% of the total workforce nationwide in 2009. The outbreak of the crisis led to a reduction of about 500,000 jobs, of which approximately 10% were due to foreign branches. Between 2005 and 2009, the number of jobs created by foreign investors increased by 350,000, ie by 62%. In 2009, we notice the impact of the crisis, the number of jobs in foreign subsidiaries decreased by 5% over 2008 level, while nationally it was registered a decrease of 11%. This highlights the strong decline registered in the domestic companies once the crisis has erupted. The stronger decrease registered by the domestic firms suggests that they were more deeply impacted by the crisis and less efficient than foreign branches. The turnover of foreign companies is impressive if reported to the values obtained by domestic firms. Having 24% of total labor force employed in 2009, foreign companies reached 42% of the national turnover. These show that both productivity and skills of the employed people of foreign companies are superior to those of local companies. Most of the workforce of foreign subsidiaries is to be found in manufacturing, although the number of firms is not half of those recorded in other sectors.

Unlike Romania, in Poland the number of employees in foreign subsidiaries was about 10.6% in 2009 and the highest level was recorded in 2008 when the share was 10.91. While nationally the number of jobs has increased by 900,000 s from 2005 to 2009, foreign subsidiaries contributed with 274,000 jobs, which is about 30% of the increase at national level. Overall, the number of employed persons increased by 7% at national level between 2005-2009, while the increase recorded by foreign branch was of 23%, showing that the increase of jobs in local firms was lower. The outbreak of the crisis led to a reduction of 1 % of employees nationwide, while the reducing in foreign subsidiaries was by 4%. The number of foreign companies has increased by 37% between 2005-2009 and number of employees by 30% .The average of employed persons of the new firms that entered the market is about 50, which leads to the idea that most new investments were made by small and medium firms which have less than 50 employees. In 2009,

the number of foreign firms increased by 5% and the number of employees fell by 4%. These trends are explained by a resizing typologies of foreign companies present on the Polish market: companies with over 250 employees fell by 4%, while firms with less than 9 employees increased by 9%.Unlike Romania, domestic Polish companies were able to face better the crisis. Relatively modest reduction percentages of the employees in Poland are in line with the evolution of the Polish economy, one that managed to achieve a positive growth in 2009. The performance of Polish companies (both local and foreign), not to reduce the workforce was supported by domestic demand which stimulated economy and thus enabled to maintain jobs. (The data regarding the employees were taken from Central Statistical Office of Poland and Romanian National Institute of Romania and analyzed by the authors)

Acknowledgments

Conclusions

FDI represents an important part for the transition economies. Although the values received are still modest, FDI inflows have been increasing year by year and this is reflected by the labor force employed. The particularity of the states in transition, namely the creation of the private sector led to significant restructuring of privatized enterprises and direct impacted the labor force. Once companies have become effective, the negative effect was reabsorbed. foreign subsidiaries had a major contribution in the workforce employed for both Romania and Poland. In 2009 foreign companies have 24% of the total workforce in Romania, while for Poland the percentage is lower than 10%. Last five years have led to higher growth of employment in foreign companies respecting to local ones.

SUB – SECTION: EU SUSTAINABLE ECONOMIC DEVELOPMENT AND COMPETITIVENESS

TOGETHER OR APART? STRUCTURAL FUNDS AND REAL CONVERGENCE IN THE NEW MEMBER STATES

Alexe Ileana
Academy of Economic Studies in Bucharest, Faculty of International Business and Economics

Tatomir Cristina Flavia
Academy of Economic Studies in Bucharest, Faculty of International Business and Economics

The objective of this study is to analyze the relationship between the structural funds provided by the European Union (EU) and the real convergence of the New Member States that joined the EU in 2004. We also assess the effect of the crisis on this. According to the empirical studies in this area, the impact can be both negative and positive. Furthermore, in the latter case, the correlation is not very strong and depends on several factors. To meet the research objective, we have structured this paper into five parts. In the first part, we make a short presentation of the Cohesion policy and its evolution in time. In the second part, we explore the importance of the subject in the economic literature. In the third one, we explain the methodology used in this paper. We contribute to the literature by creating a Real Convergence Index (RCI) and by assessing the evolution of this index and of the structural funds payments from 2004 until 2010 in five New Member States (Hungary, the Czech Republic, Poland, Slovakia and Slovenia). The fourth part describes the results obtained. The structural funds payments reached a maximum level in 2007 in all the countries, with the exception of Slovenia. After this point, they recorded decreasing levels, mainly because of the economic and financial crisis. Within this group of countries, Poland and Slovakia recorded an increase in RCI during 2009 and 2010, even though the amounts of payments started decreasing. The highest level of structural funds payments and the maximum level of RCI are not synchronized, with the exception of the Czech Republic. This could come as a result of the lagging effects of structural funds on the economic convergence. The fifth part of the paper summarizes the conclusions of our research. The analysis confirms the previous work in this field. Specifically, it does not provide us with a clear result regarding the relationship between the absorption of structural funds and the real convergence. The implications for Romania are not very encouraging. This means that the efforts for increasing the absorption rate of EU funds will not necessarily lead to a faster real convergence process. Consequently, the effectiveness of the Cohesion policy remains under question.

Keywords: Structural Funds, Cohesion policy, Real Convergence Index, New Members States, European Union

1. Introduction

It is very well known that the process of European integration does not lead to uniform benefits, due to the very different initial levels of national development. In this context, the EU designed the Cohesion policy as an instrument to support the convergence process within the Union. This policy should help to bridge the gaps of economic development between regions and countries, in order to achieve real convergence.

The Cohesion policy dates back to the creation of the European Economic Community. However, the first multi-financial programming period, between 1988 and 1992, was mainly created to smooth the integration of three peripheral countries: Greece, Spain and Portugal. Later on, the Treaty of Maastricht (1992) introduced the Cohesion Fund, the Committee of Regions and the principle of subsidiarity for the next programming period (1994-1999). The amounts allotted to the Cohesion policy increased with time. In 2000, this policy was adjusted according to the priorities established by the Lisbon Strategy (growth, jobs and innovation) and to the forthcoming accession wave of 2004. For the 2007-2013 period, the Cohesion policy brought new changes, in terms of simplified rules and structures, more transparency, stronger focus on jobs and growth (European Commission, Regional Policy, 2012). The financial instruments through which the EU supports the economic and social development of the countries and regions are represented by the structural funds (mainly The European Fund for Regional Development and the European Social Fund) and by the Cohesion Fund.

The enlargement process of 2004 and 2007 has added a growing challenge on the EU as a whole. It has led to more discrepancies in terms of economic development and income distribution within the Union. However, the EU funds received through the Cohesion policy does not automatically drive to real convergence. First of all, the effects of the EU funds on real convergence remain uncertain. Secondly, the absorption capacity of the New Member States puts additional pressure on the effectiveness of the EU funds. Marinaş (2007) even supports the view that because of the absorption deficiencies, the discrepancies between the EU regions have remained relatively constant and, furthermore, those within the EU Member States have increased.

2. The effectiveness of the Cohesion policy

There have always been contrasting views regarding the potential of the EU funds to boost growth and real convergence.

Manzella and Mendez (2009) make a short review on the criticism regarding the Cohesion policy. They state that a lot of analysts, academic people or even European governments continue to question nowadays the rationale behind this policy and its effectiveness. The debate focuses on the unclear mission of the policy, its insufficient concentration on growth, inadequate policy instruments, its complexity and bureaucracy. Furthermore, after decades of intervention, the contribution of the Cohesion policy to economic growth and development remains uncertain. The literature reports diverging results, ranging from positive correlations between structural funds and growth (Beugelsdijk and Eijffinger, 2005) to even negative correlation between the two of them (Miderlfart and Overman, 2002; Martin, 1999). Another study of Ederveen, Gorter, De Mooij and Nahuis (2003) analyzed the relationship between Gross Domestic Product (GDP) per capita evolution and cohesion support, but there was no consensus regarding the impact of the Cohesion policy on real convergence.

Marinaş (2007) supports the perspective of a weak Cohesion policy capacity to bridge the income and structural gaps between nations and regions. The first reason pointed out is the lack of coordination between Community's projects and the local policies. The second one refers to the existence of a national structure based on a center-periphery model, which encourages the concentration of benefits in the urban agglomerations.

There are also empirical studies focusing on a conditional view of the structural funds effects on real convergence. Martin (2003) analyzed the impact of the EU's structural and cohesion funds on real convergence and concludes that the funds can foster growth and real convergence if there is a stable macroeconomic environment and if the institutional and microeconomic structure are leading to growth. Stierle (2005) reported a possible substantial impact of the EU Cohesion policy on the catching-up process. However, he puts forward several factors necessary to

positively influence the effectiveness of structural funds in the real convergence process: stronger spatial concentration, better thematic concentration and more effective use of funds.

However, even though there are three main official objectives of the Cohesion policy (convergence, regional competitiveness and employment, European territorial cooperation), Tarschys (2008) identifies at least 32 goals of the Cohesion policy, which further question the effectiveness of the policy.

Table no.1 - Coping with 27 Member States and multiple goals of the Cohesion Policy

32 goals of the Cohesion Policy	
Solidarity	Urban development
Convergence (countries)	Retraining of the unemployed
Convergence (regions)	Fighting social exclusion
Regional growth	Integration of vulnerable groups
Regional competitiveness	Gender equality in labour market
European growth	Boosting small & medium enterprises
European competitiveness	Inter-regional network-building
Administrative modernisation	Inter-regional learning
Institutional development	Linking regional elites to Brussels
Environmental protection	Trans-frontier cooperation
Climate policy	Compensation for internal market
EU visibility to citizens	Compensation for monetary union
EU legitimacy	Making enlargement acceptable in some areas of the Old Member States
European identity	Making enlargement acceptable in disadvantaged regions of the New Member States
Redistributive justice	Territorial cohesion
Rural development	Cohesion (sense of community)

Source: Tarschys, Daniel. "The Budget Review and the Committee on Budgetary Control: Coping with Multiple Agents and Multiple Goals", 2008.

In this paper we study the impact of the structural funds (European Regional Development Fund, European Social Fund, The Guidance Section of the European Agricultural Guidance and Guarantee Fund, The Financial Instruments for Fisheries Guidance) on the real convergence of several countries that became EU Member States in 2004. We chose Hungary, the Czech Republic, Poland, Slovakia and Slovenia because they are the main regional competitors of Romania. In our analysis, we consider only the structural funds paid under the convergence objective.

In comparison with the majority of the studies that employ the GDP per capita indicator, we study the absorbed structural funds in correlation with a Real Convergence Index, made up of the GDP per capita at at purchasing power parity (PPP) and the productivity per hour worked during 2004 – 2010. Productivity is an important engine driving the real convergence process. These Central and Eastern Europe countries can provide some useful empirical results for Romania, for which we cannot yet provide the same analysis, due to its late accession in 2007.

We also enrich the economic literature on the relationship between structural funds and real convergence with new findings for the New Member States. The study assesses the impact of the financial crisis as well.

3. Data and Methodology

In this paper, we build a real convergence index (RCI). RCI comprises 2 sub-indicators: GDP per capita at PPP and labor productivity per hour worked, as percentage of the EU average. Values below 100 point to levels lower than the EU. The EU average is set to equal 100. When computing RCI, each of the sub-indicators is given the same share of 50%.

The RCI index is computed as follows:

$$RCI_{i,EU} = GDP/capita \times 0.5 + Labor\ productivity \times 0.5, \quad (1)$$

where $RCI_{i,EU}$ − real convergence index of country i with the EU.

The data used in the paper come from the Eurostat database and cover the period of time between 2004 and 2010.

We compare the level of structural funds payments, more exactly the amounts received by the countries, with the real convergence index which measures the degree of convergence with the EU.

4. Empirical results in the case of the New Member States

Almost all the territory of the 5 considered countries is under the convergence objective. More exactly, in the case of Poland and Slovenia, the whole countries are covered by this objective.

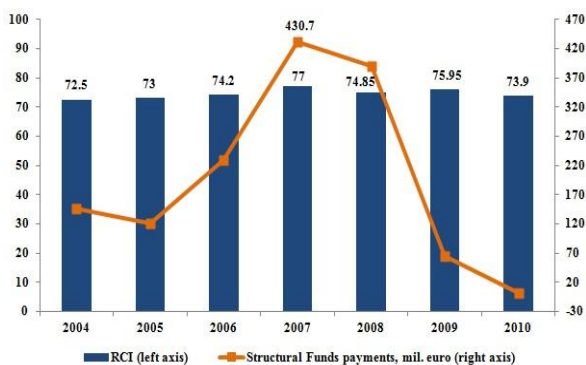
Out of these 5 countries, Slovenia reached the highest level of convergence, with an RCI of over 80 percentage points. Slovakia and the Czech Republic follow it with around 74% of the EU average. Poland's RCI amounts to only 58% even though it has received the highest share of funds from the countries analyzed.

As a general remark, the figures below emphasize that the maximum amount of structural funds payments was reached in 2007, with the exception of Slovenia. Since then, we notice a significant drop in the level of payments, the most important reason being the economic and financial crisis.

Taken separately, Hungary entered into the EU in 2004 with a Real Convergence Index of almost 60 percentage points that has slightly fluctuated around the same value and only in the recent years attained over 62 percentage points (Figure no.1). The structural funds payments increased until 2007, when they reached the maximum value. After this point, the amounts decreased significantly to 0.2 mil. Euro in 2009, while the RCI increased slightly. Consequently, we cannot assess a clear relationship between the two of them.

In the case of Poland, we observe a direct relationship between structural funds payments and RCI between 2004 and 2007, but the trend reverses starting with this year. After 2007, the amounts received by Poland from structural funds decreased constantly, but the RCI level increased to over 58 percentage points in 2010 (Figure no.2).

Figure no.1 – The case of Hungary	**Figure no.2 – The case of Poland**
As regards the Czech Republic, again there is no clear relationship between structural funds and RCI. Besides the year 2007, when the two of them reach a maximum value, we cannot assess a definite positive or negative relation (Figure no. 3).

Figure no.3 – The case of the Czech Republic   **Figure no.4 – The case of Slovenia**


In comparison with the other countries analyzed, Slovenia recorded a maximum level of payments from structural funds in 2006. The highest level of RCI was reached two years later, in 2008, with 87.35 percentage points of the EU average (Figure no. 4). Again, there is no coherent relationship between structural funds and real convergence. However, in the case of the Czech Republic and Slovenia, during the last two years included in the analysis the real convergence decreased simultaneously with the amounts of payments received. This could indicate the need of a more important role of the Cohesion policy during bad economic times.

Finally, Slovakia recorded a permanently increasing RCI during 2004-2010, with the exception of 2009. The maximum level of 74.3 percentage points was reached in 2010. However, the payments had reached the highest level three years before, in 2007 (Figure no. 5).

Figure no.5 – The case of Slovakia

During the last two years of economic crisis, in 2009 and 2010, only Poland and Slovakia recorded increasing real convergence with the EU, while the amounts of payments decreased. This could also express lagging effects of the previous higher levels of the structural funds payments on the real convergence process. Hungary recorded almost the same RCI in 2009 and 2010, despite of the increase in the payments. In the case of the Czech Republic and Slovenia, the real convergence with the EU recorded lower levels during the crisis.

5. Conclusions and implications for Romania

Our study confirms the previous results of the economic research in the field of structural funds and real convergence. More exactly, the analysis on the five New Member States does not provide us with a clear answer regarding the relationship between the structural funds payments and the real convergence index computed in this paper.

However, there are four main conclusions derived from the study. First of all, with the exception of Slovenia, for all the other countries the payments from structural funds recorded the highest level in their fourth year of EU membership, in 2007. Secondly, the maximum level of structural funds payments does not match the maximum level of real convergence, with the exception of the Czech Republic. This may be due to lagging effects of the structural funds on the economic growth and development. Thirdly, there is a general decreasing trend of the structural funds payments in the second half of the analyzed period, with the exception of Hungary. Fourthly, during the economic and financial crisis in 2009 and 2010 only Poland and Slovakia recorded increasing values of the Real Convergence Index with the EU.

Romania currently records a very low absorption rate of the EU funds, of only 7%, and a real convergence index below 50% of the EU average. The challenge is very important on the medium and long term. However, the results of the current study are not very encouraging. There is no clear relationship between the absorption rate and the real convergence achievement. Consequently, a higher absorption rate of EU funds might not generate a faster real convergence process. This conclusion further questions the existence of the Cohesion policy of the EU.

INVESTMENTS IN THE REAL ESTATE SECTOR. A CASE STUDY ON CENTRAL EASTERN EUROPE

Arjoca Diana
Doctoral School BucharestAcademy of Economic Studies Faculty of International Business and Economics

Belu Mihaela Gabriela
Bucharest Academy of Economic Studies Faculty of International Business and Economics

This paper presents the evolution of real estate market in European Union. Romania's real estate sector passed through significant milestones during the last years – due to economic boom, integration in the European Union and affordable financing. But after the 2007 subprime crisis and the 2010 European sovereign debt crisis new ways of approaching the market have to be designed and implemented. The M&A transactions seem to be an investment driver in Romanian real estate as proven by Immofinanz /Adama Case Study
Key words: real estate market, investment decisions

1.Introduction

A gradual economic recovery seems to be under way, even though limited by governments' efforts to deleverage. The compression of yields started to ease back in 2011, which would make development projects more attractive than acquisitions, also because of the fact that superior return on investments can be achieved. The option to either develop or trade rent generating assets could be the decisive factor in the performance of real estate companies in Europe.

However, even though European markets have been able to maintain a fragile balance between inflation and deflation, the growth pace is still suppressed. While Northern Europe has a healthier finances system and stronger competitive advantages, the Southern countries face higher unemployment rates and lack of consumer confidence, which makes the gap even higher – this has a direct impact on the real estate sector in these countries, making it less attractive.

2.The Real Estate Market UE

The growth rates in Southern Europe are below average, combined with the fact that the local governments are implementing medium term plans until 2014 – 2015 to cut expenditures in an attempt to rebalance the public debt, means that consumer spending is also kept to a minimum, which leads to stagnant rent levels for both retail and office properties. Moreover, the economic situation reflects directly in the decreasing occupancy level of office spaces, which traditionally also indicates economic downturn.

Also inflation and increasing energy prices have a direct impact on the real estate sector, affecting directly the occupancy costs and ability to afford higher rents, not to mention the discriminating choices of consumers for retail products.

Basically, there is no big difference between listed European real estate companies, except for the regional exposure of their portfolios – because CEE markets are perceived as uncertain and undeveloped compared to Western European markets, companies invested in this region are trading with a higher discount to the net asset value (NAV). But what has been completely neglected prior to the subprime crisis was the size of the investment market – before 2008, Western Europe has a yearly investment volume up to EUR 100 Bn., while CEE (including Russia) had a maximum volume in the boom phase of EUR 14 Bn. This crucial aspect became obvious only after the bankruptcy of Lehman Brothers in 2008, when many real estate companies

decided to exit their CEE investments, in an effort to consolidate their portfolio and concentrate on more traditional European real estate markets. Because the CEE real estate market is a relatively young one, there is little knowledge among Western European companies about this region and corroborated with the devastating effects of the recent crisis, the regional exposure has an impact on the trading discounts to NAV.

For Austrian investors, heavily invested in CEE, a particular challenge in their expansion was opening up to markets much bigger in size compared to the local one – Romania for example is three time larger in size and by taking over the majority stake in Petrom by the Austrian OMV, suddenly a company with 10 times as many employees as in the headquarters had to be managed. Practice has proven that when implementing an investment strategy, the problems increase with the square of the distance and that each national border that has to be crossed potentially attracts new risks. This happens because of entering new cultures, new legal systems, new languages, new business practices and suddenly apparently familiar problems cannot be solved intuitive anymore. Whereas on the local market, business practices are intuitively understandable, this doesn't apply anymore in foreign markets which means a much higher level of information has to be assimilated without making the mistake of interpreting them, but processing them based on local customs.

According to Dick Boer - Executive Director Corporate Finance for European Real Estate at Kempen & Co. Merchant Bank during an EPRA news conference and captured in a Kemper & Co press release, London, September 2011, there is currently "an astonishing decoupling between the valuations of those real estate firms who are exposed to the full brunt of the sovereign debt crisis, and so also fears the Eurozone may disintegrate, and those who are largely sheltered from the storm" – thus we are speaking of a North / South axis of real estate investments within Europe, visible also in terms of investment return per share and trading discount relative to NAV. The listed companies in Southern Euro Area or with investment exposure in this region have seen dramatic decrease of their market capitalisation - the average discount to NAV for companies with portfolios in this region was 48%, for those with a limited exposure to this region 22% and for companies with no exposure in this area maximum 13%, as can be seen in the following chart.

Figure 1: Trading discount to NAV of European Real Estate Companies, based on their regional exposure
Source: own presentation based on historical market caps published by the European Public Real Estate Association *www.epra.com* and Kemper & Co press release, London, September 2011

There is definitely a new trend in investment decisions – as a result of the current financial and economic crisis and the need to consolidate the investment portfolios, managers became more precautious and realistic, adapting to the current phase of the business cycle. However, one

should not forget that we are currently in a cycle and that historically observed more prudent investment behaviour is typically evident at the beginning of a downturn and diminishes gradually as the economic situation improves, until the next crisis sets up.

Even the highly debated Austrian theory of business cycles could have a saying in the real estate sector as is today. Because of the time gap in the real estate between investment and production, meaning development phase, and consumption decision, meaning the completion of the development and renting out, the resources deployed in each stage of the pre-development, development and renting phase have to be carefully measured, such that when the completion of the development is brought to the market, there is still enough consumption demand for it (1). Generally, the completion of a development from investment decision and acquisition of land up to launching the project takes 3 to 5 years, which makes capital restructuring costly and corrections are only limited possible. The basic idea behind the Austrian theory is that strong expansion of credit activities fuels an unsustainable level of investments. This is actually what lies in the grounds of the subprime crisis started in 2008, when affordable and easy obtainable credits were used to finance consumption behind sustainable debt levels. The adepts of this theory believe that while recession is both inevitable and desirable, in order to clean the bad investments made in the boom phase and consolidate the portfolios, the loss of confidence in the banking system and the credit crunch can push the economy into a longer recession than initially forecasted.

Specifications of Real Estate Investments in CEE (focus Romania)

Investment activity is controlled by international investors, in the form of corporations, private property vehicles and stock listed property companies. Decreasing asset prices in combination with a deteriorating economic outlook have made buyers more selective in their search for real estate property profits, choosing smaller deals in terms of scale and risk, but with higher margins.

Romania's real estate sector passed through significant milestones during the last years – due to economic boom, integration in the European Union and affordable financing, the land prices started to rise back in 2005 and reached a peak in 2008. The financial and economic crisis hit badly the real estate owners in the country, faced with the need to write-down drastically the value of their investments, prime properties loosing up to 30% and remote locations up to 80% in valuation. By analysing the loss in values, it can be concluded that the real estate sector has registered the most significant impact of the economic downturn.

Immofinanz Group (through Immoeast AG at that time), was hit just as bad as smaller investors, having to decrease the fair value its real estate projects in the financial year 2008/2009 with EUR 823 M13, out of which EUR 533 M directly attributable to CEE markets, and additional EUR 145.8 M14 were written off from the market value of financial investments in real estate companies with operations in Romania.

These changes led to an almost frozen year 2009 what regards real estate transactions, dropping in volume and value to the levels of 2005. The downsize of economic activity was obvious, demand being subdued in all sectors due to weaker purchasing power and tight monetary policy Most investors concentrated on redefining their investment strategies and stopping the losses. Nevertheless, at the end of 2009, construction and real estate sector was the third largest invested in in Romania with a volume of EUR 6.5 Bn. representing 12.9% of total economy .

The new strategic orientation continued throughout 2010, when major players have shown a clear need of consolidating their portfolios, by disposing of non-core assets and / or terminating joint venture agreements. In addition to these, Immofinanz Group also concentrated on financial restructuring and cash flow optimization, by merging retroactively per 30.04.2009 Immoeast AG

with Immofinanz AG, which simplified the capital structure and created new financing opportunities on the capital markets.

The year 2011 was an active year, in which major European real estate companies still pursued their efforts to consolidate portfolios and approached also mergers and acquisitions: TAG Immobilien AG completed in January 2011 the takeover of 50, 02% of Colonia Real Estate AG for the price of EUR 90.35 M , the merger of NSI and VastNed O/I was completed in October 2011 , Deutsche Wohnen and its competitor GSW are negotiation over the acquisition of the latter. Last but not least, Immofinanz Group, one of the biggest real estate investor in Romania and a major European stock listed player, completed on November 9th, 2011 the acquisition of the remaining 69.3% of the 100% share capital in the CEE residential developer Adama Holding Public Ltd. ("Adama") for a price of EUR 42.4 M .

A careful analysis of statistical data gathered among active Austrian real estate investors gives a moderate, yet slights promising forecast for the year 2012 - 75% of them estimate a decrease in real estate activities due to the Euro-crisis and 32% of them expect financing difficulties due to implementation of Basel III regulatory standards, on the other hand 57% believe that increasing inflation will redirect investment preferences towards real estate, 56% see new opportunities in IPOs and capital increases and 32% believe business opportunities and increased real estate offer generated by the portfolio restructurings .

Investors in the real estate in Romania are now more prudent and discriminating than before, looking for better locations, better access and only quality constructions, that could return a sure profit over the medium and long term. The banks are also approaching a very conservative financing strategy after being forced to acknowledge on their balance sheet huge amounts of bad loans , which were subsequently written-off. In the case of Erste Bank, this meant an accounting loss of EUR 1.5 Bn., out of which EUR 692 M loss of BCR company value and EUR 762 M write down of Erste Bank Hungary goodwill. The positive reaction however to be expected on the market after such an accounting cleaning is the untightening of the financial sector and a boost of the real estate development pipeline thereof.

Development projects were the clear value drivers in the period 2004 – 2006 and seem now again to be even more attractive than mergers and acquisitions, the main reason being the solution to improve the portfolio quality and retain developer's profit thus increasing the cash flow. In a market of customers, prime properties are the key to exit the crisis and secure a strong position on the market. According to estimates of investment banks, EUR 7 Bn. will be invested in 2012 in completing European developing projects - real estate companies with high exposure on development activities, i.e. at least 15% of their rent generating assets portfolio, mark the highest growth of cash flow per share and IRR on NAV.

Even though in CEE and SEE markets sustainable developments or green buildings are not yet a standard, the trend is also here increasingly present. Besides the reduced impact on the environmental, the investors benefit also from the longer life cycle and reduced operational costs of the buildings and can achieve a higher premium in case of trading activities. For a property to be certified as green building, it must withstand an integrated sustainability assessment, including high energy efficiency, resource-conserving materials or usage of existing transport infrastructure.

Investment Drivers in Romanian Real Estate - Case Study Immofinanz /Adama

The most recent and one of the most notable transactions was the acquisition of the CEE real estate developer Adama Holding Public Limited through the Austrian stock-listed real estate company Immofinanz Group. The acquisition of the remaining 69.22% of the 100% share capital of Adama was completed on November 9th, 2011 for a price of EUR 42.4 M . Immofinanz Group held a minority stake in Adama since 2007 and decided for the buy-out of renowned investors like the US hedge fund Tiger Global, investment bank Morgan Stanley and Lehman Brothers UK in order to fulfil its defined group strategy of expanding construction and

development activities in the residential market. Moreover, the acquisition of Adama complies with Immofinanz' portfolio consolidation strategy, which requires exit from all financial and non-core investments and 100% takeover of such participations where synergies and strategic control can be achieved .

Immofinanz Group is one of the five largest listed property companies in Europe and is included in the leading ATX index of the Vienna Stock Exchange. The company has a high-quality portfolio of more than 1,600 investment properties with a carrying amount of approx. EUR 8.5 Bn. The core business of the IMMOFINANZ Group covers the acquisition and management of investment properties, the realisation of development projects and the sale of objects. The IMMOFINANZ Group concentrates its activities in the retail, office, logistics and residential segments of eight regional core markets: Austria, Germany, Czech Republic, Slovakia, Hungary, Romania, Poland and Russia.

This acquisition by Immofinanz Group was especially interesting for the Romanian and other South- Eastern European markets, Adama being a leading property developer, that focuses on real estate projects mainly for residential, but also office and commercial use, foremost in Romania, besides Ukraine, Turkey, Croatia and Moldavia. Adama covers the entire property development chain - from the acquisition of land to planning and approval processes as well as the realisation and marketing of projects The company has ownership or use rights for more than 40 land plots in various stages of development or construction, with a total volume of 1.44 M sqm designated for approximately 22.000 residential units for the middle-class population and approximately 400.000 sqm of office and commercial space. At the moment of acquisition, Adama had 8% of the residential market share in Bucharest.

Adama is a well-known brand on the Romanian market, not only due to its high market share but mostly due to its image on the market. The social responsibility, the innovative orientation or the premium quality of the products are associations which way be utilized for designing of the brand activity . In this case, we talk about an allusive brand name which makes a cultural reference, allowing positive associations and giving leads about its principal benefits .

"Adama" is the Hebrew word for earth, traditionally standing for stability, quality and sustainability. For the product strategy, the company opted for the brand EVO, deriving from the key word Evolution. The message is that Adama is a stable, strong developer, evolving as a leading brand, in the here and now, capable of delivering tailored living solutions to its clients, by adapting according to the ever-changing demands and re-shaping regional urban landscapes. The product brand has been extended to Evocasa (residential), Evocenter (office) and Evomall (commercial).

Conclusions

We are still in the process of economic recovery after the 2007 subprime crisis and the 2010 European sovereign debt crisis and we are experiencing business decisions being taken with more precaution and decision-makers turning more realistic and risk averse.

The real estate sector being severely affected by the subprime crisis, we have seen an investment bubble in the mid 2000' years followed by an abrupt stop thereof and intense portfolio restructuring efforts up to the current period: strategic reorientation in 2010, disposals, mergers and acquisitions in 2011, fears of double-dipping but also new opportunities expected for 2012. There is definitely an on-going rethinking of real estate investment strategies, but they are not expected to be new ones, but just be reinvented – investors act within the cycle and are now, just like after every other crisis marked on the chart above, more aware of the fact that the business is being replayed, therefore are more conservative and discriminatory, but as time passes they are searching for new opportunities and accepting certain levels of risk in order to generate business.

According to statistical analysis of the crises timeline, a definite trend is evident that at some point we will be facing a replicated collapse and since the average interval decreased from 25

years in the 18th century to less than 10 in the 19th and 20th centuries and we are experiencing already the 3rd crisis in the new millennium, one should only hope that the frequency of the cycles will be much slower than the recovery and that every business lesson learned will count towards a quicker and a better start in a booming phase.

THE IMPLICATIONS OF STATE AID TO R&D ON ECONOMIC DEVELOPMENT IN THE EUROPEAN UNION

Băcilă Nicolae
"Babeș-Bolyai" University, Cluj Napoca Faculty of Economics and Business Administration

In economic terms, the importance of state aid policy refers to the maintaining of an undistorted competition and the correction of inherent "market failures" which may occur in the economy, aiming at increasing economic efficiency, based on the traditional assumption that an effective competition will have a positive impact on economic development.

The main objective of the present paper is to establish a possible correlation between state aid to research and development (R&D) and GDP level in the EU. Our research hypothesis relates to considering state aid as a significant contribution to the economic development, measured by GDP level, which will be estimated as a function of state aid. Consequently, the main variables of this study are state aid to R&D and GDP level, considered in both relative and absolute terms.

The relationship between technological change and economic development has been at the centre of the interest in both theoretical and empirical literature. The role of institutions and government policies in stimulating technological change has been provided mainly by the evolutionary theory, which considers economic development as a technological change driven process featured by a complex pattern which includes both uniformity and idiosyncrasy across time and countries.

The relationship between these variables was estimated through a panel model which used seemly unrelated regression (SUR) and ordinary least squares estimation (OLS). Taking into account that the economic value is likely to be realized after the innovation process took place we have interpreted this economic aspect in an econometric sense by using time lags. In analysing the relative importance of state aid to R&D, we have proposed an index which evaluates the relation between state aid and the relative size of the Member State's economy.

The relationship between state aid and GDP level was found to be positive and statistically significant, suggesting that state aid is positively correlated with economic development and showing that state aid programs tend to have an incentive effect for the economic activity after they have been granted, due to the spillover effect of R&D activities assumed by the government funding incorporated in the state aid projects.

On the other hand, the analysis of state aid relative to GDP has demonstrated that significant levels of volatility indicate a persistence of disparities between Member States in the period considered (2004-2009), suggesting that national particularities remain an important determinant of government support through state aid, which implies the necessity of a better coordination in the economic policies targeting innovation in the Member States.

I. Introduction

In economic terms, the importance of state aid policy refers to the correction of inherent "market failure" situations which may occur in the economy, aiming at maintaining an undistorted competition in the economic environment. Although maintaining undistorted competition represents the only objective which is explicitly mentioned by the Treaty establishing the European Community and which is confirmed by decisions taken by the Commission, state aid policy cannot be reduced to removing distortions caused by anticompetitive practices, since economic literature has constantly argued in favour of an integrative approach which relates state

aid policy to improving the allocation of resources, increasing economic efficiency and supporting economic development (e.g. De Moor and Calamai 1997; Bilal and Nicolaides 1999; Wishlade 2003).

The main objective of the present paper is to provide a contribution to the related literature, focusing primarily on establishing a possible correlation between state aid to R&D and GDP level in the EU. In this respect, our research hypothesis relates to considering state aid as a significant contribution to the economic development, quantified by GDP level, which will be estimated as a function of state aid, in order to evaluate whether there is a connection between these variables.

The paper is structured as follows: the second section provides a description of the related literature; the third section explains the main methodological aspects proposed by the research; the fourth section presents the empirical results of the paper, while the last section concludes and establishes future perspectives for research in this area.

II. Literature review

The economic literature provides very different conclusions concerning the problem of government support, ranging from keynesian economic policy, which stresses the importance of state interventions for stabilizing the business cycle, to neoclassical considerations, which regard the government interventions more as a complement of the self-regulating market mechanisms. Despite different approaches of the problem, one of the most important unifying aspects of this literature concerns the fact that state aid is used as a regulatory economic policy instrument, while its efficiency has been related to the support of economic development through the effects on innovation, investment or employment.

The role of institutions and government policies in stimulating technological change has been provided in the economic literature mainly by the evolutionary theory, which considers economic development as a technological change driven process featured by a complex pattern which includes both uniformity and idiosyncrasy across time and countries (Dosi et al. 1990; Chiaromonte and Dosi 1993: 40-55; Silverberg and Verspagen 1995: 210-225; Geels 2004: 902-915). Its empirical models provided a wide range of perspectives on the relationship between technological change and economic growth, focusing especially on patterns concerning technological diffusion (Conlisk, 1989: 791-794), growth effects of new technology, regarded as a stochastic phenomenon (Silverberg and Lehnert 1993: 9-37) and the nature of interactions between rational actors (Fagiolo and Dosi 2003: 267-271).

Recent historical developments, such as the increasing trend towards global and regional economic integration and the policy oriented approach of the EU for builduing a "knowledge-based economy" (European Commission 2005) have reinforced both the academic and political interest in technological change, expressed through R&D activities, as main engine in promoting long-run economic development.

While in the US the main direction of government support has been towards policies aimed at new capital formation and stimulation of demand (Eisinger 1988; Gray and Lowery 1990: 5-23), in the EU ambiguous Treaty rules and heterogeneous Member States' preferences have enabled the Commission to act as a "supranational entrepreneur", enforcing the prohibition of distortive state aid and at the same time creating positive integration by developing a model of what it considers to be "good" state aid policy (Blauberger 2009: 10-15).

This was pointed out by the Lisbon European Council of March 2000 that calls the Member States both to reduce the general level of State aid and to shift the emphasis from supporting individual sectors or companies towards horizontal objectives of common interest ("less and better targeted state aid").

State aid to R&D, as a component of horizontal aid, is considered more acceptable by the Commission, because it does not cause distortion of competition in the internal market and can be efficiently used to create an incentive effect on innovation by tackling the market failures that

prevent markets from naturally delivering the best results in this respect (European Commission 2004).

III. Methodology

The relationship between state aid to R&D and economic development, expressed by GDP level, was analysed in both relative and absolute terms for the period considered (2004-2009) and was estimated through a panel model which used seemly unrelated regression (SUR) and ordinary least squares estimation (OLS).

Taking into account that the economic value of knowledge progressively depreciates in time, the economic value is likely to be realized after the innovation process took place. As a result, we have interpreted this economic aspect in an econometric sense by using time lags, which are related to the fact that one of the most significant particularities of R&D activity is the time gap between the introduction of an innovation through a research project and the moment when the results of the research are embodied into a new product or process, which becomes profitable.

In analysing the relative importance of state aid to R&D, we have proposed an index which evaluates the relation between state aid and the relative size of the Member State's economy, designed to indicate the countries that support their domestic industries proportionally more and, respectively, less than EU average.

IV. Empirical results

In relative terms, the relationship between state aid to R&D and GDP level is evaluated using an index which relates the amount of national expenditure in the total EU aid, on the one hand, to the contribution of Member States to the aggregated level of GDP, on the other hand. Based on this relation, a country allocating proportionally more (less) state aid than the relative size of its economy would have a supraunitary (subunitary) index, while the EU average value would conventionally be equal to 1.

It can be noticed that while the countries situating above the EU average are: Belgium, the Czech Republic, Germany, Spain (from 2007-2009), France, Hungary (from 2006-2009), Austria, Slovenia (from 2004-2006 and 2009) and Finland, Belgium (from 2007-2009) and the Czech Republic (from 2006-2008) are the only countries that have supported their industries, relative to their size, more than twice as much as the EU average.

At the other side, the countries that during most of the period considered reported values below half of the EU average are: Bulgaria, Estonia, Greece, Cyprus, Latvia, Lithuania, Malta, Poland, Portugal, Slovakia and Sweden, indicating that they have granted significantly less aid than the relative size of their economy.

Furthermore, looking at the variation in index values (captured by the standard deviation), we notice that countries reporting more important modifications of their support to domestic industries, compared to other Member States, were the Czech Republic, Luxembourg and Hungary. In contrast, the Member States that encountered the smallest modifications in the relative amount of aid granted to their industries were: Bulgaria, Greece, Latvia, Poland, Slovakia, Sweden and the United Kingdom.

Table 1. Index of the relative importance of state aid to R&D

Country	Index 2004	Index 2005	Index 2006	Index 2007	Index 2008	Index 2009	Stdev 2004-2006	Stdev 2007-2009

Source: author's own calculations based on data from European Commission and Eurostat

Note: The index is calculated as follows: Index = (Member State's aid)/ (EU-27 aid)
(Member State's GDP)/ (EU-27 GDP)

However, when comparing the average variations experienced by Member States, we found that most of the countries follow an ascendant trend in the period considered, indicating a growing level of disparity in the relative importance of state aid to R&D. The higher variability in the granting of state aid by some countries could indicate that national prerogatives are still determinant in supporting their domestic industries. This aspect suggests that state aid to R&D does not appear to be of a general nature or designed to address general economic problems, but rather of a specific nature aiming at addressing economic and social particularities, showing that national traditions seem to remain a significant factor in shaping the development of state aid to R&D in the EU Member States.

When analysing the relationship between mean values of state aid to R&D and GDP in absolute terms, we found a positive correlation, with a 0.63 R2 value, which means that the relationship between these variables is robust. This seems to confirm the fact that countries with higher GDP tend to finance state aid to R&D to a greater extent than the countries that have reported lower values of GDP.

Table 2. The relationship between State aid to R&D and GDP

Equation : GDP(t) = C(1)+ C(2)*State aid(t)

Variable	Coefficient	Std. Error	t-Statistic	Prob.
C(1)	114968.90	27830.47	4.1310	0.0001
C(2)	830.9055	54.7456	15.1776	0.0000

Weighted Statistics

0.6355	0.6332	278.9340	0.000000	0.5569	132.1367

When using state aid values from the previous year, we have found a relationship which maintains its statistical significance and has a 0.68 R2, which shows that the investment has continued to exert an effect on economic activity after the government support was made. While governement support through state aid significantly contributes to the development of economic activity after the grant has been provided, we appreciate that it is reasonable to expect even longer lags for spillover effects because of the additional diffusion lag and also for the basic research because of the longer invention to innovation lag.

0.6951	0.6828	56.5298	0.000000	0.7666	107.9369

V. Conclusions

The present paper provided an analysis of the relationship between state aid to R&D and economic growth in the EU Member States. In this respect, we have assumed that state aid contributes in a significant manner to the economic development, measured by GDP level, which was estimated as a function of state aid, in order to evaluate the nature of the connection between these variables. The relationship between state aid and GDP level was found to be positive and statistically significant, suggesting that state aid is positively correlated with economic development. We have proved that state aid has the potential to act as a relevant determinant for the GDP level, which has also been confirmed by the econometric results showing that state aid programs tend to have an incentive effect for the economic activity after they have been granted, due to the spillover effect of R&D activities assumed by the government funding.

When analysing state aid relative to the GDP, we have noticed that significant levels of volatility indicate a persistence of disparities between Member States in the period considered, suggesting that national particularities remain an important determinant of government support through state aid, which implies the necessity of a better coordination in the economic policies targeting innovation in the Member States.

Admitting that this analysis of the relationship between state aid to R&D and economic growth has been limited to the application of basic empirical instruments to a very complex topic, we appreciate that further research could evaluate the extent to which the differences between sectors and countries with regard to government policies directed at R&D influence the economic growth in the EU Member States.

This paper aims to present the role of oil in today's world, society, and economy. It is important because anything nowadays is about oil, from economy, and society, to international politics. Since the development of air and road transportation, but especially after World War II, the transfer of wealth from some countries (the consuming countries) to another countries (the producing countries) is unique in human history; and the influence of the second group of countries in world politics is very high due to this situation.

Furthermore, past and present pattern of oil consumption have negative impacts upon environment and humans wellbeing. Oil used in energy generation, and especially its use in transportation makes it a resource with a strategic character.

In the literature of international affairs, and international economy, oil is found in almost in every article, and book; but of course, there are books and articles focused especially upon this resource, and upon its role in world politics. in last decades, there appeared another element which fight to capture world public opinion, and political agenda: this is climate change. The best reference in this context is the First report for the Club of Rome (Limits to Growth, 1972), which signaled the unsustainable way of how society works.

Taking account of this alarming signal, we intended to show (using research methods based upon numbers) that there are very negative effects of using oil in the future in the same way as in the past. There is needed another type of economy, and society, based on other types of resources than oil.

But in the same time this situation creates hardships for oil importing countries, many of western societies being vitally dependent in their mobility by oil. In the same time, transportation is responsible for some one third of oil consumption, generating huge quantities of CO2 emissions in the atmosphere, bringing what can be called climate change. Put shortly, the paper presents the negative impact of oil using from geopolitical and climate points of view, and which could be the solutions for escaping this situation.

The added value of our endeavors is connected to present the negative implications from geopolitical and climate changes points of view, and which are the actions which could put in practice.

Keywords: oil, geopolitics, energy, climate change, oil transportation routes
JEL Codes: F1; F5

The humans and environment are strong interconnected; hence environment influence human activity, but in the same time, human activity can create harm to the environment. The human society became dominant because of developing skills regarding energy production and use; and the activity which hurts a lot the environment is connected with energy. The energy production causes irreversible harm to the environment. Carbon and other greenhouse gases' rising concentration level in the atmosphere, due to fossil fuels burning for energy generation, influence the temperature patterns; and an increase of more than 2 degrees Celsius could have serious impacts globally, including the extinction on many plant and animal species, or even the collapse of the entire ecosystems (Bales and Duke 2008: 78).

Climate change would in the same time bring security risks; if the planet warms by 1.3 degrees by 2040, there will be "heightened internal and cross-border tensions caused by large-scale

migrations; conflict sparked by resource scarcity…; increased disease proliferation…; and some geopolitical reordering" (Bales and Duke 2008: 79; The Age of Consequences 2007).

Today every man can easily see that almost everything is influenced by the oil. The problem of oil is more and more politicized; oil and the secure access to it are aspects which are present on the top of all states' agenda. The problem of oil is more pressing, and it has become so, because of the fluctuation of oil prices. Stating in early 2000 oil price registered a constant rising, until summer of 2008, and since then the peculiarity of oil market was price fluctuation; this is a great problem because it can hit hard interests of the state (it can influence the balance of payments of importing states through rising expenditures for oil imports). Governments in nearly all the large consuming nations are preoccupied by energy security aspects like at no time since the oil crises of the 1970s (Victor and Yueh 2010: 61).

Starting with the middle of last century, another element started to be regarded with some attention, but its visibility was much lower in comparison with its importance; it is climate change.

Yet important shifts are taking place in global energy system (Victor and Yueh 2010: 62): one regards the changing of energy consumption countries, most of the future growth on oil demand will come from emerging economies, especially from China and India; the other concern regards the environmental impact of energy use, especial carbon dioxide emissions.

Unfortunately, man and society always pay attention to pressing problems, leaving other problems – which could be more important – unresolved, thinking they will never become pressing enough in order to impose strong hand decision. Oil is one of the most pressing problems on states' agenda, and for some states oil policy almost equates foreign policy (be they oil importing, or oil exporting countries). Climate change is recognized to be a certain fact, but this aspect is not so pressing; this is due to the fact that present situation is this: for modern society oil is a key-element, which sustains its present way of development, and oil is an extremely important asset because it is the essential element in today's transportation system, sustaining the movement of wealth and people, and being and extremely important ingredient in a lot of products which dominate modern lifestyle: 90% of the goods in one store implies the using of oil in one way or another (Giddens 2009: 10).

That for, it is important to fight to de-carbonize transportation sector: solely in OECD countries, in 2006 the oil consumption in transportation sector was 1252 millions tones, while for the 2030, there is expected to be 1289 millions tones of oil consumed in transportation sector (World Energy Outlook 2008: 508); in India the rise is expected to be from 37 (2006) to 156 millions tones (2030) of oil (World Energy Outlook 2008: 532), while in China it will rise in the same interval from 127 to 440 millions tones (World Energy Outlook 2008: 530). Globally speaking, the level of CO_2 emissions due to transportation (in million tones) is expected to rise from 6444 in 2006, to 8013 (2020), and 8921 in 2030, respectively (World Energy Outlook 2008: 393).

As these figures show, present world is characterized by a very strong dependence on oil, and the reduction of oil dependence should be one of the most important policies a state have to pursue; reducing oil dependence would not only prevent the climate change, but in the same time the capacity of oil to influence and determine the fate of world politics would significantly diminish (World Energy Outlook 2008: 12).

The peculiarities of oil geopolitics lies in the fact that it is a key-resource used in transportation, it is located in a handful of countries (which after 2000 went to resource nationalism, which can use oil as weapon, and where one can met civil unrest), it must be transported over long and (more and more) maritime risky routes (including crossing through straits), it can bring wars for access to oil resource or for control over oil transportation routes, and there are some emerging economies, very hungry for oil; but continuing the same path – of using oil more and more in industry, energy production, and transportation – will not only create greater pressure on remaining oil resources, even wars for access to it, but this trend could bring great havoc to

whole humanity, through climate changes which will affect both, rich, and especially poor countries. And all these things take place in a situation where since 1901 until 2000 world oil production had risen over 180 times (Maliţa 2009: 297). And doesn't matter which measures and steps are taken in the field of energy efficiency, the pursuing of clean energy, and alternatives oil in transportation, energy, and industry, oil will continue to be a very critical element in the stability of world economy, and regional and international security (Morse 2009: 52).

The consequences of this course of policy could be identified immediately: international role played by the states which poses important oil reserves would considerably diminish, and the role of Russia and Islam (especially Arab countries) in world politics would change (Friedman 2008: 92-102). As oil price rises, the petro-states tend to a more autocratic regime, the oil price and domestic politics being strong interconnected (Giddens 2009: 217). In this light, oil can be regarded as the enemy of democracy.

Each resource which could push up the power of the state which uses it, could be called a strategic resource. In this case, every resource which promotes economic and military power, or promote the mobility's rising, can be regarded as a strategic resource. Now, the peculiarities of oil geopolitics are due to the fact that it is a strategic resource – the whole world depends on oil as an energy resource, particularly in transportation sector. In the same time, the problem becomes more complex because the oil resources are concentrated in few countries. Coal can be found almost in each country, but oil is concentrated in Middle East, Russia, and some problematic countries in Africa, Latin America. It is noteworthy to specify that when price of oil is high, some producers resort to using energy as tool of leverage, as Venezuela (which uses incomes from oil exports to undertake anti-American activities through Latin America), or Iran (which uses its to promote its interests in Middle Eastern countries, Iraq, Lebanon, Palestine, Saudi Arabia) (Morse 2009: 48).

Regarding Russia, a low price of oil has immediate and strong impact on its domestic, and foreign policies. When price of oil is high, Moscow can easily play pipeline politics, using gas deliveries with political ends; when oil price is low, Russian state strongly needs to receive currency from its gas exports, reducing its capacity to use gas delivery as a political weapon.

Another state which has an assertive policy, and which can create trouble on regional scale, with global consequences, is Iran. As oil price is high, Iran has money to sustain subversive activities in Arab Sunni countries, and can influence the direction taken by Middle East peace process. If Iran has lower revenues, then the flow of petrodollars to terrorists would be reduced, and the adamant policy of Tehran could swift to a more moderate one.

Taking account of this situation, on short run, the main global consumers could establish and consolidate the connections with oil producing countries from Gulf, Central Asia, and Africa, forging an exchange concentrated on arms and military assistance for oil – a peculiarity of oil trade in the second part of 20-th century. The intensification of state's actions could become very present, rising even more the risks of militarization of oil trade, bringing the possibility of tensions and escalations, culminating in wars among the most powerful nations, through proxy allies.

On medium term, the intensification of tensions among the greatest oil consumers would bring a rising of their military expenditures, reducing in this way the available founds headed for the creation of a new, clean energy base. The opportunity of reorientation of founds from military destination to the development of alternative energy capacities, would simultaneously reduce the pressure on fossil fuels, and the carbon emissions which come from their burning process, too. In medium term, even if the states wouldn't enter a conflict in order to have access to oil resources, the rising of oil demand (due to developing economies, rising population at global level, the urbanization process, and of the income's rising), would bring a rising of oil price, hitting both the developed nations (because of rising cost of living, and especially the developing ones,

because, a greater part of the income there would be directed to food, whose price goes up when oil price rises).

On long term, the maintaining of the same course in oil consumption peculiar nowadays would bring a dramatic and irreversible climate change, with negative effects on the whole human civilization.

The climate change problem is the energy problem (Klare 2008: 242), and solving it depends upon the humanity's capacity to transform its way to produce, and use energy. The most important point here is the transportation, and energy sectors' de-carbonization.

Even the G-8 placed climate and energy issues high on its agenda nearly every year for the last decade, there hasn't done much beyond presenting empty propositions in the front of cameras (Victor and Yueh 2010: 68).

Present society is very dependent on oil, and security of oil supplies is a national security matter; security of oil supplies is a pressing problem not only because old supply reserves are depleting quickly, but because investors are not very open to risk in developing new supplies, in a very volatile global economical and political environment. There are massive risks (economical, as well as political) in developing new projects for oil supply, especially if they involve the transfer of oil over many national borders, facing a myriad of political uncertainties.

Facing these problems, the cross-point can be this: promoting investment to develop needed supplies of oil on short run, and incentives for climate-friendly energy capacities of production, that will change the energy system, in the long run.

Regarding geopolitics of oil, it can be specified that in 2020 India and China will depend on imported oil transported from Middle East and Africa, these two countries becoming more and more interested by African wealth (Chaponniere 2009: 24). In order to secure their economic interests and to promote their political ones, both countries intensify their military presence in this part of the world: China promotes the "Pearls Strategy", (Perelman 2005: 21-27) while India constructs military alliances in Eastern Africa on the base of agreements which she signed with Mauritius, Seychelles, Madagascar, and South Africa (Chaponniere 2009: 24). This could be simply regarded as a the geopolitics of the Indian Ocean, but taking account that these two countries will be the giants of world economy in the years ahead, the relationship between them in Indian Ocean, focusing on oil, will have global reaches, influencing even the most remote areas of the Earth.

To the scarcity and constant reduction of the quantity of non-renewable energy resources – which has brought, and will continue to bring tensions among nations – we need to add the carbon emissions generated by their burning; and both these things signal us that we must reorient to those energy sources which are renewable – but which have disadvantages regarding fluctuations in energy production (water, Sun, wind, geothermal) – and to unlimited energy resources, which work more constantly (nuclear power, and hydrogen).

Not only that the reduction – and possibly elimination – of fossil fuel energy resources will bring a type of society which embraces sustainable development, and which is not so greed in using natural resources to sustain its activity, but the importance of the resource – oil – which already has generated bloody wars would fade, creating the possibility of reducing military expenditure which would have been made in order to secure and maintain access to it in different places of the Earth. The money saved in this situation could be used in developing green energy projects in great energy consumers, and in developing countries, too, helping whole humanity to live in a better and cleaner world.

GOVERNANCE MEASURES PROPOSAL FOR ROMANIA TO ACCOMPLISH THE EUROPE 2020 TARGETS AT NATIONAL LEVEL

Berinde Mihai
Faculty of Economics University of Oradea

Chirilă Lavinia Florentina
Faculty of Economics University of Oradea

Abstract: Europe 2020 is a very ambitious strategy adopted by the European Commission for the coming decade. Its main target is to make Europe's economy become smart, sustainable and inclusive. The Lisbon Strategy was first adopted in 2000, but during the 2005 mid-term review, the Lisbon Strategy was revised and new targets for economic growth and employment were established. This change integrated the Cohesion Policy into Lisbon Strategy's implementation. In 2010, the European Commission published a new strategy, known as Europe 2020, a strategy that includes priorities meant to help the European Union and the Member States to defeat the weaknesses that they have experienced in the last period. Although the targets set are impressive and might seem very attractive, the results acquired so far, both at EU and Romania's levels are not very encouraging. Even though some progress has been made, it is too unassertive to be considered the expected result. The article presents the results obtained up to this stage by Romania in achieving the national targets set through Europe 2020, using the time-distance method to calculate the time advance or delay in implementing the Europe 2020 targets in Romania. It formulates governance proposals that must be taken into account by the Romanian authorities in order to reach the targets set at national level.

1.Introduction

Romania joined the European Union in 2007, and was determined to accomplish the targets set at national level through the Lisbon Strategy. A knowledge-based economy, the main objective of the Lisbon Strategy, represented the great chance for Romania to bring added value to its products and services and increase their competitiveness (Dăianu, 2004). In 2007 Romania adopted the National Reform Programme for 2007-2010, whose main objective was to create a stronger economy and an attractive business environment in order to provide the welfare that every citizen wishes for himself and for his family. The targets set at national level were in accordance with the Lisbon targets but they proved to be unachievable.

Results obtained in 2009 show that the Romanian economy suffered the worst contraction in its latest history as a result of the world's economic and financial crisis. Romania's GDP decreased by 7.1% after a year before it had increased with the same magnitude (Voinea, 2010:3). Because of the world economic crisis, which was felt in Romania in the last trimester of 2008, at the beginning of 2009 Romanian authorities had to contract a loan from the International Monetary Fund. The Romanian government obtained a loan of 19.5 billion Euros. Through this loan, the government financed the external and internal deficit. On the other side, the International Monetary Fund imposed measures to guarantee the loan reimbursement and to obtain a transparent fiscal policy.

The article presents the results obtained up to this stage by Romania in achieving the national targets set through Europe 2020, using the time-distance method to calculate the time advance or delay in implementing the Europe 2020 targets in Romania. It formulates governance proposals

that must be taken into account by the Romanian authorities in order to reach the targets set at national level.

2. Europe 2020

Europe 2020 is a strategy for smart, sustainable and inclusive growth marks a new beginning, as the President of the European Commission, Jose Manuel Barroso, states in the preface of the Strategy. There was a stringent need for EU to take position in order to help its Member States recover from the world economic crisis. The required reforms necessary in order to pull Europe out of the crisis had to cover fiscal consolidation, sound macro-economic conditions and front loading growth-enhancing measures (European Commission a). The first semester report on Europe 2020 strategy states that *"the EU and its Member States have the collective responsibility of undertaking the necessary – but difficult– structural, forward looking reforms at the same time as they put the fiscal situation in order and restore healthy macro-economic conditions"* (European Commission a).

The targets set through the Europe 2020 strategy, to be met until the end of 2020, consist of five indicators that are in direct relation to citizens' welfare. One of the targets refers to increasing the employment rate to 75 % of the population aged 20-64. Another target refers to increasing the percentage of investment in research and development (R&D) to 3% of the EU's GDP. The third target, "20/20/20", consists of a trinomial target regarding climate/energy that should be met until 2020 (if the conditions are right, even up to 30% reduction of emissions). The fourth target refers to lowering the share of early school leavers to 10%, and increasing the percentage of young people with a tertiary degree to at least 40%. The fifth indicator stipulates that the number of people living at risk of poverty should decrease with 20 million. In the following part we will identify the situation of Romania regarding the achievement of two targets, employment rate and R&D investment using the S-time-distance method.

3. Calculation of time distances and leads or lags for Romania, in meeting the Europe 2020 targets

Nowadays, time is a very important factor for the daily life. We live in the so called "speed century", and we frequently use the catch-phrase „time means money". On this base we decided to use the time distance method, identified by Pavle Sicherl, a method that uses time in order to simplify and to ease the access of general public to information. The time distance approach, as a new view of the information, uses levels of variables as identifiers and time as the focus of comparison. The advantage of this method is that *"it is theoretically universal, intuitively understandable and can be usefully applied as an important analytical and presentation tool to a wide variety of substantive fields"* (Sicherl, 2003:2).

The statistical measure S-distance helps us determine the period of time until two compared series reach the indicated level of the indicator X. For a given level of XL, $XL = X_i(t_i) = X_j(t_j)$, and the S-distance (or the time span separating unit (i) and unit (j) for the level XL) is defined as:

$S_{ij}(XL) = \Delta T(XL) = t_i(XL) - t_j(XL)$ (1)

In order to characterize a specific value of the S-time distance, we need three subscripts: (1 and 2) two units are used to measure the time distance and (3) the third subscript is used to measure the level of variable X. In addition, a fourth subscript (4) is required to indicate the point in time defining the time distance (T1, T2… Tn). In order to determine whether we are dealing with a lead or lag we need to use the sign of the time distance used for comparing two units. In a statistical sense, the "-" sign represents a lead in time, while a "+" sign represents a delay in time, or a lag.

$$S_{ij}(XL) = -S_{ji}(XL) \qquad (2)$$

To calculate the S-time distance at macro level, two time series are needed: the time series of the actual values of indicator and the time series of the anticipated target values (line to target). Time

distance is therefore the distance between the actual time and the time on the line to the target for each actual value of the variable (Sicherl, 2008, p. 2.):

S(Xt) = actual time t – time on the target line T for each actual value of variable Xt   (3)

$$S(Xt) = t(Xt) - T(Xt) \qquad (4)$$

Through introducing the time distance in the analysis of differences is intended to broaden and enrich the conventional static methods and measurements and obtain a better understanding of the actual situation of the indicators studied. An advantage of the S-time distance lies in the fact that the latter is expressed in time units and is thus understandable by everyone, while another advantage is its ability to leave all previous methods and results (not necessarily the conclusions) unchanged since the time distance adds a new dimension rather than replaces other perspectives (Sicherl, 2003:189). To evaluate time distances and deviations from the Europe 2020 strategy was used the application of the Socio-economic Indicators Center (SICENTER) in order to calculate the time lead or lag in implementing the Europe 2020 targets at the level of Romania. Even though the Europe 2020 strategy is at the beginning of the implementation period, we need to know from the very beginning which is the situation we find ourselves in and what needs to be done in order to achieve the highest levels expected. Using the Provisional Europe 2020 targets that Romania set for itself, we tried to identify the trends of employment rate and investment in R&D in the last period using data available on the official European statistic website.

3.1 Employment rate of population aged 20-64

The first headline target of Europe 2020 strategy regards the employment rate registered in the European Union and aims to reach to the point when 75 % of the population aged 20-64 will be employed. The national target for Romania, as Annex 1 of the European Commission's First Progress Report on Europe 2020 shows, was set at 70%, a lower percentage than the one set for EU27.

We notice in Figure 1 a general decreasing trend with a slight increase from 2006 to 2008 when, on the background of the economic crises it started dropping again. The red columns in Figure 2 represent the delay that has been increasing yearly in the last decade. In 2001 the lag in time was of one year, while in 2010 the lag is of 10 years so the distance in time deepened until 2010 (Figure 2). We notice that the measures taken so far by the Romanian government of encouraging employment did not have the results expected. It seems that a very high level of wage taxes and the fact that they have been constantly raised intimidated the potential employers and let to high levels of unemployment. We notice that the employment rate drastically decreased during the year 2001 and then suffered a slight increase up to 65% in 2006, but once the economic crisis was felt the employment rate begun to decrease again and at the end of 2010 registered a value slightly over 63%.

The Romanian economy is characterized by high tax burden felt by economic operators, often changing of fiscal measures, which led to the bankruptcy of an important number of companies, especially SMEs. As a result we obtained a severe decrease in workplaces and a deepening of the targets set through Europe 2020 strategy.

3.2 Investment in R&D up to 3% of the EU's GDP by 2020

According to the second indicator analyzed, investment in R&D, EU should reach the target of 3% of its GDP by 2020. At present, the level of investment in R&D in Europe is below 2%, compared to 2.6% in the US and 3.4% in Japan, mainly as a result of lower levels of private investment. It is not only the absolute amounts spent on R&D that counts – Europe needs to focus on the impact and composition of research spending and to improve the conditions for private sector R&D in the EU. EU's smaller share of high-tech firms explains half of its gap with the US. It is obvious that without a strong R&D oriented industry, the level of products will not become the highest on the international market. This is why the European Commission considered that it is important to raise the percentage of R&D investment.

In the case of Romania the national target set is 2% of the GDP invested in R&D. We set a national target lower than EU27's in this field too in order to be attainable. As we observe in Figure 3, at the beginning of 2000, the percentage of investment in R&D out of the GDP was under 0.5%. As we notice in Figure 3, the percentage of investment in R&D had an increasing trend until 2008, when the crisis came and the indicator dropped down to the value of 0.5% (2009).

Figure 3: The national target of 2% of Romania's GDP to be invested in R&D and its evolution in Romania

2. Romania Investment in research & development
Source: Eurostat, own calculations using SICENTER web tool application;

The distance in time of Romania reaching the targets set at national level shows a delay of 6.17 years in 2009 (Figure 4). The situation got worse in 2009 when the percentage of investment in R&D decreased considerably. Through the values registered by this indicator we realize that the Romanian industry is technically speaking left behind, with a high rate of wear. This directly affects the performance and profitability of the industry sector - most of the products that

Romania exports have a low processing degree. It seems that the first measure taken in order to reduce expenditures when the crisis came was to cut the share of the budget meant for R&D. The government has reduced the share of budget given for R&D, and as a result our economy is not competitive, we cannot compete on the international stage and we cannot attract foreign investors with anything else than cheap unspecialized labor force.

Figure 4: Time distance of Romania in meeting the national target of 2% of GDP to be invested in R&D
Note: S-time distance: (-) actual ahead or (+) behind the line to target (in years).

4. Governance measures proposal for Romania

As expected, starting with Romania's accession to the European Union, important steps needed to be taken so as to achieve as many of the targets set at European level (through the Europe 2020 Strategy) as possible . As a result of the international economic and financial crisis which we are undergoing, the National Objectives set for the previously mentioned five areas have also been affected, and were not established in all cases at the level expected by the European Union.

Regarding the two indicators taken into consideration in analyse taken in the present paper, it was noticed a serious issue determined by the decrease of the two indicators, instead of an increase. The political instability, the often changes of the Fiscal Code and the lack of transparency and predictability intimidates any entrepreneurial initiative and therefore workplaces cannot be created. Also, regarding investment in R&D it was identified a lack of interest from the government towards increasing the competitiveness of the industry and services through this type of expenditures. These issues impose concrete measures to be taken by the authorities. In the short term, proactive measures are needed in order to handle the crisis and its effects, and also to revive the Romanian economy through creating workplaces and obtaining a knowledge-based economy. So far, the authorities chose to adopt radical measures for reducing government spending and also contracted important external loans from International Financial Organizations. These measures proved to be insufficient, as the renewed economic growth is quite weak. Therefore, we consider that measures should be taken to encourage investments in the private and public sector especially. These could have revived the Romanian industry and determine it invest in R&D and create workplaces and urged the economic development trend, felt until 2008, to be resumed. The measures that we suggest in order to increase those indicators are reducing the tax burden felt by economic operators, exempt fiscal measures which lead to the bankruptcy of companies, especially SMEs. In change, SMEs should be encouraged through exemption from paying taxes if employing redundant people, also private sector should benefit from exemption from taxes and subventions for investing in R&D, creating labs, employing researchers and specialists in the field and so on. Those measures would certainly have a positive influence over other indicators of Europe 2020 strategy that are not satisfying in our country, namely the young persons' interest towards higher education and the number of people living at the risk of poverty. In opinion those measures would have a major contribution to enhancing

Romania's performance and bringing it as close as possible to the targets set by the Europe 2020 Strategy and help Romanian citizens increase their welfare.

SOCIAL ECONOMY – POSSIBLE SOLUTION TO ECONOMIC CRISIS

Capmare Irina Cosmina
National Institute for Economic Research, Romanian Academy

Resume
This paper is about the concept of social economy and tries to explain why it is so important that European Union shows so much interest in its development.

The aim of the paper is to reveal the social economy impact on society and its ability to respond proactively to the challenges of modern day society. The methodology was based on self documentation which involved a wide range of materials: reports, case studies, paper works, articles, specific sites, European Union guides. This paper underlines the influence of third sector and the way it constitutes insurance for the economic growth.

This paper plays a key role in the understanding of the evolution of this concept and mostly the fact that social economy found a new place in society. Its role was redefined, social economy starts to be in the center of attention at European level since is the key to the economic growth.

Social economy doesn't rely on a specific definition but through its characteristic and principles it refers to a third sector in economies between the private sector and business or, the public sector and government.

Even though social economy states with its benefits and importance for the community and economic growth it is not a concept well implemented in all countries and among other things it is characterized by a lack of legislations and specific literature compared to other concepts. The concept is present in the European Union development strategies, policies and they get to decide how social economy will extend in each country.

In the attempt to provide a more comprehensive concept of social economy terms such as third sector, active inclusion or employment should be mentioned because until now, there is no universally accepted definition of social economy, since is one of the few terms which enjoys multiple definitions, but focuses on the same principles or features.

The paper provides an overview on how the concept of social economy entered the daily life of European communities and has settled itself as a phenomenon, essential for economic progress of the countries and in Romania where it is still disputed the way it will develop.

What is to be notable is that Romania gives a big important to this new concept of social economy and different practices shows that our community is ready to promote the third sector organizations. We cannot base on much documentation but informatics society showed again to be useful so that internet can offer a wide range of papers and studies, some more documented than others.

The results of the study demonstrated that social economy will define a new order in the economic market and will play a significant role in the overcoming of economic crisis.

The added value of this paper consists in the fact that it brings more approaches to the related literature and personal reflections about its function in Romania, based on the way it is financed and promoted at national level.

I. Social Economy – Theoretical Approaches

The term "social economy" first appeared in France during the first third of the 20 century. For a big period of time, its definition was much broader and amorphous than it is today.

Social economy is a sector that lies between the private and business sector and the public and government sector. This designated sphere consists primarily of nongovernmental organizations,

charities, and nonprofit cooperatives. Sometimes this social economy includes another sector referred to as the "informal sector" where casual interactions and relationships are included. Social economy represents a fundamental aspect of daily European life.

In economics, "the private sector" and "the public sector" are the known terms used respectively to describe privately owned, profit-driven enterprises and government-controlled ventures. The designation "social economy" has been given to a third sector of the economy that represents cooperative concerns like community associations, volunteer organizations and businesses whose objectives are primarily social. Market activities associated with the social economy resemble market activities in the private and public sectors: people are employed, goods and services are often sold and money is occasionally made – with one critical difference: monetary surpluses are typically reinvested in the business or community rather than skimmed off the top as profit.

The importance of the European economy and society of cooperatives, mutual societies, associations, foundations and social enterprises is now receiving greater recognition at Member State and European levels. Not only are they significant economic actors, they also play a key role in involving their members and European citizens more fully in Society.

Social Economy enterprises are helping to meet the demands of a changing Europe. They are important sources of entrepreneurship and jobs creator in areas where traditional "investor driven" enterprise structures may not always be viable.

II. The Evolution of Social Economy in Europe

The beginnings of social economy in Europe lies to early XX century when nobody was suspecting yet the development that the concept will have until second war came.

Charles Gide was the first to give these organizations a central place in the social economy, whose meaning in 1900 was nonetheless still quite broad.(1) During the 1970s, when the French co-operative, mutualist and associative movements rediscovered their common traits, they would appropriate his vision and thus reaffirm their kinship. They gave a collective title, "social economy" to the family of movements they had thereby formed, and in so doing set an entire process in motion, one that has led to increasing institutional recognition for the third sector.(2)

In the Anglo-Saxon world, it is primarily the non-profit organization (NPO) and the non-profit sector which have revived interest in the third sector. Consequently, it is useful to point out their contribution to social economy analysis. While this contribution is limited, it facilitates an understanding of the concepts we have selected.

While the social economy may have been born of necessity, it still has a long way to go. Instead, individual survival strategies predominate in many of these environments, particularly in large cities. In fact, the history of the social economy teaches us that it is driven by a second force, one that is as powerful and as vital as the first: membership in a social group unified by a collective identity or shared destiny. For example, during the XIX century and the first half of the XX century, the dynamic social economy reflected a class culture that was, to be sure, dominated, but which showed considerable solidarity.

Athough at EU level there is no defined budgetary policy for social economy, finance measures are being given through communitary sources. The finance system slowly developed because of innovative sources of insuring ressources and the development of institutions that offers support in obtaining finance and management agencies of EU funds. EU funds for social economy are oriented to professional insertion, development of specific services, fight against black market work etc. In our way to a durable development social economy is caracterized also through ethic and soliday finance mecanisms which responds to the general aim of making economy to society.

The development of social economy involves, for most of the citizens awarness activities because more and more citizens want to to be sure that their money are not being used to finance imoral activities, or that are not respecting human rights or that can influence or even change the quality of life for the next generations.

According to the different cultural life models, european social economy develop solutions to current economic crisis through jobs creation, in a time where jobs are less and less on the market. Towords this, social economy comes as an impuls to the development of innovative entrepreneurship through continuous training that is necessary on high and performant economy.

III. The Power of Social Economy in Romania
III.1 First Steps of Social Economy in Romania
Social Economy is known in Romania rather late and does not present a quick growth because of the unclear specifications of the concept in the appropriate legislation.

In Romanian legislation the term of Social Economy appears for the first time in GD 829/2002 in which it was approved the National Plan Against Poverty and Promotion of Social Inclusion. Only in 2008 social economy is brought to light once with the structural funds absorption. Social economy benefits in 2008 of a second Romanian legislation definition, together with its inclusion as an eligible area for funding from ESF: Social economy is supported as a key area of Human Resources Development Operational Program, whose Framework Implementation Document was approved by Order of the Minister of Labour, Family and Equal Opportunities and the Minister of Economy and Finance 254/1169/2008.

Although social economy is for the first time conceptualized in a national document, it is not present as a crosscutting element within all major objectives related to the social situation, as one would expected. The presence thereof only in the area of increasing the employment degree of disadvantaged persons also influences the profile of aid measures and support of social economy in the future. No direct connection is made however between the social economy and the need to continue the development of integrated and high quality social services programs, as main way to avoid social exclusion.

III.2 Evolution of Social Economy in Romania
In Romania social economy is conducted by Priority Axis 6 "Promoting social inclusion" of the Operational Program Human Resources Development. The overall objective of this priority is to facilitate labor market access of vulnerable groups and promoting inclusive and cohesive society in order to ensure the welfare of all citizens.

This priority aims to develop specific programs for personal development, both in order to strengthen motivation for training and labor market integration of vulnerable groups, as well as improved access to the labor market.(3)

Specific actions to combat direct and indirect discrimination will be complemented by measures to increase the activity rate. Social inclusion can be successfully achieved only by using a comprehensive approach that addresses all aspects (employment, education, housing, health care, social protection, etc). And at the same time, using available resources effectively and focused.

Implementation of ESF (European Social Funds) in Romania is through HRD (Human Resources Development), coordinated by the Ministry of Labour, Family and Social Protection as the main component of structural funds impact on Social Economy.

In the call for proposals opened in 2010 on 6.1 "Promoting social inclusion" financing line, in the first 5 hours, there had been submitted more than 1,500 projects. One of the obligations imposed by the Applicant's Guide was the creation of social enterprises and social networks.

The high number of potential beneficiaries of European Union-financed projects demonstrates the growing interest to this field and high degree of knowledge of the characteristics and advantages of these forms of organization. Romania has made enormous progress in this plan and demonstrates the ability of organization and cohesion across the new concepts.

Social economy in Romania has brought and will bring benefits throughout the economy. Will be enhanced to create innovative and flexible forms of employment for vulnerable groups, promote local development policies, including active citizenship, cooperation and social solidarity.

At the same time, new groups and functional partnerships will be established in the economy, such as cooperatives and mutual aid associations, foundations and other voluntary associations, which will offer new services and new opportunities for people with difficulties in the integration or reintegration into the labor market.

The objectives pursued by the ESF funding lines open for Romania ends with impact on social inclusion and economic development: improving access to employment and sustainable inclusion in the labor market of those looking for a job and inactive people, including strengthening social disadvantaged people in order to ensure sustainable integration and combating all forms of discrimination in the labor market, promoting partnerships, agreements and joint initiatives by creating links between social partners and NGOs (National Nongovernmental Organizations) at the (trans)national, regional and local level.

In Romania, although social enterprises existed and still exist, they were not the ones that generated the debates on social economy. It was the non-governmental, nonprofit sector that started such debates, especially from the perspective of social services provider confronted with the public sector incapacity, on one hand, to cover the need for social services and, on the other hand, to finance or facilitate the private, non-profit initiatives in this field. A field with high potential where social economy could play a decisive role is that of community services and residential or home long-term care.

In Romania, all forms of organization with potential of being involved in social economy are present, but the extent to which such forms are involved varies. The absence of registration systems makes any evaluation difficult.

In Romania, the fiscal and financial support framework does not target directly social economy enterprises, but includes measures from which they may also benefit.

In the further years we are expecting government to implement more ways of promoting an protecting the social economy organizations.

The social economy usually develops because of a need to find new and innovative solutions to issues (whether they be socially, economically or environmentally based) and to satisfy the needs of members and users which have been ignored or inadequately fulfilled by the private or public sectors.

By using solutions to achieve not-for-profit aims, it is generally believed that the social economy has a distinct and valuable role to play in helping create a strong, sustainable, prosperous and inclusive society.

Successful social economy organizations can play an important role in helping deliver many key governmental policy objectives by: Helping to drive up productivity and competitiveness; contributing to socially inclusive wealth creation; enabling individuals and communities to work towards regenerating their local neighborhoods; showing new ways to deliver public services; and helping to develop an inclusive society and active citizenship.

Social Economy in Romania is important because it: contributes to efficient competition in the markets, offers the potential for job creation and new forms of entrepreneurship and employment, is largely founded on membership-based activities, meets new needs, favors citizen participation and voluntary work, enhances solidarity and cohesion, contributes to the integration of the economies of the candidate countries.

IV. Conclusions

Social economy is a general term used to refer to a group of people that get together to assume an active economic role in social inclusion process, eg. cooperatives, social enterprises, NGOs (foundations and associations) and other non profit organizations which have an important role in managing and building activities.

Social economy will bring benefits to the entire economy, the creation of innovative and flexible forms of employment for vulnerable groups will be enhanced, the local development policies, including active citizenship, cooperation and social solidarity will be promoted.

At the same time, new groups and functional partnerships will be established in the economy, such as cooperatives and mutual aid associations, foundations and other voluntary associations, which will offer new services and new opportunities for people with difficulties in the integration or reintegration into the labor market.

Social inclusion can be successfully achieved only by using a comprehensive approach that addresses all aspects (employment, education, housing, health care, social protection, etc.) and at the same time, using available resources in an efficient and focused way.

In Romania, there will be implemented in the next 2-3 years almost 200 projects on social economy and this is equal to 200 or more social enterprises created that will contribute to reducing unemployment, creating jobs with special work conditions to persons that need this, reducing poverty and social inclusion increasing. All these cannot be something else but the path to a sustainable economic development and a possible solution to economic crisis.

V.Notes:

(1)At the 1900 Paris World Fair the social economy had its own pavilion, which Charles Gide described as a "cathedral". He wrote: "In the large aisle, I would put all forms of free association that help the working class free itself through its own means" (quoted by A. GUESLIN, 1987, p. 5).

(2)For example, in 1981 the French government established an interministerial delegation on the social economy (Délégation Interministérielle à l'Economie Sociale), which was at times headed up by a secretariat on the social economy (Secrétariat d'Etat à l'économie sociale).

(3)According to Solicitant's Guide - Priority Axis 6 "Promoting social inclusion" of the Operational Program Human Resources Development

ECONOMIC BENEFITS OF DEVELOPING INTERMODAL TRANSPORT IN THE EUROPEAN UNION

Dărăbanţ Simina
„Politehnica" University of Timişoara Faculty of Management in Production and Transport

Ştefănescu Patrick
„Politehnica" University of Timişoara Faculty of Management in Production and Transport

Crişan Radu
„Politehnica" University of Timişoara Faculty of Management in Production and Transport

Transport plays a crucial role in economic and social development and its contribution goes beyond what is normally captured in traditional cost-benefit analyses. Transportation investments can have large long-term economic, social and environmental impacts.

The European Commission when developing transport policy, focuses on the intermodal transport, which is seen as a sustainable mobility solution, environmentally friendly and efficient in terms of resources, especially in terms of freight. European transport policies promote co-modality - combining different modes for a single supply chain - as a solution to the adverse effects of transport: pollution, traffic congestion, energy consumption.

Intermodal transport is found to be consistently cheaper than all-road solutions, and its external costs significantly lower, thereby confirming the high potential of intermodal transport in increasing the sustainability of the transport sector. So, freight intermodality is increasingly considered as major potential contributor to solving the sustainability problems of the European transport sector.

This paper addresses the pricing issues specifically related to intermodal transport. The focus in on the main economical advantages of developing intermodal transport, but also on the usage limits brought by particularities of transport modes. Special attention is given to intermodal transfer terminals with solutions for activity efficiency increase, with major implications on the quality and cost of transportation.

The theme discussed in this paper is of great importance, many authors and specialists developed it in their studies. Some names are needed to be mentioned: Todd Litman, Dr. Yuri V. Yevdokimov, John J. Coyle, Kenneth D. Boyer and few more. But, a special attention for this subject is paid by the European Commission and its subordinated institutions, that are interested in developing sustainable strategies and promoting concrete solutions for economic efficiency in the transportation field.

The methodology used for this subject is based on the statistics data from the official documents and on the research made by the authors of the paper regarding the advantages from the economical point of view derived from the development of intermodal transport.

The results we have reached show that the intermodal transportation is rapidly gaining acceptance as an integral component of the systems approach of conducting business in an increasingly competitive and interdependent global economy.

The information on this paper have implications on other related fields: social, environmental and even political and the authors brought significant contribution raising the problem of the total costs of investments in the intermodal transport infrastructure and the long-term economical benefits if it.

Keywords: intermodal transport, economic advantage, investments, costs, infrastructure
JEL Codes: L91, R41

Introduction

Infrastructure sets the degree of mobility. No major change in the transport sector will not be possible without an adequate network support and a more intelligent use of its. Overall, investment in transport infrastructure boosts economic growth, create wealth and jobs and promote geographical accessibility, trade and mobility. It must be planned so as to maximize the positive impact on economic growth, minimizing negative environmental impacts.

Transportation is a multiple service to multiple users. It is produced in transportation networks that provide infrastructure for economic activities.

The transport industry itself is an important part of the economy: within the EU, it directly employs about 10 million people and is the source of about 5% of GDP. Establishing a reliable measure of intermodal market shares is hazardous. Official statistics are few and outdated. The basic figures available and the corresponding trends however show that the market share of intermodal transport in total European transport is limited: 8% of all intra EU transport (in tkm) takes place via intermodal transport. Nevertheless, all forms of European intermodal transport have shown a considerable growth over the last decade.

Under the flagship initiative "An efficient Europe in terms of resource use", presented at the within Europe's Strategy 2020 and the new Plan 2011 on energy efficiency, the main objective of the European transport policy is to help create a system which supports European economic progress, to enhance competitiveness and provide high quality mobility services, while ensuring more efficient use of resources.

The demands of the transport industry on logistics services, and therefore also the efficiency of the logistics infrastructure is growing with the steadily increasing competitive pressure.

The development of transport system was done as a necessity of meeting the transport demands made by society. The growing needs for mobility of goods and passengers have been offered more sophisticated transport modes, both technically and infrastuctural. When designing it financial considerations always prevailed, the social considerations being in a more distant plan.

Intermodal transport: evolution and application in the economy

According to a commonly agreed definition of the main regional and international organizations and cooperation structures: UN, CEE, ITF, EU, ICB, ICC, intermodal transport is that transport system involving the successive use of at least two modes and where the intermodal transport unit is not divided to change modes.(1)

This entails that:

- two or more different transport modes are deployed, and therefore at least one transshipment takes place
- the main haulage is not carried out by road, but by rail or water, while trucks/lorries are used for the initial and final legs of the goods movement (pre and post haulage).

David Collenette (1997), the Transport Minister of Canada, noted: Intermodalism today is about safe, efficient transportation by the most appropriate combination of modes. (The Summit on North American Intermodal Transportation, 1997)

These statements define intermodal transportation as a macroeconomic concept, because an effective transportation system is a vital factor in assuring the efficiency of an economic system as a whole.

The structure of intermodal transport system is based on three elements (Fig. no 1):

1. a system of freight over long distances (usually involving modes of shipping, rail, inland waterways and / or air);
2. transport terminals to ensure efficient transfer of cargo units on a modal transport to another
3. a collection and distribution of freight flows at points of origin, respectively destination of the transport chain (usually made by road transport).
Figure 1: Basics elements of intermodal transport
Source: Ankner 2006

Intermodal transport involves a large number of operators from the private sector. The market environment in which they operate is highly competitive. As opposed to the general situation observed for many other transport services, direct competition can often be found among players operating on the same network segment. This situation largely influences the pricing strategies of operators and their overall market attitude:

- published prices, when they exist, are often found to be substantially different from real prices offered to customers. Discounts for high volumes, for frequent and/or regular shipments, and, more generally, for strategically preferred customers are common practice, and hardly documented

- similarly, cross subsidisation between routes is frequently adopted by operators seeking to gain dominant positions on specific itineraries and services. (Ricci 2002: 4)

Expansion of the intermodal transportation network is associated with economies of scale and better accessibility to input and output markets. The overall impact of intermodal transportation can be divided into four elements:

- an increase in the volume of transportation in an existing transportation network;
- a reduction in logistic costs of current operations;
- the economies of scale associated with transportation network expansion;
- better accessibility to input and output markets. (Yevdokimov 1997: 3)

Intermodal transportation is characterized by optimal frequency of service and modal choice and increased reliability. Combined, these two features define the just-in-time delivery – a major service produced by intermodal transportation. (Blackburn 1991: 27)

It appears that just-in-time delivery reduces the burden of inventory holding costs. Reduction in the inventory holding costs directly improves the productivity of an economic system.

Investments in infrastructure

Traditionally, the benefits of a transportation investment have been primarily evaluated through reduced travel time and reduced vehicle maintenance and operation costs. In order to measure total economic benefits of investing in intermodal transportation, it is necessary to understand their basic relationships with different economic activities.

Improvements in transportation reduce transportation costs. The immediate benefit of the reduction is the fall in total cost of production in an economic system under study which results in growth of the system's output.

An efficient transport network requires substantial resources. EU cost of infrastructure development, so as to meet the demand for transport, was estimated at over EUR 1 500 billion for the period 2010-2030. Completion of TEN-T requires about EUR 550 billion by 2020, of which about EUR 215 billion to eliminate critical bottlenecks. These figures do not include investments in vehicles, equipment and charging infrastructure, which may require an additional

EUR 1 000 billion, to reach emission reduction targets for the transport system. (European Commission)

There must be diversified funding sources, both public and private. It is necessary a better coordination of structural and cohesion funds with the objectives of transport policy and Member States must ensure that their budget planning provides sufficient national funds and sufficient capacity planning and project implementation. Other sources of funding to be considered are systems to internalize external costs and user charges of infrastructure, which could create additional revenue streams, which in turn would encourage private investment in infrastructure.

The biggest hurdle in the development of adequate combined traffic offers the necessary infrastructure requirements. The construction of terminals is challenging and unrealistic to expect the operators themselves to manage it. In general, as in the railway infrastructure, the public sector has to pay for it, at least in part. The installation of terminals in turn is a complex task, whose success with the integration of technology and modern logistics connected by rail and also the market potential is very closely linked. The market opportunities in combined traffic, depending on the quality of combined transport terminals vary considerably. Investment requirements for transport companies, however, are manageable. The additional costs for crane lifting containers in road transport, as compared with conventional semi-trailers, are small. (Bakukin et al. 2010: 7)

Price signals play an important role in many decisions with long-term effects on the transport system. Transport charges and fees must be restructured towards a wider application of the principles of "polluter-pays" and "user-pays". They should strengthen the role of transport in promoting European competitiveness and cohesion objectives, while the total load of the sector should reflect the total costs of transport, including infrastructure costs and external costs.

Pricing the intermodal transport

The most important criterion in the transport organization is the economics of transportation.

To organize intermodal transport economically from the perspective of market participants, many parameters are important. In particular, the efficiency of the ports (terminals, as well as countries and systems boundaries) and the economic orientation of the rail companies are of the utmost importance in order to determine the marketability.

Over longer distances, the intermodal transport offers, theoretically, significant advantages in terms of the road driving and rest periods.

The main cause of the relatively low development of intermodal transport is its inability to respond in a satisfactory customer's requests in the new logistics environment.

Road transport is recognized as being more flexible, cost-effective, transparent, effective and thus provides a good quality service.

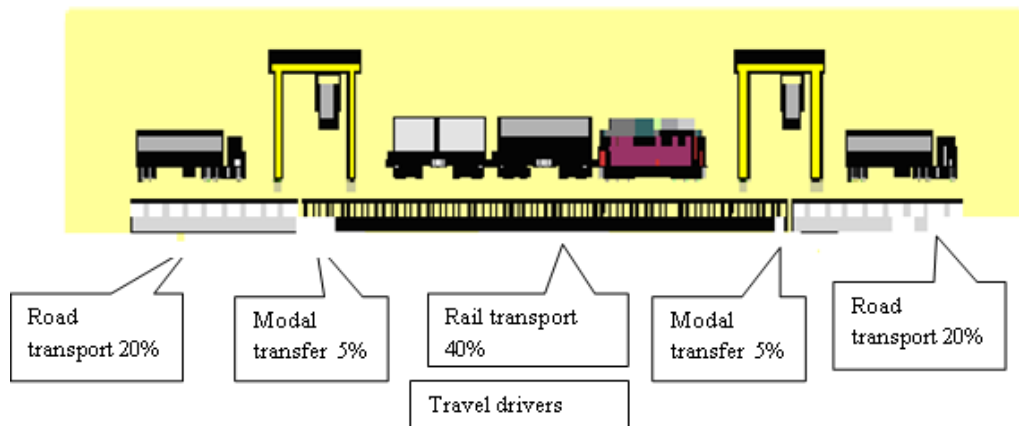
Intermodal transports are cost-effective over long distances and it is known that in Europe most of the shipments of goods are made on short distances; about 57% of the transported goods moving within a radius of 50 km. (European Commission)


Figure 2: Share of costs involved in intermodal transport

Multimodal freight transport and combined rail-road transport are two strong axes of sustainable development policy of the European Union, because such operations are carried on long distances and in large quantities. These transport present the following economic advantages: transport in a single train of 20-25 swaps, in a single barge of 130-175 containers or in a single ship of 8,000 or more containers, replace the same number of trucks and leads to significant gains in economy energy, personnel costs, vehicle maintenance and other costs that are considered internal and external.

Intermodal interfaces, strategically located where networks of different modes converge, allow goods, particularly those in standard containers, to be transferred efficiently between transport modes, thereby ensuring optimal usage of the networks as a whole. These intermodal interfaces are not only important at seaports, but are increasingly being recognized as beneficial at inland points of intersection as well.

Socio-economic benefits and positive externalities justify a certain level of public funding, but in the future transport users will probably have to pay a larger cost than today. It is important that users, operators and investors receive fair and consistent monetary incentives.

Internalize externalities, removing tax distortions and unjustified subsidies and free and undistorted competition are, therefore, part of an effort to align market choices to sustainability needs (and taking into account the economic costs of "non-sustainability"). They are also required to establish fair market conditions between modes that are directly in competition.

Oil will become more rare in the coming decades and sources of supply will become increasingly uncertain. As shown recent by IEA, the success of the global economy in terms of decarbonisation is lower, the oil price will be higher. In 2010, bill of EU oil imports amounted to about EUR 210 billion. If we do not solve the problem of oil dependence, people's ability to travel - and our economic security - could be seriously affected, with serious consequences on inflation, trade and global competitiveness of EU economy.

It is important that new transport models appear, in which large volumes of freight and more passengers are transported in common at destination with the most efficient (combinations of) ways.

Future development should be based on:

- performance optimization of multimodal logistics chains, including increased use of inherently more efficient ways in terms of resource use, where other technological innovations are inadequate (eg. freight over long distances)

- more efficient use of transport and infrastructure by using a series of improved traffic management systems and information (eg ITS, SESAR, ERTMS, SafeSeaNet RIS), by using an advanced logistics and implementation of market measures such as developing a comprehensive

integrated European railway market, elimination of cabotage restrictions, removal of barriers to short sea shipping distances, no distortion rates, etc. (Raoul 2009: 12)

On long distances, decarbonisation of road transport options are limited, and multi-modality freight should be attractive from the economical point of view, for carriers.

EU needs corridors especially developed for freight, optimized in terms of energy consumption and emissions, in order to minimize environmental impact, but which can be also attractive because of their reliability and reduced congestion and due to the low administrative and operational costs.

Recommendations and conclusions for increasing the efficiency of intermodal transport

Regarding intermodal transport has been found that a significant amount of time is lost in terminals where the transfer of goods to / from the means of transport in the deposits or their transshipment between different modes of transport is realized. Efficiency measures of the intermodal chain also apply to investment and organizational solutions applicable to intermodal terminals.

Main economical obstacles to the development of intermodal transport refers to the high investment costs for both intermodal transport units and terminals, high costs of transfer and storage; cost structure is often unknown and the division between infrastructure, terminals, traction, rolling stock operation, handling, etc., is unclear.

Development and profitable solutions of the business in intermodal transport terminals relate to measures of investment and organization. Investments measures are:

- modification of terminal groups of lines by increasing the number and length of tracks;
- improving access to train in the terminal area by reconfiguring the diagonals in order to increase the number of simultaneous paths and reduce the duration of the terminal input and output;
- expanding the area in which the transfer of road - rail cargo units is realized;
- improve terminal access road and increased parking spaces;
- the provision of transfer equipment performance and with high productivity
- the equipment with means for automatic identification of vehicles (cars, tractors and trailers) and of cargo units (containers, swap).

Organizational and operational measures aimed at:

- increase uptime daily of the terminal;
- superior organization of activities by simultaneous operation of terminal
- sizing technological processes and work teams
- increased use of electronic computing equipment (optimization solutions by setting optimal order of introduction to the activities of loading / unloading) and of information systems, command, control and communications.

Since most finished products are transported in containers and that they are the primary means to facilitate intermodality, it is estimated that, in the twenty-first century, intermodal transport, with technological improvements of used transshipment systems, is the cornerstone of international trade, being considered the most effective way of managing international transport activities from "door to door". This is because intermodal transport allows the combination, advantageously in a certain way, of the specific advantages of each mode of transport, such as road transport flexibility, high capacity of rail transport, low costs of shipping transport and high speed of air transport.

THE COSTS OF THE ELECTRICAL ENERGY IN THE ALUMINIUM INDUSTRY

Dobra Iulian
Vimetco Management

Cilianu Marian
S.C. Alum

Belu Mihaela Gabriela
Bucharest Academy of Economic Studies Faculty of International Business and Economics

The economic crisis has given the opportunity to reconsider the use of resources, so the subject of competitive advantage has become actual. In the aluminium industry the cost of electrical energy is critical not only for competitive reasons but for the mere existence and performance of numerous production facilities . Several ways of resisting the pressure of high energy costs have been experimented the most promising being those based on different forms of public-private partnership/co-operation. In many countries the big industrial producers benefit from a special treatment concerning the energy acquisition and are supported by the government in order to remain competitive.
Key words: energy, energy market, aluminium price
JEL classification: Q40, Q48, L10

1. Introduction
The expenses connected to the electrical energy represents the most important component of the aluminium production process. To the global level, in 2009, the electrical energy represented 36% of the aluminium production cost, 5 percents more than in 2008. Thus, the electrical energy represents the biggest part of the total costs followed by alumina -Al2O3 (by 34% of the costs in 2009). From now until 2015, it is foreseen that for the aluminium production the non-energetic costs will decrease and thus the rate of the energy cost in the aluminium production cost will increase.

2. Types of energy
The energy used in aluminium industry is produced mostly from coal (50%) and hydro energy (40%). During the last years the use of the hydro energy in aluminium industry decreased. For instance, in 2000, the hydro energy represented 54% of the energy used in aluminium industry compared to 40% in 2009. The percentage of the energy produced using the gas increased from 6% to 8% in the same period and that of the nuclear energy decreased from 5% to 2%.
The increase of the aluminium quantity ratio produced by using coal based energy and the decrease of the aluminium ratio produced by using hydro energy come mainly from the development of the Chinese market that generally use coal based energy. Since the Chinese aluminium production ratio will increase in the future, it is assumed that for the aluminium industry will be used more and more coal based energy. Furthermore, the increase ol aluminium production in the Middle East will lead to an increase of the gas based energy ratio.

3. The energy price
A characteristic of the energy market , in a liberalised context, is the rise of price volatility This volatility introduces additional costs for supply and presents many challenges for producers, consumers companies and policymakers. But the general trend in the energy price during the last years was a the rise.

The energy unit price increased by almost 110% from 2001 until 2008, from 18.8 USD / Mwh to 40 USD / MWh. In 2009 because of the global financial crisis the energy unit price decreased by almost 5% to the international lavel and after that increased to approx. 41 USD/MWh in 2010. The energy price in China is much more higher than in the rest of the world. This is why the above mentioned unit price was smaller if the China production would not be taken into consideration.

In 2009, the electrical energy for aluminium production was bought in medium by 32 USD / MWh that represents a decrease of 12% compared to the average from 2008 of 36.4 USD / MWh. To the international level the electrical energy price decreased in 2009 and 2011 because of the following reasons:

- The metals price decreased that led to a decrease of the energy price because the energy price established by the contract is connected to that of the metals (excepting China).
- During the last quarter of the year 2011, a lot of companies decreased their production, they decided not to start a part of their capacities stoped in 2009 or they even closed certain production activities. This is valid especially for the old installations that are less efficient and for which the energy was more expensive.
- The decrease registered to the electrical energy unit cost in 2009 would have been much more higher if it had not been taken into account the aluminium production from China where the energy is more expensive.

The energy tariffs connected to the aluminium price represented 36% of the total energy bought 2009 for aluminium production. These tariffs decreased by 32% from 2008 in 2009 from 31.2 USD/ MWh to 21.2 USD / MWh. Regarding the energy tariffs that are not connected to the metals price , these decreased from 38.5 USD / MWh in 2008 to 35.9 USD / MWh in 2009 that represents a diminution of 7%.

Before 2004 the production achieved from the bought energy represented 79-81% of the total aluminium production. After 2004 this ratio decreased considerably especially due to the increase of the aluminium quantity produced in China by using the own energy (from internal power plants).

It is estimated that (1) to the global level the percentage of the aluminium produced using the own energy increased to 40% in 2009 compared to 35% in 2008. After 1995 the quantity produced using the own energy increased in average by approx. 10%. According to Brook Hunt (1), in 2009 the average price of the own energy used to produce the aluminium was of 47 USD / MWh, by 2% more than in 2008.

Between 2009 and 2015, the electricity specific consumption is estimated (1) to decrease by 0.8% from 14.7 MWh / ton to 14.6 MWh / ton of aluminium. In 2009 it was estimated that (1) an increase of the energy costs will follow in 2010 and 2011 in order to decrease to approx. 596 USD / ton of aluminium in 2015.

Types of contracts

Also, there are many types of contracts that the aluminium producers have with the energy companies. The type of the contract influences both the energy tariff and its variation. Generally, there are three types of contracts:

a) Fixed price
b) Cost-plus
c) Partial or total increase compared to the aluminium price or compare to other parameters.

The fixed price contracts remains fixed in local currency (for instance in RON). The price of energy expressed in USD modifies when the local currency/USD exchange rate fluctuates.An exemple of fixed contract in USD is offered by Mozal company. A fixed tariff has the advantage that it offers to the producer a high certitude on the costs. .

When the energy supply contract is a cost-plus type the price paid by the energy producer varies like the energy production cost born by the energy producer. Thus, the energy price will depend on the fuel price (oil, gas, coal).Generally, this type of contract is not attractive for the aluminium producers because the variance in the energy production price may not corresponds with the variance in the aluminium price. In spite of all this it is possible that the energy price obtained by a such a contract to be , in average, smaller than the price obtained with a fixed tariff contract or a contract where the price depends on the LME. Examples of producers using cost-plus contracts are Warrick Alcoa in the SUA or partially in Portland from Australia.

There are many companies in which the energy acquisition price depends on the aluminium price. For the aluminium producer this type of contract has the advantage that the raw material price decreases when the aluminium price is low thus reducing the costs and assuring the production continuation. For the electricity producer this type of contract generally is a beneficial one. When the aluminium price is low the marginal price of the energy production is generally covered (usually by using an inferior limit of the energy selling price). When the aluminium price is high the electricity producer benefits from this fact. In spite of all this there were situations where the electricity producer suffered important losses when the aluminium price (and consequently the price of the sold energy) mentaned to a lower level than the foreseen one.

Ussualy, in order to protect both the electricity producer and the aluminium producer a such an energy contract contains both an inferior and a superior limit. The inferior limit (floor) offers protection for the energy producer and the superior limit of the tariff protects the aluminium producer.

Generally, in the aluminium industry the contracts where the energy tariff is connected to the aluminium price are very diversified. The tariff type can vary from linear relations (for instance Hillside in South Africa) up to very complicated formulas (Portland in Australia) in which the limits (superior and inferior) can at their turn depend on the aluminium price or other idices like inflation or fuels price.

Brook Hunt estimates that in 1996, the contracts in which the energy tariff depends partially or totally on the aluminium price represented 35% of the total aluminium quantity produced. Accordingly (1) this ratio decreased along the time to approx. 21% in 2003. The decrease is due especially to the significant increase of the Chinese production during the last years, the Chinese producersnot using contracts where the energy tariff depends on the aluminium price. In 2009, the number of the producers buying energy at a tariff influenced by the metals price was of 28, one less than in 2008.

Table 1
Examples (according to CRU analysis (2)

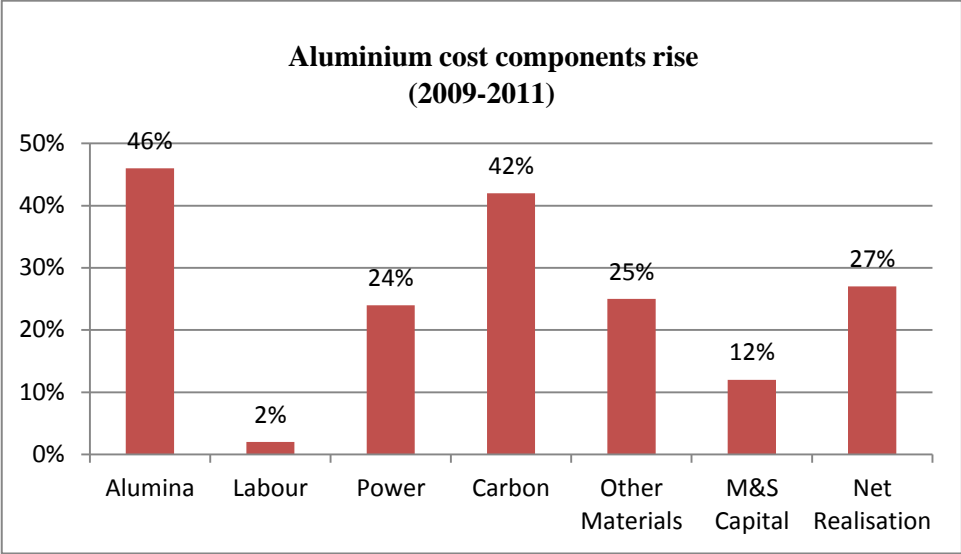
Producer	Energy Cost in electrolysis ($/ton of metal)
Alro, Romania	728*
Sunndal, Norsk Hydro, Norway	546
Mosjoen, Alcoa, Norway	645
KAP, Podgorica, Montenegro	764
St Jean de Maurienne, Rio Tinto Alcan, France	367
Bratsk, Russia	253
Irkutsk, Russia	239

*The energy costs at ALRO do not include the new taxes for the cogeneration tax and green energy .

These data are valid for the year 2010, when ALRO was accused that they bought the cheapest energy in Romania.

The table above represents different costs for a diversified aluminium producers sample. Out of the companies from this table higher tariffs for energy have the two energy producers in China and KAP plant (Muntnegru). The cheapest energy is that of the two plants from Russia followed by the one from France and than the two from Norwey.

Between 2009-2011 aluminium business costs increase from $1456/t to $2009/t. The rise of the components of the total business costs during that period is showen in Fig. 1

Figure 1


Source: Driscoll, Kelly (2011), Trends in the costs of production throughout the aluminium value chain, 15th ARABAL, Oman

Possible measures to support the aluminium industry

Implementation of a policy and coherent strategy in order to create a special treatment concerning the energy acquisition for all electrical energy band consumers (distinctly from the other industrial consumers and intermediate traders) whose prices to be differentiated depending on the level of the individual consumption and the capitalization degree of the energy.

Bonus granting for the consumers in band during the weekend and at night (it is known that there is a very reduced demand for the weekend and reduced during the night).

Opening of OPCOM market for the long-termcontracts (a compulsory condition for the drafting of the business plans on at least 5 years) otherwise development plans cannot be achieved for no company.

4. Conclusions

In many countries of Europe and from the world is normal that the big industrial producers to benefit of lower energy tariffs than the rest of the consumers. These big producers (as are for instance in Romania, Alro or Arcelor Mittal) need cheap energy in order to keep their costs down and in order to be able to compete on the international market. Consuming big quantities of energy it is normal that they to be able to negotiate lower tariffs.

At present the plus-value created by ALRO and Arcelor Mital assures directly or indirectly the existence of over 500 000 people. Consequently, it is very important that such kind of companies to be supported by the government in order to remain competitive.

CONSIDERATIONS REGARDING THE COMPETITIVENESS INDEXES COMPATIBILITY WITH THE STRATEGIES AND INDEXES OF SUSTAINABLE DEVELOPMENT IN THE EU CONTEXT

Felea Adrian Ioan
University of Oradea Faculty of Economic Sciences

This paper is structured in three parts. The first part referes to the topicality of the concepts and of the concerns related to sustainable development and competitiveness. The second part of the article presents the results of the compatibility analysis and the impact study of EU's sustainable development strategies on the competitiveness indexes.
The analysis is based on the indicators and values used and developed by the World Economic Forum, published in the Global Competitiveness Report and used to depict a nation's competitiveness and also based on the objectives published in the European Union's Sustainable Development Strategy and on the indexes used by Eurostat. In the last part of the article we presented the relevant conclusions of the analysis conducted.

Introduction

Competitiveness is the main objective of the contemporary socio-economic strategies, and it is more and more integrated in the complex concept of sustainable development, that gathers all the forms and methods of socio economic development, who's foundation is represented by ensuring a balance between these socio – economic systems and the elements of natural capital.

Competitiveness is a complex economic concept, with various interpretations and quantification methods, using aggregate indicators and systems of indicators on which not all the researchers totally agreed.

Throughout the development of the society, there were developed and published many various theories and perspectives regarding the competitiveness. Also, there are some theories that contradict the ones mentioned before.

On the other side, for these theories to be applied, a series of reports were developed, published by certain international organisms, that identified a series of factors that determine the measuring of competitiveness, based on certain criteria. Thus, there were developed different models for measuring the economic competitiveness [1, 2, 3].

Regarded from an international perspective, the national competitiveness evaluation is based on the studies conducted by the World Economic Forum (WEF), that publishes the annual report called 'The Global Competitiveness Report'; the Institute for Management Development (IMD), that publishes 'The World Competitiveness Yearbook'; the World Bank, that publishes the report entitled 'Doing Business', OCDE publishes "The New Economy Report' and the European Commission, that publishes "The European Competitiveness Report" [4].

The WEF publishes every year the Global Competitiveness Report. In the 2010 – 2011 edition, 139 countries were analysed from the perspective of different states of development, according to different criteria. In the end, there were 12 pillars identified and on this basis the countries analysed were classified.

This article refers to the indicators developed by the WEF in analysing the compatibility between the competitiveness indicators and sustainable development indicators [5].

The sustainable development concept is defined as comprising all forms and methods of socio – economic development, based on ensuring a healthy balance between the socio – economic systems and the elements of the natural capital [6].

The most famous definition of sustainable development is the one developed by the World Commission for Environment and Development (WCED) in the report entitled "Our common future", also known as the Brundland Report: "sustainable development is defined as being that development that leads to satisfying the present needs, without compromising the future generations' possibility to satisfy its own needs" [7].

Due to the complexity of the concept of sustainable development (SD) and for identifying in time the effects of sustainable development strategies, it was necessary to create a series of criteria, that could monitor and evaluate the effects of certain decisions. That is how certain indicators were defined.

Choosing the right indicators is directly connected with the way the concept of sustainable development is regarded. For example, a dogmatic approach of the concept would point out the fact that the natural resources are scarce and the tendency would be to impose some absolute limitations on collective and individual usage of the environment.

On the contrary, a more relaxed approach would point out the juggle between the social, economic and environment resources.

The main purpose of the indicators is to allow the monitoring and the evaluation of different aspects of sustainable development and to offer clear indications for the policies to use, to verify and to correct.

For this purpose, the indicators chosen must satisfy some of the requirements as the relevance for policy formulation, utility, the scientific basis, and the quantification possibility.

For analysing the compatibility between the sustainable development indicators and the competitiveness indicators we will refer to the indicators published by the statistical office of the EU, Eurostat [8].

Throughout the EU's evolution, several approaches were chosen, regarding the subject of sustainable development. Due to the complexity of the concept and maybe due to the frequent changes that took place, the European Union developed a series of strategies and programmes to eventually implement a part of the objectives expressed over the years [9].

The EU's Sustainable Development Strategu (EUSDS) is formed out of 45 points and it is structured in 5 sections, the one regarding the seven key challenges being of massive importance, and it includes the targets, the operational objectives and the associated actions.

Economic competitiveness is stated under the objective of "economic prosperity" that regards "promoting a prosperous, innovative, rigorous, competitive and eco – efficient economy, that offers higher living standards and more employment opportunities".

This article is trying to analyse the impact degree of the actions stated by the EUSDS on the competitiveness indicators published by wef.

A systematic analysis of competitiveness

Table 1 presents in a sintethic manner the analysis of the impact of EUSDS targets on competitiveness indicators (CI). The number of targets and competitiveness indicators is made according to statement [4].

Table 1 : EUSDS targets that have impact on CI

EUSDS/Key challenges (KC)	CI/WEF/Pillars	Effect
KC1 – Climate change and green energy Targets 1, 2 and 6	**Infrastructure** Indicators 2.01 and 2.07	↓
KC2 – Sustainable transport Targets 1 and 3 Target 2	**Infrastructure** Indicators 2.01-2.05 Indicator 2.07	↓
KC3 – Sustainable consumption and production Target 1 Targets 1,2 and 4 Targets 1,2 and 4	**Infrastructure** Indicators 2.01-2.09 **Degree of technological training** I ndicators 9.01, 9.03, 9.04 and 9.05 **Degree of business sophistication** Indicator 11.07	↓ ↑ ↑
KC4 – Resources conservation and management Target 2	**Inovation** Indicator 12.01	↑
KC5 – Public health Targets 1-8	**Health and primary education** Indicators 4.01-4.08	↑
KC6 – Social inclusion, demography and migration Target 7 Target 4	**Academic education and training** I ndicator 5.01 **Labour market efficiency** Indicator 7.09	↑ ↑
KC7 – Global poverty and sustainable development challenges Targets 1 and 2	**Degree of business sophistication** Indicators 11.06 and 11.08	↑

Source: author's calculation based on the information published by EUSDS and WEF GCR 2011

The indicators published by Eurostat for measuring the level of attaining the sustainable development objectives proposed [8] associates to every strategic approach a representative indicator (Level 1), a series of indicatorsfor the subordinated operational objectives (Level 2) and descriptive indicators of intervention fields for the associated policies (Level 3).
Table 2 presents the correspondence between the two sets of indicators.

Table 2 : The corespondence between sustainable development indicators (SDI) and competitiveness indicators (CI)

Source: author's calculation based on the information published by Eurostat and WEF GCR 2011

Conclusions

The conducted analysis reflects the low level of the impact of the targets set by EUSDS on the competitiveness indicators. Out of all 110 indicators operated by WEF only 27 are being used, meaning 24,5%, the competitiveness indicators under the pillar "Infrastructure" being negatively affected by some targets set under the first three key challenges of EUSDS.

The other 18 competitiveness indicators may be positively affected, meaning that the tarets set by the EUSDS stimulate the growth of the competitiveness indicators.

Out of the conducted analysis results that the seven key challenges have targets that may have a certain impact on the competitiveness indicators, but there are five pillars that are not affected: the pillar Institutions, Macroeconomic environment, Commodity market efficiency, Financial markets development, and Market dimension.

The correspondence degree between the two sets of indicators is very low. For only 19 out of all 110 competitiveness indicators there has been identified a correspondence, meaning approximately 17.3%. The conducted analysis for Level 3 SDI reflects the fact that out of the 98 indicators used at this level, 23 have a correspondent within the competitiveness indicators, meaning almos 23,5% of them.

The highest correspondence degree between the two sets of indicators may be be the with reference to theme 1 – Economic development, sub – theme "competitiveness". Referring to the three main themes of sustainable development (the ageing of population, quality governance and global partnership) there were no correspondences found between the two types of indicators. Five of the competitiveness pillars are not involved in the correspondences between the two sets of indicators: institutions, commodity market efficiency, financial market development, market dimension and the degree of nusiness sophistication.

SOCIAL PERFORMANCE ENHANCES FINANCIAL PERFORMANCE. BENEFITS FROM CSR

Gazzola Patrizia
Insubria University of Varese – Italy, Faculty of Economics

The research aims to show how Corporate Social Responsibility (CSR) should not be considered a cost to bear as an economic social actor but an investment that will contribute to the competitiveness and growth of the firm.

In the first part we consider capitalistic firm as systems for the creation of economic and financial value for their shareholders. We measure their performance by a system of monetary values.

In the second part we do not limit our view to simply the shareholders, but we consider, instead a vast group of stakeholders because it is important not only to make profits, but also how companies make them .

In these years characterized by the financial crisis, where many big companies went bankrupt, more and more companies are speaking about ethics and CSR. For a firm, acting socially responsible, means for example having fair compensations, promoting transparency and the respect of employees, neutralizing conflicts of interest, as well as taking care of the environment.

CSR is today a topic for discussion not only for business people but also for politicians, media, researchers, NGOs and consumers. Growing awareness of CSR is evident in the growth of voluntary codes of corporate conduct, in the growth of companies that are using self-reporting on social and environmental practices, and in increasingly social and ethical investment funds.

The public and governments of the world have been steadily increasing pressure on corporations to increase their CSR. Recently the European Commission has put forward a new, simpler definition of corporate social responsibility as "the responsibility of enterprises for their impacts on society" (European Commission 25/10/2011).

Companies have realized that to increase their market share or keep their market share, they must adopt CSR, but the synergy between social performance and financial performance is not automatic; rather it is the result of efforts that combine managerial professionalism and business creativity for the purpose of business growth that also takes into account the social groups.

Our research considers the conditions for the effectiveness of CSR actions in creating a positive feedback that can produce ever greater economic and social-environmental results. Thus a firm must set a system of objectives for itself which is centered on its sustainable growth, and must therefore tend toward a multi-dimensional growth that encompasses the economic, social and environmental dimensions. In the last part we explain how socially responsible business practices can enhance a company's value.

1. Introduction: the firm as a vital open system

Every firm can be viewed as a permanent organization (Mella 2003) or as an open socio-technical system that is structurally linked, by means of input and/or output flows, to a macro system that represents its vital environment.

In this sense, it is a *cognitive and viable agent* (Beer, 1981), in that we must assume that the firm-economic agent carries out a cognitive activity aimed at giving significance to the environmental stimuli, translating these into information that is structured in knowledge (de Geus, 1988, 1997), to produce a *reactive* and *proactive* behaviour aimed at reproducing the economic processes in a lasting way, thereby adapting itself to changes in its environment while maintaining its identity in

a long-lasting autopoietic process. (Maturana & Varela, 1980; Mingers, 1994; Uribe, 1981; Varela, 1981).

In order to maintain its teleonomy, the capitalist firm, viewed as an open system, is conceived of as a system of transformation that carries out the following transformations:

1. The productive transformation; this is a transformation of utility: volumes of factors of production having a given utility are transformed into volumes of products able to provide a greater utility based on rules of efficiency aimed at maximizing productivity and quality.

2. The economic transformation; this is a transformation of values: firms try to maximize economic efficiency through market choices that yield the maximum gap between revenue and cost of production, and thus the maximum operating result.

3. The financial transformation, through which the firm finances its economic processes with risk capital and debt capital, thereby raising the invested capital that optimizes the operating leverage, taking account of the cost of capital and its yield.

4. The managerial transformation, through which the operating objectives and the internal and external information are transformed into decisions aimed at maximizing efficiency (Davenport, 1993; Lax & Sebenius, 1986).

5. The business transformation, through which information is transformed into strategies to modify the strategic position of the firm and permit it to remain vital for an indefinite period.

With regard to the first four technical transformations the firm can be viewed as a *rational agent,* in that the managerial cognitive activity is aimed at maximizing its *fitness*, indicated by a system of performance measures – analytical (businesses and the various cycles of the economic processes) as well as synthetic (entire firm) – which express the entrepreneur's ability to maintain or improve the autopoiesis of the system-economic agent in a given area and over a definite interval of time.

With regard to the business transformation, the firm appears as an *economic social actor* that operates in an ethical, social, political environment to which it belongs and interacts not only through a system of physical, monetary and financial exchanges but also through human and communication flows through which knowledge, trust and reputation are produced (Prahalad & Bettis,1986; Harrison & St. John, 1998).

Firms, as social actors, always operate within a multitude of networks along with many other actors: economic, political and social.

Thus firms, in a context of growing social and political interconnections, are no longer considered solely as systems that produce economic and financial values but as actors and driving forces that are responsible for environmental development (Wilson, 1999) and are capable of producing environmental and positive social value and, in some cases, even environmental and social negative value in the form of environmental damage.

The reputation of the firm as a social actor is formed and strengthened precisely on the basis of a positive evaluation of this capacity to interact with the environment, on the ability of the business transformation not to limit itself to the growth of the firm but to produce an internal growth that is sustainable and compatible with environmental growth.

The creation and management of CSR finds a place within this context.

2. The capitalistic firm as a system that produces values.

The capitalistic firm (Gazzola, Mella, 2004; Mella, 2011) can be described as:

1. a *productive* organization that transforms utility, since it carries out a *productive* transformation of factors (QF) into production (QP);

2. a *business* organization, since it is preordained to develop an economic transformation of values by selling its production, QP, in markets at prices, pP, at least equal to the unit average cost of production, cP; if it is preordained to supply its production without a price, or if it recovers only a share of the production cost, it is a *no-business*;

3. a *profit* organization: if the operating logic of the business organization is to achieve the maximum *economic efficiency* by seeking {[max](pP-cP)>0}, then it becomes a profit organization; if, instead, the operating logic of its processes is to achieve {[min] (pP – cP) > 0}, then it becomes a non-profit (not-for-profit) organization;

4. a *capitalistic enterprise,* if the profit organization carries out a *financial* transformation, in the sense that the firm finances its economic processes with external capital in the form of *Equity* [E] and *Debt* [D], forming the *Invested Capital* (IC = D + E);

5. an *economic social actor,* in the sense that it interfaces and interacts with a set of *external,* or *institutional* interlocutors, or stakeholders – in an ethical, social and political (ethical) environment – which influence the organization's structure and processes through a system of *corporate governance*.

Once they have grown large enough and completed the third phase of Greiner's model (1972, 1998), which entails the separation of the ownership of capital from management, firms can be considered *teleonomic organizations* according to Monod's definition (1971), where the *teleonomic plan* necessary for surviving indefinitely is to guarantee an adequate profit and a sufficient degree of liquidity for the invested capital and to satisfy stakeholder expectations (and constraints) (Freeman, 2003).

3. The social performance

A suitable system of *economic and financial ratios* translate the values produced into performance indicators in order to assess whether or not the economic-financial objectives of the business and profit organization have been achieved.

These indicators allow those stakeholders (Donaldson & Preston, 1995) who have an interest in the production of value to compare the numerical data with the initial objectives and with the organization's mission (Pellicelli, 2002), highlighting the corporation's efficiency in developing its businesses with respect to its competitors within its particular market and environmental context.

Nowadays, firms should not be considered merely as systems for the production of economic and financial values but also as economic social actors which operate in a social environment to which they belong and with which they interact, not only through a system of monetary and financial exchanges but also through physical, human and communication flows that produce knowledge, trust and reputation. The quality of the products and processes, which is fundamental to the creation of economic values, is not in and of itself synonymous with the quality of the firm when the latter must be judged and appreciated on the basis of its social and environmental impact.

It is important to "Encompass not only what companies do with their profits, but also how they make them". CSR "goes beyond philanthropy and compliance to address the manner in which companies manage their economic, social and environmental impacts and their stakeholder relationship in all their key spheres of influence: the workplace, the marketplace, the supply chain, the community and the public policy realm (Beth Kytle, 2005, p. 9)."

To maintain an effective process for the creation of economic and financial values is necessary to create also social value for the firm (Siregar and Bachtiar 2010: 241 – 252).

A firm that focusses not only on the quality of the product but also on the safety of its employees, the social impact of its activities and the use of ethically-correct procedures is (Bowen, 1953) creating value (Zadek & Pruzan & Evans, 1997) by gaining the trust of its workers, the market and its collectivity of reference (Tencati, 2002).

The social responsibility of the firm cannot be merely a fact of philanthropism or good intentions. We cannot separate the responsibility to earn profits from that of protecting the health of employees, their safety, and from protecting the surrounding social and environmental context.

The firm, as a social agent, must base its growth on ethical behaviour (Crivelli, 2001) which involves safeguarding as much as possible the environmental conditions that will be "passed on" to the future generations. Thus the firm must compete on the social and environmental front as well as the economic-financial one.

In fact, in developing its strategies the firm must take into account the concept of *sustainable growth*, which defines the ability of the present generation to achieve a type of growth that, while satisfying the needs of the present, does not compromise the ability of future generations to satisfy to their own needs.

Sustainable growth does not represent an option but a necessary condition to obtain medium- to long-term success (Clarkson, 1995). For the firm, going down the road of sustainable growth means managing its businesses so as to improve its economic results; but at the same time it also means safeguarding the natural environment and promoting social justice (Borzaghi, 2003).

4. The dialogue with the stakeholders as a condition for the creation of value

In order to enhance its reputation (Figge & Schaltegger, 2000) and trust, which are the fundamental elements for the production of social value by the firm, it is thus important for the firm to be able to demonstrate the extent and limits of its own social responsibility (Simon, 2000).

The autopoiesis of the firm, when viewed as an *economic social actor*, depends on its capacity to earn the appreciation of the stakeholders who are not components of the organization but who gain external advantages, individual or social, from its existence (Toffler, 1985).

The social unit must produce social shared "value" (Harrison et. al., 1998) in the broader sense that its economic existence as a producer of economic and financial values must be appreciated, in terms of the *sustainability* (WCED, 1987) of the development path of the firm, and evaluated by a wide range of social performance measures of *outcome* or *benefit*: the efficiency of materials; technical innovation; energy efficiency; community relations; eco design; product recyclability; and employee relations.

This interaction leads to a systematic dialogue with the social agents by means of meetings and other exchanges ("stakeholder dialogue"), in order to grasp in advance the opportunities for an economic development and growth that respects society, without interfering with or changing the objectives (Seabright & Kurke, 1997) of the stakeholders, which often differ from those of the firm (Schmidheiny & Zorraquin, 2000).

The occasions for meaningful exchanges aim to create interactive, shared and transparent communications that result in strong relations with the social actors on the part of both the internal staff as well as the various outside contacts:

1 - internally, through the virtuous process of shared strategy formation and accountable co-planning, utilizing communication together with training to vertically and transversely "contaminate" the organization and stimulate the feedback flows;

2 - externally, through the greatest involvement possible of all those with an interest in the firm, whatever their formal relation may be. This should demonstrate that the firm is able to understand and satisfy the expectations of the stakeholders, making these coincide as much as possible with those of the firm. The common objective is to harmonize the various interests in order to improve the quality of life.

The attainment of perceived levels of social performance produces reputation, brand and confidence, so that the environment itself sets the conditions for the firm's legitimation and consent, which favours autopoiesis and thus a lasting existence for the enterprise as a social unit as well as an organizational type.

This implies, on the one hand, the organizational ability to recognize the set of relevant stakeholders as well as to identify their expectations and, on the other, the capability to

communicate the global "value" produced in terms of social benefits and prevented damage to the physical environment (Gazzola & Meo Colombo, 2011).

The European Commission has put forward a new, simpler definition of CSR as "the responsibility of enterprises for their impacts on society". This new definition requires the spread of a culture of enterprise-oriented dialogue with all stakeholders, with the aim of creating an environment marked by trust and mutual satisfaction of needs. The performance of firms in fact depend increasingly on the ability to collect information on the needs of stakeholders (listen permanent) and the ability to govern relations with all audiences, no exceptions. The firm's ability to establish positive relationships with stakeholders and opinion leaders, can lead to several competitive advantages.

5. The relationship between CSR and company performance

The CSR give four types of benefits (Molteni 2004a) for the firm:

1) increase in visibility, fame and reputation;
2) development of the capacity to anticipate trends ;
3) increase in motivation and involvement of personnel;
4) increase in the level of safety, and thus in the ability to prevent crises

The benefits in terms of *visibility and reputation* (Fombrum & Van Riel, 2003) lead to an advantage with regard to differentiation, which impacts in particular the number and loyalty of clients, with positive effects on sales.

Secondly, investments in CSR have an *anticipatory value* (Russo & Fouts, 1997). In a narrow sense CSR specifically concerns taking on behaviours for which there is no legal obligation but that correspond to the expectations of important or emerging social and economic groups. Over time these expectations that are being expressed are often directly safeguarded through the introduction of new laws. In this case those firms already committed in those areas are able to adapt to the laws rapidly and with lower costs, gaining for a certain period of time a competitive advantage over their less farsighted competitors.

The impact on personnel is quite complex. The highest level of *motivation and involvement* can improve the internal processes, both directly as well as through a reduction in *turnover* (Soloman & Hansen, 1985). This improvement effects the quality of the product/service (and thus the differentiation advantage) and/or productivity (thus the cost advantage). Moreover, the lower *turnover* reduces the need to sustain selection and training costs for the new personnel. A cost reduction is also obtained through lower absenteeism linked to greater job satisfaction.

Lastly, investment in CSR reduces the *risk level* of the firm. Here we refer above all to the probability of catastrophic events such as: environmental disasters, which have an enormous economic impact on the firm and its image; social scandals, such as the use of child labor, often the cause behind consumer boycotts; corporate crises due to a lack of transparency and the failure of the system of controls. A second type of risk has a less pervasive impact, but one that is equally important: workplace injuries. Safety measures that go beyond the legal obligations produce satisfaction in the personnel and help sustain productivity in the company. The reduction in the level of risk brings with it a cost benefit, since recognition by the financial operators of the effectiveness of the policies leads to a decrease in insurance premiums and passive interest rates, as well as a diminution in the average weighted cost of invested capital following the reduction in the cost of equity which, with conditions being equal, leads to an increase in the economic capital of the firm.

Let us now consider the chain of variables that link these initial effects – which are directly connected to the investment in CSR – to the firm's economic performance. The growth of sales and the reduction in costs leads to a more or less perceptible increase in income. In the case of listed companies, profit and the growth in sales are two of the main measures that effect the performance of the stock, together with the faith of investors.

The increase in the firm's economic and financial performance can have a positive feedback effect on investment in CSR. The greater availability of financial resources allows the legitimate needs of the various interested parties to be more fully satisfied.   In this sense a sort of positive feedback arises that leads to increasingly better economic, social and environmental results.

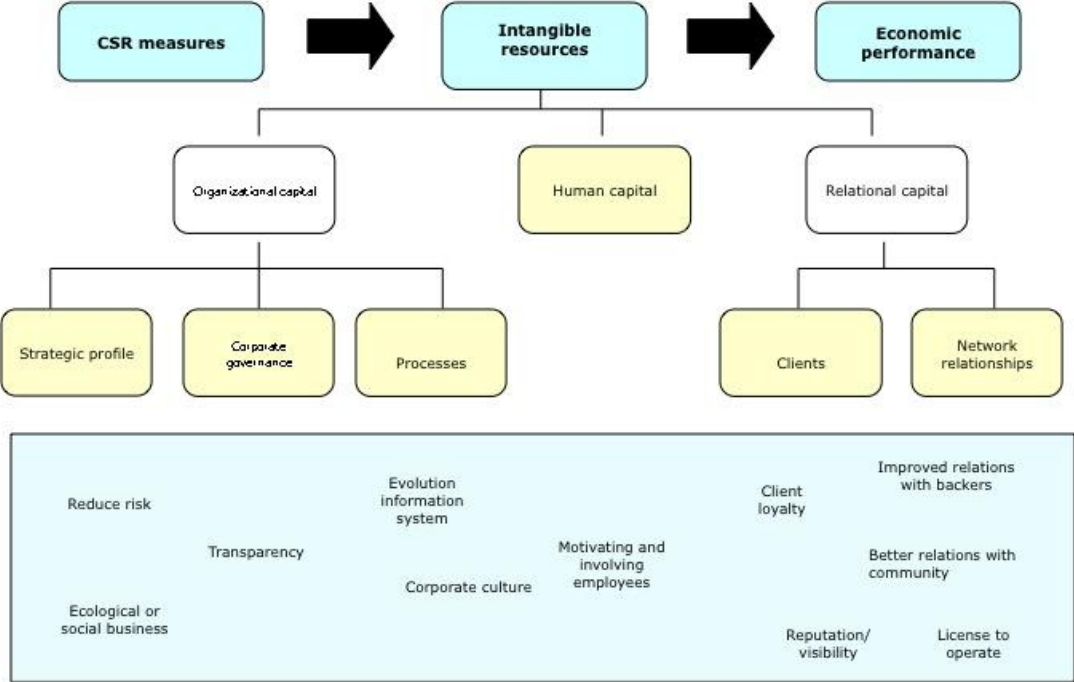
6. The case of Luxottica Group
Alpha
Luxottica characterizes the Italian present day society with its welfare program. It is a pioneer in its commitment to social responsibility towards the reality in which it operates, the environment and people. Responsibility and innovation are central to the history of Luxottica; they are the daily guidelines in business decisions and relationships with their stakeholders.

> Their mission is: to protect the eyes and enhance the looks of women and men throughout the world by making and marketing sun and optical eyewear of high technical and stylistic quality whilst respecting the environment in which Luxottica operates. As a market leader, Luxottica has the expertise, potential and responsibility to directly help people throughout the world to see better, including people who can't afford eyewear.
> This is why they created OneSight, a family of philanthropic programs designed to improve or restore people's sight through research and education, employee volunteering missions to developing nations, and donations. OneSight represents the soul of Luxottica and is based on 20 years of innovation and commitment.
> Social responsibility is the main lever with which Luxottica Group is committed to sustainable development of their business. It has shown great interest in people and this interest has declined in a vast corporate welfare program, characterized by a strong attachment to the environment and the desire for involvement of workers and trade union.
> Luxottica has created a new system of industrial relations that seeks to improve productive capacity, to improve the real wages of all workers and advocates promoting services for the workers themselves.
> Luxottica assume primary importance in the human aspects of organizational life, the quality of relationships between people, the satisfaction of their needs and satisfies their aspirations. The basic idea is that all these aspects affect the daily operation of company performance and therefore on the same market (Salomoni 2011).
> The company has focused primarily on "involvement" with the conviction that the organization is to make everyone feel part of them as belonging to a large family in which the contribution of the individual is precious for the good of all. All these concepts revolves around the idea that the sense of identification, the will of commitment and the personal adherence of the employees' to the activities and objectives of the company form, especially on the uncertainty of today's market scene, vital resources for business competitiveness.

7. Conclusion: reputation like intangible assets
Social responsibility and profitability are not two opposing terms: sustainability can bring to the firm both new business opportunities, than cost savings in addition to increasing consumer confidence towards responsible choices by companies.
The CSR then has a double meaning:
• economic in terms of social responsibility to consumers, of profit and improving relations with financial institutions.
• social, in terms of responsibility to the community, a better management of human resources, more effective prevention of risks, more efficient management of environmental resources and, in conclusion, in terms of improved corporate reputation.

From this perspective a comprehensive relational process and a continuing dialogue with the other social agents become essential elements for strategy formation (Grant, 2002), which are necessary to create a relationship of trust with the stakeholders (Vaccari, 1998) and a context of shared values. This allows the stakeholders to identify the role, values and the social objectives expected by those who directly or indirectly interact with the firm itself.

The duty to maximize profits by managers refers to a capital that is not only economically, but also human, social, environmental, this observation makes less absolute property rights of shareholders, which are related only to economic capital. (Young, 2010).

Fig. 1 – The link between CSR and economic performance (source Molteni 2004)


We can link CSR to the firm's economic performance through a causal network whose elements are for the most part *intangible resources* (Molteni, 2004a) capable of providing a fundamental contribution to the economic performance over time and that, according to time-tested views, can be divided into three classes (Edvinsson 2002), as shown in Fig. 1.

Organizational-structural capital, given by the structures, processes and technologies used by the firm; this also includes the organizational culture: that is, the set of values that characterize, unite and guide the organization;

human capital, which involves the knowledge competences and skills of those working in the organization;

C) relational capital; that is, the quality and quantity of relations that the business transformation has with the firm's stakeholders; good relations with suppliers, clients, institutions, and all the other stakeholders represent in general an intangible asset that can turn out to be of great value (Frey, 2003).

This shows the relevance of human capital and intangible assets (Gazzola & Meo Colombo, 2011) in capitalist production (Griliches, 1996) and the need for:

- *creativity*, by which products and processes are continually innovated (Christensen, 1997; Deephouse, 1999), thereby favouring applied scientific research and technological innovation (Von Hippel, 1995);
- *intelligence* in understanding internal and external processes, in order to rationalize the technical processes of production;
- *organizational learning* and the formation of learning organizations to meet the competitive challenges through new work rules (Schmitz Jr, 2001)
- *management control* (from the Decision Support System to Just-In-Time production) (Wilcox & Al.);
- *a good reputation* for the firm in its environment (Carter & Manaster, 1990).

The sharing and pursuit of objectives by means of the trust that is generated (Chirieleison, 2002) through the development of long-lasting relations leads to the spread of a culture (Kotter & Heskett, 1992) of shared responsibility. This culture is the condition for the organization's success (Parolin, 2002) as well as a source of long-term competitive advantage, which are useful and effective elements for the creation of value in the organization.

INVESTMENTS' VALUES AND EU FOUNDED PROJECTS

Ilieş Liviu
Babeş-Bolyai University Cluj Napoca Faculty of Economics and Business Administration

Mureşan Ioana Natalia*
Babeş-Bolyai University Cluj Napoca Faculty of Economics and Business Administration

Salaţa Irina Iulia
Babeş-Bolyai University Cluj Napoca Faculty of Economics and Business Administration

Being value based is one of the principles project management has to respect in order to be sustainable. Values are guidelines for human behavior that are shared by a large group of individuals. As projects can be differentiated from investments, also projects' values can be differentiated from investments' values. Connecting projects with investments' values contributes to projects' success, to a sustainable project management process and to a sustainable investment. The article explains the differences between investments and projects and presents how the investment's values can be related to the project. The topic is applicable when dealing with projects in general and can have benefic effects on investments initialized through projects financed by the European Union.

Key words: project, investment, value, project management

JEL classification: M10

1. Introduction

In a dynamic environment, with an increasing level of competitiveness, projects might be a solution for handling complexity. Projects are the principal way of creating and dealing with change (Cleland and Gareis, 2006), being used with increasing frequency in all fields.

Significant investments were made in Romania, before and after the accession to the European Union, through projects financed by the European Union in order to implement European strategies and to achieve sustainable development, one of the principal European objectives.

When dealing with projects and investments, not only goals achievement and results evaluation is important, analyzing and managing values is also a topic to be considered.

The article concentrates on how the investment's values can be related to the project, a current topic in project management, which can improve the results obtained through project implementation and increase the success chances of the project.

The central research question of this article is: "Can investment's values be related to the project?"

In order to answer the research questions, we present below the concepts of investment, project and values and the connection between values of investments and projects.

2. Methodology

Considering the high frequency of projects financed by the European Union in the last years in Romania, we consider that a better correlation between investments' values and projects might increase the efficiency of European funds spending. The goal of the research is to present a literature research on the connection between values of investments and projects. To conduct the research we:

- Define the concepts of projects, investments and values;
- Present the difference between projects and investments;

- Present the values that can be indentified in the literature in the case of investments and projects;
- Analyze the connection between the investment's values and the project – how can investment's values be transmitted and integrated into the project.

3. Projects, investments and values

Different approaches regarding the perception of projects exist (Gareis, 2005: 39-41). Projects can be seen as tasks with special characteristics: "A project is a temporary endeavor undertaken to create a unique product, service, or result. The temporary nature of projects indicates a definitive beginning and end" (PMI, 2008: 5).

Some authors also define projects as temporary organizations and social systems: A project is a temporary and transient organization surrounded by inherent uncertainty (Turner and Muller, 2003). A project can be defined as "a temporary organization of a project-oriented organization for the performance of a relatively unique, short to medium term, strategically important business process of medium or large complexity" (Gareis, 2005: 41). Organizations and also projects can be viewed as social systems which have clear boundaries to differentiate them themselves from their environment, according to social system theory (Gareis, 2005).

On the other hand, investment is defined traditionally as "the purchase of a financial product or other item of value with an expectation of favorable future returns" (Mills and Turner, 1995: 3). Investment involves diverting scarce resources – land, labor and capital – from the production of goods for current consumption to the production of capital goods (Campbell and Brown, 2003). According to Gareis, "investments are long-term employment of capital in assets, in customer relationships, in products, in the organization or in personnel" (Gareis, 2005: 48).

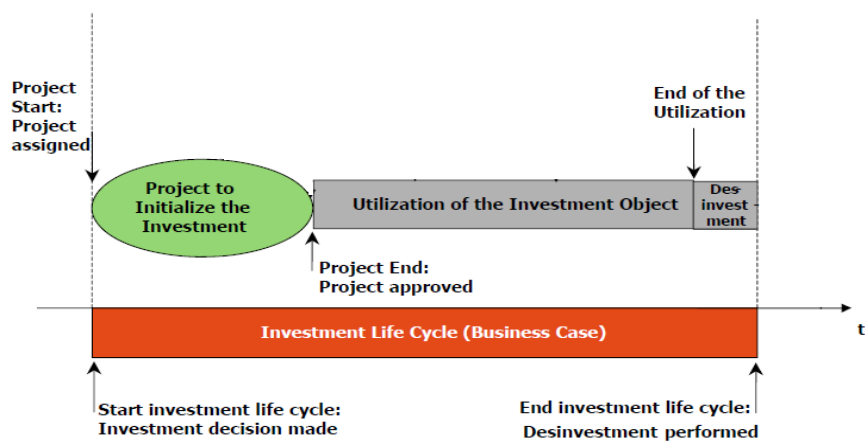
In project management literature the concepts of project and investment are often not differentiated (Gareis et al, 2010). But, *projects can be differentiated from investments*. Projects can be used to initialize an investment (Figure 1) (Gareis, 2005). Projects initialize investments in new products, markets, organizations, or infrastructures, contributing to the achievement of long-term objectives (Gareis et al, 2011).


Figure 1. The relationship between projects and investments
Source*: Gareis, 2005*

"Values are motives or frame of reference, which are fairly stable and influence actions" (Feather, 1999). Values are important and enduring beliefs or ideals shared by the members of a culture about what is good or desirable and what is not. Values exert major influence on the behavior of an individual and serve as broad guidelines in all situations (Business Dictionary).

Values are setting sense and meaning within a social system, they represent necessary constructional elements of a society and they can serve as guidelines for human behavior. Values can change over time and are influenced by many factors such as religion, age, sex, education etc. (Oelmüller, 1996).

Investments' values

In general, investments' values reflect the value of an asset to its owner, depending on his or her expectations and requirements (Business Dictionary).

From the economic point of view value is created when the net benefits resulting from an investment exceed the costs of capital (Copeland et al, 1995). Ex ante evaluation of investments require calculating the Net Present Value (NPV) by discounting future expected cash flows against the costs of capital.

But not just economic values are to be considered when talking about investments. Other types of values also have an important influence in investments, being strongly related to investor's values and beliefs, the type of investment and the desired outcomes.

It is difficult to set a border between values in a complex and dynamic business environment. Usually investment decisions are influenced by more than one value type. A concept which might be used as an example of mixing the values when dealing with investments is the *socially responsible investment*. Socially responsible investment is broadly defined as the integration of personal values, social considerations and economic factors into the investment decision. Socially responsible investment has emerged in recent years as a fashionable and increasingly popular topic.

Projects' values

Contrary to traditional professions like doctors or lawyers, no commonly recognized professional ethics or values nor universally accepted codes of professional conduct exist for project, programs and portfolio managers (IPMA).

Values appear to significantly contribute to a compelling sense of purpose beyond making money (Mengel et al, 2009). For project environments in particular, an attractive vision and a shared set of values and beliefs is important (Keegan and Den Hartog, 2004; Kendra and Taplin, 2004), being a significant project success factor.

"Project values provide benchmarks for what is considered good, valuable and desirable in a project. They determine the behavior of the members of the project organization consciously and unconsciously and provide orientation for their actions" (Gareis, 2005: 260).

In defining project values the following questions can be used as an aid (Gareis, 2005):
- What is specific about the project results?
- What is important and what is not important to the project team?
- What differentiate the project from other projects?

4. The connection between values of investments and projects

As social systems, projects develop their own culture, identity and their own values. Investments unlike projects are non-social systems; therefore they cannot have their own values. It is the investor and the investing organization that can develop and act on values which they can transfer to the project organization. The investor has to communicate their aimed values parallel to their investment. When speaking about investments initialized through projects financed by EU, the investor is considered to be the European Commission and also the funding recipient that has the obligation to co-finance the implementation of the project.

The investor as an important stakeholder

The concept of stakeholders was first approached in 1984 by Freeman that defines stakeholders as "any group or individuals who can influence or are influenced by an organization's objectives" (Freeman, 1984: 46). This definition is considered a starting point for stakeholder theory (Achterkamp and Vos, 2008). In 1986 Cleland related stakeholders' theory to project

management, highlighting the importance of identifying stakeholders, their classification and analysis. In the Project Cycle Management guide (2004) stakeholders are defined as persons, groups of people, institutions, professional organizations, companies, etc., which can be related, directly or indirectly to the project or program (European Commission, 2004).

Many authors have stressed the importance of stakeholders in project management. Littau, Adlbrecht and Jujagiri published in 2010 a meta-analysis that summarizes developments in stakeholder theory literature related to project management. Of the 2.026 articles published in the period 1984-2009, in the most important international project management journals, they identified 116 articles on stakeholders, meaning that 5.7% of the articles published in these journals mentioned the word stakeholder in the title, abstract or keywords section (Littau et al, 2010).

Identifying and analyzing the stakeholders' expectations is an important step in project management. Therefore, the question which stakeholders should be consulted or how they should be involved in the values formation process, is of great importance. From the project's point of view, the investor always plays an important role when it comes to stakeholder priorities. On the other hand, an investor could have different investment projects with different priorities in his portfolio.

Project management approaches start to integrate stakeholder value judgments into the project process. As the investor is one of the main stakeholders the value transmission process between the investor and the project has to be considered.

Transmission of values between the investor and the project

Depending on his priorities, the investor will direct his influence on the project organization in different ways. The value transmission can take place active or passive. An active transmission requires active communication though different tools. The danger of the passive transmission is the assumption of the leading role of the investor by the project organization, following the assumption of his values. *"Leaders embed their values within a culture because people are guided by what leaders pay attention to, measure and control"* (Mills et al, 2009).

Project organizations will consider the values of their investors, especially when they play the role of the dominant stakeholder. If these values are not communicated properly, the project organization will try to interpret the behavior of the stakeholder.

Values can be transmitted easier between the investor and the project, if the management paradigm of the investor and of the project is similar. Project managers should have an understanding of their own values, those of the organization (project) and of the investor (Mills et al, 2009).

Considering the project duration, the transmission of values as a management tool between the investor and the project will play an important role for short term projects as well as for mid and long term projects. As the creation of values takes time, mid and long term projects will develop their own values, similar or different of those of the investor. For short term projects it is more likely to adopt the values of the dominant stakeholder. The evolution of project values in time is a topic the project management and the investors have to consider.

Considering the phases of the investment, conception and realization projects can be differentiated (Gareis and Stummer, 2008). Concept development projects require openness and creativity. It might be necessary to deal with different project values depending on the phase of the investment. To maintain specific values through the different phases, the investor, as one of the main stakeholders, has to participate in all investment and project phases.

Integrating the values of the investor into the project

Project values and the investor's values can positively affect employee satisfaction, work attitude, commitment, effectiveness and staff turnover (Mills et al, 2009). Values are a management tool within organizations and projects. Priorities, defined as values statements alone, will not be

enough to guide day-to-day activity. They can be communicated with the aid of a project mission statement, but the main multipliers of values are the role models.

Stakeholders' values and expectations can be integrated into the project. VALiD (Value in Design) is a new approach to value delivery that integrates stakeholder value judgments into the project process (VALiD). According to its creators, the approach has proven effective in construction projects and building management in the pharmaceutical, education and project management sectors. The concept is based on the following principles:

- value delivery is the goal of all projects;
- value is subjective and based upon stakeholders' underlying values;
- successful projects deliver value for all stakeholders;
- project teams have provider and customer stakeholders, each with their own understanding of value and expectation for its delivery;
- value is judged by each stakeholder from their own perspective and aggregated to provide a project view;
- effective project value delivery requires an ongoing dialogue between all stakeholders to negotiate appropriate compromises and balance stakeholder views (VALiD).

Value is the trade-off between what each stakeholder gets and what they have to give up. It is essential that value from each stakeholder's perspective is analyzed and understood. According to the VALiD framework there are three elements which contribute to the integration of values into the project: understanding values, defining values and assessing value proposition. Through this elements VALiD helps stakeholders express the "get" and the "give" of their value as the benefits they seek from the project, the sacrifices they are willing to make in order to get those benefits, and the resources they consume in doing so (VALiD).

5. Conclusions

Values are the basis of human behavior and important factors in the decision making process. Understanding and analyzing the values when dealing with projects and investments contributes to better results and creating sustainable investments.

The principal way of connecting the investment's values to the project is through the investor, as one of the most important stakeholders. The European Commission, as the investor, in EU funded projects defines its values through the objectives formulated in its policies. But it is not enough to communicate the values as a statement. The investor has to be involved in all the investment and project phases in order to ensure that the values are correctly transmitted and understood. Transmitting and integrating the values of the investment into the project increases the efficiency of European funds and has positive effects when dealing with projects in general.

Considering the complexity and importance of the topic, future research can be done in this field. Using interviews or focus groups to find out the stakeholders' opinion on this topic might be a future point of interest in our research.

SOME REFLECTIONS ON FLEXICURITY-THE EUROPEAN APPROACH TO LABOUR MARKET POLICY

Ionete Anca
The Academy of Economic Studies Bucharest Faculty of International Business and Economics

The notion of "flexicurity" promises to overcome the tensions between the labour market flexibility on the one hand and social security on the other hand, by offering "the best of both worlds". In this review the development of the concept will be set against the background of changed economic circumstances in the last two decades. Flexicurity is seen as a way to preserve the European Social Model while maintaining and improving the competitiveness of the European Union. It is argued that, in the context of globalisation and technological change which place greater demands on business to adapt continuously, high levels of employment security will not depend only on protection of workers' specific job, but mainly on the means for workers to stay on the job market, manage smooth transitions between jobs and make progress in their careers. At the end of the day, the aim of flexicurity policies should be to ensure the welfare and well-being of our societies and all their members, now and in the future. It can therefore be argued that flexicurity is ultimately about security and sustainability. At the same time, the European ideas and principles on flexicurity first and foremost need to be seen as a framework which may offer inspiration and guidance to Member States to review and improve their labour markets in terms of establishing a sound balance between flexibility and security. Member States can and should come up with their tailor-made policies and regulations that are geared towards their specific history, starting-position and political, institutional and cultural context. As quasi prototypes of flexicurity, policies pursued particularly in Denmark and the Netherlands have been portrayed as having successfully achieved new combinations between (greater) labour market flexibility without compromising social protection. At this point in time, it remains to be seen whether flexicurity will be more than a buzzword which has outlived its temporary political purpose or an enduring component of particularly European approach of combining employment and social policies. The current paper is realized in the doctoral programme entitled "PhD in economics at the standards of European knowledge-DoEsEc", scientific coordinator Prof. PhD. Gabriela Drăgan, institution the Academy of Economic Studies Bucharest, Faculty of International Business and Economics, period of research 2009-2012.

Keywords: flexicurity, labour market policy, unemployment benefits, employment protection, European Union.
JEL classification: J08.

I. Introduction

In recent decades, European labour markets have been characterised as lacking sufficient flexibility for a new and more internationalized economy and a more dynamic nature of labour demand. At the same time, traditional social protection programmes, largely modelled on male dominated, full-time and continuous career patterns, have become both increasingly inadequate for a growing section of employees engaged in non-standard types of employment and more difficult to sustain financially due to economic and demographic pressures. Clearly, a tension has arisen between demands for greater labour market flexibility on the one hand and the need to provide adequate levels of social protection for workers and their families on the other. In this context, much of the literature on labour markets has emphasized the existence of a potential trade-off between flexibility and security.

The notion of "flexicurity" indicates a carefully balanced combination of flexibility where it matters for job creation and protection where it is needed for social security. Flexicurity is based on the co-ordination of employment and social policies. Employment policies must create the best conditions for job growth, while social policies must guarantee acceptable levels of economic and social security to all, including those who enter deregulated labour markets. Some countries, notably Denmark and the Netherlands, have been regarded as models of how labour markets can be made more dynamic without compromising social protection. Recently, the policy theme has also been prominent in several EU activities, most notably the European Employment Strategy.

II. The concept of flexicurity
From the perspective of neo-liberal theory, persistent levels of unemployment and widespread long-term unemployment in many European countries underline the need for greater flexibilization and the deregulation of labour markets. At the same time societal trends of individualization and pluralization of lifestyles have questioned whether the "standard employment contract" should remain a reference point within European welfare states. In recent decades,"atypical"forms of labour market participation have gained weight particularly in countries with restrictive employment legislation. However, while this trend might have enhanced the flexibility of firms, it has arguably weakened the degree of employment and income security for many, as well as promoted segmented labour markets with a coexistence of well protected core sectors and relatively unprotected sectors "at the margin". As a consequence, greater flexibility needs to be reconciled with satisfactory levels of security, which in turn is also a precondition for the improvement of skills and a more sustainable integration into the labour market. In short, ongoing labour market reform would need to be accompanied with appropriate types of welfare state reform.

However, the European Commission (2006) has criticized that often "policies aim to increase either flexibility for enterprises or security for workers; as a result, they neutralise or contradict each other" (European Commission 2006: 5). Flexicurity principles might be seen as a response to this one-sided approach, satisfying the needs of both employers and workers. The concept rests on the assumption that flexibility and security are not contradictory, but complementary.

The idea of flexicurity dates back to developments and debates in two European countries in particular, i.e. Denmark and the Netherlands. According to some observers, the concept of flexicurity was first used by the Dutch sociologist Hans Adriaansens in the mid-1990s in connection with the Dutch Flexibility and Security Act and the Act concerning the Allocation of Workers via Intermediaries (Wilthagen and Tros 2004: 167). Arguably, the neologism was picked up by academics in the Netherlands (e.g. Wilthagen, 1998) and subsequently in other European countries, such as Denmark, Belgium and Germany, before reaching the European Commission's agenda, as well as other European actors (Keune and Jepsen, 2006).

There is no universally agreed definition of flexicurity. Some authors define the concept rather broadly, for example as a policy aimed at "achieving a new balance between flexibility and security"(Klammer and Tillmann 2001: 15) or as "secured flexible employment"by reconciling labour market flexibility with measures to counter growing social exclusion and the emergence of a class of working poor (Ferrera, Hemerijck and Rhodes 2001: 120). The European Commission defines flexicurity simply as "an integrated strategy to enhance, at the same time, flexibility and security in the labour market"(European Commission 2006: 5).

The absence of a common definition is underlined also by the fact that at times flexicurity has been used to describe a type of public policy and at other times as a condition of a labour market, even by the same authors. For example, Wilthagen and Rogowski (2002) regard flexicurity as a deliberative and coordinated strategy for weaker labour market groups :

"A policy strategy that attempts, synchronically and in a deliberate way, to enhance the flexibility of labour markets, work organisation and labour relations on the one hand, and to enhance security-employment security and social security-notably for weaker groups in and outside the labour market, on the other hand". (Wilthagen and Rogowski 2002: 250).

On the other hand, Wilthagen and Tros (2004) suggest a more institutional definition:

"Flexicurity is (1) a degree of job, employment, income and 'combination'security that facilitates the labour market careers and biographies of workers with a relatively weak position and allows for enduring and high quality labour market participation and social inclusion, while at the same time providing (2) a degree of numerical (both external and internal), functional and wage flexibility that allows for labour markets' (and individual companies') timely and adequate adjustment to changing conditions in order to maintain and enhance competitiveness and productivity". (Wilthagen and Tros 2004: 170)

Turning to its components, four different types of flexibility and security have been identified respectively:

- External-numerical flexibility: the ease of hiring and firing workers and the use of flexible forms of labour contracts.
- Internal-numerical flexibility: the ability of companies to meet market fluctuations (e.g. via over-time, flexi-time, part time, temporary work, casual work or sub-contracting).
- Functional flexibility: the ability of firms to adjust and deploy the skills of their employees to match changing working task requirements.
- Payment or wage flexibility: the ability to introduce variable pay based on performance or results. (Wilthagen and Tros 2003, 2004).

Similar to types of flexibility, four different forms of security are usually presented in the literature:

- Job security: the certainty of retaining a specific job (with the same employer), e.g. via employment protection legislation.
- Employment security: the certainty of remaining in paid work (but not necessarily in the same job or with the same employer), e.g. via training and education (and high levels of employment).
- Income security: the certainty of receiving adequate and stable levels of income in the event that paid work is interrupted or terminated.
- Combination security: the reliance on being able to combine work with other-notably family-responsibilities and commitments, often discussed under the heading of "work-life balance". (Wilthagen and Tros 2003, 2004).

Flexicurity policies can be analysed as types of combinations between these different forms of flexibility and security, which might involve individual workers, groups of workers, or certain sectors or the economy as a whole.

III. Diverse labour market problems, policy components and obstacles to more flexicurity

According to the European Expert Group on Flexicurity , one element for the implementation and success of flexicurity policy is a supportive and productive social dialogue between the social partners and public authorities. Recognizing differences in labour market conditions and challenges, the Expert Group is less prescriptive in other respects, offering alternative pathways to flexicurity (see also European Commission 2007: 3). These are:

- Tackling contractual segmentation.
- Developing flexicurity in the workplace and offering transition security.
- Tackling skills and opportunity gaps among the workforce.
- Improving opportunities for benefit recipients and informally employed workers.

These different security pathways respond to different problems that are visible, to differing degrees, in European labour markets. For example, some countries might be faced with the

problem of segmented labour markets, characterized by a large share of "outsiders"lacking security and limited opportunity to make transitions to more permanent and secure jobs due to the impact of strict employment regulation. Such a situation might be regarded as typical for Southern European countries, and the first pathway seems more relevant there. Another challenge might be labour markets with a large share of workers with high levels of job security, especially within large industrial firms, but few opportunities to find new employment in the event of redundancy. Labour flexibility is thus generally confined to the firm level, labour turnover fairly low and long-term unemployment typically high. Such a challenge might be most commonly found in some continental Western European countries, and the second flexicurity pathway is intended to offer a response.

The third pathway responds to the challenge of flexible labour markets with a large share of low-skilled workers and a clear segmentation between low-paid and high-paid workers. Accordingly raising job quality in the low-skilled sector and tackling low productivity rates are the major policy priorities. A country which might fit this description is the United Kingdom. Finally, the fourth pathway seems particularly relevant to the situation of Central and Eastern European transition countries, where high proportions of non-active working age people receive long-term benefits and face few activation incentives. This is coupled with problems of low productivity and high numbers of workers employed in the informal sector.

The European Commission (2007) proposes to address these particular challenges by focusing on four policy domains:
- Flexible and reliable employment protection arrangements.
- Comprehensive lifelong learning strategies.
- Effective active labour market policies.
- Modern social security systems. (European Commission 2007: 5).

Given that these four areas are often regarded as the core components of flexicurity policy, I will briefly review these in turn.

According to analytical evidence, strict employment protection appears to reduce the numbers of dismissals, but hampers the transition from unemployment to work (OECD 2006: 34). Arguably it thus contributes to divisions between labour market insiders and outsiders, particularly where regulations differentiate between regular and other forms of employment contracts. Boeri et al. (2003) showed that only few countries reduced the strictness of employment protection for regular workers in recent years, while the majority of changes in employment protection took place at the margin (Boeri et al 2003:16). Deregulation at the margin of the labour market tends to favour the creation of segmented labour markets in which employees with atypical contracts carry the burden of adjustment to economic shocks. This has led to more precarious employment, a lack of adequate provision of training for those with atypical contracts, and negative impacts on productivity.

Clearly, the effect of employment protection legislation is contested. Those in favour of liberalization have argued that stringent regulation tends to encourage less dynamic labour markets, worsening the employment prospects of women, youths and older workers. However, whether employment protection reduces labour turnover and prolongs unemployment is debatable. For example, provided that severance payments and advance notice of termination are chosen optimally, Pissarides (2001) argues that unemployment insurance does not hamper job creation (Pissarides 2001: 140). Moreover, the positive effects of employment protection, such as providing incentives to enterprises to invest in training, promoting loyalty and raising productivity of employees, has been widely acknowledged (European Commission 2007: 6).

Second, lifelong learning has become another buzzword within the current EU debate on flexicurity. High participation in lifelong learning is positively associated with high employment and low long-term unemployment. Encouraging flexible labour markets and ensuring high levels of security will only be effective if workers are given the means to adapt to change and to make

progress in their career. Ongoing education and training is seen as the key to employability and adaptability throughout an individual's life course, thereby also contributing to the high productivity economic model the EU aspires to. Investment in human resources over the life course and strategies of so-called active ageing are strongly promoted by the EU as a response to rapid technological change and innovation in the face of demographic pressure. It is seen as increasing both the competitiveness of firms and the long term employability of workers (European Commission 2007: 10).

Third, unemployment benefit systems are now more readily connected with active labour market programmes. Depending on their design, unemployment benefits are able to protect more effectively against labour market risks than employment protection, offsetting negative income consequences during job changes. Their arguably negative effects on the intensity of job search activities is regarded to be counteracted by efficient activation strategies that coordinate unemployment benefits with active labour market policies. Finally, supporting transitions between jobs as well as from unemployment to jobs, active labour market schemes are regarded as essential for achieving a balance between flexibility and employment security while reducing the risk of labour market segmentation and lowering aggregate unemployment (European Commission 2006:17; OECD 2006: 12). Closely connected are policies aimed at customizing career advice and supporting equal opportunities, e.g. by improving the so-called "work-life balance" (European Commission 2006: 17).

The flexicurity debate emphasizes the interactions between these policies and institutions; flexicurity might be seen as an integrated approach aiming to optimise the combination between these four components.

IV. Concluding remarks

Despite attempts to arrive at a more precise definition, the review has shown that the concept of flexicurity has remained ambiguous. To some extent this might not be surprising given its multi-dimensional character and the emphasis on particular policy components in some countries but not in others. In addition, flexicurity has certainly a buzzword character with apparently little regard for policies which have been practiced for some time, such as active labour market policies and lifelong learning programmes. Adopting a critical, if not cynical approach, it could be argued that to some extent flexicurity has replaced the previous EU-discourse on activation and is likely to be replaced by the next fashionable and politically useful concept before long.

Clearly, for analytical purposes the concept of flexicurity needs to be specified in order to be employed in a meaningful way. However, its vagueness might have political advantages, especially at an EU discourse level, making it acceptable to a large number of actors. Yet, while its openness makes the idea of flexicurity easy to disperse to EU Member States in a sort of "pick-and-choose" approach, there is a risk of loosing the crucial emphasis put on the simultaneousness of flexibility and security. Thus, many observers might be forgiven to suspect the term to be little more than an instrument for an old agenda aimed at making labour markets more flexible and curtailing employees' rights. At this point in time, it remains to be seen whether flexicurity will be more than a buzzword which has outlived its temporary political purpose or an enduring component of particularly European approach of combining employment and social policies.

THE WORLDS OF FLEXICURITY-LABOUR MARKET POLICIES IN EUROPE

Ionete Anca
The Academy of Economic Studies Bucharest Faculty of International Business and Economics

In the past, European integration has concentrated first of all on profound economic integration, creating the Single Market with common rules and regulations throughout the European Union. European integration has been more limited in the labour market and social field, where the national state remains the dominant level of regulation. Although linguistically somewhat strange, "flexicurity", the combination of labour market flexibility and security for employees, has become recently a much praised cornerstone of European labour market policies. Obviously, in an environment with rapid technical progress and frequently changing market conditions, employers need to manage their labour force flexibly. In order to achieve this flexibility without creating an unbearable situation for employees, security is the second pillar of the concept. As such, the concept looks like an innovative European way of consolidating economic and social interests, although some argue that much flexibility is gained while the security aspect is being neglected. Flexicurity forms a part of efforts to experiment with new forms of governance in the social and employment law of the European Union. It is compatible with attempts to introduce policies at supranational level that can influence self-transformation processes at the level of Member States in order to reach overarching economic goals defined by the Lisbon agenda. It is central in the debate over the reform of labour law systems since it is a key, if not the key concept in the 2006 Green Paper on modernising labour law in the European Union. The concept has been successfully adopted in some European countries, notably Denmark and the Netherlands. The experience in these two countries will thus be described in some detail, followed by a review of flexicurity-type policies in other European countries. The current paper is realized in the doctoral programme entitled "PhD in economics at the standards of European knowledge-DoEsEc", scientific coordinator Prof. PhD. Gabriela Drăgan, institution the Academy of Economic Studies Bucharest, Faculty of International Business and Economics, period of research 2009-2012.

Keywords: flexicurity, European Social Model, labour market reform, Denmark, the Netherlands. JEL classification: J08.

I. Introduction

One of the main challenges the European Union is currently facing is how, in the era of globalization and ageing, to live up to European citizens' expectation of providing a distinct European Social Model.

At the European level, the desire is expressed to maintain a solid balance between social and economic goals. The vexed question is how this model should be further developed in a concrete manner. As of 2006, this challenging question has specifically been dealt with under the heading of "flexicurity". The objective of flexicurity strategies is to combine employment and income security with flexibility in labour markets, work organization and labour relations. This approach should transcend the simple trade-off between flexibility and security, where the former is seen to be in the exclusive interest of the employer and the latter in the interest of the employee. In a flexicurity strategy, flexibility and security should not be seen as opposites, but as mutually supportive labour market components.

Although initiated and formulated at the European level, for several reasons, the flexicurity approach has to be developed into concrete policies and regulations at the Member State level.

II. Flexicurity in Denmark

The Danish model of flexicurity rests on the combination of three elements: flexible labour markets, generous unemployment support and a strong emphasis on activation. This combination has become known as the "golden triangle"of Danish labour market policy (see, e.g., Clasen and Viebrock 2008: 440). In a nutshell, the model promotes high occupational and geographical labour mobility via low employment protection, compensated by generous unemployment benefits and ambitious active labour market policies aimed at skill improvement and activation of the unemployed. The Danish model combines high external-numerical flexibility (little protection against dismissal) with high levels of income security (generous unemployment benefits) and high levels of employment security (labour market policy based on a right for retraining). Crucially, the concept of job security is replaced by employment security (European Commission 2006: 5). Danish flexicurity policy might also be described as embracing all four components singled out by the EU, as it brings together flexible work arrangements with effective social security, active labour market policies and lifelong learning. Illustrative are policies introduced in the first half of the 1990s (and subsequently revised and scaled back), such as paid leave arrangements for childcare and sabbaticals, as well as for continued and supplementary professional development and training. The flexicurity idea here is that such policies can be beneficial to the firm, employees (on training leave), as well as unemployed persons because employers receive a grant which covers the cost of hiring an unemployed person replacing employees on leave (Wilthagen 2007: 62).

The role of the social partners in this model is pivotal. The liberal employment protection system with its relatively easy hiring and firing of workers became acceptable for trade unions due to the existence of a generous and state-supported but mainly trade-union based unemployment insurance system. Vice versa, for employers generous unemployment benefits became acceptable as they facilitate flexible responses to shifting market demands by laying off workers (Clasen and Viebrock 2008: 434). The third element in the form of active labour market policy is crucial as it supports the flow of workers between unemployment and employment by upgrading the skills of unemployed people through training.

As a model associated with a positive labour market performance it has attracted considerable international interest from policy makers and academics alike. Since the early 1990s, employment rates in Denmark in both the public and the private sector increased substantially and unemployment declined from more than 12% in 1993 to just about 5% in 2001. This trend has been attributed to the successful combination of flexibility measures, often linked to a globalized liberal market economy, and a traditional Scandinavian welfare state with its extensive systems of social security protecting citizens from the negative consequences of structural changes-hence "flexicurity". Another notable feature of the Danish system is the avoidance of a low-wage segment of the labour market (the "working poor"), which is typical for many liberal economies as such the US.

III. Flexicurity in the Netherlands

The key feature of Dutch flexicurity is the combination of atypical, flexible types of work with social security rights which are similar to those for persons in standard employment. In short, the approach can be described as "normalizing non-standard work"(Visser 2003: 42; Wilthagen 2007: 3-5). Measures have been taken to spread work, care and education more evenly over the lifecycle. A fiscally supported voluntary savings scheme enables workers to save a percentage of their wage to cover periods of leave for care, education or other reasons (European Commission 2006: 6-8). Active labour market programmes have been extended and regulations have been introduced to provide temporary agency workers with employment protection, rights to training, wage guarantees and supplementary pensions (Wilthagen 2007: 10). In short, the position of

workers on temporary contracts has been strengthened without compromising labour market flexibility (European Commission 2007: 5).

The Dutch model of flexicurity has to be understood also in connection with changes to the system of dismissal law and regulation. In the Netherlands, a rather complicated dual system of dismissal law existed which granted strong protection for workers employed under traditional employment contracts while workers in flexible employment, in particular temporary agency workers, were faced with a high level of insecurity. Aiming to reconcile the interests of employers and workers, and strengthening both competitiveness and social protection (Auer 2002: 36), in 1997 the so-called "Flexibility and Security Bill"addressed this problem, introducing flexibilization (in the form of a slight reduction of dismissal protection in standard employment), far-reaching liberalization of the temporary work market and improving types of security (e.g. more employment and employability security for non-standard workers). However, critics have pointed out that whereas part-time workers have gained from better social protection, other groups such as so-called "flex-workers"have remained disadvantaged (see Visser 2003: 45). Recognizing once again the four components of flexicurity (flexible and reliable contractual arrangements, comprehensive lifelong learning strategies, effective active labour market policies, modern social security systems) as outlined by the European Expert Committee on Flexicurity (2007), there is perhaps less emphasis on activation strategies than in the Danish case and a more important role for other aspects such as temporary work agencies. However, as in Demark, flexicurity policies have been portrayed as a prime cause for the positive labour market performance in the Netherlands (see, e.g. OECD 2006: 16). Similarly, the role of the social partners and social dialogue in developing and legitimising flexicurity policies has been emphasized in both countries (see, e.g., Visser 2003: 34-37).

In sum, both Denmark and the Netherlands illustrate that alternative ways of combining flexibility with security are not only theoretically but also practically feasible. It has to be noted, however, that what is now called "flexicurity"is not the result of a rational policy design in either country, but the outcome of gradual processes over time, as well as political struggles and compromises (Auer 2002: 70).

IV. Flexicurity in other European countries

While Denmark and the Netherlands have been at the centre of the debate on flexicurity, many other European countries have introduced policies or initiatives explicitly aimed at reconciling flexibility with security. Clearly, such initiatives cannot be reviewed in full here. However, a few examples from different European regions with different welfare state and labour market regimes have been selected here as illustration of the multiplicity of pathways to flexicurity as suggested by the European Commission. Here, I will refer to relevant policies in Austria, Central and Eastern European countries, Ireland and Spain.

A frequently cited country which has introduced successful flexicurity policies is Austria (European Commission 2007: 10). The Austrian approach is characterized by average levels of employment protection and unemployment benefits relative to the EU-15 countries, relatively high spending on active labour market programmes and a reliance on decentralized public employment services. Similar to other countries, the trend in Austria has been to shift an erstwhile emphasis on job security to employment security. Auer (2002) claims that despite Austria's tighter employment protection system and a lower generosity of unemployment benefits, the actual trade-off between employment protection at firm level and social protection at macro level seems to work just as well as in Denmark (Auer 2002: 38). One facilitating factor here might be the deeply entrenched social partnership which smoothed the process of labour market adaptation and helped to promote the idea of flexicurity.

Initiatives to increase both flexibility and security have included life long learning measures. For example, in 1998, it was made possible for employees to take paid leave for up to 12 months for

further education without additional costs for the employers. Other policies include the right for parents of young children to switch to part-time work, covered by full redundancy protection and the right to revert back to the previous working time (European Commission 2006: 14-15). Another policy component is the easing of qualifying conditions for severance pay, which itself was reformed. Whereas in the former system workers would loose accumulated rights to severance pay when changing jobs, entitlements within new system are transferable, thus reducing disincentives to labour mobility. Furthermore, Labour Foundations are easing the transition between jobs in case of threatened mass dismissals, applying principles of early intervention and joint action by all public and private parties concerned (European Commission 2007: 11; OECD 2006: 26).

In many Central and Eastern European countries, economic recovery has often proved elusive or unsustainable, with negative consequences for employment (Cazes and Nesporova 2007: 14). Despite important cross-country differences, unemployment is still high and participation rates even declining in some countries. The sudden exposure to global market competition has forced enterprises to rationalise production and contain labour costs. This mainly took place in the form of downsizing, introducing fixed term contracts or resorting to informal employment. Addressing firms' flexibility needs measures were facilitated by still weak or newly established labour market institutions and policies. Tendencies towards increasingly flexible forms of employment and high informal employment and the consequent weakening of workers' employment and social security position put pressure on governments to find a better balance between the flexibility demanded by firms and effective assistance for employees (Cazes and Nesporova 2007: 23). The International Labour Office (ILO) has sponsored a large initiative to spread best practice on flexicurity in transition economies.

Legislative and institutional reform processes were thus influenced by typical Western labour market institutions and policies such as collective bargaining systems, labour taxation, unemployment benefit schemes and active labour market policies. The outcomes have been diverse across transition countries, influenced by economic performance, trade union strength, social dialogue and national cultures. For example, the Baltic States and some Central European countries have implemented flexibility/protection patterns similar to Western Europe, further supported by the EU accession process. By contrast, troubled by military conflicts and economic problems, labour market rigidities in the Balkan countries have persisted, as well as weak employment and income security for workers. Overall, given a low demand for labour and the perception of high job insecurity, there are considerable obstacles towards increasing labour mobility and flexibility in transition countries. Cazes and Nesporova (2007) conclude that stricter employment protection has at times contributed towards improved economic activity and employment performance, and positive effects have been identified for collective bargaining and active labour market policy, but there are indications of labour market segmentation between insiders and outsiders too (Cazes and Nesporova 2007: 80).

In contrast with transition countries, Ireland's employment growth has been remarkable, both in terms of in part-time and full-time jobs, mainly in the private sector (Auer 2002: 56). Unemployment benefit levels are modest but spending on active labour market programmes comparatively high, including subsidized employment. Similarly to Austria, Denmark and the Netherlands, public employment service structures have been changed dramatically in a move towards decentralization, localization and greater scope for private placement. Although Ireland has overcome past problems of high unemployment and a slow economic growth, a problem remains in low educational levels of older workers. In 2006, the so-called "Towards 2016"agreement was reached between the social partners to take up this challenge in a comprehensive way. It identified the need for participation, productivity and activation, with a special focus on the long-term unemployed, youths and those who are furthest from the labour market. Skills upgrading has been aimed at lower-skilled and vulnerable workers. Funding has

been increased for workplace learning and tackling illiterate and innumeracy problems (European Commission 2007: 18). In 2005, a "National Workplace Strategy" was launched with a view to managing change and innovation in a knowledge-based society. A key focus is on a good co-ordination between the different departments and agencies as well as the social partners with regard to policies of employment, labour market, training, education, social security and enterprise development (Wilthagen 2007: 42).

Finally, a policy process based on social dialogue facilitating flexicurity policies can be observed in Spain. Going back to the 1980s, reforms of a restrictive system of dismissal protection increased flexibility at the margins through liberalising fixed-term contracts and temporary work agencies, while regulations concerning core jobs remained virtually unchanged. Ensuing employment growth was mainly restricted to the flexible "outsider" labour market and transitions from fixed-term or part-time to open-ended or full-time contracts remained difficult, thus encouraging segmented labour markets. Fixed-term workers represent about a third of the total employment (European Commission 2007: 21) and mainly consist of the young. They often receive lower wages and have only limited access to internal further training (Wilthagen 2007: 129).

The strong growth of fixed-term employment not only gradually transformed the Spanish labour market, it also improved the political influence of fixed-term (and part-time) workers, thereby facilitating attempts at modifying employment protection (Valdés Dal-Ré 2004: 256). Indeed, subsequent reforms eased dismissal regulations of the insider labor market and introduced security elements for fixed-term employees, albeit not fully overcoming the dual character of the Spanish labour market. For example, following a breakthrough in Spanish industrial relations at the end of 2001, the social partners agreed on the need to reconcile flexibility and security (Valdés Dal-Ré 2004: 258). Since then, policy makers have been able to exploit potential policy complementarities not available before. Most labour markets reforms in Spain were formulated in trilateral negotiations and often implied trade-offs, such as easing dismissal protection in exchange for stricter regulation of temporary agency work . For example, in May 2008, the social partners signed a comprehensive agreement to curtail the excessive use of fixed-term contracts. Since then, employees having signed two or more fixed-term contracts with the same company and having worked in the same post for more than 24 months, automatically acquire an open-ended contract. In addition, while spending on passive and active labour market policies used to be comparatively low in Spain, activation policies began to be implemented in 2002, stimulated by EU recommendations and funding.

For flexicurity to work in Spain, it must first challenge the startling levels of unemployment and gain the consent of social partners. The implementation of flexicurity via the Labour Market Reform Package was strongly resisted by social partners, in particular the trade unions. This resistance culminated in a general strike in September 2010. In some the largest issue facing the implementation of flexicurity in Spain are the trade unions. Trade union support for further flexicurity implementation will be necessary if further labour market reforms are to transform the Spanish labour market.

V. Conclusions

Flexicurity as a concept fits well into the debate on a European Social Model. It gives guidance for welfare reform processes at the level of the Member States who have to balance existing systems of welfare and employment rights and institutions with demands for new forms of employment.

There is a danger, however, in the current debate at EU level. Just as with the notion of the European Social Model, the flexicurity concept can lose its meaning and become empty and then be used in a superficial manner. Despite the Commission's efforts to translate the flexicurity concept into concrete policies through the identification of "common principles", it cannot be

denied that there is a tendency in the current Barroso Commission to downplay social protection and to concentrate efforts on issues of transparency and the marketing of coordinated policies, instead of substantive discussions of policies. However, the success of coordination, including how flexicurity policies affect the welfare regimes of the Member States, ultimately depends on the ability of European policies to become reflexive by adequately taking into account the needs and conditions of self-regulation in the Member States themselves.

ROMANIA ON THE PATH TO SUSTAINABLE DEVELOPMENT. COMPARATIVE ANALYSIS WITHIN THE EUROPEAN UNION

Kardos Mihaela
„Petru Maior" University, Tirgu Mureş Faculty of Economic, Juridical and Administrative Sciences

Nowadays, the issues of sustainable development are of great interest and importance, as countries, organisations, institutions worldwide are still searching for the right solutions leading to human well-being and life quality in a society socially acceptable, economically viable and environmentally sustainable, in an integrated vision between states and generations. Due to the difficulties of measuring such a complex, multi-dimensioned concept, one of the main questions refers to necessity and the possibility of determining countries' progress towards sustainable development. In this respect, there are a very large number of initiatives and efforts to develop the appropriate indicators; yet, there is no one agreed method.

In this generous context of analysis, the paper aims to offer some answers regarding Romania's progress towards sustainable development, based on a comparative analysis within the European Union, using data provided by three of the most widely used indicators for measuring sustainable development: Human Development Index, Environmental Performance Index and Ecological Footprint. The research methodology uses the comparative analysis and synthesis of data, followed by a dissemination of the results in order to express a personal opinion on the topic.

The research results are far from being optimistic, highlighting a serious gap between Romania and the other member states in terms of progress towards sustainable development. Therefore, they call for immediate action and increased efforts, so that European Union's objectives of real cohesion and of becoming one of the global leaders in supporting sustainable development can be reached. The merit of this study is its contribution with an original research to the efforts of assessing Romania's progress on the path to sustainable development, which may be particularly important for both researchers and policy makers. Due to some limitations induced by the methodology, the research opens the way for future studies, using complementary data and methodology.

Key words: sustainable development, sustainability indicators, human development, environmental performance, comparative analysis
Cod JEL: Q01, R11

1. Introduction

Sustainable development has become in the last decades the development paradigm of the world we live in today and countries, organizations, institutions worldwide have committed towards its goals. Nowadays, the subject is of great importance, as society is still searching for the right solutions leading to sustainable development. In this respect, one of the greatest challenges is to evaluate the progress towards sustainable development, as any decisions for further action can not be taken without having a clear picture of the current situation. Therefore, measurements are necessary. There are a very large number of initiatives and efforts to develop the appropriate indicators to measure sustainable development and, although there is no agreed method due to the complexity of the subject, some of the indicators are widely recognized and used.

In this generous context of analysis, the paper aims to offer some answers regarding Romania's progress towards sustainable development, based on a comparative analysis within the European Union, using data provided by three of the most common used indicators for measuring sustainable development: Human Development Index, Environmental Performance Index and Ecological Footprint. The paper is structured in two parts: the first part is dedicated to present

some landmarks in literature regarding the current issues of sustainable development and the second part presents the research results, according to our objective. The paper ends with a section of conclusions regarding the main ideas of the empirical research, with implications for further research.

2. Literature review

Sustainable development is today a landmark of a world in change, one of the key themes emerged from the collective concerns and aspirations of the world's peoples in the last half of the twentieth century (National Research Council, 1999: 22).

The study of sustainable development has been of great interest for researchers and policy makers and it has been the subject of very complex debates worldwide, its approaches evolving along with the permanent changes in our globalised society, in the common effort to offer the right solutions for that kind of development "that meets the needs of the present without compromising the ability of future generations to meet their own needs", as stated by one of the most frequent used definition, given by the Brundtland Commission (WCSD, 1987:8).

The original emphasis on economic development and environmental protection has been broadened and deepened to include the commitment to advancing human well-being (including increased life expectancy, education, equity and opportunity) and life quality in a society socially acceptable, economically viable and environmentally sustainable, with the added constraint that this development needs to take place within the ecological limits of the planet. Current debates focus on considering interconnections and interdependences between systems which call for an integrated approach and coordination, simultaneously pledging for equity between states and generations.

Sustainable development has received a global political dimension: an action plan for sustainable development, called Agenda 21, was launched in 1992 at Rio's Earth Summit (UNCED), followed by other initiatives: commitment to sustainable development was reaffirmed in 2000 when the UN Millennium Development Goals was adopted (UNGA), in 2002 at the World Summit on Sustainable Development in Johannesburg (WSSD) and more recently, during the preparations for the 2012 Earth Summit (UNCSD).

In the interim, sustainable development as a concept, as a goal and as a movement has been integrated in strategies, calling on all countries to integrate its principles into national policies and programs. Locally and globally, sustainable development is now central to the mission of countless international organizations, national institutions, corporate enterprises, sustainable cities and locales (Kates, Parris and Leiserowitz, 2005: 3).

As one of the key players in the present era of globalization, The European Union responded to all these efforts and adopted in 2001 its first Strategy of Sustainable Development (European Commission), as sustainable development has become one of its major political objectives. Due to the persistence of some unsustainable trends in many areas and the necessity to intensify efforts, the strategy was revised in 2005 and 2009 for a unitary and coherent strategic vision, completing The Lisbon Strategy and aiming to become a catalyst for changing the behaviour of the European society towards sustainability.

For Romania, as well as for the other EU member states, sustainable development is a perspective of the national becoming, resulting into a new development paradigm. More formally, Romania committed to sustainable development since 1990, when it changed its development model, but, as a member state, Romania has the obligation to adhere to and respect EU commitments in this direction. Thus, in 2008 Romania adopted its National Strategy of Sustainable Development (Romanian Government).

Still, one of the main issues of the subject refers to necessity and the possibility of determining countries' progress towards sustainable development, as it is difficult to measure such a complex concept and there is no one agreed method. Combining global, national and local initiatives, there

are literally hundreds of efforts to define appropriate indicators and to measure them (Parris and Kates, 2003), as these indicators must not only reflect changes in quality of life, but must also show if these changes are compatible with the planet's current ecological limits. Three of the most widely used indicators, recognized as relevant for measuring sustainable development, are: Human Development Index (UNDP, 2011) as an indicator of development, Environmental Performance Index (Yale, 2012) as an indicator for environmental sustainability and Ecological Footprint (Global Footprint Network, 2010) as an indicator of sustainable consumption.

UN Human Development Index (HDI) provides an overview of human well-being, measuring development in terms of life expectancy, educational attainment and income and serves as a frame of reference for both social and economic development. *The Environmental Performance Index (EPI)*, developed by [Yale University](#) and [Columbia University](#), evaluates environmental sustainability relative to the paths of other countries, covering both environmental health and ecosystem vitality. *Ecological Footprint* is a tool that measures our natural resource consumption and our global environmental impact, allowing us to work out whether there are enough resources in the world to sustain our activities. A large body of literature exists examining the strengths and shortcomings of the Ecological Footprint approach; yet despite acknowledged limitations, judging from the vast number of references, it remains a leading biophysical accounting tool for comparing present aggregate human demand on the biosphere with the Earth's gross ecological capacity to sustain human life.

3. Research Methodology

The research goal is to provide a representative imagine of Romania's progress towards sustainable development, in comparison with performances of the other EU member states.

The research methodology is specific for the purpose and the nature of the research and includes literature review, comparative analysis and synthesis of data, followed by a dissemination of the results in order to express a personal opinion regarding the research results. *The literature review* is based on bibliographic resources (books, studies, articles) and official documents (e.g. declarations, strategies, reports) in order to highlight the importance and the opportunity of the subject. *The comparative analysis* is based on processed and summarized data, according to the three indicators mentioned above: Human Development Index, Environmental Performance Index and Ecological Footprint. We use this triple set of indicators evaluating human development and ecological sustainability as together, they offer a potentially more meaningful evaluation of progress and trade-offs than would be possible using either of them, on their own.

The merit of this study is to contribute with a relevant research in an area more difficult to approach, due to its complexity. Although providing a clear imagine of the research topic, the research methodology generates some limitations, as the metrics employed are approximations and do not cover the full spectrum of sustainable development, offering information for specific moments and therefore, representing only a moment in the evolution of the phenomena. Certainly, more complete indicators for measuring progress toward sustainable development are necessary. However, the study may be a starting point for further research, by analyzing other dimensions of the topic, using complementary methodology.

3. Research results

As stated in the research methodology, our analysis is based on data according to Human Development Index, Environmental Performance Index and Ecological Footprint. We note that the research results must be interpreted in the specific context of the fact that Romania, unlike other countries with tradition, has become preoccupied with sustainable development issues only recently.

Human Development Index provides a composite measure of three basic dimensions of human development: health, education and income, expressed as a value between 0 (minimum value)

and 1 (maximum value). UNDP defines an HDI score of 0.8 as the limit between high human development and very high human development.

According to 2011 Ranking, Romania's HDI is 0.781, which gives the country a rank of 50 out of 187 countries with comparable data. Considering the EU countries in this ranking (Fig. no.1), Romania occupies the second last position (only Bulgaria has a lower score, the lowest in EU).
Figure no. 1 HDI 2011 Ranking for EU countries

Sourece: UNDP**,** The 2011 Human Development Report, 2011

Romania and Bulgaria are the only two countries in EU with scores below 0.8, therefore included in the group of high developed countries, while all the other EU member states score above 0.8 and are considered countries with very high human development (Netherlands has the highest score of 0.91). Although, as a trend Romania is placed above the regional average, figures still highlight its very large gaps in well-being and life chances, as compared to other countries in EU. According to Environmental Performance Index 2012, based on 22 performance indicators in the following policy categories: environmental burden of disease, effects on human health and ecosystem effects of water and air pollution, biodiversity and habitat, forestry, fisheries, agriculture and climate change, results are even more concerning: Romania has a country rank of 88 out of 132 investigated countries, with a score of 48.34. Among EU countries (Fig. no.2), Romania occupies the last position and it is also very far from EU average. Considering EPI Trend, Romania has one of the best performances (3rd in EPI Trend Ranking), but that seems not to be enough and there is still more to be done in order to reduce gaps.

Source: Yale University and Columbia University**,** 2012 Environmental Performance Index and Pilot Trend Environmental Performance Index, 2012

The Ecological Footprint is another measuring tool, allowing us to calculate human pressure on the planet. It represents the amount of biologically productive land and sea area necessary to supply the resources a human population consumes and to assimilate associated waste. In contrast to the Footprint, which addresses demand on ecosystems, Biocapacity describes the supply side, the productive capacity of the biosphere and its ability to provide a flux of biological resources and services useful to humanity. The world-average Ecological Footprint in 2007 (latest available results) was 2.7 global hectares per person. With a world-average Biocapacity of 1.8 global hectares per person, this leads to an ecological deficit of 0.9 global hectares per person. For ecological footprint (Table no. 1), Romania scores as the world average, best score in EU, but as shown by the Biocapacity score, which is lower than the Ecological Footprint (among the lowest in EU), it proves not to have enough ecological resources within its own territory to support the consume, so it is an ecological debtor country.

Table no. 1 Ecological footprint of EU contries, 2007

Country	Ecological Footprint in gha/pers	Country	Biocapacity in gha/pers	Country	Ecological remainder (if positive) in gha/pers
Romania	*2.71*	Sweden	9.75	Finland	6.30

As a general appreciation, research results highlight that there is a serious gap between Romania and the other member states in terms of progress towards sustainable development and immediate action is needed.

4. Conclusions

As presented above, the research results regarding Romania's progress towards sustainable development in comparison with the other EU countries are far from being optimistic. Romania still has an intensive resource consumer economy, a society and an administration still in search for a unitary vision of sustainable development. Romania has to reduce considerable economic, social and technological gaps, as compared to EU countries. The goal of reducing these gaps is, truly, the way to follow towards human development, in order to reach a real cohesion within the European Union.

The merit of this study is its contribution with an original research to the efforts of assessing Romania's progress on the path to sustainable development. This may be particularly important for both researchers and policy makers, since it provides a clear image of an area currently perceived as difficult to approach and it opens the way for future studies, using complementary data and methodology.

DOES THE MAASTRICHT CONVERGENCE CRITERIA WORK?

Karsai Zoltán-Krisztián
Babeş-Bolyai University, Faculty of Economics and Business Administration

During its 13 year history, the euro area experienced the most severe economic downturn in the late 2000s as a result of the 2007 financial-economic crisis stemming from the US banking sector. The crisis in the monetary union, besides posting a significant economic and social cost, revealed several weaknesses not just of the currency block as a whole, but also of its constituting members, which were masked by the prosperous economic environment characteristic for the 2000s. These conditions have put to the test the solidarity among the euro zone members, or in other words the existence of the currency block. One important problem of the currency block is the lack of harmony between the fiscal and economic policies of the member states, creating several and occasionally very divergent parts of the currency block. The aim of this research is to enhance the Maastricht convergence criteria's and the Stability and Growth Pact's role as a monitoring mechanism, allowing them to become more informative tools for the policy makers.
For this, based on the relevant literature, we propose new potential explanatory variables which could enhance the role of the Maastricht convergence criteria and the Stability and Growth Pact. Some of the studied variables, like indebtedness of the private sector, capital flow compared to the size of the economy, government revenue compared to total public debt and current account balance help in enforcing the nominal convergence, while others (real labour productivity) contribute to the real convergence. The explanatory power of the proposed variables are investigated in the case of France, Germany, Greece, Ireland, Italy, Portugal and Spain for the period comprised between 2000Q1-2011Q4.
Results of the research show that with the exception of government revenue compared to total public debt, all proposed variables have significant explanatory power regarding the evolution of the state of the economy in all seven countries analyzed. France and Germany, characterized by healthy fiscal and economic policies is also exposed to risks stemming from the evolution of the private debt. In case of Greece, Ireland and Spain the high current account deficit represented a significant explanatory variable, while the outstanding loans to the private sector proved to be significant in the case of Ireland, Italy and Portugal. The significance of real labour productivity for Greece and Italy proves that real convergence should also be obtained beside nominal convergence by economies in the currency block. All significant variables had explanatory power through their lagged value, hence counterbalancing policies can be elaborated in a timely manner in order to stabilize the economy if signs indicate a potentially unsustainable economic path.

Keywords: Maastricht convergence criteria, real convergence, macroeconomic processes, private sector.

I. Introduction

According to a comprehensive and thorough research conducted by the World Bank in 2001, in the period comprised between the end of the 1970s and the end of the 20th century there were 112 bank crises in 93 countries all over the world. A very large bulk of the studied crises caused significant economic downturns in developed countries, as in emerging economies as well (Wolf, M (2010)). Another research showed that since the early 1980s sovereign debt distresses grew exponentially until the mid 1990s (Cohen and Valadier 2010). Baldacci et al. (2011) based on a research found that from 1970 to 2010 there were 41 fiscal distress events in advanced economies and 135 events in emerging economies. The costs of these crises mainly reflected in the low

economic growth – which in most of the cases remained significantly under its potential level – and the nationalization of banks created a very large pressure on the society through the reduction of welfare. A very important feature of banking crises is the spillover effect which they can cause in the public sector (Freydl 1999; Laeven and Valencia 2008; and Rogoff and Reinhart 2009). The current sovereign debt crisis in Europe is a very recent and acute example for this. It is clearly not a desirable situation – from many point of view – to be in, when after seemingly resolving one crisis, the economic actors face themselves with another one. In order to avoid these costly crises or at least to create a more powerful monitoring mechanism, we propose a review of the Maastricht convergence criteria and an enhancement of its current form. The aim of this paper was to conduct an analysis which would provide a guide on what type of additional variables would be useful to include among the Maastricht convergence criteria.

II. Literature review

There is a vast amount of researches regarding macroeconomic variables and their role in different Early Warning System (EWS) models. Most of these studies focus on currency and banking crises, with only a few papers assessing the risk of public debt default. The fundamental of this is that many crises from our recent history (last four decades) can be included in one of the two mentioned types of crises. These studies on EWS models can be differentiated according to: (i) the definition of crisis events; (ii) the methodology adopted; (iii) country coverage, and (iv) the set of indicators used. Country coverage tends to be limited due to the quality of data or its unavailability, hence there can be found only a few studies focusing on both advanced and emerging economies.

Baldacci et al. (2011), developed a fiscal stress index which provides a signaling tool to identify and assess exposure to fiscal sustainability risks and also helps identify the underlying factors which drive changes in fiscal stress risks. However, like similar signaling tools, the developed stress index does not attempt to predict crises, as these are typically triggered by the interaction of economic, financial and political events. Results show that the top predictors of fiscal stress are different for advanced and emerging economies. In advanced countries the top predictors of fiscal stress are indicators of gross financing needs and fiscal solvency concerns. In emerging economies, the best predictors of fiscal stress are risks associated with public debt structure and liquidity constraints.

Regarding the methodology used in the studies, two approaches are common: the univariate "signaling" approach and the multivariate regression analysis of the crisis determinants. Kaminsky, Lizondo and Reinhart (1998) presented the "signaling" approach on determinants of currency crises. Berg and Patillo (1999) and Berg et al. (2005) use the multivariate regression analysis to predict crises episodes. Most of the researches which compared the performance of these two approaches concluded that overall, the signaling performance depends on the type of crisis risk assessed (Baldacci et al. 2011).

Abdih et al. (2009) propose the investigation of the impact of remittances on the sustainability of government debt. The results indicate that countries with differing balance of payments structures should consider developing and evaluating alternative measures of debt sustainability. In particular, remittance-dependent countries may need to monitor the state of the economy through several indicators, including both debt-to-GDP and debt-to-GDP adjusted with remittances.

Articeles regarding the Maastricht convergence criteria and the creation of the euro started to spread immediately after the signing of the Maastricht Treaty back in 1992. Many observers and economists warned against establishing EMU without adequate fiscal controls (Glick 1991, Walsh 1992, Schuknecht et al. 2011). In the same times there were numerous academic economists who questioned the economic rationale behind the convergence criteria of the Maastricht Treaty (Kenen 1992). A very important question mark for the skeptics was that the Maastricht Treaty aimed for a rather nominal convergence for the future members of the currency

block (Jonung and Drea 2009). The Stability and Growth Pact – which ensures that after an EU member state joins the currency block it will continue to meet the fiscal convergence criteria – has also been identified with many weaknesses (Schuknecht 2005).

III. Methodology

The relationship between the state of the economy and the Maastricht convergence criteria is studied with the help of the classical linear regression model:

$$Y_t = \beta_1 + \beta_2 \cdot X_{t2} + \beta_3 \cdot X_{t3} + \ldots + \beta_k \cdot X_{tk} + u_t, \qquad t = \overline{1,n}, \qquad (1)$$

where Y_t denotes the state of the studied economy in quarter t, n is the number of quarters, k-1 is the number of explanatory variables, β_i is the coefficient estimate for variable i ($i = \overline{1,k}$), X_{it} represents the value of variable i in quarter t, while u_t is the error term in quarter t. In order to achieve a more robust estimation process, the effects of the different explanatory variables were tested both in a bivariate and a multivariate regression model. As a time series analysis is undertaken, a great attention has been allocated for the assurance that the studied variables are stationary. For the testing of the stationary property of a variable, the augmented Dickey-Fuller (ADF) test has been used.

IV. Data and empirical results

1. Data

The dependent variable of the regression model needs to represent through a quantitative measure the state of the economy. Two approaches were considered: (i) ratings of long term sovereign debt and (ii) yearly volatility of benchmark stock market indices. Ratings of long term sovereign debt are published periodically by Standard and Poor's rating agency division (S&P, 2012). The theory behind using ratings of sovereign debt as a measure of instability of an economy is that the public sector has a very strong relationship with the other three main sectors of an open economy (1). The second approach has its basis coming from the empirically proved fact that evolution of stock indices represents the opinion of the market participants with respect to the outlook of the economy. Stock market indices tend to forecast, usually in advance with a year the evolution of the real economy. Hence, a sharp decline in the stock prices represents a potentially significant decline in the economic activity. Volatility in the context of stock market prices stands as an important parameter to capture the uncertainty surrounding an asset's price. In this paper we use the benchmark indices of the analyzed economies in order to capture its state.

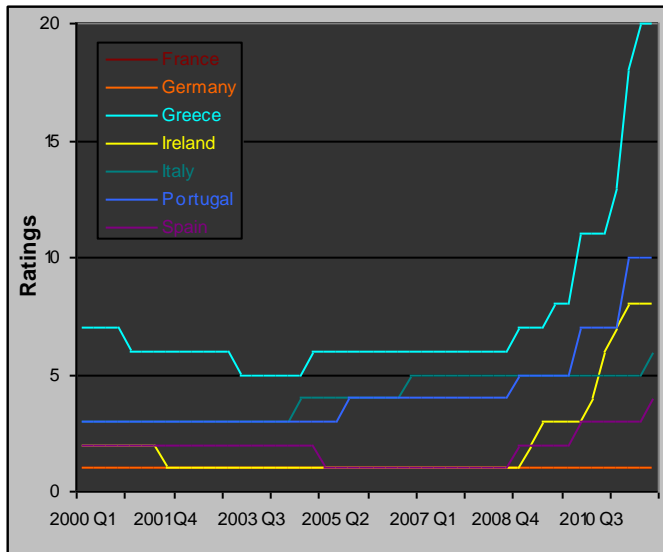
The empirical research was conducted for seven economies: France, Germany, Greece, Ireland, Italy, Portugal and Spain. The first two economies are in focus due to their healthier fiscal positions and higher growth prospects, while the remaining five economies are closely monitored as a consequence of the difficulties which they have encountered in recent years. The proposed variables for inclusion in the Maastricht convergence criteria and the Stability and Growth Pact have their grounding coming from the optimum currency area theory. In order to achieve a more functional currency block, the member counties need to achieve not only a nominal convergence but a real convergence as well. Beside the inclusion of variables representing real convergence, other variables for nominal convergence should also be considered. The proposed variables are as follows: indebtedness of the private sector, capital flow compared to the size of the economy, government revenue compared to total public debt, current account balance and real labour productivity. The data used for the analysis refer to the period comprised between 2000Q1 – 2011Q4.


Figure 1: Evolution of sovereign ratings
Source: Standard and Poor's

Figure 1 shows the evolution of the ratings for long term sovereign debt (2). During the analyzed period, Germany and France retained their AAA rating. The other analyzed countries were downgraded as a consequence of the sever effects of the 2007 financial-economic crisis, signaling a more instable state of the economies. The volatility of the benchmark stock market indices were generally under 30% throughout the mid-2000s, however in the last quarter of 2008, when many financial institutions were exposed to the risk of default, the volatility reached its peak value of 60%. Due to governmental interventions, the state of many economies has been stabilized, hence the volatilities dropped, however, not in case of all the studied economies. For Greece, Portugal, Spain and Italy volatility remained at en elevated level (Figure 2).
Figure 2: Yearly volatility of benchmark stock market indices
Source: authors' calculation

2. Results for the econometric analysis

The estimations did not yield significant results in the case when sovereign ratings were used as dependent variable. A possible reason for this could be the very low variability of sovereign ratings. Table 1 presents the estimated coefficients and *p* values for each analyzed country in the case when volatility of the benchmark stock market indices were used as dependent variables of the regressions.

For France two variables were found to have significant impact on the evolution of the stock index volatilities. Both variables belong to the group of indicators regarding private sector debt. The anticipated positive sign of the variables show, that continuous growth of private debt and its raising share in GDP will eventually lead to increased volatility levels. Other studies also showed similar relationships between debt levels and corporate default rates. In the case of Germany we have also two significant variables. During the 2000s Germany was one of the few euro area economies with relatively healthy macroeconomic policies, however this does not mean that it can afford itself to loosen policies with respect to private debt. It is important to see that for the two biggest economies of the euro area the evolution of the private debt holds an important role in determining the state of their economy.

Turning to the countries which currently face important pressure both from market participants and European politicians to implement socially painful austerity measures in order to bring back their economies on a sustainable path, we can notice that real convergence has a significant effect on their stability. Focusing on Greece will highlight the importance of three variables: current account balance, financial account balance and real labour productivity. All three variables' coefficients have the expected signs. Sustained increase in the indebtedness of the public and private sector, inflow of foreign capital and decline in real labour productivity will all lead to an increase in instability. It is not a surprise to see the significant influence of the financial account balance, as Greece funded its growth mainly through loans from foreign creditors. The effect of lag of more than four quarters suggest that if an adequate monitoring of the mentioned variables is implemented, counterbalancing policies could be elaborated in a timely manner in order to stabilize the economy.

Ireland was also a victim of private sector indebtedness, mainly due to the financial sector. This is signaled by the significance of the current account balance, financial account balance and the share of private sector loans in the GDP. For Italy besides having to deal with a high public debt, issues in the labour market are also creating significant pressure on the economy's stability. Further decrease in labour productivity could lead to more pressure from financial markets. Portugal is also one of the countries with major issues due to high public and private sector debt. Spain had a quite solid fiscal position prior to the financial-economic crisis, though it also had a fragile private sector due to the continuous current account deficits. Ultimately private sector imbalances will spill over to the public sector, mainly as a result of decreased economic activities and bailouts, hence assuring a balanced private sector could create the premises for a balanced public sector.

V. Conclusions

The 2007 financial and economic crisis and the 2010 sovereign debt crisis in the euro area are a symptom of policy failures and deficiencies in – among other things – financial regulation and fiscal and economic policy coordination. Our aim with this research was to assess the relationship between the state of the economy and macroeconomic processes in the case of seven euro area economies for the period comprised between 2000Q1-2011Q4. In our analysis we propose a new set of variables, in order to enhance the Maastricht convergence criteria and also the "preventive arm" and "protective arm" of the Stability and Growth Pact. The studied variables are as follows: indebtedness of the private sector, capital flow compared to the size of the economy, government revenue compared to total public debt, current account balance and real labour productivity.

Stability of economies with healthy fiscal and economic policies is also exposed to risks stemming from the evolution of the private debt. During the analyzed period in case of Greece, Ireland and Spain the high current account deficit represented a significant explanatory variable for the state of the economy. Outstanding loans to the private sector proved to be significant for Ireland, Italy and Portugal. The significance of the current account balance and the outstanding private loans indicate that macroeconomic variables regarding the private sector should also be included in the Maastricht convergence criteria and the Stability and Growth Pact. Real convergence should also be obtained along nominal convergence by economies in the currency block, this being underlined by the significance of real labour productivity in the case of Greece and Italy.

Overall, all of the proposed variables expect for the government revenue compared to total public debt have a significant explanatory power regarding the evolution of the state of the economy. All significant variables had explanatory power through their lagged value, hence counterbalancing policies can be elaborated in a timely manner in order to stabilize the economy if signs indicate a potentially unsustainable path of the economy.

There are several unexploited areas of this paper's topic which still need to be investigated thoroughly. For instance a future research could address the problem of modeling the state of the economy using sovereign ratings. Most probably the development of a composite index using different variables would be the most adequate approach. Another important area would be the assessment of critical threshold values for the variables proposed in this paper.

VI. Notes
(1) An open economy has four main sectors: government sector, enterprise sector, household sector and external sector. The enterprise and household sector together represent the private sector of an economy.
(2) Sovereign rating classes are ranked in order to transform them into a quantitative variable. The highest rating class received rank 1, while the lowest rating class received rank 21.

THE GROWTH SUSTAINABILITY CONCEPT IN THE EUROPEAN UNION, UNIVERSITY OF REIMS CHAMPAGNE-ARDENNE

Jubénot Marie-Noëlle

Abstract:
Definitions or approaches to sustainable growth are numerous, varied and often controversial. Despite, the three priorities (smart, sustainable and social growth) of Europe 2020's strategy, there are fears that the Lisbon Agenda could place sustainable development beneath an over-arching aim of increasing economic growth. In addition, this ambitious and new strategy is strangely built with old theoretical foundations. The general goals are divided into several sub-targets supposed to apply to all countries of the European Union. This necessarily requires adequate institutions to manage, and the creation of easily measurable indicators. However, the problem lies in the shared governance between the EU institutions and national governments.
Key words: sustainable growth, Brundtland announcement, Europe 2020's gaols, the 'win-win-win' scenario.

JEL codes: O, E

Introduction

The first objective of this paper is to show the originality of the European concept of sustainable growth from a variety of conceptual and theoretical approaches. The second is to analyze the possibility of achieving such a goal. In fact, the problems do not just come from the recent financial crisis and its consequences, but also practical difficulties in managing this strategy. In the first section, we will discuss the genesis of the concept of sustainable growth and some definitions that are commonly associated. In the second part, we will explain the concept of sustainable growth adopted by the European Union. And finally, in a last part we will analyze the feasibility of such a project

Concepts of sustainability

The term sustainable development was brought into common usage by the World Commission on Environment and Development (The Bruntland Commission) in 1987. Since the conclusion of the Brundtland Commission (World Commission on Environment and Development, 1985), the two competing notions of *strong* and *weak* sustainability have dominated the theoretical debate on sustainable development. Loosely speaking, *strong* sustainability argues that we must live within the environmental and ecological limits that the planet clearly has. A position which accepts that non-ecospheric natural capital (minerals) can be depleted but the ecosphere must be protected absolutely – 'there is no substitute to the planet' – a planet over people approach. *Weak* sustainability argues that humanity will replace the natural capital we have used, and that we depend on, with human-made capital. A position that propounds that human made capital (e.g. technology) will substitute for natural capital so this can be run down, providing a critical minimum level is maintained – essentially a willingness to pay approach. Theorists virtually unanimously agree that the latter has formed the conceptual basis for sustainable development. Theorists are virtually unanimous in their assessment that *sustainable development* as a concept has largely evolved from the latter position. The all-pervasive nature of neo-classical economics has also come to permeate throughout thinking on sustainable development, with a broad acceptance that intra-generational and inter-generational equity can only be achieved within the confines of economic growth. Sustainable Development calls for development that "meets the need of present generation without compromising the needs of future generations.
In fact, sustainable Development generally combines three objectives:

(i) Economic objectives (Growth; Equity and Efficiency);

(ii) Social objectives (Empowerment; Participation; Social Mobility; Social Cohesion; Cultural Identity; Institutional Development);

(iii) Ecological objectives (Ecosystem Integrity; Carrying Capacity; Biodiversity; Global Issues).

It constitutes a 'win-win-win' scenario for achieving progress within the economic, social and environmental pillars of sustainable development. The three are supposed mutually beneficial.

A great deal of both academic and policy literature in the ten years immediately following the Brundtland announcement (World Commission on Environment and Development, 1985) concerned itself with understanding and articulating the core principles of sustainable development.

However, one also speaks of sustainable growth when taking into account other factors such as debt sustainability, the sustainability of the tax burden.

The definition of sustainability may also vary depending on the country that is taken into account. Often rich countries are concerned about the environmental consequences of growth so that we highlight the benefits of social problems related to growth in developing countries.

After this brief overview, we can now address the European Union concept of sustainable growth.

II) The European Union approach

The European Union established a Strategy for Sustainable Development, the Europe 2020 Strategy, for the first time in May of 2001, in Gothenburg. This was laid out in the position represented at the World Summit on Sustainable Development that was held in Johannesburg in 2002. The Europe 2020 Strategy is based on stable, balanced, and sustainable growth, aimed at facilitating Europe's exit out of the current financial crisis and then laying out the foundations for future development. The Maastricht Treaty was already adopted the principle of cohesion. In which, explicitly the three objectives focused on convergence, namely: (1) harmonious and sustainable development; (2) high level of convergence of the economic performance; (3) economic and social cohesion and solidarity between the member countries. To implement the above principle, the Cohesion Fond, used for diminishing the disparities among regions and countries, was set up only for the countries with a GDP per capita below 90% of the EU average.

The still fragile situation of the financial system is holding back recovery as firms and households have difficulties to borrow, spend and invest. The public finances have been severely affected, with deficits at 7% of GDP on average and debt levels at over 80% of GDP – two years of crisis erasing twenty years of fiscal consolidation. Our growth potential has been halved during the crisis. Many investment plans, talents and ideas risk going to waste because of uncertainties, sluggish demand and lack of funding. In Europe, the crisis has wiped out years of economic and social progress and exposed structural weaknesses in Europe's economy. The steady gains in economic growth and job creation witnessed over the last decade have been wiped out – our GDP fell by 4% in 2009, our industrial production dropped back to the levels of the 1990s and 23 million people - or 10% of our active population - are now unemployed. The crisis has exposed some fundamental weaknesses of our economy.

Moving out of the crisis is the immediate challenge. The new European economic strategy for Europe—"Europe 2020"— includes three key growth drivers, namely:

• *Smart growth* (fostering knowledge, research and development, innovation, education, and a digital society),

• *Sustainable growth* (making production more resource efficient), and

• *Inclusive growth* (raising participation in the labour market, the acquisition of skills, and the fight against poverty).

These three priorities would mutually reinforce.

Sustainable growth means for example: a low-carbon economy, protection of the environment, preventing biodiversity loss, developing new green technologies and production methods, efficient smart electricity grids. In this end, all must be done to improving the business environment, in particular for SMEs and helping consumers make well-informed choices. The importance of integration of environmental programmes into European policy was reaffirmed in the Sixth Environmental Action Programme (European Commission, 2002).

19% of children in the EU are currently in or at risk of poverty. Welfare systems reduce the risk of poverty by 38% on average in the EU, but this impact varies from less than 10% to nearly 60% across the EU. To reduce social exclusion and aimed inclusive growth, Europe's employment rate must raise – especially for women, young people and older workers. Investment in skills and training must be developed and labour markets and welfare systems need to be modernised. Regional development and investment also support inclusive growth by helping disparities among regions diminish and making sure that the benefits of growth reach all corners of the EU. The social dimension of growth is also crucial to this effort through the promotion of employment opportunities, the creation and updating of skills, and the protection of the weakest by way of appropriate social safety nets and income support.

These targets are often interrelated. and it will take strong leadership, commitment and an effective delivery mechanism to change attitudes and practices in the EU. Despite disparities in levels of development and standards of living, the proposed targets take as relevant to all Member States, old and newer alike. The Commission proposes that these EU targets are translated into national targets and trajectories. The mix of EU and national efforts should be mutually reinforcing.

All EU policies, instruments and legal acts, as well as financial instruments, should be mobilised to pursue the strategy's objectives. The Commission intends to enhance key policies and instruments such as the single market, the budget and the EU's external economic agenda to focus on delivering Europe 2020's objectives.

To achieve the three goals, the European Commission proposes the following EU headline and measurable targets:

– 75 % of the population aged 20-64 should be employed, including through the greater involvement of women, older workers and the better integration of migrants in the work force;

– 3% of the EU's GDP should be invested in R&D.

– The "20/20/20" climate/energy targets should be met (Reduce greenhouse gas emissions by at least 20% compared to 1990 levels; increase the share of renewable energy sources in our final energy consumption to 20%; and a 20% increase in energy efficiency)

– The share of early school leavers should be under 10% and at least 40% of the younger generation should have a tertiary degree.

– 20 million less people should be at risk of poverty.

These targets must be not only measurable, but also capable of reflecting the diversity of Member States situations and based on sufficiently reliable data for purposes of comparison.

The crisis has added temptations of economic nationalism. Then, the single market, financial levers and external policy tools, will be fully mobilised to tackle bottlenecks and deliver the Europe 2020 goals. The Small and Medium Enterprises are in the heart of this new strategy. The Europe 2020 includes creating a business environment supportive of SME development: in developing SME competitiveness, improving the SME access to financing, improving the SME access to foreign markets, promoting an entrepreneurial culture and strengthening management

performance, creating a supportive legislative, regulatory and fiscal environment, to provide financial support to SME development and sustainability.

Is the European definition of sustainability sustainable?

Actually Crisis remains prominent. The recent unfolding of the European sovereign debt crisis has highlighted the risks arising from the rapid accumulation of public debt and the markets concern over long-term debt sustainability. Given that the reconstruction of the financial the unemployment rate remains high in major advanced economies, one would expect to observe a slower global economic growth.

The EU Sustainable Development Strategy involves combining a dynamic economy with social cohesion and high environmental standards. It requires a new emphasis on policy coordination and integration. A notable addition to theoretical conceptualisation of sustainable development over the past five years has been the incorporation of a fourth 'institutional' dimension. Sophisticated theoretical understandings are beginning to emerge, with greater emphasis on the social equity and participative aspects of delivery and the democratic and political processes for achieving this. Institutional inconsistencies can lead to fragmentation and a failure to integrate sustainable development with governance, so:

– Vertical inconsistencies can exist between every state and European policy intentions, or practices.

– Horizontal inconsistencies can exist between aspects of policy delivery, either between or within different sectors.

At a European level, the procurement is being used as a stand-alone policy instrument, given the erosion of state-level powers from international agreements and conventions. Procurement processes are being pulled in different directions by the drive for continued EU market integration, on one hand and the need for increased environmental policy integration and regulation on the other. There is a raft of legislation, which shapes procurement in member-states. The EU has in place a legal structure for procurement that is intended to harmonize with the fundamental freedoms of the common market, envisaging market integration and trade facilitation, though it remains to be seen if these changes will fit in with Environmental Policy Integration.

There is insufficient evidence knowledge about whether or how a policy or action could contribute to more sustainable forms of development. In addition, there is a lack of evaluation. In order to better monitoring the Lisbon Strategy, the World Economic Forum in 2008 constructed a composite index, the Lisbon Index (GIURCA VASILESCU, 2008). It includes 8 fields, each associated with one indicator associated. Then, these 8 indicators are aggregated to form the Lisbon index. The indicators chosen to compose the Lisbon index are:

1. The level of Information Society;
2. Dimension of innovation, research, development;
3. Liberalisation (related to the harmonization of competition rules, state aid, and single market);
4. Transport infrastructure, utilities and telecommunications;
5. Financial Services;
6. Enterprise;
7. Social inclusion;
8. Sustainable development.

The three priorities (smart, sustainable and social growth) of Europe 2020 and the Stability and Growth Pact evaluation would be achieved simultaneously. In fact, there are fears that the Lisbon Agenda, which was adopted in 2000 with the aim of making Europe the most competitive and dynamic knowledge-driven economy by 2010, could place sustainable development beneath an over-arching aim of increasing economic growth. Conceptually, there are different levels of

sophistication (Scottish Executive Social Research, 2006) of this problem. Sustainable development might be understood as the simple intersection between the economic, environmental and social pillars. However, in the Russian doll model or embedded model, all economic activity should be bent towards social progress and that this must be achieved within environmental limits. Therefore, there is a slight move away from the 'weak sustainability' model towards a more eco-essential approach. The 'win-win-win' scenario appears too simplistic and unattainable.

In addition, there is a necessary political compromise between the global environmental management and protectionism aims of the North and the human health and development needs of the South.

Purvis and Grainger (2004) denounce, cited by Scottish Executive Social Research (2006), the attempt to incorporate environmental and intergenerational dimensions within neo-classical economic development theory. That is intended to work within the existing economic system of production and distribution.

So, this sustainable development approach relies upon the traditional and often criticised belief that increased economic growth will deliver the necessary improvements to the human condition.

Conclusion

Combining, in the new European Strategy, both the usual criteria of sustainable growth, in other words: the ecological and social criteria (this latter not integrated in the sustainability definition) with a criterion on the development of the digital economy is not traditional. Moreover, measurable indicators have been created to evaluate the achievement of these targets. However, this growth priority both smart, sustainable and sociable seems difficult to maintain. For example, it is very complicated to achieve several objectives simultaneously, even if they are in part interrelated. Some criteria will necessarily be privileged over others. In addition, the conservation of traditional growth approach, based on neoclassical theory, seems paradoxical.

NEW PUBLIC MANAGEMENT ELEMENTS IN ROMANIA'S PUBLIC SERVICES IN THE EUROPEAN CONTEXT

Moraru I. Marilena Ortansa
Bucharest University of Economic Studies Faculty of International Business and Economics

New Public Management (NPM) is considered as a global paradigm emerging in response to economic, institutional, political, and ideological changes.

Many attempts to define the New Public Management have been made and there are several definitions of this notion, referring to the implementation of management ideas from business and private sector into the public services.

Over the past few years, Romania has been facing a great challenge as it has to enhance its public management for achieving the European standards and values of transparency, predictability, accountability, adaptability and efficiency.

The necessity of a modern administration at European standards exists both at the level of the citizen, and at the level of institutions delivering public services.

According to the provisions of its last stand-by arrangement with IMF, Romania placed emphasis on restoring medium- and long-term sustainability and paved the way for future growth. Structural reforms were a large component of the program, including tax administration, pensions, public wages and employment, and social benefits, improving public sector efficiency, as well as enhancing the business environment.

Since 2009 a public financial management structure was introduced for multi-year budgeting while limiting intra-year budget revisions. Fiscal rules were introduced on spending, public debt and primary deficit, and a framework for managing guarantees and other contingent liabilities was approved. Local public finance law was amended to bolster fiscal discipline and limit risks from local governments.

Thus, presently, the legal framework envisages the use of new instruments and structures to support local administration authorities to increase their administrative capacity in order to perform in accordance with their new authority and thereby increases the quality of the already decentralized public services.

The Common Assessment Framework (CAF) – the total quality management tool was introduced in Romania, public institutions acknowledging the need for change and improvement, the importance of people's involvement within the organization's self-assessment process, the importance of measuring the results, objectives prioritization, the need to assume responsibility for the identified improvement actions, as well as the need to share knowledge and experience.

Most of the Romanian public institutions apply the diagnosis obtained through CAF implementation as a solid ground to develop and implement their Multi-annual Modernizing Strategies, thus assuring the sustainability of the results accomplished so far.

Concluding, we consider that the changes incurred and the significant transformation of Romanian public services include important elements of NPM.

Theoretical approach
New Public Management (NPM) evolved from a range of reforms in Western public sector, including public services, originating from new ways of thinking about the role and nature of government and public administration.

Nowadays, New Public Management (NPM) is considered as a global paradigm emerging in response to economic, institutional, political, and ideological changes.

Many attempts to define the New Public Management have been made and there are several definitions of this expression, the common element being "the implementation of management ideas from business and private sector into the public services"(Haynes, P. , 2003).

The starting point of New Public Management is considered to be Christopher Hood's article in 1991 "A Public Management for all Seasons". The main characteristics of NPM, according to Hood, are: applied and entrepreneurial management; specific standards and measures of performance; output controls; desegregation and decentralization; competition in the provision of public services; implementation of private-sector styles of management; and discipline and cost-cutting in resource allocation (Hood, C. 1991).

NPM changes the emphasis from traditional public administration to public management (Larbi, G. A., 1999), thus orienting the state toward managerialism. The traditional model of organization and delivery of public services, based on the principles of bureaucratic hierarchy, planning, centralization, direct control and self-sufficiency, is apparently being replaced by a market-based public service management.

The new public management, according to the OECD report (OECD, 1998) is characterized by:

- a focus on results in terms of efficiency, effectiveness, quality of service and whether the intended beneficiaries actually gain;

- a decentralized management environment which better matches authority and responsibility so that decisions on resource allocation and service delivery are made closer to the point of delivery, and which provide scope for feedback from clients and other interest groups;

- a greater client focus and provision for client choice through the creation of competitive environments within and between public sector organizations and nongovernment competitors;

- the flexibility to explore more cost effective alternatives to direct public provision or regulation, including the use of market type instruments, such as user charging, vouchers and the sale of property rights; and

- accountability for results and for establishing due process rather than compliance with a particular set of rules, and a related change from risk avoidance to risk management.

Public administration reform

In this context, we may consider that the public administration reform is an important element of NPM, due to increased efficiency and market-based reforms leading to contemporary change and innovation.

Romania has pursued a consistent public administration reform (PAR) strategy since 2001. The current government reaffirmed the general direction of the reform effort, but placed a higher emphasis on reform of service delivery through a decentralization process.

The following actions have been taken for putting into practice the public administration reform in Romania, based on NPM main directions:

- the implementation of the strategy regarding the acceleration of the public administration reform, in order to create a new legislative framework in providing the services by the public administration, to create new institutional structures, to increase the efficiency and the effectiveness of civil servants activity, to change the perception and the organizational behavior and, last but not least, to create a citizen oriented administration;

- establishing the Governmental Council for Monitoring the Public Administration Reform, having in its composition 8 ministers of most representative ministries, responsible for supervising the whole process of the public administration reform;

- establishing the Central Unit for Public Administration Reform (CUPAR) within the Ministry Administration and Interior (previously named Ministry of Public Administration), in order to ensure the implementation of the decisions of the Governmental Council;

- National Institute of Administration was created as a specialized institution for training the civil servants and local elected officials;
- National Agency of Civil Service has as task to provide the civil service management and to draw up the normative documents regarding civil service.

Strategy of the Ministry of Administration and Interior during 2007-2013 on public administration reform, foresees the following measures:
- continuation of the process of decentralization of basic public services: education, health and social assistance;
- limiting the functions of de-concentrated services through the transfer of competencies to the authorities of local public administration;
- implementing a system of strategic planning for each authority within the system of central and local public administration in accordance with the public services it provides;
- establishing a system of evaluation and monitoring of the public service performances;
- developing and implementing instruments in order to increase the performance of public administration;
- elaboration and implementation of the chart of public services that would include the quality standards for services and their assessment methodologies;
- introduction of quality standards by the competent public authority that can allow the monitoring and assessment of a public service;
- introduction of the cost standards corresponding to the quality standard of a public service, so that the public expenditure become justified, transparent and submitted to financial control;
- simplification of administrative procedures for increasing the efficiency of public services delivery.

In 2009, Romania signed a stand-by arrangement with IMF that also placed emphasis on restoring medium- and long-term sustainability and paved the way for future growth. Structural reforms were a large component of the program, including tax administration, pensions, public wages and employment, and social benefits, improving public sector efficiency, as well as enhancing the business environment.

Since 2009 a public financial management structure was introduced for multi-year budgeting while limiting intra-year budget revisions. Fiscal rules were introduced on spending, public debt and primary deficit, and a framework for managing guarantees and other contingent liabilities was approved. Local public finance law was amended to bolster fiscal discipline and limit risks from local governments.

Decentralization
Since the early 1990s the decentralization of the competencies of the central public administration authorities has been an important policy initiative in the process of transition to a market economy and a democratic society, becoming a major priority for the reform of public administration. The legislative framework includes: Law No. 195/2006 on decentralization with further amendments, Law No. 273/2006 on local public finance with further amendments, Law No. 215/2001 on local public administration with further amendments, Law No. 188/1999 regarding the civil servants statute with further amendments, as well as the GEO No. 179/2005 regarding prefect's institution with further amendments.

The legal framework envisage the use of new instruments and structures to support local administration authorities to increase their administrative capacity in order to perform in accordance with their new authority and thereby increase the quality of the already decentralized public services. For example, the Law on Local Public Administration introduced concepts such as: City Managers and Intercommunity Development Associations. It is also recognized that decentralizing new competencies and increasing the quality of the public services requires proper financial support through continuing the fiscal and financial decentralization reforms.

Other very recent examples include:
- Decentralization strategy in the health sector approved by GD No. 562/2009;
- minimal standards of quality and costs for decentralized public services approved by GF No. 961/2009;
- Decentralization strategy in the youth sector approved by GD No. 886/2010.

Total quality management – common assessment framework (CAF)
CAF, especially designed for public-sector organizations, taking into account their characteristics, is an efficient instrument in supporting public-sector organizations to use quality management techniques to improve their performance. The CAF is a total quality management (TQM) tool which is inspired by the major Total Quality models in general, and by the Excellence Model of the European Foundation for Quality Management in particular.
The model is based on the premise that excellent results in organizational performance, citizens/customers, people and society are achieved through leadership driving strategy and planning, people, partnerships, resources and processes. It looks at the organization from different angles at the same time; a holistic approach to organization performance analysis. CAF is a result of the co-operation among the EU Ministers responsible for Public Administration. The pilot version was presented in May 2000, being revised in 2002 and 2006.
In the first phase CAF focused on the self-assessment, in the second one on the improvements after the self-assessment and in the third phase is drawing attention to the mature culture of excellence in an organization.
Nowadays, there are more than 2000 CAF users spread all over Europe and beyond Europe's borders (Patrick Staes and Nick Thijs 2010).
European CAF Users' Events are organized regularly to act as an inspiring meeting point for CAF users and to further spread TQM across the public sector in Europe. In 2003, 2005 and 2007 CAF Users from all over Europe met in Rome, Luxembourg and Lisbon at the first three European CAF Users' Events. The Romanian Presidency organized the 4th European CAF Users' Event in Bucharest in 2010. The 4th Event had a special focus on the 8 principles of excellence and the newly developed CAF External Feedback as well as the tailor-made CAF version for the education sector (Patrick Staes, Nick Thijs, Ann Stoffels and Sven Geldof, 2012).
The promotion of Common Assessment Framework in Romanian public administration started in 2005 and there was delivered several training sessions for the civil servants within the public institutions, both from central and local level. The implementation of the self assessment instrument is done on a voluntary basis, without being imposed by the Government yet.
So far, 54 public institutions from central and local level have implemented the self-assessment instrument, assisted by CUPAR, and eight of them have already run the second cycle of CAF implementation, thus enabling them to measure the progress and the level of performance achieved.
Through the use of the CAF model, public institutions have succeeded in accepting the need for change and improvement, the importance of people's involvement within the organization's self-assessment process, the importance of measuring the results, the importance of prioritizing the objectives, the need to assume responsibility for the identified improvement actions, as well as the need to share knowledge and experience.
Most of the Romanian public institutions use the diagnosis obtained through CAF implementation as a basis to develop their Multi-annual Modernizing Strategies, assuring in this way the sustainability of the results achieved.

Further support for enhancing NPM in Romania – Operational Programme Administrative Capacity Development

The Operational Programme Administrative Capacity Development (OPACD) is designed to substantially contribute to the implementation of the methodologies and procedures that have been prepared under the PAR process to date and to invest significantly in the training of personnel who hold responsibility for the new administrative methods.

In this context, the Priority Axes of the OP ACD are designed to:
- address horizontal management problems at all public administration levels (central and local) with a focus on key attributes that strengthen the reliability of the administration, in particular decision making, better regulation, accountability and organizational effectiveness;
- specifically target improvements to the decentralisation of service delivery in certain prioritized sectors (Health, Education, Social Assistance) and improve the quality and efficiency of service delivery.

OPACD targets real improvements in the delivery of public services and the emergence of a more open, efficient and cost effective public service, knowing that:
- efficiency in public services lead to increased productivity in the economy, e.g. through simpler procedures, improved customer services, etc.;
- well-functioning institutions and public administrations are a pre-condition for the successful design of public policy and implementation of strategies in order to promote socio-economic development and to contribute to growth and employment;
- effective institutional and administrative capacity is the key to good governance – an essential element of the Lisbon Strategy.

Concluding remarks

Over the past few years, Romania has been facing a great challenge as it has to enhance its public management for achieving the European standards and values of transparency, predictability, accountability, adaptability and efficiency.

The necessity of a modern administration at European standards exists both at the level of the citizen, and at the level of institutions delivering public services. Within the process of changing the public administration, administrative simplification is fundamental for the modernization and reform of the administration. Complicated procedures, long and sinuous circuits of documents, delayed deadlines to solution an action and the multitude of required forms are certainly decreasing productivity. Bureaucracy and resulting complications are remediable deficiencies when the manner to approach administrative actions changes. This translates into new working methods, thus simplifying administrative procedures.

Today, the trend in building a sound public management service is to have a more direct approach toward the matter, relying on a fairly new perspective: the expertise of the private sector. This new angle is standing as a response to the continuously changing public arena, the barometer of the country evolution socially economically and politically. Romania has understood that values of the public service lie in the human resources and the investment that are to be made to insure a high quality of this precious asset are actually money well spent for insuring an efficient and European public system.

The Romanian Government is bringing in the public arena tomorrow's leaders by putting on the spot young Romanian nationals offering them the possibility to pursue undergraduate, graduate and doctoral studies at prestigious international universities, in a wide range of fields from public administration, public health policy to business administration.

This undergoing is a valuable investment in the future of the pubic management and its sustainable development in Romania. It also stands as a much-needed vehicle for promoting new standards of efficiency, transparency and accountability in Romania's public administration being a pillar of strength element within the NPM.

Especially in times of financial crises and severe cost cuts in public administrations, like occurred two years ago in Romania, the national focus is on efficiency and effectiveness, attention to transparency and accountability, awareness for public service delivery. Together with these principles of New Public Management (NPM), methods and techniques were constructed in Romania's public service administration.

The Common Assessment Framework was introduced in Romania, as a sustainable and trusted model for public management, embraced by top management and widely implemented by public organizations in Europe with self-assessment on a regular basis. CAF is a valuable contributor in extending the Quality culture and principles among civil servants in Romania and Europe.

Concluding, we consider that the changes incurred and the significant transformation of Romanian public services include important elements of NPM. Thus major steps towards decentralization were made, public services became more efficient, and the costs were cut as well as the number of public agencies and institutions, significant progress was made to reduce bureaucracy. As well, at local level the appointments of public institutions managers are made based on exam, competition and managerial contract, being introduced also the function of city / country manager.

IMPACT ANALYSIS OF LEGISLATIVE AND INSTITUTIONAL FRAMEWORK ON THE POLICY FOR REGIONAL DEVELOPMENT IN THE LIGHT OF THE REGIONAL OPERATIONAL PROGRAMME

Munteanu Nicolae-Eugen
West University of Timişoara Faculty of Economics and Business Administration

The analysis of the administrative capacity of institutions in the regional development starts from the analysis of the existing framework for the implementation of regional politics in Romania and studies the extent to what the structures and competencies were regionally enlarged as to contribute in the regional development.

The basic hypothesis considered for such analysis had in view the fact that the differences recorded with respect to the implementation capacity of the regional development policy are caused by the various levels of the administrative capacity of the national, regional and local institutions existent in Romania.

Although the regional development activity is, both centrally and regionally, dominated by the Regional Operational Programmme 2007-2013 (ROP) implementation, significant activity also exists outside the ROP, but only regionally.

The regional strategies incorporate to a great extent the strategic objectives established nationally, being coordinated with the national financing instruments for economic, social and territorial development. The undertaking degree of responsibilities regarding the objectives fulfillment of the regional development policy is relatively low both regionally and locally, and the main indicator which contributes in sustaining this conclusion is the absence of an adequate level regarding the property holding on certain strategies and also the methodological lack of strategies. Nationally, the current activity of Ministry of Regional Development and Tourism in the field of regional development totally overlaps the management activity of ROP.

The management of structural funds 2007-2013 granted through ROP deals with various situations in which, due to the fact that the Law of regional development remained behind the legislation for the structural instruments implementation in Romania, additional resources are necessary to be granted in order to be found solutions through other types of regulations.

The Romanian legal and institutional setting allowed a centralized top-down approach for the regional development process and brought forward the approach of the type "local development which falls among certain priorities of regional development established nationally". Definitely, the local development is important for the regional development, but it is not self-sufficient in this respect. Therefore, the centralized approach should be completed by a decentralized approach, as a natural next phase.

Keywords: regional development, institutional and legal framework, region, management of structural funds
JEL Classification: O18, R58, P48.

Introduction

In Romania, the development regions are territorial-statistic units, created pursuant to the Regional Development Law no. 151/1998, subsequently modified by Law no. 315/2004, they are not deemed administrative units, but represent territorial structures in which the national policy of regional development is implemented and evaluated and they also are the basis for the preparation and implementation of regional development strategies.

As territorial structures for regional development, there were created, regionally, eight Regional Development Boards (RDB) and eight Regional Development Agencies (RDA). At national

level, there were created one National Regional Development Boards and one National Agency for Regional Development (currently the Ministry of Regional Development and Tourism).

The coordination of the preparation and monitoring activities which result from the regional development policies is performed by RDB, as deliberative body, without legal entity, created for each region and functioning on principles of partnership, while the "executive" level is ensured by RDA, also created for each development region and functioning in the field of regional development as non-governmental non-profit bodies, of public utility and having legal entity.

Legal and institutional framework in the regional development field
The evaluation of the legislative and institutional setting for the regional development in Romania has in view three dimensions, which converge to the formation of the regional development framework: the legislative dimension, which implies the identification of the potential and specific limits for the current legislative setting for the regional development regulation, the functional or organizational dimension, which implies the description of the current institutional setting and the analysis of functional processes, and also the contextual strategic dimension, which has in view the description and the analysis of the degree to which the objectives of the regional development in Romania correlate with the financing national instruments for the economic, social and territorial development.

From the perspective of the regional development objectives subsequent to the adherence to the EU, the legislative framework for the regional development was completed with specific regulations regarding the ROP implementation. In this respect, within RDA's there were certified Intermediate Bodies for ROP implementation, which perform their activity pursuant to a responsibilities assignment agreement concluded with the Management Authority.

The ROP, which is implemented in Romania during 2007-2013 period, adopts a territorial approach of national dimensions, being concentrated on a range of sectors relevant for a balanced development of the regions of Romania.

Although the activity in the field of regional development, both centrally and regionally, is dominated by the ROP implementation, there is a significant level of activity also outside ROP, but only at regional level.

Centrally, the Ministry of Regional Development and Tourism (MRDT) activity for the regional development evolved from a combination of programmes financed both from Phare funds and from national funds (during the pre-accession period) towards a regional development activity carried out exclusively within ROP (during the post-accession period). The MRDT documents, both the informing and publicity ones, and the formal ones (e.g. Reports of annual activity 2009, 2010, 2011) indicate a total overlap of the regional development activities and the ROP implementation.

However regionally, the situation is slightly different. Although the regional development activity outside the ROP is still undergoing the evolution process, the current level of activity of RDA and, in some situations still in a small number, of various Associations of Intercommunity Development, represent an element which could indicate a significant potential in this respect. It is obvious, from the analysis of RDA's activities, that they transpose to a great extent the responsibilities of such organizations as defined by the Law no. 315/2004. In other words, the existing legal framework drew some activity directions in the field of regional development and they are implemented by RDAs. The legislation which created the necessary setting for the operation of the intercommunity development associations (e.g. Law no. 215/2001) proved its significance by the fact that it facilitated and stimulated this type of collaboration which is substantial for the regional development process.

The responsibility of fulfilling the Regional Development Plan objectives at regional level is not clearly assigned to RDB, as it could be expected; RDB is not liable to ensure the correlation of

the regional development projects with the regional development objectives, as they were defined in the respective Regional Development Plans.

Strong points and weak points of the institutional and legal framework in the light of ROP

By analyzing the programming and regulation documents from European and national level and also the Framework Agreement for the responsibilities assignment regarding the Regional Operational Programme 2007-2013 concluded between MRDT and RDA's, we could highlight some of the strong points and weak points of the institutional and legal framework regarding the ROP management and implementation:

Table 1. Strong points and weak points of the institutional and legal framework

Strong points of the current legal and institutional setting	Weak points of the current legal and institutional setting
Strong implementation system with important positive accumulations, both centrally and regionally, fully accredited according to the European regulations in the field.	Currently, there are unused resources for making more diverse and flexible the contract with respect to the assignment of responsibilities from MRDT towards RDA's. Absence of a system policy for the adoption of an ethics code and a compensation / remuneration method according to the system's performances. Absence of written procedures regarding the identification of sensitive positions and their rotating occupations, prior to any possible occurrence of irregularities.
Important responsibilities, such as the regional development, are decentralized at regional level in a relatively coherent approach, which resulted in an intensive cooperation for the promotion of impact projects, which went beyond the local/district administrative borders.	The Management Authority and Intermediate Bodies responsibilities (direct or assigned) do not fully provide yet from a procedural point of view the promotion of projects with regional impact.
The existence of a coherent framework agreement between various legal entities allowed to be reached and consolidated in time a balanced and strong system, which enjoys recognition and which allows both the concentration of technical expertise and the undertaking of responsibilities.	There were developed work procedures which involve the complete transmission, between various legal entities, of documents with significant large volume on paper (in original and in copy), with stamp and signature and manual numbering system on each page, which slowed down the whole process, on one side, and which did not fully avoid the irregularities, on the other side. The absorption degree could be consolidated and ensured by developing new responsibilities assignments within the system.
Both of the system's entities, the Management Authority and Intermediate Bodies, have gained significant expertise and	The law of regional development remained back at the level specific for the pre- accession

Strong points of the current legal and institutional setting	Weak points of the current legal and institutional setting
experience, during the pre-accession period and during the current programming exercise, experience which is very useful for the preparation and implementation of the future programming period regarding the regional development.	period, not being updated the provisions regarding the institutional setting developed for the implementation of structural instruments and also for the implementation of ROP. Although the RDA's have accumulated during the pre-accession period important expertise for the implementation of non reimbursable funds, they were used only for the implementation of Regional Operational Programme 2007-2013 and not for other sectorial programmes.
RDB gained experience in ROP implementation and it is the first structure of the region to have worked directly with the central and local authorities for the implementation of the regional development policy.	The competence system regarding the RDB functioning could not be fully and coherently operated.
The legal and institutional framework regarding the regional development policy had an almost continuous evolution in time, which determined significant expertise accumulations and also undertakings of responsibilities.	The absence of available and adequate resources for: fundamental analyses, construction of strategic visions, application of public consultancy mechanisms, in a cyclic process and based on strictly measurable result indicators, represent an important resource for the diminution of the system's coherence and stability.

Source: Author data processing

Conclusions
The current activity of Ministry of Regional Development and Tourism in the regional development field completely overlaps the management activity of Regional Operational Programme. This aspect is demonstrated by the private documents of Ministry of Regional Development and Tourism – activity reports, information and publicity documents.
Although the management of structural funds 2007-2013 granted through Regional Operational Programme relate to a legal and institutional framework which allowed significant expertise accumulations and undertakings of responsibilities, it does not benefit from a full undertake of responsibilities by all the actors involved, and therefore the Management Authority replaces through personal efforts of substantiation and decision the solutions necessary for the provision of a regional impact of the promoted projects. In such a context, in the implementation of structural funds 2007-2013 granted through Regional Operational Programme, a lot of instructions and corrections should be considered. Subsequent to the implementation of recommendations included in the audit reports, clear and coherent audit trails are used, but they are not yet doubled by internal ethics politics, remuneration formulas concurrent with performance or procedures for the identification of "sensitive positions".
The implementation speed for the projects financed through Regional Operational Programme is slowed down due to the large volume of documents required upon the reimbursement of the

payment requests, and also due to the number of "pairs of eyes" involved in the analysis, which double the processing time.

This situation is one of the elements which describe the limitations of the current centralized approach of the regional development in Romania.

The legislative efficiency could be defined as the measure which, within the regulation setting, helps the programme, management and implementation processes. The legislative sustainability shows how stable and durable the whole system is, and also its capacity to be adapted to the environment conditions or modifications, both internally and externally (at decisional, economic and social level).

However, adaptation of the legal framework is imposed currently in order to establish a functional setting for the undertaking and prioritization of strategic objectives, in order to have a durable and harmonious development of the regions, and to guide the identification and implementation of the most adequate projects with regional impact.

The management of structural funds 2007-2013 granted through Regional Operational Programme deals with various situations in which, due to the fact that the Law of regional development remained behind against the legislation for structural instruments implementation (including Regional Operational Programme 2007-2013), it has to assign additional resources in order to find solutions through other types of regulations. The Management Authority has to take a substantial decision and to convince the actors of the system with respect to such taken decisions, without benefiting from any advantages of a fully coherent legislative setting.

The legal and institutional framework of Romania created the premises for a top-down (centralized) type of approach for the regional development process, such approach being adequate for a starting stage, when the regional development experience was extremely reduced in Romania. While the regional development experience is accumulated at regional level, the main limitation of the centralized type of approach begins to be noticed, more exactly the fact that such approach fails to put in value the regions' potential to manage regional development plans directly linked to the specific needs of the regions. Therefore, the centralized approach should be completed by a decentralized approach, as a natural next phase.

The current institutional and procedural setting gives advantage to the approach of the type "local development which falls among certain priorities of regional development established nationally". Definitely, the local development is important for the regional development, but it is not self-sufficient in this respect. The approach of the regional development through projects of regional interest is a complementary approach, which currently is insufficiently developed.

COMMON AGRICULTURAL POLICY POST-2013 IN THE VIEW OF ROMANIA AND FRANCE

Niculescu Oana-Marilena
Bucharest Academy of Economic Studies Faculty of International Business

Summary
The paper belongs to the field of research "International Business and European Integration". Entitled "Common Agricultural Policy Post-2013 in the View of Romania and France", the paper aims to analyze the positions of both countries in the context of the Common Agricultural Policy (CAP) reform. The objectives of this paper are to emphasize the need for a strong CAP, based on two pillars, the position of different countries or groups of states regarding CAP reform and the allocation of European funds on four axes within the Rural Development policy. The paper is related to the research aiming to analyze some issues of the most debated, controversial and reformed European policy. In the same time, it continues my previous research consisting in different papers concerning CAP reforms, food security, agricultural market stability, Romanian agriculture with a view to the future reform and follows the theme of the doctoral thesis entitled "CAP Reform and its Implications for the Romanian Agriculture" (coordinator prof. dr. Gheorghe Hurduzeu, Bucharest Academy of Economic Studies, Faculty of International Business, doctoral studies within 2009-2012). The research method consists in collecting and analyzing data from internal and international publications, the use of statistical data in order to realize a comparative analysis between Romania and France regarding the agricultural output volume variation within a period of ten years and the distribution of the European Agricultural Fund for Rural Development (EAFRD) on four axis in the period 2007-2013. This paper tries to reflect the similarities and differences between one of the oldest Member States of the European Union (EU) - France which has a modern agriculture and belongs to the conservative group and a New Member State - Romania, whose agriculture has a deep dual character and where the medium size farm is not developed enough. The results of the research consist in the fact that Romania should consider French agriculture a model and should adopt a strategy focused on setting up of producers 'organizations and of agricultural chambers, the encouraging of young farmers to settle down in the countryside, agro tourism with a view to increase the value of the Romanian village.

Key words: Common Agricultural Policy, reform, Rural Development, Romania, France
JEL Codes: Q18

I. Introduction

The cooperation between Romania and France has a long tradition. In the spirit of the strategic partnership dated February 2008, the political dialogue aims to express the common positions regarding CAP which has to be reformed in the perspective of 2013. Agriculture is the engine of rural development and has to contribute to the management of territories and to the increasing of the natural heritage of rural areas along the whole Europe. Since 2010, EU Member States have expressed a common position regarding one of the objectives of the CAP, namely to ensure EU citizens with high quality, diversified products at appropriate prices. In October 2011, the European Commission presented the legal proposals designed to make the CAP a more effective policy in order to enhance the competitiveness of agriculture and rural development. The proposals are going to be discussed with other European institutions so that the future CAP to be implemented on January 1st, 2014.

II. Literature/research review

Through the subject presented, the paper belongs to the research consisting in books, studies, documents and communications aiming to analyze issues of one of the oldest EU policy.

The CAP reform is an important need as it is stated in the Communication of the European Commission (2010, 2011) and in the research of many European think-tanks. In the study published by Romanian Centre for European Policies (RCEP), Luca (2009) highlights the dual character of the Romanian agriculture and the fact that the middle farm size is not developed enough. In the most recent Romanian study regarding CAP, Giurcă, Alexandri and Rusu (2012) make a retrospective analysis of the publications regarding CAP reform, the implications of implementing the proposals of the European Commission in Romania. Zahrnt (2009) speaks about the winners and losers of CAP reform and later (2011) shows that EU Member States pay for wasting public money.

III. Research method

The research method consists in collecting and analyzing internal and international data from different publications as well as a comparative analysis between Romania and France in terms of:
- variation of the agricultural output volume over a period of ten years using statistical data;
- allocation of EAFRD on four axis.

IV. Results of the research

4.1. The position of EU member states on CAP reform

Most member states wish that a strong agricultural policy to be maintained, having a significant budget. Their position is against the renationalization of the CAP and the co-financing of the measures under the first Pillar.

France belongs to the **conservatory group** represented by the former EU-15 countries like Germany, Belgium, Luxembourg, Spain, Portugal, Greece, whose position advocates for keeping a CAP with a generous budget and maintaining the support for the first Pillar, especially for direct payments. **Franco-German Protocol** emphasizes the need to adjust closer the future CAP to the global realities, to meet better the requirements of the European citizens regarding food security and to provide them food at reasonable prices, to ensure environment preservation and rural development. Priorities are considered the following principles: simplification of the CAP, stability of financial resources and a stronger market-orientation. In terms of direct payments, their redistribution is considered inadequate considering the different economic conditions and contributions of the Member States to the community budget. World economic crisis began in 2008 in the United States and spread later to Europe - where the first country affected was Greece - and this implies that measures must be taken in order to cope with increased volatility of prices. It also highlights the need to increase the role of producers 'organizations and the importance of farmers' income stability. With regard to the second Pillar, Rural Development, measures focused towards the diversification of the rural economy and quality of life are foreseen. It is emphasized the increase of farms' competitiveness, the environmental measures, climate changes and management of natural resources.

Romania has a similar position with the **New Member States** which favors a balanced distribution of direct payments, the progressive convergence of the subsidies to those received by farmers from EU-15 and the establishment of a loan fund based on equity in order to reduce the discrepancies occurred between farmers and the increase of competitiveness among farms. Therefore, Romania asks for the establishment of a convergence mechanism that should better reflect the equity principle with regard to the payments per hectare. Certain criteria should be used that take into account the utilized agricultural area and the number of animals ,the rural population, labor employed in agriculture [Giurcă, Alexandri and Rusu 2012 : 226].

Romania does not agree with capping the direct payments for the large farms neither with greening of payments but shares the Commission's proposal to create a mechanism for emergency crisis. With regard to the second Pillar, Romania supports the Commission's proposal to have a Rural Development policy focused on competitiveness and innovation, climate and environmental changes. An important issue to be considered refers to the support for small farms in order to avoid land abandonment, depopulation and to attract young people in agriculture.

Poland, where the middle size farm is better represented in comparison with Romania, is interested **to modernize and consolidate farms**. Regarding direct payments, Romania agrees to give up the historical criteria (yields per hectare); these payments must be made according to the objectives set for them, have to be simplified, equally allocated; additional payments should be added. The future CAP must ensure food security, sustainable development and has to be more market-oriented. Subventions should provide income stability and the support of small, organic farms.

The **reforming group** includes countries like **Great Britain, Netherland, Denmark, Sweden**. Their position, with some differences, are in favor of phasing out the direct payments by 2020 and the transfer of funds to Rural Development. The most vehement position belongs to Great Britain - one of the biggest contributors to the EU agricultural budget - which supports the full liberalization of the CAP, considering that this policy distorts the market, is expensive, supplies expensive foodstuffs and is paid from European citizens' money.

4.2. The need for a "Common" Agricultural Policy

The demographic growth, the changing diets in the emerging countries, the risks induced by climate changes, soil degradation and water supply shortages are reasons for the rising of the food global demand. EU is facing the challenge of maintenance and perpetuation of production capacities and a stable commercial relations system. In this way, the evolution of the Romanian and French agricultural output volume variation for ten years is shown in the figure below.
Source: Eurostat

Figure 1. Variation of the agricultural output volume in the period 2000-2009

The above figure shows that the Romanian agricultural output variation is higher than in case of French production. This reflects a higher exposure of the Romanian agriculture in front of risks, the availability of resources to manage these risks (irrigation, fertilization, etc.) being reduced. To

stabilize the production volumes in the context of food security is an important issue and this implies the modernization of agricultural holdings. Furthermore, the instability of production volumes leads to price volatility, having a negative impact towards the consumer's access to agricultural output.

With regard to the role of the CAP, Romanian public opinion distinguishes among EU Member States and considers that providing decent living standards for farmers is a priority. On the other side, French people focus on supplying high quality products.

A strong CAP can lead to a sustainable rural area that allows an economic activity even in less favored area (LFA). CAP reform is closely linked to the EU 2020 Strategy in terms of green, sustainable and inclusive growth.

Currently, in Romania 29% of the population is employed in agriculture and 45% lives in rural areas; the contribution of the rural area to the net added value is 30%. In France only 3% of the population deals with agricultural activities, 17% live in rural areas whose contribution to net added value is 13%. Romania has to develop its infrastructure to facilitate the access in the countryside and to increase the life standard of rural inhabitants.

Semi-subsistence farms represent a significant percent in the structure of the Romanian agriculture, the output being used mainly for own consumption. Therefore, Romania must adopt measures in order to integrate them into the market but also to develop medium size farms. In Romania, rural population is aging, farmers over 65 years represent more than 40% while in France only 13% belongs to this group of age. Therefore, Romania has to provide support for young farmers to settle down in rural areas. In this respect, the support for young farmers increased from 25,000 Euros to 40,000 Euros (Measure 112 "Settle down of young farmers").

Ensuring increased agricultural productivity and upgrading the agricultural equipment are other requirements that Romania has to apply in order to develop its agriculture and to align to EU standards.

4.3. Similarities and differences between Romania and France regarding CAP

At the public debate concerning the future CAP launched by the European Commission in June 2010, many EU citizens and institutions took part; the main views expressed focused on the supply of healthy, safe food at affordable prices, sustainable use of land, rural area support and food security.

The Romanian contribution to the public debate focused on the following areas: good quality, safe products at reasonable prices for health, development of short circuits in the food chain, the preservation of the environment, the promotion of the biological output and landscape management, new working places and appropriate revenues, food security for all Member States.

The position of French authorities revealed several future expectations such as: safe, healthy, diverse and high quality food, better environmental and natural resources preservation, fight against climate changes, landscape diversity and dynamism of rural areas.

The analysis of the opinions reflects that the order of priorities is different but the expectations of both countries regarding the reform in agriculture are comparable.

The position of Romania and France on the future CAP reflects several common points like:
- to provide the European citizens good quality, diverse food at affordable prices, food security being one of the objectives of the CAP;
- to keep a similar structure of agriculture based on two pillars (Pillar I – direct payments and market measures and Pillar II – Rural Development);
- the need to maintain the European CAP budget at least at the level of 2013; the budget allocated to the CAP should fulfill its important objectives and meet many challenges agriculture is facing today;
- both countries are against tax increase, renationalization of CAP and co-financing;
- a more transparent and simpler CAP;

- the coordination with other EU policies such as Cohesion Policy and Competition Policy
In the field of expenses, the positions of Romania and France can be considered divergent. Romania might expect to an increase of funds allocated while France can expect to a decrease of funds, particularly Pillar I – direct payments can be directed to pay the social public goods (important criteria for Romania) and environmental (important option for France). With regard to Pillar II, both countries consider that the budget has to be at the same level or even increased.

4.4. Rural Development Policy
The development of the second Pillar was made in the period 1999-2001 after Agenda 2000 put together, for the first time, under a common umbrella issues concerning rural development. European Agricultural Fund for Rural Development (EAFDR) is a financing instrument created by the EU in order to support member states in the implementation of the CAP. For Romania it represents an opportunity for the rural area in value of 7.5 billion Euros while in France the amount is 7.6 billion Euros. In Romania the European funds for agriculture can be accessed through the National Program for Rural Development (NPRD) which addresses to rural development and aims to decrease the economic and social disparities between Romania and other member states.
The priorities of the program translated in four axis are:
- Axis 1 „Improving the competitiveness of agriculture and forestry";
- Axis 2 „Improving the environment and rural areas";
- Axis 3 „Quality of life in the rural areas and the diversification of rural economy";
- Axis 4 „LEADER"
The distribution of funds on axis in the period 2007-2013 reflects several differences between Romania and France. While in Romania most funds are allocated for axis 1, in France axis 2 ranks first; in both cases axis 4 represents a small percent as it is shown in the figure below. The distribution reflects the fact that, for Romania, the priority is the need to modernize farms and infrastructure while in France most of the funds are designed for the environment and for practicing agricultural activities in LFA.
Source: Own calculations based on the European Commission's data
Figure 2. Distribution of EAFRD on axis in the period 2007-2013

The second Pillar of the CAP must promote innovation and the transfer of technology in the benefit of agriculture and ensure a sustainable management of natural resources as well as to preserve biodiversity.

V. Conclusions

Even if Romania joined EU in 2007, Romanian agriculture has a strong dual character. Therefore, **Romania** has to adopt a strategy aiming to modernize the agricultural holdings, to develop medium size farms and to focus on the setting up of producers 'organizations and of agricultural chambers, the support of young farmers to set up in the rural area, the development of agro tourism. **France**, whose agriculture is one of the most advanced in the EU, can adopt new measures in order to have a more attractive rural space.

SUSTAINABLE URBAN DEVELOPMENT ELEMENTS

Popa Florina
Institutul de Economie Naţională

Sustainable development, the concept of our times, is an perspective objective, which should ensure economic progress, social and environmental impact of society for a long term. Approaches for regeneration and urban development require consideration of key issues related to natural regeneration in relation to social, economic, environmental and cultural aspects of urban life, as well as a public sector collaboration with private, local affected communities involvement in collaboration actions.

In this paper, there are pursued some important elements of sustainable urban development related to: outlook vision of city development in urban-regional context, providing financing and investing resources in the selected areas, the importance of creating local and regional partnerships, highlighting the role of public-private cooperation as an important instrument of urban governance.

In areas of a country, policies must be formulated according to the stage of urbanization, to allow the rural-urban and inter-urban ties for each stage; the aim must be improvement of options for development.

Key words: sustainable urban development, urbanization, partnership.
JEL Codes: JEL:R-R0-R00;R1-R10-R11-R19.

Introduction

Sustainable development should be considered in relation to qualitativ and quantitativ progress in the same time. This concept of our times does not confine to environmet protection or ecological feature of works, but it is an outlook aim, which have to ensure economic, social and environment progress of society, for a long time. In this way, public policies must be thought in the way where the measures established give the possibility of meeting current needs, without compromising those of future generations. It is also necessary public and private sector partnership, cooperation with affected local communities and their involvement in collaborative actions.

1.1. Key elements of sustainable urban development

According to Community Urban Aquis, a sustainable urban development is achieved through long term oriented integrated urban development plans, designed for cities and neiberhoods in regional context. In an area, these plans are efficient insofar as they are integrated in the city's major strategies; the impact is greater if the assessment is based on the potential of the area and of the local population.

Approaches for regeneration and urban development assume consideration of key issues related to physical regeneration in relation to social, economic, environmental and cultural aspects of life and urban development; it is also necessary public and private sector collaboration, cooperation with affected local communities and their involvement in collaboration actions.

Still from an early stage, partners involved in urban development plans, on medium and long term, have to design, a strategy for development ongoing after the public investment programs period, too. Monitoring and evaluation are an integral part of each development plan; they develop and reinforce each other, on clearly defined bases, they allow the assessment of progress, achievements and shortcomings.

As such, it can be mentioned some of the main elements for sustainable urban development:

-a perspective view of the city, each project must be incorporated into the urban-regional context (analysis of target areas, building strategies which define objectives, priorities, measures and medium and long term projects);

-horizontal, cross-sectoral coordination of the measures of urban regeneration and urban physical reconstruction - the main elements of the integrated approach for a sustainable urban development;

-resources focus towards funding and investment in selected target areas in order to produce a lasting impact;

-creating strong local and regional partnerships (an increased involvement of citizens and local and regional stakeholders, including private sector, shared responsibilities, implementation units), new instruments of urban governance, administration and urban management;

-capitalization of knowledge, experience exchange and know-how (benchmarking, networking);

-progress monitoring (ex-ante, medium term and ex-post evaluation, a set of criteria and indicators).

Building a sustainable urban project requires new forms of governance. The majority of performance targets, the project lasting, desire to improve the framework of life, the city contribution to the great stakes of the planet, require strengthening partnerships throughout project execution.

A project implement implies a working committee formed by join of different institutions (prefecture, general council, city planning agencies), whose should join riverain associations which should be aware of the beneficial feature of changement for their life environment. Performance and efficiency objectives primarily imply engineering and works manager involvement.

An important role in governance come to people. Given that public spaces firstly belong to citizens, diminishing the role of car in the life of each individual requires a mentality change along with urbanization and organization forms changing. Acceptance of urban density, energy consumption decrease, water decrease, also requires behavioral change, and at the same time, there is necessary change in urban facilities (bringing nature in the heart of city) and construction systems, which must be better adapted to human needs evolution.

Citizen participation is an ongoing process that does not stop to a space or a project construction of, but it must take place throughout the all period of works, facilities, utilities changes, rehabilitation of public equipments achievement etc..

Providing financing in urban development requires detailed plans and negotiations. Urban development programs should include long-term strategy that would ensure financing for a period of five to ten years, providing guarantee throughout all period of program fulfillment. Shorter periods are worn, because it takes time for local community involvement and integration of citizens in the social and economic context of the city and region, so to have a share to their development. In the case of development projects with more great values than, for example, recycling and development of industrial sites, it is also required the involvement of the private sector because public resources are not sufficient covering.

The role of local public administration is crucial to ensure local infrastructure, social services and business support, as it has the advantage of knowing the problems and the needs community is facing at. In the case of project financing from structural funds, local administration can access them, alone or in partnership; the eligibility condition is to ensure the technical capacity and the resources necessary to co-finance the project .

Among the financial instruments of urban regeneration, the are also, Neighborhoods Funds, which have become popular in urban policy in some Western countries, which can help to account for local communities get involved in the process of regeneration and development of disadvantaged urban areas. Also, financial engineering instruments, JASPERS, JEREMIE, JESICA and JASMINE are additional financial resources for urban operations.

Recourse to private sources, in working with the private sector on the strength of partnerships establishment, expounds the advantage of access to funding enough to achieve important projects for local development.

1.1.1. Public-private partnership important factor for sustainable development

Public-private partnership refers to forms of cooperation between public authorities and business, whose objective is to provide financing, construction, renovation, management or maintenance of infrastructure, or provide a service.

In urban economic development, public-private partnership can be defined as an agreement between public and private sectors to provide services and promote urban economic development.

In the last decade, the phenomenon of public-private partnership has developed in many fields, generated by budgetary constraints manifested in the Member States, which led to the need to resort to private financing. Public-private partnership developing is a part of an overall change of the state role in the economy, which evolves from the direct operator position to the organizer, regulator and controller.

Public authorities often resort to public-private partnership to undertake infrastructure projects, especially in sectors such as transport, public health, education and national security. As part of the Initiative for Development, the Council has approved a range of measures designed to increase investments in transeuropean transport networks infrastructure, in the fields of innovation, research and development, especially through this process.

Even if a cooperation between public and private sector can provide advantages that allow execution of a project for public interest objectives, the resort to public-private partnership can not be considered the only solution for the public sector, because for each project, it is necessary to evaluate to what extent the partnership option offers a real added value compared to other possibilities, such as a traditional contract.

It is possible that select the private partner should not be based exclusively on the share of capital contribution or on his experience, but to consider his offer features - the most economically advantageous - in relation to specific services to be provided.

Public authorities have initiated forms of partnership with the private sector for public services management, especially, at local level. Thus, public services related to waste management, water and energy distribution are increasingly entrusted to businesses, which can be public, private or a combination of them. In this form of cooperation, the administrative decision for an urban development plan does not belongs exclusively to public accountability, but it is a result of public-private negotiation and a contractual agreement. This means the multiples stakeholders involvement with different objectives and tasks, urban restructuring policy tending to become a task of many actors in modern land use planning.

Governments can play an efficient role by supporting private sector in the new economic initiatives, changing its focus from direct involvement and intervention, to creating a favorable business environment (Porter 1995). This new about urban governance generates the public sector competences change, problems referring to the degree of urban adminsitration intervention in the market and of transaction costs that it involve. Defining a balance between public sector tasks and competences versus private sector is difficult.

In the urban development policy, public-private partnerships have become somewhat institutional arrangements, because they lead to mutual benefits and socio-economic symbiosis. The partnership is such that an institutionalized form of cooperation of public and private actors working togheter for a common goal; both parties accept the risks of investment based on a predefined distribution of revenues and costs. Basically, a public-private partnership is an organization made to carry out a given project; its main advantages are flexibility, speed, cost-effectiveness, generally, transaction costs diminishing.

The chosen partnership models differ (building claim, joint venture, concession), the distinction between them being given by the division of competences between public and private sectors, the degree of risk share or of the way of financing (van der Burch, 2000).

Settlements based on public-private partnerships have become frequent in the fields of provision of infrastructure (for example, parking facilities), residential constructions, urban development and revitalization projects, public service provide while the number of urban planning fields with partnerships applicability increase .

The main obstacles involved in the fulfillment of a public-private partnership refers mainly to the following:
 -long-term programming horizon;
 -complexity of various projects;
 -delay problems related to the change of partners condition;
 -cultural differences between private and public partners;
 -competition rules for public projects as they are submitted by institutional actors, such as the European Commission (Burch 2000).

Summarized, the attributes of a public-private partnership consisted in: get involve of multiples public and private participants, agreement related to objectives and strategies, mutual benefits, hire key resources, a variety of activities. Additionally, geographic and temporal scale of public-private partnership depends on its objective and of the work it involve.

There are arguments that provide reasons for both for private get involve and for public intervention in providing urban services.

According to neoclassical economic theory and to state failure theory, competitive markets are important for providing services and their capacity to meet the customer needs, by the services provided. The lack of competition leads to incapability for adopting new technologies in an appropriate manner. As such, the private involvement in the production of urban services is inevitable to enhance their quality and efficiency.

But the market mechanism does not always work effectively to provide urban services, which motivates the need for public intervention (Walsh 1995, Batley 1996):
- the non-exclude particularity of public goods (police services, street lighting or street cleaning);
- market failure, determined by the nature of urban services have a tendency to monopoly, the need for some initial substantial investments and earnings uncertainty;
- equity; the government should provide public access to certain basic goods and services such as education and health, regardless of their capacity and device to pay for such services at market prices.

The share of public side in public-private partnerships vary by countries, due to differences related on the intensity of state presence. For example, the partnerships are usually dominated by the public sector in a country with a strong state.

The attributes of this form of cooperation are given by two theories: growth coalition theory and exploit conditions theory.

According to the theory of *economic growth coalition*, urban region has become an engine of growth driven by business interests, particularly, by landowners who will benefit from the increase of value of the land and property, along with urban economy growth. In turn, local governments benefit from the increase of income and property taxes; it is assumed that all participants are autonomous and volunteers.

In *theory of exploiting conditions*, the participants are constrained by political, economic and institutional forces. Local governments often tend to develop acceptable policies for the business community due to the dominant influence of the latter. Some analysis (Lawless 1994), considers that the two theories overestimate the influence of local businesses community and underestimate the important influence of local political context and the role of local government. Various

models of public-private partnership in countries are the result of the important impact that the national context and local institutions have on their training and operation.

1.1.2. Sustainable urban form

As is currently seen, the contemporary city form has direct influence on the environmental conditions. According to specialists' opinion, urban form actions on housing, ecosystems, endangered species and water quality through land use, habitat share, pollution and contamination of soil and replacing the natural ground with inaccessible areas.

Some urban forms can help reduce energy consumption, pollution levels, thereby meeting sustainable development requirements. To achieve this objective, competent bodies (designers, local and international NGOs, civil society and governments) have initiated redesigning measures and restructuring of urban places; new approaches are considered at different spatial scales[1]:
 - regional and metropolitan levels such as bio-region (Forman 1997, Wheeler 2000);
 - city level (Girardet 1999; Nijkamp and Perrels 1994; OECD 1995);
 - construction level (Roelofs 1999; Edwards and Turrent 2000).
 Urban form is a complex of features tied on the way of land use, transport system and urban projects (Handy 1996) and, as Kevin Lynch defines it (1981), represents "the spatial pattern of large physical, indifferent, permanent objects of the city"[2].

Ideal sustainable urban form, according to the concepts of architecture, is one that has a high denisity and an appropriate diversity, with mixed use of land, project based on sustainable transport, rich vegetation, use of solar energy. Among the objectives pursued, the most important refers to lower energy consumption, waste and pollution reducing, diminishing of car use, open space and sensitive ecosystems preservation, development of habitable human environment and designed to community.

1.2. Conclusions

The new paradigm of urbanization phenomenon is based on the notion that density and urbanization which leads it, are essential to achieve economies agglomeration and productivity gains. Urban sustainable strategy takes into account higher densities, shorter distances and smaller divisions, as basic elements of success. For each country, industrialization and urbanization are conditions for obtaining an average stage of income, the essential element being harness of urbanization potential to provide an overall equitable economic growth and to eradicate poverty. Policies should issue from contribution of institutions and instruments needed to promote economic concentration and social and environmental externalities management. Restrictive measures implemented by politicians, in relation to the spread of urbanization and mega-cities size, is counterproductive, as they exercise constraints on population movements in search of economic opportunities; failed interventions guide resources to unprofitable locations for business. Restriction actions on mobility, directed at specific objectives, can hamper the development flow and slow economic progress and so, they worse the living conditions of the poor.

In areas of a country, the urbanization occurs in different weights, so that sustainable policies must be formulated according to the stage of urbanization, to allow the rural-urban and inter-urban ties for each stage; the aim must be to facilitate economic densities by improving possible options for population and firms.

SUSTAINABLE DEVELOPMENT ASPECTS IN ROMANIA - REPUBLIC OF SERBIA IPA CROSS-BORDER COOPERATION PROGRAMME

Popescu (Stîngaciu)Ana-Maria
West University of Timişoara Faculty of Economics and Business Administration

Munteanu Nicolae-Eugen
West University of Timişoara Faculty of Economics and Business Administration

This research paperis basedon the analysis of the sustainability aspects in cross-border cooperation programmes. The importance of this research topic consists in presenting if the implementation of the activities of the projects submitted under cross-border cooperation programmes is based on the sustainability aspects. In this matter, the article will present theoretical aspects of sustainable development, territorial cohesion and cross-border development and focuses on practical questions related to sustainability aspects in the case of the Romania – Republic of Serbia IPA Cross-border Cooperation Programme. One of the main challenges of the cross-border area is also environmental challenges. Sustainable development is represents the fundamental objective of the European Union and refers to the economic, social and environmental dimensions of development. Countries cannot develop without existing cooperation between them, therefore EU policy is based on economic, social and territorial cohesion. Methodologically, the research is based on identifying of appropriate theoretical concepts corresponding to the chosen theme, collecting and processing data. The paper concludes with answers to key questions related to the integration of sustainable development aspects in cross-border cooperation programmes and projects. The results of the research have implications that could contribute to the current problem of absorption rate of EU funds, offering information about IPA cross-border cooperation programmes and increasing the capacity of potential applicants to elaborate and implement projects for obtaining and using financial EU funds. The added value of the paper results from the fact that EU financingis atopical issueof greatinteresttoEuropean and national level. To the best of our knowledge, this topic has not yet been researched within the national literature. The author contributed by performing methodology of qualitative research, a study case regarding the Romania-Republic of Serbia IPA CBC Programme, which can be very useful for a better understanding of the European Union financial allocations through cross-border cooperation programmes.

Keywords: sustainable development, cross-border cooperation, IPA, territorial cohesion, environmental impact

JEL Classification: F 15, H 77,O 38, R 58

Introduction

Borders are important for Romania's development because of its geographical position and the length of its internal and external borders in the new architecture of the EU. The Romania-Republic of Serbia border is 546,4 km long, partially land (256,8 km) with the River Danube forming a natural frontier for approximately 289.6 km. The eligible border regions within the Romania-Republic of Serbia IPA Cross-Border Cooperation Programme (Map 1) cover an area of 39,351 Km2, of which 22,149 Km2 is in Romania and 17,202 Km2 is in Republic of Serbia. Thus 56% of the eligible border area is in Romania and 44% is in Republic of Serbia. The priorities agreed by EU Member States, incorporated in all policies of the European Communities are equal opportunities, environmental protection, energy efficiency, information society known as horizontal themes. They refer to sustainable development, environmental protection and

improvement, promoting equal opportunity and non-discrimination, promotion of information society and IT solutions and increasing energy efficiency. These themes must be respected by applicants for developing and implementing their projects.

Map1. Romania-Republic of Serbia IPA Cross-border Cooperation Programme. Self processing

European territorial cooperation, as well as cross-border cooperation, is important, both economically and politically. The importance of cross-border cooperation is demonstrated through the inclusion of the CBC issue in the National Development Plan 2007-2013. One of the priorities in the achievement of the overall objective of the National Development Plan is to reduce the development disparities between Romania and EU Member States average. This goal was predicted to be accomplished by implementing projects that meet the needs and opportunities of each region and area.

The Romania-Republic of Serbia IPA Cross-border Cooperation Programme is the basis for this research and sustainability analysis. The Programme is financed by the EU under the Instrument for Pre-Accession Assistance (IPA) and co-financed by the partner states in the programme, Romania and Republic of Serbia. The objectives of the programme are to increase the overall competitiveness of the economy and to improve the quality of life for the communities in order to achieve a sustainable socio-economic development in the border area. The horizontal themes are found in each programme implemented by EU Member States or cross-border cooperation programmes between candidates and potential candidate's countries and must be respected by applicants for developing and implementing their projects submitted under these programmes. Therefore, the environment represents an important issue and not only in cross-border cooperationprogrammes. At project level, the environmental issue appears in the phase of project' evaluation, the potential applicants must provide information on how and if the activities that they propose to carry out the project have or not impact on the environment. They also must specify whether the impact is positive or negative.

The objective of the paper is to analyse sustainability aspects in cross-border cooperation programmes. The paper presents theoretical aspects of sustainable development, territorial cohesion and cross-border development. The paper focuses on practical questions related to sustainability aspects in the case of Romania-Republic of Serbia IPA CBC Programme.

Initial results after the first call for projects proposals provide the first information about the implementation of the Programme.

Aspects of Sustainable development, Territorial Cohesion and Cross-border development

Sustainable development is a fundamental objective of the European Union since 1997 and it was defined in The Report of the World Commission on Environment and Development as

"development that meets the needs of the present without compromising the ability of future generations to meet their own needs" (Brundtland 1987: 54). Sustainable development is the achievement of a higher quality of life for present and future generations.

Harlem Brundtland discussed in the famous report presented in 1987 about the fact that no country can develop in isolation from others and emphasised that the pursuit of sustainable development requires a new orientation in international relations.

The most important EU policy is the Cohesion Policy which represents the main measure to ensure a balanced and sustainable growth in Europe by promoting harmonious development and reducing the regional disparities.Conceptually, European Cohesion policy is based on three objectives: convergence, regional competitiveness and employment and territorial cooperation among the European countries. These are the main factors of the regional economic development. These objectives, between 2007 and 2013, aims to support cross-border cooperation through joint and regional actions, in order to increase the overall competitiveness of the regional economy and to improve the standard of living for the populated areas, to support transnational cooperation through actions leading to regional development as well as interregional cooperation and exchange of experience.

PromotingEuropeanterritorialcooperationis also one of the Romania's prioritiesprovidedin the National Development Plan 2007-2013.This prioritymustbe achieved through joint actions incross-border cooperation field. Cohesion policy means economic, social and territorial cohesion and sustainable development refers to economic, social and environmental development.

Europe 2020 Strategy is based on three priorities: smart growth (economy based on knowledge and innovation), sustainable growth (economy more efficient, greener and more competitive) and inclusive growth (economic, social and territorial cohesion). At national level, Member States will need to implement joint programming and increase cross-border cooperation.

We can conclude that these concepts are intersecting with each other and all lead to socio-economic development reducing the disparities between different countries and regions.

Cross-border Cooperation Programmes between Romania and Republic of Serbia

In 2003 was first initiated the cooperation between Romania and Serbia &Montenegro through the External Border Initiative Programme for Romania. The programme was meant to maintain and develop the traditional economic and cultural relationships between Romania and these countries. This was the basis for the introduction of the new instrument (IPA). The purpose of the programme was to increase the level of cross-border cooperation, this is why a special attention was given to the "people-to-people" actions type. For the 2004-2006 through the Neighbourhood Programme, the financial allocation for the Romania – Serbia & Montenegro was 16 million euro (Phare) out of which 1,8 million euro for the people-to-people actions and 4,20 million euro (CARDS) of which 1.2 million euro was allocated to the support of people-to-people actions. The programme aimed to create joint frameworks for promoting neighbourhood cooperation in the following areas: business support cooperation, environmental protection, local public services cooperation, small scale infrastructure improvements, and local tourism development.

The development of joint people-to-people actions has represented an important first step for many institutions in the border area, because it has raised the interest in joint activities and in undertaking planning and implementation of activities in collaboration with partners from the other side of the border. This stimulated the cross-border partnership, the cross-border networking and built relationships that are the basis for more sustainable cross-border initiatives in the future.

Romania-Republic of Serbia IPA Cross-border Cooperation Programme

The Romania – Republic of Serbia IPA Cross-Border Cooperation Programme resulted due to the cooperation between the Romanian and Serbian national, regional and local authorities, supported by the European Commission Delegation to Romania, the European Agency for Reconstruction in Belgrade, the Serbian Ministry of Finance, and the Romanian Ministry of Regional Development and Tourism. Given the fact that horizontal themes must reflect in each programme financed by EU funds, CBC programmes have also added horizontal themes including sustainable development and environmental protection which must be respected during the implementation period.In the description of the Romania-Republic of Serbia IPA CBC Programme it is stated as specific objectivesincreasing the overall competitiveness of the economy in the border area and improvement of the quality of life for the communities of the eligible area. Starting from the specific objectives of the Programme, there are four priority axes as a basis for intervention in order to tackle common challenges facing both regions from Romania, as well as from Republic of Serbia (Diagram 1).

Priority axis 1: Economic and Social Development

Measure 1.1 Support for local/regional economic and social infrastructure

Measure 1.2 Develop the tourism sector, including the strengthening of the regional identity of the border region as a tourist destionation

Measure 1.3 Promote SME development

Measure 1.4 Support increased levels of R&D and innovation in the border region

Priority axis 2: Environment and emergency Preparedness

Measure 2.1 Improve systems and approaches to adres cross-border environmental challenges, protection and management

Measure 2.2 Develop and implement effective strategies for waste and waste water management

Measure 2.3 More effective systems and aproaches to emergency preparedness

Priority axis 3: Promoting "people to people" exchanges

Measure 3.1 Support the development of civil society and local communities

Measure 3.2 Improve local governance in relation to the provision of local services to communities in the border areas

Measure 3.3 Increase educational, social, cultural and supporting exchanges

Priority axis 4: Technical Assistance

Measure 4.1 Support for the implementation, overall management and evaluation of the Programme

Measure 4.2 Support for the publicity and information activities of the Programme

Specific objectives

Diagram1. Priority axes Romania-Republic of Serbia IPA CBC Programme. Self processing

From the sustainability analysis, the axes and measures of the Programme represent an integral sustainable development approach. On project level, in elaboration phase, the potential applicant must focus on one measure for preparing the project proposal. It is a requirement to respect the horizontal themes by each project applicant when deciding the activities of the project as well as in the implementation phase of the project submitted and approved. At the end of the implementation period the beneficiaries have to complete a questionnaire in which they must stipulate if the project had environmental impact. Regarding the biodiversity, it must be specified if the project had activities with effect on the Nature 2000 sites and if they did, then they have to mention if the effect was positive or negative and the area which might be affected. With regard

at the environmental emergency and air, the beneficiaries have to specify if the project addresses environmental emergencies or if the project contains activities aimed with effect on the air quality and if the effect was positive or negative. The impact on environment is measured also through the activities that affect cultural heritage, historical heritage and activities having a positive impact on landscape, natural and national parks, protected natural areas and thermal springs. In this case the beneficiaries have to specify whether the projects had positive or negative effect. It must be stipulated also if the projects includes activities that have resulted in a shift from road to water transport, activities aimed at developing river transport infrastructure, activities aimed at rehabilitation the river banks or at reducing potential flood areas and other flood prevention activities. The sustainable development and environmental protection is preconditioned by the programme, so if these aspects are respected during the implementation period, then the cross-border cooperation programmes will be sustainable as well.

The Romania-Republic of Serbia IPA CBC Programme is being implemented through calls for proposals. The projects submitted under the first call for proposal ends in 2012. The number of signed projects was 46 and the total value of all selected and contracted projects is 19 million euro. On 25 of March 2011was launched the second call for proposals to be financed and the deadline for the submission of applications was 27 of June 2011 and the total funds available for this call were15,3 million Euros.

After the evaluation period, a number of 45 projects were approved.The projects are based on the partnerships formed by eligible institution from Romania and Republic of Serbia. In general, the project activities have to reflect the objectives, the priorities and the horizontal themes in the application form.Inthe first call for proposals which is still in implementation phase, from 46 projects approved 6 projects are under priority axis 2 Environment and Emergency Preparedness and in the second call for proposals, from 45 projects approved 5 projects are environmental projects.

Conclusion

Since the projects under the first call for proposals are still in the implementation phase and the projects under the second call for proposals are in contracting phase, ex-post conclusions on the success and the real implementation of activities based on the sustainability aspects of the projects or programme cannot be completely presented yet. However, considering the fact that some of the projects under the first call for proposals completed during this period, some answers to key questions related to the integration of the sustainable development aspects in IPA cross-border cooperation programmes might be presented:

What is the structural impact of the projects?

Based on the programme indicators, one of these indicators is to increase the cooperation between public authorities, municipalities and the target for 2015 is 197 projects between public authorities in joint development, joint implementation and joint financing. For 2015 is estimated a number of 1200 participants benefiting from the joint public cross-border events organized within the projects.The Romania-Republic of Serbia IPA CBC Programme brings together organizations from various regions from the eligible area of the programme, active in various sectors. Cross-border cooperation betweenauthorities from different countries for joint implementing the projects submitted implies changes in some of the components of the organizational structure of the institutionssuch as administrative procedures, transparency and partnership principles. The requirement to find partners abroad and work together is one of the greatest achievements of EU findings. In many occasions the partnerships do last longer than the period of the projects and this is a proof of structural impact and sustainable development.

The activities of the projects have environmental impact?

Of the 46 projects under the first call for proposals, 3 projects are focused on environmental emergencies (whether is alarm systems or intervention, or monitoring and combating the negative environmental effects), 6 projects are focused on improving air and water (monitoring and combating plants with negative effects on air quality, combating pollution of rivers in the eligible area, 10 projects addresses the cultural heritage (either promotes or rehabilitate archaeological sites or cultural objectives), 2 projects positively affect the landscape (cleaning and setting up sites without interfering with the protected areas), 1 project improves the transport infrastructure, 6 projects promote tourism attractions and 2 projects addresses on flood prevention. Currently there are no data on greenhouse emission, the projects that may have impact on them are still in implementation.

ECONOMIC POTENTIAL RECOVERY – A EUROPEAN CHALLENGE IN THE MEDIUM TERM

Rădulescu Andrei
Post-doctorand Academia Română Senior Investment Analyst SSIF Broker

The waves of the worst global financial and economic crisis since World War II have seriously affected the economy of the Euro Area. The first wave of the global crisis determined the worst recession in decades for the member states of the region. At present, the Monetary Union is confronted with the second wave of the crisis – the public debt problem. Despite the efforts adopted and implemented by the European policymakers over the past quarters, the sovereign debt crisis is far from over. Spain has recently become the "favourite target" of the financial markets.

Among the consequences of the waves of the crisis for the Euro Area one can mention the potential output decline and the economic divergence (asymmetric evolution of member countries). In this context, the potential output recovery and the relaunch of the real economic convergence process represent the main challenges for the policymakers in the medium run.

This paper analyses the evolution of potential GDP of the member countries of European Monetary Union (12). I employ the Hodrick-Prescott methodology on data from the World Bank Database.

According to the results, the economic potential of the member states of the Euro Area (12) decreased to the lowest level of the past decades. At the same time, the analysis presents the differences exiting across the member states in terms of potential output. Some countries suffered an important potential output loss over the past quarters (it seems that Greece and Portugal have become asymmetric shocks in the Monetary Union). For these countries, the first wave of the global crisis transformed in a permanent shock. The decline of investments and the depreciation of human capital over the past quarters express a huge probability that potential output is going to maintain at a low level in the Euro Area over the following years.

The recovery of potential GDP towards the pre-crisis levels is dependent on a higher participation rate of active population, strong reforms of labour markets and, importantly, the return of investment flows. Other measures in order to attain the objectives of Europe 2020 (smart, sustainable and inclusive growth) would also help the process of potential GDP recovery in Europe.

I. Introduction

The Euro Area is strongly affected by the waves of the worst global financial and economic crisis since the end of the World War II. The first wave of the financial crisis determined a contraction of about 4% y/y of the GDP. At the same time, this wave of the crisis revealed the macroeconomic disequilibria accumulated by some member states during the first decade after the launch of the euro – leading to the second wave of the crisis (the sovereign debt issue).

The public debt crisis launched in Greece in 2010 is far from over, as the measures adopted and implemented by the policymakers over the past quarters are not perceived as credible by the financial markets. Spain has recently become the "favourite target" of the financial markets: the CDS (credit default swap) registered a record level (over 500 basis points).

The waves of the crisis present severe consequences for the economy of the Euro Area, among which one can mention: the decline of potential output, the increase of long-term unemployment, the economic divergence of member countries.

In this context, the Monetary Union in Europe is confronted with unprecedented challenges: potential output recovery, finding a credible solution to the public debt crisis and the relaunch of the economic convergence process.

This paper analyses of the evolution of potential GDP of the member countries of European Monetary Union (12). I employ the Hodrick-Prescott methodology on data from the World Bank Database.

According to the results, the economic potential of the member states of the Euro Area (12) decreased to the lowest level of the past decades. At the same time, the analysis presents the differences exiting across the member states in terms of potential output. Some countries suffered an important potential output loss over the past quarters: it seems that Greece and Portugal have become asymmetric shocks in the Monetary Union. For these countries, the first wave of the global crisis transformed in a permanent shock. The decline of investments and the depreciation of human capital over the past quarters express a huge probability that potential output is going to maintain at a low level in the Euro Area over the following years.

The rest of the paper has the following structure: the second chapter reviews the main methods for potential output estimation; the third chapter presents the methodology employed in the current paper; the fourth chapter analyses the results; the main conclusions are mentioned in the last chapter.

II. Methods for potential output estimation

The literature distinguishes several methods employed in order to determine the potential output. According to Brandner *et al.* (1998) there are three main methods used in determining the potential output: the OECD approach, the IMF approach and the European Union approach.

The OECD distinguishes between the values added by the private sector and by the government sector, with the potential output obtained as the sum of these components. In this approach, the value added of the private sector is estimated from a Cobb-Douglas function, under the following form:

$$Yt = \alpha Nt + (1-\alpha)Kt + Ut \qquad (2.1)$$

where Yt represents the logarithm of the value added of the private sector, Nt represents the logarithm of the labour input, Kt represents the logarithm of the capital stock, α represents the elasticity of output with respect to labour and Ut represents the error term, seen as the total factor productivity.

Then, the potential output of the private sector is obtained from the following relation:

$$Yt^* = \alpha Nt^* + (1-\alpha)Kt + Ut^* \qquad (2.2)$$

where Yt* represents the potential output of the private sector, Nt* represents the potential labour supply (NAIRU), Kt represents the capital stock and Ut* represents the trend rate of the productivity factor (obtained by applying the Hodrick-Prescott filter). Then, the potential output of the economy is obtained by adding the potential output of the government sector to the business sector potential output.

According to the same source, the IMF approach does not apply a uniform method in computing potential output across the member countries. In some cases the potential output is "… *related to equilibrium in the labour market as given by NAIRU and estimated within the framework of a Cobb-Douglas production function* …". One of the differences when compared to the OECD approach consists of the fact that the elasticity of output with respect to labour (as we saw in the above case, α) is approximated with the level of wage to GDP ratio. According to Brandner *et al.* (1998), "*in other cases, estimates of the potential output are based on statistical estimates of trend output*".

The European Union has its own method of determining potential output, different from the approaches of the OECD and IMF. According to Brandner *et al.* (1998), the approach of the

European Union for estimating the output gap consists of directly applying the Hodrick-Prescott filter to real output.

III. Hodrick – Prescott methodology

One of the methods employed by the literature in order to estimate the potential output is the Hodrick-Prescott (HP) filter. This methodology distinguishes between a cyclical component and a trend component of the GDP (Yt = Yt* + Ytc). The cyclical component of the GDP is obtained according to the following mathematical relation:

$$\text{Min} \sum_{t=1}^{T}(Y_t - Y_t^*)^2 + \lambda \sum_{t=2}^{T-1}((Y_{t+1}^* - Y_t^*) - (Y_t^* - Y_{t-1}^*))^2 \quad (3.1)$$

where Yt represents output, Yt* represents the trend of output, λ is a measure of smoothness, so that the lower the value of this parameter, the closer potential output follows actual output.

In the extreme case when λ = 0, then the trend would equal actual output. Hodrick-Prescott suggests a value of 1600 when working with quarterly data and 100 for annual data. However, some other contributions in the literature suggest the use of other values for λ. Bouthevillain *et al.* (2001) evidence some studies where the value chosen for this parameter is 400 for annual data. On the other hand, they mention other contributions where for a value of 1600 for quarterly data corresponds to a value of 6 to 8 for annual data.

There does not exist any ideal filter for the decomposition of output into trend and cycle. According to Bouthevillain *et al.* (2001), the Hodrick-Prescott filter presents the advantages of simplicity and transparency, which explain the fact that it has been one of the most widely employed filters in the analysis of the macroeconomic series. Two problems they mention are the compression and the leakage effects. The compression effects might appear, as a consequence of the fact that "*the cycles that should belong to the cyclical component*" are not completely included in the cycle, and thus the "*variability of the cyclical component is underestimated*". These effects have impact in the assessment of the public finances because of the volatility of trends and also might make it difficult to determine the expansionary fiscal policies especially during the boom periods as "*they potentially suggest an overall positive assessment of fiscal policies*". The leakage effects consist of the fact that "*cycles that should belong to the trend are not in fact included in the latter*" and consequently the
"*variability of the trend is underestimated*". Beyond this, they do not take into account possible "*jumps in productivity growth*". In the case of the Hodrick-Prescott filter, the magnitude of these effects depends on the choice of λ. According to these authors, the compression effects diminish with the increase of the value of λ. Pointing to the trade-off between the two effects, they conclude that the lower the value of λ, the lower the leakage effects. In fact, choosing the value of λ while applying the Hodrick-Prescott filter, one should take into account the costs of these effects and weight them.

After shortly describing the method, I now compute the potential GDP of the Euro Area (12) and of the member countries, using a value of 100 for λ. I use data (annual observations) of real GDP, expressed in 1995 prices, for the member countries of the Euro Area (12) for the period 1961 – 2011, from the World Bank Database. All computations have been performed with the package Eviews 4.1.

IV. Interpretation of the results

The following figure presents the evolution of potential GDP of the Euro Area (12) over the past five decades. There is obvious the downward trend during this period. This downward trend of the potential output in the Euro Area (12) was determined by the lack of reforms to the structural shocks that hit the member countries of the region over the past decades: oil shocks, globalization, enlargement of the European Union.

The potential output of the region decreased from around 5.2% y/y during the 1960s to 3.4% y/y during the 1970s. The potential GDP was estimated at around 2.3% y/y during the 1980s and the 1990s. During the 2000s it declined to an average of 1.4% y/y.

As can be noticed on the figure, the rhythm of the decline of potential output intensified during the past years, in the context of the waves of the worst financial and economic crisis since the end of the World War II. At present, according to these estimates, potential output of the Euro Area is below 1% y/y (the lowest level since 1960, at least).

Figure 4.1. Potential GDP Euro Area (12)

The waves of the Great Recession have strongly affected the structural components of the GDP: investments, labour supply and total productivity factor. On the one hand, capital investments declined severely across European countries during the period 2008 – 2010 (see figure 4.2.). This evolution was determined by the increase of the cost of capital, given the risk perception in the context of the crisis.

Figure 4.2. Gross fixed capital formation (%, y/y)

At the same time, the crisis led to a strong increase of unemployment rate (almost to 11%), the youth being the most affected category (over 20%, the highest values being observed in Spain and Greece (over 50%)).

Last, but not least, the total productivity factor was negatively influenced, either by the decline of investments, but also by the depreciation of human capital.

In what regards the cross-country analysis, the following graph presents the evolution of potential GDP for the member states of the Euro Area (12) during the period 1961-2011. As can be noticed, the countries that suffered the most severe declines of potential output after the launch of the Great Recession (period 2008-2011) are: Greece (-3.7 p.p.), Ireland (-2.9 p.p.), Spain (-1.7 p.p.), Luxemburg (-1.6 p.p.), Finland (-0.9 p.p.) and Portugal (-0.9 p.p.). According to the

Figure 4.3. Potential GDP – member countries of EMU (12)
Figure 4.4. Potential GDP Greece
estimates, potential output of Greece turned negative since 2009 (as can be noticed in the figure 4.4), evolution determined by the flight of capital (in the context of the public debt crisis), with negative impact for investments.

However, there can be noticed a group of countries with lower rhythm of decline (of the potential output) compared to the rate registered at the Euro Area level (-0.6 p.p.): Austria (-0.3 p.p.), Belgium (-0.4 p.p.), France (-0.5 p.p.).

On the other hand, the only one country in the Euro Area (12) that registered an increase of potential GDP during the period 2008-2011 was Germany (0.2 p.p.). This evolution expresses the fact that the first economy in the Euro Area benefited from the waves of the crisis. This result is sustained by the shape of the economy during 2010 (3.6% y/y) and 2011 (3% y/y). The economy has gathered the benefits of the structural reforms implemented before the global crisis hit the European continent (at present the unemployment rate in Germany presents the lowest level since the early 1990s).

These evolutions of the potential output across the member states of the Euro Area (12) confirm the real economic divergence across the region. This divergence increased over the past years, as several countries in the region (the periphery countries) seem to have become persistent asymmetric shocks (the figure 4.5. expresses the real divergence since the first wave of the crisis hit the region).

In fact, the Great Recession revealed the structural disequilibria accumulated by the member countries after 1999. In other words, the nominal convergence established by the Maastricht Treaty was not sufficient, as several economies accumulated severe macroeconomic disequilibria during the last years of the Great Moderation (especially unsustainable level of private debt, with negative consequences for the public finance stances since the launch of the crisis).

Figure 4.5. Standard deviation (potential GDP)
V. Concluding remarks

According to this analysis the potential output presented a downward trend across the Euro Area (12) over the past decades. The waves of the worst global financial and economic crisis since World War II exacerbated the rhythm of decline of the potential output of the EMU member countries, as capital investments contracted severely (mainly in 2009) and human capital depreciated.

At the same time, the analysis presented the differences among member countries of the Euro Area in terms of the amplitude of decline of the potential output. In some countries, the potential output turned negative, as the investments contracted for several years and the unemployment rate surged to record level (especially for young people) (for instance, the youth unemployment rate in Euro Area is over 20%).

In this context, one of the main challenges for the European policymakers on the medium run should be the recovery of potential output. It would be a very difficult process, as, normally, the potential output recovers gradually after a prolonged period of crisis (at present, the Euro Area faces the second recession since 2008).

The recovery of the potential output requires an acceleration of the rhythm of growth, but this seems impossible given the context of fiscal consolidation during the following years. Among the economic policy measures that may support the recovery of the potential output one can mention: the relaunch of capital investments (especially in sectors with a high added value), higher investments in Research&Development and in Education across the member states, the structural reforms (mainly in terms of labour markets). These measures are consistent with the Europe 2020 strategy: smart, inclusive and sustainable growth.

There can be mentioned several reasons that determine me to expect a low potential GDP at the Euro Area level over the next years: the high risk premium (with negative impact for investments), the increase of financial regulation (with immediate impact in a higher selection of investment projects for part of the financial system), a higher tax burden (with negative impact either for investments, or labour force supply).

INTANGIBLE ASSETS THROUGH THE COHESION POLICY

Roth Anne-Marie-Monika
West University of Timisoara Faculty of Economics and Business Administration

Popescu (Stingaciu) Ana-Maria
West University of Timisoara Faculty of Economics and Business Administration

Intangible assets in general and intellectual capital in particular are important to both society and organizations. It can be a source of competitive advantage for business and stimulate innovation that leads to wealth generation. Technological revolutions, the rise of the knowledge-based economy and the networked society have all led to the same conclusion that intangibles and how they contribute to value creation have to be appreciated so that the appropriate decisions can be made to protect and enhance them. The Cohesion Policy represents the main EU measure to ensure a balanced and sustainable growth in Europe by promoting harmonious development and reducing the regional disparities. The general objective of the paper is to highlight the important role of the Cohesion Policy in the development of intangible assets. The objectives and the instruments of the Cohesion Policy are designed to support programs on regional development, economic change, enhanced competitiveness and territorial cooperation through the European Union, to develop human resources and employability.

1.Introduction

Sustainable economic development, no matter the geographical area it is applied to, relates to improving living standards and incorporates a new focus and challenge for the economy: the measurement of intangible and social assets.

Growth in all the European economies must be supported by solidarity between all regions and citizens, and this is possible through the Union Cohesion policy.

The aim to ensure the harmonious development of the economies by reducing the differences existing between regions and the support of the less developed ones, exist since1957 when Belgium, the Federal republic of Germany, France, Italy, Luxembourg and Netherlands signed the Treaty of Rome, through which they were determined to ensure the economic and social progress of their countries by common actions.

Later, the European Community, in order to promote its overall harmonious enlargement, developed its actions leading to the strengthening of its economic and social cohesion, as also stated in the Treaty of the Functioning of the European Union, article 158. On December 2009 entered into force the Treaty of Lisbon which amended the European Union treaties not replacing them, instead had improved them. The economic and social cohesion referred to in the article 158 of the European Union Treaty mentioned above, was modified with "economic, social and territorial cohesion" (Official Journal of European Union, C 306, 2007: 85).

The objectives of the Cohesion Policy are focused on convergence, regional competitiveness and employment and territorial cooperation among the European countries. These are the main determinants of the regional economic development.

2. Knowledge-based economy and society. Intangible assets – generators of sustainable competitive advantage and convergence

National economies are in a continuous transformation, influenced by globalization and structural change. The globalization process has been an important changes driver in the context of

economic development. "Through its increased mobility of capital, workers, goods and services, globalization is changing the rules by which the economy has been governed during much of the post-war era" (Pike et al., 2006).

Our society is constantly changing at an increasing speed. We talk more and more about the New Economy or about Knowledge Economy which is characterized by a number of factors different from those that characterized the traditional economy.

Some of these features may be referred to as computerization, changing technologies, increasing uncertainty, sustainability, globalization and application of new knowledge. The quality and uniqueness of the knowledge component has become the most important source that someone may have in order to gain a competitive advantage.

The New Economy is developing a global network society where information and communication technologies (ICT) are reshaping communication both within and between organizations. Growing interest on intangible assets is closely related to the development of knowledge society and the undeniable importance of new knowledge-based workers (Porter, 1998). In this context, many authors discuss the importance of a firm to survive, highlighting the importance of human and social capital performance within the organization. Concepts such as intangible assets, intellectual capital, knowledge creation, basic skills and innovation, are now a centre stage in explaining economic assets that create continuous value to an organization, in exchange for financial and physical resources and gains (Ulrich, 1998).

In a broader perspective, the term knowledge society refers to any society where knowledge is the primary production resource instead of capital or labor. A knowledge society creates, shares and uses knowledge for the prosperity and welfare of the people who belong to it. Also, lately, the emerging concept of the "new economy" was revealed as a new approach of the economic science. A segment of economists consider that modern economies are dynamic and adaptive systems rather than closed systems struggling.

In Peter Drucker's (1993) vision, the future relies on other key success factors: "the traditional factors of production - land, labor and capital - have not disappeared. But they have become secondary".

Knowledge, unlike labor, land and capital is an asset that becomes more valuable on the extent of its use. The more used, the knowledge becomes more effective and efficient. Knowledge is key component of the system of modern economic and social development.

The new economy involves giving a greater interest to the so-called knowledge society, the employees (who are the holders of knowledge), intellectual capital, intangible assets and learning organizations. A failure to value intangible assets into companies' management and control systems in a systemized way makes sustainable management impossible and endangers the achievement of any company's economic, social, and ecological goals in today's knowledge-based economy.

People are key aspects for the evolution of value and co-creation of products and services that add value. Their distinctive capabilities are the basis of the competitive advantage. According to the new resource-based perspective of a entity, competitive advantage is achieved by continuous developing existing resources and creating new resources and capabilities in response to constantly changing market conditions. Among these resources and capabilities in the new economy, knowledge is the most important value creation asset.

3.The instrument of the Cohesion Policy

At present, the Cohesion policy represents more than one third of the European Union overall budget, about 35% of spending, more than 80% of subsidies for the less-developed regions of the Member States. Half of these funds are invested in the Member States that joined European Union in 2004.

The objectives of the Cohesion Policy are supported by three funds: the European Regional Development Fund (abbreviated as ERDF), the Cohesion Fund (abbreviated as COH) and the European Social Fund (abbreviated as ESF), divided between them (Table 1). The ERDF and ESF are also referred to as Structural Funds.

The general rules governing those funds are settled by the Council Regulation of the European Commission no. 1083 of 11 July 2006, which not amends the provisions of other regulations, as Council Regulation no. 1081 in 2006 or Council Regulation no.1084 from the same year.

The European Regional Development Fund is one of the financial instruments of European Union Cohesion Policy, created in 1975 for supporting programs on regional development, economic change, enhanced competitiveness and territorial cooperation through the European Union.

The Cohesion Funds are focused on transport, environment, trans-European networks, energy efficiency and renewable energy, applying to Member States with a gross national income of less than 90% of the European Union average.

The European Social Fund was created in 1957 and is the main European Union source of financial support to develop human resources and employability. This fund increases the adaptability of workers and enterprises by strengthening access to employment and participation in the labor market, by combating discrimination and facilitating access to labor market for disadvantaged people, by improving education ant training and helping develop the institutional capacity and efficiency of public administrations.

Table 1: The instruments of the Cohesion Policy, 2007-2013

Objectives	Structural Funds and instruments		
Convergence	ERDF	ESF	COHFunds
Regional Competitiveness and Employment	ERDF	ESF	
European Territorial Cooperation	ERDF		

Source: Introduction to the Structural Funds: 6, table available also at
http://ec.europa.eu/regional_policy/policy/object/index_en.htm

The Convergence objective, representing al least 81.54 % of total funds across the European Union, is the priority of the Funds. In order to complete their convergence process the regions under the Convergence objective receives significant financial aid until 2013.

The resources for the Convergence objective are distributed between the regions as follows: 70.51% for the regions corresponding to level 2 of the common classification of territorial units for statistics (NUTS level 2 regions) made by the Council Regulation no. 1059 in 26 May 2003 whose GDP per head is less than 75% of the average GDP of the 25 Member States before 1 January 2007 (excluding Bulgaria and Romania); 4.99% for the regions which lost the eligibility for this objective because their GDP per head will exceed 75%% of the average GDP of the 25 Member States before 1 January 2007; 23.22% for the Member States whose GNI per head is less than 90% of the average GNI of the 25 Member States before 1 January 2007 1.29% for the Member States whose GNI per head will exceed 90% of the average GNI per head of the 25 Member States before 1 January 2007.

The Regional Competitiveness and Employment objective represent 15.95% of total funds. The resources for this objective are distributed between the regions of the European Community not covered by the Convergence objective (78.86%) and the NUTS 2 level regions covered by the Convergence objective (21.14%). The later mentioned regions are those who were under Convergence objective in the period 2000 – 2006 and no longer meet the eligibility criteria of the mentioned objective because their GDP per head exceeded 75% of the average GDP of the 15 Member States (Austria, Belgium, Denmark, Finland, France, Germany, Greece, Ireland, Italy,

Luxembourg, the Netherlands, Portugal, Spain, Sweden and the United Kingdom). These regions will also receive financial aid in the transitional phase.

The European Territorial Cooperation objective covers regions which have land or sea frontiers, in order to support actions promoting the territorial development, the interregional cooperation and the exchange of experience. These funds are representing 2.52% of total funds and are divided as follows: 73.86% for the financing of the regions corresponding to level 3 of the common classification of territorial units for statistics (NUTS 3 level regions) along their internal and certain external borders and those NUTS 3 regions which have maritime borders separated by a maximum of 150 km for the purpose of cross-border cooperation; 20.95% for the financing of transnational areas and 5.19 % for financing of interregional cooperation, cooperation networks and exchange of experience along the entire territory of the European Community.

4.Cohesion Policy's main objectives to support development of intangible assets
Promoting employment and social cohesion
Global economic, social and environmental changes will have profound effects on the labor market and social situation in the Union. Cohesion policy has a key role to play in increasing employment, finding new ways to tackle rising unemployment, promoting self-employment, acquisition of new skills, social inclusion and the economic and social integration of migrants and vulnerable populations. Empowering people to effectively engage in transformation processes will be essential.

The equity (social inclusion) objective
It is uncontested that achieving an equitable distribution of well-being is one of the objectives of governments. There is also increasing agreement that development is about both efficiency and equity, and that public action, at whatever stage of development of an economy, should address social problems.

In Europe, pressure has mounted for greater attention to be given to social issues at EU level. A concern is that high and rising inequality, and increasing fear of globalization, could jeopardize economic integration (market-compensating motivation). Another is that national welfare systems are increasingly constrained by EU budgetary rules (political-economy motivation). A third is that the EU's existence is based on the expectation that citizens should enjoy equal rights (federal motivation). The failure to reduce inequality in several European countries, and its rise in others, are signs of the extent of the problem.

The question relevant for this Report is not "whether" but rather "how" governments should pursue equity objectives. In particular, the issue is whether there is a rationale for inequality to be tackled by a place-based development policy rather than by financial transfers to people independently of where they live. Before addressing this question, it is first necessary to clarify the concept of inequality and to define the policy objective.

Multidimensionality and social inclusion
There is widespread agreement that no single dimension can capture a person's well-being and the degree of inequality. A life worth living, including the opportunity both to achieve what an individual considers relevant and to widen her or his set of options, embraces labor skills, health, education, housing, security, income, working conditions, self-respect, a role in decision-making and so on. Income is a relevant component of these dimensions but it does not reflect them all, as empirical data confirm.

Income is one factor in achieving well-being, though it cannot achieve many aspects of well-being and, accordingly, cannot be seen as an end in itself. The capacity of any individual to convert a given amount of any "commodity", including money, into achievements that are relevant for their life depends on a combination of (social and physical) circumstances and on access to other "commodities" often produced by policy. Indeed, several dimensions of well-being strongly depend on public institutions performing essential tasks and provide public goods

and services. These different dimensions are also interdependent in terms of their effect on well being.

This multidimensional perspective is gaining increasing acceptance, as documented by the findings of the OECD mind-opening "Global project to measure the progress of societies". It has long been adopted by the European Union in promoting, through the Social Protection and Social Inclusion Process, the commitment and cooperation of Member States to reducing inequality. This political and methodological debate has utilized the concept of "social inclusion", which includes access for all citizens to basic resources, social services, the labor market and the rights needed "to participate fully in economic, social and cultural life and to enjoy a standard of living and well-being that is considered normal in the society in which they live". Together with the multidimensional approach, this concept also embodies both a threshold and an interpersonal notion of inequality and focuses strongly on the process through which greater equality is pursued.

Building on this perspective, the academic debate and various international policy Reports, it is possible to develop an operational definition of social inclusion. This can be defined as the extent to which, with reference to multidimensional outcomes, all individuals (and groups) can enjoy essential standards and the disparities between individuals (and groups) are socially acceptable, the process through which these results are achieved being participatory and fair.

This definition captures both a threshold and an interpersonal concept of inequality: a threshold concept, where the achievement of society consists of guaranteeing everyone some essential standards, which depend on (evolving) social preferences and attitudes94; an interpersonal concept, where the achievement of society consists of ensuring that disparities between individuals (or groups) are socially acceptable. The two concepts are complementary but distinct.

When disparities are reduced, the proportion of people falling under the threshold could increase and, conversely; when the essential standard is achieved by a growing proportion of people, disparities could increase.

The reference to "a participatory and fair process" captures the idea that both the dimensions and the thresholds used in defining social inclusion must be established through a democratic process, in which everyone is given a chance to form an expectation and to voice it, information is exchanged, public scrutiny and criticism take place; and a consensus emerges on which dimensions are relevant and what is "essential". This is the condition for making local choices more informed and in line with people's preferences and for allowing citizens and collective local actors the freedom to experiment with solutions while exercising mutual monitoring.

Multidimensional outcomes should identify people's substantive opportunity to live according to their values and choices and to overcome their circumstances. The reference to circumstances underlines that social inclusion policies should focus so far as possible on those factors that are outside the control of the individual. These include both personal characteristics inherited or acquired through life (gender, physical traits, social background, etc) as well as contextual factors, including the functioning of public institutions, which can affect everyone, or particular groups, sharing certain features (religion, culture, outlook, etc).

On this basis, a "place-based policy aimed at social inclusion" can be defined as: a territorial strategy for improving social inclusion, in its various dimensions, through the provision of public goods and services, by guaranteeing socially agreed essential standards to all and by improving the well-being of the least advantaged.

What is the economic rationale for such a strategy? Why is an exogenous intervention in a place needed in order to promote social inclusion? Why, if an exogenous intervention occurs, should it be centered on public goods and services? And why should the adoption and implementation of the policy be left to the local area?

5.Conclusion

The E.U. sustainable development strategy promotes the creation of a prosperous, innovative, rigorous, competitive and eco-efficient economy, which supplies high life standards and fully qualitative employment opportunities throughout the EU, thus also emphasizing the economic and intangible aspects as important for a sustainable development.

In consequence, sustainable competitive advantage is a central point, if not to say the core of both the national and corporate strategy. It allows maintenance and improvement of the company's competitive position in the market and enables the business to survive competitors for a long period of time. Quantitative and qualitative fundamental change in competition requires organizational changes to an unprecedented level. Current sustainable competitive advantage must be built on the organizational capabilities and must be constantly reinvented.

THE RELATIONSHIP EUROPEAN UNION – BLACK SEA REGION FOLLOWING THE IMPACT OF THE ECONOMIC CRISIS

Rusu Livia

Bucharest Academy of Economic Studies Institute of Doctoral Studies Faculty of International Business and Economics

This paper refers to the possible interaction between the European Union and the Black Sea region, following the consequences the international and financial crisis placed upon the Eastern neighbourhood of the Union. It provides a comprehensive picture on the economic situation in the Black Sea area, correlating the economic realities from the field with the required domains of policy actions.

The research performed tries to reveal the impact the economic crisis had on the Black Sea region, to identify the suitable sectors of cooperation following the recognition of the common challenges and problems. Moreover, it offers a quick insight for the possible future interaction of the region or the countries within with the European Union or at intra-region level.

The paper complements and enhances other researches (not that many though) on the subject. It studies previous researches, it uses the valuable information offered by the most comprehensive international economic data bases and it takes into account the present framework of dialogue developed by the European Union for its Eastern neighbours.

The research methodology included quantitative and qualitative approaches. The analyses of the international literature and the interpretation of the data covered a range of fields pertaining to the European economy. The reading of the information processed was made in a personal key and it was correlated in an integrated, systematic and interdisciplinary manner. The instrument of Opinion Survey was used in two circumstances: in one case, elements were extracted from an existent poll, while in another a personal Survey was created to further inquire on the theme.

The results of the research are of interim and final nature. The final results highlight the economic overview of the Black Sea region, pointing out the challenges and the risks on short, medium and long term. As a response to these challenges and risks, several common domains of dialogue can be identified, including a cooperation attempting to boost growth, competitiveness and productivity at the level of the entire region, through a sustainable development strategy. An important conclusion relates to the relevance of the European Union, as a main partner for the area. The Survey on the interaction European Union – Black Sea region generates interim results. Its limitation is given by the relatively small number of respondents.

The implications of the paper can be reflected in the political decision-makers field and in the policy-debate domain; the findings could be used by economic operators. The research offers a good portrait of the economic realities of the region, it tries to link the possible cooperation between the European Union and the Black Sea region with the concrete needs and it offers an insight from the region for an eventual future interaction of the above mentioned actors.

Keywords: Black Sea region, economic crisis impact, common problems, interaction, European Union.
JEL Codes: E0, F0, F50, F53, F55, H70, O10, O52, O57.

I. Introduction

The field of the research covers the domain of international relations. The theme of the paper relates to the cooperation between the European Union and the Black Sea region, area with a recognized growing strategic and economic relevance. It considers a neighbourhood composed by ten states: Bulgaria, Greece, Romania, Armenia, Azerbaijan, Georgia, Republic of Moldova, Ukraine, Turkey and Russian Federation.

The subject occupies a significant place on the international agenda. It became quite frequent in the European think-tanks policy-discussion, given the recognized role the region plays in the global energy equation, as well as in the context of the global political influence / power game. The paper represents a personal contribution to the research and to the debate in the field.

The objectives of the research are multiple. The questions the paper tries to respond refer to the following aspects: to what extend the economic crisis affected the Black Sea region, if so, are they common challenges encountered for all countries in the area so that various and specific (at the same time) sectors of cooperation could be envisaged in the relationship with the European Union? The research also indicates interim findings concerning the possible future interaction between the European Union and the region. The paper analyses the impact of the international economic crisis on the states and, hence, the region, determining similar concerns for the countries, even if in different degrees. It demonstrates that there are common risks on short, medium and longer term. These challenges can be associated (if there is willingness towards their resolution) with actions on same domains, in the attempt to pursue reforms, resolve common problems and generate sustainable economic growth, international competitiveness and improved productivity. Last, but not least, it indicates an advantageous approach for the intra-region cooperation.

II. Literature analysis

Despite the growing acknowledged importance of the Black Sea region, in the present, there is still little policy-oriented research on the state of play, challenges and opportunities for the interaction in and with this geographical area. Moreover, the impact of the recent international financial and economic crisis is less highlighted, this having a significant implication on the shaping and the concrete "business as usual" of the European Union - region interaction, as well as on the intra-region cooperation.

As reflected in a previous analysis (Gavras 2010: 5-29), the Black Sea region economic growth registered starting with the year 2000 suffered a strong negative impact due to the global economic crises. The damage (varying from country to country) begun to be noticed quite suddenly in the last quarter of 2008. The study reflects the important consequences on the financial systems of the countries in the region; it also indicates that the banking systems resisted better than expected and it highlights the need for changes (1). The recommendations regard the fiscal and individual bank level, some structural aspects and suggestions designed to promote economic development in the area through cooperation. Concerning the dialogue with the European Union, the study offers a brief highlight of the evolution of the relationship; very few recommendations are made. It is worth to mention that the analysis refers to the Black Sea region in general, without specifically indicating the countries taken into account. However, it can be deducted (Gavras 2010) that the area considered includes the countries the present article tackles. Regarding the cooperation at the regional level, a less positive outlook can be noticed, while a question mark is placed on the efficiency of the main structure operating in the area. There is no preference of the author for a future cooperation with a specific regional organization.

An extremely recent publication articulates a perspective on the Black Sea regional cooperation and the process of policy coordination amongst the countries, but not in an attempt to draw the interaction as a response to the economic crisis implication. It points out that there is no general definition of the Black Sea as a regional entity and it underlines the meaning of the Black Sea Economic Cooperation. It emphasizes the European Union as being the structure the region is looking to and examines the various cooperative schemes in the Black Sea sub-regionalism, including the role of the European Union (Manoli 2012: 1-12).

According to the Annual Report 2009 elaborated by the Black Sea Trade and Development Bank, there is a difference in the decline registered by the economies of the region as shown by the main financial and key economic indicators, as a consequence of the crisis. The prospects for

growth during next years are moderate, while it is foreseen a greater degree of variation in the growth rates. The report presents few recommendations in order to boost growth, along with the general advised line regarding measures taken by governments (structural reforms) to increase productivity and efficiency (Black Sea Trade and Development Bank). In the Annual Report 2010 elaborated by the Black Sea Trade and Development Bank, the economic and financial indicators reflect a process of recovery, even if the positive growth is situated at a lower level than the one observed during the crisis previous years. The recommendations envisage the need to develop local financial systems. As the Black Sea Trade and Development Bank represents the financial pillar of the Black Sea Economic Cooperation, the reports deal with a Black Sea region considered from the point of view of this inter-governmental regional structure (2).

The considerations related to the challenges the region faces and to the required reforms meant to preserve the gains, sustain long-term growth and strive for convergence with the European Union income levels and living standards contained by the Black Sea Trade and Development Bank in its vision for long-term strategic framework 2010-2020 are similar (even if more concise presented) to the ones evoked in the analysis belonging to Gavras.

The Global Competitiveness Report 2010-2011 and the Global Competitiveness Report 2011-2012 provided relevant information that proved useful in building a more comprehensible imagine of the picture represented by the economies of the countries in Black Sea region in the past years (World Economic Forum).

Last, but not least, for this paper were available pertinent elements on the official website of the European External Action Service. The framework of dialogue designed in less than a decade by Brussels with a heterogeneous region encompasses bilateral, as well as multilateral tracks, all trying to accommodate in a more or less successful manner, the needs of the individual actors and of the entire area in general (European External Action Service).

The present paper complements the research highlighted above, deepening the analysis related to the impact of economic crises on the Black Sea region. It identifies problems common to all countries (even if in a different degree), determining thus concerns relevant for the whole geographic area. In this context, the common challenges will generate possible future cooperation domains with the European Union or at intra-regional level. The paper does not reflect recommendations regarding the most appropriate way to interact between the actors mentioned here, this being an item treated separately by the author in a follow-up research.

III. Research methodology
The research methodology includes both quantitative, as well as qualitative approaches. They were applied seeking two purposes: to create the theoretical and scientific support for the research (mainly through documentary study) and to systemize, analyze and interpret the data reflecting the economic realities with a view to reach the proposed objectives. The literature studied belongs either to internationally recognized experts in the field or to international structures with well-known reputation in economic assessment. The works incorporate pertinent contributions both to the development of the subject, as well as to the perspective of the relationship between the European Union and the Black Sea region.

For an enhanced analysis of the economic current state of play of the region, including the impact of the international financial and economic crisis, the World Bank data system and the Reports on Global Competitiveness were accessed. Given the interdisciplinary feature of the theme, various domains were taken into account, especially related to European economy. The literature revision, the analysis and the interpretation of the data are personal and correlated in an integrated, systematic and interdisciplinary manner. A particular focus was placed on the examination of the economic evolutions in the region, associated with the relationship European Union – Black Sea region theme through the perspective of the supposed interest of the countries

from the region to obtain, on medium and long term, increased international competitiveness, higher productivity and economic efficiency, hence economic growth.

A significant relevance was also granted to the factors considered by managers as most problematic in conducting their businesses in the states belonging to the area. The information was extracted from the 2011 World Economic Forum's Executive Opinion Survey.

A quick insight on the interaction European Union – Black Sea region and its perspective was considered essential for the overall framework. For this purpose, an Opinion Survey with 16 questions was opened starting with February 2011 to respondents from the countries in the area. So far, 154 answers where received from subjects representing academia, private-sector operators, officials. The tool is useful, as it is expected to reflect the view and the ownership of the region on the future of the cooperation with the European Union.

IV. The results of the research

The results of the research can be placed in two categories: interim and final.

The conclusions drawn from the analysis of the economic indicators included in the World Bank data system are final, accurate and justify the evaluation of the impact of the economic crisis on the states of the Black Sea region and on the entire area. They also provide an engine in identifying the possible future sectors of cooperation.

One first conclusion of the economic research is that the region will continue to present, for a long time to come, the feature of heterogeneity. This will have a consequence on the attempt to design compact long-term policies for the area as a whole, to obtain the consent of the states to cooperate along those policies and to implement them.

The main economic overview conclusions can be summarized in the followings.

For the years following the crisis, the general trend at the regional level consisted in a slow recovery, with positive values for the annual economic growth (even if lower than in other similar developed regions of the world). The highest rate in 2010 was registered by Turkey (8.9%) and the lowest by Bulgaria (0.2%). The exception was Greece, the country pursuing the negative rate from previous years (- 4.5%). Even if the economic growth rates were mainly positive, few countries succeeded to notably advance in the global classification of the world most competitive economies for 2011: Turkey, Georgia, and, to a certain extent, Azerbaijan and Armenia. Romania and Greece had the worst drop amongst the world economies. That suggests a stringent need at the region level of economic measures destined to improve the productivity and the international competitiveness.

The inflation (GDP deflator), even if varied in the values registered, with few exceptions (Greece, Bulgaria) kept its negative influence of the prices instability (with impact on the social dimension), inducing a drop in the population purchasing power.

With the exception of Turkey, for the rest of the countries, the public foreign debt / GDP levels increased, as a result of the borrowings made in order to finance the governmental spending. Greece continued to maintain values over 100% for this indicator.

The unemployment stayed high, the significance being that an improvement in this sector depends on profound structural reforms.

The external performance of the economies in the region got better at the region level as a whole; the external trade continued to play an important role in the GDP formation. Pending on the economies' international ventilation, the countries of the Black Sea region demonstrate a very good degree of international openness of their economies (especially R. Moldova and Bulgaria, with values for the indicator over 100%).

The foreign direct investments show a general decreasing trend, with values under the previous years' levels. It is not expected a substantial improvement on short term if the economies of the western European countries, as well as the region ones (Russia for instance), do not recover from

the crisis and if the macroeconomic and business environment of the receiving states does not ameliorate.

The remittances from the migrant workers registered an increased dynamic, over the 2007 level in some cases (Georgia, Armenia, Azerbaijan, Ukraine), but with record drops for others (Greece and Romania).

The brain drain phenomena continued to affect the area, with the notable exception of Azerbaijan and, to a less extent, Georgia. There is an accentuated tendency in the migration of the potential labour force with pessimist forecasts for the years to come and negative impact on the economic development on longer term.

On short term, the region can face the same risks as the ones faced by other world similar economies: new tensions on European economies and financial markets, volatile capital inflows, rise in the food prices, escalation in the energy prices (the majority of the Black Sea region states being net energy importers). All these questions could be translated in a possible agenda of discussion between the European Union and the region.

On medium and longer term, there is a need to pass to actions meant to manage the structural challenges in all economies (associated with the longer term risks), even if in different degrees: the fiscal sustainability and the problem of the governmental spending, development of a sound local bank system, transformation or a mix of the social security, education and health system in order to tackle the labour force issue (quantity and quality), investments to ensure the foundation for further economic development.

Another important final conclusion is that the European Union remains the main commercial partner for the Black Sea region (primary destination for the exports and the imports), the main source generating foreign direct investments, the major loan provider, the principal supplier of official development assistance, the main source of remittances and the major destination for the brain drain phenomena. A recovery in the European Union's economy will have a positive impact on the economy of the Black Sea region.

The research individuated a series of factors common to all states (even though in a various weight), factors considered by managers as most problematic aspects in conducting their businesses in the region. These are as follows: policy instability, corruption, access to financing, inefficient government bureaucracy, government instability/coups, inadequate supply of infrastructure, inadequately educated workforce, tax regulations, tax rates, inflation, poor ethic in national labour force, foreign currency regulations, restrictive labour regulations, crime and theft, poor public health.

That means that the problems, hence the potential areas of a further cooperation between the European Union and the Black Sea region consist in a mix of sectors encompassing and inter-linking the democracy and rule of law aspects with economic (including commercial) and financial themes, as well as social, education and health issues. The complexity of the framework and the multitude of the problems needing a solution induce the idea that for the area it would be useful an integrated regional vision seeking to achieve a sustainable development area, with an intelligent, competitive and coordinated economy. Such strategy would allow the region to obtain, on medium and long term, increased international competitiveness and higher productivity. This represents yet another possible field of future dialogue with the European Union.

Concerning the interaction European Union – Black Sea region, the available results of the Survey indicate the preference for a further coherent, unique and structured way of cooperation. They also show that the actual interaction is effective to certain extent (56.3%) and that a future cooperation could take place under the European Neighbourhood Policy chapeau (70%) on a bilateral, as well as a multilateral track. A format at the Black Sea region level as a whole is favoured (50%). The interaction should concentrate on economic aspects, but also on fields as infrastructure, environment and tourism. The development of the economies of the region lacks

adequate financing (68.8%), a harmonized /unified economic and commercial framework (25%), trained human resources (18.8%) and encounters political difficulties (12.5%).

The Survey on the interaction European Union – Black Sea region presents the limitation given by the relatively small number of respondents (despite the long period granted for answers and the various attempts to engage the addressees). However, it is relevant from a double angle: firstly, it shows that the general interest in the region a genuine and real cooperation European Union – Black Sea region is somehow diminished and, secondly, it indicates the need to better develop the interaction and to stronger disseminate the concrete cooperation exits. The results of this Survey are interim findings and could be used in a follow-up dedicated research.

V. Conclusions

The research has implications in the field of international economic relations, including for the political decision-makers interested in seeking and applying adequate foreign policy actions in the Eastern neighbourhood. In an equally important manner, it enriches the analysis on the most appropriated interaction sectors in the relationship European Union – Black Sea region with a contribution reflecting the needs derived from the economic realities in the field. It also confirms that the European Union should pursue its combined approach towards the region, on a multilateral track, developed in parallel with a bilateral dimension.

This paper complements similar preoccupations from other researchers in this area and contributes to the policy discussion on the theme. For the economic operators, it highlights the countries better situated from the perspective of a potential investment decision, as well as the factors posing problems for doing business and domains needing economic action.

The study can be seen as a unique source of insight and a qualitative portrait of each country's economic and business environment, as well as an understanding of the overall regional situation or how it compares with the state of play in other countries. The paper also draws the attention to the need of a greater coherence, determination and real, concrete action in practice regarding the cooperation between the countries in the Black Sea region. It points out that there is a need for an acknowledgment of the problems common to all (the crisis affected all). These can be solved even if the degree of impact on each country's economy is different, because the achievement of sustainable growth, increased international productivity and competitiveness are goals shared at region level. A new understanding and innovative concepts of interaction (perhaps solidarity principle) may prove useful in drawing the intra-region interaction.

VI. Notes

(1) The data reflect evolutions until 2008. The analysis includes projected figures for 2009 and few predictions for 2010.

(2) The countries considered in the Reports of the Black Sea Trade and Development Bank are: Albania, Armenia, Azerbaijan, Bulgaria, Georgia, Greece, Republic of Moldova, Romania, Russian Federation, Serbia, Turkey, Ukraine.

FISCAL DISCIPLINE AND CONVERGENCE OF THE EURO AREA CANDIDATES. CLOSER TO THE PERFORMERS OR TO THE LAGGARDS?

Tatomir Cristina Flavia
Academy of Economic Studies in Bucharest, Faculty of International Business and Economics

Alexe Ileana
Academy of Economic Studies in Bucharest, Faculty of International Business and Economics

The objective of this paper is to examine how the current financial crisis has affected the fiscal discipline and convergence in the seven Central and Eastern European countries which have not yet joined the Euro Area (EA), namely Bulgaria, the Czech Republic, Hungary, Latvia, Lithuania, Poland and Romania. In the first part, we emphasize the importance of fiscal discipline for the effective functioning of the European Monetary Union (EMU). In the second part, by exploring the current status of the literature in this field, we identify scarce theoretical and empirical research on the non-EA countries' fiscal discipline and convergence. In the third one, we briefly present the data and methodology used in the paper. We report the fiscal discipline of the non-EA countries by analysing their distance from the Maastricht criteria regarding the budgetary deficit and the public debt as shares of GDP in the fourth part. We also assess the fiscal convergence of the seven candidates for Euro adoption in order to understand whether they add to the strengths or to the weaknesses of the EMU, from a fiscal point of view, by employing two benchmarks: the EA core and the EA periphery. The sovereign debt crisis emphasized the asymmetry between core and periphery countries. It is of major importance to know if the EA candidates will exacerbate the fiscal imbalances by joining the periphery group of countries or by contrast, will promote fiscal discipline and sustainability alongside the core EA member states. The fifth part concludes. The non-EA group of countries has not experienced major fiscal imbalances in the last four years, but the efforts must continue in reducing the budgetary deficits and controlling the public debts. In times of crisis, the EA candidates achieved more convergence with the EA core than with the EA periphery, by reducing the distance from the EA core. This is due to a deterioration in the fiscal performance of the EA core states and not to an improvement in the non-EA group of countries. The result is not encouraging for the fiscal convergence given the fact that we would expect an improvement in the non-EA countries' fiscal performance in order to catch-up with the best performers of the EA and not the reverse. In terms of public debt, the fiscal convergence with the EA core would not be desirable, due to the high levels of public debt achieved by these countries.

Keywords: Fiscal Discipline, Maastricht criteria, Fiscal Convergence, Euro Area, Euro Area candidates

JEL codes: E61, E62, E65, H60

1. Fiscal discipline matters for the Euro Area
In the context of the EMU, the fiscal discipline has always been in attention, since the monetary policy is given to a central supranational authority, which has the main goal to provide price stability in the medium term in the EA, whereas the fiscal policy is still within the hands of the

national governments. Moreover, the recent international crisis and the European sovereign debt crisis have relaunched the debate on an apropriate fiscal framework at the European Union (EU) level. There are different views on this matter. On the one hand, there are voices that support a fiscal union for the EA in order to become sustainable. De Grauwe (2006) takes this view further, advocating for a political union needed to ensure the succes of the EMU. On the other hand, there are voices blaming extended fiscal powers for Bruxelles (Mckay, 2005).

The fiscal discipline and convergence is a precondition for the effective functioning of a monetary union, since the existence of divergent national fiscal policies may generate divergent macroeconomic adjustments in a monetary union. The risk of fiscal imbalances and their consequences on the stability of the single currency was a matter of concern for the EMU architects from the beginning. The solution to control the fiscal imbalances emerged in the Maastricht Treaty (MT) and the Stability and Growth Pact (SGP).The European countries have experienced more than a decade under the rules stipulated in the MT and the SGP, which set numerical limits on government deficits (3% of GDP) and public debt (60% of GDP). Although these numerical rules are attractive because they are predictable and transparent, EU countries experience shows that national states, taken individually, are not very effective in providing fiscal discipline. Moreover, in the last years some issues concerning the EA came at the surface: the lack of fiscal discipline, the unsustainability of public finances and the loss of fiscal rules credibility (Schuknecht et al, 2010).

In this paper, we define the fiscal convergence as the reduction of the gap between an irresponsible country from a fiscal point of view (countries with excessive prolonged budgetary deficits and/or public debts) and the best performers of the EA. In addition, the concept of fiscal discipline highlights the fiscal performance of a country in fulfilling the Maastricht criteria.

Our study is important for three main reasons. First, fiscal convergence and discipline has become a subject of intense debate after the introduction of the Treaty on Stability, Coordination and Governance in Economic and Monetary Union (known as the Fiscal Treaty), which limits the structural deficit at 0.5% of GDP and requires automatic adjustment rules and penalties for countries exceeding the limits. Second, there are currently seven EU countries (except Great Britain, Denmark and Sweden, countries that benefit from the opt-out clause or temporary derogation from adopting the Euro) that must adopt the single currency sooner or later, which entails mandatory fulfillment of the nominal convergence criteria. Therefore, it is important to analyse their situation in order to understand whether they add to the strengths or to the weaknesses of the EMU, from a fiscal point of view. Third, the fiscal convergence in the non-EA countries is much less studied than in the EA.

2. Key findings in the literature up to present

Theoretical studies on fiscal convergence are very limited in number. The only papers we know so far that developed a theory of fiscal convergence are Skidmore et al. (2004) and Onorante (2004). The model of fiscal convergence proposed by Skidmore et al. (2004) is based on the government spending convergence, specifically states with low levels of government spending will experience an increase of the budgetary aparatus, while states with high levels of government spendings will experience a decrease, thus leading to convergence in time. We can not employ this model in our paper, since the MT criteria refers to budgetary deficit and public debt, not to government spendings. In the model proposed by Onorante (2004), the fiscal constraints lead to a default coordination among states, characterized by lower deficits, lower interest rates and inflation rates under control. Joining the monetary union increases the fiscal activism, so it is preferable an ex-ante fiscal convergence both for the new members benefits and the stability of the monetary union.

As regards the empirical studies, there is poor work concerning the fiscal convergence in the EU Member States. Sanz and Velazquez (2003) test for the EU convergence in government spending

compared with OECD countries, showing that the EU countries converge to a fixed state faster than the OECD countries. Arestis, Khan and Luintel (2002) argue that an arrangement for fiscal sustainability is a necessity for an effective monetary union, by analysing the budgetary deficits convergence within the EA and between the EA and the U.S. deficits. The main results show the existence of fiscal convergence in most European countries, reaching the 3% of GDP target for budgetary deficit immediately after the launch of the Euro and the existence of lower fiscal shocks in the EA than in the U.S. Mongelli and De Bandt (2000) suggest, by analysing the fiscal convergence in the EA countries before the creation of the EMU, that the highest level of fiscal convergence in this countries was achieved in 1992-1995, recording a decrease after that. The heterogeneity in fiscal convergence and the lack of discipline in the EU countries was highlighted by Kocenda et al. (2008), by assessing the fiscal discipline of the new EU members with respect to EU15, between 1995 and 2005. Thus, the ability of the monetary union to provide fiscal discipline for its members is under question.

The novelty of our study consists of at least two main characteristics. First of all, such an analysis on the fiscal discipline of the EA candidates is missing in the literature, as far as we know. Secondly, there is no such work regarding the fiscal convergence of the non-EA countries with the EA performers and EA laggards.

3. Data and Methodology
We test for the fiscal discipline of the non-EA countries in the last four years of economic and financial crisis by analysing their distances from the convergence criteria as set in the MT: fiscal deficit up to 3% of GDP and public debt up to 60% of GDP. In addition, we complement this approach with an alternative way of measuring the fiscal convergence by reporting the non-EA countries performance to two different benchmarks: 1) the core of the EA represented by Austria, Belgium, France, Germany, Netherlands and Finland and 2) the periphery of the EA represented by Greece, Portugal, Spain and Ireland. For each benchmark we compute the average of the budgetary deficit/public debt expressed as percentage of GDP. We use annual data series taken from Ameco, one of the European Commission databases. The budgetary deficits and the public debts are expressed as shares of the GDP.

4. Main findings
Overall, the fiscal performances of the analysed countries were deeply affected by the crisis, both in terms of budgetary deficits and public debts. The austerity measures adopted by the national governments in order to achieve macroeconomic stability led to higher levels of deficits and debts especially in the EA core and periphery countries (Table no.1).

Table no.1: Fiscal performance of the non-EA, EU core and EU periphery countries

EU Member States	Budgetary deficit (%GDP)		Public debt (%GDP)	
	2008	2011	2008	2011
EA core				
Austria	-0.93	-3.44	63.83	72.19

Source: AMECO database, European Commission, Authors' work

As regards the EA core countries, in 2008, when the economic and financial crisis started, they were characterized by budgetary deficits lower than the 3% of GDP limit, except France. The average of the budgetary deficits in this group was of 0.13% of GDP, the best performance being achieved by Finland, with a budgetary surplus of over 4% of GDP. Even though the budgetary positions were not worrying, the average level of public debt was above the 60% of GDP limit when the crisis hit. The four years of crisis led to an increase by over 3 percentage points in the budgetary deficit average (from 0.13% of GDP in 2008 to 3.24% of GDP in 2011) and by over 10 percentage points in the public debt average (from 63.41% of GDP in 2008, to 74.97% of GDP in 2011), putting pressure on the public finances in the EA core.

As regards the EA peripheral countries, the sovereign debt crisis emphasized the asymmetry with respect to the core countries.The root of the debt crisis is considered by the European leaders to be the fiscal indiscipline in peripheral countries. The EA periphery (commonly known as the PIGS countries) was hardly hit by the crisis, due to the fiscal imbalances recorded in 2008: the budgetary deficits average over 6% of GDP and the public debts average over 67% of GDP. The recent crisis worsened the fiscal positions in this group, increasing the budgetary deficit from 6.32% of GDP in 2008 to 7.92% of GDP in 2011 and the public debt from 67.24% of GDP in 2008 to no less than 110.53% of GDP in 2011.

In the non-EA group of countries, the fiscal imbalances were not so worring when the crisis started: the average of budgetary deficits was 3.02% of GDP, while the public debt average was 30.15% of GDP. Regarding the budgetary deficit, Bulgaria was the only country that fulfilled the Maastricht criteria both in 2008 and 2011. The austerity measures adopted by the Bulgarian government have shifted the budgetary balance from a positive position in 2008 to a negative one in 2011. On the opposite side, Hungary improved its budgetary position from a 3.6% of GDP deficit to a 3.7% of GDP surplus in the last four years. However, the Hungarian succes is only theoretical, being the result of an increase in the cyclical revenues by over 10% of GDP, obtained through the nationalization of the second pension pillar. In 2008, the year when the economic and financial crisis started, only the Czech Republic and Bulgaria fulfilled the Maastricht criteria regarding the budgetary deficit. In 2011, Hungary and Bulgaria managed to comply with the Maastricht criteria regarding the deficits. The rest of the non-EA countries were under the Excessive deficit procedure both in 2008 and 2011, with national budgets under pressure because of the more or less effective austerity measures adopted in order to counteract the negative effects of the crisis.

All the non-EA countries fulfilled the public debt criteria in times of crisis, having the advantage of low public debt levels when the international crisis started, except Hungary which violated the 60% of GDP limit for public debt both in 2008 and 2011. However, we can observe an increase in the level of public debt in the seven countries due to the loans contracted to achieve macroeconomic stability. For example, in the case of Romania, the increase in public debt was over 20 percentage points in the last four years because of the agreement with the international financial institutions – International Monetary Fund, European Central Bank and World Bank – but still under the limit imposed by the MT.

In terms of budgetary deficits, the non-EA countries achieved more convergence with the EA core than with the EA periphery, by reducing their distance from the EA core from -2.89 to 0 (Table no.2). This is not because of a significant improvement in the non-EA group, but rather because of a higher increase in budgetary deficits recorded by the best EA performers. Thus, the two groups attained similar budgetary deficit averages of 3.2% of GDP in 2011. The gap between the non-EA countries and the EA peripheral countries has widened in the last four years, from 3.3 in 2008 to 4.7 in 2011. This implies a better fiscal performance in the non-EA group, bringing these countries closer to the EA core.

Table no.2: Fiscal discipline and convergence in the non-EA countries – budgetary deficit

Budgetary deficit (% GDP)	Distance from EA core		Distance from EA periphery		Distance from the Maastricht criteria	
	2008	2011	2008	2011	2008	2011
Czech Republic	-2.1	-0.89	4.09	3.79	0.77	-1.13
Latvia	-4.11	-0.96	2.08	3.72	-1.24	-1.2
Lithuania	-3.14	-1.75	3.05	2.93	-0.27	-1.99
Hungary	-3.58	6.86	2.61	11.54	-0.71	6.62
Bulgaria	1.8	0.78	7.99	5.46	4.67	0.54
Poland	-3.55	-2.35	2.64	2.33	-0.68	-2.59
Romania	-5.55	-1.62	0.64	3.06	-2.68	-1.86
Average	**-2.89**	**0.01**	**3.3**	**4.69**	**-0.02**	**-0.23**

Source: AMECO database, European Commission, Authors' work

In terms of public debt, the non-EA countries achieved more fiscal convergence with the EA core, narrowing the gap by more than 4 percentage points and leaving the peripheral countries far behind. The distance from the EA periphery doubled in the last four years due to the surge in the PIGS public debts. However, we can not assess this as an economic success because all the countries analysed report higher levels of public debt.

Table no.3: Fiscal discipline and convergence in the non-EA countries – public debt

Public debt (% GDP)	Distance from EA core		Distance from EA periphery		Distance from the Maastricht criteria	
	2008	2011	2008	2011	2008	2011
Czech Republic	-34.71	-35.04	-38.54	-70.60	-31.30	-20.07
Latvia	-43.62	-30.17	-47.45	-65.73	-40.21	-15.20
Lithuania	-47.91	-37.22	-51.74	-72.78	-44.50	-22.25
Hungary	9.48	0.91	5.64	-34.65	12.88	15.88

5. Conclusions

In the context of the recent crisis, the non-EA countries made considerable efforts to achieve the fiscal discipline by fulfilling the Maastricht criteria. Their fiscal positions have not experienced major imbalances, but the efforts must continue in reducing the budgetary deficits and controlling the public debts.

In times of crisis, the EA candidates as a group achieved more convergence with the EA core than with the EA periphery, by reducing the distance from the EA core. This is due to the deterioration of the budgetary deficit in the latter group of countries.The result is not encouraging for the fiscal convergence given the fact that we would expect an improvement in the non-EA countries' fiscal performance in order to catch-up with the best performers of the EA and not the reverse. In terms of public debt, the fiscal convergence with the EA core would not be desirable, due to the high levels of public debt achieved by these countries. The EA periphery group remains by far the laggard in our analysis, increasing the fiscal gap both with the EA core and non-EA countries and running excessive unsustainable budgetary deficits and public debts.

CONSIDERATIONS UPON ROMANIA'S MANUFACTURING COMPETITIVENESS IN THE EUROPEAN CONTEXT

Vasilescu Felician
Academy of Economic Studies

Luțan Iustina
Academy of Economic Studies

Rujan Ovidiu
Academy of Economic Studies

Manufacturing structure is essential to ensure the dynamic equilibrium of the whole economy. In fact, this industry is the one that disseminates through the organization and conduct of business as well as by the products delivered, elements of technological progress and new, modern work methods, with significant economic effects. Today in the Romanian industry, an urgent matter is material and energy cost savings thus increasing the value added. According to the economic development, within the industrial structural changes, usually occur the following main trends: the declining share of production from mining industry, while increasing the intermediate and final production, the declining share of industries with labor intensive and reduced complexity and diminishing, starting from a certain development level, of the share of industries with intensive natural resources deficits, especially energy resources, increasing the branches characterized by intensive and highly skilled labor, priority development of branches based on inventions vastly incorporating R&D, etc.. Some of those trends are increasingly emphasized by research, technological transfer and international trade, processes that enhance the interdependence between and within national economies. Labor-intensive industries reduce their share in total industry in developed countries. Demand for products manufactured by these industrial branches begins gradually to be met by developing countries. Production based mostly on the traditional technologies, easily transferable, is moving gradually from more developed countries to least developed ones. In contrast, in the industrialized countries are rapidly developing those industries incorporating important R&D results. These processes had been the subject for several specific research.
Although labor productivity decisively influence GDP per capita during long periods of time, the correlation between GDP annual growth rate and labor productivity growth rate differs between countries.
GDP per capita is strongly and positively correlated in most countries with labor productivity per capita relative to production and income per capita relative to consumption.

Keywords: Labor intensive industries, Energy intensity, Value added in manufacturing, Highly skilled labor, Capital intensive goods

Introduction

Concept of economic structure and specialization in production of a nation has been dominated by Ricardian doctrine of comparative cost. (Krugman, Obstfeld and Melitz 2012: 25-26). Hence the need for countries in production specialization, considering the available resources and international trade advantage, as well as the possibility of a fair distribution of benefits resulted from international trade exchanges for all countries participating in the international division of labor, due to competition that occurs in world economy. It was concluded that this theory was based upon unacceptable and unverifiable assumptions, such as, for example, the fact that quantity and quality of production factors are immobile within the international relations, etc. and

considered a single production factor: labor. J. Viner, noted that such a simplification raised a barrier to exploring the consequences that differences between regions and countries have upon the production factors endowment. (Viner 1957: 19). The matter concerning the production factors endowment of a national economy in analyzing the production and foreign trade structure, has become a fundamental issue of economic research, first ones to tackle this were the Swedish E. Heckscher and B. Ohlin (Ohlin 1967: 43-57; Krugman, Obstfeld and Melitz 2012: 97-99). According to their theory, the geographical distribution of the production factors is particularly important, influencing the specialization in production and development.

Previous research

In general, the inequity specialization is obvious for those countries to export only goods characterized by intensive unskilled labor and low productivity level for importing goods intensive in highly qualified labor and a higher productivity level. Emphasizing the independence of the industrial structures relative to natural sources is accompanied by increasing national dependency towards the world market. So, the dependence gradually moves from the national economy to the world economy through foreign trade. This tendency results from the development path in a large number of countries, for which the satisfaction degree for natural resources demand from own production decreased significantly. Within the development stage in which the tertiary sector starts to grow, the industries with high consumption of natural resources gradually reduce their weight, for capital-intensive ones and especially those that encounter highly skilled labor and apply the latest R&D results.

Methodology

G. Fels and F. Weiss point out that there are some characteristics of these structures, relative to the development stages mentioned: gradually moving, in accordance with the economic development, from labor intensive industries to large consuming natural resources and hence to the standard goods producing industries, where in general, production technologies are well known and easily accessible (Fels and Weiss 1977: 32; Trefler 2005:21-29; Eicher, Mutti and Turnovsky 2009:88 – 98). Labor-intensive industries reduce their share in total industry in developed countries. Demand for products manufactured by these industrial branches begins gradually to be met by developing countries. Production based mostly on the traditional technologies, easily transferable, is moving gradually from more developed countries to least developed ones. In contrast, in the industrialized countries are rapidly developing those industries incorporating important R&D results (Bowen, Leamer and Sveikauskas 1987: 791–809). These processes had been the subject for several specific research. Although labor productivity decisively influence GDP per capita during long periods of time, the correlation between GDP annual growth rate and labor productivity growth rate differs between countries. In the developed ones the association is stressed positive, productivity being the main engine of growth. In the less industrialized countries the mentioned correlation is weaker, suggesting that other factors determine the economic performance of a country in a given year. (Srebotnjak,Hizsnyik and Toth 2011:2). GDP per capita is strongly and positively correlated in most countries with labor productivity per capita relative to production and income per capita relative to consumption.

Results

Negative correlation between GDP per capita and energy intensity is apparently valid in most countries, highlighting the fact that economies, as they become richer use less energy to produce one unit of GDP.(Srebotnjak,Hizsnyik and Toth 2011:5). Compared with other EU countries, Romania registers a modest performance. As regards the value added in manufacturing, the country is ranked 18, as outlined in *Figure 1*.

Figure 1: EU member countries value added in manufacturing, 2007
Source: EUROSTAT, Annual detailed enterprise statistics on manufacturing (NACE Rev.1.1 D), 06.03.2012

Figure 2 shows a comparison regarding the position of different branches within the Romanian manufacturing industry, and EU27 as well as the share of this industry in Romania and in the corresponding industries at EU27 level.

Figure 2: Comparison between Romania and EU27 regarding the Value Added indicator, the position of manufacturing components in total and the share of Romanian manufacturing branches in EU27, during 2007.

Another interesting comparison is the Romania's position in the EU27 regarding the energy consumption of manufacturing sector, respectively the value added as shown in *Figure 3*.

Figure 3: Comparison between Romania and EU27 regarding the value added and energy consumption of manufacturing sector branches.

Conclusions

Only for a limited share, the supply of production factors can be adapted to different industries demand. In each region or country, the exported goods relatively contain in larger quantities the cheap factors, while imported goods incorporate scarce and expensive resources for the importing country. Romania exports particularly labor-intensive goods and imports capital intensive goods, hence the labor productivity aspect in general and especially in export industries being vital. Compared with other EU countries, Romania registers a modest performance. As regards the value added in manufacturing, the country is ranked 18. Comparison regarding the position of different branches within the Romanian manufacturing industry and EU27 highlights divergence, and the share of this industry in Romania and in the corresponding industries at EU27 level is almost insignificant. The Romania's position in the EU27 regarding the energy consumption of manufacturing sector, and the position regarding the value added are obviously divergent

ROMANIA'S FIRST FIVE YEARS IN THE EUROPEAN UNION. A SHORT ASSESSMENT

Vădăsan*Ioana
West University of Timişoara Faculty of Economics and Business Administration

It's been more than 5 years since our country has joined the European Union, on January the 1st 2007. It's been a long road, as fulfilling the Copenhagen criteria had not been an easy task.
But was it all worth it? Are we better off today, five years after? Did we know how to take advantage of European Union membership? Did we know what to do and how to do it, in order to benefit from (all) the advantages of the Single Market?
These are some questions we will try to answer in this paper.
In this paper, we will present data regarding: the evolution of Romania's foreign trade, overall, as well as with the rest of the European Union countries; the evolution of Romania's economic growth, in comparison with European Union's average economic growth; the evolution of foreign direct investments in Romania; the absorption degree of structural and cohesion funds, in comparison with other countries of the European Union.
We will analyze these data, and we will make comparisons between Romania and the European Union, in order to see the similarity between Romania's evolution and EU's evolution. We will also analyze the structural and cohesion funds absorption degree, in comparison with other European Union countries.
Finally, we will try to assess whether we knew how to take advantage of our European Union membership, as being member implies both advantages and disadvantages. Knowing how to fully benefit from the advantages and how to diminish the disadvantages is the winning strategy.
Did Romania know how to maximize its advantages?
As we will see in the conclusions of this paper, the answers to these questions are not always in our advantage. There are still some lessons to be learned, especially regarding the absorption of structural and cohesion funds, and attracting foreign direct investments.

Keywords: foreign trade, economic growth, foreign direct investments, structural and cohesion funds.

JEL Classification: E24 Employment, Unemployment, F11 Models of Trade, F15 Economic Integration, F21 International Investment, O47 Measurement of Economic Growth.

The Foreign Trade

The countries of the world have different terrains, climates, resources, worker skills, etc. Therefore, some countries will be able to produce goods that other countries cannot produce, or can produce only at extremely high costs (Arnold, 2010: p.376).

The foreign trade is also necessary for a country's economic growth. The trade promotes specialization, and specialization increases productivity. Over the long run, increased trade and higher productivity raise living standards for all nations. Gradually, countries have realized that opening their economy to the global trading is the most secure road to prosperity (Samuelson and Nordhaus, 2010: p. 339).

Romania's foreign trade has shifted after 1989. If before 1989, Romania had a foreign trade surplus, and its main partners were the countries members of the Council for Mutual Economic Assistance, after 1989, the main trade partners have become the countries members of the European Union. This trend has continued after Romania obtained EU membership, in 2007.

Overall, our trade balance is a negative one. In 2007, our exports represented just 57%, in comparison with our imports. The percentage was 58% in 2008. The crisis brought a decline in our negative balance, but still, the exports are inferior to our exports (table 1).

Table 1. Romania's foreign trade, 2007-2011 (millions euros)

	2007	2008	2009	2010	2011
Imports	50 993	57 240	38 953	46902	54824
Exports	29402	33725	29084	37368	45041
Balance	-21 591	-23 516	-9 869	-9 534	-9 783

Source: www.insse.ro

As we can see in Tables 2 and 3, more than 70% of Romania's exports and imports, for 2010-2011, are with other European Union countries, while intra-EU trade was, in 2010, of 64% (table 4).

Table 2. Romania's export flows, 2010-2011 (millions euros)

	2010	2011
TOTAL	37 368	45 041
Intra EU	26 953	32 031

Table 4. Intra-EU trade, 2007-2010 (millions euros)

	2007	2008	2009	2010
Intra-EU trade	66%	65%	65%	64%

Source: http://epp.eurostat.ec.europa.eu

If we take into consideration our main trade partners, we can see that the EU's countries occupy the first places (tables 5 and 6): Germany is our main trade partner, for both exports and imports, followed by Italy (exports and imports), France, Turkey and Hungary (for exports), and Hungary, France and China respectively (for imports).

Table 5. Romania's exports by main destinations, 2007-2011 (millions euros)

	2007	2008	2009	2010	2011
Germany	4980	5535	5442	6765	8390
Italy	5013	5219	4461	5165	5783
France	2270	2491	2378	3102	3371
Turkey	2071	2205	1450	2611	2782
Hungary	1637	1726	1266	1775	2516

Table 6. Romania's imports by main destinations, 2007-2011 (millions euros)

	2007	2008	2009	2010	2011
Germany	8755	9409	6741	7856	9371
Italy	6485	6620	4551	5434	6227
Hungary	3534	4295	3250	4051	4776
France	3185	3210	2401	2780	3161
Turkey	1670	2414	1902	2555	2530

As we can see, Romania has strong trade relations with partners from other EU countries. Unfortunately, these trade relations have been focused more on imports, rather than exports, showing that Romania is mainly a consumer country. In this context, it is important to remember that Romania, in terms of population size, is on 7th place in the European Union.

The economic growth

In the last 23 years, Romania has experimented years of severe economic recession, as well as years of prosperity. Starting with the year 2000, the country has recovered from the long transition, showing positive rates of economic growth (table 7). Romania's economy was extremely dynamic, especially in the period 2001-2008. However, the economic crisis has affected us as well, the years 2009 and 2010 being characterized by negative economic growth rates.

Table 7. Romania's economic growth rate, 2000-2011 (%)

2000	2001	2002	2003	2004	2005	2006	2007	2008	2009	2010	2011
2.4	5.7	5.1	5.2	8.5	4.2	7.9	6.3	7.3	-6.6	-1.6	2.5

The evolution of EU economic growth rate shows much lower economic growth rates than in Romania. Less dynamic, the European economy had barely reached 3.3% economic growth rate in 2006, while in other years, the economic growth rate was almost close to zero (0.3% in 2008). The economic crisis had affected the EU as a whole, with a negative economic growth rate in 2009 (-4.3%). However, in 2010 and 2011, the European economy started to recover, showing positive economic growth rates (2% and 1.5% respectively).

Table 8. EU's economic growth rate, 2000-2011 (%)

2000	2001	2002	2003	2004	2005	2006	2007	2008	2009	2010	2011
3.9	2.2	1.3	1.4	2.5	2	3.3	3.2	0.3	-4.3	2	1.5

If, before the crisis, Romania was among the most dynamic European economies, the years 2009 and 2010 brought negative economic growth rates (-6.6% and -1.6% respectively). Only the year 2011 marked a slow recovery (+2.5%), while the European average was positive since 2010.

The Foreign Direct Investments

Being the largest market in South-East Europe, Romania has benefited, since 2004, from massive inflows of foreign direct investments. This can be explained thanks to macroeconomic stabilisation, strong GDP growth, large-scale privatisation and the advantages of (future) EU membership (Pauwels and Ionita, 2008: p. 1-2) (table 9).

Table 9. FDI Inflows in Romania (millions euros)

2003	2004	2005	2006	2007	2008	2009	2010	2011
1946	5183	5213	9059	7250	9496	3488	2596	2440

Source: www.bnr.ro

As we can see in table 9, the FDIs have spectacularly increased in 2006, one year before our country's accession to the EU. However, starting with 2009, one can see a worrying decrease in FDIs inflows.

80% of the total FDI stock comes from the EU, and about 50% of the total comes from just three countries: the Netherlands, Austria and Germany. The top 10 investing countries in presented in table 10.

Table 10. Top 10 investing countries, 1990-2009

Netherlands	Austria	Germany	France	Greece
21.8%	18.1%	13.4%	8.5%	6.6%
Italy	Cyprus	Switzerland	Belgium	USA
5.1%	4.7%	4.2%	2.2%	2.1%

Source: www.bnr.ro

Romania has attracted important FDIs inflows during the years with positive economic growth rate, fact that can be explained, among other things, by our (still) cheap labour force. But the FDIs inflows can also be explained by our appetite for consumption.

The decrease of FDIs inflows could be explained, among other things, by the fact that Romania is no longer an attractive market. The qualified labour force is more and more difficult to be found, and the households' incomes have been strongly affected by the crisis.

Structural and cohesion funds

The structural and cohesion funds, financial instrument of the European Union, having the purpose of reducing, even eliminating, the economic and social development disparities among European regions, are, or could be, one major advantage of EU's membership. Between 2007 and 2013, Romania could beneficiate from 19.67 billion euros, through European Regional Development Fund, Cohesion Fund and European Social Fund (Sabau-Popa, 2010: p. 221).

According to the National Strategic reference framework for Romania, the EU funding could generate 15-20% additional GDP growth by 2015, a growth of 28% of Gross Capital Formation more than the baseline scenario, an increase of 23% of the employment in the trade sector, etc. (European Commission).

But accessing the structural and cohesion funds seems to be very difficult, for the new member states. All the countries that joined the EU in 2004 and 2007 encountered problems in accessing the EU funding. By the end of 2010, in several EU countries, the absorption degree was the following (table 11):

Table 11. Absorption degree in several EU countries, 2010

Romania	Bulgaria	Latvia	Estonia	Poland	Czech Republic
9%	10.2%	29.3%	26.43%	20.43%	12.44%

Source: http://www.fonduri-structurale.ro/detaliu.aspx?eID=8617&t=Stiri

However, the effective absorption degree in Romania could be much lower, according to recent estimations: only 3.69% (http://www.fonduri-structurale.ro/).

For 2012, many economists consider that the structural and cohesion funds could strongly encourage Romania's economic growth. But the very low absorption degree raises questions about our capability of attracting and spending 6 billion euros by the end of 2013.

Under these circumstances, it is very difficult for Romania to benefit from its European Union membership. Moreover, the low absorption degree could cause a significant reduction of funds allocated for Romania for the next financial perspective, 2014-2020. (http://www.euractiv.ro/).

Conclusions

As presented in this paper, one can notice that Romania had a good start of its European adventure; but shortly, many problems have been raised, showing that the country was not fully prepared for accession.

In order to fully beneficiate from the advantages of membership, one must increase the absorption degree of structural and cohesion funds, as well as the country's attractiveness for foreign direct investments.

Being member of the European Union implies both costs and benefits. But it depends only on each member state whether it can turn into its advantage this membership, or whether it remains a secondary European Union country.

SUB-SECTION: THE IMPACT OF FOREIGN LANGUAGES ON THE BUSINESS ENVIRONMENT

NEW TRENDS IN TEACHING AND LEARNING BUSINESS ENGLISH: ADAPTING TO INTERNALIZATION

Abrudan Cristina Laura
University of Oradea Faculty of Economics

This paper focuses on how new trends have appeared in teaching business English as a result of globalization. During the recent years, along with all the changes that have taken place in every domain of our lives, we have witnessed major changes in how business English students want to learn. It is interesting to analyze the way in which technology muscled its way onto the teaching scene amid a mixture of delight and anguish – perhaps more anguish than delight in many teaching contexts. Over the last ten years, the international business had four major influences that had an impact on the teaching and learning of business English. This has had a huge impact on the teaching of business English in terms of teachers needing to have more than just knowledge of basic business vocabulary and grammar. Effective communication can be achieved when we are aware of how people from different countries and with different levels of English communicate globally, and how globalization has changed the business practices on the international stage.
Keywords: globalization, new trends in teaching business English, cultural awareness
JEL Code: Y9

The last ten years have witnessed the rapid development of the world of business along with an explosion of interest in globalization, global issues, and global education in every area of our lives. Due to recent developments in communication and technology, as the world in general and especially the world of business has become smaller, international business is done more quickly, easily and effectively. We live in a world in which the economic bases have shifted, new economic houses have emerged, and new markets have opened. The world has been globalized ad the face of today's international business has a totally new complexion.

As far as teaching and learning business English is concerned, the situation described above, having to deal with the internalization of business, has led to significant changes in both what we teach and how we teach it.

Regarding the teaching profession, and especially the English teaching profession, this can be documented in the journals and conference programs of international English teaching organizations such as TESOL (Teachers of English to Speakers of Other Languages) and IATEFL (the International Association of Teachers of English as a Foreign Language). It is interesting to analyze the result of a survey of teachers in over 110 countries, survey published by the English Teaching Professional magazine, where they had to give their opinions on the future of business English language teaching. 67% percent of teachers thought that, over the next ten years, we would witness an increase in the importance of English as a global language and over 80% thought that the number of students would increase accordingly. Moreover, today's business English students have different needs and expectations of what they learn and how they learn.

The changing face of the international business
Over the last ten years, the international business had four major influences that had an impact on the teaching and learning of business English.

1. Changing technology
Generally speaking, the field of technology has developed significantly, and particularly, the field of communications which now permit us to connect with people all over the world in just a few

seconds. Financial transactions are done at a push of a button and people are able to communicate quickly and easily due to the huge development in technology.

2. New powerhouse economies
The second major influence has been the emergence of new powerhouse economies, such as China, India, and Russia, leading to a shift in the economic bases. Ten years ago, there were some other leaders in terms of manufacturing, quality and efficiency. Nowadays, the above mentioned countries provide goods more cost effectively due to cheaper raw materials and labor force.

3. New markets
The third major influence is the emergence of new markets. The collapse of the communist Soviet block has led to the appearance of new markets in Eastern Europe having consumers hungry for new products.

4. The financial sector
The financial and commodities markets' internalization have had a great influence on our lives. Having to deal with open markets, the economic exchanges in financial goods and commodities have become freer and more dynamic after many years in which unparallel global wealth has been created. However, this has also had a negative effect whereby crises in one country, now has a major impact on the economies of others. No matter of it is positive or negative today's business world is more closely joined together through the international exchange of financial goods and services.

The impact on what we teach
All these four changes have meant that business people are more likely to be dealing with a wide range of different countries, different cultures, and different ways of expressing and interpreting things. This has had a huge impact on the teaching of business English in terms of teachers needing to have more than just knowledge of basic business vocabulary and grammar. Effective communication can be achieved when we are aware of how people from different countries and with different levels of English communicate globally, and how globalization has changed the business practices on the international stage.

Vocabulary – a constantly changing area
The English language is notoriously fast in adapting to the changing world. New words enter English from every area of life where they describe the changes and developments that take place from day to day. Being a living language, English is continuously developing, changing constantly, sometimes even more quickly than lexicographers can keep pace with. English grows through the acquisition of new words, coming from many sources such as: other languages (e.g. damame, pierogi), retail (e.g. man stand, size zero) and changes that come from how professionals do business (we will give lots of examples below). Often, this development of the English language is done when words that once were used in specific areas, for specific activities, now become part of everyday language. There is no other place where this is seen more than in the use of business vocabulary; while some words have become part of the everyday use; many words apply to specific occupations or business practices.

Professional English teachers know that it is a challenge to keep track of and explain new business vocabulary. So, what are these new words? How do we find them? How do we evaluate them? Risking to be predictable, some of these words are impossible to avoid: credit crunch is a good example in this respect. But did you know that credit crunch is not really a newly minted term? Economists first coined this term more than a decade ago, in order to describe a downturn in the Japanese economy, but have become widely used in the last year or so to describe the

current global slowdown. This example show us that what words are considered to be new doesn't necessarily mean that they are brand new to the language, but that they are newly important to native speakers and this professional English teachers and students.

But what makes the vocabulary of the English language develop? Being a living language, the current economic, social and cultural climate makes our vocabulary expand, making us learn terms that were previously known only by a handful of specialists. The recent world financial crises have also brought subject-specific words into the public domain. As an example, we will mention *sub-prime mortgages, toxic debt, derivatives*, *foreclosures* and a very specific sense of *correction*. Just a year ago, who would know what these words were. But, these are not new words to the English language.

Although it dominates the headlines of the newspapers, the current global economic situation does not represent the only source of new words for business English teachers and students. Changes in environmental issues and technology throw up new words on almost daily basis, and it is extremely difficult for us to keep up with these.

Technology – a rich area for new language

Perhaps the biggest area of change is in technology and particularly the Internet as new methods of communicating and sharing information develop and gain more and more popularity. During this last decade, we witnessed the way in which technology muscled its way onto the teaching scene amid a mixture of delight and anguish – perhaps more anguish than delight in many teaching contexts.

It is fascinating to see how adaptable the English language is. In the following lines we will give a few examples in order to illustrate this. For several years now, *Facebook* and *Google* have been around and dominate more and more our lives, and now they are used as verbs as well as nouns. An even newer socializing network on the web is *Twitter*, perhaps while you are out and have a *dongle* plugged into your laptop. Marketing departments look for increased web traffic and many companies use social networking sites in order to launch and promote their products; so if you want to spread something around on the Web, *go viral*. We all know that the concept of *Web 2.0* has been around for several years, but nowadays the concept **2.0** is being used in other ways. As an example, we've met *'management 2.0'* in order to describe the future generation of business managers. And while we download applications for our computers, I-phones, I-pads, and so on, they are now often simply called *apps*. Finally, have you seen the acronym *picnic*? It stands for 'problem in chair, not in computer'.

Taking into consideration the few examples given above, we come to the conclusion that business English teachers need to constantly update his/her business vocabulary knowledge.

Grammar versus lexis

The shift in emphasis from a grammar based methodology to a lexical one represents another area to look at. We cannot claim that there is one, homogenous business English today, as it is said that half the business English spoken at any time is between two non-native speakers. So, there are many 'Englishes' spoken by people of different counties and of different cultures. Of course, this has always been the case, as we all know the existing differences between British English, American English and Australian English. However, today this list can be completed with the appearance of a number of rather new 'Englishes', such as Chinese English, Indian English, Japanese English, Nigerian English, and so on. Moreover, if we take into consideration the increasing need for speed in modern business, the teaching of business English shifts its emphasis from complex and grammar-heavy ideas of correctness to fast and effective communication. Therefore, a new trend in teaching business English focuses on a more lexical approach, teaching widely and easily understood standard phrases, rather than straight grammar. These phrases are called 'functional', as they serve a function of business and communication.

In order to be clearer, let's give an example of a sentence commonly found in e-mails: "We would be grateful if you could send us the leaflet until Friday." From the grammatical point of view, we have to deal here with a tricky construction: this the Second Type of Conditional Sentences, that is If + Past Participle Clause, with a 'would' clause, complicated further by the fact that the past participle in this case is a modal verb, followed by a verb in the present participle. Such grammatical constructions are taught at an intermediary level or above, in a general English course. However, looking at this sentence as a lexical item with a function, we could simplify a lot this sentence, saying: 'Please send us the leaflet until Friday.' Thus, a sentence having a difficult grammatical construction has become a phrase easy to understand and used by an Elementary level student.

Of course, this does not mean that grammar is totally absent from modern business English classes, but it means that teachers are required to have a deeper awareness of the needs of the students and of the necessities of nowadays business world. But we also need to focus on what level the students communicate; for example, there is a huge difference between students who communicates, on a daily basis, with international clients through e-mail, and students who have to write vast reports to their native speaker boss. We are talking here about a shift to an approach based on business skills, along with a shift in focus from a grammatical notion of language to a more practical, functional lexical one. Basically, it is a change in emphasis to a more skills-based approach. Of course, the skills of listening, speaking, writing, and reading have always represented a major point in our English classes, but nowadays, English teachers are expected to be able to train business students in soft skills, necessary to perform work functions such as business communication, negotiations, meetings, presentations, etc. If we think of presentations, the necessary language used in this field is not the only 'equipment' provided by today's business English teachers. It is needed to give suggestions regarding the Power Point presentation, structuring of the presentation, and also body language. These are regarded as 'extra-linguistic' skills. But still, the emphasis is on fast and effective communication, having as a basis the functional, lexical language. The message you want to send will be clearly, quickly, and easily understood if you use the correct lexical structures, the proper quantity of information in your Power Point presentation and the correct body language.

The importance of cultural awareness
Living in a globalised world and having to deal with people from all over the world, business students have to be trained to deal with a wide range of nationalities, they need to learn what to expect and how to behave. Although English has been acknowledge as the international language of business, there isn't yet standardized and generally accepted business etiquette. In order for a business English course to be complete, there has to contain some references to cultural differences. In this respect, we have to mention that while Asian students of business English are learning how to shake hands properly, in a firm manner, their counterparts in the opposite part of the world are probably learning how to exchange different currencies properly. Modern business English textbooks take into consideration the global economical environment in which we function, and the topics these books use have changed, using more and more references to issues such as emerging economies, globalization, cultural differences, and so on. A more up to date vocabulary along with practical business skills can be found now alongside the traditional grammar and standard skill exercises. We cannot forget also the huge increase in the use of case studies, as they give the students the opportunity to get in touch with real situations of business practice, and to use their business skills in realistic contexts. All of these textbooks focus on fast and effective communication between people of different cultures and languages and not necessarily native speaker countries.

The impact on how students learn

Our lives today differ significantly from the lives of our grandparents or even our parents and the recent years, along with all the changes that have taken place in every domain of our lives, have witnessed major changes in how business English students want to learn. We all know that the emphasis is on the content of the course, as well as on the length of it and on the flexibility in terms of time. An increasing number of people need to study English at different levels, for different reasons, however, what students need and what employers and Human Resources Department representatives want is not always the same thing. Our working lives have altered dramatically, perhaps due to the changes in the way business is done nowadays at an international level. Paradoxically, the increase in the speed of work did not lead to less time spent at work, and there has been a notably global shift towards longer working days and longer hours spent in offices.

The need for flexibility has a great impact on how students want to study and the great innovations in the field of technology led to the possibility of students to study at home via the Internet alongside with the face-to-face classes, in the so called 'blended-learning' courses. Taking into consideration the rapid changes in the field of technology, it is very possible that in ten years time, our children won't have books from which to read and learn, but I-pads that will successfully take the place of the traditional book.

Students are more and more aware of the need for studying business English. Business Spotlight has published the results of an international study of 25,000 business people, and found out that 90% of them felt that English was either critical or important in their work. However, only 9% of the respondents considered that their level of English was good enough to efficiently conduct their businesses. Thus, there are now more and more people willing to study business English at different levels, meaning that our students want more focused and interesting courses that meet their requirements, leading to a fast progress and to the possibility of instantly putting into practice the things they learn.

Both students and teachers should analyze carefully why students learn business English, in order to be able to create a balance between effective communication and accuracy. Another major aspect is linked to the atmosphere in the class that has to be cooperative and friendly so as to eradicate the students' fear of failing and the teachers need to ensure they have the requisite cultural knowledge and soft skills as well as the necessary language to do this.

LES APPROCHES PLURIELLES DANS LE MODELE CARAP: SAVOIRS ACQUIS PAR L'INTERCOMPREHENSION

Constantin Felicia
Universitatea din Oradea
Facultatea de Ştiinţe Economice

Bogdan Rodica
Universitatea din Oradea
Facultatea de Ştiinţe Economice

Custom sets that teaching foreign languages refers to teaching and learning a language taken in isolation, within an essentially monolingual framework. Academic orthodoxy Chardenet (2007) refers to training the teacher in one foreign language only, following the unnatural preoccupation for the completion of knowledge and skills in this language. The dynamics of the societies forces towards the transition from monolingualism to multilingualism, by introducing the pluralistic like teaching devices. Defined as "teaching approaches that put into practice the teaching-learning activities while involving more (= more than one) linguistic and cultural variety," pluralistic approaches are designed as opposed to traditional teaching approaches, the aim of which is a particular language or culture in isolation (Candelier, 2007: 7). Intercomprehension is, along with the intercultural approach, the integrated teaching of foreign languages and awakening to languages, a pluralistic approach that allows the development of diverse and unthinkable emotional and practical knowledge and skills, inventoried in a Framework of reference for pluralistic approaches to languages and cultures (CARAP). Considered from different perspectives - as a method, strategy, training device or educational purpose - intercomprehension is mainly a general competence of the multilingual individual. A doctoral program attended at the University of Reims, France, as part of a team coordinated by professors J.E. Tyvaert and E. Castagne, has allowed us to experiment intercomprehension with a public trained for skills training for acquiring the perception and understanding of foreign languages not known a priori. According to Jamet (2010), it is a metalinguistic cognitive type activity (the awareness of areas of formal transparency and of significance), meta-pragmatic (the use of knowledge acquired in the native language to decide the needs triggered in a certain situation) and meta-cultural (by means of the encyclopaedic knowledge of the world), activity practiced by inferential type strategies. The regular observation of ICE type training sessions has led us to a reflection applied to non-philological learning environment. We consider that organizing a module of initiation in French for beginner economic students, a course relying on intercomprehension principles, would be an excellent introduction to multilingualism. In this paper we will tackle the knowledge that, according to CARAP, seems attainable by means of this alternative method of teaching - learning a language, in the light, even if only virtual at the moment, of the introduction of French in the curriculum by specific means of intercomprehension. Established as prolegomena to the traditional study, an introductory course of intercomprehension of French would be able to provide students with quicker global linguistic knowledge otherwise acquired in a longer period of time, with more effort and without guaranteed results.

Keywords: pluralistic approaches, intercomprehension, skills, CARAP, didactics
Cod JEL: Y8

Préambule

La compétence linguistique des futurs économistes s'approfondit pendant les cours de langues étrangères suivis à la faculté. La coutume pose que la didactique des langues étrangères se réfère à l'enseignement-apprentissage d'une langue prise isolément, dans un cadre éminemment monolingue. Conformément au curriculum, l'apprenant qui étudie l'anglais dans les facultés non-philologiques n'étudie pas (sauf rares exceptions) le français, celui qui étudie le français n'étudie pas l'allemand. Georges Lüdi observe que les modèles qui *«dominent encore très largement les systèmes éducatifs»* sont ceux *«qui réunissent en général, dans des classes de langue, des enseignants et des apprenants autour du projet de l'appropriation d'une langue cible*

particulière» (Cali, Stegu et Vetter, 2008: 20). Dans ce sens, Chardenet précise que «*si la didactique des langues s'est constituée de façon transdisciplinaire en s'attachant à réfléchir sur l'enseignement / apprentissage de telle ou telle langue, elle n'a jamais réussi à transgresser **l'orthodoxie académique** qui renvoie **la formation de l'enseignant à seule langue étrangère** et à **la complétude des savoirs et des compétences** dans cette langue.* (Chardenet, 2007)

Or la dynamique socio-politique et surtout les enjeux économiques forcent le passage du monolinguisme vers le plurilinguisme, par l'apparition de dispositifs de formation de type pluriel. Les approches plurielles, définies comme «*des approches didactiques qui mettent en œuvre des activités d'enseignement-apprentissage qui impliquent à la fois plusieurs (= plus d'une) variétés linguistiques et culturelles*» sont conçues en opposition avec les approches didactiques singulières traditionnelles, dont l'objet d'attention «*est une langue ou une culture particulière, prise isolément*» (Candelier, 2007: 7). Comment pourrait-on dépasser les limites imposées par les contraintes administratives et curriculaires dans les institutions d'enseignement? Comment pourrait-on passer au plurilinguisme sans trop ébranler un état de faits auquel il n'est pas facile de renoncer inconditionnellement pour satisfaire aux besoins du plurilinguisme? Pour répondre à ces questions, nous nous référons en ce qui suit aux approches didactiques plurielles promues par un référentiel élaboré en 2007.

Les approches plurielles (le modèle CARAP)

Le Cadre de Référence pour les Approches Plurielles des Langues et des Cultures (nommé dorénavant CARAP) a été élaboré en 2007 par une vaste équipe coordonnée par Michel Candelier au sein du Centre européen pour les langues vivantes de Graz - institution du Conseil de l'Europe - comme produit du programme «Les langues pour la cohésion sociale: l'éducation aux langues dans une Europe multilingue et multiculturelle». Cette thématique propose de mettre en discussion un changement de paradigme majeur, par «*l'évolution vers une conception globale de l'éducation aux langues, qui intègre l'enseignement et l'apprentissage de toutes les langues afin d'utiliser les synergies potentielles*» (conformément à la présentation des programmes CELV sur le site officiel de l'institution).

Le recensement de l'équipe de CARAP rend compte de **quatre approches plurielles:** l'approche interculturelle, l'éveil aux langues, l'intercompréhension entre les langues parentes et la didactique intégrée des langues apprises.

1. L'approche interculturelle, nommée dans un article «*le quatrième "mousquetaire" de la famille des approches plurielles*» (Candelier, P., 2008: 71) [a] une influence irrécusable sur la didactique des langues «*même si ce n'est pas toujours de façon explicite et réellement conforme à ses orientations fondamentales*» (Candelier, 2007: 7). A propos de ce modèle, le Cadre Européen Commun de Référence pour les Langues prévoit que l'objectif fondamental en est le développement de la personnalité à partir de l'intégration harmonieuse des expériences de l'altérité langagière et culturelle, par la directe préoccupation de l'enseignant et de l'apprenant: «*dans une approche interculturelle, un objectif essentiel de l'enseignement des langues est de favoriser le développement harmonieux de la personnalité de l'apprenant et de son identité en réponse à l'expérience enrichissante de l'altérité en matière de langue et de culture. Il revient aux enseignants et aux apprenants eux-mêmes de construire une personnalité saine et équilibrée à partir des éléments variés qui la composeront*». (CECR, 2001: 9)

2. La didactique intégrée des langues, la situation spécifique dans l'enseignement institutionnalisé, a comme finalité d'«*aider l'apprenant à établir des liens entre un nombre limité de langues, celles dont on vise l'apprentissage dans un cursus scolaire*»*;* cette didactique prévoit «*de façon "classique" les mêmes compétences pour toutes les langues enseignées ou ... des "compétences partielles" pour certaines d'entre elles*» *(*(Candelier, 2007: 7-8). Le fait que la première LE s'appuie sur les acquisitions de la LM et que l'accès à une autre LE est facilité par l'appui sur celles antérieurement appréhendées, conduit à une représentation intégrée du

répertoire plurilingue; la représentation de la spécificité de chaque langue comme un « iceberg » émergeant d'une base commune à toutes les langues (proposée par Cummins en 2001 pour rendre compte de la compétence bilingue) implique l'existence d'une base sous-jacente commune à deux ou plusieurs langues et des liens d'apprentissage et d'influence établis entre elles. (Egli Cuenat, 2009: 2)

3. *L'éveil aux langues* devient de plus en plus connu grâce à des projets européens récents et aux démarches d'inclusion dans l'enseignement institutionnel; par l'éveil aux langues, une attention particulière est accordée non seulement à la langue de l'école et à toute autre langue en cours d'apprentissage, mais aussi à des langues que l'école n'a pas l'ambition d'enseigner, à toutes autres variétés linguistiques, sans exclusion. Le nombre significatif de langues sur lesquelles on travaille transforme l'éveil aux langues dans une forme «extrême» des approches plurielles. L'objectif ambitieux de cette approche est ainsi formulé: *«Conçu principalement comme accueil des élèves dans la diversité des langues (et de leurs langues!) dès le début de la scolarité, comme vecteur d'une meilleure reconnaissance dans le contexte scolaire des langues «apportées» par les élèves allophones, comme une sorte de propédeutique développée à l'école primaire, il peut également être promu comme accompagnement des apprentissages linguistiques tout le long de la scolarité».* (Candelier, 2007: 9)

4. *L'intercompréhension,* l'approche plurielle qui s'établit entre des langues parentes, *«propose un travail parallèle sur plusieurs langues d'une même famille, qu'il s'agisse de la famille à laquelle appartient la langue maternelle de l'apprenant (ou la langue de l'école) ou de la famille d'une langue dont il a effectué l'apprentissage»* (*idem*: 8). L'appartenance à une même famille offre aux langues des atouts tangibles, qui se manifestent prioritairement au niveau de la compréhension et qui mériteraient une attention systématique (conformément aux projets innovants en France et en Allemagne dans la seconde moitié des années '90, continués dans d'autres pays de l'Europe ou de l'Amérique Latine). Candelier observe également que «*les publics scolaires sont encore très peu concernés par l'intercompréhension*», malgré son caractère ludique surpris par Castagne et Chartier; pour eux, «*la magie de l'éducation à l'intercompréhension, c'est surtout d'ignorer qu'elle est éducation*». (Castagne et Chartier, 2007)

Intercompréhension - approche plurielle

Castagne (2007) remarque l'absence d'une définition rigoureuse de l'intercompréhension, mais souligne qu'elle a la capacité de nous faire *«constater un changement de paradigme de la communication monolingue symétrique au dialogue plurilingue asymétrique».* En principe, il s'agit d'une compétence de réception et de compréhension fondée sur les rapprochements de tout type entre les langues apparentées génétiquement, identifiés et valorisés par des stratégies spécifiques d'accès au sens, déclenchées au moment de la lecture d'un texte et/ou de l'écoute de sa version oralisée. Simplifiant, on pourrait dire qu'une personne peut arriver à comprendre globalement une ou plusieurs langues apparentées à sa langue maternelle (textes écrits accompagnés de la version oralisée, par une méthode qui est radicalement différente des méthodes d'apprentissage traditionnel. L'intercompréhension, en quoi consiste-t-elle?

Si l'intercompréhension vise en général l'échange plurilingue *où chacun s'exprime dans sa langue et comprend celle de l'autre*, certains auteurs privilégient l'étape de la formation de la compétence de réception et de compréhension de langues étrangères a priori inconnues. C'est le cas du dispositif de formation InterCompréhension Européenne, développée à l'Université de Reims, France, au sein d'une équipe coordonnée par les professeurs J.E. Tyvaert et E. Castagne.

Les participants sont placés devant des textes courts (de type article de presse ou des articles sur objectifs spécifiques) écrits et accompagnés de la version oralisée, dans une langue qu'ils ignorent mais qui appartient à la même famille linguistique que leur langue maternelle. L'enseignant-moniteur explique les principes de base dans le fonctionnement de la formation en ICE et attire l'attention des apprenants sur les libertés et les contraintes de la méthode: aucune information n'est

fournie dès le commencement, on ne renvoie pas à des tableaux multilingues avec des informations sommaires susceptibles d'orienter la réflexion, le moniteur dirige l'apprenant vers la découverte personnelle, en lui demandant des hypothèses à partir de la nature du texte, du thème de l'article, du contexte, de l'analogie avec sa langue maternelle et en gérant le parcours de capitalisation des informations lexicales et grammaticales. Normalement, le **temps prévu de déroulement des formations ICE serait de 48 heures pour le m**odule d'éducation à l'intercompréhension écrite de 3 langues *apparentées* à la langue maternelle. Si nous opérons artificiellement une réduction de trois langues à une seule langue étrangère, afin de parvenir à une adaptation au but de notre démarche présumée, la durée se réduit à 16 heures. Par rapport au parcours classique d'un cours traditionnel, les participants découvrent la nouvelle langue étrangère par effort propre, aux effets extrêmement motivants. Le niveau de maîtrise présumé de l'intercompréhension écrite des langues apparentées serait le niveau A2 / B1 dans le contexte d'une approche trilingue. Tous les témoignages sur les effets de l'intercompréhension nous autorisent de supposer que la focalisation sur une seule langue, par des stratégies intercompréhensives spécifiques, permet d'atteindre au moins le niveau A2 dans la compréhension écrite.

L'Intercompréhension qui dans la profusion d'études parues les dernières années a été appréhendée sous des angles divers - comme méthode, stratégie, dispositif de formation, objectif éducationnel général ou compétence de l'individu plurilingue - est avant tout une approche plurielle qui permet de développer des savoirs, savoir-être et savoir-faire divers et insoupçonnés, à travers des compétences *trans-linguistiques / trans-culturelles et inter-linguistiques / inter-culturelles.*

Proposition

L'observation régulière des séances de formation expérimentées par l'équipe française nous conduit à une réflexion appliquée au milieu non-philologique. Nous apprécions que l'organisation d'un module d'initiation à la langue française, construit selon les principes d'un parcours d'intercompréhension, représenterait pour les étudiants économistes débutants une excellente introduction au plurilinguisme. Nous prenons comme référence de notre évaluation globale le Cadre de Référence pour les Approches Plurielles des Langues et des Cultures, qui est le seul document qui procède à une analyse nuancée des savoirs, savoir-être et savoir-faire spécifiques aux initiatives didactiques "alternatives" par rapport aux formules traditionnelles.

Nous nous arrêterons en ce qui suit **aux savoirs** développés par l'intercompréhension, des composantes fondamentales pour la formation du futur lecteur plurilingue. Nous nous interrogeons sur le type de savoirs développés par une approche didactique alternative du type ICE de Reims, applicable aux étudiants roumains débutants non-philologues, dans un cours d'initiation à la langue française. A raison d'une heure par semaine on peut proposer aux étudiants un entraînement à la compréhension globale du français, équivalent d'une initiation à la langue étrangère. Conformément au CARAP, nous posons que les apprenants qui suivraient un parcours de type intercompréhension pourraient acquérir les savoirs dont il est question plus loin.

Les savoirs acquis en contexte plurilingue

Les savoirs acquis par les apprenants dans le cadre d'un dispositif de formation de type approche plurielle, l'intercompréhension en l'occurrence, touchent à deux domaines également importants: la langue et la culture. Nous nous limiterons aux aspects qui concernent la langue (Candelier, 2007: 51-69), plus précisément:

a). **la langue comme système sémiologique**: dans le contexte d'un processus de distanciation, l'apprenant qui observe plusieurs langues systématise les savoirs et prend en compte le caractère conventionnel de chaque langue. L'apprenant dans un milieu d'apprentissage intercompréhensif a des connaissances d'ordre linguistique sur sa langue maternelle (ou une autre langue de l'école), ce qui implique la maîtrise «*des concepts et des techniques permettant de comprendre le fonctionnement des langues*» à des niveaux d'analyse différents, à l'écrit ou à l'oral

(morphosyntaxique, phonétique, phonologique, etc.). Nous retenons un aspect exploitable lors de la formation*: l'apprenant connaît quelques catégorisations relatives aux langues et les reconnaît grâce à des indices formels* (*idem*: 51), plutôt que par une présentation traditionnelle de type expositif.

b). **la langue et la société:** l'apprenant qui connaît en égale mesure des caractéristiques de son environnement et de son identité linguistiques et quelques faits historiques et géographiques qui ont influencé / influencent l'apparition ou l'évolution de certaines langues, a plus de chances de devenir plurilingue. (*idem*: 52)

c). **la communication verbale et non verbale**: moins préoccupante comme objectif direct de l'apprentissage par ICE, la maîtrise des principes de fonctionnement de la communication se traduit dans les savoirs implicites et explicites sur le propre répertoire communicatif et sur celui des autres (*idem*: 53); les apprenants et l'enseignant-moniteur connaissent tous et s'assument les limites du répertoire communicationnel dans la nouvelle langue étrangère, mais ne renoncent pas aux efforts d'accès au sens.

d). **l'évolution des langues**: **s**avoir que les langues sont en constante évolution et qu'elles composent des familles, modifie l'approche aux langues; les relations dites «de parenté» qui relient les langues entre elles, la composition et le nom de quelques familles de langues, les phénomènes d'emprunts entre langues et les conditions dans lesquelles les emprunts s'effectuent (les situation de contact des langues ou les besoins terminologiques dus au développement de la réalité) sont quelques-uns des savoirs qui, selon l'équipe de CARAP, relèvent de la compétence plurilingue. (*idem*: 54)

e). **la pluralité, la diversité, le multilinguisme et le plurilinguisme**: tous les savoirs qui figurent dans cette catégorie devraient être enseignés plus explicitement dans l'école, afin que les apprenants s'approprient dans l'école des acquis qui pourraient ouvrir leur disponibilité au plurilinguisme. Avoir des connaissances sur la diversité des langues signifie savoir qu'il existe une grande pluralité de langues à travers le monde et donc une grande diversité d'univers sonores (déclinés en phonèmes ou schémas rythmiques) et d'écriture. Les connaissances sur le multilinguisme et le plurilinguisme déterminent la reconnaissance d'une grande variété de situations de multilinguisme et plurilinguisme, dans des situations évolutives et complexes qui ne laissent pas toujours coïncider les frontières entre langues et pays. Le grand atout de la diversité langagière c'est le fait que l'apprenant s'habitue à observer et à cultiver la situation de multilinguisme / plurilinguisme dans l'environnement personnel ou dans des lieux proches ou lointains (*idem*: 55)

f)*.* **les ressemblances et les différences entre les langues**: tout élève qui a appris au moins une langue étrangère est conscient de l'existence des ressemblances et des différences entre les langues. Or, le contact avec des langues en contexte plurilingue leur donne un plus de saillance et l'apprenant s'habitue à cultiver ces rapprochements: dans le passage de langue à l'autre on recourt à des découpages différents et spécifiques de la réalité; la catégorisation grammaticale fonctionne par endroits différemment dans les langues étrangères par rapport à sa langue maternelle; chaque langue dispose d'un système phonétique / phonologique propre; l'absence de l'équivalence mot à mot d'une langue à l'autre fait que les langues n'utilisent pas toujours le même nombre de mots pour exprimer la même chose; des mots de langues différentes qui se ressemblent à l'oreille n'ont pas forcément le même sens; la composition des mots et l'organisation des énoncés peuvent être différentes selon les langues; des différences de fonctionnement apparaissent dans les systèmes scripturaux (plusieurs sortes d'écriture, des nombres différents d'unités utilisées pour l'écriture, des sonorités proches qui donnent lieu à des graphies complètement différentes dans des langues différentes), etc. (*idem*: 56-57)

g). **les langues et l'acquisition / apprentissage:** l'apprenant plurilingue sait que l'on peut s'appuyer sur les ressemblances structurelles / discursives / pragmatiques entre les langues, pour faciliter l'apprentissage; en plus l'apprentissage est meilleur quand il y a une attitude

d'acceptation vis-à-vis des différences linguistiques. L'apprenant commence à réfléchir sérieusement à ses propres capacités d'apprentissage des langues et aux stratégies d'apprentissage dont il dispose et qui renvoient aux *«répertoires de savoirs explicites de l'ordre du méta-apprentissage qui peuvent faciliter les processus d'appropriation dans le domaine des langues et dans tout autre domaine».* (*idem*: 69)

Conclusion

La recommandation de Coste (2010: 197-198) relative aux quatre cheminements didactiques pluriels se réfère dans ce contexte à la nécessité d'identifier ou d'opérer des modulations fines de ces approches dont le potentiel semble être affecté par certaines limitations. Il s'agit tout d'abord de la difficulté de mise en perspective curriculaire unitaire, puisque les courants innovants connus ont des histoires et des champs d'expérimentation différents et conduisent à des choix curriculaires contextualisés séparés; dans un deuxième temps, ces approches qui *«restent pour l'essentiel à la fois militantes et marginales»,* ne bénéficient pas d'une place dans l'enseignement de masse «*rares étant les systèmes éducatifs qui leur reconnaissent une place officielle dans leurs programmes*» (Coste, 2011).

Notre proposition n'est pas fondée sur un modèle déjà implémenté, mais sur l'adaptation des vertus de l'intercompréhension aux besoins réels des étudiants non-philologues débutants en français. Ceux-ci n'ont pas comme exigence professionnelle la maîtrise parfaite d'une ou de plusieurs langues étrangères, au niveau de toutes les quatre compétences: compréhension orale et écrite, expression orale et écrite. L'intercompréhension fait partie de ces approches plurielles non-axées sur une langue unique, qui exploitent des potentialités déjà en place pour développer des compétences dans de nouvelles langues et qui, selon Castagne (2010) sont marquées par *une énergie plurielle* qui anime de nos jours les sciences du langage.

La pratique de l'intercompréhension permet d'arriver vite à un niveau de compétence plurilingue satisfaisant du point de vue de la compréhension écrite. Mais elle permet également de développer toute une série de savoirs auxiliaires, sans un grand effort et dans un cadre détendu, interactif et participatif. On retient d'ordinaire pour les langues étrangères des formes d'organisation identiques à celles des autres disciplines scolaires, dans le sens du rythme, de la durée, des formes d'évaluation, du milieu, des attentes - on étudie une ou deux langues étrangères à l'école pendant plusieurs années, à raison de 2 heures / semaine avec un professeur que l'on voudrait natif. En conformité avec les paramètres du CARAP, l'intercompréhension translatée comme option didactique d'une formation plurilingue des non-philologues, en l'occurrence les économistes, assure largement l'occasion d'acquisition des savoirs nécessaires aux futurs locuteurs plurilingues.

Cette perspective de l'introduction au français moyennant l'intercompréhension reste pour l'instant virtuelle. Similaire à des **prolégomènes à l'étude traditionnelle,** un cours introductif d'intercompréhension du français serait à même de fournir plus vite aux étudiants des savoirs qui autrement seraient acquis dans une période plus longue, avec un effort plus important et sans résultats garantis.

PROPOS SUR LE SAVOIR-FAIRE DES ETUDIANTS NON-PHILOLOGUES ACQUIS PAR DES APPROCHES PLURIELLES. ETUDE DE CAS : LE METALANGAGE

Constantin Felicia
Universitatea din Oradea
Facultatea de Ştiinţe Economice

The Framework of reference for pluralistic approaches to languages and cultures (CARAP), developed in 2007 under Michel Candelier's coordination is an imperative instrument for all the teachers and decision makers preoccupied with the didactic stances of plurilinguism. Much less known than the Common European Framework of Reference for Languages, CARAP provides an inventory of knowledge, attitudes and skills the students will get to master within certain plural didactic approaches, oriented towards the development of plurilinguism. These didactic approaches are profoundly original compared with a traditional training path. We will consider as a reference point for our reflection one of the most promising and dynamic plural approaches: intercomprehension, more exactly the model developed by the InterCompréhension Européenne (ICE) team of the University of Reims, France. The census of knowledge, attitudes and skills allows a systematic look on linguistic and cultural realities that the future plurilinguistic individual is meant to assimilate. Our attention will be focused on skills.

Attending the ICE meetings made us familiar with a running manner excluding the preoccupation for the acquiring of a complete foreign language grammar, circumscribed to assuming its partial knowledge, in one or two of the competences defining it (written and oral understanding). The results of the experiments allow us to state that a minimum of grammar is enough to get the access to the global understanding of texts written in a foreign language: « intercomprehenders » getting involved in the global understanding of foreign languages previously unknown, related to their mother tongue, using a very reduced metalanguage, complementary with a wide range of relieve strategies. This observation has led to our professional activity, marked by the recurrent confrontation with the reality of teaching classes – economic students' inability to remember, understand, and naturally use a significant part of the grammar metalanguage acquired in their mother tongue. To emphasize this, we applied an empirical survey related to the fundamental grammar terminology in their mother tongue and interpreted the answers of a significant number of first and second year students of the Faculty of Economics. The results prove a disquieting inability to manage the already acquired morphological and syntactical categories within grammar analysis of mother tongue and subsequently transferred to the process of teaching-acquiring foreign languages. We have established a contiguity between the natural path in a training session in ICE type intercomprehension and the didactic path in institutional education, concluding that (1) a simplification of the grammar taught within traditional education is beneficial for students and teacher and that (2) the use of certain intercomprehensive techniques, such as the parangon, is extremely profitable when approaching certain aspects connected to foreign language grammar.

Keywords: intercomprehension, skills, metalanguage, CARAP, parangon

Préambule

L'enseignement-apprentissage des langues étrangères est habituellement organisé dans des séquences didactiques unitaires, qui suivent le principe des trois unités propre au classicisme, donc à une approche traditionnelle: unité de lieu, de temps et d'action - l'activité a lieu dans une salle de classe, se déroule pendant une heure ou deux heures et les participants avec des rôles définis (enseignants et apprenants) respectent un parcours bien fixé, dont les lignes directrices sont bien établies. L'étude de la grammaire et du lexique d'une langue sont dans ce contexte les deux lignes fondamentales qui sous-tendent la communication écrite et orale. Or, dans le contexte propre à une approche didactique plurielle telle que l'intercompréhension pratiquée dans le programme *InterCompréhension Européenne (*ICE) de l'Université de Reims, l'apprenant, que l'on appelle dorénavant *l'intercompreneur* adulte n'est plus averti à chaque étape à propos des

compétences actualisées didactiquement. Il est autonome et semble quasiment démuni face à un morceau de langue étrangère inconnue, *non-étudiée* auparavant et qui *ne sera pas étudiée* dans le futur proche selon les rigueurs de l'approche traditionnelle.

L'expertise de la Direction Générale de la Langue Française (DGLF, 2006: 9) intègre l'intercompréhension dans la catégorie des approches plurielles, celles qui mettent l'apprenant dans la situation de faire émerger le potentiel intercompréhensif par l'établissement des «*liens entre les diverses langues qui s'intègrent dans sa compétence*» Parce que l'intercompréhension est un terme qui recouvre déjà plusieurs expériences et formes de manifestation, il faut préciser que nous prenons comme référence de notre réflexion le programme *InterCompréhension Européenne*, implémenté à la Faculté de Lettres de l'Université de Reims, dans le cadre du Master Gestion Multilingue de l'Information. Un rôle important revient dans ce dispositif à l'enseignant-moniteur, celui qui ne doit pas exposer de manière déclarative les connaissances mais enseigner progressivement et par la méthode inductive la modalité de valoriser les multiples compétences dont l'apprenant dispose; conformément aux observations de Bandura relatives à l'auto-efficacité personnelle, tant que l'intercompreneur n'aura pas pris conscience des limitations de ses conceptions il les gardera et tant qu'il n'aura pas pris conscience du potentiel dont il dispose, il ne l'utilisera pas *«les moyens ne sont pas des entités fixes possédés par l'individu. L'exercice effectif du contrôle nécessite l'orchestration des connaissances, des sous-compétences et des ressources pour gérer des situations changeantes. Les moyens comprennent non seulement les compétences cognitives et comportementales, mais également les compétences émotionnelles et motivationnelles autorégulatrices pour faciliter la motivation et gérer les manifestations émotionnelles perturbatrices. De plus, les résultats dépendent de la façon dont les personnes utilisent les moyens disponibles et de l'utilité potentielle de ces derniers.*» (Bandura, 2003: 47-48)

Savoir-faire dans le CARAP

Le Cadre de Référence pour les Approches Plurielles des Langues et des Cultures (CARAP) élaboré en 2007 sous la coordination de Michel Candelier est un outil incontournable pour tous les enseignants et décideurs préoccupés par les hypostases didactiques du plurilinguisme et le seul référentiel qui permet de répondre à la question *«quels sont les moyens dont disposent / pourraient disposer les apprenants en contexte plurilingue de type ICE?»*. Paru six ans après le Cadre Européen Commun de Référence pour les Langues, le cadre dont nous parlons se rapporte exclusivement à la série des approches plurielles, des démarches didactiques réunissant au moins deux langues étrangères: l'approche interculturelle, la didactique intégrée des langues, l'éveil aux langues et l'intercompréhension.

L'expérience de l'intercompréhension dans le cadre du dispositif de formation InterCompréhension Européenne de Reims apporte un regard originel sur l'enseignement de la langue étrangère: l'enseignant-moniteur ne doit pas fournir d'information explicite d'ordre grammatical et lexical. Cette règle de fonctionnement rejoint une réalité objective: les apprenants (non-philologues en principal) ont une réelle difficulté dans le maniement du métalangage; ils ont une grammaire interne réduite, représentée par «ce qui est resté» après une longue période de pause dans l'utilisation de la grammaire (par exemple dans l'école roumaine, l'étude de la grammaire s'arrête, sauf certaines spécialisations, à la fin du collège; elle comprend la grammaire étudiée à l'école pendant les cours de langue maternelle et les fragments de grammaire pratiqués pendant l'étude d'autres langues étrangères. Malgré certaines limitations au niveau du métalangage grammatical, les apprenants – intercompreneurs sont à même d'acquérir les sept catégories de savoir-faire distinguées par les auteurs du CARAP: Savoir observer / savoir analyser; Savoir identifier / savoir repérer; Savoir comparer; Savoir parler des langues et des cultures; Savoir utiliser ce que l'on sait dans une langue pour comprendre une autre langue ou produire dans une autre langue; Savoir interagir; Savoir apprendre.

L'apprenant impliqué dans un processus d'apprentissage typiquement plurilingue réussit tout d'abord à acquérir l'habitude et **le savoir observer et analyser**, qui se réfèrent: *aux éléments linguistiques* dans des langues plus ou moins familières, par la maîtrise consciente de démarches d'analyse qui permettent de formuler des hypothèses sur le fonctionnement des langues (par la démarche inductive, l'habileté de généraliser à partir d'analogies identifiées et de prendre appui sur une langue connue) et *aux formes et aux fonctionnements linguistiques,* par le savoir d'écouter attentivement des productions dans différentes langues, de savoir observer et analyser des systèmes phonologiques et d'écriture. Grâce à ces capacités, l'intercompreneur arrive à déchiffrer un texte rédigé en écriture non familière, à observer et analyser le fonctionnement d'un système morphologique ou syntaxique dans une langue non familière à partir d'éléments structurels constants, malgré les variations lexicales, ce qui permet un accès au moins partiel au sens d'un énoncé (Candelier, 2007: 105-106). L'apprenant qui dispose du **Savoir identifier / savoir repérer des éléments linguistiques** dans des langues plus ou moins familières est, selon Candelier capable de repérer les formes linguistiques, les formes graphiques, les catégories, les fonctions ou les marques grammaticales, à partir de différents indices linguistiques (sonores, graphiques, etc.) ou bien sur la base de marques grammaticales. (*idem :* 107-108). L'identification et l'analyse des éléments devraient s'accompagner du **Savoir comparer** les phénomènes linguistiques de langues différentes afin de percevoir la proximité et la distance linguistiques. La maîtrise des démarches de comparaison consiste dans *«la capacité de percevoir une ressemblance globale entre deux ou plusieurs langues, formulant des hypothèses sur leur éventuelle parenté, sur la base de ressemblances entre langues»,* à base d'un éventail de critères de récupération de la distance linguistique (*idem*: 109-110). Le **Savoir parler des langues et des cultures** et ensuite expliquer aux autres certains aspects de sa langue maternelle, est mis en pratique lors des formations à l'intercompréhension dans les dialogues entre les apprenants ou entre l'apprenant et le moniteur. L'intercompreneur peut donner voix à **ce qu'il sait sur la / les langue(s)** et utiliser ensuite ces informations pour comprendre une autre langue (et ensuite produire, s'exprimer dans cette langue). On construit progressivement une «grammaire d'hypothèses» (un ensemble d'hypothèses) sur les correspondances ou non-correspondances entre les langues. Cela permet la constitution du **Savoir identifier des bases de transfert,** c'est-à-dire les éléments d'une langue qui permettent un transfert de connaissance au niveau inter - langues ou au niveau intra - langue et la capacité de comparer les bases de transfert entre la langue-cible et les langues mentalement activées (*idem*: 111-112). Le **Savoir interagir** nous intéresse dans le cadre du modèle ICE de Reims dans le sens des interactions entre les apprenants eux-mêmes ou entre l'apprenant et les participants aux séances de formation et témoignent d'un savoir-faire général: ce savoir se traduit dans la capacité de tenir compte du répertoire des interlocuteurs pour communiquer dans des groupes bi/plurilingues, de reformuler, d'argumenter ou de parler des stratégies d'interactions. *(idem*:113-114). **Le Savoir apprendre** se manifeste dans le savoir s'approprier des éléments, des usages linguistiques et des références propres à des langues plus ou moins familières. L'apprenant plurilingue devient capable de mémoriser et éventuellement de reproduire des éléments sonores et graphiques non familiers par l'habileté de tirer profit, dans le processus d'apprentissage, des acquis linguistiques et des expériences interculturelles préalables et par les transferts (réussis ou ratés) effectués d'une langue connue vers une autre langue inconnue. (*idem*: 115-116)

Considérations sur la terminologie grammaticale
Tout ce savoir-faire lié principalement au savoir grammatical, est progressivement acquis par les apprenants plurilingues; ils se fondent sur les connaissances acquises dans leur langue maternelle ou dans une autre langue maîtrisée, qui deviennent bases de transfert vers la langue non-étudiée auparavant. Le moniteur doit gérer avec délicatesse le poids du métalangage grammatical véhiculé lors des formations plurilingues, l'intercompréhension en l'occurrence.

Le passage des connaissances de grammaire déclaratives, exposées au tableau, vers une grammaire réduite et simplifiée ne devrait pas nous surprendre, d'autant plus que les enseignants ont une certaine liberté au niveau de la classe. Béguelin, De Pietro & Näf observent que la formation initiale et continue des enseignants leur permettent de devenir autonomes par rapport aux nomenclatures officielles et aux méthodes qui existent sur le marché des langues. Cet état de faits présente un triple avantage, parce qu'il permet *«d'alléger le poids de l'enseignement grammatical prodigué aux élèves, en accordant la priorité*, *plutôt qu'à une inculcation extensive, à des interventions ciblées de l'enseignant sur la grammaire intériorisé*e *des élèves»*, *«de doter les élèves d'un savoir(-faire) grammatical léger mais opératoire, qu'ils construiraient eux-mêmes ... dans le cadre de démarches didactiques»* et *«d'aller vers une simplification de la terminologie grammaticale – par le biais d'une meilleure harmonisation entre langues».* (Béguelin, De Pietro & Näf, 1997: 10)

La question de la terminologie grammaticale reste un problème dans l'enseignement des langues étrangères, mettant parfois l'apprenant et l'enseignant devant des situations difficilement réconciliables avec la langue maternelle. Dans le cadre de l'approche intercompréhensive style ICE, qui repousse autant que possible toute explication grammaticale et tout métalangage, nous évoquerions les propos de Dominique Willems, qui déplore justement l'absence d'un noyau de terminologie grammaticale commun aux langues de l'Europe, d'autant plus que l'apprentissage d'une LE ne peut pas se réaliser complètement en l'absence d'une réflexion grammaticale: *«Quelle que soit la place accordée à l'activité métalinguistique dans l'apprentissage des langues étrangères, il paraît acquis qu'un minimum de réflexion grammaticale et de généralisation par rapport aux phénomènes d'observation empirique est effectivement à l'œuvre lors de l'apprentissage d'une langue étrangère, et qu'il ne peut que favoriser un apprentissage heureux. Il est dès lors étonnant qu'on ne se soit pas encore mis d'accord, au niveau européen, sur un minimum de terminologie grammaticale, commun à l'ensemble des langues de la Communauté, et que l'enseignement grammatical, dans la plupart des pays, s'effectue de façon indépendante pour les diverses langues enseignées, multipliant ainsi pour l'élève – pour qui la grammaire ne constitue pas nécessairement la matière favorite – les approches et les terminologies parfois contradictoires».* (Willems, 1999:129)

À partir d'une observation qui s'avère valable non seulement en Italie, mais également en Roumanie ou en France, Ferrario et Galazzi Matasci notent que le traitement privilégié de l'étude de la littérature au détriment de l'approfondissement du système linguistique conduit à des connaissances généralement fragmentaires en langue seconde; cela va de paire avec le caractère partiel de la grammaire maternelle *«la situation n'est pas moins grave dans le domaine de la langue maternelle où la réflexion sur le fonctionnement du système est très faible, voir inexistant, dans certains cas. Il en résulte une connaissance intuitive et spontanée en L1* (n.n. la langue maternelle) *qui s'avère parfois très approximative».* (Ferrario et Galazzi Matasci, 1984: 324)

La question qui se pose concerne cependant le contrôle plus ou moins conscient de la réflexion métalinguistique sur la langue maternelle et sur les connaissances apprises d'une façon plus ou moins formelle (Giacobbe, 1984: 365). Après les centaines d'heures obligatoires de grammaire, que reste-t-il dans l'esprit des adultes et jeunes adultes qui ne se préparent pas pour une profession ayant connexion avec l'utilisation du métalangage grammatical? L'enseignant qui expose des problèmes de grammaire est persuadé que son auditoire maîtrise facilement dans la langue maternelle les catégories grammaticales dont il parle lors du cours de langue étrangère, à force de les avoir étudiées. Or, une étude empirique que nous avons réalisée en 2010 sur un nombre d'environ 100 étudiants roumains en économie de l'Université d'Oradea, première et deuxième année d'étude, nous conduit à des observations surprenantes qui nous obligent d'être plus réticents dans la projection du métalangage dans les cours de langue française. Nous n'avons pas la prétention d'une rigueur scientifique propre à des expérimentations bien cadrées et menées par des laboratoires de recherche, mais nous estimons que le questionnaire offre des données

assez claires pour pouvoir dresser un état de fait qui est répliqué chaque année, conformément à nos observations (à de rares exceptions). Les questions étaient très simples, **du type: «***Qu'est-ce que c'est …? Donnez trois exemples»* **et visaient** *toutes les catégories morphologiques et syntaxiques étudiées dans la langue maternelle (ex. Qu'est-ce que c'est le substantif / le pronom / l'adjectif / l'adverbe / la conjonction / la préposition / le verbe (au présent, au passé composé, à l'imparfait, au plus-que-parfait, au conditionnel, au conditionnel passé, au participe, au gerunziu$_{RO}$, au supin$_{RO}$? Donnez trois exemples; Qu'est-ce que c'est le Sujet / le Prédicat/ l'Attribut / le Complément direct, le Complément indirect, le complément circonstanciel de lieu, de mode, de temps, de cause, de conséquence, de but/ le Complément d'agent, etc.? Donnez trois exemples).* L'interprétation des résultats nous permet d'observer que :

- les étudiants sont capables de donner les définitions simples en proportion de : 75%-100% pour le substantif, le verbe, l'adjectif, le numéral (accompagnées d'exemples corrects) ; 50% pour la préposition et le pronom (les autres ayant donné seulement des exemples) ; 30% pour la conjonction et 20% pour l'adverbe;

- les étudiants ne font pas clairement la distinction entre *la préposition et la conjonction*: les deux sont perçues à travers leur fonction de «relier des mots entre eux» ou «des propositions entre elles»; les exemples de prépositions mélangent des prépositions, des conjonctions, des pronoms relatifs et des adverbes courts (les conjonctions récurrentes sont *să$_{RO}$ / que$_{FR}$; şi$_{RO}$ / et$_{FR}$*); la préposition est positionnée devant le mot (substantif, sujet) et apparaît comme un «mot aide»; 50% des répondants n'ont pas donné de définition et d'exemples pour la *préposition* ou pour la *conjonction*;

- pour le *verbe* au *présent,* les exemples sont majoritairement de Ière personne singulier et IIIème personne singulier et pluriel, à la diathèse active (avec quelques verbes pronominaux), avec et sans Sujet; pour les verbes au *passé composé*, les exemples sont corrects, mais seulement 50% des répondants ont donné une définition plus ou moins acceptable; pour le verbe à *l'imparfait*: 70% des réponses apparaissent sans exemples ou avec des exemples erronés, en confusion avec toutes les formes verbales (sans pouvoir en établir une régularité); pour le verbe au *plus-que-parfait*: malgré les confusions constantes, on observe que les répondants qui ont donné des formes correctes ont remarqué explicitement la présence de ce qu'ils ont nommé «*la particule „se"*»; à côté des formes correctes, il y a des formes incorrectes qui apparaissent justement par la supra-licitation de cette particule (*vizitaseseră)*; pour le verbe au *passé simple*: 90% des réponses n'ont pas d'exemples ou de définition; le verbe au *conditionnel*: 80% des réponses ne donnent pas de définition et d'exemples; pour le verbe au *conjunctiv$_{RO}$ / subjonctif$_{FR}$*: 50% des répondants interrogés n'ont pas donné de définition et d'exemples ; les exemples donnés sont corrects, avec la mise en évidence de la conjonction *să$_{RO}$ / que$_{FR}$*; le verbe au *participe,* défini comme «relié au déroulement de l'action dans le passé» a des exemples corrects; le verbe au *gerunziu$_{RO}$* est défini par le trait formel - la présence des groupes "*ând*" sau „*ind*" - ce qui détermine l'absence de confusions; le verbe à l'infinitif est défini comme «la forme verbale du dictionnaire»;

- le *pronom* est défini correctement comme remplaçant d'un nom, mais les exemples donnés sont en général de pronom personnel, avec le relatif *"care"* et le démonstratif *"acesta"*

- le *Sujet et le Prédicat$_{RO}$* sont définis essentiellement par les questions auxquelles ils répondent;

- les *Complément Direct$_{RO}$ et le Complément Indirect$_{RO}$* sont définis par les questions auxquelles ils répondent; 60% des répondants n'ont pas donné de définition ou d'exemple pour les deux types de compléments; les C*ompléments circonstanciels de lieu, de mode et de temps* sont tous correctement définis (*ils expriment le lieu, le mode, le temps*) et sont accompagnés des questions auxquelles ils répondent; le *Complément d'agent:* reconnu par des répondants en relation avec la diathèse passive; souvent confondu avec le Sujet.

Nous observons par conséquent qu'une bonne partie de la grammaire qui reste après l'école est oubliée, que certaines notions sont retenues avec leur référence correcte grâce aux marques formelles et aux questions qui aident l'identification, d'autres sont confondues, d'autres en sont

erronées. Vu la similarité entre les inventaires grammaticaux des grammaires pédagogiques du français et du roumain et les résultats de l'enquête sur le métalangage grammatical du roumain, nous osons affirmer avec toutes les précautions que d'autres apprenants européens non-philologues connaissent des syncopes similaires dans le métalangage grammatical. Nous observons que les catégories morphosyntaxiques sont surtout définies par des indices, des questions - aide, des indices formels, des exemples type.

La technique du parangon

Conformément au Trésor de la langue française (http://atilf.atilf.fr/dendien/scripts/tlfiv5/advanced.exe?8;s=3476038365*;)*, le parangon est synonyme de modèle, comparaison ou pierre précieuse, perle. Dans notre approche, «mettre en parangon» ou «faire le parangon entre plusieurs éléments» signifie établir une comparaison entre plusieurs structures (lexicales ou grammaticales) similaires. Le recours au parangon nous dispense de l'utilisation d'un métalangage qui

1. est assez **épineux à manier** par les apprenants non-philologues; par ex. *le conditionnel, la conjonction, le participe, l'article, le complément d'objet direct, complément d'objet indirect,* etc.

2. parfois, fidèle à la tradition grammaticale, **recouvre des réalités grammaticales distinctes**; par ex. *l'Attribut* est en langue roumaine, conformément à Mioara Avram (1986: 278) la partie secondaire de proposition qui détermine un substantif ou une autre partie du discours à valeur de substantif, ce qui nous fait observer l'existence de l'Attribut adjectival, nominal, pronominal, verbal ou adverbial. L'usage en français «r*éserve le terme d'attribut à la fois à un type générique de fonction et aux constituants de forme variable qui remplissent cette fonction. Dans cette perspective, l'attribut du sujet est le deuxième constituant du groupe verbal dont le verbe introducteur est le verbe être ou un verbe susceptible de lui être substitué... le même type de rapport prédicatif est établi par certains verbes transitifs entre leur complément d'objet et un troisième constituant du groupe verbal dit attribut du complément d'objet directe*» (Riegel, 1989: 233-234)

3. **n'existe que dans l'une des deux langues**; par ex. *l'article partitif* exprimé en français mais qui n'existe pas en roumain. Conformément à Riegel, l'article partitif *du, de l', de la, des* «*provient d'une ancienne construction partitive de l'article défini et en a gardé et l'indétermination quantitative et la valeur partitive*» (*idem*: 161). Cet article est utilisé devant des noms de masse et des noms abstraits (au singulier et au pluriel) en français. Pour l'étudiant roumain, surtout non-philologue, l'utilisation du terme *article partitif* est problématique, parce qu'il ne trouve pas de correspondant dans la langue maternelle. La reconnaissance de ces formes dans un texte est encore plus compliquée, parce que les mêmes formes graphiques ont une autre valeur en français. Il s'agit des structures *du, de la, de l', des*, obtenues par la combinaison de la préposition *de* avec les articles définis *le, la, l'* et *les* (les formes *du* et *des* sont des amalgames, c'est-à-dire des segments formellement inanalysables). Nous présentons plus loin quelques fragments d'un article (Nicolas Sarkozy face aux défis de 2009, «année décisive») publié en 2009 dans *Le Figaro*, l'édition en ligne. Les extraits contiennent les forme *du, de la, de l', des*.

*«Mais 2009 «peut aussi être une année fondatrice», a expliqué Nicolas Sarkozy, en évoquant la refonte **du** capitalisme et les négociations sur le climat»... «L'actualité, celle **du** Proche-Orient notamment, est venue illustrer ses propos»... «Nous n'avons pas le choix, le sommet de Londres doit être un succès», a lancé le chef **de l'**État à propos **de la** rencontre des dirigeants du G20 prévu le 2 avril dans la capitale britannique.»... «Quand on fournit les deux tiers **du** gaz dont l'Europe a besoin,...»... «J'ai été content d'entendre les paroles d'Obama», a relevé le président **de la** République»... «Sur un autre front de tension, celui **de la** crise gazière entre la Russie et l'Ukraine, le chef **de l'**État n'a pas mâché ses mots.»... «Nicolas Sarkozy attend des États-Unis «qu'ils nous disent s'ils sont prêts» à des efforts comparables à ceux **de l'**Europe»... « C'est la crédibilité **de l'**Ukraine qui est en jeu»... «Au diapason **de l'**agacement croissant **des** Européens*

devant cette crise qui se prolonge»... «Nicolas Sarkozy a placé sous le sceau **de l'urgence ses** *vœux aux ambassadeurs étrangers.»*

Pendant le cours de français, l'enseignant avait exposé aux apprenants la problématique de l'article défini (avec ses formes amalgamées) et celle de l'article partitif, avec une courte définition et des exemples. Dans la démarche habituelle, l'enseignant dirige la traduction des propositions qui soulèvent des difficultés, indiquant à différents reprises s'il s'agit d'un *article partitif* ou de l'*amalgame entre la préposition et l'article défini.* Cela suppose le passage par une forme de théorisation, avant d'arriver aux exemples et de les fixer, de revenir à la traduction proprement-dite, d'établir l'analogie et de donner la version en langue maternelle. La technique du parangon que nous proposons se réfère à un raccourcissement: prendre une forme type de référence pour chaque situation (nous proposons pour la *préposition+ l'article partitif* les structures du type: *Ministère du Tourisme // de la Culture // de l'Éducation // des Affaires Étrangères*; pour l'article partitif les structures du type: *du pain, de la confiture, de l'eau, des fruits*). Au cas d'une structure qui comprend la forme *du, de la, de l', des*, nous renvoyons directement au parangon, au modèle; par analogie, le sens est identifié rapidement.

Par exemple, dans le fragment *«Quand on fournit les deux tiers **du** gaz dont l'Europe a besoin...»,* l'apprenant a du mal à traduire la séquence centrale. Si l'on choisit la voie traditionnelle, passant par la catégorie grammaticale, on risque de bloquer la traduction, parce que l'apprenant a du mal à appliquer l'indication *«c'est un article partitif / une forme contractée, formée d'une préposition combinée avec l'article défini masculin singulier»*; si l'on évoque le parangon *«c'est comme dans le Ministère du commerce»*, la traduction est vite débloquée; un léger ajustement est nécessaire avant d'arriver à la version exacte en langue maternelle. Chaque séquence similaire est désambiguïsée grâce à l'appel au parangon: *«c'est comme... // c'est comme dans...».*

Conclusion

Nous concluons par soutenir une grammaire simplifiée dans les cours de langues étrangères pour les non-philologues, citant Näf qui promeut une **terminologie à deux vitesses**, destinée respectivement aux enseignants et aux élèves, soucieuse de ne pas *«dé-sécuriser encore davantage les enseignants et leurs élèves, mais au contraire leur donner des outils aussi simples et fiables que possible».* (Näf, 1999: 80)

POLITICAL CORRECTNESS: MYTH OR REALITY?

Istodor Daniela
Universitatea de Vest din Timisoara Facultatea Economie si Administrarea Afacerilor

PC is difficult to define and determine. PC is a term used mostly in a meaningless or abusive way. We may try to define PC as follows: new names given to professions, gender of a minority by the majority instead of their common names (used in their community) in the common language, of which people or the group spoken of, consider them to be offending and outrageous. PC means (represents) the militant attitude of promoting new names. Changes like these- "disabled person" for cripple, "mentally ill person" for madman, "learning disability/ difficulty" for mental handicap and so on, are a simple courtesy. With the introduction of the "politically correct terms", a vast category of euphemisms came into being.

People are often preoccupied and occupied with their language. It is now no longer acceptable to refer to anyone as a chairman or to use adjectives for nouns. For example the mentally ill, the disabled.

However, those who like to joke about changing terminology forget that language is constantly changing and that language is how we express ourselves. Today, in Anglo-American society at least, to say someone is a cripple or an idiot or mentally handicapped is unacceptable, as opposed to saying that someone has a physical disability or a learning difficulty (or learning disability). But more that that, to say that someone is a disabled person or has a learning difficulty does say something about how we regard them or wish them to be regarded.

The struggle to produce as many non-offending, neutral, non-condemning words opened the door for the creation of very many words with a clear euphemizing function. We should ban the use of the term political correctness. It is a camouflage, a confusion, an obstacle, a disguise, a red herring, an irritant, a diversion. It hardly explains anything.

Key words: mentality, minority groups, names, euphemisms, language.

The difficulty of definition

One starts with a great disadvantage. PC is difficult to define and pin down: there is no organisation, no sacred texts (though, strangely, at least one sacred oppositional text has emerged). Its opponents frequently find themselves outpaced by critics and media distortion, first, by being preoccupied to find themselves politically correct, or, second, by being forced into the position of replying to a criticism rather than getting on with what they regard as some unexceptionable work.

One of the arguments against PC is that it lacks perspective; it blows things out of proportion. That point cannot itself be debated until we get PC itself into proportion, its extent, and its effects. One of the obstacles to clarification is the very use of the term: "Oh, that is so PC" or "You are so PC", we say, as if as that, of itself, decided the issue.

My thesis will be that PC is a term used mostly in a meaningless or abusive way, which discourages debate. The irony of its present use is that, as several writers have commented, the term was first used by members of the Communist Party, as an ironic, self-mocking term in reaction to so-called "correctlineism". Its more modern usage originated on the campuses of the United States of America in the 1960s.

We might try to define political correctness as follows:

New names regarding professions, sex, physical abilities/disabilities, being part of a minority, instead of the names given to them in the language.

A mere definition of political correctness:

We may try to define PC as follows:

-        New names given to professions, gender of a minority by the majority instead of their common names (used in their community) in the common language, of which people or the group spoken of, consider them to be offending and outrageous.

-        PC means (represents) the militant attitude of promoting new names.

PC is a specific mentality originated in the second half of the 20th century in the United States. Its origins however are well in the past.

In the 60's many minority groups, such as black people or homosexuals, began to fight for political rights and against the discrimination they have had to put up with. Among various requests, one of them was that they should not be called by their old names anymore (considered offensive), but by their new names, that should not express a moral judgement. Accordingly the US black people were to be referred to, not as blacks or afro- Americans, but as African-Americans. Strangely or not, the coloured people from France preferred blacks to noirs. PC is rhetorical.

PC is an ideological attitude, based on more suppositions:

-        society is made up of small and larger communities;

-        small communities (called minorities) are being discriminated by the larger communities (majorities) economically, politically and linguistic.

-        Counted minority also means implicitly moral minority; accordingly, the major community imposes itself on the minorities with its own value system in which minorities are devalued.

According to Michel Foucault, one of the ways to control the minorities is to call them in different ways, names which also contain ethical value judgements.

According to Mike Salovesh, a professor of Anthropology at the Northern Illinois University, the term "politically correctness" was first used in the Communist Party of the USA. It served as a part of disciplinary process intended to see that Communist Party members stuck to the party line. In any event, "politically correct" fell into disfavour as part of the many factional disputes that characterized ideological Communism in the 30's. The reappearance of the phrase in English translations of the *Little Red Book* of Chairman Mao Tze-Tung was due to a translator grabbing what was then an obsolete usage in US Communist Circles.

"Politically correct" was resurrected by people who were conscious propagandists for tiny organized right-wing groups. This time, the term was deliberately used to suggest that whatever was being called PC was really a result of a deliberate communist plot. Then, the term itself and the frequent use of the initials PC migrated from the right-wing groups to the political propaganda of conservatory thinking. Its use became notable in conservative journals. Then PC began turning up in lists of words Republicans were advised to use consciously to attack members and polices of the Democratic Party. This was the campaign that eventually led to a widespread recognition of the term PC. The campaign's success is clear in today's two streams of usage for PC. For some, it serves as an accusation that someone else is blindly following the political line of some alien left-wing mob, party or philosophy. Others see it as a possibility to be denied: "It's not that I want to be PC or anything, but could we stop calling people "gimpsy" or "crippled" and say instead, that they have a *walking disability*?"

Another close analysis of this matter belongs to David Bergdahl, professor at Ohio University. He supports the idea that the term "politically correct" originates in the famous Little Red Book and that the term was used in the massive relocation and re-education of the urban elites-one sought to be politically correct to unlearn the bourgeois attitudes of city and university life; for a brief period of time the term was used by American leftists "in a self mocking way", but the term

was quickly taken by several writers to condemn "pointy-headed intellectuals" and our concern with language from the perspective of the subjugated rather than the dominant culture.

Also interested in this topic, Michael J. Gottlieb, from Yale University, implies that with the exception of those who do have a political agenda and are clearly thinking about the use of a particular term (e.g. Those who would now advocate the use of the term "queer" instead of "gay" for a variety of political reasons), many people accept what seems to be the most neutral opinion, completely unaware of its implications or actual meanings. While some people prefer to be called "black", other prefer "African-American" (the same goes for "Indian" rather than "Native American"). For Michael J. Gotlieb this means that many people want to avoid the risk of saying anything wrong and opt for whatever was most recently used on the NBC. His conclusion is that rather than assuming a political agenda, the term "politically correct" in reality refers to the lack of any agenda and serves as a kind of default- the "accepted" category of descriptive euphemisms. This is frustrating for those who spend time thinking about language and its usage.

Surprisingly, PC had no big echo in Europe; PC is the solution to an American mentality problem, resolved quickly through specific American methods. In Europe also, coloured people (Africans, Asians) might have felt offended by their callings, but here in Europe, the problem and its solutions have maintained themselves at an individual level (possibly as a result of the common sense and culture that has always surrounded the European climate).

Affirmative action is specific to the American legalism, equivalent of the Anglo-Saxon fairness.

Political correct Terms in American and British English

The following examples of PC terms show how PC influences the vocabulary of a language and the way in which it succeeds in hiding the original meaning of a given word, which has been perceived as offending or pejorative. Thus, all PC terms are a special kind of euphemisms. Diseases of all kinds, various occupations of the lower class workers, sexual and ethnical minorities, environmental issues, all were renamed and euphemized. In this respect, one must take a closer look at the following examples:

PC TERM	NEUTRAL WORD
horizontally challenged	Fat
least best	Worst
aesthetically challenged	Ugly
involuntarily leisured	Unemployed
Vertically challenged	Short
vocally challenged	Mute
temporarily metabolically abled	Alive
photonically-non-receptive	Blind
folicularlly challenged	Bald
oppressed;African-American; non-white	Black
oppressor;melanin- impoverished	White
gravitationally challenged	Obese
oxygen exchange unit	Tree
economically challenged/disadvantaged	Poor
Academic dishonesty	Cheating
automotively- challenged	bad- driver
visually oriented	Deaf
verbally- dislexic	Drunk
gerontologically advanced	Old

Ethnically homogenous area	Ghetto
physically challenged	Handicapped
domestic engineer	house wife
selectively perceptive	Insane
motivationally deficient	Lazy
sexually non-preferential	Bisexual
mentally challenged;special; exceptional	Retarded
terminologically inexactitude	Lie

The popular usage

A review of the film *There's something about Mary* in the New Statesman tells us: "During its two- hour running time there are verbal and visual jokes about mental and physical disability, homosexuality, fetishism and police brutality. As Mary herself comments, PC is out".

When there was a threat from the EU to curtail all humanitarian aid to the Afghani Taliban regime, The Times report began with the sentence: "PC in Brussels is threatening to wipe out nearly two decades of humanitarian work by one of the oldest aid agencies in Afghanistan". The reference hear was to the Afghanistan appeal, set up and run since 1983 by the broadcaster Sandy Gall, to help Afghani children disabled by polio and landmines. The Brussels move was widely seen, the report went on, as a sanction against the Taliban's discriminatory treatment of women and its refusal to work toward a negotiated settlement in the civil war.

Philip French, reviewing the controversial film on the holocaust *La Vita e Bella,* remarks that governments, the church popular opinion, and "other arbiters of taste " have decided that some subjects are "taboo or, as we now say, political incorrect". The holocaust was one of them.

Let us consider these examples one by one. The use of "PC" in the review of There's something about Mary is a short form for saying: "Those who do not welcome jokes about gay people and those with a physical or mental disability had better watch out if they choose to see this film". That at least gives the term some useful meaning.

The Brussels decision about humanitarian work in Afghanistan might well disadvantage the disabled children with whom the charity has worked, but what has political correctness to do with being opposed to the oppression of women by the Taliban? Those who support the women would regard their stance as a moral one.

Finally, Phillip French confuses taboo with PC. We do not joke or make light of the holocaust because it is too serious a matter, out of sensitivity to the memory of the dead, and it would be in plain bad taste to do so. Again, using the phrase "PC" is meaningless.

Dogma or morality?

What these admittedly haphazardly collected references show is how imprecisely, indeed usually meaningless, the term "PC" is used. Indeed, it is used at times almost as a synonym for dogma- as if those who are said to be politically correct have no philosophical, moral, practical or other argument for their actions or stance, but only some mysteriously arrived at act of faith.

Sieghart (October 1998) perfectly captures the point of the frequent meaninglessness of the term when she refers to the enormous advances is race relations in Britain since 1964. She writes:" In my children's inner London state school, teasing other children because of the colour of their skin is thought unpardonable", adding, significantly so far as my argument is concerned: "This is not PC; it is morality pure and simple."

Considerations about the language

People are often preoccupied and occupied with their language. It is now no longer acceptable to refer to anyone as a chairman or to use adjectives for nouns. For example the mentally ill, the disabled.

However, those who like to joke about changing terminology forget that language is constantly changing and that language is how we express ourselves. Today, in Anglo- American society at least, to say someone is a cripple or an idiot or mentally handicapped is unacceptable, as opposed to saying that someone has a physical disability or a learning difficulty (or learning disability). But more that that, to say that someone is a disabled person or has a learning difficulty does say something about how we regard them or wish them to be regarded.

Changes like these- "disabled person" for cripple, "mentally ill person" for madman, "learning disability/ difficulty" for mental handicap and so on, are a simple courtesy, not least as, so far as it is possible to judge, those who have been given these negative labels have expressed a preference for a more positive term, if they are to be labelled at all. Such labels can also – though not always- be more properly descriptive.

Much myth attends these terms. For example, "intellectually challenged" is often a mocking term used of someone not quick to cotton on to an idea but I have yet to hear it suggested that it be used in any professional way. Nor have I heard a short person seriously said to be "physically challenged" or a bald one as being "follicularly challenged".

The importance of the way in which language is used in its expressive sense is heightened in an age of mass communications, when terms can gain immediate and universal currency. That the "politically correct" use of language is not a new thing is noted by Cameron (1994) who pointed out that "that most modern of irritants, the Great Generic Pronoun Controversy" was raised by John Stuart Mill in parliament 150 years ago.

There are those cold word warriors who reach to extremes and tie themselves in the knots of ridicule. Maddox (February 1999) reported from the United States that a senior white Washington official lost his job because he used the word "niggardly" at a meeting. I also read about protests because the use of the word "management" because it meant, "men handling matters." Niggardly has no more etymological connection with what Americans call the N- word (it derives from the Middle English word for miserly), than management has to do with men (it derives from the Latin meaning "to handle"). Such diversions can be dangerous ("the man has lost his job") when they are not humourous.

Many of the labels from the 80' s are now obsolete. Here are some examples of PC that are now acceptable:

Old term	80's	90's
Deaf	Hearing impaired	Aurally challenged
Blind	Sight impaired	Visually challenged
Retarded	Mentally handicapped	Mentally challenged
Queer	Gay; homosexual	Queer
Fat	Big boned	Horizontally challenged
Used	Second hand	Pre-owned

Political Correctness and freedom

But there is the other more serious side to the linguistic coin. Changes in language and the adoption of certain politically correct stances are no substitute for services, efficiently and effectively available. We wondered if political correctness has done any good? Piles of documents have been produced but at the end of the day, if we weigh in the balance which groups or individuals are better off as a result of politically correct activities, we might find that it exactly replicates those power relationships which it was originally intended to undermine.

Those who oppose changes in language often regard them as trivial, yet, by their own reasoning, if they are trivial how can political correctness at the same time pose a threat to our fundamental values, indeed, according to some, our very civilisation?

What seems to underline this concern is less the change in language than a concern about who will do the changing- Orwell's "the thought police", "the neo-stalinists" or "politically correct social workers". The latter must be the most dangerous group, partly because it is difficult to identify the others. So, it is a nonsense to believe that any group changes languages because language evolves, in a very subtle and unseen fashion.

Dissent from communal norms can force dissenters into silence for fear of being associated with ideas, groups and individuals with which they do not agree; the wish not to appear politically incorrect. Loury describes it as "a certain course of symbolic meaning-in-effect, quite apart from the real-world consequences of its pursuit". The example which Loury gives is of those who, while opposing apartheid, did not support sanctions because they believed them either to be ineffective and/or likely to have a deleterious effect on the majority of Black South Africans. It is not difficult to see how this constraint on opinion works with regard to discussions on the age of homosexual consent, black crime, abortion, the underclass, or the bombing of Iraq. One consequence is that views may appear to be more polarised than would otherwise be the case.

Words instead of action

There is also a danger that words can be mistaken for deeds. Jules Feiffer makes this point when he writes:"I used to think I was poor. Then they told me I wasn't poor, I was needy. They told me it was self-defeating to think of myself as needy, I was deprived. Then they told me deprived was a bad image, I was underprivileged. They told me underprivileged was over used, I was disadvantaged. I still haven't got a dime. But I sure have a great vocabulary".

Something of the same point is made by Ehrenreich (1992), a liberal critic of political correctness, who wrote: "I like being called Ms. I do not want people saying "man" when they mean me, too. I am willing to make an issue of these things. But I know that even when all women are Ms, we shall still get 65 cents for every dollar earned by a man. Minorities by any other name- people of colour or whatever- will still bear the huge burden of poverty, discrimination and racial harassment. Verbal uplift is not a revolution".

Anthony Douglas remarks that "the only political correctness people can detect in the world outside lies in the use of language, the words used rather than the services received". He also remarks that while senior managers and politicians can "afford the luxury of being politically correct, front-line staff has to get on with a complicated and difficult job, doing the best they can with limited options and resources".

George Orwell (1970), describing the impoverished state of political writing after the war, saw the same debasement of debate as we can see today. He wrote:" the word *fascism* has now no meaning insofar as it signifies "something not desirable"". He goes on to castigate the word "democracy" for its lack of definition and as an all- purpose covering for our own favoured political regimes. He writes: "The person who uses them [the words "fascism" and "democracy"] has his own private definition, but allows his hearer to think he means something quite different". Today Orwell might bring his strictures to bear on the phrase "political correctness" and those who use it.

In the war propaganda, the enemy "bombardments" are equivalent to the "surgically accurate attacks" of the ones on the other side; the term "surgically"outlines not only the precision, but also the idea that the attack is a small evil that produces a larger good. You can easily see the power to subdue of the metaphor. It is the same case with the "collateral victims of the war" and "the collateral damage".

Euphemisms and Political Correctness

With the introduction of the "politically correct terms", a vast category of euphemisms came into being. The struggle to produce as many non-offending, neutral, non- condemning words opened the door for the creation of very many words with a clear euphemizing function.

According to Gary Kamiya, writing in the *San Francisco Examiner,* the term "politically correct" or PC first attracted a sizeable audience with the popularity in 1987 of the Allan Bloom surprise bestseller, *The Closing of the American Mind*. By 1990 the term had become a topic of national interest. As Kamiya sees it:

PC touched a national nerve. Everybody – academics, middle brows, conservatives and liberals- all had an opinion on it. The debate over PC has become an ongoing public forum on race, education, politics, art and morality- a fact which has led some observers to suggest that the controversy itself has become part of the curriculum. (G. Kamiya- in *San Francisco Observer)*

Conclusions

It is wiser to to be more careful when using of the term *political correctness*. It is a camouflage, an obstacle, a disguise, a red herring, an irritant, a diversion. It hardly explains anything. Issues of equality and anti-oppression are important and no one should be embarrassed to say so. Dunant writes:" the problem is less with the aims of PC than its methods…" Progress can be made on those questions which political correctness supposedly addresses, but which it succeeds in either obscuring, distorting or bypassing.

But what is important are these questions: the rights of children, the role of women, the civil rights of mentally ill people, the right to an ordinary life for people with a learning difficulty, matters of race, changing family patterns. Take away political correctness and they remain. Claims to have done "the political correct thing", accusations that "the political correct thing" has been done, only muddy the waters of debate. It is not that either left or right are unconcerned with the questions; all too obviously this is not the case. It is that their analyses and prescriptions differ. What we need to do is to take political correctness out of the equation: it is our error to believe that it is even part of it. To throw the word about as a meaningless term of abuse in intellectual laziness, debases the currency of debate and diminishes the importance of the issues. Once we have abolished the words "political correctness", the battle can begin.

KULTUR UND INTERKULTURALITÄT IN DER WIRTSCHAFTSKOMMUNIKATION

Magheţiu Anca-Raluca
Universitatea de Vest, Timişoara Facultatea de Economie şi de Administrare a Afacerilor

Intercultural communication is, especially for the younger generation, nothing extraordinary anymore. Wether they are at their job, on a business trip abroad or shopping online, they communicate in an intercultural context. The target is to find a common ground which is plausible and understandable for all parties involved in the communication process. This is of course not always easy to obtain because they start from different conditions. Each partner comes with a background of different experiences, out of which different expectations develop. Each and every one of us lives, thinks and acts in a different system of ideas, which continues to exist, even though we communicate in a formally common Lingua franca (the English language). The purpose of the paper is to show some ways in which culture is reflected in the business environment, to illustrate some functions and purposes of the intercultural business communication and to explain the importance of intercultural skills in business communication.

In such an intercultural context we certainly have to face misunderstandings, stereotyping, conflicts and communication errors, which cannot always be avoided, but their number can be minimized, if we know and understand the way in which they emerged. Intercultural communication should not be viewed as something problematic, but as something that opens new horizons, encourages the willingness to learn and leads to further education. Difference should be perceived as a new chance, a chance to develop together new and forward-looking ideas.

The ability to communicate in an intercultural context is an important skill that should also be taught in a foreign language class. It is of utter importance that students, besides knowing the foreign language, learn about the cultural background, the work ethics and the habits of that particular foreign country and thus can interact in a pleasant and easy manner with their foreign counterparts.

Keywords: intercultural communication, business environment, culture, intercultural skills, stereotypes.

1.Kultur reflektiert im europäischen Wirtschaftsleben

Jeder Geschäftsmann, der im Ausland tätig sein will, sollte die Sprache lernen. Das sollte man als Ausländer als Erstes tun, um mit den neuen Geschäftspartnern/Kollegen zurechtzukommen. Auch wenn diese perfekt Englisch sprechen, ist es nützlich soviel Zeit wie möglich zu opfern um ihre Sprache zu lernen. Wie bereits in diesem Kapitel erwähnt wurde, besteht Sprache nicht nur aus Wörtern, sondern dazu gehören auch Körpersprache, Kleidung, Umgangsformen, Etikette, Ideen und Verhalten der Menschen. Genauso wie die Sprache, hat auch das Verhalten eine Grammatik, eine innere Logik, die zu verstehen und zu beherrschen ist.

Was die Arbeitsmoral betrifft, gibt es unter Nordeuropäern die hartnäckige Überzeugung, dass die Südeuropäer faul sind. Man sagt Südeuropäer arbeiten um zu leben und Nordeuropäer leben um zu arbeiten. Diese unterschiedliche Arbeitsmoral wird von den Nordländern als eine goße kulturelle Hürde angesehen, wenn beispielsweise Unternehmen aus dem Norden zur Sonne und den billigen Arbeitskräften des Südens gelangen. Es wurde jedoch statistisch festgestellt, dass die Menschen im Süden genauso hart arbeiten, wie im Norden. Die Behauptung, dass eine Rasse oder Kultur härter arbeitet als eine andere, ist ein subjektives Werturteil. Es bestehen zwar messbare Unterschiede zwischen den produktiven und weniger produktiven Volkswirtschaften, aber die zugrundeliegende Ursache ist nicht, wie hart die Menschen arbeiten, sondern wie effizient. Das Problem ist das Management, nicht die Motivation.

Unterschiede gibt es auch im Falle verschiedener Konventionen, wie z.B. der Pünktlichkeit. Wenn man Menschen zu einem Abendessen für 7 Uhr einlädt, werden die Gäste es als höflich betrachten in Deutschland pünktlich auf die Minute zu kommen, im amerikanischen Mittelwesten 5 Minuten vorher, in Japan eine Stunde vorher, in Großbritannien 15 Minuten danach, in Italien bis zu einer Stunde danach und in Griechenland irgendwann am Abend. Für jeden ist dieses Verhalten akzeptierte Konvention. Die Handlungsweise anderer ist nicht aus Sorglosigkeit, Inkompetenz oder Bosheit unterschiedlich. Die meisten Menschent tun das, was ihnen in dem Moment richtig zu sein scheint. Das Urteil darüber was richtig ist, hat seine Wurzeln in Gewohnheit, Tradition, Überzeugungen, Wertvorstellungen, Einstellungen, akzeptierten Normen, mit anderen Worten, in der Kultur, zu der eine Person gehört. Problematisch wird es erst dann, wenn Unterschiede sich störend auf die Arbeit auswirken.

2. Aufgaben einer interkulturellen Wirtschaftskommunikation

Der Prozess der Globalisierung prägt keinen anderen Bereich so stark wie den der Wirtschaft. Wie noch nie zuvor erscheint heute eine Internationalisierung des Wirtschaftslebens, die die direkte Kommunikation, Interaktion und Kooperation zwischen Angehörigen verschiedener Kulturen verlangt. Dass es dabei zu Schwierigkeiten und Konflikten, zu Missverständnissen und Misserfolgen bei der Durchführung von Projekten kommt, ist immer wieder betont worden. Hierfür werden unterschiedliche Verhaltensnormen, Wertvorstellungen, Kommunikationsweisen, Handlungsvoraussetzungen und oft genug auch mangelnde Sprachkenntnisse verantwortlich gemacht. Will ein Unternehmen Ressourcenpotenziale voll nutzen, Synergieeffekte erzielen, im Konkurrenzkampf besser bestehen und Reibungsverluste vermeiden, so muss es für einen möglichst konfliktarmen Umgang mit seinen Mitarbeitern, Kunden und Kooperationspartnern unterschiedlicher Kulturzugehörigkeit sorgen.

Bei der Analyse der Wirtschaftskommunikation in Bezug auf mögliche oder tatsächliche Missverständnisse gibt es eine merkwürdige Diskrepanz: was von Personen, die sich professionell mit Wirtschaftskommunikation befassen, als höchst problematisch angesehen wird, ist nach Aussage von Personen, die in der Wirtschaft tätig sind, oft nur ein geringes oder gar kein Problem. Für diese Diskrepanz gibt es drei mögliche Erklärungen:

(1) Die in der Wirtschaft Tätigen sind gegenüber dem, was sie tagtäglich tun, höchst unsensibel, erkennen die Problematik ihres Tuns nicht und führen die jeweiligen Missverständnisse in Verhandlungen oder Misserfolge auf andere Ursachen als interkulturelle Probleme zurück.

(2) Die in der Wissenschaft Tätigen sind gegenüber dem, was in interkulturellen Wirtschaftsbeziehungen geschieht, hypersensibel (meist allerdings ohne eigene Erfahrung und oft ohne empirische Grundlage) und sehen Probleme, wo offensichtlich keine sind.

(3) Wirtschaftskommunikation ist nicht mehr Teil einer spezifischen Kultur, sondern als Kommunikation der *global village* inzwischen abgehoben als eine Art übernationale Größe. Sie hat inzwischen eine eigene Kultur entwickelt, die der Summe der historisch gewachsenen Kultur gegenübersteht.

Ziel einer wissenschaftlichen Beschäftigung mit interkultureller Wirtschaftskommunikation sollte daher nicht so sehr die Beschreibung von Traditionen, Normen und Wertvorstellungen, die sich im wirtschaftsbezogenen Handeln innerhalb einer Kulturgemeinschaft manifestieren, und wodurch sie sich von denen anderer Kulturen unterscheiden, sein. Eine wissenschaftliche und zugleich praxisorientierte Beschäftigung mit Interkulturalität in der Wirtschaftskommunikation muss ihr Augenmerk vielmehr auf den Interaktionsprozess richten, der sich in der Zusammenarbeit zwischen Mitgliedern verschiedener Kulturen in einem gemeinsamen Handlungskontext, etwa in einzelnen Internationalisierungsmaßnahmen eines Unternehmens, im internationalen Marketing oder bei der Kooperation von Unternehmen aus verschiedenen Ländern manifestiert. Zweck einer solchen Beschäftigung ist es, einerseits festzustellen, welche Probleme in diesem Bereich tatsächlich auftreten, und möglichst die Ursachen hierfür

aufzudecken, und andererseits, Konzeptionen für Beratung und Trainingsprogramme zu entwickeln, die diese Probleme weitestgehend vermeiden oder wenigstens abmildern können.

Die Beschäftigung mit Interkulturalität in der Wirtschaftskommunikation, die auf Erklärung tatsächlich gegebener Konfliktpotentiale, auf Vermeidung von Missverstehen und auf Sensibilisierung für das kulturell Andere zielt, kann eine wesentliche Hilfestellung für Manager und Mitarbeiter in jeder Form der internationalen Kooperation sein. Schließlich kommt es darauf an, nicht nur eine Verständigung untereinander zu gewährleisten, sondern auch ein Verständnis füreinander aufzubringen.

3. Zur Bedeutung der interkulturellen Kompetenz innerhalb der Wirtschaftskommunikation

Für Laurenz Volkmann (2002:12) lässt sich der Begriff interkulturelle Kommunikation (IK) als Fähigkeit oder Fertigkeit von Fremdsprachenlernern, von Teilnehmern einer interkulturellen Begegnung begreifen, über Differenzen zwischen der eigenen und der Zielkultur zu wissen, sie in konkreten Situationen zu erkennen und Strategien zu entwickeln, einfühlsam auf die Gepflogenheiten der anderen Kultur einzugehen. Es geht also darum, Missverständnisse vorzubeugen, eventuell auftretenden Komplikationen zu glätten und die Kommunikation im Allgemeinen reibungsloser zu gestalten.

An der Bedeutung der IK in der Welt von Business und Handel lässt sich keinesfalls zweifeln. Der Binnenmarkt führt zu einer wachsenden Anzahl von Joint-Ventures, Fusionen und Übernahmen zwischen europäischen, amerikanischen und japanischen Unternehmen. Es veranlasst auch multinationale Firmen, nationale Tochtergesellschaften in Produktbereiche umzuwandeln, die von multinationalen Teams geleitet werden. Ihre Leistungsfähigkeit wird davon abhängen, wie gut Manager verschiedener Nationalitäten zusammenarbeiten. In einer Organisation zusammenzuarbeiten ist etwas anderes, als Geschäfte zwischen Käufer und Verkäufer zu tätigen. Es erfordert ein tieferes Verständnis dafür warum Leute mit unterschiedlichem Hintergrund sich auf bestimmte Weise verhalten.

Es gilt beispielsweise für viele deutsche Manager als wichtiges Ziel, sicher und selbstbewusst aufzutreten, eine bestimmte Autorität auszustrahlen und sich bei der Präsentation klar und überzeugend durchzusetzen. Genau diese in der eigenen Kultur wichtigen Qualitäten bzw. ihre kulturgebundenen Ausdrucksformen (Sprache, Körperhaltung, Gestik usw.) können jedoch in internationalen Verhandlungskontexten nicht nur Irritationen hervorrufen, sondern diese auch grundlegend behindern: Was in der einen Kultur als überzeugend, sachkompetent angesehen wird, kann in der anderen Kultur als Ausdruck von Arroganz und Desinteresse am Kommunikationspartner ausgelegt werden. Was in der eigenen Kultur teilweise als Schwäche angesehen wird, beispielsweise die Fähigkeit zur Selbstkritik, zur Relativierung von Behauptungen, zur Perspektivierung von Meinungen, kann in interkulturellen Gesprächssituationen eine der wichtigsten Voraussetzungen für das Erreichen eines gemeinsamen Kommunikationsziels sein.

Häufig reagiert man auf die unterschiedlichen Verhaltensweisen mit Vorurteilen und Überheblichkeit (etwas ist *typisch deutsch, italienisch, britisch*). Unsere Reaktionen sind in gleicher Weise von unseren eigenen Einstellungen und Wertvorstellungen geprägt wie von denen, die dem Verhalten anderer zu Grunde liegen. Daher sollte man versuchen Urteile beiseite zu lassen und zu fragen, warum wir so reagieren.

Zu den Lernzielen der IK gehören demnach (Volkmann 2002: 23):

-Kenntnisse der kulturellen Kodes, des Selbstimage der eigenen Kultur;

-Wissen um das sog. fremde Heterostereotyp, d.h. wie sich Mitglieder einer anderen Kultur selber subjektiv einschätzen;

-Wissen um konventionelle Stereotype, welche die Wahrnehmung der anderen Kultur steuern und prägen;

-Wissen um konventionelle Stereotype, welche das Bild des eigenen Landes in der anderen Kultur prägen;

-Wissen um die heterogene Struktur der eigenen und fremden Kultur, um Teil-, Sub- und Alternativkulturen;

-keine blinde Übernahme der kulturellen Standards der anderen Kultur, diese wird in der Regel sogar als unangenehm empfunden;

-Rückgriff auf die in der eigenen Kultur erworbenen Kommunikationsstrategien;

-die Fähigkeit, kulturelle Barieren bewusst und kompetent zu überschreiten;

-Empathie und Respekt für die unterschiedlichen Verhaltensformen und Werte in der Zielkultur zu entwickeln.

Jedes interkulturelle Handeln setzt voraus, dass die Beteiligten mit anderen, mehr oder weniger fremden Konventionen, Normalitätsannahmen und Weltsichten ihrer jeweiligen Partner konfrontiert werden. Normalerweise wird eine gemeinsame, dritte Handlungsgrundlage im Prozess des Zusammenarbeitens oder –lebens permanent ausgehandelt und verbessert. Dies geschieht, laut Jürgen Bolten (2007:146), unterschwellig, kann sich aber auch, vor allem im ökonomischen und politischen Bereich, sehr geplant vollziehen. In beiden Fällen kommt es jedoch vor, dass der Aushandlungsprozess dadurch gestört oder unterbrochen wird, dass eine gegenseitige Akzeptanz der jeweiligen Handlungsvoraussetzungen nicht erzielbar ist.

Ein hierfür sehr relevantes Beispiel ist die von Kultur zu Kultur sehr unterschiedliche Korruptionspraxis. Man verfügt noch nicht über einen weltweit identischen Begriff von Korruption und dies ist auch nicht möglich, weil die Bedeutung von Begriffen Wandlungsprozessen ausgesetzt ist, die nicht weltweit synchron verlaufen. Außerdem entstehen Bedeutungen erst dadurch, dass sie innerhalb kultureller Gruppen kommuniziert, vereinbart und in Handlungen erprobt und korrigiert werden.

Um es konkret auszudrücken: Ab welcher Grenze eine Handlung als korrupt bezeichnet wird, hängt nicht zuletzt damit zusammen, wie sich die Normalität von Reziprozitätsbeziehungen in einer Kultur definiert. Aus sehr vielfältigen Ursachen, dazu zählen auch klimatische und religiöse, ist dies von Kultur zu Kultur sehr verschieden, was man beispielsweise an der unterschiedlichen Praxis des Schenkens feststellen kann. So wie ein Nicht-Beschenken aus der Sicht der einen Kultur als unhöflich bewertet werden kann, kann umgekehrt ein Beschenken aus der Perspektive der anderen Kultur schon als Bestechung registriert werden. Z.B. sind in China Zahlungen zum Aufbau oder Erhalt einer Geschäftsbeziehung keineswegs ungewöhnlich. Anders als ein Westeuropäer würde ein Chinese normalerweise nicht auf den Gedanken kommen derartige Zahlungen unter dem Begriff Korruption zu verbuchen.

Problematisch wird es sicherlich dann, wenn entsprechende Zahlungen aus chinesischer Sicht von einem Westeuropäer als selbstverständlich erwartet werden, weil sie normal sind, der westeuropäische Partner allerdings in moralische Konflikte geriete, wenn er tatsächlich (aus seiner Sicht Schmiergeld) zahlen und sich der Korruption schuldig machen würde. Keiner der Partner wird an den bestehenden kulturellen Normalitätssystemen etwas ändern: dem Westeuropäer werden seine moralische Bedenken kaum genommen werden können und auf chinesischer Seite wird es sicherlich für diesen konkreten Fall nicht zu einer Systemänderung kommen.

Was ist in einer solchen ausweglosen Situation zu tun? Man darf keine Lösung aufzwingen, welche die Souveränität einer der beiden Positionen missachtet. Mit Souveränität ist hier nicht das Beharren auf ursprünglichen Standpunkten gemeint, sondern die Wahrung eigener und die Respektierung der fremden Identität. Wenn diese Toleranzgrenzen überschritten werden, dann wird es zumindest von einem der beiden Partner keine Akzeptanz für die Grundlage des gemeinsamen Handelns geben. In einem solchen Fall, in dem eine Verständigung über die unterschiedlichen Positionen zu keinem gemeinsamen Aushandlungsergebnis führt, ist es ratsam

sich nicht anzupassen, sondern die Geschäftsbeziehungen vorerst aufzugeben oder so zu führen, dass der strittige Punkt bewusst ausgeklammert wird.

Interkulturelle Kompetenz bedeutet in diesem Zusammenhang, dass man in allen Bereichen sozialer Interaktion in der Lage ist, größtmögliche Toleranzspielräume auszuhandeln. Hierzu ist es notwendig, die Souveranität der Partner anzuerkennen und zu respektieren, in der Lage zu sein, Unvereinbarkeiten zu erkennen und zu thematisieren, seine eigene Position erklären, die fremde verstehen und für die Permanenz von Aushandlungsprozessen werben zu können.

DER LERNER ALS ZENTRALER FAKTOR IM FACHSPRACHENUNTERRICHT

Magheţiu Anca-Raluca
Universitatea de Vest, Timişoara Facultatea de Economie şi de Administrare a Afacerilor

Teaching Languages for Special Purposes (LSP) is a complex and challenging process, because it differs a lot from teaching general language: the goals and contents are different, one has to focus on the practical needs of the language learners, the learners are supposed to already have some professional skills in the field they are studying in, the learner is the central figure in the didactic process. This means that the teacher of LSP has to have some knowledge in the field in which his learners are working or intend to work. The teacher needs also to take into account a series of other subjects such as psychology, sociology, linguistics and didactics in order to create a unitary course.

The purpose of the paper is to show the way in which the learner of LSP (in this particular case the learner of business German) and his needs are reflected in literature and if a profile of the LSP learner can be established. Certain features of the LSP learner have to be taken into account such as their age, the skills in their specific field, their cultural background and their language level. Each of these factors contributes to the way in which an LSP course is conceived and organized. The question also arises whether there is a good learner, what characterizes him/her and under which circumstances does he/she learn best. And finally the paper tries to integrate the LSP learner into certain learner types with their distinctive features, strengths and weaknesses. Of course other elements like the course planning and organizing, the text choice, the types of exercises used and the assessment methods must not be ignored, as they are also crucial for the success of the LSP course, but the learner with his background and future needs remains the key element of the equation.

Keywords: LSP learner, LSP teaching, business German, professional skills, cultural background

Der Lerner ist mit seinen sprachlichen und fachlichen Vorkenntnissen, seinen Wünschen und Erfahrungen, sowie seiner Lernfähigkeit und Lernmotivation zentraler Bezugspunkt im fachsprachlichen Unterricht. Ihm gegenüber steht der Fach- oder Fachsprachenlehrer, der durch seine fachlichen und sprachlichen Kompetenzen die Ausgangssituation beurteilt und auf konkrete Bedürfnisse eingeht.

Fachsprachenunterricht muss für sehr unterschiedliche Zielgruppen konzipiert werden, entsprechend den unterschiedlichen Lernvoraussetzungen und angestrebten Zielqualifikationen. Lerner- und sprachbezogene Einflussfaktoren, die bei der konkreten Unterrichtsplanung in Betracht gezogen werden müssen, sind:

-das Alter;
-die Fachkompetenz;
-der kulturelle Hintergrund;
-die vorhandenen Sprachkenntnisse.

1. Die **Altersspezifik** wurde bisher im fachbezogenen Fremdsprachenunterricht vor allem im Hinblick auf erwachsene Lerner berücksichtigt, die im Vergleich zur Schuljugend stärker ausgeprägte kognitive Interessen und einen höheren Grad von Bewusstsein und Zielorientierung besitzen. Diese Eigenschaften müssen bei der Formulierung der Lernziele, der Auswahl der Materialien und der Gestaltung des Unterrichts entsprechend berücksichtigt werden. Obwohl der Faktor Alter die Lernvoraussetzungen entscheidend mitprägt, wird er im fachbezogenen Fremdsprachenunterricht nicht immer als unterrichtskonstituierend angesehen.

2. Eine immer mehr diskutierte Größe ist dagegen der Einflussfaktor **Fachkompetenz**. Dabei werden im Allgemeinen zwei Gruppen unterschieden: Fachleute und Nichtfachleute. Bei den Nichtfachleuten handelt es sich um Lerner ohne eine für die angestrebte Ausbildung relevante Fachkompetenz und damit um Lerner ohne entsprechende fachsprachliche Kenntnisse in der Mutter- bzw. Herkunftssprache. Bei diesen Gruppen muss der Aufbau von Fachkenntnissen mit dem Aufbau von Sprachkenntnissen einhergehen, d.h. das Fachvokabular muss, möglichst anschaulich, auch inhaltlich erläutert und mit Blick auf seine Bedeutung im fachlichen System situiert werden; es findet also eine Art Begriffslernen statt.

Bei der Gruppe der Fachleute liegen dagegen sowohl fachliche als auch fachsprachliche muttersprachliche Kompetenzen vor, die beide beim Aufbau des Unterrichts zum Tragen kommen. So müssen z.B. Lerninhalte und Spezialisierungsgrad der Texte dem fachlichen Vorwissen angepasst werden, um das Lerninteresse positiv zu beeinflussen: fachlich zu schwierige Texte lassen den Lerner resignieren, fachlich Bekanntes führt zu Desinteresse.

Da sich Fachkompetenz auf Grund von Befragungen oder Tests relativ genau einschätzen lässt, wäre es zumindest theoretisch möglich, unter fachlichem Aspekt homogene Lerngruppen zu bilden und damit Lerninhalte zielgruppenadäquat zu bestimmen und entsprechende Materialien und Methoden einzusetzen. Viele Berichte aus der Praxis des Fremdsprachenunterrichts zeigen jedoch, dass diese Homogenität, sei es aus organisatorischen oder wirtschaftlichen Gründen, nur relativ selten realisiert werden kann.

3. Eine ähnliche Situation gilt für die Berücksichtigung **des kulturellen Hintergrundes**, der ebenfalls eine wichtige Größe im Bereich fachliches Handeln darstellt. Neben Einzelhinweisen auf kulturell bedingte Unterschiede, problematisiert Fluck (1992: 181) folgende, unterrichtsmethodisch zu beachtende Verhaltensstrategien und Lern- und Diskurstechniken:
-mechanisches Auswendiglernen von Lehrstoffen;
-fehlende Problematisierung der Stoffe;
-additive Strukturierungsprinzipien;
-personenbezogenes Mitteilungsverhalten;
-reaktives Unterrichtsverhalten (Verzicht auf Fragen, Kritik usw.).

Lernschwierigkeiten, die aus solchen Kulturkonflikten resultieren, können den Fach- und Fachsprachenunterricht gleichermaßen beeinflussen. Damit einher gehen häufig die Konzentration der Lerner auf den Lehrer und/oder das Lehrbuch, sowie eine sich daraus ergebende zunächst mangelnde Bereitschaft zur Auseinandersetzung mit vervielfältigten Arbeitsblättern. Solche Schwierigkeiten beschränken sich allerdings nach den Erfahrungen der Praxis auf nicht fachkompetente Lerner, denn Fachleute haben in der Regel im Zuge der Beschäftigung mit dem Fach in ihrer Ausbildung den Mitteilungsstil der entsprechenden Disziplin und ihre Fachsprache ganz oder bis zu einem gewissen Grade angenommen. Die Begründung dafür liegt in der weitgehenden Gleichartigkeit der internationalen Fachwelt, so dass sozial-kulturelle Faktoren gegenüber der allgemeinen Kommunikation in der interkulturellen Fachkommunikation an Bedeutung verlieren. Dennoch erscheint es nicht unangebracht zu sein auch dieser Gruppe auf einer allgemeineren Ebene die Fähigkeit zur interkulturellen und bikulturellen Kommunikation zu vermitteln.

4. Neben der Ermittlung der Fachkompetenz ist es wie im allgemeinen Fremdsprachenunterricht notwendig, den jeweiligen **Sprachstand** möglichst genau zu bestimmen. Bei den sprachlichen Voraussetzungen der Lerner sind im Fachsprachenunterricht auch die Fremdsprachenkenntnisse außerhalb der Zielsprache von Bedeutung, um z.B. inhaltlich und methodisch gezielte Therminologiearbeit leisten zu können, denn ohne die Kenntniss von Anglizismen lassen sich bestimmte Bereiche in Wirtschaft und Technik kaum verstehen und terminologisch aufarbeiten. Deshalb gilt für den Fachsprachenunterricht, dass der Ist-Zustand der vorhandenen Sprachkenntnisse auf den verschiedenen Ebenen wie folgt ermittelt, analysiert und in die Unterrichtsplanung einbezogen werden sollte:

-allgemeines Sprachniveau;

-Stand der einzelnen Fertigkeiten;

-Kenntnisse weiterer Fremdsprachen;

-Fachsprachliche Kenntnisse in der Erstsprache;

-Strategien zur Informationsentnahme und –verarbeitung (z.B. Lesetechnik).

Es ist ein unbestreitbares Verdienst des Fachsprachenunterrichts, den Lerner und seine Bedürfnisse ernst genommen und in den Mittelpunkt der Kursplanung gestellt zu haben, mit entsprechenden positiven Rückwirkungen auf den allgemeinsprachlichen Fremdsprachenunterricht. Festzuhalten aber bleibt für den fachbezogenen Unterricht generell die hervorragende Bedeutung komplexer Bedarfsanalysen, die sowohl auf die besondere fachliche und berufliche Situation der Lerner, als auch auf die erwünschten Ergebnisse und den individuellen Vermittlungsweg Rücksicht nehmen.

Ulrich Nehm (2006: 346) zitiert eine englische Studie von Hedge (2000: 76), derzufolge sich der gute Lerner durch folgende Fähigkeiten auszeichnet:

-Definition eigener Lehrziele;

-effektiver Einsatz von Sprachmaterial;

-sorgsame Organisation der Lernzeit;

-aktive Entwicklung von Lernstrategien;

Diese Charakteristika werden durch Persönlichkeitsfaktoren des Lerners ergänzt, die diesen maßgeblich beeinflussen: Alter, Intelligenz, Eignung, Persönlichkeit, Motivation und Lernvorlieben. Ein guter Fremdsprachenlerner nutzt jede Gelegenheit, sich in der fremden Sprache zu vervollkommen und sich intensiv mit dem System der anderen Sprache, auch kontrastiv zur eigenen Sprache, auseinanderzusetzen. Außerdem sucht er jede Chance zur realen Kommunikation in der Fremdsprache und kontrolliert die Entwicklung seiner Lernersprache.

Laut Nehm lernt der Sprachlerner am besten:

-wenn er als Individuum mit eigenen Bedürfnissen und Interessen ernst genommen wird;

-wenn er genug Gelegenheiten erhält, kommunikativen und reflektiven Gebrauch von der Fremdsprache in einer Vielfalt von Aktivitäten zu machen;

-wenn er einer Fremdsprache in einer Weise ausgesetzt wird, die für ihn verständlich und relevant erscheint;

-wenn er sich auf eine Vielfalt von Sprachformen, Fertigkeiten und Strategien konzentrieren kann, die den Fremdsprachenerwerb und das Lernen von Konzepten unterstützen;

-wenn er sozio-kulturelle Informationen erhält und direkte Erfahrungen mit der Zielkultur sammeln darf;

-wenn er sich der Bedeutung und Eigenart der Zielsprache und ihrer Kultur bewusst wird;

-wenn er angemessene Rückmeldung (*feed-back*) über seinen Lernfortschritt erhält;

-wenn er den Freiraum bekommt, sein Lernen eigenständig zu gestalten.

Eveline Hoffman (2003: 206) bietet eine Klassifizierung nach Lerntypen. Der Begriff **Lerntyp** wird in der deutschen Unterrichtspraxis meist mit Wahrnehmungstypen wie z.B. dem visuellen oder dem auditiven Lerner, oder auch mit Orientierungstypen wie z.B. dem kontakt- bzw. personenorientierten oder dem nach Einsicht strebenden Typ assoziiert.

Eine andere Unterteilung in Lerntypen, die dem Handlungsaspekt stärker Rechnung trägt, ist eine in den USA entwickelte Typologie, die auf die Kombination von je zwei vorherrschenden von insgesamt vier beim Lernen vor sich gehenden Handlungen basiert. Diese Handlungen sind:

-konkrete Erfahrung,

-reflektierende Beobachtung,

-abstrakte Begriffsbildung,

-aktives Experimentieren.

Auf Grund der Kombination von zwei beim Lernen vorherrschenden Handlungen ergibt sich nach J. Piaget und J.P. Guitard eine Klassifizierung in den folgenden vier Lerntypen:

1.Konvergierer/Converger: Der Lernertyp Converger lernt vorwiegend durch abstrakte Begriffsbildung und aktives Experimentieren. Diese Personen sind besonders gut in der Lage, Ideen und Theorien praktisch anzuwenden. Sie wollen vom Lehrer wissen, wie sie etwas tun sollen, und der Lehrer muss dies mit ihnen üben. Ihre Stärken bestehen vor allem in ihrer Entscheidungskraft und ihrem logischen Denken. Manchmal entscheiden sie sich jedoch etwas zu schnell, ohne ihre Ideen genügend getestet zu haben (*learning by doing and thinking*).

2.Divergierer/Diverger: Die unter dem Lerntyp Diverger erfassbaren Lerner lernen vorwiegend durch konkrete Erfahrung und reflektierende Beobachtung. Sie können sich viele unterschiedliche Seiten eines Problems verdeutlichen und sind deshalb besonders gut beim „brainstroming". Sie wollen vom Lehrer wissen, warum sie etwas tun oder lernen sollen, und der Lehrer muss sie dazu motivieren. Ihre Stärken liegen in ihrer Kreativität und ihrem Einfühlungsvermögen; allerdings haben sie auch manchmal Schwierigkeiten sich für eine von vielen Möglichkeiten zu entscheiden *(learning by observing and feeling)*.

3.Akkomodierer/Accommodator: Die Lerner des Typs Accommodator lernen vorwiegend durch konkrete Erfahrung und aktives Experimentieren. Sie sind am stärksten praxisorientiert und verlassen sich beim Lösen von Problemen mehr auf ihre Intuition als auf logische Analyse. Sie fragen den Lehrer: „Was, wenn...?", und der Lehrer muss diese Situationen mit ihnen trainieren. Ihre Stärken liegen in ihrer Aktivität und Risikobereitschaft, wobei sie sich aber auch verzetteln können *(learning by doing and feeling)*.

4.Assimilierer/Assimilator: Der Typ Assimilator lernt vorwiegend durch reflektierende Beobachtung und abstrakte Begriffsbildung. Solche Lerner sind am stärksten theoretisch orientiert, können viele Informationen aufnehmen und systematisch ordnen. Sie interressieren sich im Unterricht vor allem dafür, was sie lernen; also muss der Lehrer ihnen Fakten vermitteln. Ihre Stärken liegen vor allem im Planen von Aktivitäten und im Entwickeln von Modellen und Theorien. Manchmal bauen sie dabei allerdings „Luftschlösser", die dem Test der Praxis nicht standhalten *(learning by observing and thinking)*.

The aim of this paper is to analyze how business students can achieve communication skills, namely listening and speaking, through computer-based interactive simulations. In today's foreign language teaching, methods using computer applications and multimedia environments are more and more gaining territory to the detriment of traditional methods. These applications are used successfully in reading, writing, listening and speaking practices both by foreign language teachers and by students throughout the world. Moreover, these means are helpful in practising the four skills of a language: reading, writing, listening and speaking. With the advance of Internet, the computer has been transformed from a tool for information processing and display into a tool for information processing and communication. The instant worldwide connections enabled by the Internet have changed the way teachers and learners work in their teaching and learning of second/foreign language. The Internet provides the opportunity for business students to interact with native speakers and, in the same time, to listen to business people around the world, in this way getting acquainted with different accents and speeches. When students listen to a native speaker, they are automatically emerged in the latter's world. There are many idioms and phrases used by native speakers of the language but they hardly are included in the traditional lesson materials. Through specific Internet sites, the students become familiar with these idioms and phrases and most important is that they learn how to use them in a context. From a cultural point of view, the students become familiar with the turn taking habits, addressing different people, greetings, invitations and many cultural related issues. What is important to keep in mind is that the teacher must create an appropriate learning environment to suit the situation and conform to the needs of the class. A learning environment for the training of communicative competence has to take into consideration the complexity of human experience and the semantic flexibility that allows speakers to use meanings according to their communicative purposes.

Keywords: computer, skills, listening, speaking, business students.
JEL Code: Y90.

1. Introduction

"What skills are important for business graduates?" "Are business schools graduates prepared for today's tough job market?" These are fundamental questions to be taken into consideration when teaching and preparing business students for their future career. Depending on their career choice, either computer or communication skills may be more important for them. However, in most fields, being strong in both is the ideal, and almost all faculties have the resources to help their students master technical and communication skills.

Most people spend most of their professional lives writing, speaking, and listening. According to a survey implemented in 500 American businesses, over 90% of the personnel officials stated that increased communication skills are needed for success in the 21st century. The importance of communication is not surprising considering the impressive amount of time people spend communicating on the job. A study based on responses from over 1000 employers at Fortune 1000 companies found that workers send and receive an average of 1798 messages each day via

telephone, email, faxes, papers, and face-to-face communications. Some experts have estimated that the average business executive spends 75 to 80 percent of the time communicating, about 45 minutes of every hour. (1) The Internet is one of the most recent and advanced tools in education provided by the advance of technology. The Internet can be useful with any skill area in learning a foreign language, being a great resource in practicing language skills. Having strong written, and oral, business communication skills will make business graduates more competitive and more productive on the job. As multimedia technology becomes more accessible to teachers and learners of foreign languages, it has become a practical tool to improve communication skills such as listening and speaking. Students can interact with textual, aural, and visual media in a wide range of formats. This paper presents different multimedia means used in foreign language (English) classes with business students meant to improve their communication skills, speaking and listening in particular.

2. The advantages and disadvantages of using computer-based means in teaching Business English

Together with great technological development of computers, increased speed and processing power, language learning computer-based means is undergoing a continuous change, becoming more and more elaborate and resourceful. The Internet activity can be particularly useful in teaching Business English to business students. It is a "comfortable method to learn some particular expressions in business English" and "imaginative". (2) According to Evans (1996),the results of a survey applied to students showed that students not only used the Internet activity on their own (74%) but preferred doing so (75%). (3)

However, the use of the Internet is more effective with some skills more than others. For example, it is more effective in speaking and listening than in translation. Although teachers' reaction to the Internet usage varies from those who strongly oppose it as a place with too much and very disorganized information, to those who are in favour of it, if the Internet is used effectively and under teacher supervision, it can be a good source and tool in delivering education. When teaching a foreign language, "The internet is [a] suitable place to practise languages as it offers the possibility, with the right software, of using images and audio resources at the same time, combining sounds and images as in communicative situations in the real world. It also provides users with a highly appealing and innovative format". (Labayen et. al., 2005:9)

2.1 The advantages of using computer-based means in teaching a foreign language

Some of the advantages considered when using multimedia in teaching Business English are: easy and quick access to words, sentences and files, advanced searching possibilities, automatic test giving and checking, progress evaluating and report generating facilities. There are many CD-ROMs containing glossaries and online scripts, so that when problems are encountered, the students can get online help. Moreover, many students wish to learn or use their computer skills, therefore the opportunity of developing computer skills along with developing their language skills may seem attractive to them. It also helps the students to become familiar with different aspects of the culture of the language they are learning.

Business students need a lot of help and resources to practice speaking, listening, reading, and writing skills, especially when they are learning specialized vocabulary in a foreign language. By using the Internet, the students have access to a wide range of audiovisual materials from radio, TV to videos in the target language. They have access to comprehension reading exercises, writing of abstracts and letters, vocabulary learning through business articles, searching for jobs or for a certain product, translation from English into Romanian or from Romanian into English and many more.   Apart from the multimedia packages on CD-ROMs, a large variety of exercises and examples can be found on the Internet. Except for the main portals: https://www.google.ro/, www.yahoo.com, www.bing.com, there are also direct links to specialized pages for business

English teaching and learning: resource pages: http://www.better-english.com/vocabulary.htm, online business dictionaries: http://www.businessdictionary.com/, business correspondence pages: http://www.englishclub.com/business-english/correspondence-samples.htm.

The use of the Internet is beneficial for the teachers, too, giving fast and competent language information, covering various aspects of use, facilitating lesson preparation by providing vocabulary, texts or recordings for classroom use, or providing resources for different vocabulary presentation. Electronic dictionaries, (http://dictionary.reference.com/, http://ro-en.ro/, http://hallo.ro/), for instance, have become a must in teaching Business English to Romanian students. Dictionaries undergo the process of transformation into more practical tools, becoming a combination of a variety of components. One of the main characteristics of CD-ROM dictionaries is providing fast access to words in hyperlinked word entries. Another important aspect is advanced searching possibilities (searching with and/or/not operators, specifying frequency for written or spoken words, style, part of speech), which is not only word search, but also multimedia search (looking for pictures or sound effects), subject search (words relating to a given topic), word origin search or pronunciation search. Electronic dictionaries store huge amounts of data, examples, grammatical information, definitions, pictures, synonyms or related words, interactive pronunciation practice and automatic feedback.

2.2. The disadvantages of using computer-based means in teaching a foreign language

At the same time, there are disadvantages that teachers and students alike should be aware of when using the Internet: lack of a person in charge of the information found on the Internet, easy access to improper content, surfing the web during and after the class time for the materials not connected with the learning process, or virus threat. Searching for materials online can be sometimes time-consuming and many students find it difficult to read papers on a computer screen. Also, there is the threat to be covered in too much information with little control over the quality and accuracy of the contents. Therefore, a certain technical expertise is required from both teachers and students. Other disadvantages include the high cost of the hardware, lack of quality software, and the necessity of additional training both for instructors and users. Financial limitations also include the investment in training for the use of the Internet in language teaching and learning requires some technological knowledge and computer skills from both teachers and learners. In addition to these problems, Rowe (1983) considers that one of the most serious drawbacks would be, as he describes, "Teaching language for the sake of language." (Rowe 1983:192). What the author means is the overemphasis on reading and writing. Yet, according to Rowe, language is two-way communication: listening and speaking, reading and writing. Furthermore, the written language is not a separate reality independent of the spoken language. "Language is a skill not just a body of knowledge. You can read for weeks about skiing and memorize all the rules, but you don't really start learning how to ski until you strap on the skis and head down a snowy slope." (Rowe 1983:192). Yet, the use of computer and the Internet is essential for the development of listening comprehension and oral skills. According to Kruse (2004), the web content can be updated easily and the information can be in use immediately. So, this allows the lesson contents to be much more updated which may eventually cause high levels of awareness and success. Also, Kruse (2004) emphasises the fact that the cost of using computer systems and Internet can be relatively low. (4) Video and audio resources represent an effective solution to development of listening and speaking skills of foreign language learners because they are available on the Internet and the maintenance costs are relatively low.

3. Means to develop listening skills to business students

If a student wants to develop good communication skills, he has to be a good listener. To be a good speaker requires being a good listener and a good communicator. In fact, communication starts with listening. In a business meeting, for example, it is very important for business people

to listen to their counterparts carefully, attentively and with an open mind. They can know other people's view more precisely by listening unbiased. In fact, better communication is listening more and more. It is better to start thinking process after listening and understanding others. A well known quoted phrase says "Think twice before you speak, because your words and influence will plant the seed of either success or failure in the mind of another."(5)

Listening skills have been regarded as the brain's ability to perceive and analyse music, heard aurally. According to Pratt (1990), "Aural perception is self-evidently indispensable in musical activity" (Pratt 1990:1). Karpinski (2000) suggests that, without aural skills, musicians are "usually condemned to thinking about music, without learning to think in music". (Karpinski 2000:4). In face to face interaction, listening enables complex interpretive processes. "Processing requirements such as reciprocity of interlocutors' perspectives, the etcetera principle (filling in the gaps of what one hears with knowledge of the language and the world), and combined retrospective and prospective meanings all come into play."(Meskill 1996:2)

Research indicates that even though some foreign language students are often required to speak in English in their social settings, they mostly enjoy listening especially when they are watching television or films.(6) Therefore, using videos and films in classroom can be very enjoyable for the students because for many of them learning is usually associated with boredom and dullness. Listening is one of the fundamental language skills because it is a key to the acquisition of language. In our case, business students need to be able to listen effectively because in their future career they will have to prove confidence and proficiency in all areas of their English. Also, due to the fact that business people and future business graduates will have to establish contacts with foreign business partners, they have to get acquainted with highly ambiguous factors such as accent, pronunciation, or speed. Students need to aurally comprehend far more than they need to speak. That is why in Business English classes, for the students to achieve communicative competence, greater emphasis must be placed on the creation of a listening environment which reflects and responds to factors encountered in the real business world. Another aspect to be considered in a business environment is represented by the details. Negotiating or making deals online require the ability to understand the detail, too. Business students should be able to deduce divisions between words to recognize elision, contracted forms, assimilation, and linking characteristics. Therefore, they should perceive listening as a way of helping their speaking by giving them expressions, exposing them to language, and allowing them to apply it in a business environment. Modeling the real world, decision making in a simulated environment occurs under pressure, often including conflict, emotional factors, and difficult circumstances. Simulation creates a unique environment for developing and executing decision-making skills. In a listening class for business students, the teacher should use authentic listening texts rather than coursebook texts whenever possible. Some of the main sources for authentic listening are: recordings of authentic texts from the media, films (e.g. "Margin Call"), live talk - listening (e.g. a business person developing businesses in Romania; students react well to listening to someone speaking especially for them. They can notice the body language which will help them understand better. The speaker can moderate the speed of the language and students have the opportunity to interact with the speaker), recordings of native speakers or other English speakers (e.g. radio recordings or TV/video/DVD). The advantages of authentic texts are that they are topical and varied in terms of genre and content, are spoken with a variety of accents by different types of speakers, and contain real language, with current expressions and natural hesitations, repetitions and so on. Radio is one of the most accessible forms of listening, but sometimes they prove to be difficult for the students to listen to because they cannot see the body language or the facial expressions of the speaker. The most successful resources in listening classes proved to be DVD/video recordings because they allow students to have access to more information when listening since they also have visual clues as to meaning. The Internet is a powerful source for the students to practise their listening. There are many sites which are

interactive and allow students to listen or listen and watch. Sites such as: http://www.businessenglishsite.com/business-listening-test1.html, http://www.businessenglishmaterials.com/ have activities especially designed for business students. Also, www.youtube.com is broadcasting many listening comprehension improving videos. YouTube is a video upload-watch-download site and is increasing its popularity day by day. According to statistics, the site has more than six million videos and the total time necessary to watch all these videos is 9.305 years. (7) This huge video pool offers priceless opportunities to practice listening in an entertaining and convenient environment.

4. Developing speaking skills by means of computer

According to Chaney (1998), speaking is "the process of building and sharing meaning through the use of verbal and non-verbal symbols, in a variety of contexts" (Chaney 1998:13). In teaching and learning a foreign language speaking plays a crucial role. In the today's business world, the requirements for business graduates in terms of communicative skills in a foreign language are high. By teaching speaking teachers should improve students' communicative skills, because, only in that way, students can express themselves and learn how to adapt to social and cultural rules specific to each communicative circumstance. Practising speaking, students improve fluency (speaking smoothly), pronunciation (saying words properly), and enunciation (saying words/phrases clearly). Fluency can be improved through speeches or presentations, group discussions, role plays, negotiations and debates, interviews and meetings, chatting in small groups. Pronunciation is the ability to say words properly with the correct sounds in the correct places. In our case, business students need to listen to native English business people and then practice the pronunciation of specific vowels and to try to understand movement and location of mouth and tongue when making sounds. Enunciation is a very important aspect of speaking in that poor enunciation can make someone almost impossible to understand. Again, business students need to be exposed to native speakers and, then, to work on trouble word combinations, on reductions, on sentence level stress points, on word level stress points, or on sentence level intonation patterns.

The most important aspect of teaching speaking to foreign language learners is interaction. The teachers need to create a communicative environment based on real-life situations, authentic activities, and meaningful tasks that promote oral language. By using this method, students will have the opportunity of communicating with each other in the target language. Thus, teachers should create a classroom environment where students have real-life communication, authentic activities, and meaningful tasks that promote oral language. Business students must adapt their presentations to different business circumstances. It is useful for students to know that speech should differ in formality, such as when speaking to business people. They also need to learn about the differences among various dialects. Examples from the media may provide occasions for different forms of speech. Oral presentations can be derived from newspaper and magazine articles, as well as business reports. Dramatic acting and watching plays may provide the richest opportunity to see how character and circumstance affect speech. (8) Dialogues are useful in learning standard phrases and vocabulary used in common business situations. Storytelling is an excellent method to teach speaking for students can briefly summarize a tale or story they heard beforehand, or they may create their own stories. Story telling also helps students express ideas in the format of beginning, development, and ending, including the characters and setting.

There are many resourceful sites that can be used in Business English classes, such as: http://www.eslgold.com/speaking.html (for situations for practice, speaking tasks, quizzes, phrases for conversation, business communication tips), http://www.eslflow.com/roleplaysdramatheatregames.html (for role-plays),

http://esl.about.com/od/businessenglishdialogues/Business_English_Role_Plays_Dialogues.htm
(for business dialogues).

5. Conclusions

The technological explosion, the economic crisis and the more and more challenging requirements of the job market are main factors causing the urge to learn foreign languages. The urge of the situation calls for changes in educational practices in order to provide better results in less time and at an acceptable cost level. According to many researchers, the key to achieve these results is the computer, namely the Internet. Computer-based communication technology provides tools for language learners to improve their language skills. Learners are exposed to numerous software programs to improve their reading, listening, speaking skills and grammar knowledge. Texts and visuals are aids to language processing when appearing in conjunction with the aural text. The motivational aspect of video is as an advantage for language instruction. Combined media enhance target language processing, therefore rendering input more direct and obvious for the language acquisition process. The Internet offers teachers and students an impressive amount of materials and communication possibilities to improve their language teaching and learning. Yet, for the successful integration of the online environment in language courses, both teachers and students need to be prepared to adopt new roles and use the available technology in appropriate ways. Students, especially business students can only benefit from technology – based activities if these activities are relevant to their needs and interest.

MANAGING PROBLEMS WHEN TRANSLATING ECONOMIC TEXTS

Sim Monica Ariana
University of Oradea Faculty of Economics

Pop Anamaria Mirabela
University of Oradea Faculty of Economics

Theoretically, translation may pass as science; practically, it seems closer to art. Translation is a challenging activity requiring a set of abilities and posing few difficulties that appear during the translation process. This paper investigates the extent to which sub-technical vocabulary can constitute a problem to Romanian students of economics reading in English, by looking at the translations produced as independent or pair work during English classes and analyzing the various errors which may appeared. The exigencies required by the efficient business communication have increased in the past few decades because of rising international trade, increased migration, globalization, the recognition of linguistic minorities, and the expansion of the mass media and technology. All these led us to approach the topic of translation which is actually a job that requires skills, stages of research necessary for disclosure of transfer characteristic into the target language, training, experience and a good sense of languages. The paper defines the theoretical issues and terminology: translation, types of translation, economic texts and then focuses on the presentation of the practical work carried out throughout the academic year of second year students and it also describes the basic skills and strategies that students as translators need to master in their daily experiences with translation tasks. The main skills proposed are: reading comprehension, researching, analytical, and composing skills. Considering that only 28% of the entire European population can read English, and even less people in South America and Asia can, it is obvious that an effective communication of business matters relies on an accurate understanding of terminology. Economics is a field of knowledge in accelerated scientific and technological development. As there is a permanent and ever increasing need to quickly update their knowledge, economists read and learn directly in the original language of the publication and stick to it in daily usage, including conferences, scientific events and articles written in Romanian. Besides researching properly the markets, finding distribution channels, and dealing with legal issues, a successful business person should not neglect the language aspects, be it spoken or translated. These are some of the main reasons why we consider that our students as future graduates should be well-equipped with some of the skills necessary when reading and translating technical texts, be it for personal progress and development or for the job requirements.

Keywords: translation, terminology, skills, problems.
JEL Code: Y90.

1. Introduction

Marketerii consideră că piaţa locală se canalizează într-un mod mai degrabă natural decat educat, în direcţia *paid-earned-owned-media*.

Pentru *a aplica*, concurenţii trebuie să rezolve un *brief* dat de Ursus, trebuind să livreze un *print* şi o idee sau un concept de campanie *online*. (http://www.roafaceri.com/k)

... scontarea acreditivelor de export, *factoring*-ul intern şi scontarea biletelor la ordin...(http://www.scribd.com/doc/21280306/Analiza-SWOT-a-BancPost)

... proiectate să aducă îmbunătăţiri semnificative în condiţiile de finanţare a acestui segment onlinie de *credit revolving*, un credit pe *afacere non-revolving.* (http://www.scribd.com/doc/21280306/Analiza-SWOT-a-BancPost,

That is how it is said in Romanian! Or at least that is the best way to make it understood in the economic or maybe more accurately, banking environment. It shows, once again, how little economic terminology is settled into Romanian language. And this is a fact not only with economic terminology but also with other scientific fields (mathematics, physics etc.) as we lack the translations of various basic bibliographical texts. Moreover, there are cases when at conferences in Romania, doctors held their presentations in English and not in Romanian due to the absence of the appropriate Romanian terminology. This is where the difficulties in translating specialized texts begin: the use of terms in foreign languages — especially English — is so common that if we wanted to substitute them it means to urge the specialist reader to "untranslate" an important part of the text to be able to understand it. On the other hand, keeping these terms in their original language may render the text unintelligible to the layman who enters a bank or other institution, who wants to be part of an online contest or anybody else who has little knowledge of the foreign language. So, what is to be done?

For instance, the French Academy has been striving against the ever increasing use of English neologisms, requiring that many words borrowed be replaced with French equivalents, Daily Mail reports. The struggle has come to the point that they started to list words that are prohibited on the very official site of the Academy. Some find the actions ridiculous, considering French language, as all languages in the world, as a living thing and thus undergoing natural changes; while others argue that it is exactly the French Academy that have to protect the French language(1). Moreover, there was a law passed in 1994 requiring that all government publications, all advertisements and contracts to be in French exclusively.

As far as Romania is concerned, there was an article on the protection of the Romanian language published in 'Romania Liberă' newspaper from September 16, 2007 entitled 'Draft resolution on protection of the Romanian language to the European Parliament'. Obviously, loans will continue to enter the Romanian language, but we ought to get us informed regarding their use and limit ourselves to those that facilitate understanding, learning and information acquisition as well as the cultural exchange. It means to make use, not abuse only for fashion sake. We must not forget that a language lives as long as it changes and it 'dies' when it stops evolving. (Coseriu 1997:9).

2. What is translation?
As Webster's New World dictionary defines it, 'to translate' means:
1. to move from one place or condition to another; transfer;
2. to put into the words of a different language;
3. to change into another medium or form to translate ideas into action;
4. to put into different words; rephrase or paraphrase in explanation.

Even if we can speak of translation beginning with the Tower of Babel (Finlay, 1971:17) etymologically, we observe that 'translate' comes from Latin 'trans+latus' meaning 'carried across' (Lewis 1958:265).

Nevertheless, translation is an activity performed for specific purposes, no matter which they may be, its main purpose being 'to serve as a cross-cultural bilingual communication vehicle among peoples' as Constanza Gerding-Salas rightly emphasizes. (2)

The importance of the translation activity has greatly developed due to many reasons: rising international trade, globalization, migration, the impressive development and the expansion of the mass media and technology. Consequently, the translator finds himself playing an important part in this process of huge changes, becoming 'a bilingual or multi-lingual cross-cultural transmitter of culture and truths by attempting to interpret concepts and speech in a variety of texts as faithfully and accurately as possible'.(3)

2.1 Types of translations.
There are the main types of translation: a. word-by-word translation;
b. word-for-word translation; c. literary translations; technical translations.

The word-for-word translation, that is also named literal translation, is used as the basis for further work with the text; this type of translation can only give a clue on the overall meaning, and it might well be misleading.

In the word-for-word translation or 'for information' translation, it is necessary to accurately transfer the main idea of the translated text from the source language to the target language. This translation is used to understand the structure of the original text; it is accurate, still sometimes sloppy, not polished enough.

The translation of literature should give the notion of the original text rendering not only the concept, but also the vision, atmosphere, style, and emotion. In this type of translations, the fluidity of the text prevails over accuracy.

Technical translations should always start by assessing the target reader and the end user of the translated text. This is an exact translation; the people reading it need to be able to accurately and totally understand and use the information given.

2.2. Translating economic texts

As a subdivision of technical texts, the translation of economic texts is highly demanded at banks, companies, professional accountants, and multinational corporations and so on; it covers financial, accounting, marketing, and management matters. Therefore, a qualitative translation requires specialists with a certain background and expertise in the field. The person in charge with the translation of such specialized texts should be familiar with economic terms at the same time being capable of understanding their meanings, and be aware of many facets of the economic field. It has often been underlined that the main obstacle to fully understanding technical texts is not technical vocabulary itself as one may expect (highly specialized words usually used only by specialists), but an intermediate lexical category between the general and the fully technical one, constituting the largest proportion of scientific and technological texts and known as *sub-technical, semi-technical* or *nontechnical vocabulary*. This consists of items of vocabulary from normal English operating within a science context.

Another problem is that translators have a hard time to transfer the same meaning to the other languages, especially when it is about new concepts or technical terms that have no Romanian equivalents. For example, Liviu Ornea admits that during his lectures he uses a lot of English technical words like 'produs warped' or simply 'warped product' as the Romanian version 'produs răsucit' is less scientific; or, another sample is 'twistor' the notion introduced by Roger Penrose, which would be 'răsucitură', or 'încolăcitură' in Romanian. So, the only solution is to keep the English version until there is going to be a common corpus of terminology scientists could rely on. (4) Regarding this problem, Delisle (1981) illustrates what a subtle form of torture translation is: '*Translation is an arduous job that mortifies you, puts you in a state of despair at times, but also an enriching and indispensable work, that demands honesty and modesty.'*(5)

Economics is a field of knowledge in accelerated scientific and technological development that each year incorporates a large number of new terms into the specialized vocabulary. As there is a permanent and ever increasing need to quickly update their knowledge, economists read and learn directly in the original language of the publication and stick to it in daily usage, including conferences, scientific events and articles written in Romanian. There are many ways through which business terms have entered the Romanian vocabulary: contacts between business people, specialised business journals and newspapers, and books, as well as TV programmes on business. The number of specialised terms borrowed from English into Romanian in the field of Economics is extremely high, and their necessity cannot be contested, although many of them are present only in the jargon of specialists. Nevertheless, a great number of these loan words will not last in the Romanian language, and for those that will stay, it will take some time before they are really adopted and adapted to the Romanian language.

It is only later on that the first attempts to translate these terms start to appear timidly, and this leads to further problems such as finding the suitable corresponding Romanian term. This process is often carried out by people who have no translating experience. They can also be carried out by professional translators who are not familiar with the associated vocabulary or economic practice, resulting in seriously distorted meanings. Amateur translators seldom perform very thorough in-depth proofread research into terms that have already been translated in economic literature, which results in highly heterogeneous translations from one publication to another. Training translators becomes vital not only in the acquisition and command of languages and translation strategies and procedures, but also in specific knowledge areas and, in professional ethics as well. Inadequate translations can not only lead to minor confusions, but it can sometimes prove to be a matter of life and death if we think about cases of serious inadequacy in knowledge areas such as science, medicine, legal matters, or technology.

A good option, in certain cases, would be to keep the original English term in brackets to increase the reader's comprehension.

> e.g. Începând cu controversa doctrinară dintre suporterii băncii centrale şi cei care favorizează libera activitate bancară sau *free-banking-ul*, […] teoreticienii Şcolii monetare ("*Currency School*") şi cei ai Şcolii bancare ("*Banking School*"). (6)

Extensive bibliographical research must always be undertaken to search for terms that have already been published in earlier publications, making an effort to stick with the choice made by the first translator. In Holland, for instance, there was a group linguists who gathered and worked out a minimal economics lexicon agreed throughout the country and intensively used by specialists and widely understood by everyone. This could be a useful hint for our country as well as we lack such generally agreed and unitary corpus of special business terms.

Last but not least, the economic translation is a poorly paid field, which is inevitably reflected in the quality. We have to admit that poorly paid work leads to rush jobs, consequently lowering the quality of the final result. All these difficulties could explain the economists' reluctance to adopt translated terms. Perhaps some of the above mentioned measures could really help improve the quality of economic text translations, whether they decide to leave the terms untranslated or not.

3. Practical Aspects

Besides researching properly the markets, finding distribution channels, and dealing with legal issues, a successful business person should not neglect the language aspects, be it spoken or translated. There are numerous instances when companies get themselves into trouble with translations that are inaccurate or culturally inappropriate.

These are the main reasons why we consider that our students as future graduates should be well-equipped with some of the skills necessary when reading and translating technical texts, be it for personal progress and development or for the job requirements.

Here are some examples of translation problems encountered during our regular English classes taught to students at the Faculty of Economics, University of Oradea.

English classes are held weekly; students have an intermediate/ upper intermediate level of English knowledge (they have been tested prior to establishing the English groups); we work from a book conceived especially for second year students that approaches different fields of business so as to let students get used to the specialized vocabulary.

Besides reading, writing and solving a great amount of vocabulary exercises, we have tried our hand at translating some short texts from English into Romanian. Certainly, in order to produce an acceptable translation, you must find acceptable words in the other language. Even though everything seems a piece of cake at a first glance, there appeared a number of difficulties when actually producing a correct and coherent Romanian translation.

Here we will make a very important distinction between two kinds of language: general language and specialized terminology. In general language, it is undesirable to repeat the same word over

and over unnecessarily. Variety is highly valued. However, in specialized terminology, consistency (which would be called monotony in the case of general language) is highly valued. Indeed, it is essential to repeat the same term over and over whenever it refers to the same object. It is frustrating and sometimes even dangerous to change terms for the same object when describing how to maintain or repair a complex machine such as a commercial airplane.

Now, returning to the question of acceptable translation producing an acceptable translation requires finding acceptable words. In the case of specialized terminology, it should be the one and only term in the other language that has been designated as the term in a particular language for a particular object throughout a particular document or set of documents.

By means of some workshop activities, our attempt is to develop some translation skills as a cooperative activity with the students—through a graded and sequential procedure. We must assume that students have sound linguistic knowledge, both theoretical and practical, and a wide cultural bilingual background, achieved during their first years in college.

After reading the text (reading comprehension is actually the first preparatory step), students are advised to practice the following basic reading comprehension skills: scanning, skimming, reading for gist and main ideas, reading for details, identify the meaning of new words and expressions paying attention to structural aspects (prefixes, suffixes, roots, word order), identify the meaning of new words and expressions by finding synonyms, antonyms, identify cultural references in the choice of words in the text.

When coming across unknown words, students are encouraged to use dictionaries as 'the most commonly heard advice to translators is 'if you don't know the meaning of a word, look it up in *the* dictionary.''(Enani 2001 as cited by Antar S.Abdellah, 2002). Students use both bilingual dictionaries for looking up meanings of new words and monolingual dictionaries to check the usage of the new words in the source language and in the target language; they are also advised to refer to specialized magazines and journals to follow the use of the particular word.

The next level of translation refers to the accuracy and sound aspect of the translation and for that students are supported to pay special attention to aspects like: the correct word order in the target language, the ideas of the text should be conveyed in clear sentences in the target language, sometimes they are invited to rephrase certain sentences or even make changes to the text so as to render the overall meaning translated.

The most obvious mistakes students have made in carrying out the translation tasks was to take it for granted that they know all the meanings of business words, based on a familiarity with the central or more general meaning that these words possess: *stock* was mostly translated *stoc* and only seldom as as *actiune/titlu de valoare, interest* was rendered as *interes* and almost never as *dobinda, balance* was considered *balanta* and only a few students translated it as *bilant,* while *maturity* was translated like the easy to guess Romanian equivalent *maturitate* instead of its more specialized meaning *scadenta*, *security* became *securitate* most of the times even if it had nothing to do with the text, instead of *garantie* which gave meaning to the text..

While in some cases these translations produced smiles due to the insufficient awareness regarding the full knowledge of a word, there were cases when the translation sounded absurd (security, *agreement- agreement*) or even obstructed the understanding of the text.

4. Conclusions

Terminology or the so-called sub-technical vocabulary is an important area in business English and it needs to be approached as such when it comes to learning and rendering it. Whether these words are created by a process of homonymy or polysemy, there is no perfect overlap between English and Romanian when it comes to translate them. Thus, such linguistic differences may create confusion in translation and it is the task of the English teacher to deal with them and to enable or facilitate understanding, by using different learning strategies and translation techniques.

SECTION: ECONOMICS AND BUSINESS ADMINISTRATION

SUB-SECTION: ECONOMICS

PRICE VS QUALITY COMPETITION AND THE SPATIAL PATTERN OF AVERAGE PRICES IN INTERNATIONAL TRADE

Affortunato Francesca
University of Chieti-Pescara, School of Advanced Studies

Mattoscio Nicola
University of Chieti-Pescara, Department of Quantitative Methods and Economic Theory

This work investigates the relationship between the average export prices and the distance between the origin and the destination market in international trade. Distance between trading partners obviously stands at the core of I international trade literature and is strictly related with the issue of how countries and firms compete on export markets when transport costs become increasingly stiff. Heterogeneous-Firm Trade (HFT) models predict that only most competitive firms are able to export on distant markets, where it is more difficult to recover from freight costs. However, this simple concept does not lead to unambiguous predictions on the spatial pattern of average export f.o.b. prices.
This work uses bilateral product-level data for five top-exporters (US, Germany, China, France, Italy) and all their world partners in order to test the main hypotheses derivable on this issue from theoretical literature. An huge dataset of bilateral international trade flows, the BACI dataset of CEPII, provides data both on values and quantities, allowing to construct products' unit values (at the 6 digit level of the Harmonized System), approximating average exports' prices. These data are used as the dependent variable of the econometric test and regressed on a set of explanatory variables: the distance of the destination market from the exporter and other importer's characteristics. Thus, this test assesses which of the considered theoretical models fit the data best, shedding some light both on the sign and on the determinants of the spatial pattern of average prices. The main finding of this work is that theoretical models not embedding a quality dimension for products do not seem to fit the data very well: it is clear from the econometric test that a positive correlation between average exports' prices and distance often emerges, denoting a "quality competition" pattern in addition to a possible alternative pattern of "price competition". Moreover, theoretical models with a quasi-linear demand function (in contrast with a CES one) are able to better explain same evidences emerging from the data.
Keywords: average prices, distance, quality, inter-firm selection, spatial price discrimination

1. Introduction

This work investigates the relationship between the average export prices and the distance from the origin market to the destination market in international trade. According to the most recent theoretical contributions in international trade (IT hereafter) theory, the following analysis uses bilateral trade data in order to test different hypotheses on the spatial pattern of average prices.

International trade is still strongly affected by geographical distance, in spite of the technological progress which lowers transport costs (Hummels, 2009: 3). Trade flows always depend on the number of goods traded, on their quantities and prices. Distance has a compelling influence not only on the first two of these factors, determining the incidence of "zeros" in bilateral flows (Baldwin and Harrigan, 2011: 73), but also on products' prices. Indeed, geographical distance implies transport costs, which hinder exporting firms' competitiveness on distant markets.

Whereas it is obvious that there is a positive relation between the "cost insurance and freight price" (c.i.f. price) of products (1), that is their price on the destination market ("consumer's price"), it is not straightforward how distance affects the "free on board price" (2) of exports, that

is their price on the origin market ("producer's price"). This work analyzes the relation between the export average f.o.b. prices and the distance between the trading partners.

Recent works of IT literature alternatively assign to the price-distance relation a negative sign (Melitz, 2003: 1717; Melitz and Ottaviano, 2008: 304), a positive sign (Baldwin and Harrigan, 2011: 79) or neither systematically a positive nor a negative sign (Kneller and Yu, 2008: 14). When present, the empirical test is carried out on a single country's trade data.

This work uses bilateral trade data in values and quantities for the 5 top-exporters and their world's partners (at the 6 digit level of the Harmonized System) to construct the unit values (as an approximation of average f.o.b. prices) and regress them on data for distances between trading partners and other characteristics of the importers (used as control variables).

2. Theory on the average price-distance relation

2.1. Mechanisms and variables affecting the average price-distance relation

Alchian and Allen (1964) formulated the hypothesis known as "shipping the good apples out": the average prices of goods increase with the distance from the destination market, depending on a "compositional" effect in demand, due to the fact that per unit transport costs (3) benefit high-priced, high-quality goods as distance increases. Together with the modelling choice for transport costs', quality has always played an important role in the analysis of the price-distance relation.

One of the most recent waves of IT literature, that of Heterogeneous Firm Trade (HFT hereafter), grounded on Melitz (2003), has important implications on the analysis of the spatial pattern of average prices. These contributions are complementary to the Alchian-Allen hypothesis, since the HFT models are based on different mechanisms and on the assumption of iceberg transport costs (Baldwin and Harrigan 2011: 81).

Four HFT models have been analyzed (Melitz, 2003; Melitz and Ottaviano, 2008; Baldwin and Harrigan, 2011; Kneller and Yu, 2008), and different predictions for the price-distance relation have been drawn. The four examined HFT models share same basic assumptions: they are monopolistic competition models with firms randomly drawing a marginal cost c from a common distribution $G(c)$ with support $[0, cM]$. Transport costs are "iceberg", increasing in distance.

But they differ in other hypothesis:

- with a CES demand, firms adopt a "mill pricing strategy"; with a quasi-linear demand, firms "space-discriminate" when setting their optimal f.o.b. prices (Martin, 2009);

- firms may differ only for their efficiency or also for quality: if present, quality is modelled as a log-linear function of marginal cost, $z = c\sigma$, where z stands for the quality level, and $\sigma \geq 0$ is the elasticity of quality to marginal cost and is country-specific. As a consequence, firms may be selected in each export market on the basis of their quality-adjusted prices, when $\sigma > 1$ ("quality sorting") or on the basis of their observable prices, when $0 \leq \sigma \leq 1$ ("efficiency sorting");

- the importer-specific cost cut-off, separating firms efficient enough to export from those which are not, is always a direct function of freight costs and either a direct function of market size or an indirect one, through its relation with a price index, negatively related with market size.

The HFT literature explains the average price-distance relation through two types of processes (see Affortunato and Mattoscio, 2012, for a more thorough review):

1) a possible intra-firm level process of spatial price discrimination;

2) an inter-firm selection process in export markets.

The first process regards the possibility that firm may set different levels of markup and price in different markets (Melitz and Ottaviano, 2008). With regard to this issue, two problems arise about how to model: a) preferences, ruling the price elasticity of demand; and b) transport costs, ruling the relation between the demand elasticity to c.i.f. and f.o.b. price (Martin, 2009). This last issue is bypassed, since freight costs are always modelled à la Samuelson.

With regard to the second process of firms' selection into export markets, firstly introduced in Melitz (2003), the standard HFT theory predicts that only most efficient firms can export. In models with asymmetric countries, this means that average prices decrease with distance, when quality is not considered ($\sigma = 0$) or when quality is not efficiently produced ($\sigma \leq 1$); whereas it means that the average prices increase with distance (when quality is efficiently produced ($\sigma > 1$).

2.2. The predictions for the average price-distance relation in HFT theory

Below (Table no. 1) the predictions drawn from the four examined models are listed, according to the models' assumptions on the said key-variables (quality, preferences and transport costs).

Table no. 1 - Predictions on the spatial pattern of prices from HFT theory

MODELS	ASSUMPTIONS			PREDICTIONS ON		
	Heterogeneity dimension	Demand curve	Transport costs	Spatial Price Discrimination	Firms' Selection	Total Effect
Melitz (2003)	Efficiency	CES	Iceberg	0	-	-
Baldwin and	Efficiency Quality	CES	Iceberg	0 \newline 0	- \newline +	- \newline +
Melitz and Ottaviano (2008)	Efficiency	Linear	Iceberg	-	-	-
Kneller and Yu	Efficiency Quality	Linear	Iceberg	- \newline -	- \newline +/-	- \newline +/-

Table made by the authors

The firm's optimal price is unrelated/negatively related with distance in models with a CES/quasi-linear demand. The inter-firm selection effect implies a positive/negative relation of average prices with distance in the case of quality/efficiency sorting. The last column lists the signs of the average price elasticity to distance resulting from these two mechanisms.

A second important relation is that of the average prices with the importer market size: though this is not the main focus of this work, some attention is due to this relation which helps assessing the theoretical models' performances when carrying out the empirical test. To sum up:

- average f.o.b. prices are positively correlated with distance (and negatively with market size) in HFT models with CES demand and "quality competition";

- average f.o.b. prices are inversely correlated with both distance and market size in HFT models with quasi-linear demand and "efficiency competition";

- average f.o.b. prices are ambiguously correlated with both distance and market size in HFT models with quasi-linear demand and "quality competition".

In the next paragraph, the econometric test and its results are described.

3. Testing the predictions on the average price-distance relation

3.1. Methodology and data

In this section, an econometric test is run to evaluate the above examined theoretical predictions on the spatial pattern of average prices. The econometric model regresses unit values (approximating average prices) on a measure of distance and on other explanatory variables:

$$UV_{kij} = \alpha_k + \beta X_j + \varepsilon_{kij} \qquad [1]$$

where the dependent variable UV_{kij} (the unit value of product k, exported from country i to j) is a proxy for average f.o.b. price and is regressed on a set X_j of independent variables. UV_{kij} is:

$$UV_{kij} = V_{kij}/Q_{kij} \qquad [2]$$

where V_{kij} and Q_{kij} are total values and quantities of product k, shipped from country i to j.

The set Xj of explanatory variable contains the following importer's characteristics:

- real GDP, approximating for market size;
- real GDP per capita, accounting for wealth;
- a "border dummy", for contiguity;
- a "language dummy" for sharing a common language with the exporter;
- a product k's average unit value, approximating a price index (as in Martin, 2009):

$$UV_{kj} = \sum_i w_{kij} UV_{kij} \qquad [3]$$

where w_{kij} is the weight of good k exports from country i.

Unit values are from the BACI dataset (CEPII), developed by Gaulier and Zignago (2010); "products" are 6-digit Harmonized System codes and only codes for which at least 50 observations were available are used in the regression. Data on physical distances, border and language are from CEPII. Real GDP and real GDP per capita for 2007 are from the World Bank.

3.2. Results

Running the regression [1] on the above cited data the following results emerge (Table no. 2):

Table no. 2 – Statistical determinants of export unit values (2007) (4)

	US	Germany	China	France	Italy
Log distance	0.219***	0.086***	-0.095***	0.065***	0.099***

	(0.005)	(0.015)	(0.016)	(0.007)	(0.033)
R2	0.078	0.043	0.055	0.021	0.024
Sample	242,144 observations on 2,780 HS6 codes	253,246 observations on 2,861 HS6 codes	285,773 observations on 2,846 HS6 codes	179,194 observations on 2,149 HS6 codes	208,298 observations on 2,458 HS6 codes

Table made by the authors

From Table no. 2 it is evident that the correlation both between average f.o.b. prices and distance and between average f.o.b. prices and market size is always statistically significant. Also the average unit value has a high coefficient and is highly statistically significant.

Since only China has a negative coefficient for the average price-distance relation, whereas the coefficient is positive for all the other exporters, theoretical models not embedding a quality dimension for products do not seem to fit the data very well. If competition between exporting firms was only a price competition, only cheaper products should be able to compete on distant markets and the correlation between prices and distance could never be a positive one.

Other important considerations emerge by looking at the sign of the combinations of the price-distance relation and of the price-market size relation: there is always an alternation of negative-positive or positive-negative signs respectively in the case of China/others. In lines with the Baldwin-Harrigan model, this result could be interpreted in the sense that an efficiency/quality sorting pattern emerges respectively for China/others, in contrast with theoretical models without quality. However this constant alternation of signs could be due to the aggregation along the HS6 codes. In order to clarify that, the same regression [1] has been run separately on each HS6 code.

Table no. 3 – Combinations of Signs for the Price Elasticity to Distance and Market Size

	Number of HS6 Codes with			
	Positive-Positive Price Elasticity to Distance and Market Size	Positive-Negative Price Elasticity to Distance and Market Size	Negative-Positive Price Elasticity to Distance and Market Size	Negative-Negative Price Elasticity to Distance and Market Size
US	1,392	1,140	182	106
Germany	1,078	1,304	247	277
China	561	581	887	844
France	725	915	257	305
Italy	654	1318	296	234

Table made by the authors

The Baldwin-Harrigan model seems to be incompatible with the emergence of all possible combinations of sign for the correlation of average prices with distance and with market size.

By contrast, the Kneller-Yu model can explain the results ensuing from this last regression. The importer's market size enters models with quasi-linear preferences through its relation with the price index: as market size increases, competition becomes tougher and the price index decreases. Thus, only the most competitive goods are shipped on bigger markets: the average prices relation with market size is negative/positive in the case of efficiency/quality sorting.

In lines with the Kneller-Yu model, a quality sorting pattern may emerge in three cases, that is when the combination of signs for the price elasticity to distance and market size is:
- positive-positive (implying that the "selection effect" always dominates);
- positive-negative, when the "selection effect" dominates for distance and the "spatial price discrimination" leads for market size;
- negative-positive, when the "spatial price discrimination effect" dominates for distance whereas the "selection effect" prevails for market size.

By contrast, an efficiency competition emerges in the remaining case of a negative elasticity of average prices both to distance and to market size.

4. Conclusions
The main finding is that theoretical models not embedding a quality dimension for products do not seem to fit the data very well, being clear from the econometric test that a positive spatial pattern of average prices often emerges, denoting a "quality competition" pattern.
The Kneller and Yu model shows the best performances in explaining the data, since:
- it predicts a sorting pattern which may operate both as a price and as a quality competition;
- it allows the emergence of all the four possible combinations of signs for the correlations of average prices with distance and with market size;

- it embeds a price index as one of the variables influencing the price-distance relation, as it clearly appears form the data.

The implications of the analysis relate to at least two fields of study: i) the firm-level strategies to keep competitive on export markets and the reallocation of resources as a consequence of firms' selection; ii) the performances of trading countries in the global market and the consequent changes in their welfare. In the light of this work's results, both firms and countries may vary their strategies or policies according to their choice of how to compete on export markets: they should encourage firms' physical efficiency to price-compete; they should enhance firms' efficiency in terms of the goods' quality content, if they want to lead on a quality competition.

Notes

(1) The c.i.f. price (i.e. cost, insurance and freight price) is the price of a good delivered at the frontier of the importing country, including any insurance and freight charges incurred to that point, or the price of a service delivered to a resident, before the payment of any import duties or other taxes on imports or trade and transport margins within the country (UN, 1998).

(2) The f.o.b. price (free on board price) of exports and imports of goods is the market value of the goods at the point of uniform valuation (the customs frontier of the economy from which they are exported). It is equal to the c.i.f. price less the costs of transportation and insurance charges, between the customs frontier of the exporting (importing) country and that of the importing (exporting) country (UN, 1998).

(3) IT scholars typically express transport costs in *ad valorem* terms, that is as the percentage change in price induced by freight costs (Hummels, 2009: 8): $p_{cif}/p_{fob} = 1+f/p_{fob}$, where f is the per-unit freight cost and p_{cif} and p_{fob} are the c.i.f. and the f.o.b. price. Since Samuelson (1954), this f-term has been treated as an *ad valorem* tax equivalent (iceberg costs), that is as if f was a constant percentage of the value traded, implying that the c.i.f. price of a good relative to its f.o.b. price is not a function of the f.o.b. price: $p_{cif}/p_{fob} = \tau$, with $\tau>1$. By contrast, in industrial organization literature, an additive approach is preferred (keeping the f-term additive, as in the general formulation), so that the c.i.f. price-f.o.b. price ratio is an inverse function of the f.o.b. price and more expensive goods have a less than proportional greater trade costs.

(4) Dependent variable is log unit value of exports by HS6 product and export destination, relative to HS6 code mean (that is, HS6 code fixed effects are included in all regressions). Independent variables are the listed characteristics of export destinations. Estimator is OLS. Standard errors in parenthesis. Asterisks denote statistical significance: *** Significant at the 1 percent level; ** Significant at the 5 percent level; * Significant at the 10 percent level.

University of Chieti-Pescara, Department of Quantitative Methods and Economic Theory

The European integration process has always been markedly characterized by the increasing incidence of Intra-Industry Trade. This has been theoretically justified on the grounds of the new approaches emerging in international trade literature, based on imperfect competition and differentiated products. In recent years another distinctive economic feature of the European Union is the importance gained by the so called "cultural and creative sectors", which are often studied and monitored for their great growth potential. We provide here a systematic decomposition of world trade in "cultural/creative goods" for the year 2009 (using harmonised bilateral flows for 213 products defined as "cultural products" by UNESCO, 2009) into three trade types: inter-industry, intra-industry (IIT) in horizontally versus vertically differentiated products. We show that the world trade in cultural goods is significantly characterised by two-way trade of vertically differentiated products. Moreover we specifically focus on the Italian peculiarities in the "cultural trade": therefore we first work out which ones of the world countries are the "top exporters" of these categories of products and then we compute an indicator of the Italian goods quality relative to each one of these competitors.
Not surprisingly, we find that the most important bilateral IIT intensities in cultural products are observed in Europe. However the presence of developing countries is not unimportant. This can be explained partly as a consequence of the increasing level of trade integration among some Asian countries and as a consequence of an increasing de-specialization of first industrialized countries in the production and trading of these products. Finally, with reference to the relative quality of Italian cultural products compared with that of the other top-exporters in these sectors, we find that the Italian products performances are good relative to those of emerging countries (such as China and India), but not as much if compared to other European countries (such as Germany, France and the United Kingdom).

Keywords: cultural and creative goods, relative quality, intra-industry trade, vertical differentiation
JEL codes: F1, F59, D4, Z1

Introduction

We seem to be in the middle of a long lasting hype about culture and creativity as possible key drivers of socioeconomic development processes. In the last few years this issue has been analysed in economics (Throsby, 2001), cultural geography (Scott, 2000), sociology (Zukin, 1995), media and communications studies (Cunningham, 2002), urban planning (Landry, 2000) among other disciplines. Given the heterogeneity of the related literature, trying to provide a unambiguous definition of cultural (and creative) economy could be difficult. As pointed out by O'Connor (2007), the debate on cultural industries began with Theodor Adorno, who, with his colleague Max Horkheimer, first coined the term in 1947 (Adorno and Horkheimer, 1979). The term "cultural industries" started to be very popular in 1984 with the Greater London Council. Since then, almost every national government had adopted its own definition, broadening or narrowing the range of activities object. Apart from the emerged problems of definitions and comparisons it is important to stress how these activities are not simply requiring public assistance, but how they represent productive and dynamic sectors (Lavanga, 2006).

In this context the main goal of our paper is to focus on an issue still not much debated, as that of international trade flows in cultural goods. Even if relevant reports, both at the EU level (Eurostat, 2011) and at a global level (UNCTAD, 2010), provided a measurement of world trends in cultural and creative goods and services, a thorough analysis on the patterns of bilateral trade in cultural goods and on the characteristics of these bilateral flows in terms of products differentiation is still missing (to our knowledge). The paper starts by introducing the literature related to issues of intra-industry trade (IIT) and by explaining how we apply the methodologies for identifying vertical IIT to cultural products. Then a data analysis is provided with the interpretation of results.

1. Methodology and data for disentangling vertical from horizontal IIT in cultural goods

1.1. Quality differentiation and vertical intra-industry trade

Since the 1960s, the identification of two-way trade flows within the same industries between countries with similar development and technological levels and with similar endowments has become one of the most important empirical findings in international trade studies.

This significant incidence of intra-industry trade (IIT), originally identified within the European Economic Community by scholars such as Verdoorn (1960), Balassa (1966) and Grubel (1967), has then become the most distinctive feature of the European integration process. Since these seminal analyses, many works (see Grubel and Lloyd, 1975, among others) have deepened the comprehension of this phenomenon and provided insights of the related methodological issues. Recently, two amendments to the original conceptual and empirical framework have gained ground: a) the overcoming of the original opposition between specialisation and IIT; b) the need for detailed bilateral trade data, in order to properly assess the incidence of IIT, without incurring in biases due to the overlapping at the industry level or to geographical aggregation.

According to Helpman and Krugman (1985), monopolistic competition and internal economies of scale lead to IIT in horizontally differentiated products, whereas dissimilarities in factor endowments and technological levels drive trade patterns in inter-industry trade, as in the old comparative advantage theory. As Feenstra (2004) points put, such an interpretation of IIT is coherent with the idea of complete specialization. However, it completely misses the analysis of the vertical differentiation of products, which, on the contrary, entails the idea of IIT as an exchange of "different" goods. As a consequence, it is necessary to understand the price mechanism in order to discern between horizontal IIT (two-way trade in homogeneous products) and vertical IIT (two-way trade of qualitatively differentiated products).

The first scholars interested in the measurement of vertical IIT were Abd-el Rahman (1991) with French data, Freudenberg et al. (1992) with German data, and Greenaway et al. (1994) with British data. Measuring the relative importance of vertical IIT at one point in time, they demonstrate that vertical IIT is not marginal. The first longitudinal multi-country study was done by the CEPII (1997). This analysis showed that vertical IIT is responsible for both the rise of total two-way trade in Europe and for the consequent reduction in inter-industry trade (whereas horizontal IIT remains stable over time).

1.2. Disentangling vertical from horizontal IIT in cultural goods

The two main methods for disentangling vertical from horizontal IIT (see Greenaway, Hine and Milner, 1994; and Fontagné and Freudenberg, 1997) rely on the same assumption regarding the association of price, unit values and the quality of traded products: that differences in prices within one product category mirror differences in quality. Three comments have to be made regarding such an assumption (as pointed out by Fontagné, Freudenberg and Gaulier, 2005):
- it is only acceptable with the most detailed trade data, where aggregation of different products within one product category is minimised (one must use HS 6-digit trade data);

- though there are good reasons leading to slight departures from a strict association of prices with quality, trade economists are accustomed to this simplification;

- prices of traded products are not known, as each transaction has its own characteristics (such as time, place, volume, partners, and special conditions) and thus its own price. This is why average unit values are used instead of prices.

The CEPII has developed a database (BACI) based on COMTRADE, aimed at constructing a harmonised world trade matrix for values and quantities at the 6-digit level of the HS. Predicted mirror flows ratios from a gravity-type equation are used to convert CIF to FOB figures. These very detailed data at the product level allow to compute the unit values of worldwide bilateral flows at a level of disaggregation which is the closest one to the idea of a "product" available at an international level, making it possible to carry out analyses based on the calculation of unit values as an approximation of average goods' prices (see Affortunato and Mattoscio, 2012).

Following the above mentioned methods, our approach is to apply to our products of interest (HS6 "cultural" codes) the following methodology:

1) we conduct the analysis on bilateral trade data on "cultural goods" worldwide, at the product level, for the year 2009, calculating the unit values (value/quantity) for each elementary flow in cultural goods at the most detailed level (HS6);

2) we first categorize whether the flow is inter-industrial or intra-industrial, depending on the degree of overlapping: when the value of the minority flow is at least 10% of the majority flow (see Fontagné and Freudenberg,1997), the total trade in this product is considered to be ITT;

3) we check whether unit values are similar (relying on a 25% difference in unit value) in order to allocate the associated trade flow to a given category of product differentiation: horizontal in case of unit value similarity, vertical otherwise;

4) we make all calculations at the product, declaring country and partner levels.

Table no. 1 – How to disentangle vertical form horizontal IIT

Degree of overlap betwee export and import value	Similarity of export and import values		
Does the minority flow represent at least 10% of the majority flow?	Do export and import unit values differ less than 25%?		Unit value not available
	Yes	No	
Yes	Two-way trade in horizontally differentiated products	Two-way trade in vertically differentiated products	Two-way trade non allocated
No	One way trade		

Source: Fontagné, Freudenberg and Gaulier (2005)

Since we are particularly interested in the Italian peculiarities in the "cultural trade", we then conduct a second type of analysis, always based on the comparison of unit values for each HS6 "cultural" code: first we work out which ones of the world countries are the "top exporters" of these categories of products and then we compute an indicator of the Italian goods' quality relative to each of these competitors (see Abd-el-Rahman, 1991).

2. Results

Not surprisingly, we find here that the most important bilateral IIT intensities in cultural products are observed in Europe. What is more interesting when considering the IIT ranking in terms of values is the presence of developing countries. This is due, to our understanding of the phenomenon, partly to the increasing level of trade integration among some Asian countries (as well as the important role of geography) and partly to the peculiarities of the "cultural" H6 codes and to the fact that many first industrialized countries are increasingly de-specializing in the production and trading of these products (as measurements of the main trade specialization index, such as the Balassa and the Lafay ones, confirm).

Table no. 2 – The worldwide top bilateral IIT shares in cultural products

The worldwide top ten bilateral IIT (shares)			The top ten bilateral IIT (values)

France	Netherlands	18,48	31,75	France	Italy	13,98	43,36
Singapore	Australia	18,25	12,09	Belgium-Luxembourg	Netherlands	17,06	42,65

Table made by the authors

With regard to the final step of our analysis, the results for the Italian performance in terms of cultural goods quality relative to the top-exporters of these products are as follows:

- the first striking result is the huge percentage of Italian cultural products which can be identified as vertically differentiated relative to each one of the other top-exporters;

- the second important consideration steams from the evidence that Italian cultural products reveal a high percentage of high-quality cultural exports relative to many emerging countries (in particular China, India, Singapore, Thailand);
- however, the most important issue is that Italy shows a somewhat poor performance in terms of cultural products quality relative to rich countries (most evidently relative to Japan, but also relative to other European countries, such as France, Germany and the United Kingdom).
Figure 1 – Italian cultural goods' quality at a glance

Conclusions

The revelation of two-way trade within industries, between countries of similar development levels, is one of the most important empirical finding of the 1960s concerning international trade. In contrast to the simplistic opposition between inter-industry trade (based on differences in prices leading to specialisation) and IIT (seen as two-way trade of differentiated products with similar prices), there are both empirical evidence and theoretical arguments in favour of two-way trade of qualitatively differentiated products. Accordingly, IIT in cultural goods has been divided into two parts: IIT in horizontally differentiated (i.e. similar) products and IIT in vertically differentiated products (i.e. differing by quality). In order to empirically study IIT, more detailed possible industry breakdowns are necessary. Moreover both values and quantities (to be able to construct unit values) are indispensable at the product level (HS 6-digit codes) for bilateral trade flows. For our analysis, we use the database BACI (CEPII), constructing a harmonised world trade matrix for values as well as quantities at the 6-digit level of the HS, in which predicted mirror flows ratios from a gravity-type equation are used to convert CIF to FOB figures in order to have not only exports but also imports expressed FOB.

Following Fontagné and Freudenberg (1997) and Fontagné, Freudenberg and Gaulier (2005), our approach is to conduct an analysis aiming at disentangling vertical and horizontal IIT in the trade of "cultural goods" as defined by UNESCO (2009). Therefore, we calculate the unit values (value/quantity) for each elementary flow in cultural goods at the most detailed level, we categorize whether there is inter-industrial or intra-industrial trade, depending on the degree of overlapping and finally we check whether there is horizontal IIT (in case of unit value similarity) or vertical IIT (otherwise). Not surprisingly, we find that the most important bilateral IIT intensities in cultural products are observed in Europe. However the presence of developing countries is not unimportant. This can be explained partly to as a consequence of the increasing level of trade integration among some Asian countries and as a consequence of an increasing de-specialization of first industrialized countries in the production and trading of these products. Finally, with reference to the relative quality of Italian cultural products compared with that of

the other top-exporters in these sectors, we find that Italian performance are good relative to those of emerging countries (such as China and India), but not as much if compared to other European countries (such as Germany, France and the United Kingdom).

COMPARATIVE STUDY ON LABOR MARKET FLEXICURITY AUSTRIA - ROMANIA[15]

Avram Costin Daniel
University of Craiova Faculty of Economics and Business Administration

Avram Alexandru
West University of Timisoara Faculty of Economics and Business Administration

Present in the European political discourse in the early '90s, the concept of flexicurity, achieved by the contraction of two terms, flexibility and security, emerged in the European Union with the adoption of the Communication "Towards Common Principles of Flexicurity: More and Better Jobs through Flexibility and Security" in June 2007.

This study, result of the research internship undertaken in October-December 2011 at WIFO, aims to capture the main dimensions of labor market flexicurity, the quality of social partnership and the present status of the targets set by of Europe 2020 Strategy.

Europe 2020 Strategy aims, among other objectives, at achieving a series of targets specific for the labor market, in the European context, such as:

- Employment for the population aged between 20-64 years,
- Reducing the number of early school leavers,
- Increasing the share of university graduates in the population between 30-34 years,
- Reducing the number of people affected by poverty and social exclusion.

Keywords: labour market, flexicurity, employed population, unemployment, market requirements

JEL Clasification: J62, J82, F59

Flexicurity - concept, principles

International Labor Organization, since it was founded in 1919 by the Treaty of Versailles, has as main task the improvement of working and life conditions. ILO standards are a reflection of the Member States' will to ensure, by international regulations, the fundamental human right to work and social security as well as its related rights:

- freedom of association;
- prohibition of forced labor;
- equal opportunities and fair treatment for all.

The concept of labor market flexicurity has resulted from the contraction of two terms, taken carefully into account by both employees and employers, respectively:

- *flexibility*, an aspect monitored, in particular, by employers and employers' associations;
- *security*, an element found in the attention of employees and trade unions.

Health and safety at work is synthesized as the heart of the International Labor Organization's preoccupations. Framework Convention on Social Security no. 102/1952 established, with the flexibility required by the diversity existing between the Member States, minimum levels of benefits in nine areas of social security deemed as essential: health care, sickness benefits, unemployment compensations, old age benefits, compensations for accidents at work and occupational diseases, benefits to families, maternity benefits, disability benefits, survivors' benefits.

Any State interested in ratifying the *Convention on social security* must comply with the minimum standards for at least three of the areas identified, of which at least one should refer to: unemployment compensations, compensations for accidents at work and occupational diseases, old age, disability or survivors' benefits, and the state may commit itself afterwards to respect rules regarding other areas of social security. Community standards consider the social dimension of EU labor market as a whole:

- free movement of people, goods, services and capital;
- increasing the welfare of EU citizens and especially those who work within it;
- working conditions: job security, wages and working time, labor relations, unemployment and employment, protection of employees (in case of insolvency, the protection of young people at work) etc.

For the first time the term flexicurity was used in the Netherlands in the mid '90s to correct discrepancies between an inflexible labor market in terms of employers, who could dismiss employees with contract of indefinite duration only with great difficulty, and an uncertain situation on the labor market for employees who needed an increase in job security. The balance between flexibility and security on the labor market, expressed by flexicurity started to become a serious concern for the social and political partners from Denmark, Belgium, Germany, Austria and France, so the term flexicurity began to offer consistency to the European political discourse from 1996-1997.

The flexicurity concept can be defined as "a political strategy that seeks to increase labor market flexibility in a synchronous and deliberate manner, in work organization and labor relations on the one hand and social security and employment on the other hand, especially for the vulnerable groups of workers inside and outside the labor market "[16].

The popularity of the term flexicurity lies not only in its quality of political strategy, since flexicurity is also a historical process involving not only politicians but also social partners, between which sometimes heated debates occur and they are both accustomed to the art of negotiation and compromise. „Flexicurity represents, first of all, the degree of security of the job, employment, income and of the combination facilitating the careers and biographies of workers, with a relatively weak position, and allowing sustainable and qualitative participation on labor market and social inclusion, while providing a degree of numerical flexibility (external and internal), functional and wage related, that allows appropriate and timely adjustment of labor market to the ever changing external conditions in order to increase competitiveness and productivity"[17]. Secondly, flexicurity can be considered an appropriate analytical framework for analyzing flexibility and security of labor by international comparisons or comparisons within certain branches and sectors of the national economy.

Comparative Data on Taxes and Social Contributions

The labor market in each country is influenced by the overall level of tax and contributions paid by employers and employees. In our analysis we have monitored the general level of taxes in GDP, top statutory income tax rates, standard value added rates and an example of calculation of personnel costs for a gross salary of 2000 euro per month, in Romania and Austria.

a. Tax Revenue in GDP

Fiscal philosophy on which the budgetary and fiscal policy mix is based is very different in Romania compared to Austria. While Romania collected in 2009 only 27% of GDP from the state budget, well below the European average - 38.4% -, Austria collected 42.7% in the same year, according to table 1.

[17] Ton Wilthagen, Frank Tros, *The concept of flexicurity a new approach to regulating employment and labor market's Transfer,* European Review of Labor and Research, nr. 10/2004, p. 166.

Tax Revenue in GDP

Table no.1

%

EU 27	38.4
EA 17	39.1
Austria	42.7
Romania	27.0

Source: Own processing from http://ec.europa.eu/eurostat

b. Standard Value Added Tax Rate

VAT is an important source for each EU country budget. Under the impact of international financial crisis that led to a reduction in consumption and therefore in VAT revenues, some countries have increased the rate of VAT, as the case of Romania, which increased the VAT rate by 5 percentage points, while other countries, including Austria left unchanged the VAT rate, as can be seen from the analysis of Table No. 2:

Standard Value Added Tax Rate

Table no.2

%

	2010	2011
EU 27	20.4	20.7
Austria	20.0	20.0
Romania	19.0	24.0

Source: Own processing from http://ec.europa.eu/eurostat

c. Top statutory income tax rates

The level of the income tax on both persons and companies is very important. The two countries, Romania and Austria, practice different levels of income taxation, Romania among the lowest in the EU, while Austria is practicing levels above the European average, as can be seen from the analysis of Table No. 3.

Top Statutory Income Tax Rates

Table no.3

%

	Tax on personal income		Tax on corporate income	
	2010	2011	2010	2011
EU 27	37.6	37.1	23.3	23.2
EA 17	41.4	41.8	25.6	25.5
Austria	50.0	50.0	25.0	25.0
Romania	16.0	16	16.0	16.0

Source: Own processing from http://ec.europa.eu/eurostat

d. Comparative Example of Wage Expenses

For exemplifying the wage related expenses, a parallel calculus was made, based on the current legislation, for a salary of 2000 euro / month for a person who lives in Vienna, respectively in Bucharest, with no other dependents, the results being reported in Table 4 and Table 5:

Calculation situation of net wage

Wage Earner	Vienna	Bucharest
Gross monthly wage	2000	2000
Social security contribution	-361	-330
Income tax	-229	-267
Net monthly wage	1410	1403

Source: Own processing from http://ec.europa.eu/eurostat

The situation of wages paid by the employer

Employer costs	Vienna	Bucharest
Gross monthly wage	2000	2000
Social security contribution	467	520
Employer contribution	98	36
Local tax	60	-
Employer total costs	2625	2556

Source: Own processing from http://ec.europa.eu/eurostat

Conclusions

The existent differences fall in the logic of European construction characterized by unity in diversity, but they greatly challenge the authorities' ability to ensure a high potential of convergence of all the countries participating in European economic area.

In conclusion, in Table 6 we shall present the differences highlighted by the study.

Summary of comparisons

Specification	Austria	Romania
Stability of labor legislation	High Stability	Legal Instability
Rigidity of legislation on the employment protection	Insured in the European legislation	Insufficient
Consensual social dialogue	Non-regulated, but functional	Regulated, but nonfunctional
Taxation	High	Low
Share of the employed population	High	Low
Research and development expenses in GDP	Important	Very Low
Poverty Rate	Low	High

We appreciate that the current situation of Romania may be modified if the authorities will pay attention to Europe 2020 Strategy's objectives, for which will be necessary to develop concrete programs of action by involving all political parties and social partners. The potential of convergence between Austria and Romania is high, and both countries can gain from the development of partnership and collaboration relationships. On the Romanian labor market there are currently strong employers from Austria such as OMV, Erste Bank, Raiffeisen Bank, Wienner Staditche and others, while on the Austrian labor market there are Romanian employees working who have adapted to local market's requirements.

Abstract: In this paper we will present a SWOT analysis on the potential of rural tourism in the region Crisana.
Crisana region is a historical region delimited at north by the river Somes and Maramures region, at west by the river Tisa, at south by the Mures river and Banat region, and at east by the peaks of the Apuseni Mountains and Transylvania region. Crisana Region stretches on both Romania and Hungary, and we will refer only to the Romanian side of it. Crisana region has an area of 17,717 km2 and if we refer to the current counties, this region includes much of Arad county, without the area between the river Mures and Timis county, north of Hunedoara county Bihor county and part of western Salaj county.

Key words: Crisana, touristic potential, rural tourism

JEL codes: R1, R11, P25

Introduction

The Crisana region is a historical region delimited at north by the river Somes and Maramures region, at west by the river Tisa, at south by the Mures river and Banat region, and at east by the peaks of the Apuseni Mountains and Transylvania region. Crisana Region stretches on both Romania and Hungary, and we will refer only to the Romanian side of it.

Crisana region has an area of 17,717 km^2 and if we refer to the current counties, this region includes much of Arad county, without the area between the river Mures and Timis county, north of Hunedoara county Bihor county and part of western Salaj county.

Materials and methods

To analyze the rural touristic potential areas for the Crisana region, we used the SWOT analysis method. The specific of the SWOT analysis is that it studies both the internal features (the positive and negative factors) and external environmental influences (opportunities and threats).

Results and discutions

The data with this analysis was made was selected from the published articles upon this subject (Ghinea, 2002) , and processed properly, according to the indicators that we considered relevant for this article.

a.Strong points (Advantages)

    -favorable geographical position, the gateway into the country from the West, several border crossing points, both road and rail;

    -varied landscape and beautiful natural landscape with potential for practicing various forms of tourism - the mountains about 25%, 35% hills and 40% plains, table 1;

Table 1. Landscape of Crisana region

County	Relieful		
	mountains %	hills %	plains %
Arad	35	15	50
Bihor	24	32	44
Hunedoara	68	32	-
Salaj		predominantly	small

Table 2. Hydrography and forested areas

County	Hydrography		Forested areas, mii ha
	Reprezentative courses and lakes	density,km/km^2	
Arad	Mureş, Crişul Alb, Tauţ, Ghioroc		212
Bihor	Barcău, Crişul Negru, Crişul Repede, Cefa, Tămaşda, Inand, Homorog		195
Hunedoara	Mureş, Crişul Alb, over 100 natural lakes, Bucura, Zănoaga	0,5-1,1	313
Salaj	Someş, Crasna, Barcău,	0,7-0,8	106

-particularly karst topography (over 6000 caves from which dozens are arranged and are great attractions for both tourism and caving);

-large number of natural reserves and protected areas (Arad county has 17 and 2 of them are natural monuments, Bihor county has 61 of which 16 are natural monuments, Hunedoara county has 12 of which 2 are natural monuments, and Salaj county has 4. In total there are 94 reservations of which 20 are natural monuments);

-diversity and the relatively high number of natural attractions and antropics: about 1100, of which about 550 in villages (in Arad 414 objectives of which about 200 in rural areas, in Bihor 435 of which about 200 in rural areas, in Hunedoara 140 of which about 100 in rural areas and in Salaj 135 of which 60 in rural areas), historical and architectural monuments, archaeological sites, fortresses, castles, places of worship (churches, wooden monasteries century. XVI-XVIII);

-mountain paths in the Zarand Mountains, Codru-Moma, Bihor, practicable and for cycling, European path of long distance E7 which is crossing the Arad county from west to east;

-flora and fauna of great diversity and a valuable hunting and fishing because of the diversified landscape of forest area (approximately 510 000 ha, 28% of the region), water courses and natural lakes and artificial tab. 2;

-rich network of rivers and hot or mineral water sources with potential for geothermal drilling, famous spas (Baile Felix, 1 Mai, Moneasa Geoagiu Bai, Lipova, Stana de Vale), tab.2 ;

-temperate continental climate, with moderate to mild winters, relatively warm summers, mean annual temperature -2 – 11^0 C, and the winds occurs in almost all directions at speeds ranging from 2 to 7.7 m/s, so there are good conditions for practicing tourism, tables 3 and 4;

Tabelul nr. 3. Climatic favorability

County	Climate	Average anual temp., ^{0}C			Average annual precipitation, mm
		plain	hill	mountain	
Arad	Continental-moderate	11	8-9	6	600-1000
Bihor	Cont.temperate moderate	10,5	8-10	2-4	600-1400
Hunedoara	Continental temperate		10	-2	530-1400
Sălaj	continental temperate moderate	9,6	6		630-1000

Table 4. Direction and wind speed

County	Direction, %						Speed, m/s
	SE	S	SW	W	NW	N	
Arad	13,7	13			10,7	12,4	2,6-6
Bihor		28,1		3,6		8,6	7,5-7,7
Hunedoara				14-15	12-14		2-6
Sălaj	16,1		10,5		9,2		3-4

-region with tourist attraction, especially domestically and internationally less, providing favorable conditions for practicing a variety of forms of tourism: hiking, climbing, caving, rafting, adventure tourism, winter sports, short and long term rest , children and youth camps, spas etc;

-variety of accommodation: hostels, lodges, tourist stops, campgrounds, cottages and hotels from 2-4 stars (only ANTREC affiliated pensions there are 14 in Arad county, 35 county towns in Bihor, 14 villages in the Hunedoara county and 2 towns in Salaj County);

-population structure shows a significant share of the rural areas, a large number of bigger villages (263), even larger number of small villages (1430), population density is rather low, averaging 70 inhabitants/ km^2, while de national average is 92-93 inhabitants/ km^2, tab.5;

Table 5. Population structure and administrative units

County	Population, %		Area, %		Density, loc/km^2	Administrative units	
	men	women	urban	rural		villages	Small villages
AR	48,17	51,83	51,82	48,18	61,7	67	267
BH	48,81	51,19	49,68	50,32	82,7	90	429

SJ	49,06	50,94	42,23	57,77	66,8	55	281

-rich cultural offer: festivals and celebrations, theatrical performances, concerts, exhibitions, sport competitions, customs and traditions preserved, intercultural, ethnic and religious diversity due to ethnic cohabitation: Hungarians, Germans, Serbs, Slovaks, Bulgarians, tab.6;

Table 6. Structure of the nationalities

County	Nationality, %		
	romanians	hungarians	gypsies
AR	80,5	12,5	2,8
BH	66,5	28,8	3,4
HD	91,9	6,1	1
SJ	72,2	23,7	3,5

-working structures that favor tourism business: industrial areas on the outskirts of big cities, chambers of commerce exhibition halls, conference rooms and business meetings organized at several hotels, active and competent institutions to promote and develop tourism tourist information office and NGOs with the object of activity in tourism, travel agencies, human resource training institutions (universities, colleges, chambers of commerce);

-ethnographic exhibitions and events, actively practicing traditional arts and crafts, local traditions in farmers activity;

-accessibility is acceptable given railway network with an average density of 50-55km/1000

km^2, the national average of 47.8 km/1000 km^2, public road network from 7967 km of which 2006 km are modernized and a density of approximately 30-32 km/100 km^2, compared to the national average of 30.7 km/100 km^2, tab.7;

Table 7. Railway and road network

County	Railway network		Public road network		
	length, km	density, km/1000 km^2	length, km	modernized, km	density, km/100 km^2
AR	485	62,5	2079	498	26,8
BH	474	62,8	2491	581	33
HD	339	48	1972	634	27,9
SJ	176	45,5	1405	293	36,4

b.Weaknesses (Cons)

-industrial units polluting activity or dismantled and a negative visual impact;
-in many villages the rural activity collection, recycling waste, and restoring the natural ecological areas, poorly developed;
-pollution of rivers and lakes;
-restricted leisure offer, recreation areas lack forested areas;
-state of degradation of many buildings and monuments;
-quality of the presentation and translation into museums or tourist attractions is generally poor;
-the including of local traditions and folklore for the touristic activities is sporadic and ineffective;
-weak and undiversified offer of souvenirs;
-poor quality of bus and car routes to stations, routes of buses with no fixed programs and the lack of displays for the program, poor quality of trains, buses and other means of transport;
-poor infrastructure, poor quality of roads (inadequate and poorly maintained roads), lack of access roads discourage potential tourists, the streets within the villages are at best cobbled, very few are paved;
-lack of indicators for the tourist attractions - conventional international tourist signs are brown;
-campsites for tents and caravans, absent;
-urban facilities (bank offices, post, exchange, etc.) insufficient or old in rural tourism;
-lack or insufficient capacity of car parking areas and toilets in tourist areas or traffic routes;
-poor awareness of the importance of tourism to the economy, especially in rural areas;
-unattractive wage levels, which stimulate labor migration outside the country;
-professional training in the field does not exactly match the needs of employers;
-failure in school education in environmental protection and tourism;
-poor awareness of opportunities and potential career in the tourism industry;
-low levels of education and communication in various languages of international circulation;
-insufficient use of IT tools and the Internet for information, marketing and booking, promoting the tourism potential failure caused by lack of involvement of tourism operators in developing and promoting national and international tourist market touring programs of the region;
-lack of regional brands, even if there are brands for certain counties;
-lack of a database of festivals and cultural events that allow an effective promotion for domestic and foreign tourists;
-reduced collaboration of the public / private sector on issues of marketing, poor information, lack of motivation and lack of confidence on population regarding touristic potential capitalization and on loans for investment in tourism from they could benefit;
-promotional materials are inadequate or poor quality;
-low participation in fairs;

c.Oportunities
-superior capitalization of the touristic potential, development of recreational areas, improvement of the region's towns image, are opportunities that can be exploited by the organizations interested in developing the local tourism;
-participation in national and international tourism fairs;
-exploiting the advantages and disadvantages offered by organizing the first international tourism congress in Romania, in May, 2011, at Alba Iulia;
-the existence of a tourism strategy in the Hungarian euroregion Haidu - Bihor and national strategy of developing the tourism, as well as developing strategies for the Western Regions V and VI Northwest;
-government funding programs for retraining;
-increased tourist traffic to Central and Eastern Europe and an often request upon the tourism types based on nature and undamaged landscapes;
-direct vicinity of Hungary, which in the east does not have a very attractive landscape for tourism;
-romania's EU integration, harmonization of legislation with the European Union 's one and for the entry into the Schengen area;
-programs from the local and central authorities for developing the rural enviroment, like adopting the tourism strategy for the Arad county;
-building in the future a section of highway for the Budapest - Bucharest route, a route that should pass trough Bors and a section of the IV paneuropean road, Nadlac-Arad-Timisoara
-numerous and active partnerships between institutions and business people in the border regions Haidu Bihar - Bihor and Arad - Bekes;
-internal and external funding opportunity programs in which the target is the tourism sector;
-relatively good economic development, low unemployment percentage, especially in Bihor and Arad;
-cross-border cooperation in tourism development in the context of achieving Euro-region Danube DKMT, Mures, Cris, Tisa.

d.Threats
-neighborhood / county competition with a more developed and capitalized rural tourism potential (Cluj, Satu-Mare, Alba)
-degradation of historical and architectural monuments;
-gradual loss of traditions and customs in rural areas;
-cultural pollution and the magnifying dimensions of the kitsch phenomenon;
-depopulation of villages and youth migration to cities or other countries;
-low standard of living for a significant segment of the population;
-failure to comply with legal regulations resulting environmental damage, damage upon the protected areas of forest, fish and wildlife, water pollution;

Conclusions
Crisana region is a historical region delimited at north by the river Somes and Maramures region, at west by the river Tisa, at south by the Mures river and Banat region, and at east by the peaks of the Apuseni Mountains and Transylvania region. Crisana Region stretches on both Romania and Hungary, and we refered only to the Romanian side of it. Crisana region has an area of 17,717 km^2 and if we refer to the current counties, this region includes much of Arad county, without the area between the river Mures and Timis county, north of Hunedoara county Bihor county and part of western Salaj county.
Crisana region has great rural tourism potential areas, but insufficiently explored.

Local authorities and entrepreneurs should find ways of development projects that conquer worth all this potential.

STUDY REGARDING THE POSSIBILITY TO DEVELOP TOURISM AND CROSS-BORDER COOPERATION THROUGH A BUSINESS INCUBATOR AT VADUL CRIŞULUI (BIHOR COUNTY)

Bántó Norbert
University of Oradea Faculty of Geography, Tourism and Sports, Doctoral school of Geography

Ambrus Attila
„Ady Endre" Theoretical High School - Oradea

Introduction
This article presents the results of a research that was realized within the framework of the project entitled „*Business incubator for cross-border tourist development*" that runs within the Cross-border Co-operation Program between Hungary – Romania 2007-2013 and it is implemented by the city hall of Vadu Crişului Community, in partnership with the city hall of Hajdúszoboszló city, respectively the Hotel Owners Association from Hajdúszoboszló. The project was submitted within the framework of Priority axe no. 2 - „Enforcement of social and economical cohesion in the border region" respectively has a total budget of 552.633,86 Euro, according to the official website of the Cross-border Co-operation Program between Hungary – Romania 2007-2013 (www.huro-cbc.eu).

According to the documentation of the project, this is shortly presented also in the official website of the program (www.vaduCrişului-hajduszoboszlo.ro), at Vadu Crişului a business incubator will be established, which will be constructed on the old city hall's emplacement, while in the city of Hajdúszoboszló a tourist information center will be constructed at the main entrance of the Spa area.

The research was realized with the help of a questionnaire that contained 20 questions. This questionnaire was presented and handed to those who offered services in tourism, respectively to the representatives of different organizations/institutions, with the reason to analyze the existing advertising of resources and modalities, respectively the proposed ideas for developing tourism in general and especially the cross-border co-operation.

The methodology of the research
The research method used to conclude this study was the questionnaire. This questionnaire was handed out in the period between 15th of November and 15th of December 2011 in 8 territorial administrative units, of which 7 in Bihor County (Auşeu, Borod, Bratca, Bulz, Măgeşti, Vadu Crişului and Şuncuiuş) and one in Hajdu-Bihar County (Hajdúszoboszló).

Even though the Romanian side of the study included 7 territorial administrative units, all these gathered at one place do not have a high number of economical agents with tourism activity like in the resort of Hajdúszoboszló that stands alone in the Hungarian side.

Totally 181 questionnaire were filled out, from which 77 in the micro-region of Vadu Crişului and 104 in the resort of Hajdúszoboszló. The questionnaire was applied in the study region first of all to those economic agents whose activity is directly or indirectly linked to tourism, and second of all questionnaires were handed out to some representatives of local administration, with representatives of some institutions or organizations whose activity runs in the area of study. Even though the business incubator will be built in Vadu Crişului, the community however holds a very small number of economic agents with tourism activity. This way we extended the study area in the Romanian side (in Bihor County) from one community to a micro-region composed of 7 communities, located in the north of the Craiului Forest Mountains (Munţii Pădurea Craiului).

These are linked one to another through the Crişului Repede River Defile, respectively the E60 European road.

Results of the research

For comparative analysis, we must have taken into account the socio-economic specific at both of the evaluated entity, so while at the community in Hungary the axle was put almost entirely on the economic-agents (hotels, pensions or apartment owners who rent rooms especially during the summer), until in the communities from Bihor County, we must have taken into account the diversity of the actors implicated in the development of the micro-region, not just in the actual moment but also in the previous periods. In this meaning, for the development of the Vadu Crişului micro-region, we identified three big categories of social and economical actors who were questioned:

> - The economic agents implicated directly of indirectly in the tourism from the micro-region – different categories and types of housing units, public alimentation units.
> - Opinion leaders from the micro-region localities, practically those factors from the public administration, educational system or leaders of a confession who have the possibility to influence the development of the micro-region.
> - Non-governmental institutions and organizations with headquarters in Oradea, but whose profile of activity is based in a greater percentage in the study area, and who contributed along the years in any percentage to the development of the micro-region in question.

In this way, the first differentiation of the two zones is observed through the overlapping territorial (administrative) element, with the subjects' profile.

Table 1. Activity profile of those questioned (expressed in percentage %)

	Services	Culture	NGO	Administration	Education / research
Hajdúszoboszló	95	2	3	-	-
Micro-region of Vadu Crişului	57	10	23	5	5

Because of the experience in dealing with foreign partners/clients, the Hungarian locality can be identified with higher numbers not just in length and time, but regarding the number of co-operations.

In this way, among those questioned in Hajdúszoboszló, 87 % have at least one co-operation (foreign clients), in the framework of which Romania was the country most commonly named by 84% of those questioned, being followed by Poland (65%), Germany (62%), Slovakia (42%), Ukraine (18%) and Russia (with 10%). Compared with those questioned in Bihor, 72% have at least one partnership, most commonly named a co-operation with Hungary, and more than 30% of those questioned have an exclusive partnership with this country. Only 6% of those who have a partnership do not have a common history with an economic agent or NGO from the neighbor country.

From the perspective of the cross-border cooperation, the importance of having a webpage was highlighted; a webpage that can be accessed in more than one language, respectively the knowledge of a foreign language. In this way, we mention the fact that in Bihor, only 54% of the interviewees have an own webpage comparing to 71% of the participants in Hungary.

In case of those who answered the questionnaire in Romania, those who own a webpage, in 61% of the cases information can be accessed in another foreign language, while 38% of the web-pages can be accessed also in Hungarian language. In case of Hajdúszoboszló resort 83% of those who own a webpage, the information's can be accessed in at least one international foreign language, while 56% of the web-pages can be accessed in Romanian language as well.

Referring to the knowledge of one (or more) foreign language(s) of an employee, collaborator or members of a company/institution/organization, the numbers are higher from a general perspective.

In this way, among all those questioned in Romania, 88% knows at least one foreign language – mainly English – 75% of all those questioned, while the Hungarian language is at a level of 43%, with the specification that these values are higher in average in Oradea, than in the area of Vadu Crişului. In Hungary, even though the number of those who speak a foreign language is close to the one in Romania, namely 83%, the ratio of dispersion is different, the main language is English – 85%, followed closely by German with 77%. The Romanian language with 21% is very close to the Russian that has a value of 20%.

The situation is changing regarding the willingness to learn a (or another) foreign language, so 45% of those questioned expressed their interest to learn Romanian language, this being the prevailing of this category, being followed by Russian language with 33% and Polish language with 28%. These three languages show us the perspectives from Hajdúszoboszló regarding the international tourist arrivals.

If in the first part I analyzed general data about the subjects and possible perspectives of approach methods in direct co-operation, in the second part, the questionnaire was based on a connection towards the own administrative or regional unit. However, the principal was to give a chance in order to comparatively approach data that will build itself, but the answer possibilities were almost identical in parallel for questions 3 and 4, the differences occurring in the "forte point" of the region.

Referring to the selection of the most important needs, must be noted the necessity to separate the possibilities of answering for Internet services, where for Bihor we added the element of the telephone, comparing to Hajdúszoboszló, where necessity is accentuated towards the wireless internet. But, more importantly, in the field of tourism services, we considered the necessity to differentiate the *extension* and *diversification* of these, taking into consideration the hypotheses of development of the two territorial units and the fact that in Romania the chances covered by this chapter were not totally exhausted.

Even if a differentiation exists among the value results, it is interesting that the base pylon has the same common element in both cases, with the specification that in the Vadului micro-region the sanitation element occurred preponderantly, which in Hungary occupies the penultimate place (see fig. no. 1). Sanitation is an element that differentiates the two regions, but this is now put under a close attention by the actors from outside the defile, mainly from Oradea, and in the same time solving this is seen as a primary element through the implication of local authorities.
Fig. no. 1 Elements for developing in the study area

Regarding the marketing, however, the differences are essential, even contradictory. The elements most commonly met in the case of one are less prioritized in the case of another, a situation that in the first analysis can be perceived negatively.

As a dominant character of both of the axes, must be mentioned that exactly those (three) elements that describe and internal approach – webpage of the micro-region, tri-lingual tourist signs, tourist destination network are the most commonly met for the situation in Romania (with appearing frequencies of 67, 49 and 46%) while for Hajdúszoboszló, exactly the other three appear as priorities, detaching the companies from advertising through specialized companies (with 73%). The other two, and namely the creation of a web-page having as objective a partnership with another tourist region, but not with the same profile – 32%, respectively, a bi-lingual paper on tourism – with 35%, are written in the elements of communication towards the exterior.

Highlighting the side of the communication towards the other exterior entities, the first and most clear approach of differentiating was imposed at the editing of the questionnaire. All these come exactly from the basic characteristics as tourist zones of both entities and not just from the infrastructure that they posses. Considering those mentioned, those elements must be highlighted, which are considered by the locals to have the most potential of attractiveness in an advertising campaign.
Fig. no. 2 Marketing approach of the micro-region   Fig. 3 Marketing approach of the resort
From the perspective of Bihor County, 3 favorite groups are crystallized, of which the most eloquent being the *caves* – with a frequency of 80% followed at a relatively high distance by mountain paths (hiking roads) with 49%, respectively the specific habits of the area that received 43%. With the existing possibility to mention also other themes of promotion, those questioned remembered the most the extreme sports, gastronomical traditions or connected services to the caves.

Regarding Hajdúszoboszló locality, no elements were noted that might unite some overwhelming majority, none of them passing a value of frequency greater than 50%. Sport Center was most often mentioned – 45%, followed by the holidays organized by local authorities (34%) and traditions of the neighbor area with a total of 28%.
Fig. no. 4 Advertising of the Vadu Crişului micro-region   Fig. no. 5 Advertising Hajdúszoboszló
resort
For the micro-region of Vadu Crişului *the extension of the tourism services* must be based on the natural characteristics of the region and on own initiatives, more emphasized than the initiatives and support or the implication of the administrative authorities. Practically, the possibility and request is seen for an intermediate structure between the own necessities and the representatives of those in the issues of extending the tourism services, but this one not to be exclusive, and one of public invoicing.

General diversification of the services in tourism (which appears exclusively for Hajdúszoboszló), is the theme that represents the differences already from the hypothesis of those two entities, infrastructure and investments or the level or services that must be calculated from the beginning as opposed between the balneary resort from Hungary and the region in Bihor County. The frequency of these is 59% and occupies the 1st place among the necessities for future development.

It is clarified an even more stronger tendency that is seen for Hajdúszoboszló locality as a necessity of development first of all in the diversification of the tourism services, highlighted the implication of the local authorities, chance seen in the co-operation of the tourist area without similar characteristics (namely, direct non-competitor), but from the cross-border region (the opening towards the Romanian side is relevant, persuaded on the first place with the wish of learning the Romanian language), however, information and gaining creditability that Vadu Crişului and the surrounding area has a tourist potential needs real improvements.

After an analysis that describes mainly the approach from the perspective of own characteristics and possible form of advertising, respectively basic element of the pylons for development, in the next phase we will evaluate the chances of cooperation from the angle of the partnership with the neighbor region cross-border and formulas for the possible implications.

Table no. 2 Chances of cross-border co-operation (expressed in %)

	Surely they would have positive effect	There could be a possibility	Not really think of it as viable	No way
Bihor	75	18	3	3
Hajdúszoboszló	69	24	6	1

To the question, addressed the actors implicated in the socio-economic or administrative life from the micro-region of Vadu Crişului regarding the methods in which they consider they could be implicated in this type of cross-border partnership, the most common answer was regarding the support of an advertising center of the micro-region, followed by at a considerable distance the answer of accessing some European funds.
Fig. no. 6 Method of implication of the actors from the micro-region of Vadu Crişului in the cross-border co-operation

From the prism of knowledge in the role of a client in the tourist area of the neighbor country, those from Romania have been more often in Hungary – 83% of them, while referring expressly to the Hajdúszoboszló resort, more than half of those interviewed had already experience (52%). Regarding the services, an average of 4.6 out of a possible 5.0 can be considered as satisfactory. On the reverse side, 11% of those from Hungary have been as tourists in the micro-region of Vadu Crişului, at the appreciation of the received services 46%, while the average awarded regarding the services was 3.5. An encouraging point regarding the development and implementation of the partnerships is the knowledge of the official language of the other country, and the openness towards perfecting this element.

The Vadu Crişului micro-region has a perception on the necessity of re-grouping towards the interior -, while the Hungarian resort shows an opening towards the exterior, but not towards a location that can be a competition in the first place. Hajdúszoboszló tends towards advertising the already existing tourist potential and infrastructure, pulsing through ensuring a diversity of programs. In comparison, in the micro-region of Vadu Crişului, even if the first phases of diversification are observed towards the potential of the area, right now it still needs extension, but lacks that force of grouping around one element or a set of elements that can assume the role of a promoter.

Pursuant to, a basic level for both situation can be described, while with these elements and with those described earlier that can be attached, a new phase can be initiated, someway under an institutionalized form of the co-operation between the two entities:

The level of Vadu Crişului micro-region

Greater implication from:	Grouping towards:		Basic elements in advertising:
Local authorities (with special reference to the road infrastructure)	Interior / edification of the own potential (creation of a webpage about the region) & the necessity for *the extension of the services*		Caves

The level of Hajdúszoboszló resort:

Greater implication from:	Grouping towards:		Basic elements in advertising:
Local authorities (road infrastructure)	Exterior: necessity of diversification of the services & advertising through specialized campaigns (of the specific holidays)		Thermal water and the connected treatments

In this way, as solution to the grouping of the micro-region, followed by the extension of the services, the central point should be occupied by an intermediate structure formed between local authorities – mainly city halls -, and organizations who support own initiatives, including NGOs, so one of the solutions could be counted as viable would be the existence of an advertising center of the Vadu Crişului Defile.

Considering however the comparison among the answers to question 9, briefly, the connection method to the diversification of the programs for the tourists, in the first phase can be observed that those from the Hungarian resort gave exact location (Hortobágy, visit to the city center of Debrecen, visit to the Zoo from Nyíregyháza, visit to the viticulture area around the city of Eger, Oradea), while in the case of Bihor, these answers had a more general character (caves, hiking mountain paths);

Conclusion and propositions

Considering that the economic agents from Hajdúszoboszló, at the actual infrastructure and tourist potential, shows an opening towards the diversification of the programs, where as a basic element the implication of authorities can be listed, the creation of a common webpage with a tourist region, but not with the same profile, and last but not least, the allocation of a resource for international advertising foresees the possibility to close a cross-border partnership with a tourist zone/resort/micro-region. From the perspective of Vadu Crişului micro-region, right now a main actor does not exist who could have the coagulation power and resources, but the centering could be based towards the co-operation of the local authorities – including the creation of a common webpage, while the main brand foresees the caves in the area. Around this element the extension of services can be attached that result from the existing tourist potential. With no existing structure of grouping, the establishment of an advertising/promotion center can be conceived or tourist cluster, but, the centrifugal forces that would recognize a center (administrative) as a pylon of advertising are still in an initial phase. As a common point for promotion, and as a pilot project, through the cross-border co-operation – for which maximum support exists, foresees the creation of an advertising center in the Defile, the administration of it, including the representation of the values and interest must come from an actor accepted by all members of such alliance/co-operation. The establishment of an intermediate coalition/grouping must be considered among the actual situation with high level of centrifuge and the institutionalization of the co-operation through a group with local action.

FORMS OF CROSS-BORDER TOURIST CO-OPERATION
IN THE BIHOR–HAJDÚ-BIHAR EUROREGION.

Bántó Norbert
University of Oradea Faculty of Geography, Tourism and Sports, Doctoral school of Geography

Introduction

In this article I've proposed to present and to analyze tourist project realized with the help of the PHARE CBC program and the Cross-border Co-operation program between Hungary-Romania 2007-2013 in the Bihor–Hajdú-Bihar Euroregion, named from now on HURO. This program continues the cross-border co-operation programs already implemented in the region in the past (Interreg IIIA in Hungary and Phare CBC in Romania), being implemented in the framework of a common institutional structure, by using common funds and in the same time developing results and experiences that were gained previously.

These projects received a relatively small amount of financing (generally between 50.000 and 500.000 Euro), comparing to the projects implemented through Regional Operational Programs, through which more considerable funds are accessed. Although these projects are welcomed and in many cases the results were very promising, however the outputs were not always the ones expected or planned. Within the framework of this article we present shortly and in a synthesized way each project that was started in the domain of tourism, highlighting the benefits and the shortcomings of them.

Methodology of work

The used methodology for realizing this article is based first of all on a qualitative and quantitative analysis of the cross-border tourist projects developed in the past 6 years in the Bihor–Hajdú-Bihar Euroregion, analyzing the specific database through the comparative analysis and inventory method. We obtained information's about the objectives, realization and financial resources for the implementation of the project from the official website of the Cross-border Co-operation program between Hungary-Romania 2007-2013 (www.huro-cbc.eu), from the websites of the projects and from online articles released by local and/or national press.

Cross-border tourist projects in the Bihor-Hajdú Bihar Euroregion within the framework of the PHARE CBC program

The cross-border cooperation on the Romanian-Hungarian border, received pre-accession PHARE CBC funds even before 1998, when the border between Romania and Hungary became eligible for this program. In this way, in the period between 1996-2003 – according to the website of the regional office for cross-border co-operation of the Romanian and Hungarian border Oradea -, (www.brecoradea.ro) for cross-border projects the amount of 28 million Euro were granted for the Romanian side and 34 million Euro for the Hungarian side. According to the website www.huro-cbc.eu, in the period between 2007-2013 a total amount of 248 million Euro are available (four times more than in the period of pre-accession) for stimulation of cross-border cooperation. This amount is made up of EU contribution through the European Regional Development Fund and the contribution of the two member states.

The PHARE CBC 2004-2006 program from Romania was implemented together with a secondary program called INTERREG IIIA from Hungary and has one component for each of the three years. The program was implemented through the scheme of grants, financing being

granted after the selection of project proposals received as an answer to the public announcement of the open auction.

In this way, in this period, four cross-border tourist projects were implemented. The biggest project from the financing point of view was entitled *"Romanian-Hungarian Corridor for preserving biodiversity"* (PHARE CBC RO 2003/005 702-01). The project had the purpose of creating a "green corridor" for preservation of biodiversity, which includes the protected areas on both sides of the border. The beneficiary of the project was Direcția Silvică Oradea, and the main partner was the Criş-Mureş National Park Administration from Hungary. The implementation period of the project started from December 2003 and lasted until November 2007.

On one hand, equipment for monitoring biodiversity were purchased through this project, but the most important thing was the realization of the infrastructure regarding the management of the protected areas, namely the construction of the administrative headquarters of the Apuseni Natural Park from Sudrugiu and three visitor's center from which one is located in Bihor County and namely Padiş Plain (according to the description of the project on the website of Apuseni Natural Park - www.parcapuseni.ro).

This project was by far the greatest from financing point of view, but also the results were considerable (construction of 4 properties equipped and furnished, purchasing of some equipments, etc.) Through this project the ground for Apuseni Natural Park was established.

Table 1. Cross-border tourist projects implemented between the beriod of 2007-2012 in Bihor –
Hajdú-Bihar Euroregion

Nr.	Title of the project	Type of program	Total value of the project (EURO)	Finalization date
1.	Romanian-Hungarian Corridor for preserving biodiversity	PHARE CBC	2.600.000	11. 2007
2.	Unity and diversity in the tourism of Bihor–Hajdú-Bihar Euroregion	PHARE CBC	74.200	12.2007
3.	Traditional craftsmanship's – opportunity for developing a durable Bihor – Hajdu Bihar Euroregion. Cultural routes in Bihor and Hajdú-Bihar Counties	PHARE CBC	45.299	08. 2009
4.	Development and promotion integrated by common thematic tourist packages in the Bihor–Hajdú-Bihar Euroregion	PHARE CBC	102.341	15.11. 2009
5.	Development and promotion of rural tourism and ecotourism in the North-East plain and in the Apuseni Mountains	HU-RO	141.071	25. 11. 2010
6.	„Adventure, rest, fun" – promotion of tourist offers in Hajdú-Bihar and Bihor Counties	HU-RO	510.795	30. 04. 2011
7.	Innovative realization of some common tourist packages in order to develop tourism in Hajdú-Bihar and Bihor Counties	HU-RO	96.510	31. 05. 2011
8.	Common development and integrated promotion of thematic rural tourism in Bihor–Hajdú-Bihar Counties.	HU-RO	174.866	30.06. 2012.
9.	Opportunities for capitalization of the cultural patrimony through cross-border co-operation in order to develop tourism and business environment	HU-RO	505.920	06.05. 2012.
10.	Business incubator for cross-border tourist development	HU-RO	552.633	31. 12. 2012.
	TOTAL		*4.803.635*	

In the year of 2007, the Chambers of Commerce and Industry from Bihor County as the beneficiary, having partnership with the Development Agency from Hajdú-Bihar County and the Chamber of Commerce and Industry from Hajdú-Bihar, they implemented the project entitled *"Unity and diversity in the tourism of Bihor–Hajdú-Bihar Euroregion"*, (RO2004/016-940.01.01-68-2.2, in the framework of Phare CBC program Romania and Hungary, Phare CBC 2004/ Interreg IIIA, financed by the European Union through the Ministry of European Integration as the Contracting Authority).

The general objective of the project foreseen the relationship intensification of regional cross-border co-operation between Romania and Hungary, among the two border counties and among the communities and economic actors in this area; superior capitalization of the tourist potential on a local and regional level, promotion of business co-operation; creation of a diversified tourism based on local resources that can satisfy the needs of more tourists and can generate a favorable environment for establishing a new group of cross-border businesses;

This project was the first that formed as purpose the integrated promotion of Bihor-Hajdú Bihar Euroregion as a European tourist destination based on realizing 6 tourist packages and a tourist brand. Subsequently another three projects were realized that had similar objectives and purposes.

The result consisted in the realization of 1500 brochures, which were initially planned to appear in 6 languages, but at the end only two languages were realized: in Romanian and Hungarian. On the other hand, however, besides the brochures, 1000 multimedia CD's were realized containing information's about Euroregion tourist destination and two tourist websites that already appeared in six languages. Through this project 6 tourist packages were proposed with different circuits and destinations.

This was the first project of this type, which proved to be a good initiative, because specialists recognized the fact that these two counties can be complementary destinations and not competitors. We identified however also some shortcomings about the translation of the materials. Even though those two websites (www.turismbihor.info and www.tourismbihor.info) are active even today, they were not updated for about 4 years.

The project entitled *"Traditional craftsmanship's – opportunity for developing a durable Bihor – Hajdu Bihar Euroregion"* was implemented between the period of August 2008 and August 2009 and it was financed by the Ministry of European Integration through the Romania – Hungary Phare CBC 2006 Program (Phare CBC RO 2006/018-446.01.01.)

The project was applied by the "Anytime Ready Association"(Asociaţia Gata Oricând) in partnership with the Center for Protected Areas and Durable Development – Bihor (CAPDD Bihor), Tourist Association of Kis-Bihar (Kis-Bihari Idegenforgalmi és Turisztikai Egyesület); County Department for Culture, Cults and National Cultural Patrimony of Bihor County. The project proposed to create premises for cross-border initiatives for socio-economic development of the Bihor – Hajdu-Bihar Euroregion, based on using the cultural, immaterial patrimony of the two counties, through promotion and capitalization of traditional craftsmanship's that can be found here.

According to the information on the website of the Center for Protected Areas and Durable Development (www.capdd-bihor.org), the main *activities and results* of the project were the followings:

-Realization of a database of all popular craftsmen in the Bihor – Hajdu-Bihar Euroregion.
-Organization of a type of event called "*School of craftsmanship*" and one called "*Camp for popular creation*"
-Opening of a promotion center craftsmanship in Oradea

-Organization of a seminar on the subject of capitalization and preservation of traditional craftsmanship in the Bihor-Hajdu-Bihar Euroregion where popular craftsmen participated from the two counties and representatives of local APL's

-Realization of a presentation brochure about the popular craftsmen in the two counties

-Realization of a common brand to promote traditional products

-Realization of 2 thematic routes and including traditional craftsmanship workshops as tourist attractions.

The long term results of this project were pretty low, however the truth is that it was a project with a budget that did not reach 50.000 Euro.

The fourth cross-border tourist project, realized from PHARE CBC funds was entitled *"Development and promotion integrated by common thematic tourist packages in the Bihor–Hajdú-Bihar Euroregion"* (RO 2006/018-446.01.01.01.15, Financed by Phare CBC 2006/INTERREG IIIA Program), realized by the Faculty of Economic Sciences from the University of Oradea in partnership with the Bihor County Council, Auto-government of Hajdú-Bihar County, Chamber of Commerce and Industry of Bihor County, General Association of Economists from Romania – Bihor branch and Bihor – Hajdú-Bihar Euroregion Foundation (as associate). The ongoing period for this project was between 15.08.2008 and 15.11.2009.

This project – similar with the one realized by the Chamber of Commerce and Industry of Bihor County – had the general objective to support initiatives of co-operation in the domain of tourism with the purpose of growing the competitiveness of actors in the domain of tourism, respectively the growing the competitiveness of actors in the domain of tourism in the domain of developing and promoting thematic tourist packages within the Bihor–Hajdú-Bihar Euroregion.

Specific objectives of the projects were the facilitation of the reciprocal knowledge and favoring the Hungarian-Romanian exchange of experiences in order to created an integrated network of development and tourist promotion in the Euroregion, supplying instructions in order to improve the tourist activity and the development of common, thematic tourist packages, giving assistance and consultancy for the interested actor in tourism from the Bihor–Hajdú-Bihar, support of the common promotion of thematic tourist packages (according to the website of the faculty - www.steconomiceuoradea.ro).

Within the framework of this project 6 tourist packages were proposed (balneary tourism, landscape tourism, recreational, traditional and habits tourism, cultural tourism and business tourism), each of them having more routes and destinations. The project was more complex then the one implemented by the Chamber of Commerce and Industry of Bihor County because besides the created packages a catalogue was prepared of all the actors participating in tourism in the two counties, offering in the same time the possibility of cross-border cooperation among them.

The first tourist project realized within the framework of Cross-border Co-operation Program Hungary and Romania 2007-2013 (HURO/0801/160) was entitled: *„Development and promotion of rural tourism and ecotourism in the North-East plain and in the Apuseni Mountains"* and implemented by The Association of Environment Friendly Tourism from Debrecen (Debreceni Természetbarát Turisztikai Egyesület) in partnership with InfoTour Association from Carei and the Center for Areas and Durable Development from Bihor County.

The main purpose of the project was to analyze the sources of development of tourism in the plain area of the two participating countries (three counties) and the Apuseni Mountains area. The project emphasized some approaches that are necessary to ensure the development of the tourism in the area. In this way studies were realized, which analyzed the tourist potential of the area and the way in which this is capitalized. In the final period of the project, more work was put in the promotion of the tourist products towards the tourist: two movies/short films were realized, one about the values of nature in the region and one about the possibilities of rural tourism and ecotourism. The followings were also realized: another 10 short movies about the tourist

attractions, a webpage (www.thematic-routes.eu) where more information can be found about the opening of the tourist attractions, database of local tourism services, films, studies, useful information's. Also 3000 multimedia DVS's were realized and in addition tri-lingual informational panels were placed on the created tourist routes (according to the website www.thematic-routes.eu).

Within the framework of some consultancy of the interested factors, 10 thematic tourist routes were identified: route of guesthouses, route of craftsmanship's, route of vine, route of landscape values, route of health, route of water, route of famous people, route of museums and traditional houses, route of traditional products and route of caves and karst formations.

It is the first project of this type, which includes 3 counties, respectively 10 routes. It contains some very original ideas, even though a small dose of subjectivity is denoted. Unfortunately the project did not benefit from a generous financing so this way it could not have been advertised properly.

The cross-border project entitled: *"Adventure, rest, fun - promotion of tourist offers in Hajdú-Bihar and Bihor Counties"* reunited as partners the Hajdú-Bihar County Council, Megyegazda Nonprofit Kft. (Ltd.), together with the Oradea City Hall and Bihor County Council.

The purpose of the project was to develop tourism in Bihor and Hajdú-Bihar County, not just in local and national plan, but in international plan as well through a common offer. To reach this purpose, the tourist areas of the two counties were taken into inventory, and after organizing them, tourist packages were released with main attractions from this region. In parallel, to promote tourism on the level of the two counties, the project partners have launched an advertising campaign that contained 7 tourist packages within the framework of the project, on themes like cultural patrimony and monuments, popular art, national parks, gastronomy, rural tourism and business tourism, calendar for county holidays in 2011 or therapeutic tourism and wellness. For each theme an informative brochure was printed in 4 languages, the purpose of the tourist packages were to increase the number of tourists registered in the housing units from the cross-border region and to increase the incomes resulting from tourism. In the framework of the project 45.000 informative booklets were printed. To complete the tourist information, the partners have realized a website to promote the offers of the two counties (www.bihar-bihor.eu), which is available in 7 languages.

This project answers the best to the requests of the actual advertising, being the most complex, diversified and by far the most advertised tourist project among all of the projects analyzed in this study. Of course, this fact was backed up by a budget over half of million Euros.

This contains elements, which covers all types of tourism that can be practiced in this area. Regarding the viability of these packages, it is still will be seen which one of them will consecrate.

Another cross-border tourist project was implemented by the Chamber of Commerce and Industry from Hajdú-Bihar County in partnership with Association for Business Promotion in Romania and the Federation of Employers of Bihor County. This project ran under the name of: *"Innovative realization of some common tourist packages in order to develop tourism in Hajdú-Bihar and Bihor Counties"*

The general purpose of the project was to consolidate economic competition in the region with the development of the tourism, and also promoting objectives, destinations and tourist manifestations from the two counties as well as the realization of a more active propaganda.

Another purpose is to encourage co-operation among companies and organization with tourist profiles on both sides of the border. Local actors in the tourism sector must recognize the fact that the only way they can stay competitive is if they realize strategically thought developments together with other actors (companies, organizations) in this way overcoming on competition.

Within the framework 6 big packages were created, each having more "sensational" tourist packages. Almost all of the packages contain a destination on both sides of the border or involves

the fact that tourists who arrived from outside the area to a balneary resort can take a trip of a day to the neighbor county, which is based on the complementarity of the tourist objectives.

Most of the packages contain a program for a day, but in some cases also circuits are proposed, which can be realized in more days.

This was the fourth type of project that realized tourist packages in the Euroregion. In this time, however, the implementation of an innovative element was tried, especially in the names of the packages full of fantasy, which sometime are not only fantasist but even a little futuristic. With all these the project managed to bring some new elements and ideas to the tourist packages as well as the other projects offered the opportunity to create a business relationship among those actors who are implicated in tourist activities on both sides of the border.

The Department of Geography and Territorial Arrangement within the Faculty of Geography, Tourism and Sport of Oradea University, is implementing during the year 2011 and 2012, as the Leader, a project entitled: *"Common development and integrated promotion of thematic rural tourism in Bihor–Hajdú-Bihar Counties."* (HURO /0901/017/2.1.3). The project has a total length of 18 months and the Hungarian partner is the Department of Social Geography, Development and Regional Planning of the University from Debrecen.

The general purpose of the project is the sustainable development of the cross-border tourism in the Bihor–Hajdú-Bihar Euroregion, through developing new, thematic product that are specific for the rural tourism, to promote these products and their development with the help of tourism in the border side rural economy of the area. The project addresses to all interested parties in developing thematic tourist products – investors, owners of pensions, hotels, motels, restaurants, farms, persons from rural environment who wish to begin a business in the domain of tourism, tourism agencies in whose offer appears the thematic tourist products, tour operators, non-governmental organizations, etc.

Because this project is not yet finished it is hard to predict its success or failure, but considering the fact that the project will be developed by a staff formed by professionals (university professors) it is almost certain that the result will be no other than satisfactory.

Another ongoing cross-border tourist project in entitled: *"Opportunities for capitalization of the cultural patrimony through cross-border co-operation in order to develop tourism and business environment"* (HURO/0901/192/2.1.3.) This project was realized by the City Hall of Salonta together with the City Hall of Debrecen, respectively the Arany János Cultural Association from Salonta and it was implemented between the period of 06.12.2010 and 06.05.2012. Even though Salonta in not in the area of study, I included this analysis in this project because it is connected to the cross-border tourism from the Bihor–Hajdú-Bihar Euroregion.

The general objective of the project is to develop tourism with the purpose of enforcing the socio-economic cohesion within the Bihor–Hajdú-Bihar Euroregion.

Specific objectives of the project are: durable development of existing cultural-historical values, prospecting common tourist development opportunities among Salonta and Debrecen through common cultural-tourist activities, respectively extension and consolidation of cross-border relations through the realization of a tourist partnership.

Within the framework of the project the following activities were realized: project management, communication, advertising materials were printed and edited, common participation at tourist fairs, study-tour to Brussels, respectively tourist development strategy was developed for the two cities (Salonta and Debrecen) for the period of 2011-2016. This project is also not finished yet, but because of the high volume of financing (total budget over 500.000 Euro) it is expected to give spectacular results in the same measure.

The project called *"Business incubator for cross-border tourist development"* was submitted within the framework of Priority axe no. 2 - „Enforcement of social and economical cohesion in the border region" by the city hall of Vadu Crişului Community, in partnership with the city hall of Hajdúszoboszló city, respectively the Hotel Owners Association from Hajdúszoboszló. The

general objective of this priority axe is to intensify economic competition in the area through development in the business environment and improving the quality of human resources.

The service providers from Hajdúszoboszló offer also today quality tourist services, but they wish to be more prepared for welcoming the guests from Romania and also they wish to diversify their offers of programs and mountain trips, while Vadu Crisului has a generous offer from this point of view. Within the framework of the project in Vadu Crisului a business incubator will be established, which will be built on the site of the old city hall, and in Hajdúszoboszló city tourist information center will be built, at the main entrance of the spa. At the finalization of the program, in both localities a tourism agency will be opened that will promote balneary tourism and mountain tourism together, making both locations more attractive for tourists. The business incubator will offer the headquarters for 11 companies with the condition that they will create jobs in the community of in the region.

Conclusions

Even though trough these projects in the last 6 years more than 5 million Euros were accessed for tourism development for the Euroregion, this did not lead to a substantial improvement of the tourist flow. Normally, measurable results of a project are direct proportional with the volume of financing. This way we cannot expect that a project of 50.000-100.000 Euros to bring major change in the tourist circulation of the region. For notable results, massive investments are required first of all in the general infrastructure and the one specific for tourism, especially in Bihor County, because without adequate access paths or diversified and quality housing units it is very hard to generate more requests than the existing ones. For this, more projects would be necessary that are financed within the framework of Regional Operational Program through which major investments can be made that would have major impact on this domain.

A THEORETICAL APPROACH OF THE CONCEPT OF SOCIAL CAPITAL IN SUPPORTING ECONOMIC PERFORMANCE

Boldea Monica*
West University of Timisoara, Romania Faculty of Economics and Business Administration

Any activity requires the presence of labor resources. If centuries ago the concept was that their presence was enough, now it takes a lot more. Moreover, since Aristotle the issue was taking into consideration all aspects of the community life that can lead to a "better life". In the current conditions we may consider resources in the broader context of the human factor and of the relations established within a society. Thus social capital was conceptualized. As opportunities of economic growth - based purely on the quantitative aspects of the determinants – were limited, the need occurred to reconsider the qualitative and structural components.

Social capital considers a number of the integrative components of social life. These refer to the relations established at family level up to the level of societal institutions. It is necessary that these relationships be well established, and for the proper performance it is necessary that aspects of education and health should be properly valued and assessed. This helps setting up strong institutions. Developed countries have the ability to create a proper environment for the manifestations of social capital; in these countries one can observe the growing importance of formal and more impersonal relations. But this just reinforces the occurrence and development of economic activities based on efficiency criteria leading to the countries' economic development.

The interpretations of economic development issues have undergone changes in recent decades. If previously it was considered that the essential difference between rich and poor countries is reflected in the amount of physical capital per person, later on the concept of capital has been expanded to include as well human capital, the lack of which was considered a serious obstacle to development, particularly in the case of poor countries. And given the fact that the transactions within an economic system take place in an institutional and cultural framework that defines the majority of the transaction's features, the present paper analyzes the concept of social capital - which alongside other forms of capital significantly influences economic progress - in order to emphasize the link between the functionality of institutions, culture and the level of economic development.

Keywords: social capital, trust, civic cooperation, effectiveness, economic development

Individual behavior and the economic activity

The economic activity comprises first of all relationships of production, exchange and consumption of goods, implying – at a deeper level – interactions with other individuals, the coordination of human activity being basically a social problem, referring to how people's behaviors are interconnected, thus being closely related to the social order in general.

The individuals' preferences are formed under the influence of the environment in which they live, the alternatives being determined by the structure of institutions in which they are integrated and in which they perform their activity. The individuals' behavior is shaped by social and cultural norms, regarding both perception and decision, their needs being induced by the society, and the choices they make are conditioned by the social and cultural context they are part of (Ekkehart, 1998).

To explain the phenomena related to their material life, people make use of the economic theory. The human activity is largely repetitive; people consume goods, which are to be produced under certain conditions and distributed according to certain rules. The condition for an activity to take place is precisely the existence of order in the society, an order provided by culture, habits,

institutions and by rules. The economic mechanism, on the other hand, requires a stability regarding behavior in order to reduce the degree of uncertainty.

The performance of an economy depends not only on the existing technologies but also on the way these are used, i.e. the way the individuals act and interact. North (1995) emphasizes the role of institutions in the functioning of the economic mechanism, arguing that they have an essential role in shaping preferences and in establishing the level of transaction costs. Coase argued the importance of the New Institutional Economy, namely the fact that a country's institutions (the legal system, political system, social system, education and culture) are the ones that manage the performance of an economy. The institutions are considered to also have the role of providing the necessary knowledge to the agent in his interaction with other decision makers; in this regard, the institutions provide a means of orientation leading towards reducing uncertainty and allowing the formation of a valid expectation about the future actions of the agents, disposing of the information on the expected behavior of the others.

Given these conditions, the social norms have a more and more increasing role in the successful development of some economic activities. These norms are based on cultural values (Coleman, 1988) and therefore rooted in a country's national culture. If social norms induce compliance with contractual obligations and fairness in conducting business, the need to resort to the judiciary to impose these obligations is far less necessary; the legal system is more efficient and the economy is more likely to develop. North (1981) argues that "the existence of ethical and moral codes in a society represents the glue for the social stability that makes the economic system turn viable". Viewed through Putnam's analysis of social capital (1993), the issue arises of how social capital can be formed – "trust, norms and networks that improve the efficiency of the society by facilitating coordinated actions". First there would be education – through participation in various civic and religious organizations – which may lead to establishing rules and attitudes that facilitate cooperation. Second, cooperation is the result of including norms of reciprocity into the society's culture. And in order to understand the contractual behavior it would be important taking into account its relationship with the formal institutional structure and with the informal social norms, as neglecting the institutional framework's impact on the contractual behavior and cooperation in general can lead to flawed conclusions.

The way people act is largely determined by their experience – their perception of values and ways of forming preferences, decision-making and acting – mental patterns (North) or the software of the mind (Hofstede). These mental patterns are influenced both by people's national and organizational culture – both of them playing an important role in the working of an organization in particular and of a country's economy in general.

The transactions within an economic system take place in an institutional and cultural framework that defines the majority of the transaction's features; the standard theory ignores this element, considering that this framework is given, it is not likely to change and it is exogenous to the system (private property, freedom of trade, the lack of non-economic and cultural barriers). Following these assumptions makes it almost impossible to justify the performance differences between the world's economies. Studies have shown that the efficiency of running a business depends particularly on cultural factors, which vary from country to country, or even within a country from one region to another.

The impact of social capital on economic development

Many economists and other social scientists studying less developed countries have been aware that the institutional environment in these countries differed from that in industrialized and developed ones. In the early postwar decades there were intense debates about the degree to which standard neoclassical economics needed to be modified to apply to less developed countries; the standard neoclassical economics was based on institutions that existed in industrialized countries but that did not necessarily exist in less developed countries. After World

War II development economics assumed that the institutions of the economy were different, but there was little attention among economists to the evolution of these institutions or to deep explanations of them. Thus occurred the need for new variables to be introduced, one of the most important being the social capital.

The concept that underlies social capital has a much longer history. Aristotle and Thucydides observed and analyzed human behavior, stressing that there had to be a framework within which the members will together pursue the object of their common purpose; point of view which was subsequently criticized with the "rational choice theory". Many other thinkers questioned the complicated relationship between "modern society" and the importance of "old institutions", in particular family and traditional communities. Analyzing the evolution of capitalist societies it can be observed that urbanization and industrialization were transforming social relationships in an irreversible way, observing a breakdown of traditional bonds and the progressive development of alienation in society. Tocqueville integrated the concepts of social cohesion and connectedness, and the first direct use of the term "social capital" might be allotted to Dewey, although in 1900 he did not offer a definition.

Early attempts to define social capital focused on the degree to which social capital as a resource should be used for public good or for the benefit of individuals; it can be defined as representing the norms and social relations embedded in the societies' social structure, due to which people coordinate their actions in order to achieve the expected results; thus it can be noted that social capital comprises those features of social relationships – interpersonal trust, norms of reciprocity, participation in civic organizations, and interpersonal and inter-organizational networks – which facilitate cooperation and collective action oriented towards a general benefit, being thus incorporated into the structure and quality of social relationships between people.

Social capital, in terms of social potential, is considered to improve the economic activity background in a way similar to technical infrastructure; social capital influences the quality of education and health, facilitates access of individuals to markets, supports complex operations and enables the activities' long-term planning. Thus it was established close correlation between social capital, the quality of social governance and organization and the level of a country's economic development (Putnam, 1993), showing that economic activity improves its effectiveness in a community that disposes of a substantial stock of social capital, where the networks of individuals civically involved strengthen norms of reciprocity and further leads to social trust, these networks facilitating communication and cooperation, thus offering a solution to the collective action issue. Other ideas state that generalized trust (based on the ethical behavioral habits and moral norms of reciprocity tacitly accepted by the members of the community) is essential for cooperation and economic development, determining the industrial structure of an economy; it can be argued that social capital is a necessary precondition for successful development, but a strong rule of law and basic political institutions are necessary to build social capital. He believes that a strong social capital is necessary for a strong democracy and strong economic growth. The USA, Japan, and Germany are high trust societies, where trust is not restricted to the family, but generalized, and there can be easily found large, professionally managed corporations, as people are better able to cooperate on an enlarged scale, while in Italy and France, for example, smaller and family owned and managed firms dominate the industrial structure. The strength of family ties may be detrimental to the emergence of large organizations, and where these are not accompanied by a strong culture of work and education it may lead to stagnation. Even so, this does not necessarily mean that high trust, and hence large organizations are better for aggregate growth, since what they gain in scale may be lost in flexibility and promptness of decision-making.

Less developed countries cannot ignore the issue of social capital; the former communist countries face a shortage of social capital, the communist period being characterized by a hypertrophied relation between state and citizen, respectively the lack of voluntary association in

joint projects. On the other hand, the level of trust proved to be much lower, given that individuals did not compete for limited resources – that having immediate effect on trade. Also, it can be noted that the lack of informal rules that constrain individual behavior is often futile to states' legislative efforts.

Studies in the field have identified several forms of social capital, including trust as integrative part of social structures, rules and sanctions, informational channels (Coleman, 1990), the main components of social capital being trust, norms of conduct and networks of people (Putnam, 1993), trust and norms of conduct being allotted special importance, reflecting a different perspective on institutions existing in a society. Coleman states that social interaction brings about long lasting patterns of relations, which represent a resource available to individuals; such resource may be accumulated or depleted over time. The World Bank defines social capital at the broadest level as "the norms and networks that enable collective action" Another conclusion states that these rules are the result of repeated interactions in the community (Ostrom, 1990), and – once established – they are transmitted to future generations through a process of socialization. Of course, a common way to create social capital – intentionally and consciously – would be the establishment and enforcement of formal rules by an authority; their repeated acceptance and employment further leads to their functioning similar to informal norms. Compared to other forms of capital – financial or human capital – the social capital is less tangible and more difficult to measure, its dimension being of more qualitative nature; moreover, the goals pursued by one group can be in accordance or contrary to those of other groups, so that the externality effect cannot be overlooked, which can be positive – offering incentives also to individuals outside the group responsible for creating the capital social, or negative – in case the group members develop and encourage intolerance against non-members. Collier (1998) focuses on both these aspects, analyzing social capital in terms of those externality-generating social interactions which are either themselves durable or whose effects are durable, distinguishing among the various institutional levels at which social capital may be present – the family, the organization, the government and the civic society (the World Bank site also considers communities, ethnicity and gender as specific sources of social capital, particularly relevant in the context of development).

The concept of social capital is related to a certain number of other concepts. Narayan (1999) discusses its relationship with the notions of social capability (defined by Adelman and Morris), of social exclusion and of civic engagement. Corneo and Jeanne (1999) study the connection between growth and social organization, a concept related to social capital but independent of it. Cole, Mailath and Postlewaite (1992) is a classical reference of the contribution on the link between social norms and growth, although Hirsch (1976) provided an earlier analysis of the social limits to growth. Knack and Keefer (1997) discuss three main relationships – between trust and civic norms and economic development, between associational activity and growth, and between trust and civic norms and their determinants, including associational activities and formal institutions; their findings show that "trust and civic cooperation are associated with stronger economic performance", adding though that "associational activity is not correlated with economic performance".

Studies have also shown a positive correlation between the degree of trust in a particular geographic area and the effectiveness, respectively, the level of economic development of that area, stressing that the issue of trust is more sensitive in societies / groups consisting of a large number of people, given that the available information is scarce due to the impersonal character and to the reduced frequency of interactions; trust is considered as an essential component of social interactions both on the market and within the enterprise, starting from the idea that trust, as an institution, plays an important role in facilitating cooperation between agents, but the idea of the existence of a market for trust being obviously a contradiction of terms (Arrow, 1974). Its

key role is to reduce uncertainty by limiting probable alternatives, turning predictable the behavior of partners.

Even the legal system's effectiveness depends on the trust of contracting parties on its working properly; it would be important to note that detailed contracts are concluded when the parties show reduced mutual trust. Several studies also show that the quality of government is positively influenced by social capital. Hall and Jones (1999) point out that a relevant part of country productivity is due to the country's institutions and government policies (i.e. social infrastructures).

One of the possibly most relevant contributions of social capital is to the formation of human capital, fact which was early recognized by Coleman (1998) who argued that the same basic individual skills have much better chances of being well cultivated and developed in a socially rich environment than in a socially poor one, stressing the link between social capital and education. He also stresses the fact that social capital, determining the degree of social cohesion, may have a relevant influence on the rates of crime and violence (Coleman, 1990). Positive correlation between average education and social capital was found also by Helliwell and Putnam (1999), stressing the virtuous dynamics between human capital and social capital accumulation, trust-enhancing policies being considered able to start a multiplier mechanism. These policies may have relevance for the purpose of long-term growth, i.e. reputation mechanisms may substitute trust in well-operating markets, but in emerging markets such element of stability is absent, so that the level of trust and trustworthiness may determine whether some innovative or idea-intensive activities develop or not.

Conclusions

The analysis of social capital allows us to consider social development in terms of its accumulation. Clearly put, social capital comprises those features of social relationships – interpersonal trust, norms of reciprocity, participation in civic organizations, and interpersonal and inter-organizational networks – which facilitate cooperation and collective action oriented towards a general benefit, being thus incorporated into the structure and quality of social relationships between people; the notion of social capital refers to a form of capital that is encompassed in the social structure of a group, rather than in physical objects or in single human beings, like physical and human capital. Therefore it can be noted that the institutions' input towards economic success is related to their capacity to support impersonal transactions. The importance of trust to economic performance is reflected by the fact that the lack of it leads to a decreased number of opportunities.

Emphasized is also the social potential induced by social capital, being considered to improve economic activity background in a way similar to technical infrastructure; social capital influences the quality of education and health, facilitates access of individuals to markets, supports complex operations and enables the activities' long-term planning. In this regard it was also stressed the importance of social cohesion towards a country's economic development, the concept of social capital being considered as influencing development theory, practice and policy.

It can be noted that the analysis of social capital at enterprise level would bring about clearer results, as the internal organization of an enterprise is intentionally designed to register profit, so this is one of the few cases in which social capital is the product of a specific investment (money spent not only to design internal structures, but also to train managers and workers to work in groups) and not only the by-product of other activities.

We can add that one of the key contributions of social capital is to the accumulation of human capital; it is much easier to develop individual skills in a socially rich environment than in a

socially poor one. Since human capital accumulation constitutes an engine of growth in advanced economies, social capital could be regarded as a deep root of growth processes.

DECOMPOSING THE GAP IN SCHOOL ACHIEVEMENT BETWEEN FINLAND AND ROMANIA – SOME METHODOLOGICAL ASPECTS

Botezat Alina
Romanian Academy ICES „Gh.Zane" Iaşi

This paper analyzes the advantages and shortcomings of the Blinder-Oaxaca decomposition. Using PISA data for Finland and Romania, we focus on the drawbacks of the detailed decomposition, when the explanatory variables are categorial. From the best of our knowledge, this kind of analysis is performed for the first time using PISA data.

We show that, using covariates which are categorial, the partial characteristics effects can be different when we use different reference categories of the respective variable. However, the overall characteristics effect of a categorical variable does not depend on the omitted category. The more critical aspect of the interpretation of detailed decomposition, when explanatory variables are categorical, regards the unexplained part of the gap. As we empirically show, the both components of the unexplained part are sensitive to choices of the reference category. These aspects should be taken into account when we perform detailed decompositions with categorial variables.

Keywords: decomposition, categorial variables, test score gap, PISA
JEL Classifications: J24, I21, C14

I. Introduction

In a knowledge based society, skills and knowledge acquired through education play an ever more important role. The economic growth and the development of a country largely depend on the education system. Hence, understanding the differences in school achievement between countries is of huge importance since it allows improving the school systems and, therefore, directly provides relevant information for educational policies.

In this paper we analyze the differences in reading test scores of the students from Finland and Romania. We choose Finland as benchmark for our analysis because it is the best performing country in the PISA study and is considered to have the most effective and equitable school system (Ammermueller 2007). Using PISA (*Programme for International Student Assessment*) data from 2006, we apply a decomposition method widely used in the literature with education data. Based on the example Finland - Romania, our purpose is to focus on the methodological part, showing the advantages and the shortcomings of the method. We refer here to the the *Blinder-Oaxaca decomposition*, which starting with the papers of Blinder (1973) and Oaxaca (1973) has become the most cited decomposition method in applied labor economics. Originally it was designed to decompose and explain wage gaps by sex or race, but in the recent years it was extensively used in decomposing differences in school achievement. A comprehensive overview of the Blinder-Oaxaca decomposition is provided by Fortin, Lemieux, and Firpo (2010).

Krieg and Storer (2006) use the Blinder-Oaxaca method to decompose the differences in test scores between high- and low- performing schools in the state of Washington according to "The No Child Left Behind Act". The motivation of using this method was to determine which factors explain the differences in test scores between schools: the background characteristics of the students or the institutional settings. Ammermüller (2007) uses a slightly different form of the traditional Blinder-Oaxaca decomposition in order to explain the gap in PISA test score between Finland and Germany. The total score gap was decomposed into a characteristics, a return and a characteristics-return effect. The paper reports also these three effects separately for four groups of explanatory variables: student background, resources, institutions and school types. But the results show that, considering only the mean of the distribution, the differences in characteristics could not explain entirely the test scores gap between Finland and Germany. Cho (2007)

performs the Blinder-Oaxaca decomposition in order to explain the change in the college enrollments gender gap.

II. Methodology

1. The classical Blinder-Oaxaca Decomposition
The aim of the Blinder-Oaxaca decomposition is to split the differences in mean outcomes between two groups in two components: one, which is attributed to differences in characteristics (endowments) and a component generated by the differences in the regression parameters, given equal endowments. Since we primary focus in this paper on differences in school achievement, the outcomes we refer to are test scores. Formally, the gap in test scores between two groups can be written as:

$$\Delta = E[Y1|D = 1] - E[Y0|D = 0]$$

where D is an indicator of group membership. $D = 1$ denotes here the group that scores higher, so that the total difference is positive.

The main assumption of the model refers to the structural form of the functions which links the observed and unobserved characteristics in the following way:

$$Y_l = X\beta_l + \varepsilon_l$$

for $l = 1, 0$
where $E[\varepsilon_l|X] = 0$.

Using the law of iterated expectations, the gap can be expressed as:

$$\Delta = E[X|D = 1]\beta_1 - E[X|D = 0]\beta_0$$

To get the two terms that describe the differences in endowments and the differences in regression coefficients, we must construct a meaningful counterfactual, that excludes general equilibrium effects (Fortin, Lemieux, and Firpo 2010). According to the selected reference group, we add and subtract in the above equation the corresponding counterfactual. In this sense, the assumption about the *nondiscriminatory norm* (Oaxaca 2007), β_0 or β_1, is important, since the decomposition results are not stable to the choice of the reference group *(index number problem)*.

In the original specification, Oaxaca (1973) uses as benchmark the more favored group (in terms of nondiscrimination), weighting the differences in average endowments by its coefficient and the coefficient gap by the vector of average characteristics of the more disadvantaged group. In studies analyzing scholar achievement gaps, some authors report the decomposition results from the point of view of the more advantaged group (Krieg and Storer 2006; Duncan and Sandy 2007; Sandy and Duncan 2010; Schneeweis 2010), other studies present the gaps from the point of view of the more disadvantaged group (Cho 2007; Ammermueller 2007; Patacchini and Zenou 2009), while some papers report the results from both specifications (Cook and Evans 2000; McEwan and Marshall 2004).

The gap in test scores in the equation above can be decompose as follows:

$$\Delta = E[X|D = 1]\beta_1 - E[X|D = 0]\beta_0 + E[X|D = 1]\beta_0 - E[X|D = 1]\beta_0$$
$$= E[X|D = 1](\beta_1 - \beta_0) + (E[X|D = 1] - E[X|D = 0])\beta_0$$

Here we use the counterfactual that describes the average test scores that the individuals from group 1 would get if they would have the returns of group 0. After rearranging the terms, the estimated gap can be decomposed as:

$$\widehat{\Delta} = (\bar{X}_1 - \bar{X}_0)\hat{\beta}_0 + \bar{X}_1(\hat{\beta}_1 - \hat{\beta}_0)$$

The right hand side of the equation is due to differences in the average regressors. In economics of education this term is usually called the "explained" or the characteristics effect (Δ_c). It captures the difference of the test scores that would vanish if the individuals from group 0, given their returns to the average characteristics, would have the same characteristics as the individuals from the group 1. In other words this component reflects the gap in test scores that

would exist if the students from the both countries were evaluated by the school coun- try from country 0. The second term is due to differences in the coefficients and is named the return effect (Δ_r) or the "unexplained" part of the gap. In studies regarding gaps in outcome between different countries, this term reflects the "country-specific portion" (Zhang and Lee 2011). If it is positive it shows, how much the individuals from the group 0 would on average score better if, given their own characteristics, they would face the returns of group 1.

2. Detailed decomposition

In many studies it is useful to perform a detailed decomposition by looking at the contribution of a certain group of variables or of every single variable to the characteristic and return effect. For example, it would be interesting to see how much of the characteristic effect is due to the differences in the student background or in parents' education alone. Performing a variable-by-variable decomposition, the effects of the total gap can be written as the sum over the covariates:

$$\hat{\Delta}_c = \sum_{k=1} (\bar{X}_{1k} - \bar{X}_{0k})\hat{\beta}_{0k}$$

$$\hat{\Delta}_r = (\hat{\beta}_1 - \hat{\beta}_0) + \sum_{k=1} \bar{X}_{0k}(\hat{\beta}_{1k} - \hat{\beta}_{0k})$$

$(\bar{X}_{1k} - \bar{X}_{0k})\hat{\beta}_{0k}$ represents the component of the characteristics effect that is described by the differences in the average characteristics of the kth covariate, multiplied by the respective $\hat{\beta}$. $\hat{\beta}_1 - \hat{\beta}_0$ is the portion of the unexplained gap due to group membership (Jones and Kelley 1984). The differences in the returns to the kth covariate, evaluated at the average value of the characteristics X_k [$\bar{X}_{0k}(\hat{\beta}_{1k} - \hat{\beta}_{0k})$] represents the kth component of the return effect.

In the field of education it could be informative to separate the contribution of variables that describe the student background, for example, to the characteristic effect from the contribution of other variables related to the resources, institutional aspects etc. Furthermore, the contribution of individual variables to the total gap can be detected performing a more detailed decomposition.

Zhang and Lee (2011), for example, decompose the PISA 2006 test gap in math scores for a group of OECD countries. Calculating the gap in test scores as the difference between each individual country and the OECD average, they apply a *Blinder-Oaxaca detailed decomposition* using different blocks of variables, namely demographic characteristics, study time and activities, family background, and school characteristics.

Ammermueller (2007) performs a similar detailed decomposition for differences in reading test scores between Finland and Germany, dividing the gap into three components: a characteristic (endowment) effect, return effect and a component reflecting the interaction between the first two effects. The explanatory variables are grouped in four categories: student background, resources, institutions and school types.

Duncan and Sandy (2007) analyze the achievement test score gap between public and private schools. Based on the Blinder-Oaxaca technique, they perform a detailed decomposition, calculating the explained and unexplained effects both at the level of each explanatory variable, as well as for the groups of some variables, that describe the family background and school quality. In a paper from 2010 (Sandy and Duncan 2010), they apply also a variable-by-variable decomposition in order to identify the sources of the test score gap between urban and suburban schools.

III. Critical aspects regarding the detailed Blinder-Oaxaca decomposition

Beyond the relevant information that a detailed decomposition can offer, the interpretation of the estimated coefficients can be misleading, especially when the covariates are categorical, with

more than two categories (Fortin, Lemieux, and Firpo 2010). In order to illustrate this aspect, we use the PISA test score gap in reading between Finland and Romania. The data contain many relevant variables that are categorical: parents' education (no secondary education, lower and upper secondary education, tertiary education), the number of books at home (less than 10 books, between 11-50, 51-100, 101-250, 251-500 and more than 500 books) etc.

Table 1 presents the estimated coefficients of the regression of the reading score on the individual (gender, age (in months), grade) and student background variables for the Romanian students (the reference group in the decomposition). We look at the results of mother's education and of number of books. In column 2, mother's tertiary education and *book6* are the omitted categories, while in column 4 we use the level of no secondary education and book1 as the reference categories, so that for the categorical variables the estimated coefficients in the first regression are equal to the corresponding coefficients in the second regression minus the value of the coefficient of the variable, which in the first regression is the omitted one (see note 1).

Table 1: *OLS Regression Coefficients for Romanian Students*

Variable	First regression		Second regression	
	Coefficient	(Std. Error)	**Coefficient**	(Std. Error)
Dmale	-42.01	(2.14)	-42.01	(2.14)

Intercept	539.77	(64.12)	436.62	(64.31)

Source: PISA 2006 data, own calculations. Standard errors are in brackets.

Based on the results from both regressions in Table 1, we can compare for each category, which are not omitted in any of the both regressions, the magnitudes of the characteristics effects. Comparing the results from column 2 and 4, we can argue that having in Romania more students whose mothers have an upper secondary education level than in Finland, the characteristics effect of this variable is almost three times as large (22.90) in one case (column 4) as in the other case (7.99) (column 2). Using the same pattern to interpret the estimates regarding the variable *book5*, we can argue that the corresponding partial characteristics effect is fourteen times larger in the second case (column 4) as in the first case (column 2). But this interpretation should be viewed as caution, since in the two cases the returns are obtained relative to different reference categories of the respective variable. This issue is especially problematic when the categorical variables do not have an absolute interpretation (Fortin, Lemieux, and Firpo 2010).

Even if the differences in the partial effects between columns (2) and (4) are large, the overall contribution of mother's education and of number of books to the characteristic effect is the same

in both cases, as can be seen in the Table 2. Thus, the overall characteristics effect of a categorical variable does not depend on the omitted category. We also show this formally.

Suppose that we have in our regressions an explanatory variable with four categories ($k = a, b, d, c$), from which one of them is the reference category and this variable is the only covariate in the regression. We perform two regressions, one in which the first category is the omitted one and then, in the second regression, we omit the 4th category. We denote by $\gamma_{l,k}$ the coefficients of the first regression ($\gamma_{l,a} = 0$) and by $\beta_{l,k}$ the coefficients of the second regression, where $\beta_{l,d} = 0$. The overall characteristics effect corresponding to the first regression can be written as follows:

$$\sum_{k \neq a} (\bar{X}_{1,k} - \bar{X}_{0,k})\hat{\gamma}_{0,k}$$

Using the fact that $\hat{\gamma}_{0,k} = \hat{\beta}_{0,k} - \hat{\beta}_{0,a}$ (see note 1) and $\sum_{k \neq a} \bar{X}_{l,k} = \sum_k \bar{X}_{l,k} - \bar{X}_{l,a}$, we get:

$$\sum_{k \neq a} (\bar{X}_{1,k} - \bar{X}_{0,k})\hat{\gamma}_{0,k}$$
$$= \sum_{k \neq a} (\bar{X}_{1,k} - \bar{X}_{0,k})(\hat{\beta}_{0,k} - \hat{\beta}_{0,a})$$
$$= \sum_{k \neq a}(\bar{X}_{1,k} - \bar{X}_{0,k}) \hat{\beta}_{0,k} - \hat{\beta}_{0,a}(1 - \bar{X}_{1,a}) + \hat{\beta}_{0,a}(1 - \bar{X}_{0,a})$$
$$= \sum_k \bar{X}_{1,k} - \bar{X}_{0,k}\hat{\beta}_{0,k}$$

The more critical aspect of the interpretation of detailed decomposition, when explanatory variables are categorical, regards the unexplained part of the gap. As showed above, the unexplained component is the sum between two differences: one between the intercepts and the other between the coefficients. Performing a detailed decomposition when different categories of a variable represent the reference categories, the values of the both components of the unexplained part are not the same in each case. This fact is illustrated in Table 2.

When the omitted categories are *book6* and *mother's tertiary education*, the effects which incorporate the difference in the coefficients are -13.36 for the *number of books*, and -6.41 for *mother's education* compared to -24.33 and -13.18 in the second case (*book1* and *mother's no secondary education* are omitted). The rest of the unexplained gap of these two variables is captured by the intercepts, so that the total unexplained part of the gap is the same in both cases (137.31).

Due to the fact that the both components of the unexplained part are sensitive to choices of the reference category, some studies about school achievement gap treats the unexplained part as a residual and don't interpret the results of the detailed decomposition for this component (McEwan and Marshall 2004; Sandy and Duncan 2010).

Table 2: *Oaxaca-Blinder Detailed Decomposition Results*

Variable	First case		Second case	
	Coefficient	(Std. Error)	**Coefficient**	(Std. Error)
Equation 1: Differential				
Prediction_1	548.50	(1.13)	548.50	(1.13)

IV. Conclusions

This paper analyzes the advantages and shortcomings of the Blinder-Oaxaca decomposition. Using PISA data for Finland and Romania, we show especially the drawbacks of the detailed decomposition, when the explanatory variables are categorial. From the best of our knowledge, this kind of analysis is performed for the first time using PISA data.

We showed that, using covariates which are categorial, the partial characteristics effects can be different when we use different reference categories of the respective variable. However, the overall characteristics effect of a categorical variable does not depend on the omitted category.

The more critical aspect of the interpretation of detailed decomposition, when explanatory variables are categorical, regards the unexplained part of the gap. As we empirically showed, the both components of the unexplained part are sensitive to choices of the reference category.

These aspects should be taken into account when we perform detailed decompositions with categorial variables.

Notes

1.   Suppose we have the following model, corresponding to group 0: $Y_i = \gamma_{0,a} + \gamma_{0,b} D_{bi} + \gamma_{0,c} D_{ci} + \gamma_{0,d} D_{di} + u_\gamma$, where D_{ki} represent the dummy variables for the categories k, the category a being the reference one. When d is the base category, the model is the following:

$Y_i =$
$\beta_{0,d} + \beta_{0,a} D_{ai} + \beta_{0,b} D_{bi} + \beta_{0,c} D_{ci} +$
$+ u_\beta =$

$kicategory\ s\ in\ Table\ (3.1)es, test\ score\ gap, 381381381381381381381381381$
$381381381381381381381381381381381381381381381381381381381381381\beta_{0,d} +$

$$\beta_{0,a} (1 - D_{bi} - D_{ci} - D_{di}) + \beta_{0,b} D_{bi} + \beta_{0,c} D_{ci} + u_\beta = \beta_{0,d} + \beta_{0,a} + D_{bi}(\beta_{0,b} - \beta_{0,a}) + D_{ci}(\beta_{0,c} - \beta_{0,a}) + u_\beta . E(Y_i|D_{ki} = 1) - E(Y_i|D_{ki} = 0) = \beta_{0,k} - \beta_{0,a} = \gamma_{0,k}.$$

POPULATION MOBILITY ACROSS REGIONS AND COUNTIES DURING DEMOCRACY IN ROMANIA

Bunea Daniela
Bucharest Academy of Economic Studies Faculty of Economics

As an introduction to a more comprehensive study about internal migration determinants, this paper investigates on the main trends in the evolution of this phenomenon within Romanian borders for the last two decades, 1990-2010. For this, I compute indicators such as gross migration and net migration, and I display some illustrative graphic representations of the main patterns. Thus, my focus will be on: arrivals, departures and balances of migration, both numbers and rates; highest and lowest rates; intra-flows and inter-flows; and the favorite destinations to migrate from county to county.

The main findings of this quantitative statistical analysis reveal low levels of migration, oscillatory flows and rates with sharp falls in 1991, two regions (Bucharest-Ilfov and West) with exclusively positive balances and one (North-East) with only negative balances, only 11 counties registered net inflows (especially from Centre and West), intra-migration strongly dominated inter-migration, inhabitants from almost one third of the counties have chosen the capital as their favourite destination, and almost half of the counties showed no temporal change in their preferences.

Keywords: internal migration, regions, counties, destinations, Romania

JEL Code: R23

I. Introduction

Internal migration in Romania is defined by the National Institute of Statistics (INS) comprises *"changes of permanent residence and temporary settling of residence in another locality, different from that of permanent residence inside the borders of the country"*, except for movements inside the same locality, sector or commune (Romanian Statistical Yearbook 2010: 39).

The remainder of the paper has the following structure: section II presents statistics related to the main measures of internal migration (inflows, outflows and balances) by region and county, section III makes a ranking of favorite destinations county to county, section IV is dedicated to inter- and intra-county migration, while section V offers an advance on future research.

II. Arrivals, Departures and Balances of Internal Migration

The total number of migrants during the post-communist period reached the value of almost 7 million persons (annual average of 333,207 migrants and a rate of 15‰) (fig. 1). Divided by sub-periods, in the 1st one (1990-1994) the number was of about 1,850,000 migrants (16.1‰ rate), in the 2nd one (1995-1999) fell at 1,436,800 migrants (12.7‰), in the 3rd one (2000-2004) increased at 1,551,300 migrants (14.1‰), and for the last one (2005-2009) continued to grow at 1,700,700 persons (15.8‰).

The year-by-year evolution of aggregate migration is also illustrated in fig. 1. Thus, internal migration (numbers and rates) registered an oscillatory evolution within the period 1990-2010, with minimums of 240,231 migrants and 10.55‰ both in 1993 and maximums of 786,471 migrants and 33.88‰ both in 1990. Moreover, sub-periods 2001-2004 and 2006-2008 were characterized by constant increases.
Figure 1. Internal migration in Romania (numbers and rates of migration)

Fig. 2 illustrates the net migration rates by region in Romania from the first post-communist year until 2010. One can observe a first group formed by the regions Centre, South-East, Bucharest-Ilfov and West, and a second one formed by the other four regions, each with different shapes of evolution. The first group followed an L-shaped evolution (except for South-East) with different intensities, while the second group followed an inverse L-shaped evolution. Bucharest-Ilfov and South had the most pronounced fall and, respectively, rise from 1990 to 1991. Centre had positive rates in the intervals 1990-1997 and 2000-2006, South-East was positive in 1990, 1993 and during 1995-1999, South was positive during 1997-2000 and 2007-2008, South-West only in 1996 and 1999-2000, and finally, North-West was positive during 2006-2010. Instead, Bucharest-Ilfov and West had positive values during the whole period, with a one year exception for the first in 2000; whereas North-East was negative all the time. Overall, net rates were very small, within the range [-5,+5‰].
Figure 2. Net migration rates at regional level

For the entire democracy period 1990-2010, the counties of Ilfov, Bucharest, Timiş, Constanţa and Arad recorded the highest rates of in-migration, while Vaslui, Botoşani, Gorj, Ialomiţa and Bucharest recorded the highest rates of out-migration. As for the lowest rates, Maramureş, Harghita, Satu-Mare, Giurgiu and Covasna had the lowest in-migration, whereas Satu-Mare,

Ilfov, Harghita, Bihor and Covasna had the lowest out-migration. As regards the highest balances, these were registered by Vaslui, Botoşani, Teleorman, Tulcea and Olt (negative), and by Ilfov, Timiş, Arad, Bucharest and Constanţa (positive). For sub-periods, see table 1.

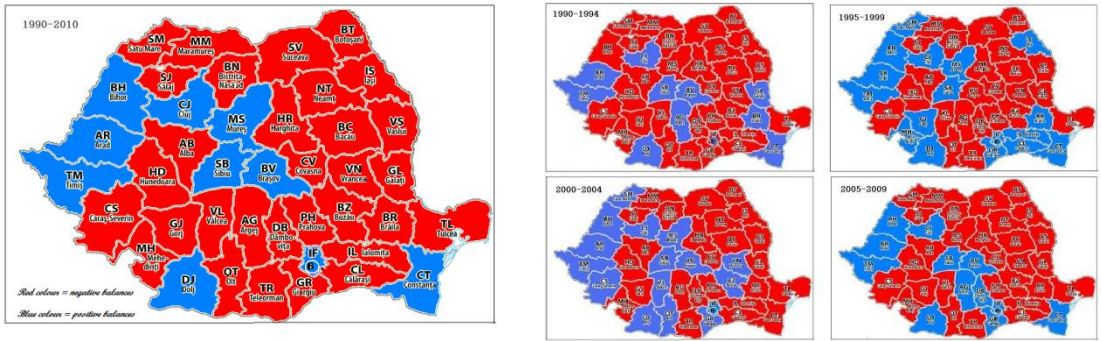
Table 1. Highest and lowest values of gross migration in Romania by sub-period

		1990-1994	1995-1999	2000-2004	2005-2009
In-migration	*Highest*	Timiş Constanţa Bucharest	Gorj Constanţa Bucharest	Bucharest Gorj Ilfov	Ilfov Bucharest Timiş
	Lowest	Giurgiu Harghita Maramureş	Maramureş Satu Mare Prahova	Maramureş Brăila Galaţi	Harghita Covasna Maramureş
Out-migration	*Highest*	Vaslui Botoşani Ilfov	Vaslui Hunedoara Gorj	Bucharest Gorj Hunedoara	Bucharest Gorj Vâlcea
	Lowest	Bucharest Braşov Bihor	Satu Mare Sibiu Giurgiu	Ilfov Brăila Giurgiu	Harghita Covasna Cluj
Balance	*Highest Negative*	Vaslui Botoşani Giurgiu	Hunedoara Maramureş Bistriţa-Năsăud	Hunedoara Vaslui Maramureş	Vaslui Hunedoara Botoşani
	Highest positive	Timiş Bucharest Constanţa	Arad Timiş Constanţa	Ilfov Arad Timiş	Ilfov Timiş Arad

Source: Own elaboration based on INS data

Thus, I can conclude that Bucharest and, at a lower scale, Gorj, had high rates of both arrival and departure, and Satu-Mare, Harghita and Maramureş had all low rates of both entries and exits.

Further, considering the ratio between negative and positive balances, I obtain an uneven distribution of balances in favor of the negative ones. Thus, over 1990-1994, 30 counties turned negative values and 11 positive values; 1995-1999, 23 counties turned negative and 18 positive; 2000-2004, 25 were negative and 17 positive; 2005-2009, 28 counties negative and 14 positive; for the whole interval, 1990-2010, 31 counties were negative and 11 were positive.

Fig. 3 depicts the full picture of migratory balances at county level over the entire period and the four time spans. Making an aggregation, 16 counties recorded negative balances in each of the sub-periods: Alba, Bacău, Bistriţa-Năsăud, Botoşani, Covasna, Harghita, Hunedoara, Maramureş, Neamţ, Olt, Prahova, Sălaj, Suceava, Teleorman, Tulcea and Vaslui. Other 8 counties had only positive balances in every sub-period: Arad, Bucharest, Cluj, Constanţa, Dolj, Ilfov, Sibiu and Timiş. The map for the entire period 1990-2010 counts only 11 counties with net inflows, Ilfov (12.9‰), Timiş (7.9‰), Arad (5.3‰), Bucharest (4.6‰), Constanţa (3.9‰), Braşov (2.8‰), Sibiu (2.5‰), Cluj (1.6‰), Bihor and Mureş (0.4‰), and Dolj (0.3‰).


Source: Own elaboration based on INS data

Figure 3. County maps of net migration by period

III. Where Did People Migrate? Favorite Destinations by County

Table 2 displays the favorite destinations of each of the 42 counties. I have split the time interval 1994-2010 in order to account for the possible changes produced meanwhile into four sub-intervals. First, it seems that, on average, people from 13 counties preferred to move, in the first place, to the capital (Argeş, Bacău, Brăila, Buzău, Călăraşi, Constanţa, Dâmboviţa, Galaţi, Giurgiu, Ialomiţa, Ilfov, Prahova, and Teleorman). Secondly, the counties Arad, Bihor, Caraş-Severin, Neamţ, Prahova and Sălaj suffered no temporal or hierarchical change as regards their favorite destinations. Other 11 counties, even though they were not subjected to temporal changes, did change hierarchy. Therefore, a total of 17 counties had no inter-temporal alterations related to their internal destinations.

Table 2. Favorite destinations county to county by time intervals

IV. Inter versus Intra-County Migration

During the period 1994-2010, intra-county (short-distance) migration dominated inter-county (long-distance) migration, with an average difference of 24 p.p.. Notably, from 2001 to 2005, intra-county migration strongly dominated inter-county migration; otherwise, the percentage distribution of the two types is quite the same (fig. 4).

Intra-migration is relatively higher because it implies lower costs of moving, both monetary and psychological (leaving family, friends, community) and because of the service sector expansion.
Source: Own elaboration based on INS data

Figure 4. Distribution of inter and intra-county migration in Romania

Fig. 5 offers an identical reproduction of national rates by intra-county rates, which are visibly higher than inter-county rates whose evolution is rather different and relatively less pronounced. The highest rates (inter, intra and national) were registered in 2010.
Source: Own elaboration based on INS data

Figure 5. Total, inter and intra-county migration rates

The highest and lowest values of intra-county migration for the period 1995-2010 are found in table 3. Over 1995-1998 and 2007-2010, only 4 counties had a total number of intra-migrants inferior to 10,000, while over 1999-2002 and 2003-2006, there are 10 and, respectively, 7 such counties. Bucharest and Sălaj had the highest and, respective, the lowest intra-flows.

Table 3. Extreme values of intra-county migration in Romania

	1995-1998		*1999-2002*		*2003-2006*		*2007-2010*

V. Future Research

In a future paperwork I will investigate on the main determinants of Romanian migration using an appropriate econometric approach.

MIGRATORY FLOWS ACROSS SPANISH PROVINCES: 1960-2010

Bunea Daniela
Bucharest Academy of Economic Studies Faculty of Economics

Internal migration is a controversial topic among researchers because of both its determinants and consequences on the market economy. Different empirical studies have offered different answers to how migration is influenced and influences economic disparities within a country.

As an introduction to a more comprehensive study about the determinants of this phenomenon, this paper carried out a quantitative statistical analysis of the main evolutions of domestic migration across and within Spanish provinces. The period of analysis is 1960-2010 during which migration patterns changed considerably from intense to moderate flows and from moderate to constant flows.

Over the entire period, only seven provinces registered exclusively net inflows and only two provinces remained inflexible as regards their favourite internal destinations, inter-provincial migration dominated intra-migration only during the first decade, the provinces on the Mediterranean axis formed the main attraction pool due to their climatic conditions and tourism expansion, negative balances dominated positive balances except for 1981-1991, Madrid turned negative in the decade of the 90´s while Barcelona did it in the 80´s.

I. Introduction

Internal migration in Spain has witnessed geographical and compositional changes over time. Population redistribution through internal migration in the past four decades must be analyzed considering economic, social and political transformations. In general, the transition from an industrial-based economy to a service-based one, in which tourism is the key issue, has been accompanied by the transition to a more liberal, open and international economy as consequence of the entrance in the European Community in 1986. Besides the socio-economic changes, there has been a political shift from dictatorship (following Franco´s death in 1975) to democracy and from centralism to regionalism (García Coll and Stillwell 1999: 98).

The Spanish National Institute of Statistics (INE) defined internal migration as those *residence changes from one municipality to another inside the same national territory*, i.e. entries and exits. The remainder of the article comprises five sections: section II is dedicated to a short literature review on Spanish internal migration, section III displays the main trends in migration patterns, section IV puts together inter- and intra-provincial migration, section V offers some information on the favourite internal destinations, and section VI offers some insights on future work.

II. Literature Review

Over the last decades domestic migration patterns in Spain changed dramatically (Bover and Velilla 1999; Antolín and Bover, 1997). Thus, *during 1960-1975*, Spain was subjected to intense migratory movements amid: reducing regional inequalities in income and unemployment; rapid and very polarized industrial growth, causing severe rural out-migration with massive transfers of employment from agriculture to industry, constructions and services; mainly young adults left the rural areas and moved to the big industrial cities in search of jobs; flows were mainly unidirectional from the rural underdeveloped southern regions to the urban industrialized northeastern, plus Madrid. Later, *during 1975-1985*, new patterns of internal migration emerged:

decreasing flows in spite of great differences in (non-)economic factors between provinces; declining long-distance (inter-provincial) migration and increasing short-distance (intra-provincial) migration; following the expansion of the welfare system, traditional industrial provinces with net in-migration have become areas of net loss (Barcelona, Biscay, etc.) or of only marginal gain (Madrid, Valencia, etc.), while some of the traditional rural provinces have experienced positive net migration, due in part to the return of former out-migrants. And finally, *until 1995*, gross inter-regional migration started again to rise, although high aggregate unemployment rates continued to persist.

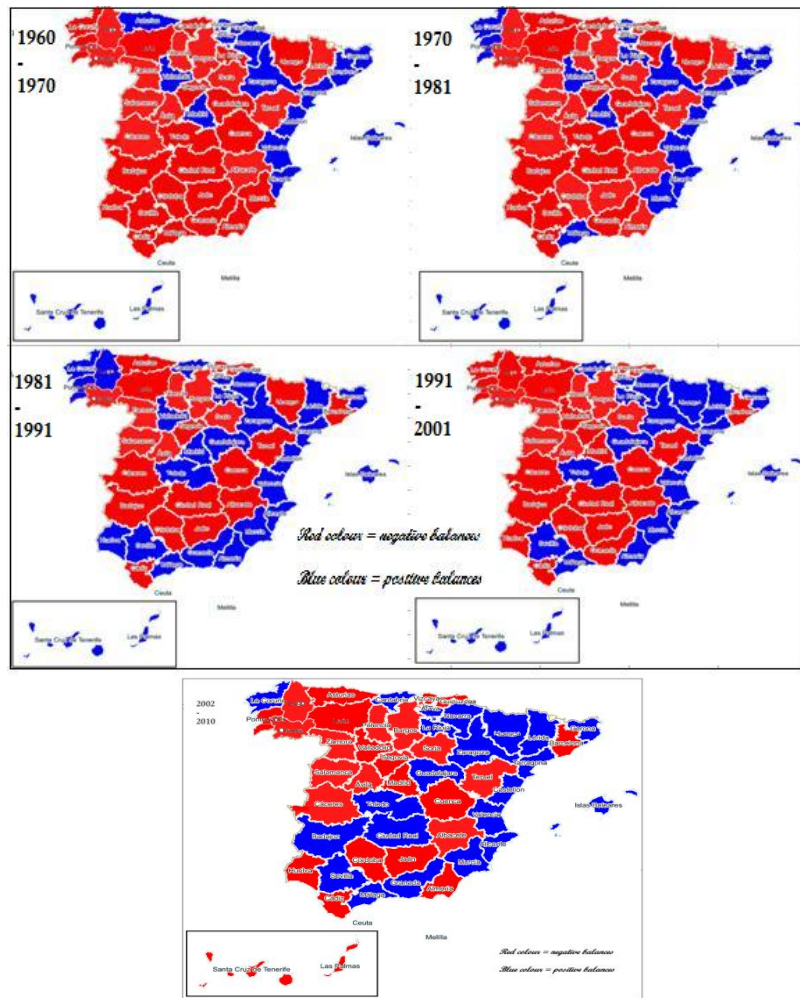
Hence, "*the factors that have shaped inter-provincial population redistribution in the 1980's are technological change and innovation, sectoral and occupational restructuring, globalization and feminization of the labour force, as well as demographic structure*" (García Coll and Stillwell 1999: 102). They also point to the creation of the autonomous communities in 1978, the return to rural areas and migration patterns among the elderly as exerting a great influence on migration.

In a recent review, Hierro and Maza (2010: 620) points out the main features of internal migration in Spain since the early 1980s: steady increase of internal migration; high rates of intra-provincial movements mainly explained by a drift of people from large cities towards smaller towns and rural areas, as well as from metropolitan areas towards suburbs; increasing return migration; major role of location-specific amenities in migration decision; dramatic drop in overall net migration rates and important reversals from strong net in-migration to net out-migration (and vice versa); and an increasingly high role played by the foreign-born population.

Samuel Bentolila (2001) distinguishes between demographic and economic factors. The **demographic factors** are: population aging due to lower natality and higher mortality (negative impact); changes in family structure due to increasing divorce rate (positive impact) and higher participation of the women in the labour force (ambiguous impact); high level of family self-help, i.e. children leave parental house at elder age, or use their parents´ networks to find employment, also a supporting legislation for household heads to keep their job (negative impact); and an increasing educational level. The **economic factors** comprise institutional changes and economic differentials. The *institutional changes*, all with positive effects in reducing differences between regions, are: political decentralization (creation of the autonomous communities), higher proportion of social aid in national GDP, lower unemployment benefits since 1993, increasing help for the least developed regions as a consequence of both national and EU funds, favourable fiscal system for house acquisition, and an overwhelming trade union coverage.

III. Main Evolutions of Migration across Spanish Provinces

According to census data (1960-1970, 1971-1981, 1981-1991, 1991-2001), Spain witnessed constant falls in internal migration from one decade to another; if in 1960-1970 the migration rate reached 82.5‰ in 1991-2001 fell at 33.02‰. Instead, according to the year-by-year data, there was a constant upward trend from 2003 to 2007, after which migratory flows decrease slightly and remained quite steady. On average, 2002-2010, Spain registered an annual average number of migrants of 1,589,463 persons, i.e. an annual average rate of 35.57‰. See fig. 1.

During the inter-census period 1960-1970, 33 provinces had negative balances and 17 positive balances (Madrid +19, Soria -20.8); during 1970-1981, 31 provinces turned negative while 19 positive (Alava +9.4, Cuenca -10.4); during 1981-1991, 23 balances were negative and 27 positive (Balearic Islands +4.1, Guipuzcoa -4.5); while during 1991-2001, 29 provinces turned negative and 21 positive (Guadalajara +12.1, Biscay -2.8). Instead, for the year-by-year period 2002-2010, Spain had 28 provinces with net outflows and 22 with net inflows (Guadalajara +20.9, Cuenca -3.5). Fig. 2 illustrates the balance map by each decade. And after, I will analyze in more detail the patterns in domestic migration.
Source: Own elaboration based on INE data
Figure 1. Numbers and rates of internal migrants in Spain 1960-2010


Source: Own elaboration based on INE data
Figure 2. Provincial maps of net migration, 1960-2010

1960-1970 - migration reached very high levels:

- the highest positive net migration rates belonged to Madrid (19‰), Barcelona (18.3‰) and Alava (16.3‰); at the opposite pole there were Soria (-20.8‰), Cuenca (-19.1‰), Guadalajara and Teruel (both with -17.9‰);

- positive balances were also registered along the Mediterranean axis (along the east coast from the French border to Alicante, including Balearic Islands) and the Ebro axis (the diagonal joining Catalonia with Basque Country, along the Ebro river valley) due to the tourism economy.

1970-1981 - the volume of balances decreased both for those with positive figures and with negative figures:

- the highest balance rates belonged to Alava (9.4‰), Tarragona (7‰) and Madrid (5.8‰); Cuenca (-10.4‰), Ciudad Real (-9.5‰) and Segovia (-9.4‰);

- the Mediterranean axis continued to have positive net streams and both Murcia and Malaga joined this axis as tourism strengthened;

- on the west coast, the balances of Corunna and Pontevedra turned positive, whereas the balances of Navarre, Guipuzcoa and Asturias became negative because of the industrial and mining crisis (Ródenas Calatayud 1994: 172);

- compared with the previous decade, the balances of Barcelona, Guadalajara, Madrid, Biscay and Soria recorded the largest variations;

- the direction of migratory streams was from the southern and central areas to Madrid (from the Centre) and Barcelona (from Andalucia).

1981-1991 - the volume of balances decreased very much:

- the highest net rates belonged to Balearic Islands (4.2‰), Gerona (3.9‰) and Malaga (3.7‰); Guipuzcoa (-4.5‰), Biscay (-4.3‰) and Teruel (-3.1‰);

- Almeria and Granada joined the Mediterranean axis, whilst Navarre and Cantabria consolidated the Ebro axis;

- Lugo, Seville and Huelva became positive; Barcelona and Biscay turned from positive to negative; Madrid and Valencia decreased significantly their positive balances;

- the changes occurred in migration trends were due to the industrial crisis during the early 1980s which provoked the closure of many companies, an increase in job losses and a reduction of labour demand; Madrid and Barcelona were affected by the entry in the labour force of the baby-boom generation in the 1960s and by previous in-migration, both altering labour supply and demand (García Coll and Stillwell 1999: 102); the descending trend was somewhat slowed down by the admission into the European Community (1985);

- the Mediterranean axis became the main attraction pool;

- compared with the previous decade, the provinces of Badajoz, Alava, Cuenca, Caceres and Ciudad Real recorded the largest changes.

1991-2001 - internal flows continued to fall:

- the highest net migration rates were those of Guadalajara (12.1‰), Tarragona (5.3‰) and Toledo (4.3‰); Biscay (-2.8‰), Teruel (-2.1‰) and Guipuzcoa (-1.9‰);

- Madrid turned negative for the first time, together with Corunna, Granada, Huelva, Lugo, Pontevedra and Valladolid; Huesca was the only province to turn positive;

- compared with the previous decade, Guadalajara, Tarragona and Toledo registered the strongest variations;

- similarly to the last two decades, the provinces forming the Mediterranean axis continued to attract more and more migrants.

2002-2010:

- Madrid and Barcelona continued to remain negative but accelerated their out-migration;

- Almeria turned negative after two decades of being a net receiver of migrants;

- Las Palmas and Santa Cruz de Tenerife turned negative for the first time;

- Badajoz, Cadiz, Corunna and Granada turned again positive;

- the greatest changes belonged to Guadalajara, Toledo and Almeria.

Overall, 1960-2010, only seven provinces recorded permanent positive balances of migration, six of them situated on the Eastern Spain: Alava, Alicante, Balearic Islands, Castellon, Gerona, Tarragona and Valencia. Instead, 16 provinces recorded only negative balances: Albacete, Avila, Burgos, Caceres, Cordoba, Cuenca, Jaen, Leon, Orense, Palencia, Salamanca, Segovia, Soria, Teruel and Zamora.

IV. Intra-Migration versus Inter-Migration

During the period 1960-2001, the annual rate of migrants dropped from 16.1‰ (1960-1970) to 13.7‰ (1970-1981) and 12.1‰ (1981-1991), and increased to 13.4‰ in 1991-2001. As regards the inter-provincial rate, this fell continuously from 9.2‰ in the first decade to 3.7‰ in the last, while the intra-provincial rate rose from 6.2‰ to 7‰. This means a shift from long-distance movements to short-distance ones. Also, the internal migration rate for those leaving abroad at the beginning of the census periods expanded rapidly from 0.8‰ to 2.7‰. See table 1.

This shift from inter- to intra-migration is attributed to the development of the service sector (and its properties). As evidence, the employment percentage in services rose from 38% in 1977 (27%-Orense, 60%-Madrid), to 57% in 1995 (40%-Orense, 75%-Las Palmas & Balearic Islands), 60% in 2004 (45%-Teruel, 75%-Las Palmas & Madrid), and finally, to 68% in 2010 (55%-Cuenca, 80%-Palmas).

Table 1. Evolution of provincial migration in Spain 1960-2001

Spatial scale	1960-1970		1970-1981		1981-1991		1991-2001	
	No. (1000s)	Annual rate (‰)	No. (1000s)	Annual rate	No. (1000s)	Annual rate	No. (1000s)	Annual rate (‰)
Intra-provincial	1,703	6.2	1,913	6.3	2,086	6.1	2,483	7.0
Inter-provincial	2,510	9.2	1,867	6.1	1,595	4.7	1,297	3.7
Foreign migration	209	0.8	399	1.3	408	1.2	975	2.7
Total	*4,423*	*16.1*	*4,181*	*13.7*	*4,090*	*12.1*	*4,756*	*13.4*

Source: Own elaboration based on INE data

N.B.: Data exclude the autonomous cities of Ceuta and Melilla, and rates are computed by dividing the number of migrants (annual average) by the initial population of each censual period.

Additionally, for the year-by-year period 1998-2010, figs. 3 and 4 show that intra-migration was, on average, 20 p.p. higher than the inter one and both types follow the national trend, with peaks in 2007 and bottoms in 1998.
Figure 3. Distribution of inter and intra-provincial migration in Spain
Figure 4. Inter and intra-provincial rates of migration in Spain

V. Favorite Destinations for Migration: Province to Province

Cadiz and Huesca were the only provinces that did not change their three favorite destinations, meaning that Spanish migrants were very flexible as regards their choices. People from Madrid chose the adjacent Toledo and Guadalajara, Badajoz, Ciudad Real, Alicante, Malaga and Barcelona. Instead, people from Barcelona preferred in the first two decades (´60 and ´70) long-distance destinations such as Cordoba, Granada and Seville, whereas in the last decades (´80-´00) the neighbors Gerona, Tarragona and the capital Madrid.

The most popular destinations were: Madrid, Barcelona, Valencia, Seville and Zaragoza, followed by Biscay, Granada and Valladolid.

VI. Future Research

In a future article, I will carry out a comprehensive analysis of the main determinants of Spanish migration using an extended gravity model which accounts for both push and pull motivations.

SUSTAINABILITY OF ECONOMIC GROWTH AND INEQUALITY IN INCOMES DISTRIBUTION

Burz Răzvan-Dorin
West University of Timisoara, Romania, Faculty of Economics and Business Administration

Boldea Bogdan Ion
West University of Timisoara, Romania, Faculty of Economics and Business Administration

The problem of inequality in incomes distribution is a present one, much discussed. Economic growth is considered an essential force to reduce the level of poverty by increasing the labor demand and finally the wages within the economy. But the extent to which poverty is reduced as a result of economic growth depends mostly on the initial inequalities in income and on how the distribution of income changes with economic growth. A lot of researches are focused on studying the evolution of inequality in incomes distribution and others have attempted to explore the relationship between income inequality and economic growth. There are also studies which try to identify the main factors which have impact on inequality in incomes distribution. The objective of this study is to put in discussion another possible factor that affects the variability on inequality of incomes distribution – economic growth variability. As background research, until now, we did not find any studies which are investigating this possible relation between inequality of incomes distribution and economic growth variability. To provide some empirical evidences for a positive impact of social output volatility on inequality of incomes' distribution we are involving a small sample of 27 developing countries for an observation time span between 1995 and 2006. The values of the Gini coefficient reported in World Income Inequality Database are used as dependent variable. As a first step in testing our research hypothesis, we are involving a static panel data model with pooled ordinary least squares (OLS), fixed effects (FE) and random effects (RE) estimators. The F statistics tests the null hypothesis of same specific effects for all countries. If we accept the null hypothesis, we could use the OLS estimator. The Hausman test can decide which model is better: random effects (RE) versus fixed effects (FE). The FE model was selected because it avoids the inconsistency due to correlation between the explanatory variables and the country-specific effects. For a robustness assessment, we also apply the so-called GMM-System estimation. According to our results, an increase in the volatility of the social output (a decrease in the sustainability of the growth processes) leads to a greater inequality in incomes distribution. Such outcome appears to be robust to the changes in estimation methodology.

Keywords: inequality, inequality in incomes distribution, inequality factors, economic growth, economic growth volatility,

JEL Classification: O15, Q01

I. Introduction
Inequality is a feature of contemporary society which has lately led to the initiation of extensive debate on how it should be addressed. Themes are diverse but can be grouped in two directions – one to address the level of inequality and the other aiming the factors that influence the level of inequality. As follows:
– *inequality is positive, negative or both depending of the circumstances*. If it is positive should be increased and if negative should be eradicated. Or should we find an optimal level of inequality – the duality case. Moreover, if *the level of inequality has an influence on economic growth* to what extent is that level;

– *is there a relationship between the dynamics of economic growth and inequality*. How the economic growth and why not, its fluctuation correlates with the level of inequality. Why first of all a relationship with economic growth? Because economic growth is generally accepted as an indicator of welfare growth, while inequality as an indicator of social security which is being reflected indirectly, in many countries, by the issue of eradication/reduction of poverty;

– in what way global economic growth was passed over the regions/states. In recent years economic growth led to an increase or decrease in inequality between states. As a phenomenon, inequality has the same trend or has been manifested differently depending on the degree of development of states (developed, developing, and underdeveloped);

– in what way economic growth of states has impacted the members of their populations. There was a decrease, continuity, or an increase of inequality. The conclusions differ depending on the degree of development of states (developed, developing, and underdeveloped);

– what *other factors* influence the level of inequality, and what is the place, based on importance, of the economic evolution (increase / decrease / economic fluctuations) among them.

Without proposing to sentence the issues raised we will make a short review of the literature to point out a few opinions and research on these issues.

A lot of researches are focused only on studying *the level and the evolution of inequality* in incomes' distribution. Many analysts claim that world income inequality fell sharply in the second half of the 20th century especially because of globalization (Omerod 2000: 42-45; Wright 2000: 34-38; Wolf 2001: 25). There are also opinions that cross-country income inequality is rising (Wade 2001). After using seven different popular indexes for global income inequality estimation Xavier (2002) concluded that in general during the last two decades within countries disparities have increased slightly, but at cross-country level they have declined substantially.

Regarding the *desired inequality level*, an increase is driven by the worsening situation of the poor or by the improvement situation of the rich. If the first situation is undesirable, being a potential promoter of social tension and political instability, the second one is disputed, the general opinion being that an excessively equal income distribution can be bad for economic efficiency.

From the point of view of the *relation between inequality level and economic growth*, some studies suggested that countries with a more equal income distribution tend to have higher levels of income (Galor and Zeira 1993, King and Levine 1993, Banerjee and Newman 1993, Persson and Tabellini 1994, Aghion and Bolton 1997, Galor 2000 etc.; after Tabassum and Majeed 2008: 727-743).[19] Forbes (Forbes 2000: 869) concludes that over short and medium time intervals, increases in inequality tend to precede increases in growth. He emphasizes that these estimates do not directly contradict the previously reported long-run negative relationship across countries. Later, Tabassum and Majeed (2008: 727-743) concluded that it might be possible that more inequality facilitates economic growth for a short time period but overtime, it has strong negative effect on economic growth due to credit market imperfection.

Based on a bigger range of data Barro (2000: 5-32) found that the empirical results are sensitive to the specific choice of sample of countries. In poor countries higher inequality tends to slow down growth and in richer places encourage growth. The same conclusion was made by Castelló-Climent (2007). From this perspective Subarna and Heyse (2006) concluded that developing countries with higher income inequality do not grow at a slower rate than developing countries with a more equal income distribution.

A lot of researches approach the problem from the reversed perspective – *the relation between economic growth and inequality* (how economic growth affects the level of inequality). Kuznet (1955: 1-28) suggested that, at low levels of per capita income, inequality increases in the initial

---

[19] The first country that notified the European commission was Great Britain, on 24th November 2011, then Ireland on 15th December , on 21st December Germany, followed by Belgium, Luxembourg, Malta, Austria, France and Nederland on 22nd and 23rd December 2011.

phase of development and then decreases in the course of development. Later research, based on other data, found no evidence for Kuznets hypothesis (Deininger and Squire 1997: 38). Recently García (2007) concluded that unlike the Kuznets hypothesis of the 1950s, we can-not expect the growth process to autonomously bring about a reduction of inequality – "redistribution will remain a policy concern even in affluent societies".

From the literature review we can conclude that the empirical findings are largely inconclusive, so it cannot be stated with certainty the different hypothesis. In general, the inconsistency of the results is put mostly on data quality, limited availability of data, period length, sample selection and estimation technique.

There are also studies which try to identify *the main factors which have impact on inequality* in incomes' distribution. Dobrotă (1997: 273) enumerates among causes: inequality in wealth, differences in ability, differences in attitude, different qualifications, different number of hours worked, the different positions on goods markets, discrimination, the degree in which government is involved in redistributing income, unemployment, etc.. Examining the long-run determinants of income inequality Roine et al. (2008) found that economic growth disproportionately benefits "the rich"; financial development is also significantly pro-rich, particularly in the early stages of a country's development; openness to trade has no clear distributional impact; tax progressivity significantly reduces top income shares; government spending has almost no effect on inequality at all. Afonso et al. (2007) found that public policies significantly affect income distribution, notably via social spending, and indirectly via high quality education/human capital and via sound economic institutions. Hesmati (2004) studying the different factors that affect the global income inequality concludes that the factors having the highest impact on inequality across countries are political and capital market factors, and within-country inequality land reform, expanding education and active regional policy, and that the within country redistribution has little impact on the global inequality. Kaasa (2003) grouped the factor described in the literature into five groups: economic growth and the overall development level of a country, macroeconomic factors, demographic factors, political factors, historical, cultural and natural factors.

In the following study we want to put in discussion another possible factor that affects the variability of inequality of incomes distribution – economic growth variability. As background research, until now, we did not find any studies which are investigating this possible relation between inequality of incomes' distribution and economic growth variability.

II. Data and methodology

For this analysis we looked at a small sample of 27 developing countries for an observation time span between 1995 and 2006. For these countries we took into consideration the values of two indicators: GDP and Gini coefficient. The GDP values were obtained from the "World Development Indicators" of the World Bank and are used to reflect the output volatility. For the description of inequality we use the values of the Gini coefficient reported in "World Income Inequality Database" of United Nations, which is one of the most popular representations of income inequality. To study the correlation between the proposed indicators as methodology we used a descriptive model in which the output volatility is the independent variable and the values of the Gini coefficient are the dependent variable. A formal description of our research hypothesis can be synthesized as:

$$GINI_{i,t} = \beta_O + \beta_i X_{i,t} + \delta_t + \eta_i + \varepsilon_{i,t} \qquad (1)$$

Where:
– the dependent *Gini Index* variable is linked to a set X of the considered explanatory variables;
– η_i is the unobserved time-invariant specific effects;
– δ_t captures a common deterministic trend;

– ε_{it} is a random disturbance assumed to be normal, and identical distributed (IID) with E $(\varepsilon_{it})=0$; Var $(\varepsilon_{it}) = \sigma^2 > 0$.

As a first step in testing our research hypothesis, we are involving a static panel data model with pooled ordinary least squares (OLS), fixed effects (FE) and random effects (RE) estimators. The F statistics tests the null hypothesis of same specific effects for all countries. If we accept the null hypothesis, we could use the OLS estimator. The Hausman test can decide which model is better: random effects (RE) versus fixed effects (FE). The FE model was selected because it avoids the inconsistency due to correlation between the explanatory variables and the country-specific effects. For a robustness assessment, we also apply the so-called GMM-System estimation. The GMM-System methodology – as proposed by Arellano and Bover (1995: 29-51), Blundell and Bond (1998: 115-143) and Windmeijer (2005: 25-51) – is involved because estimators like fixed and random effects, IV or standard GMM may yield to biased results. Also, since a small panel sample may produce "downward bias of the estimated asymptotic standard errors" in the two-step procedure (Baltagi 2008: 154) we use the "Windmeijer correction" for the estimated standard errors. More exactly, Windmeijer (2005: 25-51) observes that part of downward bias which can appear for the standard errors in small samples is due to extra variation caused by the initial weight matrix estimation being itself based on consistent estimates of the equation parameters. In order to correct this bias, it is possible to calculate bias-corrected standard error estimates which take into account the variation of the initial parameter estimates. We employ a version of this correction applicable for GMM models estimated using an iterate-to-convergence procedure.

The GMM-System tries to simultaneous estimate the Equation 1 together with a re-specification designed to eliminate the country-specific effects by using first differences of the involved variables as:

$$\Delta GINI_{i,t} = \beta_i \Delta X_{i,t} + \delta_t + \eta_i + \Theta \Delta Z_{i,t} + \varepsilon_{i,t} \qquad (2)$$

Where:

– Z is a set of instruments for the dependent and explanatory variables.

The system-GMM approach estimates equations (1) and (2) simultaneously, by using lagged levels and lagged differences as instruments. The presence of both lagged levels and differences is justified by Arellano and Bover (1995: 29-51) and Blundell and Bond (1998: 115-143) which showed that lagged levels can be poor instruments for first-differenced variables, particularly if the variables are "persistent". For comparison purposes, we are reporting the results of a dynamic GMM (Arellano and Bond 1991: 277-297).

III. Empirical results

After applying the Hausman test we reached the results reported in Table 1. The values of the Hausman tests confirm the viability of the inclusion of the fixed effects. It appears that the level of GDP is positive and statistic significant associated with the *GINI* index.

Table 1. Inequality in incomes distribution and economic output volatility: a static panel data model

Explanatory	Fixed Effects	t-Statistics	Significance
GINI(t-1)	0.24	4.05	***
Real GDP volatility (10 years variance coefficient – standard deviation / average)	0.26	2.16	**
Cross-section F test	6.23 (p=0.00)		
Cross-section *chi-square*	144.79 (p=0.00)		
Period F test	2.63 (p=0.00)		
Period *chi-square*	28.84 (p=0.00)		
Cross-section / Period F	5.68 (p=0.00)		
Cross-section / Period *chi-square*	173.40 (p=0.00)		
R^2	0.90		
Observations (balanced)	297		

t-statistics (heteroskedasticity corrected) in round brackets.
***/**/*- statistically significant, respectively at the 1%, 5%, and 10% level.

Source: made by authors

Table 2 shows the results of the extended model. The most important result is that the output volatility variable remains positive and statistically significant, displaying some robustness to the changes in methodology. However, the estimation of relative importance of output volatility to be sensitive to such changes and the statistical significance decline in the GMM-System framework.

Table 2. Output volatility and incomes inequality: a GMM-System and dynamic GMM estimation

Explanatory	Dynamic GMM	GMM-System
GINI (t-1)	0.07*** (6.90)	0.74*** (4.57)
Real GDP volatility	0.18*** (5.02)	0.21* (1.65)
M1		-2.18 (0.03)
M2		0.56 (0.57)
Sargan	0.54	1.00
Observations (balanced)	270	270

t-statistics (heteroskedasticity corrected) are in round brackets. The null that each coefficient is equal to zero is tested using the second-step robust standard errors.
***/**/*- statistically significant, respectively at the 1%, 5%, and 10% level.

Source: made by authors

M1 and M2 are tests for first-order and second-order serial correlation in the first-differenced residuals, asymptotically distributed as $N (0, 1)$ under the null hypothesis of no serial correlation (based on robust two-steps GMM estimators). Sargan is a test of the over-identifying restrictions, asymptotically distributed as χ^2, under the null of instruments' validity (two-steps estimators). White period instrument weighting matrix and White period standard errors & covariance (no degree of freedom correction) are used for dynamic GMM.

IV. Conclusion

We can conclude, according to our results, that social output volatility has a positive impact on inequality of incomes' distribution. The results clearly indicate that an increase in the volatility of the social output (a decrease in the sustainability of the growth processes) leads to a greater inequality in incomes' distribution.

The clear observation that spans is that for a developing country to have a sustainable development it must make efforts not only to increase its GDP but also to maintain a continuous trend of its increase. It matters not only the level achieved but also how it is achieved. Although in a given period of time the economy shows permanent positive results in GDP terms, if it has variations, although it remains positive, the country development is not a sustainable one from the point of view of inequality evolution.

GLOBALIZATION AND MASS-MEDIA
IN THE CONTEXT OF ECONOMIC CRISIS

Burtic Daniel
University of Oradea, Romania Faculty of Economic Sciences

Globalization is a reality that we cannot deny or run away from. The economic, political or social issues, even if they have a starting point, spread very quickly, covering large areas in a very short time. Modern communication systems enable crisis transfer. They also bring us information about the actions that have been taken in order to overcome those critical circumstances. Does recession have positive aspects, too? If it has, what are these positive aspects and how can they be used to produce highest benefits? We will try to describe the concepts we maintain by means of some notorious works written by authors with a vast experience, some of them being Noble Prize winners. The idea that we propose is to bring hope out of this situation generated by crisis and globalization. The economic crisis has created a huge opportunity to the mass-media system: it brings the required information to citizens from different nations. Taking this into account, mass-media has played and still plays an important part in making the people involved find solutions and communicate whenever the decision makers are trying to hide facts. With the help of innovation and transformation, let's look for solutions to develop our abilities, relationships, products, markets and results. We should never forget that the greatest and most impressive changes are often born in times of crisis.

I. Introduction

Is it professionalism or pure coincidence? This question arises every time we look for success factors when dealing with crisis situations. Is it enough being happy with the reality of globalization and copying other people's solutions, hoping they will also be good for us, or should we do more? This is our main concern when approaching the globalization phenomenon, a concern which is deepened by mass-media in the context of economic crisis. This is the reason why, in the first part of this study, our aim is to approach globalization and present economic crisis on a positive note, emphasizing the opportunity we have to find appropriate solutions to the complex circumstances we are facing. In this process, the first winners are those who overcome crisis successfully and manage globalization skillfully. In the second part, we will try to demonstrate the link between globalization and mass-media, having in mind the dissemination of the flow of information. We would also like to reveal the dark side of mass-media; the costs regarding time and resources which especially the young generation pays for this modern vice called multimedia. The perspective from which we approach this subject is related to immediate every day reality. Our aim is to provide a descriptive and explanatory study. From this point of view, our analysis will sometimes become passionate, but will be strongly rooted in the reality that is shaped by each and every action of man.

II. Globalization and economic crisis

When discussing about globalization and future, we cannot ignore economy and mass-media, because both are essential and decisive factors in modern man's life. Globalization can be analyzed in 2012 from the perspective of economic crisis and of the adopted solutions as well as from the perspective of its consequences on the entire world. The economic crisis we are now undergoing is one of the deepest crises ever existed. „When crises acquire worldwide

dimensions, as it is often the case with the worst ones, their end depends on the possibility that the international reaction should be characterized by cooperation or conflict. In this case there are so many things at stake. If they are not given much attention, crises will bring about huge losses, wiping out industries from the face of the earth, destroying wealth, leading to massive dismissals of employees and overloading the administrative department with heavy taxes. But it's even worse than that. Crises overthrew governments and bankrupted nations; they forced countries to apply the *lex talionis* and get involved in commercial wars. Sometimes crises paved the way to armed conflicts, in the same way The Great Depression prepared the ground for the Second World War. We are not allowed to ignore crises." (Roubini and Mihm 2010:36). In this respect, both on a macroeconomical and microeconomical level, the present stage is characterized by all kinds of challenges, unknown things as well as opportunities which should not be overlooked.

A Crisis or growth?
It seems that in every person's life moments of crisis mingle with moments of growth. Is giving birth to a child a moment of crisis? What about weaning? Are puberty, adolescence, looking for a job, marriage, having the first child, all moments of crisis which indicate each person's growing up and development? We can ask ourselves if all these elements in somebody's life are crises or growth stages. It is true that when we undergo them, we feel pain rather than pleasure and disappointment instead of hope, but when all these become simple memories, we understand that they actually were growth stages. We forget all the pain and remember only the beautiful part. „In economic analysis, we start from man and his needs. The evolution of human society is actually the history of a constant growth process, multiplication and diversification of needs and this evolution process interwove with the entire development and progress of society." (Bădulescu and Vancea 2011:7)
Similar to man's life, but on a much larger scale, the life of nations and of all mankind carries on. There are many records which prove that difficult economic stages have given birth to spectacular ideas, which turned hardships into opportunities. In 1937, Howard Stephenson wrote a book, *They Sold Themselves*, about people who could easily find a job during the devastating economic crisis in the 1930's. He says that those who were successful in finding a job were „people who didn't have a brother-in-law to hire them to sweep the floors of a warehouse; these people were full of creativity and managed to fill good positions or even started their own business which brought them satisfaction and prosperity." (quoted by Roubini, Mihm, 2010:41). In this respect, we have the example of George Washington Carver, who was born into slavery, lived till the age of 10-12 on the cotton plantation of his first master and afterwards worked as a servant in different households. He finished high school after he had been 20 years old, then he took the degree of Bachelor of Science and a master's degree at the Iowa State Agricultural College. The Alabama state built him a national monument because after the cotton crops had been devastated by the cotton beetle, Carver promoted and organized the cultivation of fields with peanuts, sweet potatoes and beet root, helping people in Alabama become rich.
The moments of crisis are difficult especially when you experience them personally. But your whole perspective will change when you see them as growth stages. Here is how, in 2009, a year after he had been awarded the Nobel Prize for economy, Paul Krugman spoke about the Great Depression from the 1930's: „When they think about this topic, most of the economists consider the Great Depression from the 1930's a free tragedy, which they think wasn't necessary." (Krugman 2009:7). Mister Krugman continues saying that three or four measures would have been enough and, if they had been adopted in 1929, they would have led the following year to a „kindergarten recession". Even to this famous economist, the crisis that started in 2008 carries within itself a much deeper anxiety than the one from 1930. Why is it so?

B. Trust or mistrust?

If we remember history well, when states emerged in Europe, people put their hope in the state. The state was the agent or the instrument which would solve all the problems. It was empowered to do justice by the laws it issued and applied. The state was also in charge with education, health and citizens' safety. Whether we refer to the communist or the capitalist state, each of them tried to show its almightiness. First, the communist state revealed its real face and the most obvious aspects were the economic incompetence and the leaders' lack of ethics. At the end of the 80's, the European countries, some which underwent violent revolutions while others experienced „velvet" revolutions, passed from communism to capitalism. In capitalist vision, the role of the state is still very important. In every election campaign, politicians promise to solve all people's problems. Of course, they promise more than they can do or even intend to do. Thanks to mass-media, the public opinion has become more and more aware of the discrepancies between words and facts. It seems that nowadays people trust less and less those who represent the state, no matter who these are or whatever state we refer to. Every day mass-media brings into light many corruption cases or, at best, cases of administrative incompetence. The „almighty" capitalist or communist state went bankrupt.

Together with the establishment of capitalism, we have witnessed another worshipping, namely to the market. It was said that the market would bring solutions to every problem. „Let the market function and everything will be all right!", was the idea we've heard from many political and economic decision makers. But lately we have witnessed the market bankruptcy. The instability is so big that we need more and more money to cover at least the critical part of deficits. Disappointed by the state, by the market and by the system, people have started going out in the streets. Last year we saw what happened in London, in New York, in the African states and in Greece, when extremely unhappy people protested and almost all these demonstrations degenerated into acts of violence. Unfortunately, in the first part of this year people from Romania have gone out in the street, too. It seems that their protest does not regard only one aspect, but is caused by dissatisfaction on multiple levels.

Beyond what it can be seen, a collective conscience seems to take shape and this phenomenon is prompted by the modern means of communication. Nowadays, information spreads at a very high speed. We read or listen to the news, but the whole process is much more complex, we take over unconsciously and involuntarily the mentality of those who convey us the information. Here is how the famous psychologist C.G. Jung explains this phenomenon: „Each Roman was surrounded by slaves. The slave and his psychology invaded ancient Italy and every Roman became in his own self a slave, without even noticing it. Because Romans lived on a constant basis in a slave context, they were unconsciously infected with their psychology. No one could avoid such an influence." (C.G. Jung 1928:135). C.G. Jung's diagnosis is also valid for our society. Dissatisfaction as well as a negative vote is rather a rule than an exception.

If we come back to the economic field, in our opinion in this period of time the nations' leaders, especially those involved in the economic sphere, have adopted an anti-panic management strategy. Therefore, they speak of debt guarantee funds in order to „settle down markets". They also speak of a „negative economic growth", instead of an „economic decrease", so different communications strategies are set up rather than some practical recovery measures. In this context, we wonder how big will be our losses in reestablishing a proper balance? And our second question is how big will be the invoice or the share each of us will have to pay for? Will this generation try to pay the bill or will it condemn the next generation to cover its cost?

II. Globalization and mass-media

We live in a world which absorbs more and more information. The economic crisis has increased both the amount of information that is supplied and the demand for information. More than that, the flow of messages carries the deep mark of the worldwide area. The interest of the citizens

who live in more developed countries is not limited to the events taking place in their own country, but to all the factors involved in the worldwide stage which have an impact on the entire world's economy. In the same way, the community members of less developed countries have learned from the very first days of the economic crisis that what happens in their countries is the direct result of the worldwide economic situation or, more precisely, of the events taking place in the more developed countries. Thus, we can see the interest of all parties in finding out more and more. Mass-media has proved to be extremely skillful and examined this issue in every possible way. Each news bulletin has received a double amount of space from the time allocated to the economic field. Analysts, economists, politicians, jurists and other specialists have been invited to debates, which turned either violent or peaceful, each debate trying to meet the increased demand for information. In this way, mass-media represents an important tool in the globalization process. „In the last few decades, the world became more and more «globalized». Goods and services trade reached an international dimension and this is also the case with migration of work and spreading of information. Globalization went hand in hand with technological progress, each supporting the other." (Roubini and Mihm 2010:498) As Roubini suggests, on the overall the main feature of globalization is the continuous flow of information, propagated all over the world by media industry at a very high speed. The development of the communication system had a huge impact on all countries.

A. Mass-media – globalization accelerator
One of the accelerators of globalization is television. This filtering tool and means of broadcasting information on a global level enables social exchanges and also promotes and outlines behavioral patterns and lifestyles. The impact of movies on viewers is not limited to the time spent in front of the TV set, but extends to the values which are presented, taken over and eventually adopted. Mediafax quotes from a research made by Eurodata TV Worlwide, which shows that the inhabitants of the earth spent in 2009 an average of three hours and 12 minutes daily in front of their TV set,

Timpul petrecut la TV

Minute pe zi — 300, 250, 200, 150, 100, 50, 0

Regions: America, Orientul Mijlociu, Europa, America Latina, Asia-Pacific, Africa

Series1

Regiuni

Source: Mediafax

which indicates an increase of 3 minutes compared to 2008.

„Therefore, this research shows that as a result of recession people haven't changed their behavior towards their use of mass-media. As far as a region analysis is concerned, the North America consumers spend the longest time in front of their TV sets, with an average of four hours and 40 minutes daily, followed by those from Middle East, who, on the average, watch TV four hours and 34 minutes daily and by those from Europe, who watch TV programs three hours and 42 minutes. In Latin America, a normal consumer watches TV around three hours and 30 minutes daily, while those from Asia-Pacific region spend around two hours and 41 minutes in front of their TV sets. Africa is the only region where the average time spent by consumers in front of their TV sets hasn't increased, but remained constant to three hours and 52 minutes." (Mediafax)

B. The dark side of modern systems of communication
It seems that television remains one of the most enjoyed sources of information for the postmodern man. Nowadays man's life without a TV set is unconceivable, even if many things have been said or written about the dark side of the television impact. In almost every home, the

TV set, whether it is bigger or smaller, expensive or cheap, represents a props element of the living room and sometimes of the bedroom.

As a globalization tool, the internet skips some of the underdeveloped regions, overlooking the population from the poorest areas of the earth which, out of economic reasons, doesn't have access to internet. Even if internet represents an efficient means of communication and information, its participants being able to exchange messages quickly in spite of the huge distances between them, it can have negative connotations. Especially for children, internet is time and resource consuming. In our globalized world, internet tends to become a life pattern changing tool.

A research on the behavior of 8 to 18 years old mass-media consumers, initiated by Kaiser Family Foundation and published in 2010, shows that the time children spend in interaction with mass-media is gradually growing. (Kaiser Family Foundation)

According to this research, children spend 7 hours and half daily interacting with mass-media. In 10 years, we notice an increase in mass-media use to 79 minutes daily. This research also shows that a portion of time children are connected to several media channels and, if we sum up all the hours, we come to an average use of mass-media services of 10 hours and 45 minutes per day. So, in 10 years we have an increase in mass-media use of 3 hours and 15 minutes daily.

Media Use Over Time

Among all 8- to 18-year-olds, average amount of time spent with each medium in a typical day:			
	2009	**2004**	**1999**
TV content	4:29[a]	3:51[b]	3:47[b]
Music/audio	2:31[a]	1:44[b]	1:48[b]
Computer	1:29[a]	1:02[b]	:27[c]
Video games	1:13[a]	:49[b]	:26[c]
Print	:38[a]	:43[ab]	:43[b]
Movies	:25[a]	:25[ab]	:18[b]
TOTAL MEDIA EXPOSURE	10:45[a]	8:33[b]	7:29[c]
Multitasking proportion	29%[a]	26%[a]	16%[b]
TOTAL MEDIA USE	7:38[a]	6:21[b]	6:19[b]

Changes in Media Use, 2004–2009

Among all 8- to 18-year-olds, change in average amount of time spent with each medium in a typical day:

[Bar chart: Music/audio + :47, TV content + :38, Computers + :27, Video games + :24, Movies n/c, Print - :05†]

†Not statistically significant. See Appendix B for a summary of key changes in question wording and structure over time.

Source: Kaiser Family Foundation

If we study the behavior associated to mass-media use during 2004-2009, we notice an increase in the average amount of time spent daily as follows: music-audio 47 minutes, TV 38 minutes, computer 27 minutes and video games 24 minutes. In 2009, there was a decrease of printed materials. It seems this was only the beginning, because after 2009 we witnessed an accelerated decrease in printed media product use.

But the biggest difference in TV watching is that nowadays 8 to 18 year-olds, on the average, watch daily around one hour (56 minutes) of TV content and movies on other platforms, too, including internet (24 minutes), cell phones (15 minutes) and iPods (16 minutes).

Talking and Texting on a Cell Phone

Among 8- to 18-year-olds, time spent in a typical day using a cell phone for:											
	Among all	AGE			GENDER		RACE/ETHNICITY			PARENTS' EDUCATION		
		8-10	11-14	15-18	Boy	Girl	White	Black	Hispanic	HS or Less	Some College	College +
Talking	:33	:10[a]	:36[b]	:43[b]	:28[a]	:38[b]	:25[a]	:46[b]	:37[b]	:35[ab]	:41[a]	:28[b]
Texting[†]	1:35	~	1:13[a]	1:51[b]	1:14[a]	1:58[b]	1:22[a]	2:03[b]	1:42[ab]	1:40[ab]	1:56[a]	1:21[b]

Note: Statistical significance should be read across rows, by section.
[†] Among 7th–12th graders only.

Source: Kaiser Family Foundation

Concerning the use of cell phones, the research indicates an obvious tendency in using this terminal more for texting than for talking. Only one third of the time the cell phone is used classically, two thirds being used for written communication.

Time Spent with Cell Phone Media, by Demographic

Among 8- to 18-year-olds, time spent in a typical day using a cell phone for:									
	Among all	AGE			GENDER		RACE/ETHNICITY		
		8–10	11–14	15–18	Boy	Girl	White	Black	Hispanic
Listening to music	:17	:08[a]	:18[b]	:23[b]	:16	:18	:08[a]	:35[b]	:21[c]
Playing games	:17	:06[a]	:18[b]	:22[b]	:17	:16	:09[a]	:29[b]	:24[b]
Watching TV	:15	:06[a]	:15[b]	:22[b]	:14	:17	:09[a]	:23[b]	:19[b]
TOTAL CELL PHONE MEDIA	:49	:20[a]	:51[b]	1:06[b]	:47	:51	:26[a]	1:28[b]	1:04[c]
Percent who did any of the above	43%	28%[a]	48%[b]	48%[b]	42%	44%	33%[a]	59%[b]	53%[c]

Note: Statistical significance should be read across rows, by section.

Source: Kaiser Family Foundation

Our contemporary society joins the virtual media on a constant basis, which is increasingly accessed from mobile terminals. The cell phone is often used for listening to music, playing games and watching TV. Almost half of its use time, the cell phone is used as an internet access terminal. Coming back to the economic aspect, internet is the medium in which on-line orders and financial transactions are made, being the new human interaction platform. Optimism or skepticism regarding internet doesn't change the reality of on-line expansion in all fields. The use of the internet is vital both for local and worldwide economy.

IV. Conclusions

„Nothing lasts forever, and crises will always come back. But they should not darken our horizon; they should not overshadow permanently our economic existence. If we set up protective dams around our financial system, we will be able to overcome the crises of the coming years. Although high waves will roar against us, we will be protected. But if we don't manage to get ready for inevitable hurricanes – if we deceive ourselves, thinking our obsolete defenses will never be broken – , the danger of future floods will surely lie ahead of us." (Roubini and Mihm 2010:460)

In the first part of this study, we tried to show that globalization and present economic crisis also have a positive aspect, emphasizing the opportunity we have to find appropriate solutions to the complex circumstances we are facing. In this process, the first winners are those who overcome crisis successfully and manage globalization skillfully.

In the second part, we tried to demonstrate the link between globalization and mass-media, having in mind the dissemination of the flow of information. The negative aspects are related to the costs regarding time and resources which especially the young generation pays for this modern vice called multimedia. The perspective from which we approached this subject is related to immediate every day reality.

We've got crisis, globalization and mass-media, but what are we doing about them? „Globalization is a reality, the reality of our times, having positive outcomes, as science

propagation, but also vicious effects, as the lamination of national cultures. Nowadays the idea of refusing or accepting globalization cannot even be raised." (Guetta 2000:328) With the help of innovation and transformation, let's look for solutions to develop our abilities, relationships, products, markets and results. We should never forget that the greatest and most impressive changes are often born in times of crisis.

We have got crisis, but can we make an opportunity out of it!?

DYNAMICS OF DEVELOPMENT IN EUROPE: ANALYSIS OF TWENTY YEARS DATA ON GDP AND HDI

Bucciarelli Edgardo
University of Chieti-Pescara, Italy Department of Quantitative Methods and Economic Theory

Alessi Michele
University of Chieti-Pescara, Italy School of Advanced Studies, Doctorate of Philosophy, XXVI cycle

Persico Tony Ernesto
University of Chieti-Pescara, Italy School of Advanced Studies, Doctorate of Philosophy, XXVII cycle

The aim of this study is to analyze the data on both GDP per capita and HDI related to the member States of European Union for the period from 1990 to 2010 in order to verify if these data are more related to the macro-region to which each State belongs than to European area. In particular, this paper considers four macro-regions: North, Centre, East and Mediterranean. Each of the four macro-regions are characterized by a peculiar dynamic of economic growth over the temporal period here considered. The results show that macro-regional dynamics prevail on European ones when European States are characterized by low values of both GDP per capita and HDI. More specifically, the values on GDP per capita are more correlated to the macro-regional average than to the European one. At the same time, States with high values of both GDP per capita and HDI are more related to the macro-regional dynamics of HDI.
Hence, it is possible to observe that not only allows a macro-regional level of analysis to highlight socio-economic dynamics of dependence, but also to underline that some macro-regions are characterized by the prevalence of the economic component on the social one whereas other macro-regions are typified by the opposite dynamic. In fact, if the level of both GDP per capita and HDI are high, the social aspect prevails on the economic one.

Keywords: socio-economic development, European economies, correlation analysis.
JEL code: C32, O11, O52.

1. Introduction and related literature

"United in diversity", which is the official motto of the European Union (EU) adopted in May 2000, shows two of the main characters of EU: the desire for integration and the diversity. That European diversity is undeniable and inescapable is clear as EU is an economic and political union of 27 member States. The EU arises from member States' desire for achieving a complete integration. In fact, one of the basic principles of the European Governance is the commitment to promote integration by also making reference to the idea of conditionality (Smith 1998). Conditionality "*entails the linking, by a State or international organisation, of perceived benefit to another State, to the fulfillment of conditions relating to the protection of human rights and the advancement of democratic principles*" (Smith 1998, p. 256). The path towards the European Strategic Development Framework has revitalized the current European debate about GDP and HDI analysis, making it a key element of European socio-economic development and, in particular, of the new strategic framework for cohesion policy (Barca 2009, Evers 2010). Indeed, the socio-economic reality of the European Union is quite unbalanced today, with the growing presence of situations of macro-regional disparities. One of the main objectives is represented by the challenge of promoting a development which bridges economic gap in the EU by implementing policies of socio-economic cohesion (Barro and Sala-i-Martin 1991, Allard *et al.* 2008). On this regard, our research is related to the studies concerning European socio-economic

development and is aimed at describing relationships among European States. In particular, our main purpose is to observe if economic growth and human development of each European State are more related to European area than to the macro-region to which each State belongs.

2. Research methodology

We have chosen to use the Gross Domestic Product per capita in current US$ (GDPpc) to represent economic growth and the Human Development Index (HDI) to describe human development. We have analyzed 28 European States; indeed, we have also considered data concerning Croatia which is an acceding State of the European Union, with full membership expected in July 2013. Each European State belongs to one of the following macro-regions:

- NORTH (N): Denmark, Finland, Ireland, Sweden, United Kingdom;
- CENTRE (C): Austria, Belgium, France, Germany, Luxembourg, Netherlands;
- EAST (E): Bulgaria, Czech Republic, Estonia, Hungary, Latvia, Lithuania, Poland, Romania, Slovak Republic;
- MEDITERRANEAN (M): Croatia, Cyprus, Greece, Italy, Malta, Portugal, Slovenia, Spain.

The time period considered goes from 1990 to 2010.

Data on GDPpc have been obtained from World Bank database accessed on 24 April, 2012 whereas the data on HDI have been gotten from UNDP database retrieved on 24 April, 2012.

Firstly, we have determined both GDPpc percent variations (VGDPpc) and HDI percent variations (VHDI) over a five years horizon. The data on VGDPpc and on VHDI are presented on Table no 1.

Secondly, we have calculated the following correlations with the aim of verifying if the data on GDPpc for each European State are more related to European area than to the macro-region to which each State belongs:

- CEU: correlation between GDPpc of each State on yearly basis between 1990 and 2010 and the European yearly average of GDPpc;
- CEUc: correlation between GDPpc of each State on yearly basis between 1990 and 2010 and the European yearly average of GDPpc. This average was corrected by removing the GDPpc value of the considered State;
- CMR: correlation between GDPpc of each State on yearly basis between 1990 and 2010 and the yearly GDPpc average of the macro-region to which each State belongs;
- CMRc: correlation between GDPpc of each State on yearly basis between 1990 and 2010 and the yearly GDPpc average of the macro-region to which each State belongs. This average was corrected by removing the GDPpc value of the considered State.

Finally, we have determined the following differences in order to highlight if data on macro-regional basis describe data on national basis better than data on European basis: DIF (difference between CMR and CEU) and DIFc (difference between CMRc and CEUc). The obtained values are shown in Table no 2.

Table no 1 - *Percentage variations of data on GDPpc and HDI for European States from 1990 to 2010*

3. The result of the research

Each of the four macro-region N, C, E and M is characterized by a peculiar dynamic of economic growth. Indeed, the VGDpc analysis shows that, for some States, macro-regional dynamics are more significant than the European ones. This is particularly evident in the region E whose values of economic growth are higher than 100% over the period 2000-2005 (see Table no 1). The VHDI analysis reveals, on one hand, that macro-regions with the lowest values of GDPpc are characterized by a great internal variability, and, on the other hand, that macro-regions with high values of GDPpc are typified by a level of HDI which varies according to their typical ranges of VHDI. Moreover, the study of the correlation of GDPpc (see table no 2) shows that States belonging to macro-region E are strongly correlated with macro-regional data.

If we focus on VGDPpc, it is possible to note (see Table no 1) that the variations of each macro-regions are coherent in both sign and value. In general, the range of variation is between 14% and 30% for each macro-region. In particular, it is between 39% and 69% for E, between 16% and 30% for C, between 17% and 36% for M, and between -5% and 19% for N. It is possible to identify best in class States for each macro-region. For example, if we look at E, the economic growth rate of Poland and Hungary is high, above all over the period 1995-2000, and then, it tends to coincide with the economic growth rate of the macro-region they belong to.

Then, if we pay attention to VHDI (Table no 1), it is possible to note that there is a variability which is higher than the variability related to VGDPpc. The VHDI trends are characterized by a high variability within the macro-regions with low values of GDPpc rather than within the macro-regions with high values of GDPpc where the values of HDI varies according to the typical macro-regional ranges of VHDI. For example, if we consider N, there is an increase of 4% over the period 1990-1995 and a growth of 0,80% from 2005 to 2010.

Now, it is important to observe if the data on GDPpc for each European State are more related to European area than to the macro-region to which each State belongs. On this regard, when DIF and, more specifically, DIFc (see Table no 2) assume positive values, the macro-regional dynamic explains the data better than the European one. Moreover, the data on GDPpc for 17 States out of 28 are more correlated to CMRc than to CEUc. Specifically, in E, 7 States out of 9 are more correlated to CMRc than to CEUc whereas in N, the most of countries is more correlated to CEUc. Hence, the average value of macro-regional GDPpc reasonably well represents the potential dependence of each State on macro-regional dynamics.

Table no 2 - *Correlations between national GDPpc and European GDPpc and macro-regional GDPpc*

made by the authors

4. Conclusions

The analysis of the data on GDPpc reveals that European States with low values of GDPpc are more linked to the macro-regional trend than to the European one. In particular, the values of GDPpc are better explained by the average values of the macro-region to which each country belong than by the European average values. This is verified by a corrected correlation which is calculated by removing the value of the considered State from both macro-regional and European averages. The percentage variations of HDI are slightly different from the ones of GDPpc. The analysis of the variations of both GDPpc and HDI show that States with high values of both GDPc and HDI are rather tightly linked to the dynamics of the macro-region to which they belong. In conclusion, the macro-regional dynamics especially influences the States with low values of both GDPpc and HDI. Therefore, in an era of globalization, it is still fundamental to take into consideration the socio-economic characteristics of macro-regions in order to understand the European dynamics of development.

CHANGES IN CONSUMER'S BEHAVIOUR ON THE ROMANIAN RETAIL MARKET IN THE CONTEXT OF ECONOMIC CRISIS

Catana Adina
Faculty of Economics, University of Oradea

In order to observe the impact of the economic crisis of consumer's behaviour on the Romanian retail market, I focused my research on the evolution of consumption expenditure of households. I studied aspects from European Union and Romania. The study is based on the research taken in the project of PhD research with the theme: The impacts of Economic Integration on Romanian Retail. I used data from Eurostat, the Romanian Statistical Institution, specialised studies etc.

1.Introduction

The global economic crisis, through its effects, caused changes in consumer behaviour. A new character was identified, the wise consumer, which is more judicious in shopping and considers the prospects for the future. It changed the consumer life in general, and how he/she makes buying decisions. The effects of the crisis are multiple: lower income, rising prices, rising unemployment, job losses, loss or fringe benefits, increase loan rates due to the devaluation of currency. All this leads to redefining income destinations, sense of fear, uncertainty, etc. In crisis consumers have lost their optimism, they had to postpone and rethink their future projects, reduce expenditure for less necessary goods, limit to the main needs, reduce maintenance costs of housing, and they were limited in consumption and home activities searching ways to support consumption at home, therefore consumers have resorted to limiting consumption. (money.ro, 2010)

Consumption expenditure evolution in the European Union

In order to determinate the consumption evolution in Europe, I used data from Eurostat: the consumption expenditures of households at each EU member countries, data in percentage changes household consumption expenditure also nationwide.

Figure 1: The consumption expenditure evolution of EU member countries during 2000-2013
Source: the author according to the data available on Eurostat

From the chart above we can see changing developments in consumer spending for households in all the states of the European Union. Thus, the total consumption in the European Union fell with 2.2% in the year of 2009 compared to 2008. Most affected by the economic crisis were states like Portugal, with a decrease in consumption by 2.4% in 2009 compared to 2008, Estonia with a decrease of 1.8%, Spain with a decrease of 1.1, %, France with a decrease of 1.1% in 2009 compared to 2008 when there was registered an increase of 3.6% over the previous year. In Lithuania, the consumption expenditure of households increased by 3.2% in 2009 compared to 2008, when consumption had increased by 10% over the previous year. A similar situation was found in Romania where consumption grew by 3.8% in 2009 compared to 2008, year in which it recorded an increase by 10.1% compared to 2007, and Latvia had an increase consumption by 3.1% in 2009 compared to 2008, when consumption increased by 15,8 % compared to the value registered in 2007. The economic crisis produced no negative effects on Iceland, where the expenditure consumption increased by 12% in 2009 compared to 2008 and with 11.6% in 2008 compared to 2007. (Eurostat, 2011)

In 2010 there weren't any decreases in consumer spending, but there were registered procentual increases of consumption with values ranging between: 0.1% in Czech Republic, 1.2% in France, 1.4% in Italy, 4.3% in Iceland and 4.5% in Hungary. (Eurostat, 2011);

3. Consumption expenditure evolution in Romania during the last decade

Romania is a country with the most significant evolution of consumption in Europe and is one of the largest markets in terms of population (7th place in the European Union after Poland), and the country with the highest GDP growth during 2005 and 2008. (Contrast Management Consulting, 2011).

Also, the Romanian retail market recorded the highest growth rate from the Central and Eastern Europe region in the last 10 years. However the average amount spent by a Romanian consumer is still less than half compared to the European average (23%).

Figure 2. Evolution of final consumption expenditure of households from Romania during 2002-2013
Source: the author according to the data available on Eurostat

Thus, as can be seen in Figure 2, there were significant increases of consumption in Romania: 20.2% in 2002 compared to 2001, 16% in 2003 compared to 2002, 10.1% in 2008 compared to 2007, and in 2009 when the economic crisis had led to a reduction of the revenue, increasing unemployment etc the consumption expenditure registered a smaller increase, by 3, 8% compare to 2008. In 2010 there was an increase in consumption by 7.9% compare to 2009, while in 2011 consumption increased by 6.1% over the previous year.

Projections for the following years are meant to increase, those with 2.65%. In 2012 compared to 2011 and by 7.3% in 2013 to 2012. (Eurostat, 2012). Increases in recent years have been lower due to the economic crisis, the imbalances in the economy, the uncertain political situation from Romania, etc.

In this period, Romanian consumers had to give up certain activities (GFK România 2010), in the way in which they:

- spent 32% less money on clothing and footwear;
- reduced holidays and travel expenses by 28%
- allocated 25% less money for savings and investment;
- spent 23% less on having dinner with friends, 21 % less on dining outdoors;
- decreased by 20% mobile costs;

- reduced 19% budget for housing decoration;
- reduced 18 % electricity costs that households own;

Consumers have turned to other activities such as receiving guests at home, walks in the park, watching movies at the cinema. According to a study by the European Audiovisual Observatory, in Romania, in 2009 cinemas have reported earnings 70% higher than in 2008. If in 2008 cinema tickets were sold in the amount of about 46 million lei in 2009, cinema receipts were over 78.2 million lei. (kappa.ro, 2010)

Studies (http://ww.kappa.ro, 2011) show that in 2010, 10 million Romanian consumers have been affected by the economic crisis, especially in the manner of reducing extra-wage incomes and 2.1 million peoples had lost their jobs. People with an average and low income were the most affected by the crisis effects in 2009. They cancelled almost all projects in order to survive. For the population with high incomes, the impact was more on psychological level, but they became more moderate, more cautious, delaying taking the decisions to projects than the financial impossibility to would bring them fulfilment. (financiarul.ro, 2010).

A similar evolution had the consumption credit. During 2004-2008, there was a period of expansion in consumer loans, placing Romania in a different situation compared to other states of the European Union: loans balance of the consumption is significantly higher than prime mortgage balance. Currently, the share of consumer credit in the total balance of loans to population is of 66% in Romania and in the euro area its share only of 13%. Banks in Romania have ongoing consumer loans that are worth 16 billion or the equivalent to 13% of the GDP, well above the euro area of 7%. Exuberance with which banks have granted such loans in recent years has generated the problems that now the banking system is facing, meaning that consumer credit arrears are much higher than mortgage (businessday.ro, 2010).

The decrease of incomes determined the increase of the income rates in total disposable income so the available budgets for consumption fell. Consumers have become aware of the promotions in stores, the main anti crisis traders lever, focusing on cheaper products, including the brands owned by the stores. As evidence, discount store chains have opened most new sale items between 2008 and 2011. Currently, the retail stores, the discount stores are preponderant, counting 365, and the superstores that are in a number of 224. Most of the discount stores were opened in 2007-2009, namely 46 in 2007, 52 in 2008, and 86 in 2009. In 2010 the number of new stores decreased as a negative effect of the world economic crisis, the decline of the consumers' purchase power and their orientation towards purchasing necessities at low prices. (financiarul.ro, 2010).

The main effects of the economic crisis in terms of consumer's behaviour lead to a reorganization of the budget for shopping and thus to reshape its life style. Consumers will be more careful, more judicious in consumption.(money.ro, 2010).

Studies show that the mood of the Romanian consumer has changed dramatically in the last years; on top of the list of consumer concerns were aspiring to a better standard of living and more comfort, now the mood of the Romanian consumer is characterized by uncertainty, fear and a sense of vulnerability (money.ro, 2010).

4. Trends regarding consumers and retailers behaviour

Although consumers have not yet recovered after the shock created by the economic crisis, however, they have changed their behaviour regarding consumption, being forced to adapt to a new lifestyle. Starting from this fact, various researchers made predictions about consumer behaviour, considering that they will adopt a long-term behaviour inspired by a new set of values, modified by the economic crisis. Several trends (Comăneci, 2011) were identified:

-*Consumers are prepared for hard times*. Left with the feeling that proved to be an economic collapse caused by the global recession, consumers will adopt future preventive behaviour,

considering savings and investment as priorities. Consumers would be better informed before making purchases, choosing products that will be efficient and provide long-term benefits, trying to be careful and find on time the hidden additional costs of products or contracts;

-*Retail Trade Renaissance*. Along with the rapid development of the online commerce experience, offering discounts, there isn't a wining battle against the Internet. Many consumers recognize that they chose to buy products at reduced prices, or expect the time when promotions are announced. Traders need to become more creative and work harder to attract customers to stores. They should be able to offer more than selling a product. Services must be extended to advice and demonstrations, while exclusivity and design concept of selling space should provide to the client a picture of the real world as opposed to the virtual world experienced when buying on-line;

-*Interest in the intellectual preparation*. The economic uncertainty caused changes in the perception of the job. As a result, consumers show increasing interest in studies that provide a higher qualification. In future, companies could invest more in training and the continuous education of employees, than other paid benefits.

-*Identifying new markets.* People often work, even after the time when they can retire because of the financial needs or because they are attached to a particular lifestyle. Thus, this untapped market may become a target group for different companies producing various beverages, foods, or other products with aging properties. In UK, almost one quarter of women under the age of 18 and one third of men are overweight, also more than 30% of children. This could become a market niche by creating obese services: catering, with controlled meals, nutritional products with more information on the packaging, etc.

-*Choice for organic products.* Modern urban dwellers increasingly express the need for more natural products, organic, finding different ways for consumers to have access to such products. In U.S., 26% of users have purchased vegetable seeds online, 19% have bought fertilizers for vegetables and flowers, and 27% grow vegetables at home. In UK one in five consumers grows vegetables and fruit. In U.S. 40% of people have a garden and grow vegetables and fruits. This could also increase the demand for rural tourism, farm holidays, and can exploit a niche market, consumers of seeds of vegetables and fruit and other auxiliary products used for cultivation.

5. Conclusions

On the analysis of consumer household budgets in the European member countries, especially Romania, I identified the following aspects of consumer behaviour:

In Europe, the trend between 2000 and 2008 resulted slightly flattening at the top of the regional income distribution band, caused in particular by substantial relative falls in regions with high levels of income. Over the same period, the 10 regions at the bottom of the scale, all in Bulgaria or Romania, caught up by a range between 4.4 and 12.0 percentage points compared to the EU average.

Romania is a country with the most significant evolution of consumption from Europe, is one of the largest markets in terms of population (7th in the European Union after Poland), and the country with the highest GDP growth during 2005-2008.

This upward trend is expected to continue over the next ten years, when the prediction is of an average increase of 5% per year for the Romanian market. The main pillars that will support this growth are: increasing the purchasing power of the population, the further expansion of modern trade sector and changes in consumption behaviour.

Today, customers are better informed and have higher expectations from retailers. They expect stores to offer products at good prices to help them save money. Buyers are armed with a lot of information and change easily a brand to another. Stores are facing the new behaviour of consumers which arises from the fact that they have become more educated and better informed about products they wish to purchase. Consumers are increasingly seeking safety, healthy

experiences no matter if it is about goods or services. Shopping places become for consumers as important as the products they buy.

Beyond the negative effects of the crisis we can identify the positive effects like those that have forced temperance to the Romanians' behaviour which now make their purchasing decisions. Consumers will spend less money on unnecessary expenses, will be more cautious and will not spend money of products that are not meant to satisfy their most fundamental needs, and those who have difficulties in paying rates on loans will not contract loans before they inform themselves better.

Constraints caused by the behaviour of the consumer forces companies to seek innovative solutions, unique, creative, which can lead to the revival of the industry. Similarly, since 2009, all merchants have operated cost savings that had as consequence significant efficiencies in their activities. In fact, everyone has to get used to living in an unpredictable climate and learn lessons from crisis.

DEVELOPMENT STAGE OF RETAIL TRADE IN THE EUROPEAN UNION

Catana Adina
University of Oradea, Faculty of Economics

According to Karel De Gucht, Trade Commissioner from the European Commission, trade is working for Europe's economic recovery by ensuring growth and jobs. The European renewed trade strategy will open markets and connect Europe to the main sources and regis of global growth. The aim is to ensure that European business gets a fair deal and that countries' rights are respected so that all can enjoy the benefits of trade.
Thanks to the ease of modern transport and communications, it is now easier to produce, buy and sell goods around the world which gives European companies of every size the potential to trade outside Europe.
This paper's objective is to analyse the development stage of the European Union's retail, and its member countries. The study is based on the research taken in the project of PhD research with the theme: The impacts of Economic Integration on Romanian Retail. For my research I used data from Eurostat, National Statistical Institute, European Union official website
In the past 10 years, the volume of retail trade in EU member states has increased, but the extent of the changes varies substantially from one country to another.

Key words: commerce, development, transformation

1. Introduction

In Europe, in the past 50 years, retailing has evolved differently from one region to another, the result of this process focusing on the commercial development of heterogeneous systems (different) from one country to another. Retail trade owes in each country its own configuration and influences originated in the culture, tradition, economic context and the legislative, climate or religion. Regardless the geographic location the essential merit in the realised structural changes is mainly the responsibility of economic operators may they be producers or traders. (European Commission, 2011).

2. Characteristics of retail trade in European Union

In the last decades, retail activity was marked by numerous evolutionary trends that have led to a number of changes including the following (Patriche, 2000, p):

- concentration, reflects the increases of the number of big operators and vertical connections that are established between producers and middlemen;
- transformations due to the differences between countries, the deceleration of the increase rate of hypermarkets in developed countries, the franchise expansion and the development of distance selling;
- the diversification of the activity through its involvement in other service sectors;
- internalization, by orienting towards consumer goods markets of other countries;

Activity's diversification manifests in the manner in which producers conduct retail operations, or offer to retailers certain consumer services: consulting, financing, product tastings, demonstrations, transport on the doorstep etc.

Internationalization begins by approaching the areas close to the member states because of cultural similarities. Consumption patterns become similar and thus the euro-consumer's profile is shaped.

Concentration is especially evident in developed countries, being accompanied by the rationalization of the direct retail sector, and also by the appearance of buying groups and voluntary chains, that offer the advantage of economies of scale. Wholesale operators, are often considered to be remnants of the past and are removed, either due to the manufacturer's desire to control himself the distribution process of commodities, as a consequence to retail companies practices to expand inside marketing channels. (Patriche, 2000, p.62).

Retailers have rapidly become multinational forces. There can be observed the dominance of a growing minority of traders in this market. Each and every one of them fights for market shares as large as they can get in order to dominate the market.

For example, in several member states of the European Union, five main retailers represent over 70% of the agri-food products: Finland - 90%, Sweden - 82%, Slovenia - 82%, Ireland - 81%, Estonia - 79%, Austria - 79%, Germany and France - by 70% (Global Retail Concentration, Planet Retail, 2006).

Naturally, the concentration of power is not indictable unless it slides towards abuse of dominant position. The development of European purchasing groups itself where the supermarkets of different countries join forces to take over suppliers, contributed to the increase of the buying power of retailers, thus increasing the possibility that they may resort to restrictive and confidential agreements with competitors, by exchanging information that exceed national borders of the member states. In 2005, of the eight largest retailers - Carrefour (France), Metro Group (Germany), Tesco (Great Britain), Rewe, Schwarz Group, Edeka (Germany), Auchan (France), Aldi (Germany) - seven were operating both in Central and Eastern Europe and Western Europe. Edeka is the exception. The first four retailers mentioned above are the largest chain stores as market share in both regions. (A. Vass, 2008).

Large units of retail are multiplying considerably.

3. Retail development in the European Union in the last decade

Since 2000 retail trade in the European Union grew steadily and reached its peak in early 2008. The ascending trend of retail activity was interrupted by the economic crisis that caused a decline in the evolution of this activity, which lasted until mid-2009. Since then, retail trade increased again, and after a year it reached the value recorded for 2007.

Figure no.1. Retail developments' evolution in the European Union between 2002 and 2011
Source: Created by author based on data taken from Eurostat

Figure no. 1 shows the evolution of the value of retail trade in the European Union, during December 2010 and up to November in 2011.

During this period, growth was stopped and the volume of retail trade remained almost unchanged.

In recent decades, household consumption has seen many changes (Pop Cohuţ I, 2004, after Didier M, 1998, p.33), passing from the concerns for buying products strictly for maintenance of life - food, clothing, housing - to goods and services to follow and embellish life. These changes were caused by:

- mass production's expansion,
- the occurrence and perfection of means and communication systems,
- the continuous increase of the level of education of the population,
- the revenue increase;
- the increase of leisure time etc.

In this context, the study of family budgets revealed some clear trends of consumption's restructuring. Among these concerns are those of the German economist Engel, who noted that comparing the evolution of different consumptions with the evolution of the national revenue, others more slowly, while others, have the same rhythm. These observations were the basis for his laws regarding consumption. Engel's laws reveal the existence of a hierarchy of needs:

- in the situation in which the standard of living is lower, the most urgent needs are the first to be satisfied: food, clothing, housing;

- the increase of the standard of living primarily is reflected in the goods that aren't indispensable, as: leisure time, transportation, vacations (health care expenses represent a special case because they are supported mainly by social security);

- a consequence of this law is that the part of the budget intended for relatively useless goods increases when the income increases. Therefore, some have considered that due to the this law, rich companies will tend, more and more, to transform themselves into services company, these being part of luxury goods.

Figure no.2. Retail evolution on groups of goods in the European Union during December 2010 - November 2011
Source: Created by author based on data taken from Eurostat

Figure No. 2 represents the evolution of trade in different product categories, depending on the distribution of the expenses regarding on commodity groups: food, beverages and tobacco, non-food products, motor fuel, as the analyzed period was between December 2010 and November 2011. Of the three product groups, the largest sales were recorded by fuel, followed by food and non-food products. The highest sales are for fuel, these figures being recorded due to high prices of these categories. It can be seen that non-food products have registered higher values than food products, and according to Engel's law it can be stated that the buying power of European citizens has increased and therefore the available income meant to satisfy superior or luxury need has increased.

Retail volume of food products (plus beverages and tobacco) reacted stronger during the time of the economic and financial crisis than the volume of trade with non-food products. However both groups of products developed in ways largely comparable. Retail volume of fuel (sold in specialized stores, of filling and certain stations) followed a less clear tendency since 2000, with higher sales in 2003, 2006 and the beginning of 2008 and a constant decline since then.

Figure no.3. Retail trade evolution in the European Union countries during 2001 and 2010

Source: Created by author based on data taken from Eurostat

424
Figure No. 3 shows that the volume of retail trade in the member states of European Union, generally increased in the last decade, but the magnitude of the changes differ substantially. Between 2000 and 2007, retail trade volume has doubled in Romania and Bulgaria, Estonia, Latvia and Lithuania. Between 2001 and 2006, can be observed increases of 50% or higher in Slovakia, Slovenia, Czech Republic and Ireland.

In all these countries, development stopped between 2006 and 2008 when the retail trade volume dropped significantly. However, the general development in the last 10 years for these countries is still positive and the increases of the total retail volume is still higher than for the rest of the European Union.

Retail trade had a similar development pattern in other countries, where it had registered increases of 30% or greater in: Cyprus, Hungary, Denmark, Greece and Spain.

An exceptional development of retail trade was in Poland and Luxembourg, which were not affected at all by the economic crisis. Retail trade increased between 2011-2010 with more than 50%.

Positive evolutions with no significant effects during the crisis could also be seen in the United Kingdom, France, Sweden and Finland (in these countries the decrease due to the crisis in 2009 was compensated a year later.

In countries like, Malta, Germany and Italy, retail volume declined between 2001 and 2010. In these countries, the crisis was perceptible and retail declines were felt since the middle of the last decade.

In practice two forms of retail can be identified, that is modern trade represented by stores with large areas for sales and traditional trade, which incorporates shops located in neighbourhoods with small lots. Since the emergence of the first large stores the weight of modern trade in the total value of commerce is growing at the expense of traditional, its share reaching values up to 50% in developing countries and up to 70-80% in developed countries.

4. Conclusions

From the analysis of retail in the European Union, we can draw the following conclusions:

Now, the retail trade in the European Union has the following characteristics:

-concentration, reflected in the increase of the number to big operators;

-the deceleration of growth rhythm of hypermarkets in developed countries,

-the diversification of the activity through its involvement in other service sectors,

-internalization, by orienting towards consumer goods markets of other countries.

The volume of retail trade in the member states of the European Union, generally increased in the last decade, but the magnitude of the changes differ substantially from one country to another. The ascending trend of retail activity was interrupted by the economic crisis that caused a decline in the evolution of this activity, which lasted until mid-2009. Since then, retail trade increased again, and after a year it reached the value recorded for 2007.

The highest sales, according to products' category were fuels, followed by non-food goods, and food, beverages and tobacco. This fact is due to higher fuel prices, in all EU countries. It can be observed that non-food products are better sold than food products, because due to the increase of the standard of living the allocated sums for services of the disposable income, are rising.

UNDERGROUND ECONOMY, GDP AND STOCK MARKET

Căuş Vasile Aurel
University of Oradea
Faculty of Economic Sciences

Economic growth is affected by the size and dynamics of underground economy. Determining this size is a subject of research for many authors. In this paper we present the relationship between underground economy dynamics and the dynamics of stock markets. The observations are based on regression used by Tanzi (1983) and the relationship between GDP and stock market presented in Tudor (2008). The conclusion of this paper is that the dynamics of underground economy is influenced by dynamic of financial markets. Thus, using specific stock market mathematical tools analysis, one can analyze the dynamic of underground economy.

Keywords: underground economy; currency demand; stock market volatility; wavelet analysis.

JEL Classification: C30, G12

Introduction

Underground economy size, scourge that touches all the world economies has values that can not be neglected. Therefore, between the fundamental principles underlying fiscal policy there is the one regarding the control and it level reducing. All paperworks that refer underground economy point out two important aspects: its inconsistent definitions and measurement difficulty. In this paper we try to address only the second aspect, which is measuring the size of underground economy. We use the widest definition of underground economy that is one which considers underground economy as all economic activities whose results are not in the GDP.

Emphasize from the beginning, that underground economy can not be measured directly and therefore any method that allows a good approximation of it is welcome. First we provide an overview of the main methods for estimating the size of underground economy (Caus, 2011)

Methods for estimating the size of underground economy

Literature refers mainly to three lines of approach to the process of determining the size of underground economy:

a) Issuance by the authority of speculative value, taking actions to counter and measuring results;

b) A second direction is based on logical reasoning and a good knowledge of economic activity (formal and informal). This method calls and international comparisons with countries which have a similar structure in terms of economic, legal and cultural;

c) A third line is the estimates based on clearly defined evaluation methods, for which calculation methodologies are developed, methods based on the same idea, namely that the economy scars that appear on the labor market, monetary aggregates or as disagreement between income and expenditure form.

In this last way of determining the size of underground economy the following general approaches are known:

- methods based on national accounts system;
- evaluation based on data from fiscal controls and other control methods;
- methods using macro-economic modeling.

Methods based on national accounts system

A way of measuring the underground economy in this group of methods is to compare the results achieved in national accounting records, in the determination of GDP by two approaches: income approach and expenditure approach. In general, calculating national product in terms of providing income figures lower than those obtained by summing costs. "Unexplained residual" set up by the

spread between the two units can serve as a basis for estimating size of underground economy. These methods have several drawbacks, among which most important are (OECD 2002):

− errors in estimating both units;

− errors caused by differences in statistical coverage;

− GDP estimates are not always independent estimates based on income tax (unnoticed revenue by the tax authorities may be absent in the national accounts).

We present some examples where these methods were used:

- in 1965, Ray M. (1965) calculated that 52.44% of income that would have been collected from the tax on goods movement in Italy was stolen from taxation. His method was based on identifying consumption and gross domestic product and estimates the amount that would have paid versus what was actually paid;

- Pissarides and Weber (1989) concluded that the unobserved economy represented 5.5% of GDP in the UK;

- Feige and MeGee (1983) find that the underground economy represents 10% of gross domestic product of Sweden.

Evaluation based on data from fiscal controls and other control methods

This evaluation method is based on data obtained from authorities as a result of direct checking, ignoring thus voluntary responses, based on questionnaires. This method emphasizes those professions declaring less income than real one. Fiscal outcomes are applied, by extension, to the entire population.

Methods using macro-economic modeling

a) Monetary transaction method

The existence of the underground economy is closely linked to the monetary area, in particular by strong inclination to liquidity, which shows those working in this field. The reason for this behavior is obvious: cash transactions are less visible than banking.

Monetary transactions method (method of Feige 1979) assumes that there is a constant relationship in time between the volume of cash transactions and total GDP, official and clandestine. The method is based on Fischer's known quantitative relationship:

(1) $$M \cdot V = p \cdot T$$

where M is money supply, V velocity of money circulation, p price level and T the volume of transactions.

Observing the total money supply M, which includes both currency and deposits, total GDP size can be inferred. By deducting from it the official GDP, the informal GDP is obtained, as a residue in terms of GDP. The hypothesis that this assessment is built on is that the speed of money circulation, in the two sectors is equal.

b) Cash-deposits ratio method

Is widely used and is based on the ratio of currency in circulation and sight deposits. According to this, clandestine economy transactions are reflected in changes in the ratio of currency in circulation and sight deposits held in banks.

Gutmann (1977) states that this ratio is only affected by tax changes and regulations issued by the government, causing behavioral changes which are motivated by the desire of people to hide certain economic activities in order to avoid payment of taxes.

c) Liquidity demand method

Starting from the idea that the release of increasing amounts of high value denominations to facilitate payments is a testament of underground activities expansion, the authors try to accredit the idea that they could then determine the size of informal activities. This method, simplifying a very complex reality, gives early indications that show trends in this area, but not relevant informations on the size.

Contrary to statements by Gutmann, Tanzi (1980) assumes that the demand for liquidity is not only affected by tax changes in regulation, but also by other factors. However, Tanzi support Gutmann's idea that excess cash generated only by changing the tax regime is found, in whole, in the underground economy.

The underlying assumption of the method application for cash is: assuming that the speed of movement of currency is the same in the underground economy and official economy, any increase in demand for liquidity may indicate an expansion of underground activities. Using this method, Gutmann (1977) estimated that the informal economy represents 10% of legal activity measured.

Tanzi regression used is as follows:

$$(2) \quad \ln\left(\frac{C}{M_2}\right) = \beta_0 + \beta_1 \ln(T) + \beta_2 \ln\left(\frac{WS}{NI}\right) + \beta_3 \ln R + \beta_4 \ln(Y) + \mu,$$

where C/M_2 the ratio of cash and money supply, T is the taxation level, WS/NI is the ratio of total wages paid in cash and national income, R is the annual interest rate and Y is per capita income.

d)   Latent variables method

Unlike the first three methods using macro-economic modeling, latent variables method developed by Frey and Weck (1983) uses a much larger number of variables. Underground economy is estimated starting from variables changes which, on the one hand, affect the size and growth rate and, on the other hand, represents the traces which it leaves in the real economy. This method uses a technique (known as **LISREL** - **LI**near **S**tructural **REL**ations) which allows cross-comparisons of the relationship between unobserved dependent variables and explanatory variables.

The critiques on the monetary methods refer to the assumptions on which research is built:

−   involves choosing a base year, which requires a certain level of underground economy, the most often considered void;

−   cash transactions, even in this sector are increasingly being regulated by using checks and other modern means of payment;

−   speed of circulation of money, considered the same in the two sectors is very difficult to see even in the official economy.

e)   DYMIMIC method

A method different from the above is **DYMIMIC** method (Schneider 2002) (dynamic multiple-indicators multiple-causes), dynamic version of the **MIMIC** method (multiple-indicators multiple-causes). It takes into account multiple causes that determine the expansion of underground economy, and its multiple effects over time. The method is based on statistical theory of observable variables. In this case a single unobserved variable, underground economy size is used. It starts with a set of causes and a set of indicators that are influenced by the size of underground economy in order to identify the structurally dependency between these variables and the underground economy. This dependence is used to predict future changes in underground economy size.

f)   Method based on electricity consumption (physical input method)

It is one of the most popular methods using global indicators and one of the few methods based on the measurement of physical data. To measure all activities (formal and informal) in an economy, Kaufmann and Kaliberda (1996) considers electricity consumption as the single and best physical indicator for measuring activity throughout the economy. The study suggests that the increase of overall electricity consumption is an indicator for increased representation of official and unofficial GDP. Thus, the difference between the growth rate of official GDP and the growth rate of total electricity consumption is attributed to the growth of underground economy.

The main criticism of the Kaufmann-Kaliberda method is that not all economic activities require electricity consumption and, moreover, other energy sources can be used, therefore this method can not cover the entire underground economy.

GDP and stock market
In Cristiana Tudor's paper (2008) the following regression was tested, regression that links economic growth (expressed by increasing GDP / capita) and the stock market (BSE), in the case of Romania (note that we have adapted the notation to the notations of this paper and we take into account the fact that the author has specified that the logarithmic increase of the variables were used):

(3) $$\ln(Y_t) = \alpha_t + \gamma_1 \ln(X_{t-2}) + \gamma_2 \ln(Z_{t-2}) + \gamma_3 \ln(Q_{t-2}) + \gamma_4 \ln(W_{t-2}) + \hat{\eta}_{it},$$

where
X = volume of transactions on the BSE in year *t-2*;
Z = value of transactions on the BSE in year *t-2*;
Q = capitalization trading on BSE in year *t-2*;
W = number of issuers on BVB in year *t-2*;
Y_t is the indicator in year *t* (GDP growth/capita).

Gamma coefficients are the slopes of the regression equation and express the linear relationship of the four indicators to capital market development.
According to the article there is a positive link between capital market development and macro-economic development (with a time-lag of two years).
Underground economy and stock market
Relations (2) and (3) allow us to express C/M_2 ratios which (in Tanzi's view) is an indicator of the underground economy level, by the following regression:

(4) $$\ln\left(\frac{C}{M_2}\right)_t = \beta_0 + \beta_1 \ln(T_t) + \beta_2 \ln\left(\frac{WS}{NI}\right)_t + \beta_3 \ln R_t +$$
$$+ \beta_4 \ln(X_{t-2}) + \beta_5 \ln(Z_{t-2}) + \beta_6 \ln(Q_{t-2}) + \beta_7 \ln(W_{t-2}) + \omega$$

Equation (4) establishes a link between underground economy and major stock market indicators. According to this relationship the underground economy dynamic (which is found in the dynamic of C/M_2 ratio) is influenced by the level of taxation, the ratio of total wages paid in cash, the national income, the annual interest rate and the dynamic of stock market activities.
Conclusions
Given that regression (4) will be tested and may establish a relationship between volume of the underground economy and, among other things, stock markets dynamic there is a possibility to use finer mathematical tools to determine underground economy size. Wavelet analysis, which has applications in studying the behavior of stock markets, is one such tool.

Perrucci Antonella
University of Chieti-Pescara, Faculty of Management Sciences

The concept of development is not only referred to the level or to the growth rate of GDP of a country, but it concerns different aspects of individual and social life. Development leads to a changing of values, culture, behaviours and attitudes of people interested in it. That is to say that not only quantitative dimensions, but also qualitative ones became relevant in fostering development trajectories. Reasoning in these general terms a long and rich intellectual debate grow up in social sciences within which we focused the social capital and firm network debate. Social capital is a multidimensional determinant at base of the industrial district framework as the "network capital" represent a driver of firm's network framework.
By moving from social capital, as a local development driver, to network capital, as a global development driver, the present paper analyzes the firms networks determinants by identifying the conditions for some European countries. The methodology through which the results are obtained is the multidimensional scaling method which allows to define relations between countries in terms of proximity/distance with respect to the considered determinants providing a spatial representation of them.

Keywords: social capital, network capital, firms networks, multidimensional scaling.

JEL code: D71, R23 Z1, Z13

1. Introduction

From a theoretical point of view, modern political economy has developed by depriving economic interactions of their social content. Despite that a stream of research programs grow up in order to replace social interactions within the development issue. Among them the social capital concept became more and more a debated argument, by moving from the belief that the economic activity is deeply embedded in the social structure, and agents' decisions are always influenced by a wide range of social and cultural factors. Firstly discussed within the sociological boundaries (Bourdieu, 1986; Putnam, 1993; Granovetter, 1985) the concept of social capital affected also economy (among other Becker, 1974 and North, 1990; for a critical overview see Sabatini, 2005). As a matter of fact the several perspectives on social capital derive from heterogeneous academic backgrounds and frameworks, but they all agree on the ability of certain aspects of the social structure to generate positive externalities fostering competitive advantage for members of a group (Sabatini, 2005). An exhaustive review of the different approaches on social capital falls behind our aims; what we stress in this paper are the positive outcomes that a social structure and the following interactions exert on firms productive capabilities. It's widely acknowledge about these outcomes. A social structure fuels the agents interaction and consequently increases the better diffusion of trust and information. That is to say that an increase in trust-based relations reduces the average cost of transactions, just as an increase in physical capital reduces the average cost of production. Moreover the

circulation of information reduce uncertainty and the free-riding effect on the market. These mechanisms were at the base of local economic development patterns, providing a credible explanation for growth differentials among regions with similar endowments in terms of the other forms of capital. We are talking about the industrial district framework that characterized the Third Italy's development model (Bagnasco 1977; Becattini 2000). About economic outcomes of social capital we argue that they strictly depend on social and historical circumstances in which social interactions are located, that's why many marshalliani scholars talk about social capital and local development. What about a wider context? As Simpson (2005) argues in a globalised context grow up a new type of social capital, known as "network capital". It is formed from collaborative practices in a human network. Network capital is the expression of social capital in the Information Age. It exists making use of ICTs, because it is a result of cooperation via electronic networks. That's why by moving from social capital, as a local development driver, to network capital, as a global development driver, the present paper analyzes the firm's networks determinants identifying the conditions for some European countries. The paper starts with a brief overview of the topic of firms network (see par. 2). In the second section, a data analysis using a multidimensional scaling methodology is provided, in order to identify groups of countries that show similar characteristics in relation to the chosen indicators (see par. 3). At the end, some brief concluding remarks, that summarize the results achieved by the analysis, are given (see par. 4).

2. Firms networks

Globalisation has brought undisputed changes on competitive field and the way of communicating. It has increased the importance to cooperative networks and business in international markets. In this context a new type of social capital, known as "network capital", arises. Network capital is the expression of social capital in the Information Age. It exists making use of ICTs, since it is a result of cooperation via electronic networks (Simpson L. 2005). Firms can also create collaborative relationships even if these are located far from each other.

The networks' roles are multiple, since they may accelerate the innovative process, increase the capability for continuous learning, combine some specific functions shared with others, stimulate scale economies, help to anticipate trends and changes within the society for new market opportunities.

The efficiency of a network enterprises depends on its stability and its survival is facilitate by three factors: degree of trust among partners, information and knowledge sharing, presence of a planning system.

There are different ways for classifying firms networks, since they constitute a phenomenon with heterogeneous characteristics and aims. There are the "natural networks" characterized by the absence of legal identity and structurally flexible. The "governed networks", on the other hand, have a high coordination degree. According to the strategic cohesion degree, there are the "diverged networks", the " mutual influence networks" and the "converged networks". The first ones usually reach efficiency and effectiveness advantages in the short-term. The second ones are mutually determining to pursue competitive strategies. The third ones represent the most appropriate organizational solution to achieve a common strategic plan. Depending on the integration degree, there are the "complementary networks", in which the technical-productive and economic ties among firms are very strong, and the "independent networks", which ignore the processes in the companies but create shared common interests.

Firms network relationships may increase the level of development since they allow to replicate information and knowledge, and overcome the physical distance problem. The

network expansion is based on important pre-conditions, fundamental for creating stable and global relationship: opening capability, security and above all ICTs diffusion.

3. Data, methodology and results

To reach our purpose, which consists in identifying conditions for network capital development in the European countries, we use a multidimensional scaling analysis.

Multidimensional scaling is a useful tool through which it is possible to produce a graphical representation of a pattern of objects, in this case the 27 European countries, based on the degree of similarity/dissimilarity between them.

The goal is to provide a representative map that best approximates the distances observed between countries, concerning the conditions for network capital development.

This statistical method attempts to build a configuration of the various entities, merged in a small number of dimensions. This is done by defining relations between countries in terms of proximity/distance with respect to the considered indicators. The resulting positioning map has the property to partition the countries into homogeneous groups, so as that the degree of association between two countries is maximal if they belong to the same group and minimal otherwise.

We considered a matrix of 27 Eastern European countries and indicators, representing 4 sets of variables: development background, national security, ICT diffusion both at firm and individual level (see Table 3).

In particular, we have selected the following indicators (source Eurostat):
1)   Opening capability
-       Persons with tertiary education attainment by age and sex (% of 15-64 years old), 2010
-       Number of airports (with more than 15,000 passenger movements per year) (per million of people), 2009
-       External trade of EU (export/import ratio), 2010
-       Total intramural R&D expenditure (Euro per inhabitant), 2010
2)   National security
-       Police officers (per 1000 people), 2009
-       Crimes recorded by the police (per 1000 people), 2009
-       Prison population (per 1000 people), 2009
3)   ICT diffusion at firm level
-       Enterprises using automated data exchange with other ICT systems outside the own enterprise, 2011
-       Enterprises using Internet for interaction with public authorities (demand side), 2010
-       E-government availability (supply side), 2010
4)   ICT diffusion at individual level
-       Broadband penetration rate (%), 2011
-       Frequency of Internet access: once a week (including every day), 2011
-       Internet use: interaction with public authorities (last 12 months), 2011

Data refer to the most recent year basing on their availability.

The model's goodness of fit was assessed via the RSQ (0.91), that indicates the proportion of variability explained by the corresponding dissimilarity distances, and the Stress Index (0.14). As a general rule, results are found to be robust when the size k achieves an Stress Index value lower than 0,15. A two-dimensional model was judged to be acceptable according to the values of the Stress Index, reported in Table 1. Further investigation provided additional basis for choosing the two-dimensional solution: the "elbow" rule

suggests to choose the number of dimensions in correspondence to where the diagram yields an "elbow", beyond which the broken line flattens (see Figure 2).

Table 1. Stress Index and map configuration

Dimensions	Stress Index
1	0,26
2	0,14
3	0,08
4	0,06

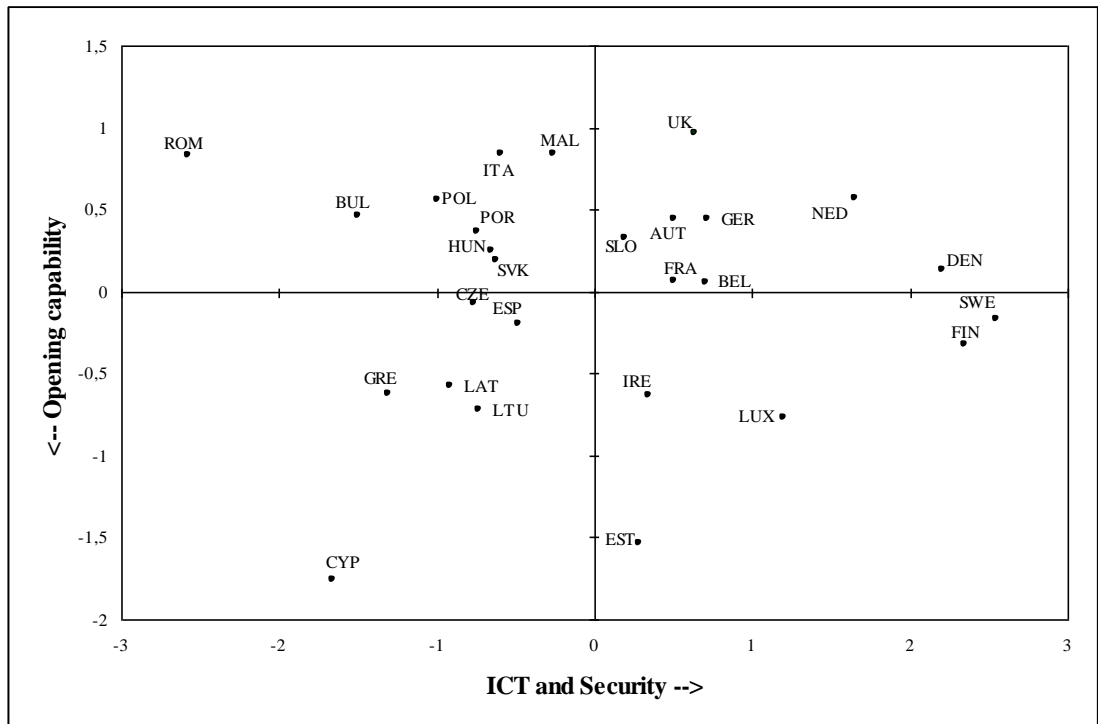
Figure 1. Scree plot
The correlations between dimensions and variables (see Table 2) were useful for naming the axes. The resulting two-dimensional image is shown in Figure 3. The horizontal axis represents the variables concerning ICT diffusion (both at firm and individual level) and national security; the vertical one is related to the opening capability.

Table 2. Correlations between variables and dimensions (r > |0,5|)

Variables	Dimension 1	Dimension 2
Persons with tertiary education attainment	0,54	-0,57
Total intramural R&D expenditure	0,89	
External trade of EU		-0,68
Number of airports		-0,58
Police officers	-0,53	
Crimes recorded by the police	0,83	
Prison population		
Enterprises using automated data exchange with other ICT systems		0,57

435

Enterprises using Internet for interaction with public authorities	0,59
E-government availability	0,59
Broadband penetration rate	0,84
Frequency of Internet access	0,93
Internet use: interaction with public authorities	0,93

Figure 2. Cluster of countries in a two-dimensional space


On the right of the chart is the northern cluster, which shows the highest ICT performances and efficiency in security; the group of central European countries, with levels of technology closes to the average values of the sample, lies on the centre; on the left is the cluster of Eastern and Southern European Countries, with its lower level of ICTs diffusion and safety efficiency. On the lower area of the chart there are some countries which show an higher opening capability with respect to the others.

4. Conclusions
In a globalised context, fuelled by ICTs, collaborative relationship among firms could happen, even if these are located far from each other. These stylized fact generated the so called "network capital". So by moving from social capital, as a local development driver to network capital, as a global development driver, we provided a preliminary analysis on some European countries, adopting the multidimensional scaling method that allows us to point out where conditions are more appropriate for firms network diffusion. It is worth to underline that this analysis is only a first step in such an investigation and shall not be

considered as exhaustive in order to thoroughly understand the reference dynamics, it can simply be useful for further and more detailed investigation.

SOCIAL CAPITAL AND INDUSTRIAL DISTRICT DEVELOPMENT: THE ROLE OF THE LOCAL GOVERNMENT

Furia Donatella
University of Chieti-Pescara, Faculty of Management Sciences

The paper represent a theoretical attempt to investigate the role that the local government can play in improving the level of social capital for the development of industrial districts. The social capital is not, as generally suggested by the socio-economic literature, an individual attitude towards something which does not imply privately appropriable economic benefits, as it is for a pure public good (which would not imply privately appropriable benefits). Social capital should be interpreted as a public component of an investment which implies private and public benefits entangled with each other. Firms could not have sufficient incentive to increase its investment in social capital, because this investment strictly depends on the economic convenience of investing in the impure public good. Starting from this point of view, we underline the importance of investing local public resources (funds, time and effort) for the development of the local social capital.

1. Introduction

Large body of research in the social sciences in the past decade underlined a positive relationship between social capital and economic success. Particularly, social capital may be the primary and leading key to the successful performance of an industrial district. Social capital, however, is frequently depicted as an impure public good, since agents face private incentives to create and preserve it, but such behaviour generates externalities. Therefore, local government can play an important role in the solution to the problem of free riding. Actually, scholars continue to debate existence, nature, measurement and impact of social capital as a conceptual framework. Before dealing with any other question, it is important, therefore, to clarify exactly what one implies while referring to social capital. Social capital has been defined in a number of different ways, but scholars generally refer to the ideas of Putnam (1995) and Coleman (1988). Putnam (1995: 664-665) defines social capital as a community-level characteristic involving "*features of social life – networks, norms, and trust – that enable participants to act together more effectively to pursue shared objectives*". In the Putnam's view, social capital refers to the quality of human relations within some well-defined group that enables its members to act in cooperation with one another for achieving mutual benefits. A wider definition is given by Coleman (1988: 598), who describes social capital as "*a variety of different entities, with two elements in common: they all consist of some aspect of social structure, and they facilitate certain actions of actors – whether personal or corporate actors – within the structure*". This concept is wider since it includes associations as well as the behaviour among other entities such as firms. Social capital, just like other forms of capital, is

productive and facilitates the attainment of goals that otherwise would not be possible. Accordingly, high stock of social capital increases individuals' and groups' ability and willingness to cooperate, improves monitoring and enforcement of contracts, and reduces free-riding and information asymmetry. Social capital therefore reduces transaction costs (see also Degli Antoni 2006), encourage innovation and dissemination of technology and thus leads to better economic outcomes. The most encompassing view – the one that has attracted plenty of interest among economists – also includes "*the social and political environment that enables norms to develop and shapes social structure*" (Serageldin and Grootaert 1997: 13). This broadest definition includes not only the largely informal and often local relationships, but also the more formalised institutions such as the government, the political regime, the rule of law, the court system, and civil and political liberties. This article is based up on this last definition. We argue it is essential to move away from "associative" based concepts of social capital as presented in Putnam (1993), toward frameworks where social capital is considered as an intangible capital stock with some public good-like properties . Economics and regional science literatures make a strong case that "*non-economic*" factors influence economic growth and development. Many authors argue that increased levels of social capital can create better chances for economic development than markets and political institutions. The idea of social capital has been used to explain phenomena varying from technology adoption to the formation of informal institutions. Scholars have attempted to document the various ways in which social capital can improve the performance of economic systems (see, for example Putnam 1993 and 2000, Fukuyama 1995, Levi 1998 and Cook 2000), both at the micro-level, focusing on household income, financial transactions, and the knowledge exchange between venture capitalists and new firms (Wilson 2000, Rauch 2001, Maula, Autio and Murray 2003, Cainelli et al. 2007, Bigsten et al. 2000, Fafchamps and Minten 2002) and at the macro-level underlining the important role that social capital can play in the growth dynamics (Kraybill and Weber 1995, Rainey et al. 2003, Rupasingha et al. 2000 and 2002, Rupasingha and Goetz 2007, Helliwell and Putnam 1995, Temple and Johnson 1998, Zak and Knack 2001, Beugelsdijk et al. 2004, Tabellini 2006).

Our analysis moves from these studies by treating the role of social capital and local institutions relationship in the development process of industrial districts. The paper is organized as follows. In section two, we describe the role that the local government can play in the provision of social capital is discussed. In section three, a theoretical model is presented, in which social capital is assumed as the public component of the impure public good provided by the local government, and the main implications of the model are discussed. Section five provides conclusions.

2. Investment in social capital and the local government role

Many economists argue that social capital should be described as an impure public good, since agents face private incentives to create and preserve social capital but such behaviour generates public benefits, or externalities. Collier (1998) was among the first to apply microeconomic theory in the analysis of social capital with an emphasis on the external benefits of social interaction. He states that "*[…] social capital is "social" because it generates externalities arising from social interaction. Both the initiation of social interaction and its consequences generate effects which are not internalized into the decision calculus of each agent*" (Collier 1998: viii). Social interactions may generate different kinds of positive externalities. They facilitate the transmission of information about the behaviour of other agents and this reduces the problem of opportunism. They facilitate the transmission of knowledge about technology and markets and this reduces market failures in information. So the presence of high level of social capital reduces information and transaction costs. When such a costs are reduced, less risk is involved and more exchange takes place, thus enlarging the scope of transactions and

interactions. Conversely, a lack of social capital results demand for more external controls such as tougher law enforcement, security systems, monitoring and enforcement (Rupasingha et al. 2000). Moreover social capital reduces the problem of free-riding and this facilitates joint action. The provision of public goods is subject to free riding if most users do not participate in collective actions to make the provision of public good a success. Conventional theories of collective action have concluded that individuals will resort to strategic behaviour by refusing to contribute toward the public good in order to obtain a benefit far greater than the cost they have to pay. When social capital is present, externalities are internalized, which has the effect of eliminating or reducing the free rider problem (Rupasingha et al. 2000). Because it generates externalities, social capital will be under-provided also in an industrial district where, despite the civic culture, agents have not sufficient incentive to increase their investment in social capital, because this investment strictly depends on the economic convenience of investing in the impure public good. The government's main policy could be to improve its provision. For instance, a firm in the industrial district may invest in R&D activities that require a cooperative effort. In this case, innovations are only partially owned by the firm and the investment may be thought of as one in an impure public good, that is each unit of investment produces both private and public benefits. The district benefits from positive network externalities, but the intentional production of joint social benefits is costly and public incentives may be crucial. Actual demonstrations of the effectiveness of investment strategies in social capital are rare. As Fernandez and Castilla argue, "*if the term 'social capital' is to mean anything more than 'networks have value', then we will need to demonstrate key features of the analogy to 'real' capital. If 'social' capital is like 'real' capital, we should be able to isolate the value of the investment, the rates of return, and the means by which returns are realized*" (Fernandez and Castilla, 2001: 85). Anyway, the local government can play an important role against certain kinds of opportunism and remove source of insecurity in such relationships and allow firms to cooperate with each other more efficiently.

3. A simple model

Our approach for assessing public resources to social capital in industrial districts is based on Brueckner's bid-rent model of property value determination (Brueckner 1979, 1982 and 1983). The result derived from this model is that efficient public good provision occurs at the level that maximizes aggregate value. In our model, firms are assumed to have identical functions of profit which depend on the level of social capital, *SC*, other local public goods, *G*, level of prices, *P*, human capital, *H*, and physical capital, *K*. All firms in a district benefit from the same level *SC* and *G*. Firms with the same level of financial resources must achieve the same profit level. Formally, a firm with resources *R* achieves profit $h(R)$ and her resources bundle must satisfy

$$\Pi(SC, G, P, H, K) = h(R). \qquad (1)$$

This equality is guaranteed since if a firm could achieve higher profit elsewhere, she would move. A firm's budget constraint can be written as K + W = R, where W represents the wages paid for H and the price of K is normalized to 1. Then, W must satisfy $\Pi(SC, G, P, H, R - W) = h(R)$. This equation determines the bid-wage function

$$W = W(SC, G, P, H; R). \qquad (2)$$

The bid-wage function specifies the wage necessary to equalize a firm's profit across differing level of *H*. Differentiating Eq. (2) with respect to *SC* gives

$$W_{SC}(SC, G, P, H; R) = \frac{\Pi_{SC}(SC, G, P, H; R - W)}{\Pi_{K}(SC, G, P, H; R - W)}, \qquad (3)$$

where subscripts denote partial derivatives. Eq. (3) shows that the required change in the wage resulting from a change in *SC* is equal to the marginal rate of return between social capital and physical capital, *K*. Similarly, the required change in the wage resulting from a change in *G* is

equal to the marginal rate of return between the other public goods and *K*. Then, assume that local revenues for social capital are financed exclusively by a local firm tax rate, t_{SC}, and the other public goods by a local firm tax rate, t_G. The tax rates are applied to the gross value of each firm *V*. By definition, one of the most important element that traditionally characterize the industrial district organizational model lie in a vertical division of labour that favours an accumulation of technical and production skills and competencies within the sector the firm belongs in (Bellandi 2003). Basing on the efficiency wage hypothesis, wages are higher than the market-clearing ones in order to increase the productivity or efficiency of labour force. From this point of view, the value of a firm is here defined as the capability of paying wages *W*.

Letting δ be the discount rate, the value of the firm *i* is

$$V_i = \frac{W - (t_{SC} + t_G) \cdot W}{\delta} = \frac{W(SC, G, P, H_i; R_i)}{\delta + t_{SC} + t_G}. \tag{4}$$

The aggregate value of an industrial district is here defined as the sum of the individual firms values within the cluster

$$V = \sum_{i=1}^{N} V_i = \sum_{i=1}^{N} \frac{W(SC, G, P, H_i; R_i)}{\delta + t_{SC} + t_G}, \tag{5}$$

where *N* is the number of firms in the district. Assuming that the local government contributes amount *S* to local district (the local community fully finances the other public goods, *G*, for simplicity), the cluster budget constraint is

$$(t_{SC} + t_G) \cdot V = SCC(SC, N) - S + GC(G, N), \tag{6}$$

where *SCC* and *GC* are (convex) cost functions for *SC* and *G*. The fact that cost is a function of the district size, *N*, reflects potential congestion costs. Combining Eqs. (5) and (6) gives

$$V = \frac{1}{\delta} \left[\sum_{i=1}^{N} W(SC, G, P, H_i; R_i) - SCC(SC, N) + S - GC(G, N) \right]. \tag{7}$$

Aggregate value is a function of the aggregate wages, the local government aid, the discount rate, and the production costs of social capital and the other public goods. Differentiating Eq. (7) with respect to the local government aid and assuming that changes in public resources for social capital have no effect on the provision of other public goods, i. e. $\partial G / \partial S = 0$, yields

$$\frac{\partial V}{\partial S} = \frac{1}{\delta} \left[\sum_{i=1}^{N} W_{SC}(SC, G, P, H_i; R_i) - SCC_{SC}(SC, N) \right] \frac{\partial SC}{\partial S} + \frac{1}{\delta}, \tag{8}$$

where, as shown in Eq. (3), W_{SC} is equal to the marginal rate of return between social capital and the physical capital, *K*. As a result, Eq. (8) establishes that $\partial V / \partial S = 1/\delta$ when the "*Generalized Samuelson Condition*" for the optimal provision of social capital is satisfied, i. e., the sum of the marginal rates of return between the social capital and the physical capital equals the marginal cost of providing social capital (a similar condition holds for all other public goods as well). Assuming that *W* is a strictly concave function of *SC* and *G*, that *SCC* is convex in *SC* and that *GC* is convex in *G*, it follows that *V* in Eq. (7) is strictly concave in *SC* and *G*. As a result, aggregate district value reaches a global maximum at values of *SC* and *G* where the Generalized Samuelson Condition holds, ceteris paribus. Thus, one can determine whether social capital is under-provided or over-provided relative to the district value maximizing level as $\partial V / \partial S = 1/\delta$.

Note that under or over provision of social capital may result either from productive or allocative inefficiencies. One might conclude that social capital is over-provided in a district in which the "*right*" level of social capital is being provided but the district is not cost minimizing.

Alternatively, the district may be productively efficient but not provide the value-maximizing level of social capital.

4. Conclusions

Basing on the literature on social capital mainly developed during the last decade, the aim of this paper was to investigate the role that the local government can play in improving the level of social capital for the development of industrial districts. The analysis conducted, both theoretical and empirical, helps to understand the role of social capital and local institutions in the development process of industrial clusters. Introducing a nexus of complementarity between cluster value and social capital, a good in a cluster of firms, the "*civic culture*" of the cluster area where the firm acts may not be a sufficient explanatory factor to increase the firm investment in social capital, since this investment strictly depends also on the economic convenience of investing in the impure public good. So the government's main policy could be improving the provision of social capital by assessing public resources, on the whole in the present age of increasing integration, where the possibility to compete internationally largely depends upon the ability to innovate and to increase labour force productivity.

ANALYSIS FOR THE DEGREE OF EUROIZATION IN ROMANIA

Dinu Marin
Bucharest University of Economic Studies Faculty of Economics

Marinas Marius
Bucharest University of Economic Studies Faculty of Economics

Socol Aura Gabriela
Bucharest University of Economic Studies Faculty of Economics

Euroization is defined as the adoption of the Euro currency by the authorities from a country outside the Euro area, as a legal currency and as an official currency, and this means that the country chooses to give up its national currency and that the national bank gives up using the monetary policy as an instrument of the economic policy. The objective of this study is to adjust the extent of meanings of the Euroization concept for Romania and to explain it under the terms of the optimum currency areas theory. Thus, an economy characterized by a high Euroization will be more ready to give up its national currency in the future, as that economy has passed the test of using the currency it wants to adopt. This study makes an analysis for the causes of Euroization, based on the economic literature and we have examined the forms of occurrence of Euroization in the Romanian economy, insisting upon the aspects related to the preferences of the economic agents for crediting and saving in the Euro currency. We consider that the increase of the Euroization degree may be considered an opportunity for the economies which propose to adopt the unique European currency, meanwhile constituting a vulnerability if adopting the unique currency is delayed and if that economy is affected by the external shocks which induce a depreciation of the national currency. The partial Euroization of the Romanian economy has encouraged the overheating of the national economy until 2008, but it fractured the adjustment capacity of the shocks by means of the monetary policy and of the rate of exchange. Thus, a partial Euroization acquired a characteristic of a unilateral Euroization, in which the capacity of the economy to neutralize the shocks gets decreased and the dependence on the decisions of the Central European Bank, respectively of the economic agents form the highly commercially and financially integrated countries with Romania gets increased.

Keywords: euroization;Euro area; financial integration

JEL codes: F15, F36

I. Introduction

Euroization is defined as the adoption of the Euro currency by the authorities from a country outside the Euro area, as a legal currency and as an official currency, and this means that the country chooses to give up its national currency and that the national bank gives up using the monetary policy as an instrument of the economic policy. Euroization supposes to give up its own currency and to adopt the Euro currency, before meeting the nominal convergence criteria. Actually, Euroization may be under several forms. One of them is that of setting up a monetary council according to the Euro currency, and this reduces the stabilization role of its own monetary policy. Another one refers to the unilateral Euroization decision, by accepting the Euro as currency, such as Kosovo, Montenegro and Monaco. The last form is the least met and it refers to the decision of the economic agents to achieve bank, trade operations in the Euro currency or to express certain priced in the unique European currency. The first section of this study makes an analysis for the theoretical meaning of this concept and the costs, respectively the benefits

associated to this decision, and the second part of the study makes a research of the degree of Euroization in the Romanian economy.

II. Causes of Euroization

Euroization is determined by certain European economies' desire to consolidate the trade relationships with the Euro area member countries, and also the need to import monetary stability and low inflation. Among the causes of Euroization, mentioned in the economic literature, we may also find: macroeconomic instability, the monetary policy regime adopted, the foreign exchange risk, and also the instability of the institutional and regulating environment. Another cause of Euroization is a volatile and unpredictable inflation, as well as the economic and political uncertainty cases. The countries with a higher Euroization are quite small countries, geographically located near Euro area countries, with political and trade relations with them. Unilateral Euroization protects the countries against the foreign exchange crises, but it cannot prevent other types of crises. For example, an unsustainable public debt or the worsening of the foreign unbalances may determine the international investors to withdraw their investments. Buiter and Graf (2002) consider that the unilateral Euroization allows a good entrance in the Euro area, thus avoiding foreign exchange crises. Nevertheless, the unilateral Euroization canno0t be considered as a substitute of the economic and monetary integration: it does not allow nominal adjustments during the convergence period and it prevents the market from assessing the sustainability of the exchange rate.

The unilateral Euroization contributed, in some of the countries, such as Kosovo and Montenegro, to a quick macroeconomic stabilization after an economic and political crisis. Nevertheless, Euroization involves long-term risks of financial instability associated to the loss of the function of lender of last resort, especially in the countries characterized by a low number of banks with foreign capital and with a fragile external position. Kosovo and Montenegro used the German mark as their currency and they unilaterally adopted the Euro currency, although they do not have an explicit agreement with the European Union which could allow it to them. Euroization is not a quick solution for the structural problems or for the stability policies. The economic benefits cannot be obtained if they are not supported by solid economic policies and by continuous reforms. These aspects suggest the fact that a high prudence is necessary in assessing the proper characteristic of the unilateral Euroization.

The most important costs involved by Euroization refer to the following:

1. **The loss of an adjustment mechanism for the economic shocks.** Euroization involves the loss of the monetary policy independence and the impossibility to use its instruments to correct the asymmetric shocks and to react in order to synchronize the business cycles with those of the Euro area. Euroization increases the uncertainty referring to the effects of the monetary policy. Due to the high degree of Euroization, the interest rate is an instrument with low efficiency in fighting against inflation. The Euroized economy should rely on other adjustment mechanisms in order to avoid the output gaps due to the asymmetric shocks or to the business cycles' non-synchronization with that of the Euro area.

2. **The loss of the function of lender of last resort.** The Euroization determines the loss of power of the domestic authorities in reacting to the pressures related to converting the credits into assets. Due to Euroization, the central bank can no longer intervene to provide emergency financing to the financial institutions facing short-term liquidity blockages. Under the terms of the total Euroization, the central bank has no longer the possibility to issue currency, and the last resorts lose their financing source. Thus, in order to avoid the liquidity crises, Euroization should be accompanied by providing alternative financing sources to the last resorts.

    The most important benefits generated by Euroization refer to the following:

- **Macroeconomic stability and lowering the rate of inflation**. Euroization encourages the macroeconomic stability by solving the credibility problems occurring when a central bank is not able to provide a low rate of inflation. Moreover, Euroization increases the financial discipline by eliminating the possibility to issue currency in order to finance the budget deficits. By implementing the monetary policy by the European Central Bank, which provides a higher credibility degree, the rate of inflation and the rates of interest in the Euroized economy are expected to be decreased towards the levels recorded in the Euro area countries. These benefits are much higher, especially for the countries which faced financial instability and where the monetary policy measures implemented did not decrease inflation.

- **Decreasing the risk premiums.** If they are determined by the evolutions of the rate of exchange and not by the country risk, then the Euroization should result in their decrease, because a sudden and massive depreciation of the rate of exchange will no longer occur. At the same time, Euroization could generate an improvement of the access to the markets with a low foreign exchange risk, with a more stable financial sector, respectively with a lower risk of sudden infusions of capital. Eliminating the foreign exchange risk and the eventual depreciation of the national currency, as well as the price stability, the unilateral Euroization allows a decrease of the rates of interest, of the financing costs and of the public debt (Schoors, 2002; Levasseur, 2004).

- **Development of the domestic financial sector.** Euroization is accompanied by a development in the financial sector, as a stable currency is a prerequisite for the financial development, resulting in a higher and more sustainable economic growth. The main benefits of Euroization are the decrease of the transaction costs, of the costs with information, of the foreign exchange risk premiums, stimulating investments and trade and macroeconomic stability. Eliminating the costs with the foreign currency exchanges is one of the major benefits of Euroization, saving costs proportionally with the number of transactions made in the foreign currency.

- **Economic and financial integration.** Euroization encourages the financial integration of that economy with those of the Euro area countries. Euroization encourages the trade integration, due to the elimination of the transaction costs and, as a consequence, the intensification of the trade with the Euro area member countries. Lower foreign exchange reserves are needed, as a margin of maneuver is no longer necessary by means of interventions to protect the rate of exchange, and to cover the imports, considering that most of them are denominated in the Euro currency.

- **Higher synchronization with the business cycle of the Euro area.** As a consequence of a higher economic integration, Euroization results in the increase of the degree of real convergence of the business cycles with those of the Euro area countries. Finally, the shocks will become more symmetrical between the Euroized country and the Euro area, while the business cycles will become more synchronized.

III. Occurrence forms of Euroization in Romania

Doing a short exercise, we may assume that Romania could decide to suddenly adopt the Euro currency, giving up its national currency. The significant advantage of such a strategy is the decrease of inflation at the level of the Euro area, without unemployment costs. Inflation in Romania would be equal to that of the Euro area, and the economic agents know this and, consequently, they correspondingly delineate their inflation expectancies. Thus, Romania benefits from the ECB credibility import, thus being able to obtain welfare benefits generated by the monetary union. Such a sudden strategy would not need the decrease of inflation before joining the monetary union. Even though the Euroization phenomenon in Romania is a partial and not total one, such as in the previous section, it may be explained according too the previously presented costs-benefits balance.

Euroization followed a Dollarization trend occurred when the transition started, and it constituted a refuge of the private economic agents and also of the state, under the terms of a difficult macroeconomic stabilization, which also reflected in the persistence of a quite high rate of inflation in the national economy. This phenomenon occurred together with Romania's commercial and financial integration with the economic agents from the European Union, being amplified by the trend of appreciation of the national currency during the economic boom period. Under these terms, there were positive effects of wealth and balance upon the domestic economic agents, which induced a trend of taking loans/making deposits in the foreign currency and also the acceleration of consumption during the economic expansion period. Nevertheless, the Euroization of the Romanian economy has determined certain risks, which occurred more pregnantly along with the economic and financial crisis. Thus, the efficiency of the monetary policy in stabilizing the economy decreased, as the mechanism for transmitting the rate of interest controlled by NBR has been fractured. Moreover, the depreciation of the national currency has negatively influenced the payment capacity of the lenders in foreign currency, this resulting in the increase of the financial risk in the banking system. As a consequence, the partial Euroization of the Romanian economy encouraged overheating the national economy until 2008, but it fractured the adjustment capacity of the shocks by means of the monetary policy and of the rate of exchange. Thus, a partial Euroization acquired the characteristic of a unilateral one, in which the economy's capacity to neutralize the shocks gets decreased and the dependence on the decisions made by the European Central Bank, respectively by the economic agents from the highly commercially and financially integrated countries with Romania gets increased.

This section includes a few forms of occurrence of Euroization in Romania, which are specific to the financial substitution of the national currency with the unique European currency – the tendency to give loans in foreign currency, to make deposits in the same currency and to emphasize the role of the banks from the Euro area within the national banking system.

IV. Loans in foreign currency

The loans in foreign currency have been determined, among others, by the stability of the macroeconomic environment, by the relative level of the rate of interest in the foreign currency and by the trend of appreciation of the national currency during the economic expansion period. The percentage of the loans in the foreign currency of the total loans given was quite stable during the period 2001-2005, despite of a level of 51.3% in 2004. In 2007, NBR relaxed the conditions for the loans in foreign currency, so that the volume of the loans increased by 71% if compared to the previous year, and the loan in foreign currency increased by 76%, and the loan in lei increased by 68%. Out of the total loans, 45% were in the national currency, and 47% in the Euro currency. In 2009 the rhythm of increase of the total loans was of 13%, and the rhythm of increase of the loans in foreign currency was of 23%. In 2010, the rhythm of increase of the loans in the Euro currency was of 5%, and the loans in lei remained at the same level as in the previous year, the percentage of the loans in the Euro currency exceeding 70% of the volume of the total loans (according to the chart below).

The loans contraction was due both to the low offer of the banks (aversion towards the risk), and also to the low demand caused by the unfavourable economic conditions: the increase of the rate of unemployment, the decrease of the available revenues, the depreciation of the Euro currency, and the high costs of the creditors.
Figure 1. Evolution of the loans in foreign currency in Romania

The increase of the loans in the Euro currency may be considered a cause of the natural catching-up process, generating the increase of the share of loans in the foreign currency given to the private sector in the GDP, so as to approach the levels recorded in the more advanced countries. Nevertheless, the increasing rhythm of the loans in the Euro currency should have been sustainable, as this increase, by supplying the internal demand, contributed to deepening the current account deficit and the increase of financial risk in the banking system. The share of the loans in foreign currency from the balances of the national banks was of 62.9 percents at the end of June 2011, on the background of recording a significant foreign currency position for the population. The loans in foreign currency became more risky if compared to those given in lei, from the point of view of the loan risk: (i) the non-performance rate for all the categories of loans in foreign currency given to population is superior or is close to that related to the loans in lei, and (ii) the dynamics of non-efficient loans in foreign currency given to companies is more emphasized than in the case of the segment in lei (recording an increase of 185 percents for the foreign currency, in comparison with approximately 91 percents for lei during the period December 2009 – June 2011).

The access to loans in foreign currency has been facilitated by the quite low level of the rate of interest for this type of credits. Moreover, during the economic expansion period, the rate of interest in the national currency was increased in order to stop the economy's overheating phenomenon, and this determined the increase of attractiveness of the loans in foreign currency. After the crises has started, the national bank kept the high level of the interests in order to keep the stability of the rate of exchange and to brake the increase of inflation, not to stimulate the loans in foreign currency. The chart below presents the difference between the rates of interest of the loans in lei and for those in foreign currency for households and for companies, in order to explain the higher inclination towards loans in foreign currency.
Source: NBR, 2012

Figure 2. Differences between the rates of interests for loans (lei vs. Euro) (%)

Another factor stimulating the loans in foreign currency was the appreciation tendency of the national currency during the period 2004-2008. The economic and financial crisis emphasized the vulnerabilities of the Romanian economy, thus reducing the financial flows towards the Romanian economy and contributing to the depreciation of the national currency. This phenomenon does not generate the increase of the private debt only, expressed in the national currency but also of the rate of non-efficient loans, and also of the public debt, under the terms in which 55% represent the public debt expressed in foreign currency and, out of it, 43 percents represent the debt accumulated subsequently to the loans in the unique European currency. According to the chart below, we can notice that the doubling of the public debt starting from 2009 supposed the significant increase of the loans in the unique European currency.

Figure 3. Foreign exchange structure of the public debt

V. Deposits in foreign currency

The preference for Euroization of the deponents depends on their confidence in the national currency. In an economy with a high inflation which puts depreciation pressure the national currency, the population will choose to save in a stable currency. During the last 10 years, the population's confidence I the national currency as a saving modality increased very little, the share of the deposits in lei increasing from 60% in 2000 to 61% in 2010. The economic crisis affected the volume of the deposits in foreign currency, of which annual increasing rhythm decreased from 57% in 2008 to 5% in 2010, due to the lack of liquidity in economy under the terms of the financial crisis. In 2009, the banks constrained their loan activity and drawn their attention towards the activity of attracted deposits. As a consequence of the new strategy, the ratio between the loans given to the customers and the deposits attracted by it decreased from 122.0% at the end of 2008 to 112.8% in December 2009. In order to assess the importance of

Euroization in the deponents' preferences, we have calculated the degree of Euroization as a ratio between the total of the deposits in Euro currency and M3, according to Honohan and Shi (2002). The figure below presents the recording of an increase of the degree of Euroization from 21% at the beginning of 2007 to 31.4% in December 2009, this level decreasing as a result of the persistence of the difference between the interests for lei and for Euro and after decreasing the volatility of the rate of exchange.
Source: NBR, author's calculations

Figure 4. Evolution of the degree of Euroization

VI. Conclusions
The increase of the Euroization degree may be considered an opportunity for the economies which propose to adopt the unique European currency, meanwhile constituting a vulnerability if adopting the unique currency is delayed and if that economy is affected by the external shocks which induce a depreciation of the national currency. The partial Euroization of the Romanian economy has encouraged the overheating of the national economy until 2008, but it fractured the adjustment capacity of the shocks by means of the monetary policy and of the rate of exchange. Thus, a partial Euroization acquired a characteristic of a unilateral Euroization, in which the capacity of the economy to neutralize the shocks gets decreased and the dependence on the decisions of the Central European Bank, respectively of the economic agents form the highly commercially and financially integrated countries with Romania gets increased.

Abstract: In the last years, the integration of young people into the labour market has become more difficult, being accomplished in a gradual, complex and less uniform way comparatively to the years prior to the crises. The rate of youth employment is much lower than among other categories of population, and the insertion of young people on the labour market has become a difficult process, both in Romania and in the European Union, process that is characterised especially through raising the period of time passed from the moment of graduating from school to the moment of finding the first 'significant' workplace (for at least six months and with a length of at least 20 hours of work per week), preferably, from qualitative point of view, in accordance to the qualification obtained. In this context, in order to analyse the way in which the integration of young people into the labour market is done in Romania, the present paper makes, in the first part, a short theoretic incursion regarding the main theories referring to youth employment, transition from school to active life and, more specific, transition from higher education to employment, the main determinants of the transition from school to active life and the way in which the process is affected by the tendencies on the labour market, the ways of measurement and evaluation used up to the present etc. In the second part, the paper tries to propose a research methodology of the transition from higher education in the field of economics to employment, analyse that will be carried out in the project called „The practice of economist students. An inter-regional partnership on the labour market between universities and the business environment" (PRACTeam) in the purpose of creating policy and strategy recommendations for diminishing the difficulties felt by young people in the process of transition from school to active life.

Conceptual framework regarding *transition from school to active life* and *labour market insertion*

The relative high rate of unemployment among youngsters, comparative to the rest of categories of active population, especially in the last period, determined the rise of preoccupations for the analyse of the young people labour market, the factors that influence their employability, the factors that determine a simplification of the transition from school to active live, from the young people, involved in a form of education, to the adult who wants to join the labour market. Literature examines the transition from school to active live and *transition from higher education to employment* closely with *labour market insertio*n or *integration of young people into the labour market* and *youth employment or unemployment* (Cardosa, 2004; Hill and Holzer, 2006; Tovatt, 2011; Bell and Blanckflower, 2011). The analyses taken so far are in correlation with aspects referring to: demographic evolution, behaviour of young people, incomes obtained during their studies, experiences during diverse forms of education, family's incomes, social

networks that the young people can benefit of, the way in which transition to the adult life is affected by the tendencies on the labour market, etc.

In this context, our concern is to identify the main determinants of transition from school to active life, the main transition models, the influence of the organising way of the educational system and the extent to which this system manages to contribute to the insertion of the youngsters on the labour market, which are the methods of measurement and identification of training needs of young people in order to simplify the transition from school to active life, in order to construct a model of analysis and interpretation of the transition from school to active life and insertion of young people on the labor market.

The literature defines the *transition from school to active life* as the process of transition from a young life comprised in a form of education to independent living, where young people gain first experiences of professional integration, no matter if they have completed studies or not (Garcia, 2007:27 cited by Pîrciog et al., 2010:75). On the other side, the insertion on the labour market represents an indicator of passing to the adult life, through independent living, marriage, the decision of having children etc., determined by the finding of a workplace after graduating from school (Hill and Holzer, 2006). This process that, in the last years, has become more ambiguous is realised most of the times in a gradual, complex and less uniform way, being influenced by the replacement of the classical, direct transition model – in which school and labour succeeded, with a model of indirect transition in which school and labour can alternate for certain periods of time and can complete even with periods of inactivity and unemployment.

Knowing this aspects, our approach will try to analyse the *transition from school to active life from the perspective of youngsters insertion on the labour market*, especially of higher economic studies graduates, being preoccupied with predilection of the way in which economic students, respectively higher economic studies graduates, from the North-West, West and North-East regions, respectively counties Bihor, Timiş and Suceava, manage to integrate on the labour market.

During the time, transition from school to active life from the perspective of the insertion on the labour market raised the formulation of some theories as well as some models of transition that try to explain the way of its accomplishment. The main theories regarding the insertion of youngsters on the labour market are: *the theory of human capital* (Becker, 1964), with accent on the analyse of the behaviour towards education and the implications that result on the labour market through wage differences between different levels of training; *the theory of competition for a workplace or the „job-competition model*" (Thurow, 1975), that emphasizes the defensive importance of education in finding a workplace as well as the level of compatibility of the qualifications provided by the educational system; *the „job search theory*" (McCall, 1970; Mortensen, 1970), that focuses on the study of behaviour of individuals during the period of searching for a workplace, the analyse of the way in which the decision of acceptation or rejection a workplace is taken, influenced especially by the level of the wage offered of diverse firms; *the „insider – outsider" theory* (Linbeck and Snower, 1988), based on the distinction between employed (initiated) and unemployed (uninitiated), those being the ones that are looking for a workplace, and among them, the biggest part is represented by young people that graduated from a school but do not have experience and enter into the competition of finding a workplace with those who have experience and who have or have had a workplace.

The insertion of youngsters on the labour market, besides the characteristics of national economies, depends on the way in which every country manages to make an institutional connection between the educational system and the work force occupation measures. Also, it matters the way in which the educational system makes a distinction between university education and vocational education. In this direction, many countries offer a general education, in which competences acquired by graduates are not necessarily in direct link with the competences necessary by the future workplace, and the vocational preparation is done at the workplace. In

other countries, the forming of competences specific to the targeted workplace is obtained through the educational and training system (Velden and Wolbers 2003). In this way, generic models identified in the special literature are: *the Japanese model*, based on a direct tradition: school education – work, based on training at the workplace; *the German model,* dual system in which theoretic forming combines with practical training; *the French model*, based on a training in the school environment, *the American model* - in which common training represents a fusing between the theoretical and practical education (Ehlert and Cordier, 2002). Out of those, the model that best succeeds to integrate youth on the labor market is *the dual model* where education and practice take place simultaneously and allows the student to be initiated (insider) on the labor market during the studies (Velden and Wolbers, 2003). This model is applied in Germany, Austria, Luxembourg, Netherlands, Denmark and Sweden, and the educational system has very close links with business organizations, with benefits for all three parties involved: for students – it helps increase the employment opportunities (82% of German higher education graduates find employment within six months after graduation), for programs offered by universities and companies by maintaining direct contact with graduates who can become future employees (Mickovska-Raleva, 2010).

In addition, the insertion of young people on the labor market is closely connected with the degree of standardization and stratification of the educational system. The degree of standardization means uniform national education system, which allows a comparison of the quality of educational programs offered by various universities, and the stratification is the degree to which education gives young people the possibilities to choose different career path during studies. I then countries where the degree of standardization and stratification is higher young people are integrated quickly on the labor market (Velden and Wolbers, 2003).

A model of transition from school to active life for students in Economic Sciences based on labour market partnership: PRACTeam project study case

The project called *'The practice of economics students. An inter-regional partnership on the labor market between universities and business environment" (acronym PRACTeam)*, co-funded by European Social Fund -"Invest in people, "Human Resources Development Operational Programme 2007-2013, Priority Axis 2" Linking lifelong learning and labor market", key Area of Intervention 2.1 "Transition from school to active life", contract POSDRU/90/2.1/S/64150, total value of the project: 20,941,500 lei, period of implementation: 01.10.2010 - 30.09.2013, has the overall goal of developing the economist students employment skills during the practical training and internship, conducted in inter-regional partnership on the labor market between universities and businesses in order to improve the insertion of economists on the labor market. Among *the specific objectives* of PRACTeam project are included: increasing the employment of graduates of Bachelor degree programs and master programs in economics, the promotion and development of an inter-regional partnership between universities on the labor market, on the one hand, and business, on the other hand, to facilitate transition from school to active life of the future economists; the development and promotion of some partnership regarding the practice and internship programs customized for each student and innovative for each host organization; increasing the interest and responsibility of the business environment for student practice by developing and promoting staff training of employees of the host organizations with role of tutors, and by organizing exchanges of experience and dissemination of good practices.

The PRACTeam project addresses a number of 2430 students and 486 tutors in enterprises in the three counties involved: Bihor, Timis and Suceava, grouped into three target groups. The first target group consists of 486 people from the host organization responsible with the activity of practice having the role of tutors. This involves in every county a number of 162 tutors in enterprises, 54 tutors each year of implementation who are trained to assist students in practice activities. For this target group the project aims to improve skills tutorials in order to support

students in the transition from school to active life. The second target group comprises students from the first cycle of studies and consists of 1620 students that are going to conduct practical training in the three counties included in the project (Bihor, Timis and Suceava). This concerns in every county a number of 540 undergraduate students, 180 students each year of implementation, drawn from the partner university centers, beneficiaries of practical training module and of the customized module of advice and guidance in career that includes aptitude testing for career guidance. For this target group the project aims to increase skills levels and increase practice employment skills. The third target group consists of 810 students in second cycle of studies, which also benefit from the module of practical training and the custom module of counseling and career orientation including aptitude testing for career guidance. This concerns in every county a number of 270 persons, selected from the partner university centers, giving a total of 90 graduate students annually at the level of the three counties. For this target group is also intended to increase skills levels and increase practice employment skills.

In terms of *methodology of implementation,* all project activities are carried out symmetrically in three counties in the area of implementation concerned, namely the local level. Thus, the first six months of each year of implementation of the project are dedicated to training the practical stages in each partner university: establishment of dispatch of practice - PRACTeam Center, identification and selection of target groups, facilitated by the organization and conduction of the PRACTeam campaign as a fair of offers of practice and internship and the renewal and completion of new partnership agreements for the practical training; the identification of training needs through PRACTeam Workshop of practice, training the tutors and training-support materials for the practical training - Manual of the tutor, student, etc. Practice Guide, attending the counseling and career orientation module by the students selected and aptitude testing of students. Last six months of each year of implementation of the project are dedicated to making the practical stages, evaluation and awarding students that prepare and conduct internships.

Upon completion of practical training, in each year of implementation, will be organized the PRACTeam Gala within which will be held the Round Table *"Experience and Good Practices PRACTeam"* – where will take place an exchange of experience and dissemination of best practices on the practical training, the presentation of experience and presentation of results and future exploitation opportunities and takes place *The contest of ideas for improving the activity of the host organization of the practical stages*. Basically at PRACTeam Gala will also present and awards at inter-regional level the best ideas for improving the activity of the host organizations, will be awarded three prizes (I-III) at inter-regional level - one students from the three partner universities and 18 prizes for the best results - will be awarded the best student / specialization (6 students x 3 partners) and will be announced the students who will benefit from internships stages.

Carrying out the PRACTeam project will allow us to establish an inter-regional education research, formation, training and communication network, and to establish an inter-regional database. In addition, the proposed project is a model of organizational practice and internship for students, which will significantly contribute to changing attitudes and increasing of the responsibility of the business environment, university and students towards the practical training.

Conclusions: a proposal of model of analysis of the transition from school to active life of economists

Without denying the importance of other determinants of the transition from school to active life, such as: social status of young people, individual characteristics, social networks whom he has available, socio-economic context in which they live, restructuring and economic developments of the country, diversification opportunities and potential professional trajectories of increasing geographical mobility, we consider relevant to us as potential mobilizing factor in the growth of *young people insertion on the labor market*, the focus on the following courses of action: *the*

analysis of educational programs in economic higher education from 3 Romanian universities: Faculty of Economic Sciences - University of Oradea*,* Faculty of Economics and Business Administration - West University of Timişoara, Faculty of Economics and Public Administration - „Ştefan cel Mare" University of Suceava, qualifications and skills which a young people can achieve by following programs of study offered by these faculties at Bachelor and Master level and how to choose and identify the career path; *the analysis of the youth labour market* at regional level in 3 development regions of Romania: the North, North - West and North - East, focusing on the following 3 counties: Bihor, Timis and Suceava, assessing the employment potential for graduates of economic higher education; *the analysis of the transition from school to active life* of university graduates in Economic Sciences, at regional level, in the 3 development regions of Romania: the North, North - West and North - East, focusing on the following 3 counties: Bihor, Timis and Suceava and the identification of the determinants of transition from school to active life.

The three directions of action will focus on analyzing the following target groups: 3 *faculties of Economic Sciences* from 3 Romanian universities: University of Oradea, Faculty of Economics, University of West Timisoara, Faculty of Economics and Business Administration and "Stefan cel Mare" University, Faculty of Economics and Public Administration; 150 *host organizations for student practice* in the 3 counties of Bihor, Timis and Suceava; 486 *practice tutors* employed in the host organizations for student practice and trained for supporting students for *labour market insertion* in the 3 counties of Bihor, Timis and Suceava; 2430 *students in Economic Sciences* supported for the *transition from school to active life* enrolled in undergraduate and master programs of the 3 universities: University of Oradea, Faculty of Economics, University of West Timisoara, Faculty of Economics and Business Administration and "Stefan cel Mare" University, Faculty of Economics and Public Administration.

For each course of action we propose to complete a specific research methodology, including *quantitative* and *qualitative* approaches with specific research tools. The final study - ***Transition from school to active life for students in Economic Sciences of the Bihor, Timis and Suceava counties*** through PRACTeam project during 2010-2013 will be structured as follows: **1.** *youth labor market diagnoses of the Bihor, Timis and Suceava counties focused on economic higher education graduates employability* (analysis of economic indicators related to employability: employed population by age and economic activity, employment by level of education, youth unemployment rate, percentage of graduates in economics in total number of graduates, share of students enrolled in the economic profile etc.); **2.** *needs identification for practice stages for students in Economic Sciences of the Bihor, Timis and Suceava counties (*research based on the *survey* of the *structured questionnaire applied to students* which has benefited practice stages in different systems, *focus - groups* organized at county level, *workshops* organized at county level etc.); **3**. *a model of transition from school to active life for students in Economic Sciences based on labour market partnership (PRACTeam project study case,* including presentation of students awarded for results in practice stage and for ideas to improve the host organization's activity, *round tables* organized at inter-regional level, research based on the *survey* of the *structured questionnaire applied to practice tutors*, open structured *interview applied to managers of practice host organizations* etc.); **4.** *impact evaluation of transition from school to active life for students in Economic Sciences based on labour market partnership (*research based on the *survey* of the *structured questionnaire applied to graduates* which has benefited practice and internship stages through PRACTeam project).

DYNAMICS OF FOOD SECURITY IN RECENT DECADES

Florea Adrian
University of Oradea Faculty of Economics

By food security we understand the people's access, at all time, to food, needed for a healthy and active life. It can be thought at global, regional, state or local level, but only as a strategy with relevance only to the family, to be able to buy, thanks to its own production or purchase, sufficient food to meet the needs of all its members. Diet must be quantity sufficient, variety and of good enough quality and each family member should be healthy to take full advantage of consumed foods.

Food security can be ensured if three conditions are met: food stocks exist (at any level, from family to national), food stocks are stable and affordable for families to have to provide. In terms of food availability at national, regional and local levels, they depend on the production, storing and marketing network. Any deficiencies in the chain lead to shortages and price destabilization. Such deficiencies occur in all three levels. The worst is nationwide, which is the inability to produce adequate quantities of food according to the population needs. This is the case in many countries in South Asia or Africa. Then, there is failure to storage, illustrated by what happened in the summer of 1995 to our country with wheat. At the family level, the food shortage is poverty, inability to procure necessary food. Shortcomings in the chain production-storage-marketing lead to higher prices, which primarily hits the poorest families.

At family level, inability to have access to food may have a transient or permanent character. The first case occurs when the family temporarily has no access to sufficient food due to a crisis of production, import difficulties, job loss or a natural disaster. When access to food has permanent character for families, we could be talking about chronic food insecurity.

An analysis over the future of mankind should identify current global food security, if there is enough food for a growing population and if the Earth has sufficient capacity to maintain it. It is also important to determine the maximum population that the world can support, developing all its capabilities

Thomas Malthus, English vicar, was the first to reveal in 1798, the gap between population growth and food quantity. The first has an increase in natural geometric progression, because each year the growth is added to the growth of last year, and this amount is the new growth for the following year. For food, basis remains constant, without the automatic addition of annual increase, so to have an exponential growth; improvements should be brought to production system.

Under pressure from technological progress, agricultural production has evolved continuously through history. After the medieval production, performed on small areas, with animal or manual means and especially for family use, by differentiating village from town a new economy has imposed; agricultural trade, with production at village and products sold in town, which caused a high demand for food. That is why in England, between 1700 1800, productivity in agriculture increased by 100% (1% annually) while the population increased only by 0.6%. In France, between 1750-1850 agricultural productivity increased by 60% (0.6% annually), while the population had a growth rate of 0.4%. This increase, although tiny, has made possible to compensate for population growth, especially it has provided the necessary food resources and manpower for industrial development, supporting the first industrial revolution of the mid-century. This, in turn, has created a revolution in agriculture by inventing tractors and other

machines that have begun to play an increasing role in enhancing agricultural work. Thus, he passed from small production to large-scale production

Malthusian prophecies do not seem to be done yet at globally level, as agriculture and, in general, food production, also increased along with population. Nevertheless, the world's population does not enjoy sufficient food.

In 1974 it was estimated that the 80's will be provided an average daily consumption of 6,000 calories per person, with variations from 3000 to 15,000 calories, in addition, annual food production could provide 19% more calories than needed to diets. Evolution of two decades (1970-1990) was also optimistic.

Interestingly, statistics show that food production was enough in the 80's to conveniently feed the entire population of the world, 500 kg of annual vegetable production per inhabitant. Even it has been told that today, in the world it is produced, more food per inhabitant than ever in history of mankind. However, paradoxically, currently hunger is endemic for 20% of humanity. One in five inhabitants of the world haven't enough food and also as a historical perspective, there were never more hungry people in the world than now. The problem is particularly serious, as 40% of Earth's hungry are children.

Beside the hungry in fact, there is still one third of world population living in poverty, even if not at the edge of starvation, but leading a life below acceptability. The fact is underscored by the cost of food for a family, in the U.S., for "basket" it is spent 10% of income, in the EU 10%, 50% in Ghana and in Tanzania 64%. From this point of view, our membership to the first world (which usually all Europe takes part) is questionable, given that this "daily basket" reaches, to us, in 2000 to over 80% of medium income of people, worse than in Africa.

Trying to identify the world poverty, we observe that it is present in Africa, South Asia and Latin America. There are areas where hunger is endemic, such as the Sahel, because of a very long time of absolute drought. UNO action in Somalia is known to rescue hundreds of thousands of people from death by starvation, hunger leading, also to serious deterioration of social relations, up to an internal war. Statistics by region showed a not very pleasant situation, while the world average would indicate otherwise. But it concerns only the XX century years. To ensure food security for the population boom coming decades, are inconceivable only two solutions: expansion of production area (extensive agriculture) or increased production per hectare (intensive agriculture). A third solution, the creation of artificial feeding of chemical, although not impossible, is for now for very distant future.

Starting from the impossibility of increasing agricultural areas, the only solution to meet future needs for food is increasing production. This, in the three key departments: agricultural production, meat and fish production. Calculations can be different: increasing total production, growth, per area unit and per capita growth (the latter in kilograms or calories). It also should be mentioned that meat production can be converted into feed, so also as agricultural production.

Given the serious problems of food shortages in third world, in the '50s was launched a major campaign to increase agricultural production, especially in poor countries, known as the "Green Revolution". Its appearance led to the definition of three types of agricultural systems:

1) An industrial agriculture, practiced in the U.S., Europe, Australia and New Zealand, based on a significant capital investment, practiced on a large scale and having all the modern techniques of production facilities, storage and transport. We can consider that, also the stat agriculture practiced in the former socialist countries belonged to it;

2) A "green revolution" agriculture type, possible in rich regions in high agricultural resources, generally flat, with good irrigation and it was practiced in the countries of South and South-East Asia, North Africa and some countries Latin America countries;

3) A low resources agricultural, specific for areas unsuitable for agriculture (dry, poor soil, high altitudes, especially a forestation and water scarcity, based on a more uncertain rain than

irrigation). Is the agriculture of the countries of Africa south of Sahara, some Latin American countries and in remote areas of Asia.

It is obvious that in the first decades after the war, there were dramatic increases in food production, especially agricultural ones, and is sufficient to mention two cases belonging to the first two types of agriculture.

In terms of industrial agriculture, Europe is a good example, because the grain production of 199 million tons in 1970, reached to 283 million tons in 1990 (a growth rate of 42%), while the cultivated land decreased from 72 million hectares in 1970 to 66 million ha in 1990. This means increased productivity tons of grain per hectare.

For Green Revolution, India is a good example for the production of 50 million tons in 1950, reached to 108,000,000 tons in 1970, and in 1990 to 170,000. tons, so doubling every decade. "Green Revolution" agricultural technique involves changing:

- Giving up their monoculture and rotation;

- Use of new plants, with higher fertility and physical resistance (temperature, drought, poor soil) and biological (diseases and insects), obtained either by hybridization or by seeds brought from elsewhere;

- Intensive use of chemical additives, which are fertilizers and pesticides (insecticides, fungicides, herbicides);

- Irrigation on a larger scale.

With such techniques, applied also in other types of agriculture, the world agricultural production has increased considerably in the first decades after the war.

Massive use of fertilizers has contributed to the extraordinary growth of grain production between 1950-1984 (the ratio of grain supplement / supplement fertilizers - 9,1), but between 1984-1989, although the amount of fertilizer was higher, grain production increase was more modest (report supplement cereal / supplement fertilizer = 1.8).Therefore we believe that we cannot count on infinite growth of agricultural production even by using more fertilizers, there is a biological limit determined by the power plant photosynthesis.

Intensive irrigation of land may be a factor that could help increase production. There are now 237 million hectares of irrigated land, 16% of cultivated land would provide more than a third of world agricultural production. In 1978, irrigated land area per capita reached a peak, however, then falling by 6%.

We should recall, however, also the limitation imposed by water scarcity, which itself represents a problem for human evolution, fresh and recyclable quantities of water available cannot cope with the explosive growth of population. The idea of using sea water by desalination is also not viable because of the prohibitive price that would achieve.

Therefore it is difficult to believe that in the future decades , solutions would be found to maintain agricultural production needs corresponding to population growth, not as global production quantitative, nor per hectare production or per capita.

Meat and derived products (milk and eggs) constitutes a key to food security, providing especially needed protein. However, it is strictly dependent on agricultural production, representing the feed conversion in animal products. These are natural (grassland) and from agricultural production. It is recognized that for a pound of beef ("live") is needed 7 kg of feed, for one kg of pork - 4 kg of feed, for one kg of chicken meat 2 kg of feed, and for a kilogram of cheese 3 kg of feed. So, issues raised by grain production, partly reflected on the animal one, stopping the increase of agricultural production is visible also in the hay.

The amount of grain used for feeding represents at world level about 40% of total agricultural production and has increased steadily since 1960, from 289 million tons to 650 million tons in 1990. So the production of beef and mutton increased 2.6 times, raising consumption with about 26 % per capita.

Discovery of new productive areas, increasing interest in this work (an example can be given the industry sea fishing, initiated also in Romanian, people with no tradition in the field, unfortunately today annihilated), and improving equipment, increased the production of marine fish.

Increase marine fish production was outstanding until 1990, but figures show a decrease in the coming years, with oscillations around a level, the perspective can foresee an increase in fish production, mainly due to aquaculture, but in any case not may expect too much.

The overall conclusion on the prospect of meeting the future mankind need for food is not encouraging. Agricultural production, having grown spectacularly in the years 1970-1990, it reached a plateau difficult to overcome, given that there is no land for cultivation in the world, lack of water will not allow too broad irrigations to bring new land into cultivation, and agricultural chemical treatment has reached the limit of possible assimilation by plants in such circumstances it is difficult to see how agricultural production will keep pace with the 2% annual growth in world population.

Pork production is increasing and not seen a reason to limit this growth, up from lack of fodder. Beef and sheep reached a limit due to lack of pasture, instead chicken can offer some hope, but still limited because of fodder from agriculture.

Nor even fishing seems to be a solution, but it can hope to increase production from aquaculture.

It is estimated that world population will increase from six billion now to more than eight billion in 2020, meaning by 40%.

We observe intriguing situation of Romania, starting from the fact that as the share of food costs in total consumption expenditure of population is higher, we are dealing with a more poor population. Analyzing data provided by the U.S. Department of Agriculture, on our economy, we conclude that 34.3% of Romanians income was used to purchase food, a share almost triple than for developed countries where food costs revolve around 10%.The same source presents the situation in our immediate neighborhood countries: Czech Republic - 15.6%, Hungary - 16.3%, Poland 20.3%. If we take into account absolute amounts, we see that in Romania a family spent an average of 1592 USD. This amount is 13% higher than a Polish family, 9% than in the Czech Republic and 46% more than the Hungarians as a family. Nevertheless due to much lower incomes obtained in Romania than in other countries compared. To remember, at this point in our analysis, is the situation in Bulgaria, which with food costs per family of 804USD, is located only half of what we, the Romanians consume.

From the data sequence above, we are tempted to detach two conclusions: either we (Romanians) are eating more than our neighbors, or on the Romanian market, foods are more costly. But this is contradicted by various statements by politicians, who, at every opportunity point out that food prices in Romania are lower than in other European countries, and then to return to the statements and say that prices cannot be lower than the European average, because then all local producers would prefer to sell their goods on the market which would get the highest price. In this final part of the statement it raises again a question mark: Why we do not identify the same behavior of producers in the Czech Republic, Poland, Hungary or Bulgaria? As for me, things are very simple: the market is one that has the last word. If there are consumers willing to pay a high price for certain products, manufacturers certainly will not reduce prices! Trying to anticipate the evolution of food prices in Europe, we must consider first the upward trend (1.4% per month on average). But, in a complete ranking of European countries, Romania holds the fourth position with 7.4%, after Turkey - 17.6%, Hungary - 9.7% and Poland 8.6%.

Given the above, Romanian food safety must be given special attention, showing extreme volatility amid an election year and the obvious political instability - not less than three governments in four months

EVALUATION OF THE PROJECT MANAGEMENT ORGANISATIONAL ABILITY OF PUBLIC ORGANISATIONS

Florescu Margareta
The Bucharest Academy of Economic Studies

Abstract:The quality of the results of a project or a public programme, as well as the quality of project management consist in management process performance.This analysis tool promotes the idea of initiating a new organisational/functional policy – organisational tools regarding project management, a new standard concerning the complexity of the project and the associated risk, as well as a new standard concerning the project management organisational/functional ability.
Political decision makers, public organisation managers, but project managers as well are the main people in charge of elaborating and taking responsibility for these standards and policies within the organisations they manage and represent.

Keywords: project, evaluation, management, process, decision makers.

INTRODUCTION

In the current context, public organisations that manage or implement projects/programmes (as an objective of their mission, but also as a form of organisation) need a new vision and a new form of organisation at least functionally in order to reach the new positions of public administration.

The quality of its processes and the performance of the activities carried out should be measured, at the current level, established as objectives, standardised and implemented uniformly precisely according to this standardisation as a reference, for every public organisation in Romania. Such an analysis and evaluation will later allow measures that are imposed in the organisation/reorganisation, at least functional, to be identified, which will allow public organisations to manage and implement projects and programmes.

The quality of an implemented project/programme is often established according to an evaluation criterion/series of criteria concerning the management process itself or the implementation stage of the evaluated project/programme.

Although it is hard to accept, processes are those that ensure the organisational performance, not departments, meaning a structure and an organisation based on process rather than on a hierarchical organisational structure. The most common mistake in management is probably making changes in departments when things do not go well, without looking for causes, that is **what processes or which of their steps** *do not ensure the desired performance.*

Changes in departments are only consequences of changes in processes. **First processes, then departments.**

When referring to the quality or performance of a project or a programme, we often take into account as an analysis procedure the evaluation of the project/programme itself or project/programme management at most and we pay less attention to the evaluation of project management organisational/institutional ability – that is how an organisation has the technical and management ability to implement projects/programmes.

We considered this an important aspect and a field which needs to be taken into account and developed, especially when referring to public organisations' organisational/institutional ability of implementing and managing projects/programmes.

As regards the analysis of the current stage of research, the possibility of identifying certain methods or case studies relevant for organisational evaluation as a project management tool does not exist in Romania. Generally, evaluation is focused on projects themselves rather than the project management ability of public organisations, beyond the stage of project proposal elaboration or financing request.

With regard to the international practice, we have analysed the Canadian organisation and project management evaluation of the public administration model. This model, adapted to the organisational nature and reality of Romania, is desired to be just a starting framework for further research and models. The example of the Canadian government is, in the current work, the basis for conceiving and developing a framework model of analysis, evaluation and promotion of an instructional-organisational structure as a project which ensures performance in project implementation and quality in public service provision based on project management. First processed and then departments…

The process of re-conceiving an institutional-organisational structure based on management processes and then on department-hierarchical ones involves the development of analysis and evaluation tools in the first step, meant to identify at least the following aspects:

- ✓ Identifying existing practices in Romanian public organisations to implement projects/programmes (the type and level of the projects etc.);
- ✓ Identifying processes and applied project management activities;
- ✓ Analysing the organisational structure and its impact on project management;
- ✓ Identifying the project management ability – organisational and functional;
- ✓ Identifying the necessity to redesign the management structure at least functional wise, in the implementation of projects meant to ensure the performance and quality of services provided and a better management of public resources (human, material, financial etc.)

ORGANISATIONAL EVALUATION TOOLS. PMI AND CANADIAN GOVERNMENT MODEL

In order to carry out an organisational evaluation it is generally necessary to identify certain elements essential for the elaboration of the final document of the evaluation: the evaluation report and recommendations regarding management process improvement. These elements concern evaluation methodology and techniques on one hand and work tools specific to the evaluation on the other.

The purpose of these elements is to carry out an evaluation organised according to processes, dynamic and participatory, involving every factor contributing to its elaboration. Estimation and quantification in terms of resources and time are also important.

There is a series of work tools for organisational evaluation and, of course, enough models to support their complexity depending on the type of organisation with its specific activities or implemented projects. However, all of these take into acoount *tools/techniques* of quantitative/qualitative evaluation (it may be a questionnaire), a *guide* for analysis and interpretation of results obtained when applying the chosen tool and a work *methodology* to detail the process and the stages of the evaluation process.

The purpose of these elements is to offer guidance for filling out the project management organisational evaluation of public organisations in compliance with standards regarding the project management organisational ability and for the complexity of the projects and the associated risk – promoted by The Project Management Institute and undertaken by the Canadian Government in its process of adapting its own administrative structures according to this model chosen as a reference.

The guide provides additional explanations and interpretations meant to assist target users in filling out and analysing. Target users are represented by the personnel involved in the management, completion, re-examination, approval and/or coordination of programmes and projects carried out by a public organisation. There is also a group of secondary users, that includes other parties interested and involved in the establishment and management of issues, the project management ability and of planning activities for investment projects.

Users of such a guide are encouraged to take into consideration a number of good practices of their own public organisations when they are filling out or re-examining this guide. Ideally,

every employee from the entire organisation should be involved in an evaluation, by comprising every functional and programme area, including directions and the support divisions: financial-accounting, legal, human resources, acquisitions etc., but also project management, strategies, project monitoring and evaluation, technology information and management etc. Therefore, the result of the evaluation is a series of data specific to the organisation, according to its activity segments in terms of implemented projects and programmes, all from a global, consolidated perspective.

This way, project management ability evaluation will provide information and aspects that are essential for the organisation as far as its ability to manage projects and programmes is concerned.

It is important, like we have mentioned before, that decision makers be involved in the completion of the guide through its particularisation according to every participant organisation's needs, so that responsibilities can be taken, from the political and managerial point of view, for results obtained afterwards. This would allow to further improve the existing situation and work practices.

Filling out the guide, through the particularisation of its relevant fields of evaluation and analysis, actually means establishing a documentation methodology and providing documents justificatory for every evaluation criterion. This approach has the goal of ensuring consistent results that can be compared between organisations and facilitating updates and evaluation audits of performances as quality assurance tools for processes carried out within an organisation. After all, a good practice includes the establishment of processes intended for completion, examination and guide approval. These processes are expected to provide the rigour and discipline necessary to ensure the guide is correct and finished in due time and is supported by documented and appropriately updated proof.

Organisations can also wish to take into consideration the elaboration of a glossary of specific terms that can have a certain context or meaning within the organisation, so that coherence and a reciprocal understanding are ensured.

Organisations are eventually encouraged to take into consideration the possibility of integrating a periodical re-examination of the guide with the established planning processes, so that the accuracy of the evaluation tool with new situations is ensured and information regarding evaluation as a management and planning tool within the organisation is exploited.

The guide follows the structure of the project management ability evaluation tool and provides support for every category taken into account (evaluation criterion). The Canadian model chosen for presentation, taken after PMI, offers the following format:

The purpose of the evaluation criterion	A summary of the purpose and field of application for every evaluation criterion relation to the evaluation of the project management organisational ability.
Interested parties	Identifies and describes the role of interested parties that would be able to offer objective perspective and proof for a given knowledge area.
	Identifies some possible causes or consequences for "rating" in a spec knowledge field/evaluation criterion.
Significance of points	There are many factors that can influence the general ability of an organisation. instance, the number and complexity of the projects carried out, the level of matur and the ability of individual resources destined to projects. As a result, while the sc of a certain criterion/field of knowledge can be considered a useful indicator for strengths of an organisation or investment opportunities, the respective field should taken into consideration in the context of the general organisation grade.

This analysis tool promotes the idea of initiating a new organisational/functional policy – organisational tools regarding *project* management, a new *standard concerning the complexity of the project and the associated risk*, as well as a new *standard concerning the project management organisational/functional ability*.

These three tools resulting from organisational evaluation ensures the performance of the organisational management act – management performance, as an element of the quality of processes carried out in that organisation (standard concerning the project management organisational ability), but also project management performance, as an element of the quality of processes carried out in project management (standard concerning the complexity of the project and the associated risk).

Political decision makers, public organisation managers, but project managers as well are the main people in charge of elaborating and taking responsibility for these standards and policies within the organisations they manage and represent.

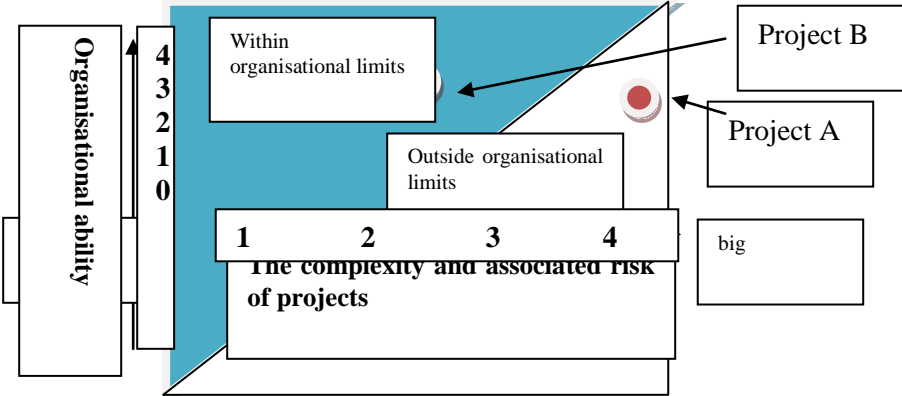
By applying this type evaluation tools for the organisational ability, two scores result from project management, as presented in Figure 1.


Figure 1: Approval of the project and expense budget based on the complexity of carried out projects and associated risks and based on the project management organisational ability

Figure 1 illustrates how the relationship between the project management organisational ability and risk associated with projects carried out by the organization and the level of complexity determine the limits within which projects can be approved for an organisation.

The ability must usually be proportional to the level of risk and the complexity of the projects for which responsibility is taken. For instance, a high level project management ability and related costs may not be an appropriate investment for an organisation engaging in a few large and complex projects.

THE EVALUATION STRUCTURE[20]

By following the above presented model, evaluation takes into account two categories: support organisation structures and applied project management standards. For an overview, see Figure 2. See Areas of interest (General criteria) and Table 25 with related detailed explanations.

Figure 2 schematically presents the 3 referenced abilities:

- Organisational adaptability;
- Project management (the fundamental structure);
- Assistance given to project management.

	Communication management				

Table 1: Areas of interest

Criteria		Definition
Organisational adaptability		
1	Investment portfolio management	This criterion refers to the selection and assistance of investment projects included in investment programmes. These investment projects and programmes are included in the organisational strategic plans along with related available resources.
2	Investment programme management	This criterion refers to the coordinated and centralised management of investment programmes, conceived to meet strategic objectives and envisaged results.
3	Organisational assistance structures	It refers to organisational mechanisms and structures, necessary for carrying out and implementing projects, programmes and the investment portfolio of the organisation.
4	Project management standards	It refers to the verification of compliance with referential methodological standards elaborated on good practices regarding project and programme management and the investment portfolio.

Project management (the fundamental structure)

5	Integrated project management	This criterion includes processes and activities necessary to identify, define, combine, unify and coordinate various project management processes and activities within activities carried out by the project team. In the context of project management, an integrated project management includes characteristics regarding actions of unification, combination and articulation, which are essential to carry out projects and successfully meet requests of the customers and interested parties and to meet planned objectives and obtain expected results.
6	Purpose	It consists in defining and controlling what is and what is not necessarily included in the purpose of the project. It includes processes necessary to ensure that the project involves the entire necessary work and not only the requested one, in order to successfully implement the project through requests constantly updated according to situations that occur.
7	Time management	It includes processes necessary to implement the project within the established periods of time.
8	Cost management	It includes the planning, estimation, budgetary and cost control processes so that the project can be implemented within the limits of an approved budget.
9	Risk management	It includes the processes of identification, planning, analysis, evaluation, control and monitoring of risks associated to the project, measures of preventing and minimising their impact.

Assistance given to project management (support structures)

10	Quality management	It includes the processes and activities of high-performance organisations that determine the elaboration of certain policies and objectives regarding quality, thus ensuring that projects will be implemented at a superior level in terms of meeting solicited needs and requests. A system of quality management includes policies and procedures that improve continuously and constantly activities and processes of a project.
11	Acquisition management	It includes processes necessary so that acquisition processes of services and products in order to obtain results established within the projects can carry out. Acquisition management includes management contracts and control processes for modifications that occur, necessary for contracts or orders to be managed by people with expertise in this field, members of the project team. This means the management of any acquisition contracts carried out by the organisation, which involves a high-performance management with contractual commitments being kept.
12	Human resource management	It includes the organisation and management of the project management team and everyone interacting in view of meeting the objectives of a project. Persons involved have well defined roles and responsibilities at an individual level within the project and the organisation.

| 13 | Communication management | It includes processes necessary to periodically ensure the generation, collection, distribution, storage and monitoring of necessary information within the implementation of a project. |

CLASSIFICATION OF EVALUATION RESULTS

It reflects the importance and relevance of a criterion or field evaluated in comparison with another one and its percentage in evaluating the organisation in terms of project management. This way, every point obtained for each field of interest/general criterion will be adjusted according to the relative percentage obtained for each evaluation category.

Table 2- A model for values and percentages assigned to the defined criteria.

Criteria	No. of questions	Percentage	Maximum points
Investment project and programme management	15	10%	75
Organisational support structures	15	10%	75
Project management related standards	15	10%	75
Integrated project management	15	10%	75
Purpose	5	10%	25
Time management	5	10%	25
Cost management	5	10%	25
Risk management	5	10%	25
Quality management	5	5%	25
Acquisition management	5	5%	25
Human resource management	5	5%	25
Communication management	5	5%	25
TOTAL POINTS	**100**	**100%**	**500**

The maximum number of points that can be obtained is 500 for the 100 questions related to the 12 analysis criteria. Expressed as a percentage, these points correspond with the organisational ability presented in **Table 3**.

Table3 : Classification of the project management organisational ability

Ability category	Definition	Rating
0 – Limited organisational ability – incipient stage	It is the starting level of an organisation that is aware of the necessity of its organisational re-conception in terms of project management, based on projects and programmes it implements or wants to implement. In this category, organisations that implement projects do not promote a consistent project management field of study, neither at a project level nor at an organisation level, based on the individual abilities of project managers and/or members of the project team in order to be successful.	**<25 / 100**
1 – Maintained organisational ability – initial stage	Organisations have the ability to successfully implement projects in order to maintain their operational ability. In this category, organisations apply a limited project management, planning is not very efficient and reference is not always centralised. Hence the dysfunctionality between structures and steps of project management, but at an organisational level as well.	**25 – 49 / 100**
2 – Tactical organisational ability – standardisation stage	Organisations have the ability to implement projects and to adjust their operations according to planned objectives. In this category, management processes tend to become standardised, information relevant to the project is often collected at a central level and tends to get an approval and supervision from decision makers/governors. There are dysfunctionalities at a central project management level, where roles are not very clearly defined and established.	**50 – 69 / 100**
3 – Developing organisational ability – maturity stage	Organisations have the ability to successfully implement projects and they meet their strategic organisational objectives. In this category, there are organisations that include their projects in strategic organisational plans and evaluate the possibility of integrating a multi-annual planning. Organisations define their planning, monitoring, control and report systems, evolved in terms of implemented projects, but at an organisational level. Project management processes are integrated in the organisational processes; project performance analysis is advanced and it provides an input for the improvement of organisational processes; decisional standards for projects are transposed and adopted at an organisational level, as a whole.	**70 – 90 / 100**
4 – Mature organisational ability – innovation stage	Organisations have the ability to successfully provide projects that modify the organisational style, thus becoming advanced organisations that apply an organisational management style based on projects. In this category, there are organisations that, when carrying out their strategic plans, take into account the typology of projects and programmes that help in developing their own procedural abilities. Operational processes referring to project, resource and time calendar approval are periodically re-evaluated and modified according to	**>90 – 100 / 100**

Ability category	Definition	Rating
	necessities that occur. There are good practices as regards project implementation; management processes are always improved, the performance and quality through qualitative and quantitative indicators, defined and standardised at an organisation level, are taken into account. Organisation is designed in such a manner, culturally and structurally, that the success of its strategic projects can be constantly optimised. Their own organisation and project management policies and standards are elaborated, updated and applied.	

CONCLUSIONS

A project management organisational policy is essential because it establishes the roles and responsibilities of every member of the management team according to the abilities of the employees, but especially according to the hierarchical position they hold within the organisation. This way, we can extrapolate and say that the project manager role is held by the Minister-Secretary of State, who holds the highest function hierarchically within the organisation, but who is also politically appointed; therefore, once the person is replaced by a new person who takes on the tasks and prerogatives of the project manager, the ability of project implementation, but also the project management organisational ability are modified. Thus, the two standards that define the project management organisational ability and the project management ability are correlated in the project management policy of every organisation or, even better said, in the political one of a superior rank, promoted at government level.

It is recommended that if such an organisational policy is implemented within the Project Management Policy, limits of approval for carried out projects normally be re-examined periodically and reviewed at least once every three years, as an integrating part of the investment plan, and it should also be included in the investment policy of the public organisation. As a result, the organisation will have to present the results of the evaluation at least every three years along with their investment plan provided in the investment policy of the organisation.

An organisation should carry out an evaluation when a significant change takes place within the organisation so that the project management ability would be different from the previous one.

In order to establish a global understanding of the project management organisational ability, aggregation methods of data relevant within the organisation must be taken into consideration. For instance, data could be collected and analysed at the level of an established project management office. Such a structured approach should facilitate data collection and allow the organisation to identify easily project management points and opportunities to invest in its ability at an individual or a global level.

Moral hazard can be found almost in all fields of human activities. Moral hazard is a change of economic agent´s behaviour when circumstances change. Theoretical background of moral hazard issue in economics dates back to 1970s. Recognition of moral hazard started by published studies of Pauly (Pauly 1968), Zeckhauser (Zeckhauser 1970), Arrow (Arrow 1971) and Mirrlees (Mirrlees 1999). Current situation of the global economy (fall 2011) was caused largely by moral hazard executed by authorities such as governments, institutions, ranking agencies, banks, chief executive officers, politicians etc. Efforts to stabilise Eurozone, governments bail-outs to banks, governments purchases of toxic assets, rescue packages given to the bank sector and big companies, which are "too big to fail", rescue packages given to debtor nations, golden parachutes given to employees which are leaving companies are nothing but the manifestations of moral hazard in economic and politic reality.This paper uses an economic experiment with 96 subjects to examine the tendencies of economic agents towards moral hazard.Design of the experiment allowed simulating third party's intervention on a market (e.g. state funding accelerating purchase, health care insurance function on the market with health care). Obtained data are statistically evaluated and it is shown, that economic agents incline to moral hazard in case, when it is possible.Study shows how rational agents became less rational in terms of average market price, after intervention of a third party on the market. Third party intervention raises the average market prices presenting a manifestation of moral hazard. It is shown, that under given assumptions, even rational economic agents diverge from rational and market efficient strategies and behave irresponsibly. Despite generally negative attitude towards moral hazard, it is shown that economic agents have tendencies to behave in such a manner.During experiment we observed robust deviation in equilibrium market price before and after the third party intervention.
Key words
Moral hazard, economic experiment, market failures, state funding accelerating purchase, equilibrium market price

I.Introduction

The problem of asymmetric information and its impact onmarket efficiency was described byAkerlof(Akerlof1970). Akerlof showed that asymmetric information is harmful and can lead to market failure. Moral hazard is one of the possible manifestations of asymmetric information. Generally we assume that moral hazard is a change of economic agent´s behaviour when circumstances change.

For instance, moral hazard is the risk of behavioural changes of insured after contract of insurance is signed. Insured simply transfer one part of a risk to the insurance company and it can

result in his behavioural changes or even in damages of insured object, since he does not bear the financial burden any more. However, moral hazard is not a problem specific only to the insurance industry as it can be found almost in all fields of human activities. Theoretical background of moral hazard issue in economics dates back to1970s. Recognition of moral hazard started by published studies of Pauly (Pauly1968), Zeckhauser (Zeckhauser1970), Arrow (Arrow 1971) andMirrlees (Mirrlees1999).Mirrlees paper was published in 1999, but completed in 1975.

Capra et al. (Capra, Comeig and Fernandez 2009) haveempirically shown that moral hazard increases the chance of failure of investment projects. Study also showed that investors can be separated upon their risk attitudes also in moral hazard environment where such pattern is not expected. Jackson and Schneider (Jackson, Schneider 2011) found that moral hazard can be mitigated by common elements in social background of economic agents. Spenkuch (Spenkuch2011) documented, that people with health insurance do not undertake preventive care actions and are willing to be insured, once they realize, that their health is weak. Andreoni (Andreoni1988) and Costa (Costa 2005) showed that bigger groups have larger tendencies toward moral hazard than small ones. Bradbury and Drinen (Bradbury, Drinen2004) pointed out how different rules between baseball leagues create area for moral hazard among pitchers and how the possibilities of moral hazard induce unsportsmanlike conduct.

One of the most known particular examples of moral hazard related to the insurance market is the case of a small city in Florida in the 1970s. This event was published in Wall Street Journal 12/23/74. In this particular case, more than 50 people suffered accidents of various organs and extremities. The witnesses of these injuries were mainly relatives of the victims and as one investigator noted, most often the parts they seemed to need the least were shoot off. Over 300 000 $ were paid to the victims.

However the issue of moral hazard is not related only with the insurance market. Current situation of the global economy (fall 2011) was caused largely by moral hazard executed by authorities such as governments, institutions, ranking agencies, banks, chief executive officers, politicians etc. The status of the European common currency and efforts aimed at its stabilization by the European Stability Mechanism are often seen as manifestations of moral hazard, because imprudent countries are protected and saved at the expense of prudent countries with better balanced budgets. Another example of moral hazard are the governments bail-outs to banks, thus, banks are no more conservative and are willing to support and finance risky projects. Moreover governments have been buying toxic assets (assets fallen in value which are no more marketable) from the bank sector and has been providing rescue packages to the bank sector and big companies, which are "too big to fail". Rescue packages have also been given to some countries. At this time, lively debate among the population is led to determine laws in order to punish clerks, politicians, and office holders when they act and decide in favour of fallacy and non-efficiency, in order to avoid moral hazard. Examples of mentioned kind of behaviour are the golden parachutes given to employees which are leaving companies (very often these companies are state enterprises). Government benefits for unemployed, for peoples in distress, for parents that have children out of wedlock etc., are nothing but an area for moral hazard, because these public supports encourage people to become unemployed, to stay in distress and to have a child out of wedlock.

According to Kenen and Swoboda (Kenen, Swoboda2000) moral hazard is created by government guarantees of private loans and financial regulations, because cost of risky behaviour is covered by a third party. They mentioned as well that international financial support may contribute to moral hazard because of transferring losses outside of the country.

Previous examples demonstrate that intervention of a third party may cause moral hazard. The aim of this paper is to study and reveal tendencies of economic agents toward moral hazard in thecase of equilibrium market price, when third party intervenes on the market.Experimental design enables the simulation of moral hazard of economic agents in the case of receiving

governmental support (e.g. rescue packages to bank sector, co-financing projects, state funding with aim to accelerate purchase etc.).

However this study treats only aggregate data, not micro data that we obtained during the experiment. We are using economic experiment proposed by Gilette (Gilette1996). To present obtained data, descriptive statistics are used and to test hypothesis, inductive statistics are used.

II. Material and Methods

Experiment was conducted on Technical university of Košice – Faculty of economics, during summer term of 2011. In total, six sessions with 16 students each have been conducted, thus 96 students participated in total. Rationality of subject was induced by monetary payments at the end of experiment, which depended solely on the subjects´ behaviour during experiment. A total of 400€ was paid to the participants. Design of experiment included social, economic and moral aspects of trading.

III. Experimental design

At the beginning of every session participants were randomly divided to buyers and sellers. Participants knew that they were about to trade an unknown good on a market consisted of a given number of sellers and buyers. Participants communicated via an internet chat room. Every buyer was given a reservation price and every seller was given production cost. Buyer profit is calculated as the difference between his reservation price and the price at which he negotiated a transaction. Thus, to make the most profit possible, buyer needed to negotiate transactions as much below his maximum price as possible. On the other hand, sellers´ profit is calculated as the difference between the actual sale price he received from a transaction and his production costs. Thus, to make the most profit possible, seller needed to negotiate transactions as far above his production cost as possible. Of course, any seller could not sell at the price which was under his production cost and buyers could not buy at the price which was above his reservation price. Equilibrium market price and individual buyer (seller) reservation price (production costs) are shown on Figure 1. In our model, the exact value of theequilibrium market price is equal to 9,025 €. To induce trading, average reservation price is above average production cost. Market restrictions have been controlled by the supervisors who had access to chat rooms where participants performed their negotiations. After theexperiment instructions have been presented, participants were asked, if they fully understood the experiment. Any further questions were fully answered. Then experiment started.

After completing five rounds of negotiation and trade, participants were told that the market structure has changed and a third party will intervene on the market. This third party now will pay 80% of the negotiated purchase price in all remaining rounds to buyers. This simulated state funding with the aim to accelerate purchase. After completing ten rounds, final payoffs have been calculated and participants have been paid. Every session lasted approximately 60 minutes.

The argument for the third party intervention is to stimulate economic activity.
Fig. 1: Equilibrium price
made by the author

IV. Assumptions

Since we suppose that economic agents are rational and profit maximizing during the whole experiment, we do not expect robust deviation in equilibrium market price before and after the third party intervention. Our hypothesis is as follows: intervention of the third party on the market in last five rounds will not affect behaviour of economic agents and the price of the good will not increase. In Table 1, particular reservation prices of buyers and particular production costs of sellers are illustrated. Equilibrium market price is 9,025 €, average reservation price is 10,31 € and average production cost is 7,04 € (higher average reservation price than average production cost in order tostimulate trade).

buyer/seller	reservation price	production cost
1	6,00 €	11,35 €
2	7,50 €	10,20 €
3	9,00 €	9,05 €
4	9,75 €	7,90 €
5	11,25 €	6,75 €
6	12,00 €	5,60 €
7	12,75 €	3,30 €
8	14,25 €	2,15 €

Tab. 1: Prices and costs
made by the author

V. Results and Discussion

Figure 2 presents the evolution of average market prices among six groups within ten rounds. By eyeballing Figure 2 one can state, that in the first five rounds, the average market price is noticeably lower, than in the last five rounds. Moreover, during first five rounds, economic agents were able to trade below equilibrium market price. Equilibrium market price is illustrated on the Figure 2 by a straight line with equation y=9,025. Thus, in aggregate, third party interventions seemed to result in a rise of the market price.
Fig. 2: Average market price over 10 rounds
made by the author

If we take a closer look on the evolution of prices in individual groups we can observe the same pattern as in the aggregate view. Figure 3 illustratesthe evolution of average prices of the good during the experiment. Equilibrium market price is illustrated on Figure 3 by a straight line with equation y=9,025. We can see, that before the third party intervention, only in three cases (groups) the average market price was above equilibrium market price. Contrary, after the third party intervention, only in one case (group) the average market price was below the equilibrium market price.
Fig. 3: Average market price of individual groups over 10 rounds
made by the author

To test our hypothesis, we first test our data for normality using the Shapiro–Wilk test and then we use appropriate methods.
Shapiro–Wilk normality test:
H_0: Sample comes from a normally distributed population.

H_1: Sample does not come from a normally distributed population.

P-value for data obtained in the first five rounds is p=0,000139 and p value for data obtained in the last five rounds is p=0,01571. We conclude, that datasets do not come from normally distributed population, thus we will use nonparametric statistics. Since data are not normally distributed and we have two observations which are related, we are using Wilcoxon Signed Rank Test.

H_0: Datasets are from identical populations.

H_1: Datasets are not from identical populations.

Obtained p value is p=2,58e-06, thus we state, that there is a systematic difference between the market prices in the treatment without the third party intervention and with the third party intervention. This conclusion confirmed given hypothesis, that third party intervention on the market deteriorate market efficiency and cause market price increase.

VI. Conclusion

Although Pauly (Pauly1968) argues, that moral hazard is not a problem of morality and ethics, but is simply the manifestation of rational behaviour. Rice and Sen (Rice, Sen2008) showed that novice NBA players´ performance increases in the last season of their contract. However in the case of experienced players, their performance does not change during the whole long term contract. The long term contract can be seen as a surety that overcomes moral hazard incentives. This example shows that tendencies toward moral hazard can be eliminated for example by social aspects of economic agents.

This study shows how rational agents became less rational in terms of average market price, after intervention of a third party on the market. Third party intervention raises the average market prices presenting a manifestation of moral hazard.It is shown, that under given assumptions, even rational economic agents diverge from rational and market efficient strategies and behave irresponsibly. Despite generally negative attitude towards moral hazard, it is shown that economic agents have tendencies to behave in such a manner.

However it is it important to mention, that this study treats only aggregate data, not micro data that we obtained during experiment. Micro data will be the subject of further analysis.

CONVERGENCE IN THE EUROPEAN SOCIAL POLICY

Ioviţu Mariana PhD
The Academy of Economic Studies, Bucharest

The European Union has developed a series of strategies that aim to limit the consequences of non-employment (due to the continuing crisis). These strategies aim by the objectives and mechanisms specific to the eco-social area, to improve the access to employment, social services, professional education and a more efficient European fund management. All this are subordinated to the coupling policy public-private in terms of partnerships both at a national level and European level. The problem is related to differences manifested between the social objectives at the national level and those imposed by the European context. The differences come from different degrees of economic development of the member states, economic development which is reflected on the living standards. The convergence between the social policies is based on the economic convergence, which represents the only way to ameliorate the discrepancies between the united nations of Europe. Social Europe dream or certainty? The answer can be found in the words of Jean Monnet: "we are not bringing together states, we are uniting people". The efforts to define the four types of actions regarding the free movement of labor force and the correlation of the social security schemes, ensuring equal opportunities, respecting labor rights and the fight against discrimination can be found in the results obtained on these priorities.

Key words: social policy, subsidiarity, economic and social convergence, the workforce flexibility, the continental model of welfare, regulated profession, felxicurity, equal opportunities, social dumping.

JEL Codes: J 01, J 08, J 44, J 64, 65, J 83

National social policies are credited to solve some local social problems. They give evidence of inconsistency or partiality with regard to certain stated objectives, often, electoral. Thus, if at a national level the convergence of the social policy objectives cannot be achieved, the efforts for common approach at the European level will face objective difficulties and precaution measures. The occupational insurance schemes face the economic crisis' effects which affect all levels (for Romania it emphasizes the impediments regarding the labor migration).

The coherence in the European social policies context becomes, currently, a concept based on relativity.

The limited competence of the European social policies is based on the following pillars: legislation, action programs and financial incentives form the structural funds.

Currently, the problematic of the interest zone is reflected in: education and training, health, living and working conditions, social protection, equal payments and equal treatment for all employees, protection of children-the elderly and of the disabled population. To this problematic package the problem with maximum urgency is added regarding the social exclusion at the European level.

The White Paper in the European social policy (published in July 1994) provides a summary of the social policy thinking of the Union, demonstration the role of the social dimension of the E.U. at the end of the 20th century.

The social dialogue, the intervention of the labor management in the social dimension of the Union aims to create a closer union between the populations of Europe. However, the decisions have been taken (based on the subsidiarity principle) far from the will of the citizens of Europe.

Implementing the legislation for equal opportunities leaves much to be desired. The decisions, the recommendations, the opinions are, often, debates reasons which do not materialize, practically in effective measures.

Social policy or social philosophy?

The social affairs and the directions of development of the European social policies for the future are facing, currently, multiple disadvantages. Some areas of the social life have remained untouched by the official regulations, directives, decisions, recommendations and resolutions. This is due to the significant changes at the European labor market level.

The increase in the number of poor people, the increase of unemployment, lower-class extension, are phenomena that contribute to the pressure on the social services.

Promoting competitiveness and social progress are presented as being dependent on the economic prosperity. The approach between the levels of productivity of labor in the EU countries has contributed to the high social standards "reconciliation". Thus, compliance and economic convergence by similar levels of development, as an effect to the economic growth, will lead to the initiation of programs regarding the flexibility and continuous training of the labor force.

Coordination, monitoring, evaluation of the social partnership are objectives but also urgent tasks due to the aggravation of the work situation on the European labor market. Economic integration cannot be dissociated from the social one. Thus, the problematic package workers-labor market-freedom of movement workforce generates the necessity of a common social policy, coherent and comprehensive.

Something has been done, but enough remains to be done!!!

The "continental" model of the welfare, (as is formulated by theory in this field of study) present doubts and suspicions regarding the harmonization of social policies. For a more efficient process of harmonization two steps must be undertaken: the first concerns the understanding and correct perception of the differences between the national social welfare systems. The second step, finding those common grounds, useful for the removal of the approximately character of social protection harmonization, within the Member states' framework. Currently, for the case of migrant workers is the exception from the efforts of harmonization of the social systems.

The national cultural tradition is rooted in the national welfare systems. Thus, unity through diversity remains the key to success on a social European level.

The tax system, geographical location, work productivity level, the labor relation climate are factors that worsen (to what extent?) the competitiveness at the European level. The current standardization of the European fiscal system has positive consequences but also negative effects, seen in terms of workforce. Different taxation of the revenues (at the European level in relation to the national one)creates discrepancies but also the interest for finding and employment abroad. These situations can imbalance the labor force, obstruction competition.

The fear that social dumping will become a common practice at a European level, cause the European social policy makers to be more attentive in terms of the origin of the workers, particularly for the southeastern Europe.

The welfare of the state becomes a theoretically exclusivist slogan while the national welfare systems continue to produce measure which, fewer in number, converge towards welfare.

The catalytic effectiveness of the European commission activity for social affairs consists of the efforts for common approach of the social policies. As an institutionalized instrument of coordination within the EU database regarding the essence and the dimensions of the European social policy, the commission aims for the substantiation of a "European society".

Can we talk about the Pareto Optimum at the formulation level of the social policies at the European level?

The equal opportunities for all idea- is about all Europe's citizens, without discrimination-represents a principle and elevates to the level of fundamental European value. Equal

opportunities for all represent a goal and one of the base components of democracy everywhere, together with liberty and the respect for human fundamental rights.

An inconsistent state is emerging in terms of the abusive restrictions towards the Romanian and Bulgarian workers. While Italy and Czech republic have informed the European commission that they will lift the restrictions on the labor market for the Romanian an Bulgarian workers, starting with 1st January, other nine member states have notified the EU executive that they will maintain the restrictions until the end of 2013.

These countries are: UK, Ireland, Germany, Belgium, France, Luxembourg, Malta, Netherlands, and Austria[21]. The concerned countries have argued their position using explanation regarding the evaluation of serious disturbances on the labor market[22].

Although the European commission should not authorize the member states to continue applying these restrictions, the European Commission Commissioner for Employment, Social Affairs and Inclusion, László Andor, intends to present his own point of view regarding the notification received for the concerned member states and their explanations in a meeting of the EPSCO Council (work, social affairs, health and consumer protection). The treaty of accession of Romania and Bulgaria to the EU, allows the EU countries -25 (the founding countries and those that joined the EU before 1st january 2007) to restrict temporarily the free access of workers from Romania and Bulgaria to their workforce markets, in order to prepare the full freedom of movement within the EU.

The general transition period of seven years is divided into 3 stages (2 plus 3 plus 2 years). During this period, a safeguard clause allows a member state to reintroduce the restrictions, if there are serious disturbances on the workforce market or the threat thereof[23]. The transitory measures will end irrevocably at 31st December 2013. The current economic crisis represents a challenge for the manner in which each government comprehends to manage and resolve the national emergencies.

A global economic climate, elastic and fluid, will be ensured by the flexible conduct of the population who migrate towards a job that will bring a growth in the income. What should be emphasized is the existing differences between the migration phenomenon of the XVIII-XIX centuries and the workforce migration today. Of course, globalization-regionalization-integration as defining features of the present give a distinctive note to the workforce migration. Substantiation of some policies for combating poverty go hand in hand with the efforts of the countries (not only at an European level) to improve their economic status.

Therefore, a review of the reality with which the labor market faces currently, and the economic and social problems aroused after the wave of emigration-immigration, is a necessity in order to explain the connecting process of the economic performances to the economic and social communication effectiveness.

The professional education- means for approaching the European values
The labor market issue has a large openness towards the economic and social: it is not limited only to dealing with the supply and demand of the labor market in terms of quantity.

Addressing the qualitative side of the labor force requires an interpretative analysis of several components regarding: the qualification level, the creative potential available to the individual, the productivity level that he needs to demonstrate, the skills but also other qualities which he must prove, currently, the bearer of workforce.

---

[21] If such notifications would not have been sent until de early new year, 2012, the Romanian and Bulgarian workers would have had the chance of a place to work within the 9 countries.
[22] The same way acted Spain on 22nd July 2011.
[23] The current economic reality is marked by the globalization that generates new relations of economic forces at a global level: the European countries don't have the economic power to deal individually with the great competitors like USA, Japan or China and India, states which, currently, are in full economic boom.

The confrontation between the workers form east with those from west, professionally trained differently, as a result of some different politic, social and educational systems, reveals qualities and weaknesses, mentalities and behavior attitudes opposite if not contradictory, in which competition manifest between employees, for the workplace they applied for.

Shifting to other jobs ability, the labor flexibility dependent on the priorities and sustainable development strategies, concerns in equal measures the labor market at the community and national level.

As regards to the European problematic, it is emerging by maintaining the same aspects but under a different context: increased competition due to pressures from outside the community area[24], alarming aging of the population, the issue on energy in terms of source of origin, prices and the security of production, distribution and use, the ecosystem under ecologic danger etc.

The ambition for exiting the present recession stumbles upon the labor market status, which rises not only the issue regarding the employment but also the issue on education, professional training and qualification.

Reducing unemployment rate from 9% in 2004 to 1% in 2007 involves creating 6 million jobs at the community level, a staggering figure if we consider the possibility of employing these jobs in relation to the professional qualification. The issue regarding higher education diplomas recognition and also of other qualification certificates, within the EU represents another key point in the finalization process of the law on free movement of workforce.

A "regulated profession" involves the recognition of the professional activity in accordance with the laws, the regulations or with other administrative provisions, on the basis of a diploma.

October 20th, 2007 is the deadline for transposing and enforcing the Directive on diplomas recognition, which will operate by incorporating its provisions within the national law.

It shall be added that the Directive for the recognition of qualification 2005/36 of 7th September 2005, contains different provisions for those situations where the profession which will be carried out is not regulated in its home country. In this case, the worker must prove 2 years of professional experience and to conclude professional liability insurance; on top of that, the state where the activity will be carried out can reserve the right to verify periodically the professional skills of the worker.

The recognition of qualifications represents an essential step towards the liberalization in de facto of workforce movement[25].

The directive on the recognition of the qualifications within the EU is based on several criteria – duration, frequency, periodicity and continuity of carrying out an activity within the community area.

The provisions relate to 3 different regimes:

-*the general recognition of professional qualification,* which provides in the event of mismatch of professional training of the worker, attending a traineeship or an aptitude test;

-*the automatic recognitions system of the qualifications acquired through professional experience*, in this category being included a range of industrial, craftsman and commercial activities where professional experience can sometimes be automatically recognized.

-*the automatic recognition system of qualification for certain specific professions* such as doctor, nurse, dentist, veterinarian, midwife, pharmacist and architect.

---

[24] The objective of this Directive is to facilitate the deployment of services and establish the qualifications obtained in an EU state which allows the deployment of activities in another member state. It should be considered the distinction between the applicable regime for carrying out cross-border services and the regime applicable for the settling of the worker in a particular country.

[25] The French national assembly approved in 2006, the new legislation regarding immigration, specifying that the provisions were tightened. France will accept only high qualification carriers and for those from outside the European area it insists on specifying the mandatory responsibility of learning French and respecting the French democratic principles.

As in other cases, France is the country that has reservations on the opening of the labor market; the recognition processes of qualifications are facing the same obstacles as the freedom of movement of workforce[26].

Qualification means professional training and it manifests as a result of the educational process. The education represents, now more than ever, the safest means of getting closer to the European values.

Felxicurity of the workforce

The new concept, with equal economic and social coverage, is addressing and it's formulated in the interest of workers which are laid off. This socio-economic safeguard measure aims to provide a minimum social security throughout the workforce migration process.

As shown the concept seeks to answer the challenges within the labor market on the flexibility of the workforce, emphasizing the liabilities and responsibilities their employers or the labor market institutions have, in terms of guaranteeing a workplace.

Introducing such concept is due to the German concept and follows the model embraced by this Germany –"the social market economy".

On the occasion of the summit, in 2007, Angela Merkel argued strongly for the creation of a European system adapted to the human being not only to the business world[27]. It should be noted that at this summit the *social affairs, the workforce and the equal opportunities* were the three forces that expressed their concern and interest for the fundamental objective: the creation of new jobs in order to modernize the economies.

The arguments and assessments towards this direction are supported by the fact that the EU borders are defined rather by *systems of value than geographical criteria*.

Or, in this view, the differences between the level of performance and the workforce competencies cannot be sensed than in the situation when the worker is put to work. But for this, he must be granted the opportunity and the right to demonstrate what he's capable of.

The reluctance in terms of potential, skills and qualification of the eastern area worker, are nothing but signals of segregationist behavior, totally inappropriate and contrary to the values so assiduously invoked and preached by the EU.

It is not an exaggeration to say that the tensions between the east-west political regimes before '89 take currently the form of some social tensions. However, under these social tensions the whiff of some political confrontation and mismatches of mentality can be sensed. It is an exaggeration to think that the differences in mentalities between the former communist countries and the Western European countries will disappear as if by magic after their integration into EU.

In terms of employment of workforce policy, the European Council recommends that the member states make efforts to change the mentality regarding the work life cycle. This requires an education to accept the transition from one work place to the other or from a position to another within the same company, but also formulating measures through national policies to help the low paid or low skilled employees, the marginalized individuals from the labor market, in order for them to find a decent job in accordance with the living standards.

From all this provisions and recommendations the need for flexibility of the labor force becomes obvious. Perhaps the most pertinent aspect of the new configuration of the labor market is its capacity to face the challenges triggered by research and development.

The labor market manifests a variable geometry which currently, in order to meet the challenges and the objectives of economic growth and sustainable development, must prove mobility. The

[27] Hartmuth Kaelble - The study "lived" Europe and "conceived" Europe in the XX century: The social particularities of Europe,pg.45,in his book *Consciousness and European identity in the XX century.* René Girault (coordinator), Curtea veche publishing house, Bucharest 2004.

labor market cannot be flexible if the workforce doesn't prove flexibility and this is under the influence of the individual, of the manner in which they are perceived, understood and accepted the new requirements of the society progress.

Although the active workforce is the one that focuses the interest on job offer, however, the reality of the labor market reveals other aspects contributing to the tensions manifested lately.

The population ageing is a phenomenon that in addition to the positive effects of life extension implies also the formulation of some strategies for maintaining the elderly on the labor market. If biology has been successful in geriatrics, they must find resonance on the socio-economic policies of using this segment of labor force.

The gender mainstreaming requires the implementation of the strategies for promoting women within the labor market. The female workforce constitutes an essential factor which must be taken into account when shaping the new culture of the flexible activities. The feminization of the labor force in certain industries and fields of activity represent another step towards the modernization of the labor market. The majority of work places newly created within the EU are held by female graduates of different forms of education.

Although they are helping in achieving the economic targets, they encounter barriers regarding the manifestation of their total potential. In this sense, solving these situations created by employment discrimination fall in the capacity and tasks of the EU Commissioner for employment, social affairs and equal opportunities, job created precisely to prevent and mitigate the frustrating conflicting states endured by the female population.

Is the equality goal achieved?

 If the state through its policies opposes to the entry of foreign capital, then, it will be forced to undertake also the protection of those dismissed due to the closure of unprofitable companies. The entry of foreign capital is considered, in this case, as a means for capitalization of the uncompetitive economic agents (or insufficiently competitive on the foreign market).

The state's intervention may be interpreted in this situation as an example of undermining the social responsibilities of the economic agents forced to pay the compensations after layoffs. It is clear that the entry of foreign capital and the mergers between the economic agents are assessed, equally, as a favorable means for economic capitalization and as a globalization factor.

There is, in this direction, a point of view already formulated according to which if "the economic patriotism" exceeds a certain level (we are wondering which level?) it becomes a impediment towards the capitalization of the economic agents. By the government intervention the market is influenced, the European competition can no longer manifest freely and openly. We consider that here, it can be sensed the influence of the political factor, even if this influence is made with the help of another government (third party).

"The economic patriotism" is a formula designed to sensitize the European citizen, with the purpose of blocking the globalization, which disadvantages also the market and the citizen itself.

Another example on the opinion polls' effects at the European level is the feedback on the union effectiveness for the EU countries.

The appreciations relating to the European employees claims for the wage growth were made by the president of the European Central Bank, Jean Claude Trichet, I a very categorical manner: Europe cannot afford higher wages if it desires to provide for all its citizens a place to work.   If employment is desired (including creating new jobs for immigrants A/N) the claims for wage growth shall be abandoned.

The origin of this contraposition can be found in the interpretation of the correlation between employment and wage increases demanded by the European citizens. It is recognized and appreciated that a moderate increase in labor cost constituted a key factor in the policy for reducing the unemployment at the European level. The opportunity cost of such measure forces to choose between two objectives.

On the same tune, there was formulated a different conclusion: by 2020 EU should establish minimum social standards (without granting compulsory welfare) because this provision is the task and the attribute of each member state.

The intensification of exchanges between the European companies is a means for social and economic integration at the same time. Therefore, the multilingualism appears as a characteristic element of the equality and fairness European culture. The dialogue within the EU constitutes one of the key moments of the community development and progress.

"***This vision on social and cultural diversity within the EU is often used as a concept opposed to the political power concentration at Brussels, and economic standardization of the European community. The social and also the cultural are considered to be shelters. The representation of the national or regional social particularities gains more strength***"[28].

The pragmatism and globalization, phenomena which currently mark our existence, and modify our mentality, attitude and behavior, determined, often, passing the interpersonal communication, in the background. In a world where personal interest dictates where alienation becomes more and more extended due to the online networks, the communication remains the only gateway towards understanding the unity in diversity. Let's not lose sight that the super-connection is a risk, which doesn't necessarily means super-communication.

The main tool used for insuring the objectives of the social Europe is the European social fund (ESF). Defined as one of the main financing instruments of the investment in humans, the ESF of over 10 billion € annual expenditure, is oriented towards supporting the workforce and on increasing the professional skills, levers of labor flexibility. Its aim is to reduce the differences between the living standards and the professional skills of the individual, at a European level.

The key words that ensure the effective use of the EFS are the convergence and regional competitiveness and employment.

Time span	Goals and objectives
1957	Joint financing for the programs regarding the increase in of job skills and the development of labor capacity of the workers.
1984	Financing of individual projects of professional training and promoting the workforce.
1989	Financing the strategies for boosting employment and job creation.
1993	Funding integrated programs in the less developed regions with GDP/capita below 75%
2000	Supports the Lisbon Strategy and European strategy on employment according to the objectives on the workforce employment and on the reduction of unemployment.
2007-2013	The allocation of about 75bilion € for the regions and EU member states for the objective on professional competitiveness growth with employment purposes.

The operating mechanism of the European Social Fund provides five strategy directions:
- supporting and efficient enabling of the specific labor market policies on:
  a) fighting and preventing long term unemployment
  b) supporting professional integration of the young and of the unemployed,
  c) assisting the individuals with high risk level of becoming unemployed.
- Promoting equal opportunities for everyone, especially for the individuals under social exclusion risk.
- Promoting measures for the improvement of training, education and counseling regarding the learning process throughout life

DIMENSIONS OF HUMAN CAPITAL – SPECIFIC HEALTH APPROACH OF NATIONS CAPITAL

Jivan Alexandru
The West University of Timisoara, Faculty of Economics and Business Administration

Toth Maria
The West University of Timisoara, Faculty of Economics and Business Administration

The paper proposes sythesizing the most important correlations between the dimensions of human capital, in order to provide a better theoretical basis for assessing realistic valence motivated human resources sustainable development of society.

In terms of conceptual work based on the fundamental role of health capital and the neglect that often has its problems, especially in developing countries. Based on the review abstract theory of human capital, research establishes correlations between dimensions. It shows the importance of ethical component in professionalism and existence of moral capital rooted in medical ethics. Specific breakdowns of health capital, referring to the health of the population and medical services.

The research findings highlight the profound connection between morality and productivity seemingly nonexistent (customized to the case of medical services), about joint economic approaches ignored. It also means that the moral, professional and medical staff working in social capital formation influence the health of a nation.

1. Introduction

Since the 1960s, the concept of human capital developed through the valuable contributions of Gary S. Becker, Theodore Schultz, which showed the importance of creating a stock of human capital and investment in human capital for long-term development of the nation. Hence replacing the term labor with human resource. Human resource (human resources) is a broad term that implies investment, suggesting the need to avoid that if no investment in this resource, its potential is limited and/or lost (as if exhauted material resources) (1). The potential results(1) – the power of creation and production of income.

Investments in human capital are investment with long-term effect. Developed countries allocate a large share of GDP expenditure for investments in research, education, health, just the desire to maintain and develop intellectual progress thus technical progress and innovation. Unfortunately, because of poverty and perceived effort in terms of expenses related exclusively short term, most developing countries do not invest large amounts in human capital, materials prioritizing investments. Conceptual mistake is to ignore the effects of long-term needs of these investment expenses – as well as negative effects of scarcity or decrease of investments of this nature immaterial -, this equates to a misunderstanding of the nature of these investments (with the slow effect, „fruits" are collected over time, over generations) and the importance of investment in human resorces (the effect is lasting, distributed and complex: effect on future income at all levels, but also the entire society functioning, quality of life and the social and human civilization).

2. Basic dimensions of human capital

Human capital consists of several interrelated factors (dimensions) operating at the same time and together form the stock of knowledge, abilities, skills, health, innovations in the nation, plus stock (baggage and wealth), cultural, spiritual and of humanism.

Innovation is the starting point and guarantee success but is „maintained" the costs (which are really sustainaible investments) in research, education and health.

Human capital consists of health capital, educational capital and capital humanitarian. Links between the three dimensions is direct and continuous since we can not talk about health without investments in education, training providers and training level (education) a minimal level of beneficiaries (businesses and people in general), hygiene, healthy life, perception etc. indicated treatments, and also can not speak without humanitarian investments in the economy of poor countries.These effects are possible by creating the effect of flattening (Friedman, 2007) globally: if a country it affected the prospects of development and preservation of human capital, certainly these effects will be felt globally more or less powerful.

Health capital can be identified in terms of capital stock „required" in a country. The question is: why mandatory? Because the health of the population is influenced by investments in education (the development of education, skills and knowledge of future doctors, nurses) and technical and material investments in the health system of a country (technology innovation). Healing technologies and innovative treatments and disease are not possible without qualified medical personnel to use these resources.

Health capital can be „built" on the humanitarian capital. For example, if poor countries is beneficial to intervene to protect the health capital of each individual (Labourdette, 1988: 19), because in case of epidemics, not only poor countries are affected but also affected the world (attention must focus on prevention, not only treatment). Another example would be the protection of health capital through membership humanitarian, philanthropic, countries affected by natural disasters, „fragile" in the face of epidemics. And these guidelines (openings) are grown, educates, promotes (not necessarily only for themselves). Each state should consider and this component (which may free market rather ignore), including allocating a portions of expenses for humanitarian capital formation, i.e. investement in philanthropy, with global benefits.

Educational capital is closely related to health, because by investing in the education system provides health training and stock conservation.

It is capital to learn and to train future generations. The education system must ensure investment for all levels and specialities and appropriate national development needs, in close vision and (especially) future. Technical creation and technological in all areas of engineering and intellecty-intensive needs of qualified staff, especially specific research on all other intellectuals (doctors, teachers etc.) to bring ideas, innovations and improvements to create more advanced forms appropriate to different areas of social life and to also provide appropriate use of technical, professional and effective as to help preserve the stock of health capital, intellectual, humanitarian, from the country, and each individual.

„Education and training are most important investments in human capital." (Becker, 1997: 17)

„Education, practical course in computers, medical care and training figures on the virtues of punctuality and honesty is [...] capital, in that they improve health, increase profits or increase a person's appreciation of literature than in her lifetime. Therefore, total concordance with the concept of capital as it has traditionally been defined, to say that the figures on education, schooling, medical care etc. are equity investments. However, they produce human capital and not physical or financial one, because you can not separate a person's knowledge, skills, health or values, as is possible to move financial and psysical capital while their owner is not personally involved." (Becker, 1997: 15-16)

All through the existence of an educated population in a country maybe impacted capital formation among the humanitarian community and the desire to action social and environmental line against polarization and exclusion, to lift poor countries, areas and people with disabilities special (including materials), through various charities (formation of a philanthropic culture, humanitarian).

Educational capital means we are able to form a „stock" of knowledge and skills in the country. Importance of an effective education in a country leads to moral, ethical formation of a culture, but then to be translated into productivity in any field.

Education begins at home: the family is the „core of society", without family, society could not exist in the forms of civilization accumulated so far. To create a society „healthy" must in its composition to assert the existence of families and children with potential for further development. The role of parents in educating children is very important because education received in childhood affect mental, physical and moral future adults.

We belive that in the education system, quality school and university training must include, in addition meanings various specializations and specific applications, spiritual formation and overall cultural and intellectual background including religion classes (awareness of ethical values in the each generation), the artistic disciplines and art history, involving participation in extracurricular activities (theatre, opera, concert, excursions, camps, environmental protection activities etc. – necessary to form an ethical culture and collaborative and integration into society and elevated values of humanity and achieved the highest traditions of humanity), in context, should not underestimate the importance of sport classes and various sports events for the formation of discipline and team work spirit; all sides of an educational culture have started training since kindergarten, because the effects will be felt long term and sustainable. Future generations depend on the future of nations, the human component should be treated with priority investment projects in each state.

An intellectual skills and knowledge acquired in two main ways, namely through: (i) educational system – including faculty expert, any specific programs (2) and (ii) lifelong learning through self-study and participation in various scientific meetings, forums, debates and conferences on topical issues specialist. A framework of higher education to be efficient, productive, valued and known as a specialist should be informed by knowledge lifelong all news from the field (or specialization); performance and competitiveness, there is a degree sufficient but there has to be part of lifelong learning.

Another aspect of educational capital is the fact that the more a country has a population of less educated, the more health its capital will be better protected, each member of the community will want to preserve health, you know how to avoid factors harmful to their health (formation of a culture of keeping health).

Humanitarian capital consist of humanitarian philanthropy undertaken by various nations to help his fellow men by supporting health and educational capital formation of poor nations and regions.

We believe that philanthropy in Europe are conducted on three levels, namely: i) the European Union by providing humanitarian aid to poor countries (for example: combating poverty, combating HIV in Africa etc.); ii) the government of each Member State (for example: helping poorer regions of Europe) and in local communities (for example: helping disadvanteged rural areas, through the actions of prefectures and municipalities).

The importamce of humanitarian aid can be understood only if each Member State there is a culture made in this regard.

We can say that individual ethics, and thus the effective within the society, has its foundation in family upbringing as honor the spirit of giving, proper execution of tasks, self-control, respect for justice, assuming responsanility facts, values high human and concern for good and beautiful are initiated through valuable education and perpetuated by family friendly environments. These

elements are reinforced through education and through education system, the models promoted by society and all social culture (the way the company encourages or restricts certain events and values).

3. Specific approach with regard to health capital

Health capital formation need arises, beyond individual concerns of individuals in each state. Arguably the health capital is beyond the genetic heritage, the highest degree of efficiency effects of a country's health system and education system. And general health of a nation – inherited and present – is a reality that is „built" the safeguard and preserve in the time, the deep and proper concern, the people responsible state, concerns permanent, general and specific (and in any case the closure and merging of hospitals, but by preserving fiercely, despite any adverse circumstances, existing capacity by building more and more units of treatment and care of people by improving their endowment, by forming health professionals more and more high level), by effort, by all means, to improve care and all services provided nation, national and local programs specific term, raising quality standards achieved, maintaining and medical raising performance levels previously gained.

If efficiency and effectiveness exists in health care, also exist health capital there. Efficiencies with respect to the existence of quality medical service at low cost, and efficiency refers to reduce the number of patients, days of hospitalization, the recovery period (productivity in health services).

Health capital refers to: (i) health of the population and (ii) state health care services (availability, organization and quality, performance).

The existence of quality health services is ensured by highly qualified medical personnel (educational capital investment) to purchase materials related medical technical quality (technical capital investment).

We can say that improving the health of the population, reducing sick leave duration, days of hospitalization and medical system effectiveness and efficiency drive the health of a nation's capital.

Consider it necessary to add some specific elements moral capital (much needed in the medical field). We say that morality has an indirect influence on health capital, namely morality influences productivity in health services. Moral values are learned from childhood, in the family; in the childhood also forms human personality, sens of responsability and duty, faith, i.e. in the case of doctors, faith in the Hippocratic oath, an oath of honor, synthesizing honesty and responsability to the professional and human commitments in relation to higher values (3): criteria value acquired in the family since childhood is critical to all these (above).

Giving that involves a doctor treating a case has a direct impact on productivity, expressed in specific types of benefits/services that the quality of results achieved under cover those needs, and mainlyno priority in saving their own efforts, and productivity is possible to express production activities related material because such savings can mean insufficient cover need, i.e. unmet customer, failure of social function (as it happens, unfortunately, if medical staff reduction).

A future doctor is „modeled" in the family because his personality is formed since childhood, he acquiring moral values, sense of duty and responsability, by the various tasks entrusted by parents to their children. These elements vital to the development of adults are influenced by environmental and transmitted through the educational process, that can be modeled by parents, teachers, professors and employers, especially parents and teachers can decisively influence a child's personality.

Moral values acquired through education preparing future family doctor to form their own beliefs, feelings, attitudes and moral conscience. The calues learned in the family influences belief in the Hippocratic oath. If there is faith in the oath is formed conscience to do everything

possible for any patient to be treated appropriately. This process forms the moral responsability. „The moral responsability to understand the human ability to engage consciously in accordance with its possibilities as a moral issue, to assume certain duties, to meet them properly and to take upon himself the consequences of performance, of failure or the failure to correct the tasks. Responsibility is not just a feature of consciousness, but an attitude, manifested in conduct comprehensive." (Grigoraş, 1982: 198) This brings to the notion of medical ethics that refers to rules and moral qualities of medical staff in relation to patients.

A doctor is more valuable as time education in the family is strong, consisting of moral, cultural and professional inclination, the more responsable, irreproachable conduct adopted in the patients, is characterized by a spirit of dedication to solving medical cases, which may contribute to recognition of its value in a professional, increase awareness, the number of patients. These are the ways and criteria of birth competition between physicians most beneficial to society.

Education through the educational system complete family upbringing, must keep a good balance in education, without underestimating either of these two components, plus the social – close (friends, collegues etc.) and generally, including means of communication table, the internet and cyberspace in general, trends of opinion etc. In addition to the values obtained in the family, state intervention and investment in educational capital of the country. Besides these, an important role is the current social and professional (practicing).

The professional and skills acquired during life by medical staff (including participation in medical conferences and seminars) contribute substantially to increasing awareness, performance and competitiveness of medical services. The office, near the doctor, also exerts a decisive influence on his personality, by creating favorable environment for leisure and avoid overexertion (overwork leads to very serious medical errors).

All influence to some extent health capitaş formation, both at each individual and the nation.

By highlighting these general issues concerning the moral, professional and social, we can say that a balance in both personal life and professional life, is vital, especially in health and education systems where there is direct contact with human resources of society.

4. Conclusions

The foregoing conclusion, that every nation has the potential development of their human capital potential can be transformed into investment in human resources. Thus, developed countries regulate, through various regulations, research, innovation, education and health systems development, environment protection, however, developing countries or underdeveloped does not pay attention to these segments of economic, social and cultural. Often, in an economic recession, developing country government stake excessive Crisis neglecting the human component as part of the economy and instead to invest long term in human potential, prefer short-term investments, without giving proper importance to human capital.

Short-term effects seen, at the level of individuals, but also seen long term effects, at the national level, in general health of population, education etc., in general valences and future population concerned. And this general condition is clear and visible effects in the economy: they are direct, especially with the average productivity of individuals (to the extent that they are better or less of medically assisted), and indirect, such as, for example, report the effect of sustained population (including pensioners, the sick people etc.) and supporting population (active, productive) by the effects on crime rates, unemployment etc. This types of effects (short and long term) are added the effects (less discussed, not only between governments, but even in traditional economic theory, neoliberalism) very long term(4) the nation state, their place and role globally in humanity.

MAIN ASPECTS CONCERNING INTELLECTUAL SERVICES PRODUCTIVITY WITH FOCUS TO EDUCATION

Jivan Alexandru
West University of Timisoara, Faculty of Economics and Business Administration

Weisz Janeta
Christian University "Dimitrie Cantemir"Bucureşti, Faculty of Tourism and Commercial Management Timisoara

Part of a larger research, this paper aims to point out several key elements of the productivity in the field of services, with application to the intellect-intensive ones: the main concern is for educational services.
Methodologically, the paper starts with the framing in the context of the knowledge based economy and its requirements concerning scientific approach on productivity. Customizations are made to educational services, followed by certain extensions of the issues discussed and synthetic correlations.
Conclusive results underline the intellectual core of most productive efforts of human mankind: investments in human capital.

Keywords: productivity, knowledge, technological progresa, education, economic growth

Jel classification: I25, J24, O15, P36

Introduction

Realities of the new knowledge-based economy requires an appropriate updated approach: to avoid simplicity approach of services productivity - matter so criticized by specialists - issue related to this indicator, must be considered in depth and horizon widened, in all aspects, starting with the identification of measurements used to measure services. Developed economies allocate part of their resources to activities with intensive data processing services and information for which, the measurement results cannot be precisely in traditional forms, so researchers need to rethink how to measure productivity and the result of economic activities.

We must make a clear distinction between work done for the production of services and the results of this work (benefit effects). For example, results of educational benefit, depend, among other things, on the intellectual faculties of the students, on the methods used for development, on all circumstances that may make progress in any way, including the preservation and development.

Customize to education. Some extensions necessary

François Perroux, assings to institutional system a role for growth, plus social and moral climate and psycho-sociological factors. Along with capital accumulation, Perroux talks about acquiring knowledge. On this aspect, Keneth Arrow says that "growth is the daughter of knowledge" (Arrow 1962: 155-173), as being true and inverse correlation in our approach, which will be shown below.

By the 60s of last century took place in the United States, a broad debate among economists on efficient sources of economic growth (Wonnacott 1978).

As "production index" for education, are used most often, the number of pupils and students and the fees for registration and, in analysis, are used index of wage or price (Jivan 2000: 55). According to ARACIS (Romanian Agency for Quality Assurance in Higher Education 2009),

this indicator is expressed by widening access to higher education, dropout rates, learning outcomes and teaching, research results and hiring graduates.

Mihail Manoilescu (Manoilescu 1986:46), comes to defining the problem of productivity in accordance with "the new interpretations of exchange value, which includes the *various and subtle causes*, explored until now by science" (emphasis added). For example, if a product or service that is based on a very recent invention, so it is new on the market, and may have monopoly, we must take into account the main elements that determine the exchange value, namely: the usefulness of its power of attraction exercised (in this regard, marketing has an important role), quality and, of course, price. In other words, the conversion value is the price the customer is willing to pay for the new product or service to obtain a degree of satisfaction. This approach raises specific problem to the intellectual services.

Productivity of educational services is found in all activity fields. For example, a computer is designed by intellect-intensive services (research, information, etc.), in which are working professionals, who must have adequate training (conducted, primarily through educational services), it is produced by industry (where teachers work with proper training), and for use in various activities, their users need also knowledge related to computer (often gained by attending appropriate courses; in the same way, a car cannot be used in traffic if the driver has not learned the rules of the road and has no knowledge to run it).

"As more is known, is increasingly need science. A large area is to increase knowledge and ignorance horizon. Development of an economy is actually based on three pillars: innovation, research and education. Any addition of individual service quality is amplified. The essence of value was and remains useful in certain conditions of availability "(Jivan 2000: 66).

Following the analysis of macroeconomic correlations between economic growth, technological change in recent years and improved quality of labor, Edward F. Denison concludes that technological change and, hence, economic growth, are not insured by the simple purchase of equipment more efficient, but only in terms of labor quality growth, thus increasing the costs for training and education. These expenses are found in gross domestic product growth, which means *that investment in education is money not spent in unproductive sector* (Denison 1962).

The conclusion is that technological progress is determined by labor quality growth, such as the better educational system, more efficient, based on knowledge, which in turn becomes a factor of economic growth.

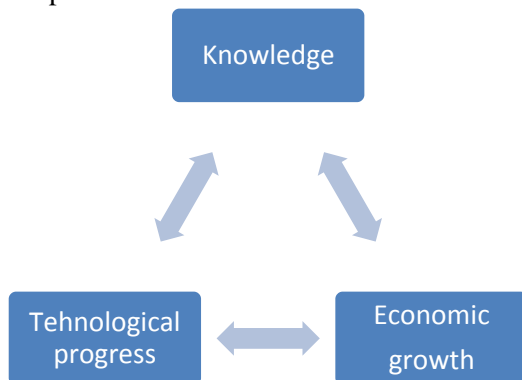
Returning to the idea of Keneth Arrow stated previously, we could say that, in the national economy, are forming a virtuous triangle (as you can see from figure 1) between knowledge, technological progress and economic growth. The three elements are closely related. Stress (not develop here) the reciprocal of this determinism.


Figure no 1. A virtuous triangle of economic growth
Synthetic correlations between scientific research, education and production activity

On these correlations, worthy of consideration is the so-called "Japanese miracle" manifested in the next period of the Second World War and which is explained by increasing the initial expenditure on education, which led to the existence of much increased number of people better prepared to quickly assimilate technology news.

It was such a new approach to economic theory and, in time to an economic analysis of the educational system. One of the first works in which it is studied from an economic perspective, the relationship between science, education and production, belongs to J.L. Maunoury in 1962, which inventories these twelve correlations:

- *Scientific research* increases the fund of knowledge available to mankind.
- *The production*, also has the products, new information, which are added to the fund of knowledge.
- Existing knowledge *are valued* both in the production process and in obtaining new knowledge.
- Scientific activity is conducted, based on existing knowledge.
- Knowledge is transmitted by the *school system*.
- The production raises problems, whose answer with economic value is found in scientific research.
- *Education* forms *the researchers*.
- *Education* forms suitable qualified labor for *production*.
- Labor force, at anytime can be brought back in the education system for retraining.
- *The production* itself *forms* skilled labor.
- The researchers *improve* their skills and abilities in the *scientific activity*.

The concept of education used above, must include all forms of training: the "classic", modern forms, to "continuing education" (much invoked today). These services with high intellectual charge, form properly trained staff not only for production but also for overall economic activity, which includes intellectual service providers, category in which enter teaching and research staff.

In terms of production activity, it is considering, in fact, economic activity in general (and any human activity performed in the social frame: unit non-profit, relief and health organizations with ecological, religious, political, cultural, etc. objectives). Optical author quoted, seems to be, knowingly, outside the *economy* system, as something special, and not as a sector that works and action largely on economic criteria, through economic units – often, large companies). We believe that more should be added, that not only production activity raises the question of scientific research: but life (in general); here is an analysis from an economic point of view, referring to the scientific research, but also the issues arise, and by life in general, not only by production activities, especially as we must have in mind also intangible economic activities, tertiary economic sphere and optical serving.

Education will be the growth factor, only under certain conditions of market regulation, namely, only if the market absorbs productive educational offer and life of society puts it in value, without spoiling it or without the need for continuous training (adaptation, updating), but to fulfill those conditions is necessary to implement an effective government strategy. Shortly, functionally, a major condition is such that the institutional organization to provide training, on the one hand, the higher formation of human resources and, on the other hand, sucking them as beneficial economic and social system. Understanding the relationship between state and free market, form that is considering leaving the state on account of economic action that will be directly affected by the consequences that they foresee in their decisions, but not losing sight of wider (external effects) and long terms implications- matter in which educational strategies are of the great importance. In this respect, the decision should be *most able to take on an expanded knowledge,* allowing major guidelines to follow, established by the contribution of the intellectual elite (at academic level, while respecting autonomy to the said university), (enhanced), based on perennial values, thus taking into account a wider scope than the term arising from market mechanisms.

We note that these mechanisms always contain the risk of myopic approaches, can very easily, as private interests in achieving efficiency in the short term, to hide the destructive effects - as can be seen (and taken into account) only from a strictly individualistic superior vision, on short term and for limited interests in spatial, temporal and conceptual terms (the area of interest: often only economic).

As an economy is larger and more developed, will be much more specialized workforce, and even higher, trading and demand for goods and services. Major cities are rich because of its increasing division of physical and intellectual labor. Therefore, countries such as Germany, France, Italy etc. attract specialized labor force, cheap, from countries like Romania, Bulgaria, Albania, etc., the first category is still developing, becoming in time economies more powerful and finally, the second category of countries, stagnating or even regress recording.

Many countries, including Romania, have governments that do not prove a very tall professional and efficient on intangible investments and have a plan or strategy to invest in the young nation, and to send enough to study and training in areas that advance healthy scientific and professional can be of major importance for the country. In most developing countries, there is a corresponding interest for training specialists and bringing them country by providing conditions to get out from the crowd and demonstrate that there are intellectual potential. Knowledge (knowledge) seems the only guarantor of economic and social progress, as research-innovation (knowledge creation), in this case, research and education plays a key role (assimilation of knowledge, training and professional modeling), education in general.

Knowledge is defined as the power to understand and capture the essence of facts, certainties and recovery information obtained in the form of experiences and lessons (Druker 1992: 95-104). In many developing countries, as is the case of Romania, the education graduates are often placed in a position to migrate due to the fact that state policies are not sufficiently flexible and visionary in the future (long-term effects) to properly integrate the national economy, the concern for providing adequate employment and paid accordingly, in order to benefit the national economy, such that the extra knowledge. An economy for the benefit of integrating these values in the nation to put a priority and preferentially, is the intellectual intensity centers, including high-impact decision - at all levels, starting with the government.

It is right here, citing inspired formulations of Tom Peters: "turn them on staff in Vital Centre of Intellectual Capital Accumulation ... and not bureaucratic sources of stress (Peters 2011: 24) ... A fully mature company, is one that provides professional ... TRANSFORMATIONAL projects dedicated / excellent customer service".

Conclusions

Professions in the knowledge-based services (the intellect) is developing very rapidly, as firms, companies need people with skills, training and know-how needed to get know each other from different sources, process it and exploit it productively. To the expenditures of this nature, must be given the status that they have: that strategic investment, on long term effects. It is therefore very important to invest in this type of human capital which can contribute to economic and social development of countries. In these respects, logical connections (compared) with the Romanian government crisis policies, speak for themselves (it is not our purpose here for other comments).

DATA ISSUES IN TOTAL FACTOR PRODUCTIVITY BENCHMARKING: A CENTRAL EUROPEAN PERSPECTIVE

Machek Ondrej
University of Economics in Prague, Faculty of Business Administration

Total factor productivity is a method of measuring overall productivity of businesses, industries or economies. It is an approach which is recently becoming popular among government regulatory agencies when applying the so-called performance-based regulation. This principle induces regulated companies (for instance, electricity or natural gas distributors) to behave efficiently even if their industries are not exposed to competitive pressures, since they are rewarded for being more productive than other firms in the industry, and penalized in the opposite case.

The aim of this article is to deal with the question what are the main data issues when comparing total factor productivity among firms or industries with focus on the Central European region, which is very heterogeneous in terms of geographic, social, economic and historic conditions.

In the first part, we introduce total factor productivity and the most common methods of its measurement – Malmquist and Törnqvist indexes. Consequently, we divide the data issues into separate categories and discuss them more in detail. The first category of issues is related to defining the set of comparable firms. Many factors, such as the degree of competition in the market, the extent of government regulation, economies of scale, firm size, geographical conditions and historic development have to be taken into consideration. The second category is associated with specifying the time period. TFP estimates should be based on long time series and the period should include the whole business cycle and be representative and exclude extraordinary events. The third group of issues is related to defining and measuring the inputs and outputs. Since a number of difficulties are associated with labor input measurement, it is often included into operating expenditures along with materials and services. The measurement of capital is even more contentious. The outputs should reflect performance, complexity and quality of service rendition. Finally, the fourth category of problems concerns determining the costs of inputs and outputs (cost-based indexes) or defining and measuring the reference technology (distance-based indexes), where some degree of arbitrary judgment and inaccuracy is inevitable.

We conclude with the suggestion to avoid methods requiring large time series such as frontier-based methods of efficiency benchmarking (data envelopment analysis or econometric methods) or Malmquist TFP benchmarking in the Central European region due to huge differences between firms and their environment. However, the question of the best performing regulatory methods is still not clarified and is subject to intensive academic debate.

1. Introduction

Productivity assessment is an important tool both for firms, which need to evaluate their performance in order to find weaknesses and improve their position in the market, and for regulatory agencies, which need to assess efficiency of firms being regulated by the government. Total factor productivity is an approach which takes into account all inputs and outputs of the evaluated firm and aggregates them into a single scalar value. Productivity measurement has recently become popular among government regulatory agencies when applying the so-called **performance-based regulation**. A regulated firm's productivity growth is compared with the productivity growth of other firms in the industry. When the firm succeeds to improve its

productivity more than other firms, it is rewarded by greater allowed revenues. This principle, often referred to as **regulatory benchmarking**, induces regulated companies (for instance, electricity or natural gas distributors) to behave efficiently even if their industries are not exposed to competitive pressures. Most frequently, total factor productivity is measured by indexes of productivity. The results, however, are dependent upon the quality of data.

This issue is particularly evident in heterogeneous regions such as the Central Europe. The aim of this article is to deal with the question what are the main data issues when comparing total factor productivity among firms or industries with focus on the Central European region, which traditionally includes Czech Republic, Slovakia, Hungary, Poland, Germany, Austria and Switzerland. In the first part, we will introduce total factor productivity and the most common methods of its measurement – Malmquist and Törnqvist indexes. Consequently, we will divide the data issues into separate categories and discuss them more in detail.

2. Total Factor Productivity and its Measurement

Traditionally, productivity is defined as a ratio of output over input. The total factor productivity (TFP) approach takes into account all outputs and inputs of the evaluated firm. Therefore, it is necessary to aggregate the set of outputs and outputs so that productivity becomes scalar value. In practice, TFP is measured by productivity indexes or productivity indicators. Indexes have multiplicative form, whereas indicators have additive form. The measures can be based either on distance function, or on price aggregation. Among measures based on distance function, we can cite Malmquist productivity index (Caves et al. 1982), Hicks-Moorsteen productivity index (Diewert 1992: 240) and Luenberger productivity indicator (Chambers 1996). The most common TFP measures which are based on price aggregation are Törnqvist productivity index (Törnqvist 1936), Fisher productivity index (Fisher 1922) or Bennet-Bowley productivity indicator. In this article, we will deal with two most frequently used TFP measures, Malmquist and Törnqvist indexes.

Malmquist index of productivity

A produced can be defined as an entity transforming a set of inputs $\mathbf{x} = (x_1, x_2, ..., x_n)$ into a set of outputs $\mathbf{y} = (y_1, y_2, ..., y_m)$. In order to define Malmquist index, we have first to introduce the notion of efficiency. **Efficiency** of a firm can be defined as a ratio of observed values of inputs and outputs and their optimal values. The analysis of efficiency can be oriented either on minimizing inputs with given outputs or maximizing outputs with given inputs. The production technology can be represented using a set of couples (input-output vectors)

$$T = \{(\mathbf{x}, \mathbf{y})\}, \text{ where x is input to produce y.} \tag{1}$$

Another possible representation of production technology is the output requirement set P(x), e.g.

$$P(x) = \{\mathbf{y} : (\mathbf{x}, \mathbf{y}) \in T\} \tag{2}$$

As a measure of efficiency, we can use the Debreu-Farrell approach (Debreu 1951; Farrell 1957). Using the above-described notation, we can define the Debreu-Farell measure of technical efficiency as the maximum possible equiproportional increase of given output so that it still belongs to the output requirement set.

$$TE(\mathbf{x}, \mathbf{y}) = \max\{\Phi : \Phi\mathbf{y} \in P(x)\} \tag{3}$$

The inverse value of technical efficiency is called distance function.

$$D(\mathbf{x}, \mathbf{y}) = \min\{\lambda : \mathbf{y} / \lambda \in P(x)\} \tag{4}$$

When applying the output-maximizing approach, the lesser the distance from a production frontier, the better is the efficiency score. In the real world, the production frontier is unknown and has to be estimated using econometric methods (e.g. corrected ordinary least squares, COLS) or mathematical programming (e.g. data envelopment analysis, DEA). Using the above described definitions, we can define the Malmquist index of productivity. Consider a period during which the production has changed from $(\mathbf{x_t}, \mathbf{y_t})$ to $(\mathbf{x_{t+1}}, \mathbf{y_{t+1}})$. The Malmquist index of productivity for period t, respectively for period $t+1$, would be the ratio

$$M_t(\mathbf{x}_t, \mathbf{y}_t, \mathbf{x}_{t+1}, \mathbf{y}_{t+1}) = \frac{D_t(\mathbf{x}_{t+1}, \mathbf{y}_{t+1})}{D_t(\mathbf{x}_t, \mathbf{y}_t)}$$

$$M_{t+1}(\mathbf{x}_t, \mathbf{y}_t, \mathbf{x}_{t+1}, \mathbf{y}_{t+1}) = \frac{D_{t+1}(\mathbf{x}_{t+1}, \mathbf{y}_{t+1})}{D_{t+1}(\mathbf{x}_t, \mathbf{y}_t)}; \tag{5}$$

If the technology has changed during the period, these two indexes would result in different values. Therefore, it is common to employ the geometric mean of the two indexes and specify the **Malmquist index of productivity** as

$$M(\mathbf{x}_t, \mathbf{y}_t, \mathbf{x}_{t+1}, \mathbf{y}_{t+1}) = \sqrt{\frac{D_t(\mathbf{x}_{t+1}, \mathbf{y}_{t+1})}{D_t(\mathbf{x}_t, \mathbf{y}_t)} \times \frac{D_{t+1}(\mathbf{x}_{t+1}, \mathbf{y}_{t+1})}{D_{t+1}(\mathbf{x}_t, \mathbf{y}_t)}} \tag{6}$$

Malmquist index is of great theoretical importance. However, it is necessary to estimate the real but unknown production frontier using econometric or mathematical programming methods.

Törnqvist index of productivity

Törnqvist index is an example of indexes which can be calculated from observed empirical data without having to estimate the unknown production frontier. These indexes are often called superlative indexes. Under certain conditions (see Färe et al 2008: 564), they approach Malmquist index. The calculation is based on observed prices (weights) of input and output factors. Let $w = (w_1, w_2, \ldots, w_n)$ denote the prices of inputs and $\mathbf{p} = (p_1, p_2, \ldots, p_m)$ denote the prices of outputs. Törnqvist index of productivity is defined as a ratio of output quantity index Y_T and input quantity index X_T. Usually, the two quantity indexes are specified in their logarithmic form as

$$\ln Y_T = \frac{1}{2}\left(\sum_m \left[\frac{p_{m,t} y_{m,t}}{\sum_m p_{m,t} y_{m,t}} + \frac{p_{m,t+1} y_{m,t+1}}{\sum_m p_{m,t++} y_{m,t+1}} \right] \ln \frac{y_{m,t+1}}{y_{m,t}} \right)$$

$$\ln X_T = \frac{1}{2}\left(\sum_n \left[\frac{w_{n,t} x_{n,t}}{\sum_n w_{n,t} x_{n,t}} + \frac{w_{n,t+1} x_{n,t+1}}{\sum_n w_{n,t++} x_{n,t+1}} \right] \ln \frac{x_{n,t+1}}{x_{n,t}} \right) \tag{7}$$

And finally, the **Törnqvist index of productivity** can be specified as

$$\Pi_T = \frac{Y_T}{X_T} = e^{\ln Y_T - \ln X_T} \tag{8}$$

3. Data Issues of TFP Benchmarking

Robust and reliable TFP estimates depend substantially on the availability of long term and reliable information on input and output measures, ideally for a large number of firms operating in the relevant industry. This approach involves multiple issues which we will discuss in this section. First, a set of comparable firms has to be chosen and the time period has to be specified. Then, as follows from the definitions of productivity indexes, it is necessary to define the appropriate set of inputs and outputs, which have to be measured accurately. In addition, production frontier (Malmquist index) or costs of inputs and outputs (Törnqvist index) have to be estimated. Besides these issues, other can arise from typographical errors, invalid observations and unusual observations that are real outliers (Coelli et al., 2005).

To sum up, we can divide the data issues into four categories:
- Defining the set of comparable firms;
- Specifying the time period;
- Defining and measuring the inputs and outputs;
- Determining the costs of inputs and outputs (cost-based indexes) or defining and measuring the reference technology (distance-based indexes).

3.1 Defining the set of comparable firms

The major issue arises when choosing a suitable set of comparable firms whose productivities will be compared against each other. A great number of factors are influencing each firm's performance (see e.g. Pedell 2006: 24). Some of them are related to the firm itself (size, ownership structure, capital structure, age and quality of assets) and others are related to the environment (inflation rate, interest groups, unemployment, purchase power, customer density etc.) For instance, regulated and competitive firms productivity should not be benchmarked since the productivity of competitive firm is likely to be higher (see e.g. Orazem and Vodopivec 2009) and similarly, the extent of government regulation affects productivity (Crafts 2006) which distorts international comparisons. The empirical evidence on the effects of firm size on productivity is mixed (compare e.g. Leung et al. 2008 and Dhawan 2001), however, economies of scale should be taken into consideration. Capital structure is also likely to affect performance; however, in Central Europe, debt is used to a lesser extent in Eastern countries than in Western countries (Machek 2011). The issue of age and quality of assets is particularly important when comparing developed countries and former states of the Eastern Bloc; in post-communist countries, the development was centrally planned which has an impact on nowadays quality and structure of assets and maintenance costs. Geographical conditions also affect costs; in mountainous countries such as Switzerland, the maintenance and construction costs are likely to be higher than in flat countries such as Hungary. The choice of adequate sample of firms seems to be the very challenging, however, in small countries, domestic data are not sufficient and international benchmarking has to be employed.

3.2 Specifying the time period

In general, productivity growth is more accurately measured in long term, since TFP can vary substantially from one year to another. The time period has to be representative, should include the whole business cycle and exclude any extraordinary events. For instance, Blanchard and Kremer (1997) found that increased competition in the countries of the former Eastern Bloc may have contributed to TFP decline because it disrupted the Warsaw Pact economic connections. Similarly, privatization of state-owned firms may cause a TFP decline, because the technology

gap may discourage enterprises restructuring (Angelucci et al. 2001). Furthermore, introduction or variation of regulatory regimes seems to reduce productivity, but in Central Europe, modern economic regulation has only a short history which further reduces the possibilities of reliable long-term TFP estimates. The lag between investment and its effects is also nonnegligible. Short-term results may look poor, because the effects of investments in infrastructure are not immediate (Brynjolfsson 1993).

3.3 Defining and measuring the inputs and outputs

There are many conceptual and practical issues in identifying the number and level of aggregation of inputs and outputs for each industry. Classical input factors which should be taken into account are labor, capital and materials.

Labor is most often measured by the number of employees or man-hours, which should be corrected, since outsourcing of activities can distort the results. Activities should be well defined and separated (for example, electricity distribution and sale). Moreover, employees can differ in their skills, education and experience, but more skilled employees contribute to the growth to a greater extent. It is preferable to distinguish among these categories of employees. Because of these difficulties, labor input is sometimes incorporated into operating expenditures (OPEX) which are taken as an aggregate measure of labor and materials.

The most contentious is the measurement of **capital**. The capital used in regulatory benchmarking has to fulfill several requirements in order to be included in the asset base (just and reasonable, useful, prudently incurred etc., see Lesser 2007). Moreover, as previously mentioned, the quality and age of capital may vary substantially, as well as its valuation methods. The capital is often measured directly and proxied by kilometers of wires (electricity distribution) or pipes (natural gas distribution) which are invariant to different depreciation schemes. However, the relation between these proxies and real capital stocks is not clear. Indirect measurement of capital is based on the value of assets, which raises the question of accurate and comparable valuation (especially replacement cost valuation methods versus historic cost methods). A good analysis of capital measurement and associated issues has been carried out e.g. by Coelli et al. (2005).

Outputs used in TFP estimates should represent the basket of services provided by regulated firms. Outputs of distribution companies should reflect how much is being transported, how far it is being transported, and the quality of service. The set of outputs should reflect both 'supply side' and 'demand side' (see Lawrence and Diewert 2006: 214). The definition of the quality aspect is particularly challenging, because there is not yet a definite way of incorporating common reliability and quality measures in TFP calculations, since it seems that increases in quality are reflected in a decrease of TFP rather than an increase. Moreover, as we already mentioned, investments in quality improvement make short-term results look poor, because the effects of investments are not immediate, and the investing firm is being penalized rather than rewarded.

There are more issues concerning availability of data and their accuracy and comparability. In tariff regulation, data are provided by regulated companies; it is logical to suppose that they not be perfectly accurate, since regulated companies seek to improve their own efficiency.

3.4 Estimating the costs of inputs and outputs or the production frontier

Usually, the costs, i.e. **weights of outputs** are derived from the share of each output in total revenue (in the case of competitive industries, where prices reflect marginal costs) or output cost shares (in the case of natural monopolies). The latter case is more complicated, since it involves either arbitrary judgments about the relative importance or econometric estimation of cost function (Lawrence and Diewert, 2006). There is an academic debate over which of these approaches performs the best. However, some degree of inaccuracy is practically inevitable. Similarly, the **weights of inputs** are represented by the share of each input in total costs. Capital

input costs can be calculated either directly from estimates of depreciation, opportunity costs and capital gains or indirectly as the residual between total revenue and OPEX, in which case the capital input variables have to be allocated according to their proportion in total asset value.

When distance-based TFP measures are employed, it is necessary to estimate the **production frontier**. This approach involves all inconveniences related to frontier methods such as COLS or DEA; especially the need of a large number of observations to obtain robust estimates, influence of noise and overall complexity. On the other side, these methods incorporate input and output weights implicitly and it is not necessary to estimate them.

5. Conclusion

In this article, we dealt with the question of the main data issues when comparing total factor productivity (TFP) among government regulated firms or industries with focus on the Central European region. This question is important both for regulatory agencies in deciding what regulatory methods to adopt, and for regulated firms in evaluating their own productivity, identifying weaknesses and threats and negotiating with regulatory agencies.

We divided the issues associated with TFP benchmarking into four categories. The first one is related to defining the set of comparable firms. Many factors, such as degree of competition, government regulation, economies of scale, firm size, geographical conditions and historic development have to be taken into consideration. The second challenge is associated with specifying the time period. TFP estimates should be based on long time series and the period should include the whole business cycle and exclude extraordinary events. The third group of issues is related to defining and measuring the inputs and outputs. Since a number of difficulties are associated with labor input measurement, it is often included into OPEX along with materials and services. The measurement of capital is even more contentious. The outputs should reflect performance, complexity and quality of service. The fourth category of problems concerns determining the costs of inputs and outputs or defining and measuring the reference technology, where some degree of arbitrary judgment and inaccuracy is inevitable.

Due to the difficulties associated with the heterogeneity of firms and their environment, which is especially evident in the Central European region, we suggest to avoid methods requiring large time series such as frontier-based methods of efficiency benchmarking or Malmquist TFP benchmarking. However, the question of the best performing regulatory method is still far from being clarified and is subject to intensive academic debate.

WHY THE INCREASE OF THE PUBLIC INVESTMENTS DOES IS NOT AN ANTI-CRISIS SOLUTION IN ROMANIA?

Marinas Marius
Bucharest University of Economic Studies Faculty of Economics

Socol Aura Gabriela
Bucharest University of Economic Studies Faculty of Economics
Socol Cristian
Bucharest University of Economic Studies Faculty of Economics

The higher public investment during times of economic recession is sustained by most economists, starting with Keynes. However, this solution does is not working in economies characterized by a poor efficiency and by corruption in the management of public funds, such as in the case of Romania. Although in the period 2006-2009, Romania has spent the largest share of GDP for public investment (from EU-27 countries), however the multiplier was less than one, as we have estimated in this study. Using the impulse-response function specific to VAR models, we have observed that the impact of public investment on GDP is limited, which validates the lower efficiency of investments in the Romanian economy. We estimate that the level of the investment multiplier estimated for Romania is smaller than multipliers estimated by OECD (2009) for other countries from the Eastern and Central Europe (0.6-0.7 size on short term). Elasticity of GDP according to public investment is 0.013, ie increase investment spending by 1% causes a more growth by 0.013% over one year. Regarding the second equation, there was an immediate impact on investment spending of industrial capital goods production, the level of elasticity being 0.051. It results that public investment lead to higher increase of industrial production on short term, but to lower economic growth rate on long term. We believe that the main reasons for a lower efficiency of these public investments in Romania are following: the dependence of the projects' objectives on the election cycle, as it generates a "new" prioritizing of the investments; the absence of transparency in the case of the public spending, this fact leading to budget allocations higher than spending made for the achievement of some projects; the absence of a multi-annual budget schedule which blocks the achievement of greater projects or the completion of the projects which have already been started; the money which has not been spent for investments according to the budget granting settled at the beginning of each year; most of the amounts have been wasted by using them during the last quarter of each year during the period 2005-2008.

Keywords: investment multiplier; economic growth; industrial production; OLS regression

I.Introduction

Theoretically, the public investments have a great short-term multiplying effect upon the aggregate demand and a long-term multiplying effect upon the aggregate offer, especially when they determine the decrease of the transaction costs. However, there are also other conditions which may influence the impact of these spending upon economy. *Firstly,* the government should make sure that will allocate sufficient financial resources for achieving the settled investment projects. Moreover, the local authorities should benefit from the central government's support whenever certain local projects may cease due to the lack of funds. Any cessation of the projects which are financed from the state budget would only generate temporary effects upon output, and the long-term multiplier will tend to zero or it will even become negative. *Secondly*, the public

investment projects should be transparent when referring to the spending and they should not be affected by the corruption spectrum. In Romania the public funds for investment are not being used with transparency, being fateful influenced by electoral cycles. Thus in the last twelve years have started 42.000 public investment projects, which are currently unfinished, the majority of them being blocked due to lack of financing. Hence, the public spending for investment have generated only a temporary increase of GDP.

Regarding the impact of public investment on economic growth, empirical evidences are different. Thus, ones of the IMF studies (2004, 2005) showed that there was no significant relationship between two variables, so that government investments have been regarded as unproductive. On the other hand, Pereira (2000, 2001) estimated in a VAR model on U.S. that public investment positively affects both private investment and domestic production and employment, the whole public investment being considered as productive. A World Bank study (2007) has concluded that there is a positive impact of capital spending on economic growth, particularly for infrastructure spending, education and health. Growth and Development Commission Report (2008) shows that the fastest growing economies have in common the existence of at least 7% share of GDP spent on investments. Other studies has shown that during 1960-2000 there was a positive elasticity of economic growth based on public capital.

Romania is characterized by a paradoxical situation in terms of public investment in that it has the highest allocation in the EU-27 in this field, but shows a poor performance of infrastructure (transport, education, health) according to the Global Competitiveness Index. Thus, capital expenditures in GDP accounted for 5.7% of GDP in 2008 and 5.3% of GDP in 2009, while the European average was 2.7%, and respectively 2.9%. Ratio of public investment in GDP has increased since 2005 year from a previous value less than 4% of GDP. The emerging EU countries (including Romania) is characterized by greater public investment rate volatility compared to developed economies, since they lower their financing capacity, especially during periods of higher budget deficits. Only countries with more prudent fiscal policies during periods of economic expansion (such as the Czech Republic and Poland) have registered an increase of public investment in 2009 compared to previous years.

II.Literature review, methodology and results

To identify the multiplier impact of budgetary capital spending we have used OLS regression and VAR model for GDP and industrial production of capital goods, the period included in this analysis being 2000:1-2011:1 (45 observations). The objectives are to determine the elasticity/multiplier of these variables depending on public investment and their reaction with impulse-response function. We have used a quarterly data series form Eurostat, expressed as annualized percentage changes, relative to the corresponding quarter from the previous year. Public investment data series was deduced from the data expressed in millions local currency units and was converted into constant prices based on the appropriate price index for government expenditure.

In the period covered by this study, the government capital spending have increased by about 20% annually, while industrial production (producing capital goods) increased on average by 6.7%, the average economic growth being 3.8%. The highest annualized growth of public investment was in the first quarter of 2000 (+ 200%) and minimum in the second quarter of 2001 (-40.6%). Most budgetary resources were allocated quarterly investment during 2007:4-2008:3, when the economy was in the expansionary gap. The recession that affected Romanian economy was not offset by increased investment spending than from Q3 2010. Concerning the level of GDP, the highest annualized growth rate was achieved in the first quarter of 2000 (11.6%) and largest reduction occurred in the second quarter of 2009 (-8.3%). In fact, Romania registered a reduction of GDP in each of the quarters 2009-2010. Industrial production began to recovery

from Q3 2009 due to rising external demand from economies with a more rapid recovery of production.
Figure 1 Evolution of GDP, industrial production and public investment

Before performing the OLS regressions and VAR models, we have investigated the stationarity of data series used to identify their integration order. Making an analysis according to the ADF and Phillips-Perron (PP) tests for the stationarity hypothesis for the two series, we may notice a rejection of the H0 hypothesis at the level for 1%, 5% and 10% significance thresholds in the case of public investment and at 5% and 10% significance thresholds for GDP and industrial production (table 1).

Table 1. The ADF and PP stationarity tests

Critical values t-statistic	d% Public investment ADF(0)	d% Public investment PP(0)	d% GDP* ADF(0)	d% GDP* PP(0)	d% Industrial* production ADF(0)	d% Industrial* production PP(0)
	-5.344231	-5.507541	-3.398412	-2.444665	-2.130408	-2.130408
1%	-2.618579	-2.618579	-3.592462	-2.618579	-2.618579	-2.618579
5%	-1.948495	-1.948495	-2.931404	-1.948495	-1.948495	-1.948495
10%	-1.612135	-1.612135	-2.603944	-1.612135	-1.612135	-1.612135

Note: *) non-stationary at the 1% significance thresholds, but stationary at 5% and 10%.

To estimate the multiplier impact of the public investments, we have ve used two models, one of them with economic growth rate as endogenous variable, and the other with change of industrial production of the capital goods, as dependent variable. To take into account structural breaks into GDP and industrial production data series we have used three dummy variables. The first one is related to the first quarter of 2009 and noted $dummy_{2009:1}$, which corresponds to reversal of GDP trend after a period of continuous growth since the first quarter of 2001. The second refers to the quarter immediately following, in which was registered the largest reduction in annualized GDP, namely 8.3%, as noted $dummy_{2009:2}$. The third will be used in regression of industrial production, highlighting the impact of the maximum rate of increase in the second quarter of 2000, being noted $dummy_{2000:2}$.

In the two OLS regression were used as exogenous variables change of public investment, autoregressive components of the endogenous variables to highlight their persistence and dummy variables to capture some structural breaks in the data series. The objective of these regressions is to determine the GDP and industrial production of capital goods elasticity according to budgetary capital spending. We have estimated the following equations:

$$gdp = \alpha_0 + \beta_0 \cdot gdp(-1) + \sum_{i=0}^{4} \delta_i \cdot pb.investment(-i) + \phi \cdot dummy_{2009:1} + \gamma \cdot dummy_{2009:2} + \varepsilon_0 \quad (1)$$

$$i.p = \alpha_1 + \beta_1 \cdot i.p(-1) + \sum_{i=0}^{4} \sigma_i \cdot pb.investment(-i) + \varphi \cdot dummy_{20002} + \varepsilon_1 \qquad (2)$$

where,

gdp – the annualized rate of economic growth;

pb.investment – the annualized rate of public investment;

i.p – the annualized rate of industrial production of capital goods;

i – the lags of public investment;

α – constant of regression;

β – the autoregressive coefficient of the endogenous variables;

δ – the GDP elasticity depending on the public investment change;

σ – the industrial production of capital goods elasticity depending on the public investment change

ϕ, γ, φ – the coefficients which refer to the influence of the dummy variables on endogenous variables

To estimate the coefficients of the two regressions we have used EViews 7 software, the results being included in the table below.

Table 2. The results of OLS regressions

	Equation (1) gdp (41 observations)		**Equation (2)** industrial production of capital goods (44 observations)
α_0	0.011 (2.71); [0.004]	α_1	0.0001 (0.16); [0.01]

White Heteroskedasticity test probability	0.31	White Heteroskedasticity test probability	0.29

( ) – t-statistic value; [ ] – standard error value; ***/**/* - statistical significance at 1%/5%/10% levels

The results show the existence of an autoregressive model of order 1 in both regressions, the coefficient β being 0.76, respectively 0.71, which corresponds to a relatively high persistence of the two variables. Dummy variables included in the first regression caused GDP reducing by

about 8.8% and 5.8% in the analyzed period, while the dummy variable used in the second model has led to industrial production increasing by 20%. Public investments have not an immediate impact on growth rate, but one lagged with four quarters, which is explained by the existence of lags between the allocation, spending of the government resources and the increase of internal product. Elasticity of GDP according to public investment is 0.013, ie increase investment spending by 1% causes a more growth by 0.013% over one year. Regarding the second equation, there was an immediate impact on investment spending of industrial capital goods production, the level of elasticity being 0.051. It results that public investment lead to higher increase of industrial production on short term, but to lower economic growth rate on long term.

Based on GDP elasticity, we have calculated the multiplier of public investment according to the following relationships:

$$\delta_4 = \frac{gdp}{pb.investment} = \frac{\Delta GDP}{\Delta Public.investment} \cdot \frac{Public.investment}{GDP} \qquad (3)$$

The share of public investment in GDP was 3.2% at the start of the period, value that coincided with both the media and the median of the data series. Therefore, public investment multiplier is only 0.4 (= 0.013/0.032), so that increase of investment spending with one local currency has led to a higher GDP by only 0.4 local currency after four quarters, which is a lack of drive effects of the investments and of the public money wasting. This situation has multiple causes such as cancellation of certain projects and starts others depending on the electoral cycle, funding of an unimportant projects at local level, non-transparent contracts establishment, etc.

As the three variables of the two models are stationary, we have created two VAR model in order to estimate the way in which the shock of the public spending is transmitted upon the GDP and industrial production based on the impulse-response function. For the purpose of selecting the number of the model's lags, we have used the Akaike (AIC), Schwarz (SIC) criteria and the Wald exclusion lag test, according to which the optimum lag is three for the *gdp* model and one for *industrial production* model. Applying the impulse response function it results that increase of the public investment by 1% in the quarter *n* lead to an increase of GDP by 0.004% in the second and third quarters, the effect being almost null after ten quarters. The cumulative increase of GDP after ten quarters is only 0.023%, which also corresponds to an investment multiplier less than one. Concerning the dynamics of industrial production, this registers an increase higher than 0.1% in the first five quarters after shock of public investment. The cumulative growth of the industrial production is stabilizing after three years at 0.08% level.
Figure 2 Impulse Reaction response of GDP and industrial production to public investment

III. Conclusions

The level of the investment multiplier estimated for Romania is smaller than multipliers estimated by OECD (2009) for other countries from the Eastern and Central Europe (0.6-0.7 size on short term), even if the GDP share of public investment is higher than average of this countries. In this context, the increase of public investment in Romania does not generate a significantly increase of GDP on the medium term, although this spending are mostly important for their long-term impact upon the potential GDP. We believe that the main reasons for a lower efficiency of these public investments in Romania are following: the dependence of the projects' objectives on the election cycle, as it generates a "new" prioritizing of the investments; the absence of transparency in the case of the public spending, this fact leading to budget allocations higher than spending made for the achievement of some projects; the absence of a multi-annual budget schedule which blocks the achievement of greater projects or the completion of the projects which have already been started; the money which has not been spent for investments according to the budget granting settled at the beginning of each year; most of the amounts have been wasted by using them during the last quarter of each year during the period 2005-2008.

JAPANESE MONOPOLIST COMPANIES – INSTRUMENTS OF THE 'NATIONAL POLICY'

Mihuţ Marius Ioan
Babes-Bolyai University Faculty of Economics and Business Administration

As the title suggests, this article discusses the problem of monopolistic Japanese companies, unique features among advanced countries, and perhaps worldwide. The japanese most ardent desire was always to reach and to overcome the Western, and, as a balanced development of all companies would have taken a long time, japanese policy makers decided to support only those with good performances, around them being concentrated all energies in the east Asian archipelago. Following these important efforts (from the State, small and medium companies, people, etc.), as it is well known, Japan has succeeded, precisely by those holdings, to become a tough opponent for developed countries and even to overcome them, becoming the second global power behind the United States.

The importance of this article derives precisely from the fact that these companies (Zaibatsu and later hondings) were the driving force behind Japan's economic development, whether we talk about the period preceding the Second World War or the next one. Even if after the American occupation, it was wanted with at all costs their liquidation, holdings being considered as close to prewar militaristic power, after the American withdrawal from the archipelago, they were rebuilt as a Japanese principle, the foundation of Japanese reconstruction.

The paper aims to embody the main dimensions on which these companies have arrived, as well as their structure, the relations between them, their organization.

On the topic discussed, the literature contains more general issue of the Japanese economy, without being paid (at least in the contemporary period) consideration to these main pillars of Japanese capitalism development. The main work in which they are giving increased attention is written at the end of the Second World War, thus the need for the additions concerning the next period is important. The authors' contribution lies precisely in the synthesis of information that he provides, from the appearance of Zaibatsu in the mid-Meiji era, until the Great Depression of the 1990s.

Keywords: Japan's economy, zaibatsu, monopolist companies, keiretsu, Japan challenge
JEL: O15, O25, N15

Zaibatsu or family cliques represents an element of uniqueness, showing the main pillar in the development of Japanese capitalism, the driving force of economic development of Japan. It is all about family economic and financial holdings that include a large number of enterprises in various sectors. They are present in the shipyards, banks, insurance system, shipping, mining, industrial activities.

The emergence of the largest Zaibatsu is rooted in the rich families of merchants of Togukawa period. During Meiji, internally, these trusts were heavily backed to face international competition that Japan was subject. Then came the First World War; they took full advantage of it, developing at a high rate. With the establishment of militarism (1930), other Zaibatsu have appeared, all beneficiaries of the war, started by the "bounty" of Japanese capitalism.

Over time, a battle for supremacy took place between Mitsui and Mitsubishi, at each one's action corresponding an offensive from the other; when Mitsui began negotiations with Furukawa and Kuhar-Mangyo, in order to seize them in its sphere of influence, Mitsubishi started immediately negotiations with Sumitomo. Mitsubishi's turn followed, with a first step to control Nisso, Nichitsu and Mori, while Yasuda (with satellites Asano and Okura) passing on Mitsui side (Barrett, 1945, p 36). Through these strategic moves, the capital ratio control throughout the industrial development has been a constant one.

Even if rivalry between them was notorious, collaboration is and was more important than the destruction of the other when it comes to foreign confrontation. Race is on the inside, but as soon as a problem arises from outside, they ally against the enemy. Internally, the act as the groups that existed in feudalism, and not as western monopolies. One of the major wishes/targets/objectives of the government's is fight against waste: for example, to avoid losses, Mitsui and Mitsubishi shipyards were merged in 1885, managing to be more competitive internationally. Another important merger was represented by the Nippon Steel, where were involved five Japanese private companies as well as the public company. Thus, the new groups are growing bigger and bigger, the cartel formation law (1925) and the Law of control on Big Industries (1931) helping them.

Throughout the period of their existence, the family cliques have shown dedication to the state, which in turn has always supported them; these two institutions were clearly working together. Under state protection, their size increased significantly, especially during the militarism, when Japan represented a great monopoly. With the entry into the war, it was the moment to use the energies at maximum. In the following table we present the zaibatsu size and the concentration degree in 1939.

Tabel 1. The zaibatsu size and the concentration degree (1939)

Name	Number of companyes controlled in 1939	Capital directly controlled (million yen)
Mitsui	112	1428
Mitsubishi	74	1291
Mangyo	100	1249
Yasuda	50	484
Nichitsu	32	471
Sumitomo	27	442
Mori	30	275
Asano	47	270
Okura	40	176
Nisso	44	165
Nomura	26	159
Furukawa	21	107
Riken	60	102
Kawasaki	24	99
Total	**687**	**6718**

Source: (Barret 1945: 32)

The total paid up capital of japanese companies was 21,073,000 yen, and, as it can be seen from the table, the capital of companies directly controlled by the trusts was 6.718 million yen in 1939 (while in 1942 it reached 8.717). Besides this directly controlled amount, there were 5.013 million yen indirectly controlled. Therefore, a total of 13.304 billion yen, representing over 63% of total capital, was held by the 14 Zaibatsu. Japan's total bank deposits were 19,117,000 yen, while trusts were set at 14,000 yen deposits, over 75% of the total. Before World War One Japanese banks have not exercised such influence as the Zaibatsu in the financing industry (Barrett 1945: 32), (Schwab and Thiercelin, 1991: 61).

These family cliques were dissolved with the defeat of Japan in the Second World War. After becoming clodes to militarists, aiming to monopolize new markets and raw material supply, Americans considered them as a leading cause of the Japanese territorial expansion. Laws against

Zaibatsu were taken immediately after the installation of the regime led by MacArthur in 1947, among the "victims" being almost 60 family cliques. Therefore, not only the significant ones were abolished, thus trying to completely eradicate them.

Although they were eliminated by the U.S. regime in place, representing a Japanese tradition, the Zaibatsu principle could not be removed. Their dispersal lasted only during the occupation of the former enemy and current ally, then resumed the composition of major trusts which have gradually grown considerably. The new giants represent a new form of those existing before the war (Mitsui, Mitsubishi and Sumitomo are the direct heirs of the prewar zaibatsu). If the great pre-war Zaibatsu were based on their own capital, nowadays loans hold the largest share, as these holdings are crystallized around the bank that acts as an *axis mundi*. Therefore, in addition to the fact that large companies hold monopoly positions, they have their own banks, helping them to form extremely strong cores, with activities spanning several sectors.

It can be seen in (Fig. no 1) and (Fig. No 2) that a major difference is mainly the non-membership of new trusts in a single family structure and their mobility in relation to the stiffness of their predecessors. In the post-war groups we also note the existence of cross holdings, which make supervision come from all sides; companies are giving themselves mutually places in their boards (boards of directors within the Group companies have lunch together at least once a week to discuss future goals and strategies (Delassus 1971: 171)). A discordant note is represented by the Bank; it holds a seat on all boards in order to be able to defend its interests and to have access to all information; for example, Mitsubishi Bank sent 27 members of the boards of the 21 companies in the group (All 1989: 16). There are frequent cases in which the government itself has economists and officials in the boards of these holdings.

As Michio Morishima underlines (Morishima 1986: 147), the Japanese had to choose between two types of development, one in which all companies would have received the same treatment and a possibility of development for all, but in a very long time, and a second one, in which a group of firms would be selected and receive special treatment. Just as athletes chosen to represent their country at the Olympics are treated preferentially, this holdings have the advantage of certain privileges. In a society based on Confucian ideology, there is not the problem of a rebellion of those who are not selected, who remain in resignation and trying to do their best to help their colleagues. Keeping parallel with the Olympics, it remains their duty to support them in their attempt to gain the best result. An identity of views was rapidly reached at a national level, glory and pride being important for all Japanese.

Medals do not hesitate to show and, in 1995, among the largest companies worldwide, in the first six positions, five were Japanese.

The (Table no 2) shows that the Japanese archipelago get where it wanted, representing the main pole of power in companies. Thus Japan is the first country to demonstrate the power of holding.
State activity was always directed toward protecting the giants, the monopolies and the pursuit of common goals with them. By the fact that it supports them, we believe that in Japan there is a state monopoly capitalism, an interventionist capitalism. While the United States supports industries with problems, the Japanese are focusing on the strong ones, in order to be more competitive internationally.
Therefore, we can say thet monopolistic companies represent instruments of national policy, the core, the center of gravity, which compete with Westerners and are always mindful of their products, in order to be in tandem with the vision and wishes of the state. They definetely have an important role in the development of Japan: contributing to export growth, helping to build national strategy, exploring international markets in order to know which way to move production in Japan, importing raw materials and organizing sctivities. Instead the state protects and supports themby all the levers at its hand, making them as we saw above, the "mammoths" of the global economy. As evidence of these dimensions, acad. Costin Murgescu (Murgescu 1985: 207) considers that the costs with collecting information ("key investment in commercial activity") would be higher than the CIA's..

AN EXAMINATION OF OKUN'S LAW: EVIDENCE FROM EUROPEAN TARGET COUNTRIES

In this paper Okun's law is tested for six European selected countries in order to compare the responsiveness of unemployment to economic growth over the period 1981-2010. In the first section there is a survey of scientific works that have observed the empirical relationship between growth and unemployment. The countries selected are representative of different socio-economic contexts today existing in Europe, i.e. EU member countries, countries that adopt the Euro, and others which are candidates to join the EU or that although EU members have chosen not to adopt the Euro. Finally, we also refer to the U.S. and Canada, which are country-systems where the regularity of Okun's rule of thumb was conceived. In particular, we intend to represent the data of the macroeconomic variables GDP and unemployment rate in their annual variations for a time series sufficiently long to show the occurrence of the supposed regularity, and then to investigate specific cases, which represent changes compared to the expected variations. In addition to any changes occurred over time in the studied relationship, these empirical observations, along with the reported literature, will help to draw conclusions about the differences regarding the inflexibility and responsiveness to changes in the aggregated output by the labor market of the countries involved in the study.

1. Introduction

The Okun's law is the specific empirical regularity between the unemployment rate and the rate of growth of output formulated by Arthur M. Okun in 1962, which enabled him to find an achievable solution to the difficult problem of estimating an economy's potential output given the actual unemployment. This dependable relationship, although not based on any strong economic reasoning and not a structural feature of the economy, has held up well within the appropriate range of unemployment rates and it can also be exploited in modern global markets both to evaluate the responsiveness of unemployment to economic growth and to study the national labor market performances. Indeed, already from the original work, Okun did not fail to highlight how the labor market structure could corroborate or affect the validity of the estimated relationship. In particular, in Okun's thought, there are three variables that may arise in relation: the degree of participation in the labor market, the number of hours worked per employee and the productivity of labor. In this context, European countries are facing, among other issues, the challenge of the globalization process and are coping with the increasing competition from both the emerging competitors and big international players such as the United States, which, despite having generated the current economic and financial crisis, have been able to tackle, better than other

country-systems, the imbalances arising from the crisis, returning to grow also due to the structure of their labor market. From this point of view, on average the European Union (EU) is characterized by a higher inflexibility of the labor market. However, the EU consists of a set of countries that are only gradually being harmonized by the legislative standpoint and slowly from the socio-economic perspective. For this reason, there is still not a single definable economic standard as European, but there are still both really different and specific macro-regional social and economic dynamics.

The structure of the paper is as follows. Next section provides a review of the literature on Okun's law. The proposed operational framework is presented in section 3. Section 4 concludes, providing some findings and implications.

2. Related literature

Okun's formulation of the empirical regularity has-been tested in several studies over time, which have, *inter alia*, proceeded to re-determine for many countries the range of variation of the two variables directly involved, the GDP growth rate and the rate of unemployment (among the many contributions, see for example Smith 1975, Gordon 1984, Knoester 1986, Kaufman 1988, Prachowny 1993 and Weber 1995). Confirmations have been obtained by the law under investigation, although with obvious differences in the coefficients that regulate the relations between the two variables. In particular, the most responsiveness of employment levels has been observed in Anglo-Saxon countries, especially the United States and Canada. Nevertheless, the European area, mainly the EU-15, is mentioned in economic literature as a case of greater structural inflexibility of the labor market, largely due to the higher government guarantees applied to employed workers. Therefore, in many European countries there is a tendency for lower growth of the unemployment when there is simultaneously a period of economic recession; but at the same time, when the GDP rises again is not registered a strong increase of employment, given that production units cannot subsequently and rapidly reduce the labor inputs per unit of output. Moreover, there are studies based on the asymmetry of the Okun's empirical regularity (see, among others, Silvapulle *et al.*, 2004) claiming that the influence of positive changes of economic growth on unemployment is different from that concerning the negative changes. This asymmetry is observed in this work particularly in the light of the empirical evidence related to those EU countries considered in our analysis.

3. Operational framework: analysis of the European context

Following Okun's law, we investigate the occurrence of, and models for estimating, the empirical relevance given by the relationship between economic growth and unemployment fluctuations for six EU select countries during the last thirty years: Germany, a key State for the birth and economic stability of the European Union; Italy and Spain, since they are two economies belonging to the Mediterranean macro-region, which represent different economic production structures; United Kingdom, EU member which has deliberately chosen not to adopt the Euro; Romania as a candidate for the Euro Area; Croatia which instead will enter the EU with effect from July 2013. Finally, to this analysis we add the two countries which can be considered as a benchmark in this study type, namely the U.S. and Canada, since they are national contexts in which the relationship discovered by Okun should be stronger. The variables considered are the annual change in percentage of Gross Domestic Product (US$ constant prices) and annual variation of the unemployment rate (percent of total labor force) on IMF data from 1981 to 2010 (2012).

Germany (1981-2010)   *United Kingdom (1981-2010)*
Italy (1981-2010)

Spain (1981-2010)
Romania (1986-2010)
Croatia (1993-2010)
U.S. (1981-2010)

Canada (1981-2010)
Figure no 1 - Data representation of the percentage annual variation in the unemployment rate and the GDP (over the period from 1981 to 2010); graphical representation of the estimation models of dependence (elaborations made by the authors on IMF data, 2012).

In the previous graphs we show the time series for each EU member, where each point represents the combination of the annual variation in GDP and the corresponding variations in the unemployment rate ($U_t–U_{t-1}$). In each of the graphs, three models are considered for estimating the dependence, linear (continuous line), quadratic (tract point) and cubic (dashed function), in which the GDP variation is considered as dependent variable and the variation in the unemployment rate is the independent variable.

Table no 1 - The model parameters estimated for the eight selected countries (GDP is the dependent variable and unemployment is the independent variable), IMF data (2012).

made by the authors

In Table no 1 it can be observed that by applying different estimation models Okun's law is always respected, with the functions characterized by a decreasing trend. Table no 1 also shows those countries (U.S., Canada, U.K. and Spain) in which the three estimation models are more representative of the phenomenon, with a higher R square and values for Fisher statistics which provide the best fit to the observed data. For the other countries, on the contrary, the low values of the statistical measures show that the dependency relationship is weak, and the correlation between the same variables highlights fewer relationships. The models produce estimates of the "worst-case" concerning Italy. In fact, there are anomalous data showing for some years a growth of GDP accompanied with increased levels of unemployment (in Figure no 1, see the top right of the graph related to Italy). Naturally, as discussed below, these dynamics might have a practical explanation linked to the known inflexibility of the Italian labor dismissal protection and the related lack of promoting the empowerment of workers laid off. The other major economy belonging to the Mediterranean macro-region, Spain, shows a rather good fit, with an almost constant growth of GDP accompanied with a progressive reductions in the unemployment rate. As can be seen from the Spanish graph, in fact, already the linear model is very good for representing the phenomenon, with about no outlier cases. For Romania and Croatia we have the shorter time series and, therefore, the results presented are less significant. However, the latter two countries have a structure of their labor markets at least partially inflexible and show extreme points, such as the critical year of the current crisis, 2009, where to a strong decrease in the GDP has not meant a decline in employment as strong as happened in Spain (increased over the previous year by more than six percentage points). Germany represent an intermediate case, where the estimation of the models is influenced by extreme cases which are in particular the 2008 and 2009, until now the most critical years on the side of the economic crisis. In fact, in 2009, there was a considerable decline in the GDP of the countries surveyed, from 3 to 7 percentage points, but the ones with more inflexible systems of labor did not show a simultaneous and equally marked adjustment in the unemployment rate. Finally, the two countries studied as a useful international comparison, the U.S. and Canada, and representing the case studies more investigated in the economic literature referred to Okun's law, show a clear-cut dependency relationship between the two variables. For these two countries, all the three kinds of estimation models fit the data really well, highlighting the lower inflexibility of the related labor markets. We notice that the only European country with the R squares ranging similar to the two overseas countries is the Spain, followed by the U.K., so it is more appropriate to make comparisons between these two countries. Indeed, we observe that the first beta of the linear model shows a greater slope of the function for the U.S. case, and therefore it appears as the country in which there is the greatest reactivity between the two variables (Romania has a higher value of beta1 but estimated on less data, and a lower R-Square). By analyzing the range of variation of the variables we note that Italian unemployment changes very low, about a point above and below zero, the worse the country represented by the estimation models. This means the high inflexibility of the Italian labor market, especially for the legal protection against dismissal or lay-off, which *de facto* is a disincentive for firms to recruit new labor force (on these findings see also OECD 1994, Siebert 1997, Nicoletti *et al.* 2000, Bauer *et al.* 2004). The confirmation of the foregoing remarks is also from the average of same variations (considered in absolute values), which is extremely low for Italy, with a result equal to 0,5 compared with about 0,7 of the Anglo-Saxon countries (U.S., Canada and U.K.) and Germany, and more than 1 related to the other countries. In Italy such inflexibility is also transmitted in less variability of GDP, with negative effects on the general economic context because, as seen from the data, such resistance have brought in the last two decades to a nearly constant growth of GDP just above zero, at much lower levels than, for example, the other countries considered in this work. The most noticeable variation with a negative sign for Italy (-5.22%) took place in 2009, when other countries (except for Romania and Croatia), although affected by international economic and

financial crisis, registered decreases of GDP lower while suffering from an immediate decrease in employment levels.

4. Findings, implications and conclusion

Economists regard the Okun's rule of thumb in order to investigate the economic effects of employment. Furthermore, policymakers may use Okun's law as a real-time rule of thumb in order to evaluate conditions in the labor and the product markets. In this study we confirm that a long run relationship exists between unemployment and output, and the results show that an inverse relationship between unemployment and output holds for the six EU selected countries. Therefore, the Okun's law can be used to give a first explanation to the European economic context, because every effort in decreasing the level of unemployment is an effort towards increasing the level of output. Hence, structural reforms of labor market rigidities must persist and more flexibility in labor markets must become an essential feature for Europe. Moreover, the six EU selected countries can enhance their socio-economic development path by investing in activities that reduce the level of unemployment. These activities should include the empowerment of individuals and mainly of the unemployed job seekers and of those workers expelled from the labor market, job creation and entrepreneurial development efforts that are aimed towards employment generation. Addressing this challenge may contribute to the reduction of unemployment, which will ultimately increase the level of output. In particular, in the paper we analyze the responsiveness of the labor market related to the economic growth dynamics by three types of estimation models of the dependence between the two variables under investigation: the annual variation for GDP and the annual variation in unemployment rate.

We have chosen countries that represent in different ways the complex European situation, and based on Okun's law we also carried out an international comparison considering U.S. and Canada as benchmarks, since they are countries in which there is a less inflexibility of the labor market than the European countries. Moreover, the inflexibility of European labor market, especially for dismissals, shape a system established on greater rights and protections, but at the same time it can become an overriding constraint for firms to increase the number of employees during periods of economic growth and for foreign direct investments. We note that in those countries where the dependable relationship between the two considered variables is weaker the employment levels are slightly changed on average, with a stringent provisions against dismissal, but also with an adverse effect on general economic trends. In fact, within these countries-contexts the data show how effective is the lack of dynamism in terms of GDP changes and, as a further demonstration, these are countries that have suffered most of the recent international financial and economic crisis. It can be seen that in those countries where there is a good degree of estimation of the three models of dependence, starting from the linear one, and where the variations of the two variables are higher but not extreme, there are more positive evidence of growth levels. In summary, the adaptability of the workforce to the needs of the economic system can be a significant support to the ongoing processes of growth and development.

ECONOMICAL ANALYSIS OF DISABLED EMPLOYERS AND THEIR EMPLOYEES IN HUNGARY

Nagymáté Nóra
University of Debrecen Faculty of Applied Economics and Rural Development Institute of Business Economics

ABSTRACT
Nowadays employment is an evergreen topic in Hungary. Many kinds of supplies are provided by the state (on the basis of the 8/1983. EüM-PM Hungarian Law), for example for the group 'people living with disabilities'. It is very difficult to provide job for these people after their rehabilitation. My main goal is to analyze the 'rehabilitation' of disabled people and to study the related firms and the connection between the employers and employees. My intentions were also to create a strategy for these people to be employed again and for the firms to be motivated to employ them. Statistical figures show, that the highest ratio of 'people living with disabilities' can be found in the North Great Plain Region of Hungary (30 per cent of the total number of 'people living with disabilities'). The employment of these people means extra costs for enterprises. At the same time the complete accessibility of workplaces is still not realized in many cases in Hungary yet. Currently only a few enterprises are specialized to employ people living with disabilities. Unfortunately, most of the enterprises don't intend to employ disabled persons. Questionnaires were created in order to study the relationship between people living with disabilities and their possibilities to get employed on the labour market again. My study had two phases. In the first phase we focused on individual persons providing anonymity of the questionnaires. The research focused on special rehabilitation firms and their employees too (they are specialised to employ disabled employers). Two questionnaires for the above mentioned firms and their employees were created in order to gather information on their activities as well as relationship between the firms and its employees. It can be stated that this paper shows the relationship between the employers and employees. I will analyze the importance of factors in working among employers and among the employees. According to the latest trends I analyse the attitude to the rehabilitation of these people and how they will be able to work again not only in 'rehabilitation firms'. My implication is that new workplaces for these people should be created by the utilisation of the European Union and the available national sources in order to integrate them into the labour market again in a long run. In the current stage of my research evaluation of the data collection is ongoing now. After summarizing all claims of participants I can make an impression in this area. I think my research is very special because of the geographical research area of data collection and the topic.
Key words

I. Introduction

Nowadays the growing rate of economically inactive population is a very big problem in Hungary. Rural development has become more and more important issue in Hungary since rural areas also contribute to the efficiency of the national economy (Kárpáti, Csapó and Árváné 2010, 71). There were radical changes in the economy as well as in the labour market in the 1990's. The rate of employment and activity was the lowest in 1996 – 1997, after that in consequence of

the economically boom it had been growing for 2000. Between 2000 and 2007 it showed stagnation, except some short temporary growing periods. There are two big groups in the sector pensioners. 'People living with disabilities' group can also be found in this sector on the basis of the 8/1983. Eüm/PM Hungarian Law. The aim of the Law is to give the possibility of adequate job based on qualification and state of health after their rehabilitation.

Generally speaking it would be better for the Hungarian economy to employ these people because the number of inactive population could be lower and the state wouldn't have to provide them supplies. According to the Hungarian Law, if there is not possible to give job for these people, they receive supply from the state.

Business financing has a very important role in the private sector (Kárpáti 2006: 9). The employer has an obligation in all sectors of the national economy to pay rehabilitation contribution the state, if the statistical number of employed persons is more than 20, and if the number of disabled persons less than 5 per cent of the total number of employed persons. Rehabilitation fee could be replaced through employing 'people living with disabilities' according to the Hungarian law.

The highest activity rate of population can be found in the capital city and surroundings area. The reason for that is that most of the logistics centres as well as headquarters of multi - companies are located in this region. Relatively high activity rate can be found also in the western part of Hungary, especially in counties located at the Austrian boarder. The lowest activity rate can be found in the South – West and North – East counties of the country. Unfortunately in these counties we can find the highest unemployment rate too. In most cases it is even double higher than the national average.

These companies are partially different to the ones in the employees' sample. This sample can also be considered adequate as almost 30 per cent of the companies were questioned out of the sampling population. On the other hand, the employers sample is representative regarding the certificate of accreditation. The two-thirds of the employers possesses only a basic certificate of accreditation while the rest one-third has rehabilitational or enhanced cartification

The frequency distribution of the types of the questioned companies are the following: the ratios of the non profit organizations and LLC's are relatively high (around 40%) and almost equal so as the ratios of the individual enterpreneurs and deposit comapnies (around 10%). The proportion of the corporations was the lowest (around 5%). Regarding the sampling population, LLC's and non profit organizations are overreprezented while deposit companies are represented excessively. The thirty percent of the non profit organization is an association. The 61,5% of the companies with enhanced certificate of accreditation is a protected workplace.

II. Literature analysis

The respondents - "people living with disabilities" - can be arranged in two groups considering that the incapacity is a congenital malformation – this means an infiltration into the labour market with disability – or an impaired health status caused by a medical emergency or an accident – this means the person had worked in the labour market without disability and later he had to cope with the changed situation according to his impaired health.

People living with disabilities have a very special situation at the labour market. Their participation in labour market is very limited. In Hungary – according to the international trends – vocational rehabilitation and workmen's compensation are provided by the state (Kálmán and Könczei 2002:209-210). The disability includes only some activities and not the whole person (Münnich 2007: 323-327). The holistic, ecological approach become more and more popular (Pordán 2007: 58-60) emphasizing that circumstances and the abilities of people living with disabilities have to be harmonized (Münnich 2006: 60-62). The main problem is that these people don't have the right to make decisions in their job (Bass 2008: 172-175) although they are very reliable, precise and capable of hard work (Holló 2007: 64).

The number of unemployed and inactive persons has been increased continuously between 2000 and 2008. Unfortunately this negative trend didn't stop yet. There are some special groups in the Hungarian population, like 'people living with disabilities' whose labour market position even more complicated. Currently different kind of supplies are available for this group, but their position could be effectively improved trough their integration into the labour market. Better utilisation of available EU funds to create new jobs and change the thinking of the society could be the way integrating them back into the active employed population.

International trends in the labour market, according to the disabled people shows that this is a typical problem not just in Hungary but in the other European countries too. In the middle of the 1990's the average per cent of the disabled pensioners was in Hungary 5,8; in Finland 9,1; in Austria 3,6; in Germany 2,3; in Luxemburg 7,1; in the Netherlands 8,1; in Norway 7,3; in Poland 10,1; in Sweden 6,6; in Switzerland 2,4; and in the United Kingdom 4,1 per cent (Fultz and Ruch 2002: 77). The European countries but the other countries in the world (Australia, USA, Canada, etc.) have similar problem in this area and they try to solve the situation in different ways.

III. Research methodology

The sample size was 1030 questionnaires and the sample was obtained by using a simple random sampling (Sajtos and Mitev 2007: 31-33) from accredited companies (Somodi 2006: 51). The employees sample can be considered adequate as 109 companies were questioned out of the sampling population of 390 companies (according to the employees). The total number of the persons working at these companies with disability is around three thousand, and the sample consists of 1030 persons (the sampling rate is around 30 percent). In the second phase I questioned the employers themselves. These companies are partially different to the ones in the employees' sample. This sample can also be considered adequate as almost 30% of the companies were questioned out of the sampling population. On the other hand, the employers sample is representative regarding the certificate of accreditation. Data processing was performed by SPSS for Windows 15.0.

Figure 1 shows that amongst employers the other factors, wage and the accessibility to work place were the most important factors. Safe job and professional progress were the less important factors as there is an excess of supply over demand, and it's easy to find new employees.
(Figure 1): The importance of factors in working among employers
Source: own research, 2012
(Figure 2): The importance of factors in working among employees
Source: own research, 2012
Figure 2 shows that amongst employees the safe job was not only the most frequent but the most important factor too. The second-leading factor is the wage followed by other factors.

IV. The results of the research

We compared the answers of the two questionnaires (employees and employers) considering job search or recruitment. In the following section I present our results of comparison. The first aspect was the type of recruitment (or job search in the case of employees) namely the way the companies find workers living with disabilities (or the way disabled people seek job) (Figure 3).
(Figure 3): Distribution of the types of job search (recruitment) among the employees (employers)
Source: own research, 2012

The comparison of the distributions of the job search (recruitment types) was performed by Chi-square test. It can be stated that this test proved the differences between the distributions of job search (recruitment types) with p=0,001 significance level.
Figure 3 shows that employers apply for the Employment Agency with a relatively higher ratio (21,5%) in contradiction to the employees (13,2%). An other relevant difference appeared while taking the connections into consideration. The 44,1 percent of the employees pulls their strings for getting a job while connections were mentioned 36,4 percent of the cases among the employers.
Overall, wage is the most determining factor at both side of the labour market. There is no significant difference in the distribution of the importance between the two groups by Chi-square statistics (p=0,582). Employees have taken the opposite standpoint to the employers according to

527

the importance of safe job, rehabilitation and accessibility to workplace. Rehabilitation and accessibility to workplace is less important while safe job is more important for the employees because of their existence. The firms have already assumed the idea of rehabilitation but unusually the employees did not accept this concept.

V. Conclusions

I studied the labour market position of 'people living with disabilities' in the Hungarian North – Great – Plain Region. I compared the answers of the employees and employers considering satisfaction with the employee/employer, job search or recruitment and the possibility of obtaining further qualifications. According to recruitment or job search we found that employers apply for the Employment Agency with a relatively higher ratio in contradiction to the employees. Employees prefer to pull strings for getting a job with a relatively higher ratio than employers. Regarding further qualifications we can claim that 70% of the employees would obtain further qualifications but the majority (74 %) of the employers would not facilitate this activity. There were no significant difference between the job satisfaction of employees and employers. On the other hand, employees rather tend to choose extrem values than employers. Employees and employers had to rank some factors according to their importance in working. Employees mentioned safe job, accessibility to work place, wage as the most relevant factors while employers considered other factors, wage and accessibility to work place as the most three important factors. Overall, wage is the most determining factor at both side of the labour market. Employees have taken the opposite standpoint to the employers according to the importance of safe job, rehabilitation and accessibility to workplace. Rehabilitation and accessibility to workplace is less important while safe job is more important for the employees. There are some unusual results comparing with the newest 'rehabilitation trends' according to the 10/2006 Hungarian law (Garai 2008: 15). It is worth mentioning that the employers and the employees sample is continuously growing, so further researches will be published.

A REGIONAL STUDY OF FINANCIAL RESOURCES INVOLVED IN RDI SECTOR IN ROMANIA IN THE LAST DECADE

Nicolov Mirela [1,2]
1University of Oradea, Faculty of Economic Science
2Aurel Vlaicu University of Arad, Faculty of Engineering

The present paper present a study done on the Financial Resources in Research Development and Innovation (RDI) sector in Romania during 2000-2010 . These studies are conducted on the regions and counties in Romania in the specified period.
The present study is part of Doctoral Grant "Implications for innovation, research and development role in the development of Romania's economic competitiveness", during 2010 and 2013 and having Director: Prof. Dr. Alina Badulescu in Oradea University, Faculty of Economic Sciences.

1. Introduction

Economists have increasingly paid attention to the role played by knowledge in explaining countries growth differentials and diffusion both across countries and regions (Barrios&Strobl, 2009; Jones, 2004; Klenow& Rodriguez-Clare, 2005). Although knowledge and technological progress are in this regard seen as the main engines of economic growth in the long run.It may inevitably increase rather than decrease regional inequalities, and spread across time and space. As a consequence, economic growth may foster divergence rather than convergence across spatial units, suggesting that convergence may evolve non-linearly. When considering the theoretical literature on growth and convergence, a wide array of arguments which arise to advocating for the long term reduction or for the persistence and self-reinforcing nature of economic inequalities across countries and regions (Galor,1996; Pritchett ,1997; Lucas ,2000).
The present paper present a study done on the Financial Resources in Research Development and Innovation (RDI) sector in Romania during 2000-2010. These studies are conducted on the regions and counties in Romania in the specified period.

2. Literature review

In the existing literature was studied the firm's investments in RDI as a way to develop technological capabilities. Technological capabilities are the ability to develop and exploit technological know-how, which is the application of scientific knowledge for commercial purposes. The firm can develop its technological capabilities using several learning approaches. The previous studies were focus on investments in RDI because of its importance in generating new knowledge, which can help the firm achieve an advantage that is difficult to replicate by competitors (Cazurra&Un, 2007).

Regional economic integration (REI) and RDI investment

There are many different definitions and types of REIs (Cazurra&Un,2007).
REIs involve the reduction and standardization of government controls and policies over the flows of products, factors, or both among a limited set of countries. REIs differ from the multilateral liberalization of trade promoted in the WTO in several aspects, as they are restricted

to a limited set of countries, tend to be accompanied by the standardization of policies rather than simply the reduction of barriers to trade, and may involve the liberalization of not just trade but also the flow of factors of production.

REIs affect firm behavior. Previous studies have not explored the impact on the firm's RDI investment. There is a large literature on the impact of REIs on country-level trade and foreign direct investment flows (Eden, 2002). The more limited literature on the impact of REI on firms has traditionally focused on the changes in multinational enterprises (MNEs) (Buckley et al., 2001). Some studies are focused on domestic firms and recommend changing strategy in the face of the new environment (Cazurra&Un,2007). REIs have a competing influence on RDI investments, one through product markets and another through factor markets. The REI results in an expanded client base and newcompetitors. These will induce the firm to invest in external RDI after REI to benefit from the easier access to sources of technology.

REIs can be classified in different types depending on the degree of reduction in the controls over the flow of products and factors among the countries (Cazurra&Un,2007):

(1) preferential tariff agreements (PTA) which consist of the partial reduction of internal tariffs to levels below those charged to trade with third countries;

(2) free-trade areas (FTA), such as the North American Free Trade Area (NAFTA), which consist of a reduction in internal limitations to the movements of products among participating countries;

(3) customs unions (CU), such as the Southern African Customs Union (SACU), which demarcate a free-trade area with a common external tariff against products of third countries;

(4) common markets (CM), such as the Common Market of the South (MERCOSUR), which are customs unions with the free movement of factors of production among participating countries; and (5) economic unions (EU), such as the European Union, which are common markets also involving the harmonization of economic policies.

Regional inequalities evolve in a non-linear way that can be traced back in the 1950s. The evolution of regional inequalities was then usually linked to national economic development paths and the process of industrialization.

Was done an analysis of income disparities who suggested the existence of a "long swing" in regional income inequalities, where there is first, a rise and then a subsequent fall of income differentials caused by the industrialisation process, accompanying national development and the decline of agriculture.

Several authors have built on this idea in a regional context suggesting the existence of a bell-shaped curve of spatial development where inequalities should first increase as developed areas benefit from external economies, location of decision-makers, political power, and capital and labour mobility (Barrios and Strobl, 2009). While a non-linear relationship between regional inequality and national income per capita clearly has important implications for economic theory and policy, there is to the best of our knowledge no explicit econometric study that has set out to investigate its existence, although a number of works have been suggestive of its possibility. In the current paper we explicitly test this hypothesis using data for EU countries. The EU economy arguably makes for a particularly suitable case study given the sizeable disparities in economic development across regions and countries compared to the US. While the studies concerned countries engaged in deep structural changes that goes along with industrialisation, there are reasons to believe that regional inequalities may be significantly affected by other types of structural changes and may concern industrialised countries. The EU, in particular, has faced a number of such changes over the past two decades in the context of the EU integration process and successive enlargements of the EU.

3. Research methodology

Research methodology in this paper is based on the simulation of the datas from 2000 to 2009 for

The expenses in research and development activities by occupation and sex and for employees working in the fields of RDI activities. Data were taken from the Romanian National Institute of Statistic updated database Tempo online at 15.11.2011. Data used in this study, for this simulation was taken in April 2012. This research is based on the real data of financial resources from RDI sector, as a case study for Romania.

(Sources:
http://www.insse.ro/cms/files/Anuar%20statistic/13/13%20Stiinta,%20tehnologie%20si%20inovare_ro.pdf)
The central objective was to see what was happened in the period indicated (2000-2010) with financial resources in RDI sector for regions and counties in Romania.

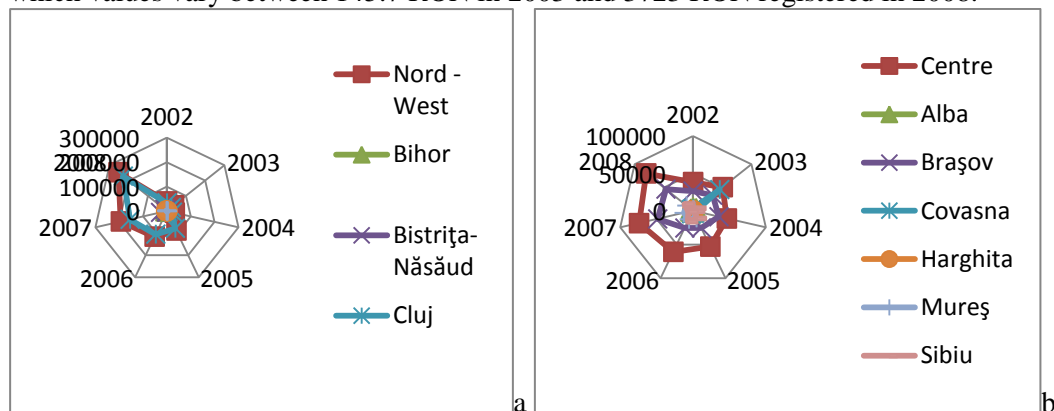
4. Descriptive statistics and results
Total expenditure in RDI activities were recorded from 2002 to 2008. Data were taken from Statistical Yearbook of Romania 2009 and 2010. In this material they will be presented on regions and counties respectively.
Making a Study in Romania on regions and counties, financial resources from RDI sector in Romania we can draw the following conclusions:
Macro region 1 is composed of North-West of the 6 counties components: Bihor, Bistrita Nasaud, Cluj, Maramures, Salaj and Satu Mare region and Central region counties of Alba, Brasov, Covasna, Harghita, Mures and Sibiu. Performing a study on a macro draw conclusions:
In the **North West region** RDI expenses represent 50.13% of values recorded in a Macro region 1. The maximum values recorded in RDI expenditures were recorded in **Cluj** County and was starting in 2002 with a value of 33266.5 RON and the lowest value was registered in 2004 at a minimum value of 22852 RON, then increased by 9.98 times to the value of 228243 RON in 2008 .High levels of RDI expenditures were recorded in the county **Bistrita Nasaud** with values between 1557.9 RON in 2002 and 27315 RON in 2007and in 2008 to be down to 40% in 2007. The lowest financial resources from RDI sector were recorded in **Maramures** county which values vary between 145.7 RON in 2003 and 3723 RON registered in 2008.


Figure 1:Expenses in RDI system in Romania: a) the values for the financial resources from RDI registered in Region Nord-West and the counties that belong to this region;b) the values for the expenses from RDI registered in Central Region and the counties that belong to this region.
[Source: graphics are from authors results based on the data took from https://statistici.insse.ro/shop/index.jsp?page=tempo2&lang=ro&context=26:]

In the **Central region** of a macro region 1 is found that counties like Brasov, Sibiu and Mures, has RDI activity where are registered RDI expenditures.
In **Brasov** was recorded the largest amounts of total financial resources in RDI activity from which the minimum values was recorded in 2005 and was 25 455 RON. In 2003 the spending

values were 33573.7 RON and in 2004 the values are 35466 RON. Maximum values recorded was 48653 RON. In **Sibiu** expenses with RDI are between values recorded in 2004 as 2607 RON and the maximum value recorded as 16108 RON in 2006. After that the values decline in 2007 to 39.5% of the value recorded in 2006. In **Mures** county the values of expenditures for RDI was in the range of 1515.6 RON in 2002 and a value of 12639RON registered in 2006. RDI minimum values for financial resources were recorded in **Harghita** county, values between 146 RON in 2005 and 1421 RON registered in 2008.

Macro region 2 is composed of the six **North Eastern counties**: Bacau, Botosani, Neamt, Iasi, Suceava, Vaslui and **South East Counties**: Braila, Buzau, Constanta, Galati, Tulcea and Vrancea.

In North Eastern region values recorded for expenses in RDI sector represented 52.4% of the values recorded in Macro region 2 in 2002 respectively 68.39% in 2008.**Iasi** County recorded the highest values for total expenditure from RDI activity between 15116.4 RON values, recorded in 2002 and the value of 176282 RON registered in 2008. In **Bacau** , the values increased from 4439.1 RON 2002 and 8497 RON in 2006 after spending values have plummeted in 2007 to 5925 RON then increase to values of 7983 RON in 2008. In **Suceava** financial resources were in the range of 2258.2 RON in 2002 and 18635 RON in 2008. The lowest values recorded in the North East are registered in **Botosani** and range were from 383.1RON in 2002 and 2871 RON in 2007. In 2008 the values were down to 2637 RON.

In the **South East region** were recorded the amounts of expenditure on RDI sector that represent 47.60% of values recorded in 2002 Macro region 231.61% respectively in 2008. In **Galati** County was the highest value for total expenditure in research -development and innovation (RDI) sector, ranging between 12964.5 RON in 2003 and 25379 RON in 2008.

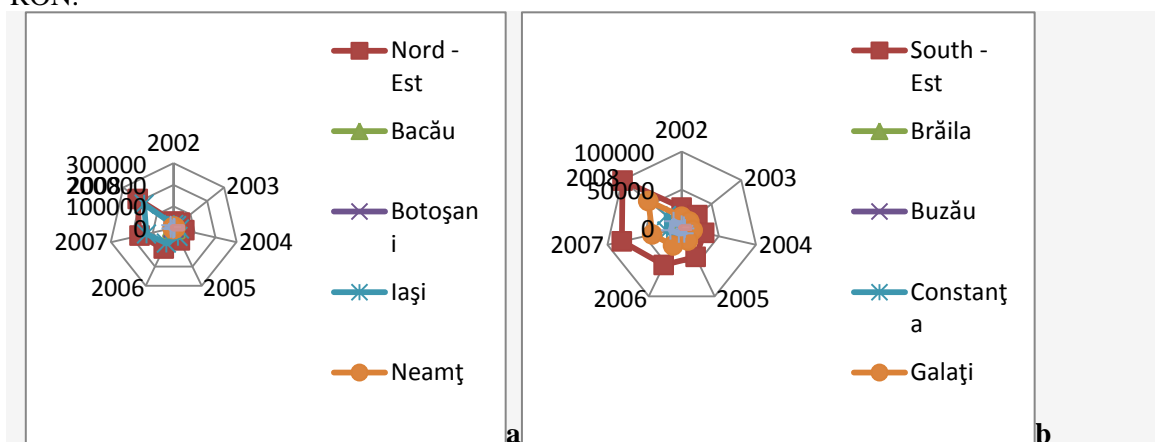
In **Constanta** county was register values between 4718.2 RON in 2002 and 25379 RON in 2008. Lowest values recorded in the South East were in Vrancea County and were between 134.5 RON in 2002 and 818 RON in 2007 . After that in 2008 the values from the expenses fell to 461 RON.


Figure 2:Expenses in RDI system in Romania: a) the values for the expenses from RDI registered in Regions Nord-Est and the counties that belong to this region;b) the values for the expenses from RDI registered in Regions Centre and the counties that belong to this region.
[Source: graphics are from authors results based on the data took from https://statistici.insse.ro/shop/index.jsp?page=tempo2&lang=ro&context=26: *]*

Macro region 3 is composed of **South Region** with his 6 counties: Arges, Calarasi, Dambovita, Giurgiu, Ialomita, Prahova and Virginia and **Bucharest-Ilfov** region with its two components: Ilfov and Bucharest. Expenses in the three macro region were values varies between 393611 RON in 2002 and 2091512 RON registered in 2008.

In the **South Region**, expenses from RDI system vary from 90884.7 RON in 2002 and 231770 RON in 2007. In 2008 the values for the expenses decrease to 229496 RON. The values recorded in the South Wallachia is 23.09% of values recorded in Macro region 3 in 2002 that 10.97% recorded in 2008 . The maximum values of the financial resources of RDI activity is registered in **Arges** county and the variation was from 69021.4 RON in 2002 to the maximum value of 167737 RON in 2007. After that, the values decline in 2008 to 163314 RON. It follows that **Prahova** counties values vary between 10146.3RON spending in 2002 to 43073 RON in 2007. The corresponding values then decrease to a minimum value in 2008 of 27199 RON. The lowest values recorded was in **Ialomita** county, with values between 0 and 765 RON registered in 2002 and 2005.

Macro region 3 includes **Bucharest-Ilfov region** which have the highest values for expenditure on RDI. Thus in the Bucharest – Ilfov region the highest values recorded for RDI activities , the values were in the range of 76.91% in 2002 and 89.03% in 2008 compared to values recorded in Macro region 3. The maximum expenditure of RDI are registered in Bucharest and values range were from 262785 RON in 2002 and 1487299 RON. The registered expenditures in Ilfov county ranged from the values of 39941.3 RON in 2002 and 374717 RON registered in 2008

Macro region 4 is composed of **South-West Oltenia Region** and have the following counties: Dolj, Gorj, Mehedinti, Olt and Valcea. **West Region** have the next counties: Arad, Caras-Severin, Hunedoara and Timis. Expenses recorded in Macro region 4 varies between values recorded in 2002 as 48176 RON and 241464 RON registered in 2008.

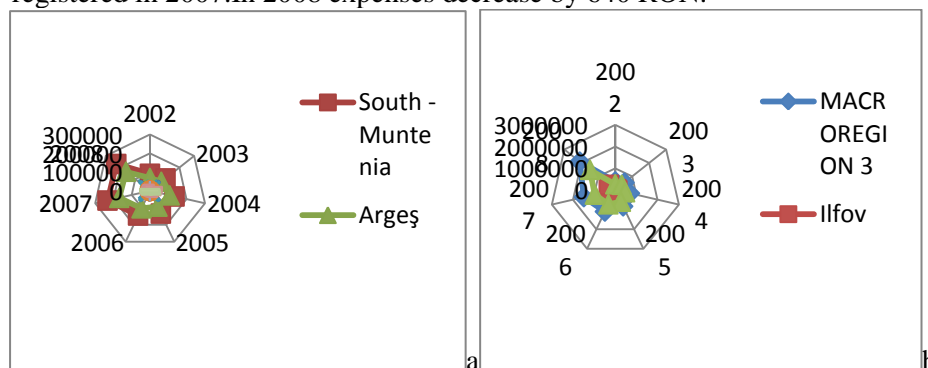
In the **South West Oltenia Region**, expenses as financial resources involved in RDI sector were in the range of 21306.5 RON, values which represent 44.83% of values recorded in Macro region 4 and were registered in 2003. The value of 88164 RON registered in 2008, represent 36.51% of values recorded in Macro region 4. The maximum values recorded for the expenditures in the South-West Oltenia were in **Dolj** county and was 11900.1 RON in 2002. This value vary between 11900.1RON in 2002 and 59395 RON in 2008. The minimum values are recorded in **Mehedinti** county and the values are in the range 19 RON in 2008 and 1342 RON 2006. Between the two lies **Valcea** county whose values are between 43801 RON registered in 2002 and 24849 RON registered in 2007.In 2008 expenses decrease by 640 RON.


Figure 3:Expenses in RDI system in Romania: a) the values for the expenses from RDI registered in Regions South-Muntenia and the counties that belong to this region;b) the values for the expenses from RDI registered in Region Ilfov and Bucharest.
[Source: graphics   are   from   authors   results   based   on   the   data   took   from https://statistici.insse.ro/shop/index.jsp?page=tempo2&lang=ro&context=26: *]*

In the **Western region** RDI costs were 55.17% of values recorded in Macro region 4 and are 26577.6 RON, value registered in 2002.The maximum value of 63.49% of values recorded in Macro region 4 was registered in 2008 and represents 153300 RON. Maximum values for RDI expenditure in the West Region are registered in **Timis** county with values ranging between

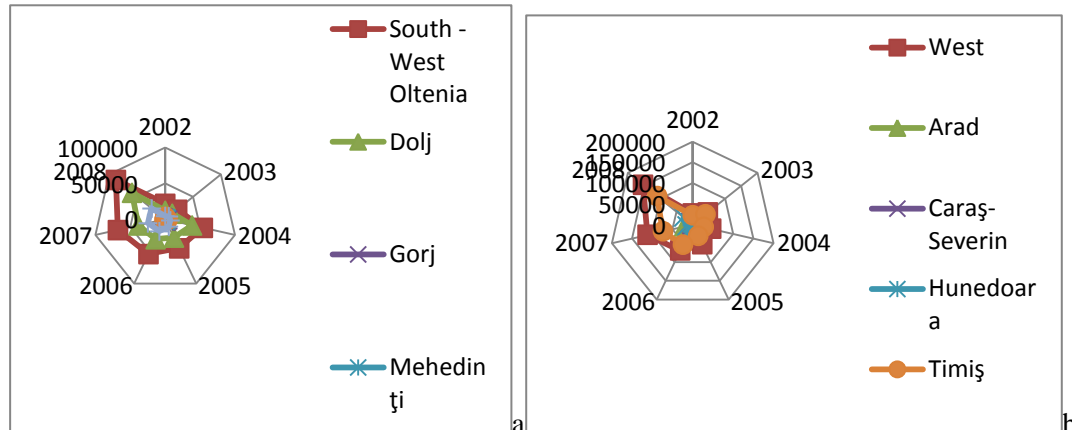
22142.1 RON in 2002 and 109603 RON registered in 2008. The minimum values are registered in Arad county. The values for Arad county were registered in 2002 for the value of 593.8 RON and the maximum value recorded was 21083 RON in 2007.


Figure 4:Expenses in RDI system in Romania: a) the values for the expenses from RDI registered in Regions South West Oltenia and the counties that belong to this region;b) the values for the expenses from RDI registered in Region West and and the counties that belong to this region.

REGIONAL ANALYSIS OF FINANCIAL RESOURCES INVOLVED IN RESEARCH DEVELOPMENT AND INNOVATION (RDI) SECTOR IN ROMANIA IN THE LAST DECADE –STUDY DONE ON MACROREGIONS

Nicolov Mirela [1,2]
[1]*University of Oradea, Faculty of Economic Science*
[2]*Aurel Vlaicu University of Arad, Faculty of Engineering*

The present paper present a study done on the Financial Resources in Research Development and Innovation (RDI) sector in Romania during 2000-2010 . The present paper analyze Regional Systems of Financial Resources of the research development and innovation sector in Romania in the last decade. In the present paper is done an analysis on the Macro Regions and Regions in Romania.
The present study is part of Doctoral Grant "Implications for innovation, research and development role in the development of Romania's economic competitiveness", during 2010 and 2013 and having Director: Prof. Dr. Alina Badulescu in Oradea University, Faculty of Economic Sciences.

Key words: Educational Finance, Higher Education and Research Institutions , Education and Research Institutions, Management of Technological Innovation and R&D , Technological Change: Choices and Consequences; Diffusion Processes; Monetary Systems; Standards; Regimes; Government and the Monetary System; Payment Systems ; Budget; Budget Systems;

JEL code : I22 ,I23 , I2, O18, O32, O33, E42,H61.

1. Introduction

The present paper analyze Regional Systems of Financial Resources of the Research Development and Innovation (RDI) sector in Romania in the last decade in Romania. In the present paper is done an analysis on the Macro Regions and Regions in Romania.

It suggests that for conceptual and methodological reasons, mostly concerning problems of scale and complexity, that approach may be complemented in important ways by a sub national focus

Taking an evolutionary economics standpoint, the paper specifies the concepts of 'region', 'innovation' and 'system' as the prelude to an extended discussion of the importance of financial capacity, institutionalized learning and productive culture to RDI. The notion of regions as occupying different positions on a continuum referring to processes constituting them was builded. (Cooke, 1997).

2. Literature review

Studies on the firm's investments in RDI, as a way to develop technological capabilities were done before too (Cazurra and Un 2007). Technological capabilities are the ability to develop and exploit technological know-how, which is the application of scientific knowledge for commercial purposes (Pisano, 1990). The firm can develop its technological capabilities using several learning approaches (Malerba, 1992). Studies on the investments in RDI were done because of its importance in generating new knowledge, which can help the firm achieve an advantage that is difficult to replicate by competitors (Helfat, 1994,1997).

The companies can invest in RDI internally or externally (Cazurra and Un 2007) . **Internal RDI expenses** are expenditures on personnel and assets in the firm dedicated to the creation of new scientific or technological knowledge or to the development of commercially-viable innovations.

External RDI expenses are expenditures paid to other firms, to universities, or to other entities dedicated to scientific or technological research, to create new scientific or technological knowledge or to develop commercially-viable innovations for the firm. Internal and external RDI investments are directly comparable concepts (Cazurra and Un 2007). Both of them are monetary expenditures. These not include the acquisition of firms or alliances with other companies in these external RDI investments as done in other studies (Capron et al., 1998;Vanhaverbeke et al., 2002; Cazurra and Un 2007).

In the existing literature concerning the impact of environmental changes on the firm's investment in RDI activities is discussed the impact of technological discontinuities. These studies indicate that radical changes in the technological environment which make the firm to realise a more intensive use of external providers of technology.

Economists paid attention very much to the role played by knowledge in explaining countries growth differentials and diffusion across countries and regions(Barrios and Strobl, 2009; Jones,2004; Klenow and Rodriguez-Clare,2005). Knowledge should give rise to substantial scale effects in productivity stemming from their non-rival nature. Knowledge and technological progress are seen as the main engines of economic growth in the long run. Latter may increase rather than decrease regional inequalities, and these elements are very unlikely to be evenly spread across time and space. As a consequence, economic growth may foster divergence rather than convergence across spatial units, suggesting that convergence may evolve non-linearly. When considere the theoretical literature on growth and convergence, a wide array of arguments arise advocating either for the long term reduction or for the persistence and self-reinforcing nature of economic inequalities across countries and regions(Galor,1996; Pritchett ,1997; Lucas,2000,Canova ,2004).

Interestingly, the idea that regional inequalities are likely to evolve in a non-linear way can be traced back in the 1950s. The evolution of regional inequalities was usually linked to national economic development paths and the process of industrialisation. In an analysis of income disparities who suggest the existence of a "long swing" in regional income inequalities, where there is first a rise and then a subsequent fall of income differentials caused by the industrialization process accompanying national development and the decline of agriculture.

Several authors have built on this idea in a regional context suggesting the existence of a bell-shaped curve of spatial development where inequalities should first increase as developed areas benefit from external economies, location of decision-makers, political power, and capital and labour mobility. While a non-linear relationship between regional inequality and national income per capita, clearly has important implications for economic theory and policy, there is to the best of our knowledge no explicit econometric study that has set out to investigate its existence, although a nu mber of works have been suggestive of its possibility. In the current paper we explicitly test this hypothesis using data for EU countries. The EU economy arguably makes for a particularly suitable case study given the sizeable disparities in economic development both across regions a nd countries compared to, for instance, the US (Barrios and Strobl, 2009).

3. Research methodology

Research methodology in this paper is based on the simulation of the data's from 2000 to 2009 for RDI sector in Romania.

The financial resources in RDI activities were analyzed concerning occupation and sex. Data's were taken from the Romanian National Institute of Statistic updated database Tempo online at 15.11.2011. Data used in this study, for this simulation was taken in April 2012. This research is based on the real data of financial resources from RDI area, as a case study for Romania.
(Sources:
http://www.insse.ro/cms/files/Anuar%20statistic/13/13%20Stiinta,%20tehnologie%20si%20inovare_ro.pdf)

The central objective was to see what was happened in the period indicated (2000-2010) with financial resources in RDI sector.

4. Descriptive statistics and results

Total expenditure in RDI activities were recorded from 2002 to 2008. Data were taken from Statistical Yearbook of Romania 2009 and 2010. In this material they will be presented on macro-regions and regions respectivelly.

From financial resources studies done on RDI in total on the macro region we can draw some conclusions:

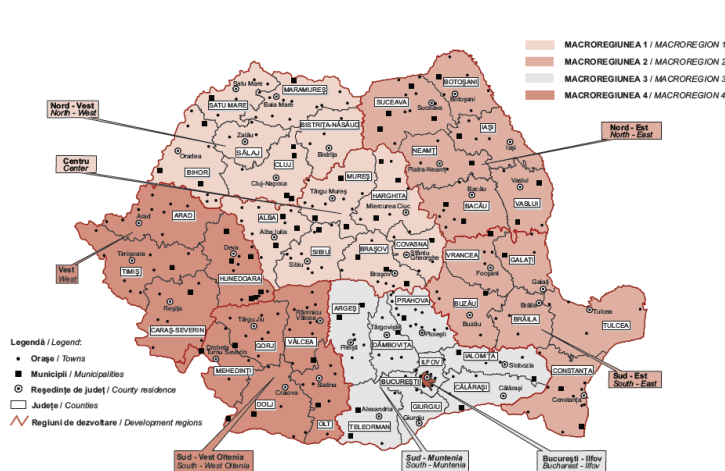
The study was conducted during 2002-2008 period , when the minimum expenditure registered was in 2002 as 574386.1 RON and the maximum value of 2980674 was registered in 2008.


Figure 1: Map of Romania with Macro Regions, Regions and Counties.

In terms of expenditure, the variations on Macro Regions and Regions for RDI sector in Romania is as follows:

In the Macro Region 1 the financial resources had a a minimum value recorded in 2002 as 77169.7 RON and maximum value of 333868 RON recorded in 2008. It seems that spending RDI values were up from 2002 to 2008.

In the Macro Region 2, the minimum value of 55429.4 RON for the expenses in RDI sector were recorded in 2002 and the maximum values were 313830 RON recorded in 2008.

In the Macro Region 3, the minimum value for expenses in RDI sector was 393611 RON value recorded in 2002 and the maximum values was 2091512 RON recorded in 2008.

In the Macro Region 4, the minimum value of expenses were 48176 RON , value recorded in 2002 and maximum values were 241464 RON, recorded in 2008.
Figure 2: Financial resources from RDI system in Romania represented in total and for the 4-th Macroregions
[Source: graphics are from authors results based on the data took from https://statistici.insse.ro/shop/index.jsp?page=tempo2&lang=ro&context=26: *]*

It seems that Macro regions showed the highest value of RDI expenditure activity in 2002 and the expenditure was minimal and in 2008.

Making a Study on the variations of financial resources in Romania in RDI activities we can draw the following conclusions :

Macro region 1 is composed of **North-West** Region on which belongs the 6 counties components: Bihor, Bistrita Nasaud, Cluj, Maramures, Salaj and Satu Mare and on the **Central region** belongs the next counties: Alba, Brasov, Covasna, Harghita, Mures and Sibiu. Performing a study on a macro regions we can draw the following conclusions:

In the **North West Region** the financial resources from RDI sector represent 50.13% of values recorded in a Macro region 1.

In **the Central Region were** recorded values for financial resources in RDI sector between 24.04% recorded in 2008 from the values recorded in Macro region 1 and the maximum value of 49.87% from 2002. (Although the maximum expenses were recorded in 2008 and the minimum in 2002). Percentage presented here is the ratio value of the recorded value from that year in the centre region values from a Macro region.
Figure 2:Expenses in RDI system in Romania: the values for the expenses from RDI registered in Macroregion 1 and Regions Nord-West and Centre;
[Source: graphics are from authors results based on the data took from https://statistici.insse.ro/shop/index.jsp?page=tempo2&lang=ro&context=26: *]*

Macro region 2 is composed of **North Eastern regions** to the next 6 counties: Bacau, Botosani, Neamt, Iasi, Suceava, Vaslui and **South East regions** with the following Counties: Braila, Buzau, Galati, Constanta, Tulcea and Vrancea.

In **North Eastern** region the values recorded for financial resources in RDI sector represented 52.4% of the values recorded in Macro region 2 in 2002 respectively 68.39% in 2008.

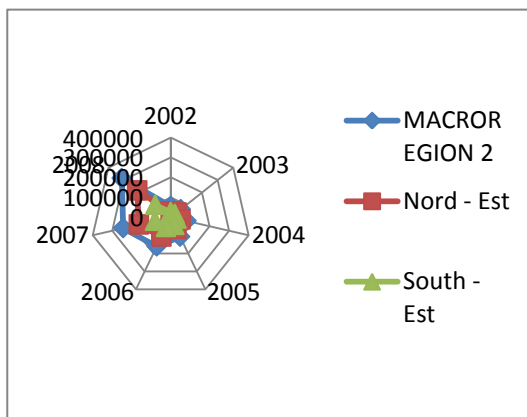
In **the South East** region were recorded values that represent 47.60% from the values recorded in 2002 in Macro region 2 and 231.61% respectively in 2008.


Figure 3:Financial Resources from RDI system in Romania: the values for the expenses from RDI registered in Macroregion 2 and Regions Nord-Est and South-Est.
[Source: graphics are from authors results based on the data took from https://statistici.insse.ro/shop/index.jsp?page=tempo2&lang=ro&context=26: *]*

Macro region 3 is composed of **South Region** with his 6 counties: Arges, Calarasi, Dambovita, Giurgiu, Ialomita, Prahova and Virginia and **Bucharest-Ilfov region** with its two components: Ilfov and Bucharest. Financial Resources from the macro region 3 were values that varies between 393611 RON in 2002 and 2091512 RON registered in 2008. In the **South Region**,

Financial Resources, from RDI system vary from 90884.7 RON in 2002 and 231770 RON in 2007. In 2008 the values for the Financial Resources decrease to 229496 RON. The values recorded in the South Wallachia is 23.09% of values recorded in Macro region 3 in 2002 that is 10.97% recorded in 2008 .

From **Macro region 3** includes and **Bucharest-Ilfov region** which have the highest values for expenditure on RDI. Thus in the Bucharest – Ilfov region are the highest values recorded for financial resources involved in RDI activities , the values were in the range of 76.91% in 2002 and 89.03% in 2008 compared to values recorded in Macro region 3.

The maximum values for financial resources involved in RDI activities are registered in Bucharest and the values range are from 262785 RON in 2002 and 1487299 RON in 2008. The registered expenditures in Ilfov county were in the range of 39941.3 RON values in 2002 and 374717 RON registered in 2008
Figure 4:Expenses in RDI system in Romania: the values for the expenses from RDI registered in Macroregion 3 and Regions South-Muntenia and region Ilfov ; [Source: graphics are from authors results based on the data took from
https://statistici.insse.ro/shop/index.jsp?page=tempo2&lang=ro&context=26: *]*

Macro region 4 is composed of **South-West Oltenia region** and have the following counties: Dolj, Gorj, Mehedinti, Olt and Valcea. **West Region** have the next counties: Arad, Caras-Severin, Hunedoara and Timis. Expenses recorded in Macro region 4 varies between values recorded in 2002 as 48176 RON and 241464 RON registered in 2008.

In the **South West -Oltenia region**, expenses as financial resources involved in RDI sector were in the range of 21306.5 RON, values which represent 44.83% of values recorded in Macro region 4 and were registered in 2003. The value of 88164 RON registered in 2008, represent 36.51% of values recorded in Macro region 4.

In the **Western region** RDI costs were 55.17% of values recorded in Macro region 4 and is 26577.6 RON, value registered in 2002.The maximum value of 63.49% of values recorded in Macro region 4 was registered in 2008 and represents 153300 RON.

LABOUR PRODUCTIVITY AND HUMAN CAPITAL IN THE EU COUNTRIES:AN EMPIRICAL ANALYS

Neagu Olimpia
"Vasile Goldiş" Western University of Arad

The role of the human capital in the economy is highlighted in several studies of human capital, endonegneous growth and macroeconomic literature. A special part of this literature is dedicated to the mechanism and the various channels through wich human capital influences economic growth. As expression of the macroeconomic performance, the labour productivity depends on the accumulation of human capital in the economy. To analyze and discuss this dependency is essential for appropriate human capital policies aiming to stimulate the human capital accumulation in the economy and the enhancement of the labour productivity.

The paper explores the link between labour productivity and the estimates of the human capital stock in the EU countries.

Human capital theory explains the labour productivity level by the workers' level of educational attainment level. Four different effects of human capital on labour productivity can be found in economic literature: worker, allocative, difusion and research. Other researchers used a production function to estimate the productivity impact of changes in educational attainment.

Research on the impact of human capital on productivity at the country level encountered many difficulties over the years. The main methodological issue is how to measure skills and human capital investment and to model possible channels of skills of influence the economic performance. The UNESCO attainment levels and enrollment series and other data sets, constructed by researchers, have been used in a large number of empirical studies of the link between education and productivity.

What is innovative in the present study is the estimation of human capital stock based on educational costs by level(primary, secondary, tertiary) weighted by the proportion of labour force with corresponding educational attainment and the testing of linear regression model for the dependency of labour productivity on human capital stock.

The assumption of the study is that the labour productivity is strongly and positively correlated with the human capital stock in the european economies. In order to confirm this, the following steps were completed: First, the appropriate method to estimate the human capital stock in the economy was identified and then, the estimations were calculated for the EU's countries, based on EUROSTAT data. Second, the correlations between statistical indicators of labour productivity and estimates of human capital stock, for each european countries were identified and discussed. Third, a regression linear model was tested for each of 22 european countries included in the study.

A strong correlation between labour productivity and human capital stock, statistically tested through regression equations with data from EUROSTAT, was found. The variation of labour productivity can be explained in proportion of 85-95% by the variation of human capital stock, considering all other factors as constant.

The added value of the paper consists of: (i) the estimation of human capital stock using the educational costs method for the european countries; (ii) the use of these estimates to show the correlation with the labour productivity levels and (iii) testing econometrical models of the dependency between labour productivity and human capital stock in 22 european countries.

An interesting and useful task for future research is to explore the details of the institutional and incentive structure that best allocates a fixed amount of educational expenditures.

Key words human capital stock, labour productivity
JEL Codes J 24, J 21

Introduction

The topic of the present paper belongs to the research area dealing with the role of the human capital in the economy, and specifically, the association of the human capital stock with the level and growth of the labour productivity. To know the facets of this association could orient the human capital policies able to stimulate human capital accumulation and enhancement of the labour productivity, as expression of the macroeconomic performance.

The aim of the paper is to explore and analyze the link between labour productivity and human capital stock in the european countries. The assumption of the study is that the labour productivity is strongly and positively correlated with the human capital stock in the european economies. In order to confirm this, the following steps were completed: First, the appropriate method to estimate the human capital stock in the economy was identified and then, the estimations were calculated for the EU's countries, based on EUROSTAT data. Second, the correlations between statistical indicators of labour productivity and estimates of human capital stock, for each european countries were identified and discussed. Third, econometrical models are tested for each of 22 european countries included in the study.

The paper is organized as follows: the section 1 presents a short literature review on the link between labour productivity and human capita, in the section 2 is described the methodology of the study, the section 3 exposes the main findings and the final section is dedicated to conclusions.

1. Human capital and labour productivity: a short literature review

Human capital theory explains the labour productivity level by the workers' level of educational attainment level (Mincer, 1974; Becker, 1997). Four different effects of human capital on labour productivity can be found in economic literature: worker, allocative, difusion and research. These effects are based on the studies of Nelson and Phelps (1966) Welch(1970), Ram (1980), Pencavel(1991).

Jenkins (1995) examined the role of education in the labour productivity in UK using a production function to estimate directly the productivity impact of changes in educational attainment.

Research on the impact of human capital on productivity at the country level encountered many difficulties over the years. The main methodological issue is how to measure skills and human capital investment and to model possible channels of skills of influence the economic performance.

For example, the UNESCO attainment levels and enrollment series have been used in a large number of empirical studies of the link between education and productivity. Enrollment rates can be considered an acceptable, imperfect, proxy for the flow of educational investment but they are not necessarily a good indicator of the existing stock of human capital since average educational attainment (which is often the more interesting variable from a theoretical point of view) responds to investment flows only gradually and with a very considerable lag. In an attempt to remedy these shortcomings, a number of researchers have constructed data sets that attempt to measure directly the educational stock embodied in the population or labour force of large samples of countries during a period of several decades. These data sets have generally been constructed by combining the available data on attainment levels with the UNESCO enrollment figures to obtain series of average years of schooling and of the composition of the population or labor force by educational level. The best known early attempts in this line are the work of Kyriacou (1991), the versions of the Barro and Lee data set (1993, 1996, 2000, 2010) and the series constructed by World Bank researchers (Lau, Jamison and Louat (1991), Lau, Bhalla and Louat (1991) and Nehru, Swanson and Dubey (NSD, 1995).

In 2006, dela Fuente and Domenech developed estimates of educational attainment for 21 OECD countries and in 2011 revised them, in order to demonstrate that the contribution of investment in human capital to productivity growth is positive and quite sizeable.

Razak and Timmins(2007) found that university qualification and its product with R&D have a positive effect on the average economy productivity. Jones and Chiripanhura (2010) set out an experimental approach to measuring human capital stock, relevant to explanation of productivity performance, that estimates the economic value to individuals of their highest level of attainment gained in the formal education system.

Masson, O'Leary and Vecchi(2012) found evidence of positive human capital effect on growth in average productivity, particularly when using composite human capital measure and multifactor productivity growth is related to the use of high-skilled labour.

The general model of human capital and growth is a production function of Cobb-Douglas type.

What is innovative in the present study is the estimation of human capital stock based on educational costs by level(primary, secondary, tertiary) weighted by the proportion of labour force with corresponding educational attainment and the testing of linear regression model for the dependency of labour productivity on human capital stock.

2.The methodological approach of the study

Exploring the link between labour productivity and human capital stock poses the problem of measurement of the two variables. While, the labour productivity is measured through statistical indicators available from general statistical sources, adequately measuring of human capital stock is controversial in the human capital literature. For labour productivity, there are several recognized statistical indicators that can be used: output per capita, output per worker, output per hour worked. Regarding the measurement of the human capital stock, the things are more complicated. Three general approaches to measuring the human capital stock can be identified in the relevant literature: measures based on educational attainment, measures based on the value of the inputs that enter the production of human capital (input or cost-based approach) and output (typically measured by labour market income) that stems from human capital (output or income based approach).For the purpose of this paper, the second method is be used.

In this method, the value of the human capital stock is calculated as being the depreciated value of the monetary amount spent on investment in human capital. Kendrick (1976) and Eisner (1985) provide seminal examples of this approach.

According to Judson (2002), the average human capital per worker, h, is:

$$h = \sum_i d_i \cdot a_i \tag{1}$$

where:

d_i is educational expenditures for the i level of education, as share of GDP;

a_i is the educational attainement of the labour force

Extending the work of Judson, the human capital stock in the economy can be estimated using the formula (2):

$$H = \sum_i ED_i \cdot EP_i \tag{2}$$

where:

H- human capital stock per capita

ED_i -educational expenditures per student for i-educational level(primary, secondary, tertiary) in PPS based on full-time equivalent ;

EP_i - employment population population with i-educational level.

In order to test the dependency between labour productivity and human capital stock, a linear regression model will be used:

$$Y = \alpha + \beta \cdot x + \varepsilon \quad (3)$$

where:

Y - labour productivity, expressed in Eur/hour

α -constant

β -regression coeficient

x - human capital stock, expressed in thousand Euro

ε -error

The study was carried out in three stages. In the first stage the estimates of human capital, according to the formula (2) was calculated for each of 22 european countries included in the study. The decision of inclusion was based on the availability of data for the period 1996-2010 from EUROSTAT.

In the second stage, the correlation coefficients were calculated (Table 1).

In the third step, the regression equation (3) was used for each country, to test the link between labour productivity and the human capital stoc in the economy and the statistical validity of the econometric models was checked.

3.Main findings
3.1. Labour productivity, human capital stock and gross domestic product
Table 1 Partial correlation coefficients, EU countries, 1996-2010

Country	Correlation coefficient between labour productivity and human capital stock	Correlation coefficient between human capital stock and gross domestic product	Correlation coefficient between gross domestic product and labour productivity
Belgium	0,81	0,96	0,85
Bulgaria	0,96	0,98	0,94
Czech Republic	0,99	0,97	0,98
Denmark	0,88	0,95	0,9
Germany	0,94	0,97	0,98
Estonia	0,92	0,98	0,96
Ireland	0,98	0,98	0,89
Greece	0,90	0,99	0,95
Spain	0,96	0,99	0,82
France	0,96	0,98	0,96
Italy	0,52	0,81	0,83
Cyprus	0,99	0,99	0,98
Latvia	0,92	0,99	0,92
Lithuania	0,96	0,99	0,96
Malta	0,32	0,94	0,37
Netherlands	0,97	0,99	0,98
Austria	0,98	0,98	0,99
Poland	-0,09	0,95	0,39
Portugal	0,95	0,97	0,97
Slovenia	0,95	0,93	0,95
Slovakia	0,98	0,98	0,96
Finland	0,97	0,97	0,98
Sweden	0,89	0,97	0,95
United Kingdom	0,95	0,89	0,90

Source: author's own calculations based on EUROSTAT data

Note: Luxembourg, Hungary, Romania were excluded due to unavailable data for all years.

As we can see in the Table 1, in all european countries there are very strong correlations between labour productivity and human capital stock, gross domestic product and human capital stock, gross domestic product and labour productivity. There are two exceptions, in Malta and in Poland. In Malta, labour productivity is weakly correlated with the human capital stock(0,32), but the gross domestic product is strongly and positively associated with the human capital stock. In the case of Poland, there is an inverse correlation between the labour productivity and human capital stock and, as in Malta and other european countries, human capital stock is positively and strongly correlated with the gross domestic product.

3.2. The link between labour productivity and human capital stock in the european countries

Taking into consideration the association of labour productivity with the human capital stock, the european countries can be divided in three groups The first group includes Germany, United Kingdom, France, Italy, Spain and Italy, where the labour productivity and human capital stock are above the average of European Union. The economic output and the labour productivity (25-50 Eur/hour) in these countries are at the highest level of European Union. There are strong economies where the stock of human capital is better valorised on employment than the EU's average.
Fig.1 The relation between labour productivity and human capital stock, in european countries, average values for 1996-2008
Source: author's calculations based on EUROSTAT data

In the second group, countries as Austria, Sweden, Belgium, Finland, Ireland and Denmark have the level of the labour productivity above of the EU's average and the level of their human capital stock is under the EU's average. In the case of these countries, the human capital stock has a lower impact on the national labour productivity as the EU's average.

The third group consists of countries with labour productivity and human capital stock under the EU's average (Bulgaria, Poland, Portugal, Greece, Czech Republic, Slovenia, Slovakia, Latvia, Lithuania, Malta and Cyprus). In these countries, the value of human capital stock is under 50.000 thousand Euro and the labour productivity is under 25 Euro/hour.

In order to further analyze the association of labour productivity with human capital stock, the econometric model presented in section 2 was tested for 22 european countries with 1996-2008 data. 5 of the 27 Member States were excluded due to unavailable data for all years (1996-2008). In 20 of 22 countries, the linear regression model was statistically validated. The values of the multiple correlation coefficients between labour productivity and human capital stock indicates a strong a positive correlation between these variables. The variation of labour productivity can be explained in proportion of 85-95% by the variation of human capital stock, considering all other factors as constant (see Apendix).

Conclusions

The paper is based on estimation of human capital stock in european countries using the costs method developed by Judson (2002). Empirical analysis of the estimation of human capital based on educational costs weighted by the educational attainment of the labour force are quite rare.

Accordingly, the added value of the paper consists of: (i) the estimation of human capital stock using the educational costs method for the european countries; (ii) the use of these estimates to show the correlation with the labour productivity levels and (iii) testing econometrical models of the dependency between labour productivity and human capital stock in 22 european countries.

The findings of the study show that is a strong linkage between labour productivity and human capital, expressed as a stock, and differences in labour productivity accross the european countries can be explained, in proportion 0f 85-95% by the differences in the level of human capital stock. The proposed linear regression model is validated in 20 of 22 countries.

Measuring the association of human capital with the labour productivity is important for policy makers, especially in decisions about education spending based on empirical evidences. Due to the fact that policy on education can have many ends other than raising productivity, an interesting and useful task for future research is to explore the details of the institutional and incentive structure that best allocates a fixed amount of educational expenditures.

THE MARKET VALUE OF HUMAN CAPITAL: AN EMPIRICAL ANALYSIS

Neagu Olimpia
"Vasile Goldis"Western University" of Arad, Romania

There is a general consensus that human capital is a major determinant of economic growth. Reflections on how human capital is related to growth can be extended by viewing on the market value of the human capital.

The concept of the market value of human capital reflects the efficiency of allocation and utilisation of the human capital in the economy. To measure this efficiency the concept of the market value of human capital is explained and developed in the present paper.

The aim of the paper is to introduce the concept of market value of human capital and the specific objectives are targeted to define his content, to propose a method for estimating it and to provide calculations of it for OECD countries.

The concept of human capital is complex and multifaceted one, consisting of: native human capital (biological), educational capital, health capital and social skills (Neagu, 2010). Clearly, human capital is intangible, a stock that is not directly observable as physical capital. Therefore, the estimation of human capital must be constructed indirectly. The stock of human capital in economy creates economic value, expressed through the economic output per capita. In order to estimate this economic value we have to find an appropriate proxy for the human capital stock producing that value.

In the purpose of our paper, we consider that the economic value of human capital can be estimated by calculating the aggregate value created by the active human capital in the economy. In this view, GDP per person employed is a relevant estimation of value created by the employed labour force. The aggregate value is created by the employed persons with different educational level.

The market value of human capital is calculated by dividing the GDP per person employed to the human capital stocks active in the economy. The human capital stock depends on educational costs (on primary, seconadry, tertiary education) as a the share of GDP per capita weighted by the employment rates. For OECD countries, the market value of their human capital was calculated for 1999-2008, showing their efficiency on utilisation of the human capital stock. The most efficient OECD countries are Australia Austria and USA and the less efficient are Mexico, Czech Republic and Hungary.The market value of human capital has a ascending trend in all OECD countries, reflecting the results of their efforts to valorise their human capital in employment.

The originality of the paper consists on introduction the concept of the market value of the human capital, defining his content and providing estimates for OECD countries.As a concept, the market value of human capital of a country shows the ability of the economy to use the existent human capital to produce economic output. The market value of human capital reflects an aspect of the economic efficiency, by relating the economic output per person employed to the human capital per capita employed in the economy. It expresses the economic output per one unit of human capital, reflecting the aggregate perfomance of that economy.

KEY WORDS: human capital, market value of human capital, employment, education costs

Introduction

There is a general consensus that human capital is a major determinant of economic growth. Reflections on how human capital is related to growth can be extended by viewing on the market value of the human capital. The concept of the market value of human capital reflects the efficiency of allocation and valorization of the human capital in the economy. To estimate this efficiency, a measure of the market value of human capital was developed in the present paper, by weighting the national output per worker employed by the employment rate and the investment costs in education. The issue of efficiency in allocation and utilization of human capital in economy is important for policy makers, in designing policy measures, under the pressure of the public resources decreasing.

The aim of the paper is to introduce the concept of market value of human capital and the specific objectives are targeted to define his content, to propose a method for estimating it and to provide calculations of it for OECD countries.

The paper is organized as follows: section 1 provides some definitions of human capital, section 2 describe the concept of the market value of human capital, in the section 3 is described the methodology of the study and the section 4 presents the main finding. The final section is dedicated to conclusions and further directions of research.

1.Definitions of human capital

The concept of human capital was first introduced and estimated by Petty (1690). Cantillon (1755) discussed the concept of human capital and estimated the cost of rearing a child until working age. Adam Smith (1776) presented a clear analysis of the concept of HC and included it as a part of the 'general stock (human and non-human capital) of any country or society', where this general stock is composed of the following resources, (i) of all useful machines and instruments of trade which facilitate and abridge labor; (ii) of all those profitable buildings which are the means of procuring a revenue; (iii) of the improvements of land; and (iv) of the acquired and useful abilities of all the inhabitants or members of the society. Afterwards, he added, the ''acquisition of such talents, by the maintenance of the acquirer during his education, study, or apprenticeship, always cost a real expense, which is a *capital* fixed and realized, as it were, in his person''.

According to Schultz(1961), skills and knowledge that people acquire during their formal schooling represent a form of human capital. Schultz invented the term to reflect the value of our human capacities. He believed human capital was like any other type of capital; it could be invested in through education, training and enhanced benefits that will lead to an improvement in the quality and level of production.

The concept of human capital was largely forgotten by economists until its re-birth in the early 1960s with the writings of Becker (1962, 1964) and Mincer (1958, 1962, 1974). These economists rekindled this old concept by reaffirming its links with economic growth and by emphasizing its importance in explaining earnings differentials.

Human capital is represented by the aggregation of investments in activities, such as education, health, on-the-job training, and migration that enhance an individual's productivity in the labour market (see e.g., Kiker 1966; Becker 1997; Schultz 1961, 1962). More recently, this concept has been extended to include non-market activities (see e.g., OECD 1996; Jorgenson and Fraumeni 1989; Schultz 1994).

The Penguin Dictionary of Economics defines human capital as "the skills, capacities and abilities possessed by an individual which permit him to earn income."

According to another definition, human capital represents "the knowledge, skills, competencies and attributes embodied in individuals that facilitate the creation of personal, social and economic well-being" (OECD, 2001, p18).

Laroche et al(1999) defined human capital as the aggregation of the innate abilities and the knowledge and skills that individuals acquire and develop throughout their lifetime. Innate abilities represent an individual's intrinsic potential to acquire skills. They can be defined as all physical, intellectual, and psychological capacities that individuals possess at their time of birth. They are received as gifts by individuals without any action or choice of their own, and they differ greatly across individuals because of heredity, parental decisions, and purely random factors. Acquired skills represent the actualization of this potential mostly through individual efforts involving a cost. These skills are acquired over one's lifetime through intergenerational transfers of knowledge, personal contacts, work experience, on-the-job-training, education and socialization. Since the number of skills individuals acquire through their lifetime depends partly on their initial abilities, this potential is an important aspect of the human capital concept.

The concept of human capital is complex and multifaceted one. Laroche et al(1999) proposed five main aspects to be considered: (i) human capital is a non-tradable good, it is embodied in human beings; (i) individuals do not always control the channels and pace they acquire human capital: as young, human capital decisions are made by parents, governments, society(educational institutions), as individuals able to make independent decisions, they internalize the decision process on human capital investments; (iii) human capital has quantitative and qualitative aspects: human capital investments are not qualitatively homogeneous; (iv) human capital can be general (possibly to use in variety of activities and transferable from one employer to another) and specific(can be used in a limited number of activities).

The definition of human capital also contains the notion of external effects. The influence that individuals have on the productivity of others and of physical capital, as well as the fact that individuals will be more productive, for any given level of skills, in an environment containing a high level of human capital are demonstrating this effect. Human capital also generates what can be referred to as social externalities. These externalities, which include, among other things, increased utility from living in a society with democratic institutions, freedom of thought and speech, and more varied literary expressions and means of communication, enable individuals to live effectively in a society whose members share common goals. The pursuit of common goals, in turn, enhances mutual trust among individuals and strengthens social institutions. The collection of all these externalities has been termed as *social capital*.

Summarizing, the concept of human capital consists of: native human capital (biological), educational capital, health capital and social skills (Neagu, 2010).

Clearly, human capital is intangible, a stock that is not directly observable as physical capital. Therefore, the estimation of human capital must be constructed indirectly. Common approach to human capital measurement include the cost based approach, the income-based approach and education-based approach. We will use further the education-based approach.

2.Conceptual aspects

A country's human capital stock is the value of the productive capacity of its workers. Human capital is important as research generally supports a relationship between high levels of capital and economic growth. Individuals' labour market outcomes are linked to their human capital, although the precise mechanisms by which this happens is unclear. Jones and Chiripanhura (2010) set out an experimental approach to measuring human capital that estimates the economic value to individuals of their highest level of attainment gained in the formal education system.

This paper focuses on human capital acquired through participation in the formal education system, i.e. excluding the human capital gained in the years before primary education and in adult life. For the purposes of this paper, the term human capital is restricted to people's knowledge, skills and competencies, which means excluding other attributes such as the health of the population. Thus, any activity that adds to these can be thought of as investment in human

capital. These activities can take place throughout an individual's life and in a range of environments.

In this paper, we understand the market value of human capital as a valorization of national education investment on the labour market. The market value of human capital depends on how efficiently human capital is allocated and employed in the economy, therefore it depends in a very large scale on the efficiency of institutions.

In the present paper, we take into consideration that the market value of the human capital for a given educational level is expressed by the national output per worker employed, the employment rate and the expenditures for that educational level.

The stock of human capital in economy creates economic value, expressed through the economic output per capita. In order to estimate this economic value we have to find an appropriate proxy for the human capital stock producing that value. In the human capital literature, there are several methods to estimate human capital stock in the economy. For example, there have been used are literacy rates, enrolment rates, and estimates of the average number of years of education attained by workers. These proxies give an idea of how much human capital a country has, but any power they have depends on the assumption that the proxy is collinear with the country's whole human capital stock.

Another approach is to estimate the human capital stock as average years of education of the labour force developed by Kyriacou (1991), Barro and Lee (1993, 2000), Nehru et al (1995). Building on their work, Judson (2002) brought an innovation: to calculate the cost of education and then to weight primary, secondary, and higher education stocks according to their costs.

Based on the findings of Judson(2002), the average human capital per worker, h, is:

$$h = \sum_i d_i \cdot a_i \tag{1}$$

where:

d_i is educational expenditures for the i level of education, as share of GDP;

a_i is the educational attainement of the labour force

In the purpose of our paper, we consider that the economic value of human capital can be estimated by calculating the aggregate value created by the active human capital in the economy. In this view, GDP per person employed is a relevant estimation of value created by the employed labour force. The aggregate value is created by the employed persons with different educational level. The employed population can be divided in three main groups: with primary, secondary and tertiary education. Each group contributes differently at the macroeconomic results, according to the human capital they embodied.

In the purpose of our paper we consider that we can estimate the active human capital stock per worker, following the reasoning of Judson(2002) and using the formula (1).

In this view, the human capital stock in the economy can be calculated by weighting the costs per student in primary, secondary and tertiary education by the employment rate by educational attainment:

$$h = \sum_i ED_i \cdot ER_i \tag{2}$$

h - human capital stock per capita

ED_i -educational costs per student in primary, secondary, tertiary education, as share of GDP per capita;

ER_i - employment rate for population with i-educational level.

The monetary value created by human capital, HCV, is given by:

$$HCV = \frac{GDP / employed}{\sum_i ED_i \cdot ER_i} \quad (3)$$

where:

i - the educational level: 1-primary, 2-secondary, 3-tertiary

ER_i is the employment rate by the i-educational level;

ED_i is the educational investment, expressed by the expenditure per student for the i educational level, as % of GDP per capita.

We assume that the governement expenditure are a good measure of the value of education provided. But there are shortcomings of this assumption. First, education expenditures measure the price of producing human capital at a given time, so is not an accurate indicator of the value of older human capital. Second, educational data provided by UNESCO are not including private spending.Third, the method does not include the foregone earnings during education, that could be quite substantial. Fourth, the quality of education output is not always a direct function of expenditures.

3.Methodology of the study

In the present study, educational and economic data regarding OECD countries are used. The following sources of data were explored: OECD Data Base for employment rates of 25-64 years olds by educational attainement, UNESCO for expenditures per student, in primary, secondary, tertiary education, as % GDP per capita and WORLD BANK for GDP per person employed in PPS, international dollars.

Using the formula (3) it was calculated HCV, in each year, between 1999-2008, for primary, secondary and tertiary education in 28 OECD countries. The results of calculations are presented in Table 1.

A higher value of HCV means a higher efficiency in utilisation of the human capital stock existent in the economy. But, we have to mention that in our formula of HCV, calculation of the human capital stock is based on the shares of educational costs in GDP per capita weighted by the employment rates of the educational levels. As these shares and employment rates are higher as the human capital stock is higher and, finally, the HCV is lower, at a fixed level of GDP per person employed. It is possible that countries with a high level of GDP per person employed and with a high level of human capital stock to have a low HCV. HCV measures the efficiency of the utilisation of the existent human capital to produce economic output.

4.Main findings

As we can see in the Table 1, the countries with the highest human capital value are: USA, Australia and Austria. In these countries, the active human capital is the best valorized on the labour market, the level of employment rates by all educational levels being the highest. The loweste levels of HCV are registered in Eastern European countries as Czech Republic, Poland, Hungary, in Turkey, Mexico and Portugal. Their values are at a half of those registered in USA, Austria and Australia.

We can divide the OECD countries in three main groups by the average level of HCV during 1999-2008: (1) with HCV values between 11-13 $: USA, Australia, Austria, Ireland, Korea, Sweden, Slovenia ; (2) with HCV values between 8-11 $: Belgium, Estonia, France, Israel, Italy, Japan, Spain, United Kingdom; (3) with HCV values between 3,9-8 $: Czech Republic, Denmark, Hungary, Iceland, Mexico, Netherlands, New Zealand, Norway, Poland, Portugal, Slovak Republic, Switzerland, Turkey.

The countries from the first group are the most effectively in their efforts to use on employment the stock of human capital produced by the education process. In these countries, the economic

output per person employed is double as in countries from the third group and the employment levels for highly skilled people are between 82-85%.

The countries from the second group are well developed countries, with a level of GDP per capita between 39.000-56.000 $. The rates of employment for the secondary and tertiary education are between 72-87% and shares of education costs of GDP per capita are 25-35%.

Source: author's calculations

The countries from the third group are, mostly, former communist countries (Poland, Hungary, Czech Republic, Slovak Republic) or developing countries(Mexico, Turkey), where the stock of

human capital is about half of that the countries from the first group and the economic output per capita is the third of well developed countries. In a separate situation are Denmark, New Zealand, Norway and Switzerland, well developed countries, with a higher level of GDP per capita. In these countries, the costs of higher educated employees are at very high level and the employment rate for these individuals, as well (i.e.90, 15% as average for 1999-2008, in Switzerland).

In all OECD countries the market value of human capital increased during 1999-2008 and the trend is ascending. Spain is an exception, the values are decreasing last years, due to the impact of the economic crisis on the labour market. In the rest of the OECD countries the economic crisis has no significant effects on the valorization of human capital stock on employment, the trends are ascendent or stables. A possible explanation could be the fact that in 2008, the financial and economic crisis was not yet turned into a jobs or employment crisis. A possible evolution of HCV for 2009-2011 could be a downward trend, due to the contraction of economic output in all countries.

Conclusions and further directions of research

The originality of the paper consists on introduction the concept of the market value of the human capital, defining his content, proposing a method to estimate it and providing calculations for OECD countries.

The market value of human capital in OECD countries was calculated for 1999-2008, showing their efficiency on utilisation of the human capital stock. The most efficient OECD countries are Australia Austria and USA and the less efficient are Mexico, Czech Republic and Hungary.The market value of human capital has a ascending trend in all OECD countries, reflecting the results of their efforts to valorise their human capital in employment.

The market value of human capital per worker, as average, evolves between 3,91 $ in Mexico and 13,02 $ in USA.

The market value of human capital has a ascending trend in all OECD countries, reflecting the results of their efforts to valorise their human capital in employment.

As a concept, the market value of human capital of a country shows the ability of the economy to use the existent human capital to produce economic output. The market value of human capital reflects an aspect of the economic efficiency, by relating the economic output per person employed to the human capital per capita employed in the economy. It expresses the economic output per one unit of human capital, reflecting the aggregate perfomance of that economy.

An added value of the paper constitutes the fact that countries can adapt, design or re-design their employment policies on the basis of the present empirical evidences on the market value of human capital. The idea is to raise the valorisation in employment of the active human capital stock in the economy.

A direction of further research could be to investigate how the allocation of human capital through the sectors of the economy influences the market value of the human capital.

It will be useful, as well, to investigate how the efficiency of institutions influence this value.

In this view, it is necessary to find a method to calculate the contribution of the different groups of labour force by educational attainment to the aggregate economic output per capita or per person employed. In this way, we could estimate more accurately the contribution of human capital stock by different educational levels to the value creation in the economy. An analysis of these estimates could be useful in orienting governamental policies in education and employment, to stimulate the accumulation of human capital generating more value for the economy.

EVALUATION OF THE STRUCTURAL FUNDS ABSORPTION RATE BY MEANS OF THE HERMIN MODEL

Opritescu Elena Madalina

The main objective of this article is to highlight the main method that could quantify the impact of the structural funds on the Gross Domestic Product. I also presented the regional disparities situation and the European funds absorption rate. The HERMIN model has been designed considering the evolution of macro-variables throughout transition and pre-accession process, as well as out of the need to analyze the gradual alignment of Romania's economic policies to those of EU. The fact that, initially, the HERMIN model was designed for the European Union's less developed economies represented the cornerstone in choosing it, as it was the case for Romania, too. However, the quantitative evaluation must always be accompanied by a qualitative evaluation, in order to comprise factors which cannot be measured by the econometrical modeling. For this purpose, when the results of econometrical model based evaluation are used, it is important to be aware of the fact that models simplify reality, no matter the impressive mathematical calculations they employ.

Also, we must not omit the fact that Romania's major development needs and the current economic context imperatively demand a high as possible level of structural funds absorption, as well as their efficient use, meant to generate a significant impact at a national, regional and local level.

One of the main instruments employed to sustain economic growth, while also reducing disparities between regions is represented by the structural funds. These funds, consisting in financial contributions of the member states, according to their level of development, are redistributed in compliance with an extremely complex regulating and procedural frame, to those EU states of regions which are fallen behind from a social and economical development perspective

Nevertheless, when absorption capacity of a member state is evaluated, the used percentage from the allocated funds is not the only monitored indicator, but also the effects they have generated in that state's economy. This analysis is imperative because at this moment, Romania is facing one of the lowest absorption rate.

Keywords: Hermin model, Structural Funds, Absorption rate, Regional disparities, Regional development

1. Introduction

At present, Europe is faced with a difficult mission, to exit a deep crisis and to decrease the unemployment and poverty, while performing, in the same time, the transition to a dynamic and competitive economy. In order to achieve this ambitious goal, rapid actions on multiple fronts are required, reason for which The European Council has adopted the Europe 2020 Strategy.

Its key objective is intelligent, inclusive and sustainable growth. Even more than its predecessor – The Lisbon Strategy – Europe 2020 aims to achieve this objective by emphasizing the need for innovation, employment and social inclusion, as well as a vigorous reaction to the set objectives concerning the environment and climatic changes.

The European Union's economic and social cohesion policy must be regarded as an integral part of the Lisbon Strategy (adopted by the European Council from Lisbon in March 2000 for a 10

year period) which aimed to transform Europe by the year 2010, "the most dynamic and competitive knowledge based economy".

The cohesion policy is also playing a decisive role in this difficult period, by significantly contributing to growth and prosperity throughout the entire Union, while also reducing over time the economic, social and territorial disparities. The objectives of the cohesion policy, also included in the Europe 2020 Strategy refer to the support offered to underdeveloped EU regions in order to reduce the development gap between them and the other EU regions, to counteracting low productivity and economic growth stagnation throughout the European Union by formulating political initiatives meant to be taken over by the member states, to the coordination of EU policies, to the approach of social aspects such as population ageing and environment issues.

One of the main instruments employed to sustain economic growth, while also reducing disparities between regions is represented by the structural funds. These funds, consisting in financial contributions of the member states, according to their level of development, are redistributed in compliance with an extremely complex regulating and procedural frame, to those EU states of regions which are fallen behind from a social and economical development perspective.

2. Regional Disparities

There has been much debate, often justified, regarding the low rate of the European structural funds absorption, having direct influence on the regions' uneven development. The most recent Eurostat report regarding the development regions' evolution reveals that in Top 10 regions whose inhabitants have the highest purchasing power, 8 are regions of European capitals. Thus, the first place is held by the Inner London inhabitants, with a purchasing power of 343% (85 800 EURO) compared to the European average (25 100 EURO). They are followed, in order, by The Great Duchy of Luxembourg – 279% (70 029 EURO), Bruxelle – Belgium – 216% (54 216 EURO), Groningen – The Netherlands – 198% (49 698 EURO), Hamburg – Germany – 188% (47 188 EURO) and Prague – The Czech Republic – 172% (43 172 EURO). Among the 40 regions that present a purchasing power of over 125% compared to the European Union average, 10 were from Germany, 5 from the Netherlands, 4 from Austria and The United Kingdom respectively, 3 from Spain and Italy respectively, 2 from Belgium and Finland respectively and one from Denmark, Ireland, France, Slovakia, Sweden and Luxembourg. The eight poorest regions in Europe are all from Bulgaria and Romania. Thus, the poorest region is Severozapaden from Bulgaria with 28% (7 028 EURO) compared with the European average, followed by the North-East Region from Romania with 29% (7 279 EURO), Severen tsentralen and Yuzhen tsentralen, both from Bulgaria, with 30% 97 530 EURO).

In Romania, the regions' top presents itself as follows:

Region	GDP per capita, EURO	UE27 average %
North East	7 200	29%
South-West Oltenia	9 100	36%
South-East	9 700	39%
South – Muntenia	9 800	39%
North-West	10 400	41%
Center	11 200	45%
West	12 700	51%
Bucharest – Ilfov	28 300	113%

Source: Eurostat

Six regions from Romania are in the "top" 20 poorest regions in the European Union (EU), according to the level of GDP per capita (as calculated according to the purchasing power parity);

the "record" belongs to the North-East Region (Suceava, Botosani, Iasi, Neamt, Bacau, Vaslui counties) with a level of only 29% compared to the European average. As one could easily predict, the exact opposite position is held by the capital, the Bucharest-Ilfov Region which presents a GDP per capita level of 113%. Nevertheless, the value the national level reaches doesn't even represent half of the European average. These disparities are not something of a novelty and are proof that there is neither a balanced development policy in the regions, nor a coherent strategy so far as the authorities as concerned. In order to balance the income at a region level, the funding of the programs implemented by means of European funds, as well as Government money should be exclusively concentrated on those parts of Romania that are regarded as underdeveloped.

According to the 2007 - 2013 Financial Perspective, the entire territory of Romania was subject to the "Convergence" Objective, as the GDP per capita in the development regions was below 75% compared to the European average. Also, Romania was eligible to the Cohesion Fund (mainly focused on infrastructure and environment), as the GDP was below 90% compared to the European Union average.

Starting from the aforementioned aspects we aim to highlight the European funds absorption rate and the main method through which the effects of structural funds on Romania's economic evolution could be quantified and through which the main factors that negatively influence the absorption rate could be identified.

3. Structural Funds Absorption Rate

The absorption of the structural and cohesion funds represents one of top priorities for the public administration, companies, farmers and non-governmental organizations. The absorption rate represents the rate at which a country is capable to effectively and efficiently spend the financial resources allocated from the European Funds.

The substantial allocation of funds from the European Union for the period 2007 – 2013, mounting at approximately 20 billion EURO must be optimally used, as it represents a key source for the short, medium and long term development of the Romanian economy and society. Moreover, considering the current economic environment, in which developing countries find difficulties in gaining access to financing on international markets, but also the non-reimbursable aspect of these structural funds, they represent a central element of the budget sustainability, in terms of investment strategy. Romania cannot afford to waste this great opportunity to modernize.

Achieving the objective of at least 90% of the allocation available for Romania is virtually unattainable. At the end of 2008, the status of the Operational Programs' implementation was dramatic, especially in some of the most suggestive chapters: closing of financing contracts with the beneficiaries and the amount of payments towards beneficiaries. For this reason, a set of measures was adopted, concerning the following aspects: improvement and simplification of applicant guides, more flexibility for the financing access criteria, reduction of requirements concerning the documentation demanded for the financing file submission, increase as to double the maximum pre-financing threshold, improvement of legislation regarding public acquisition etc. These conditions led to a visibly accelerated level of absorption throughout the year 2009.

At the end of 2010, in spite of a positive evolution of some progress indicators such as the number of submitted projects, approved projects and signed financing contracts, an extremely low level of structural instruments was being recorded (as calculated based on the reimbursements received from the European Commission), more precisely, 1.9% of the EU allocation for 2007 – 2013. This situation notably contrasted with the absorption level of the EU allocation for 2007 – 2013 (approximately 42.7% on 31 December 2010) and with the internal payments towards beneficiaries (pre-financings and reimbursements) mounting to 1.73 billion EURO (approximately 19% of the EU allocation for 2007 – 2013).

Considering the unsatisfactory status of the structural and cohesion funds absorption and aiming to accelerate the implementation of the Operational Programs, the Ministry for European Affairs (MAEur) elaborated and subjected to Government approval "The Priority Measures Plan for consolidating the Structural and Cohesion Funds Absorption Capacity" (PMP). This document aims to provide solutions to the problems and deficiencies that have the greatest impact in affecting the implementation of structural and cohesion funds and comprises measures which are structured in 7 main guidelines: the project cycle management, realized by the organisms responsible with implementing the operational programs; financial regulations regarding the management of Operational Programs (PO) and projects; public acquisition procedures and acquisition contracts; approach of the audit and control activities; the influence of institutions and of procedures outside the scope of the structural instruments management on the projects' evaluation, closing and implementation process; to provide the structures responsible with PO implementation with an adequate administrative capabilities.

On a medium term, the PMP implementation must lead to avoiding the phase out of substantial funds on the date of 31 December 2013 (when there is the highest phase out risk), and, on the long term, to creating the necessary conditions to achieve the target commonly agreed upon through the National Strategic Reference Framework 2007 – 2013, more precisely absorption of at least 90% of the structural and cohesion funds allocated to Romania.

On the date of 30 November 2011, as presented in Chart no. 1, the total number of projects submitted for financing within the 7 Operational Programs was over 31 172, mounting to a total of 240,5 billion Lei (approximately 56 billion EURO). Of the total number of projects submitted to approval, only a number of 9 823, mounting to a total of 97.9 billion Lei had their financing approved (approximately 22.7 billion EURO, of which 14.1 billion EURO EU contribution, resulting in an approximately 74% of the EU allocation for 2007 – 2013). There has also been a considerable progress in implementation, regarding the number of contracts/ financing decisions concluded with the beneficiaries. Until 30 November 2011, of the 9 823 submitted projects, there were 7 255 signed contracts, with an eligible value of approximately 66.1 billion Lei (15.3 billion EURO, of which the EU contribution mounts to approximately 12.2 billion EURO), representing around 63% of the EU allocation for 2007 – 2013. However, the total payments towards beneficiaries, representing pre-financings and reimbursements (except for VAT refund), mounted to only 13 billion Lei (3 billion EURO). The internal payments of EU funds represent 14.72% of the EU allocation for 2007 – 2013.

Chart no. 1 EU allocation for 2007 – 2013 vs. the value of the submitted/ approved/ contracted projects until 30 November 2011
Source: www.fonduri-structurale.ro – personal interpretation

At the beginning of 2012, an advanced stage has been reached, considering that approximately 67% of the funds allocated to Romania through all Operational Programs (PO) have been contracted. Although priorities at a national level aimed at obtaining an as high as possible level of the projects' submission, approval and contract closing, favoring efficiency to the detriment of the eligibility and the submitted projects' quality, the absorption rate (internal payments), also calculated for all the Operational Programs, is of only 15.60%.

Nevertheless, the new strategy forced an emphasis on absorption and implementation. For this purpose, the responsible authorities declared that, by the end of 2012, they intended to reach an external/ actual absorption rate (payments from EU) of 20% - 25% (considering that, at the end of February 2012 it had reached 6.3% compared to 5.5% at the end of December 2011) and a contracting rate of 90% minimum. The main objective is to avoid phase out by absorption of 8.6 billion EURO by the end of 2013.

4. Evaluation by means of the Hermin model

The HERMIN model is used in several EU member states in order to estimate the impact of the structural and cohesion funds on the national economies, but also to analyze the comparative evolution of the financial transfers necessary to the development of the Euro-regions. The HERMIN model had been adapted in Romania since 1998 and its more recent variant, developed by the European Center for Economic Modeling is entitled HEROM.

The European Structural Funds, as had been proved by the experience of the member states which joined EU in the '80s (cohesion states, Spain, Portugal, Greece and Ireland), have had a powerful impact on the European Union's economies which they had been transferred to. Moreover, the way they were absorbed and their different distribution, according to their destination, for infrastructure or human capital development or directly for economic actions, had a distinct impact in each of the recipient member states.

The Hermin model is estimated to reflect the impact of the cohesion policy, namely the effect of the structural funds on the GDP and employment rate, but also their contribution to the regional development and disparities reduction. The Hermin model is an annual multi-sector model and it includes the processing industry (goods tradable on external markets), market services (goods non-tradable on external markets), agriculture and the government services (non-market).

The structure of the model can best be regarded as consisting in three main blocks: one for the offer, which is distinctly detailed for each of the four sectors, one for the absorption and one for the income distribution. Consequently, the HERMIN model is designed as a multi-sector macroeconomic representation of the national economy, it is a medium scaled empirical model, entirely written in a structural form, it is a dynamic model, based on Keynesian principles.

The economy is influenced by the cohesion policy thorough a combination of offer and demand channels. The effects of short term demand occur as a consequence of political decisions to increase the income and expenses related to the initiatives of the cohesion policy. These effects will propagate in all the internal consumption components (e.g. total investments, private consumption, imports etc.) and in the internal output and national income components. Still, we must limit ourselves to the analysis of short term effects, but rather turn our attention to the long term influences of the cohesion policy, of stimulating the potential offer. Thus, on long term, it is important to consider a quantitative estimation of Community Aid Framework's (CSC) macro economical impact in 2007 – 2013.

The advantage of using this type of model resides in the possibility to quantify the CSC effects on the economy, not only by simply adding the effects. This model is a structural one, constructed on micro economical bases: the side related to the offer includes incorporating the main mechanisms through which the Structural and Cohesion funds influence the productive potential (direct externalities on the output). Some indirect externalities of the production factors (capital and workforce) are also included.

As the labor market plays an important role in transmitting the policy's mechanisms, a special attention was paid to modeling this sector, by considering the wage policies and labor market regulations (financial aspects etc.) which influence the result of wage negotiations and indicators such as employment rate and workforce participation rate. Special attention is paid to the impact of the cohesion policy on the level of qualification in different sectors and on the human capital's level of education and development. The results of the Hermin model for the year 2010 reveal that the effect on the rate of employment, compared to a no cohesion policy scenario is of +750 000 people (Regional Policy Evaluation, 2010).

The injection of structural funds will lead, at the end of the time frame for the current budgetary exercise in 2013, to a 15% higher GDP, which is the equivalent of a superior annual growth rate of 2%, in case of a total structural funds absorption. As a result, in 2020, the investments will be approximately 20% larger due to the impact of the structural funds, corresponding to an annual growth differential of 0.95%.

As a consequence, a re-estimation of the model so that it considers an absorption rate close to the one in Romania is a necessity, and the results thus obtained must represent a starting point in creating a coherent strategy to attract structural funds.

5. Conclusions

Within this article, we have tried to highlight, starting from the regional disparities situation and the European funds absorption rate, the main model through which the impact of the structural funds on the Gross Domestic Product could be quantified.

The HERMIN model has been designed considering the evolution of macro-variables throughout transition and pre-accession process, as well as out of the need to analyze the gradual alignment of Romania's economic policies to those of EU. The fact that, initially, the HERMIN model was designed for the European Union's less developed economies represented the cornerstone in choosing it, as it was the case for Romania, too. However, the quantitative evaluation must always be accompanied by a qualitative evaluation, in order to comprise factors which cannot be measured by the econometrical modeling. For this purpose, when the results of econometrical model based evaluation are used, it is important to be aware of the fact that models simplify reality, no matter the impressive mathematical calculations they employ.

Also, we must not omit the fact that Romania's major development needs and the current economic context imperatively demand a high as possible level of structural funds absorption, as well as their efficient use, meant to generate a significant impact at a national, regional and local level. Nevertheless, when absorption capacity of a member state is evaluated, the used percentage from the allocated funds is not the only monitored indicator, but also the effects they have generated in that state's economy.

STRUCTURAL FUNDS ABSORPTION GROWTH BY IMPROVING THEIR MANAGEMENT

PĂUȚU Sorina Crina
West University of Timisoara,
Faculty of Economics and Business Administration

Grant project management is now a trend in the institutions of various types in Romania due to the opportunities offered by the EU through structural Instruments. Absorbing European funds is a challenge for Romania. The Managing Authority for Structural Instruments, together with the subordinated institutions present deficiencies in their coordination and implementation, the effect being a slow process of absorption of structural and cohesion funds. Taking action to enhance absorption of Structural and Cohesion Funds was done later; some measures are neither effective nor efficient. One of the major problems in implementing the Structural Funds is the continuous change of their national legislation. Therefore it is necessary to take measures to increase the absorption of structural funds and also the national adoption of a stable legal framework applicable to Structural Funds, guides of the applicant and clearly established project calls, without any latest changes, creating a transparent system of project proposals assessment and results communication of assessments to their beneficiaries, the payments required by the reimbursement requests within 45 days specified in the contract and not just their validation, terms compliance in approval notifications and addenda to the contract funding, proper training of the personnel from the intermediate organizations and linking information provided by their staff.

Romania's EU accession involved changes in different areas. One significant change in the area of management is the promotion of Management of funding projects through grants allocated to Romania in both the pre-accession and post accession period. The deficiencies that Romania has in the use of project management were demonstrated in the pre-and post-accession funding. The issue Romania is now facing is the absorption of Structural Funds and Cohesion Funds. This is highlighted mainly by the rate of absorption. To increase the absorption of structural funds is necessary to implement solutions and measures suggested by the European Commission, as well as adopting other innovative measures. This paper suggests the necessary measures to be taken to increase the absorption of structural funds but also the dilemma faced by project beneficiaries financed through these structural and cohesion funds.

Projects management in Romania started to be important and to have a more enhanced use with the advent of the European Union allocate grant funding in both the pre and post period of accession.

If up to the accession to the European Union, Project management was a method used mainly in the institutions focused on production, nowadays this method of management is used in all types of institutions due to funding grants. Grant project management differs from project management practiced in the classic way; this difference is due to the method of projects financing and legislation that need to be respected by each beneficiary of such projects.

Project management, regardless of funding source assumes the completion of stages in project development and implementation. Thus in the *Wideman Comparative Glossary of Project Management terms* one may find stages of a project called: 1.Concept; 2.Definition; 3.Implementation; 4.Finishing (or closing).

A project life cycle is presented as follows: The question identification phase - The identification solutions phase – The planning stage – The Stage of implementation / monitoring – The evaluation / reporting stage after which this cycle is repeated to identify the emergence of new

needs or problems.Problems currently facing Romania in the development and implementation of Project management are visible in the coordination and implementation of grant issues

Romania currently allocates grants funded by the European Union through the Structural Instruments, namely Structural and Cohesion Funds. Although Romania's currently economic situation is poor, being in constant crisis and the Structural Funds represent an opportunity for development and survival regardless of the form and type of institutions, attracting such funding Is precarious.

To facilitate the absorption by the new Member States, the maximum rate of co-financing structural funds increased from 80% to 85%, being also relieved, and certain eligibility criteria. Absorption capacity is given by the responsibility of a Member State to spend financial resources from structural funds, in an effective way, targeting three areas:

- Macroeconomic absorptive capacity, defined and measured in terms of GDP (limited to 4%);
- Financial absorption capacity, defined as the ability to co-finance EU supported programs and projects, plan and guarantee these national contributions in multi-annual budgets and to collect input from the partners involved in various programs and projects;
- Administrative capacity, which is the ability and competence of central and local authorities to prepare projects and programs appropriate and timely, as well as coordination with the partners involved, compliance with administrative and reporting requirements, funding and monitoring of programs and projects and also avoiding irregularities.

Given the definition of absorption capacity specified above, we assume that it is influenced mainly by the managerial and administrative capacities of co-financing. The relationship between absorption capacity of structural funds and regional economic situation is at least a paradox, practice showing that the most disadvantaged regions are facing the greatest difficulties in absorbing these funds, although the need for financial support is essential to economic restructuring in these regions. The main explanation for this phenomenon is given by two factors: on the one hand, the difficulties faced by regional authorities for lack of experience and qualifications, followed by red tape and slow nature of EU decision-making in circumstances where sequential procedures for appointment, especially central and regional authorities, are not quite clear. Thus, questions related to absorption capacity largely depend on institutional factors, both the EU structures, as well as national ones.

To identify and understand the Structural and Cohesion' deficiencies is needed an overview of their planning, based on needs identified in their strategies concordonata European Union, the implementation and to reporting and evaluation. Because these funds do not allow complete implementation, an overview and reporting results are needed to the European Union. So it will consider how their planning and implementation by both Authorities Coordination of Structural Instruments and beneficiaries of projects financed through Structural intemrediul these instruments.

Planning of structural and cohesion funds is the National Development Plan 2007-2013 in which we identify an analysis of Romania's development needs in line with EU policies and strategies, measures proposed to eliminate the weaknesses identified in the SWOT analysis carried out and results to be obtained through implementation of proposed measures. Based on the National Development Plan 2007-2013, it was developed the National Strategic Reference Framework 2007-2013 which presents the main operational programs and interventions with results to be obtained in each operational program. Each operational program is based on an Implementation Framework Document which is the starting point in developing Guidelines for Applicants for each priority axis and key area of intervention. These documents are complemented by EU legislation applicable to such financial instruments as well as national legislation.

Implementation of these Structural Funds and Cohesion Funds on macro level is carried out through the 7 operational programs managed by the Structural Instruments for Coordination

Authority through management authorities for each operational program and the intermediate bodies. These operational programs and the financial allocations for each program are the following ones:
- Sectoral Operational Transport Programme - 4.5 billion Euro
- Human Resources Development Sectoral Operational Programme - 3.4 billion Euro
- Increase of Economic Competitiveness Sectoral Operational Programme - 2.5 billion Euro
- Operational Programme for Administrative Capacity Development - 208 million Euro
- Environment Sectoral Operational Programme - 4.5 billion Euro
- Operational Programme - 3.7 billion Euro
- Technical Assistance Operational Programme - 170 million Euro

Accessing these structural and cohesion funds by final beneficiaries is a logical process but most of the times a heavy one. The accession of a non-refundable financing form consists of an application based on a specific applicant guid,e project applications for each call, this request goes into a process of evaluative criteria established initially selected projects will be contracted and carried out by the beneficiaries based on laws established by the Structural Instruments for CoordinationAuthority and Management of each program. Monitoring and implementing powers beneficiaries enter the intermediate bodies which in turn are reviewed by superior bodies of control.

The statement that the submission stage of a project is difficult is that the call requests in a project regardless of the operational program many changes Applicant's Guide - general or specific conditions based on new changes - Changes in the request for proposals on various issues, including shift deadline for grant applications and even the applicant's eligibility. The most striking example is the request for proposals within the Sectoral Operational Programme in 2009 when submitting projects was brought forward by the extending from June of 2010, when through a press release dated 25/09/2010 (Friday) given at 16.00 hours, is announced the closure proposals date on 27.09.2010. These changes lead to demotivation potential beneficiaries and the low absorption of these funding denoting poor management of coordinating institutions.

Another negative aspect related to access and coordination process is the assessment of applications, namely the lack of transparency in the management authorities of operational programs, such as Human Resources Development Operational Programme for which payment was stopped by the European Union following an audit control to regulate irregular situation captured in the audit report in February 2012. One of these situations is the lack of communication results transparency in assessing applications for funding recipients that led to the lack of links recommended by project evaluators in the evaluation of the project files by their contraction in the Annex 1 - Application for funding. Lack of long transperency and project evaluation process, sometimes even a year after admission to the contract (request for proposals 109 of Human Resources Development Program - Industrial Transition from school to work) leads to demotivation and giving the contracting project for which funding request was submitted by the beneficiaries.

If accessing and contracting these projects with grant funding through the Structural instrument making is a cumbersome process that denotes lack of experience of staff involved in their planning and evaluation of project applications, representing a rate of about 20% of Managemtnul projects. Impleemntare stage and reporting / evaluation of these projects can not be better. Project planning is one of the main steps for successful project, but this stage is poor, Implemntare stages, evaluation and reporting their shortcomings leading to demotivation confort possible beneficiaries and a low rate of absorption.

Implementation of projects financed through Structural Instruments requires a rigorous and thorough compliance with legislation. Thus these types of projects are subject to national laws especially laws imposed by the European Union in this field. One of the obstacles in impleemntarea this type of project is necorelatiile legal and legislative changes, especially in

finance and public procurement. An example of these changes is the modification of Eligible Expenses Order afferent Human Resources Development Operational Programme which was modified in the very process of impleemntare the project, its latest version was published in August 2010. According to modify this order each beneficiary of projects funded through this program was required to review and replan the project budget. The emergence of new instructions during the implementation of projects with different specifications and new regulations are not only hindering the implementation of projects. These constant changes, especially in the instruction denote a poor initial planning and also a national legislative instability.

Legislative changes occurring during the implementation of projects and grant programs have negative effects because they involve changes and adjustments being repeatedly designed and programs. These changes lead to demotivation potential and current beneficiaries of grant projects that slow the absorption of structural funds.

Another impediment to increasing the absorption of structural funds is the pre-financing payments and reimbursement requests in the project. So if projects beneficiaries had to wait up to six months to start pre-financing payment of project activities and in some cases a period of one year to transfer the amount corresponding to a request for reimbursement, although in the financing contract stipulated a period of 45 days. These delays in payment of pre-financing and reimbursement requests result in termination of funding due to the inability of beneficiaries to submit amounts for the activities covered in the grant applications. Termination of the grant has effect on the absorption of structural funds.

Absorption of funds currently reimbursable according to the Report of the Structural Funds Managemnt Authority in March 2012 highlights of afferent absorption once effectuate the payments by beneficiaries Managemtn Authority, which is in proportion to allocate 17.77% of the total Romaine and European Union on the other hand highlights the real absorption efectuater payments by the European Commission that Romania is at a rate of 6.56% of the total European Union allocate Romania.

Given the balance of Structural Funds published by the Ministry of Finance - Authority for Structural Instruments Coordoanrea, one comparison between 2009 and 2010 but absorption afferent report of March 2012 we said that programs that have a larger share of structural funds absorption are ROP, the very first and sector Operational Programme Human Resources Development Operational Programme is ranked last transport. To increase the absorption of other software is required and corrective measures taken now to examples of good practice from other operational programs. One of the reasons that cause a low rate of absorption in the Sectoral Operational Programme Transport is the eligibility of the solicitor; specifically in this program are eligible applicants Transport Ministry and its subordinate institutions. So we can say that in this ministry is not prepared and experienced person needed to implement these types of projects or the general eligibility conditions are too demanding.

Also we see a trend of increasing rate due to absorption of Structural measures adopted by the Authority for Structural Instruments Coordoanre. These measures taken during the Applicant consisted of simplifying guidelines and conditions of eligibility measures.

In all operational programs are identified problems arising from both their impleemntarea implementation reports and the Action Plan but Prioritarare. Thus the major problems identified and measures taken are:

Llaunch requests for proposals due to lack of monitoring by the Authority for Coordination of Structural Operational Programmes Managing Authorities - monitoring of project applications and launch applications for Acle priority or d einterventie areas which have not yet been released

- Lack transaprentei applicant in formulating guidelines - the guidelines for consultation giving the applicant the potential beneficiaries

- Too short deadlines for submitting grant applications - deadline for requests for proposals at least 10 days from start to closing the call for proposals.
- Guides the applicant with unclear conditions, this effect was adopted as the simplification of the applicant but also documentetiei guide the projects.
- Long evaluation and contracting projects - monitor and identify issues that lead to these plocaje and adopting corrective measures
- Process check payment requests long - speed verification of payment claims for payments under the conditions stipulated in the grant agreement.
- Deficiencies in implementation of legislation regarding public procurement - standardization of public procurement documentation for all operational programs.
- Deficiencies in control and control check lists and documentation of public procurement - European Commission recommendation on the correlation of the national legislation with European public procurement
- Deficiencies in control and audit - audit scheduling and execution control and then control institutions to track the implementation of measures recommended by the control group through the Audit Report.
- Deficiencies in terms of number of personnel and its training in the IB and the Managing Authority - vacancies in these institutions and supplemented according to the needs identified tinanadu into account the number of projects under evaluation, contracting, during its implementation and evaluation, contracting and payments but also the volume information. Another recomanadare would be appropriate training of personnel working in these structures.
Other problems identified in the implementation of Structural think is next
- Undue delays in preparing operational programs by managing authorities
- Adoption of measures imposed by the European Union a long period of time
- Lack of experience in planning tools specific grants, because c [palnificarea pre strategic grant funding was made by the European Commission;
- Formation of intermediate bodies and regional units of delay without clear identification of roles being changed contaant structured;
- Low culture in project management for both public bodies and the private;
One of the most effective measures adopted within an Operational Programme was to reduce the percentage of co-beneficiaries. Thus in the Operational Programme Human Resources Development for institutions of higher and university invatamant percentage was decreased to 2% cofinanatare. The adoption of this measure was to increase the absorption of structural funds for universities and especially university education institutions.

Conclusions
Clearly indicate advantages, limitations, and possible applications. Given the descriptions we conclude that the Structural Instruments is an advantage for Romania in support of and remedy the problems identified and to align the country's development requirements of the European Union.
Capacity of project beneficiaries with grant allocated by the Structural Instruments intemrediul to adapt to the many legislative changes is also strength and their success.
Lack of experience in Projects Management in the institutions Romain is a weakness with negative effects. This lack of experience and knowledge of the principles of project Managemtnului sees the staff involved in coordinating and monitoring implememtarea financial instruments.
Poor planning of Structural Instruments negative effects, re-planning continues and further changes lead to inefficient control them.
Most of the problems identified in accessing, implementing, monitoring and reporting related project planning.

Legislative and political changes in the country have negative effects, modification and replacement policy leaders Managing Authorities, Intermediate Bodies leads to the appearance of changes in projects which benefit the beneficiaries of these projects are creating the confusion among them.

Stabilization of Structural applicable law is the basic condition for ensuring a degree of absorption of Structural Instruments as high by the end of 2013.

Increasing the absorption of Structural Instruments lately is largely due to measures adopted validation and payment of reimbursement claims and not related specifically contracting projects.

Necessary measures to be adopted in future consist mainly in stabilizing the legal system applicable to such proiectre, compliance temrenelor provided under contracts to finance projects to remove the bottlenecks financaire the beneficiary institutions, evaluation of projects in a relatively short and creating a evaluation transparent, uniform enforcement of regulations in all intermediate bodies, specialized personnel of the institutions managing these tools to help beneficiaries and potential benefit in the process of accessing, implementation and reporting.

The need for proper project management is clear from all the descriptions in the economic and social development of the opportunities offered by the European Union.

Identify examples of good practice in accessing and implemntarea Structural Instruments from other EU member countries is an opportunity to increase the absorption of Structural Instruments.

THE FAILURE OF INDUSTRIALISM IN COMMUNIST ROMANIA

Părean Miai–Olimpiu *
West University of Timisoara, Romania Faculty of Economics and Business Administration

This work aims to present the exact thinking and action of the Romanian Communist leaders that had as declared purpose the Romanian society's propseprity company. This falls into the line drawn by the Communists, but in the case of Romania the ambitions were far above the country's potential.

In order to understand the situation of the national economy in the past two decades we must take into account the manner in which they have carried out economic policies in the Communist leadership. This marched on exacerbated development of manufacturing industry by capital goods to the detriment of the goods consumer industry, which generated a series of social tensions.

The economic objectives of Communist Romania were limited for the exacerbated development of the industrial sector. Its presence of economic policy measures implemented in our country shows that the authorities had in mind a self-sufficient industrialization by providing greater care than conventional industries, with high energy consumption. This unprecedented enhancement for national economy was made possible by the contracting of foreign credits And this began to give increasing and more frequent misfires when the world was hit by the resouces of the crisis. The falling of the national economy has been Romania unable to repay loans on time. The obsessive decision of the authorities was to fully pay off foreign debt in oder to allow new investment in construction of some megalomaniac industrial sights, that could hardly be effective. Thus, there was no link between the overall targets of national economic policies and the needs of the company. In this work are chronologically and factually shown all the decisions adopted in the industrial policy in Romania.Certainly that at the beginning of massive industrialization results seemed to be at least some optimistic, but after the population had passed through various serious situations (floods, earthquake) to what degree very hard decisions devoid of rationality regarding the impulse energofag industry. Inevitably the complaints gathered, the economic system implemented by the Romanian communist authorities collapsed. Eventually, the economic system imposed by Ceauşescu colapsed because of his desire to increase in the country's industrialization. Basically he showen the limits.

This paper seeks to show how faithfully the faulty module was designed during the development of the country's Communist leadership.

Introduction

The industrialism can be defined as an orientation in the economic thinking which envisages the development of industry and its raising to the level of the economy main branch or an economic theory which grants the preponderance of industry in economic activity. Therefore, it is a system that considers economy as main objective of industry's development.

The socialist system was established on the basis of the historical experiences gained in the first half of the 20th century and had as its main objective to establish an industrialized society in countries that were usually in a precarious level of development. During the establishment of the Communist political regimes, the classic system of socialism outlined during Stalin and implemented as a model in most countries of the European Socialist was repressive and ineffective, i.e. it obtained results in economic development with the price of a high consumption

of resources (Murgescu 2010: 403). This happened because the Socialist property determined a net split between ownership and management. The high consumption of resources was possible because the system pursued only macroeconomic efficiency that could hide the inefficiency at firms level to which it was added the falsification of reported datas that became a phenomenon.

The national economy analysis and of the unbalanced relations between the different economic branches shows that are the result of a relationships mix between the production factors that were simultaneously Socialist (by removing the private property over the means of production), capitalist (by keeping economic coercion of labour selling andthe impossibility of controlling the use of the added value by the producers) and pre-capitalist one (by non-negotiability of working conditions and coercive organisation of labour) (Murgescu 2010: 404)

Forced Industrialisation
In 1955, at a Conference in Geneva, has raised the question of withdrawal of the Soviet army from Romania,but was completed in 1958.It is interesting that afterward plan of finalization of collectivization was resumed.

It was switched to an independent attitude towards the Soviet Union, so it was swithched from a internationalist onset to a national one. In the beginning the nationalism risen from economic sources (During the Council for Mutual Economic Assistance– CMEA, Romania was assigned a minor role in the vision of past Romanian leaders by the fact that it was wanted to become an agro alimentary main source , as opposed to the German Democratic Republic or the Czech Republic that were to follow the path of a strong industrialization). The position of economic independence towards the USSR decisions within CMEA is the decision to build in Galați the largest the steel works in the South-Eastern Europe.

During the quinquennial of 1965-1970 the medium pace of economic growth was 7.7%, and the one of the industrial production was 11.8%, although there are opinions (1) that this data was inflated. In the early ' 70 of last century, Romania recorded the second rate of economic growth in the world, after Japan (Jivan, Pațac 2004: 112). Thus, Romania had a growth of national gross product of 9.4% and 8.4% of the gross domestic product per inhabitant (Iancu 2003: 48). However, the year of 1970 represented the last year of the quinquennial, and planned growth was 12% (2). In May 1970 were very large flooding, and the agricultural output decreased by 5% towards 1969 (the overall plan of agricultural production has been achieved to 80%, the biggest problems were for the potatoes 47%, vegetables 56% and cereals, 70%).

The problems in agriculture have tried to be dimmed by the rise in the industry, but it has not reached the quinquennial plan. In the 1970s the social problems were sharpened. The investment plan has been exceeded, but the salary was increased only with 8% and it was spoken that they ought to have decrease (Burakowski 2011: 147). This is a sample for the inefficiency of investments made. a lot about increase labour productivity eas taken into discussion, but now it is proven to be an unattainable wish. Moreover, after the spring floods, Romania called for international help, but all that she got was channeled towards the development of the industrial sector, the disaster victims receiving few benefits being obliged to register on the waiting lists and lose many hours on queue in order to receive construction materials to rebuild the affected endowment.

In 1971 the problems have continued to widen, thus it has established control over the economy and high labour productivity and attempted to gain credits. It appears that instead to deal with the causes elimination of the Romanian authorities crisis it had considered stepping up industrialization. It was planned to increase industrial production annually by 11%-12.2, and accumulation of national income to be annually at around 16 %, in previous quinquennial, to 34%.

In 1973 the Romanian situation worsened, amid the onset of the crisis. Before the outbreak of the crisis was adopted a plan to tackle energy shortages (finding new deposits of hydrocarbons and

even Atomic Central construction), but realised energy surplus and that was supposed to be exported has been used to avoid losses and further stated investments.

In 1974, the issues were far from being exceeded, the production (including agriculture) and investment has not been fulfilled, which has led to a worsening of the food shortages of the population. However, in November 1974 at the 11th Congress of the Romanian communist party's the economic condition was considered a positive one. The officials arguments were that, towards 1971, the industrial production annualy grew on average by 13.2 %, agricultural output by 7.4%, national product with 11.6% and 10.6% per capita income growth, but the population was only 7.1%. Was insisted on the fact that all these results have been obtained in spite of the unfavorable global context, but also of the natural disasters effects (the floods).

In 1974 began a period of stagnation of the Communist system, resulting in a deterioration of the national economy state. Until 1977 the officials didn't give it too much importance. The economy resisted on account of a pemanent financial assistance that was assured until the late of the 1970s.

In 1975 remained below the rate of increase in the industrial production of about 12%, but food shortages were sharpened, particularly in small towns and villages, but soon they started and the cities most important because people tried to do provizi and for the Nations from the villages. In July 1975, the country had strayed very large floods. The consequences have been over estimated by the officials in order to justify internally the satisfactory shortage.

The process of industrialization continued in order to increase the accumulation rate from 30-32% to 33.5% in 1980. The Romanians were based on technologies and their technic thinking also on the imports reduction, simultaneous with exports stimulation. This led to a poor supply of the internal market and, consequently, the standard of living and the mood of the people was degraded.

The Communist authorities have said that also in 1976 the macroeconomic results were positive. Industrial production increased by 11% as a result of a substantial increase in labour productivity. Rise of agricultural production was 17.2%, on the basis of the record harvest of sugar beet, potatoes, grapes, as well as cereals and other agricultural products (Burakowski 2011: 202).

If the trends of the 1960s-' 70s would be maintained, Romania improved the position against the US, from 11.7% - 14% in 1970 to about 50% in 2000 (Iancu 2003: 51). Therefrom reveals the enormous gap that the Romanian economy had to recover.

The economic decline

The earthquake from the 4th of March 1977 is considered by many the symbolic start of the communism end in Romania. The earthquake has had very serious consequences: 1570 people lost their lives (nearly 1400 only in Bucharest), over 11,000 people were injured of whom approximately 7500 in the capital. Around 35,000 of people were left without housing and over 750 of the economy was affected, the matyerial damages were estimated to 10 billion lei. Under these circumstances, Ceauşescu (in those days was away with his wife on a visit to Africa and returned immediately) was forcedto institute the state of necessity in the country until March 10, while in Bucharest until March 15.

In 1977 the investment rates were risen associated with the quinquennial 1976-1980, the social problems have been accordingly stuffed into account. Ceauşescu appreciated that the essence of the crisis boils down to lack of balance between allocations for investment and living standards of the people.

Ceauşescu considered that the exaggerated social expectations represented the root cause of the complaints. The inability of the economy became apparent to the public, but also for leaders (tacking into account the miners strike in the Jiu Valley, to which was attended by more than 30.000 miners).

All these events, as well as the economic collapse that followed have splintered a lot the Romanian's prestige. However, it was more appreciated at international level until 1981 when it

became evident that the Romanian economy was totally exceeded. This position was reached because the policy of massive ineffective investment, badly designed and applied with some intermittently failed to produce the expected effects of the Romanian Communists. Romanian products were poorly competitive on export, the intensive paranoic decisions of the industrialization lead to increased imports of machinery, equipment and Western technologies, and thus trade balance was poor, with all Romanians' constant efforts. Moreover, Western analysts lacked confidence in the forecasts of the Ceauşescu regime (Burakowski 2011: 265).

The very heavy economic situation determined Romania that at the end of 1981 to ask its creditors to defer payment (this was recommended by the International Monetary Fund in early 1982) were at 11.4 billion dollars (Harrington 2000: Courtney, 454-455). As if this were not enough, a number of multinational companies have withdrawn from Romania, from 62 in March 1982 have left only 22 representation of some transnational companies (Burakowski 2011: 272)

Romania have pressing needs of resources, raw materials, but this claim (especially of energy resources) was raised throughout the Soviet bloc. For the national economy the disastrous decision has been unwavering in its determination of the payment in full of the foreign debt.

This decision shows the determinationbut also the desperation of the Romanian leader to escape from the foreign influences. The trend of total autarky continued, and in this context, the standard of living of drastically diminished.

On 11 March, 1985 in Kremlin the power was taken over by Mihail Gorbaciov. It may be considered the key moment or the start of the collapse of the Communist system in Romania. This is because between the frozen concepts of Ceauşescu's and those of Gorbaciov, more open and viewing hasbeen formed a growing gap as the time passed. Romania was increasingly isolated, which was reflected upon the country's economy. In 1985 the economic exchanges with other countries decreased by 5.5%.

In the last decade of leading authoritative, the Romanian economic system steped into a crisis, a systemic crisis, with many facets. The Romanian economy's crisis falls within the coordinates of the socialist system, State monopolist with peculiarities determined by the its dogmatic (Dobrescu, Postolache 1990: 32).

The forcing rate of investment in the 8th decade was the expression of the foolish wishes of Nicolae Ceauşescu that this is the only viable alternative for economic success and the Romanian society. In absolute terms, the annual volume of investments increased from 6.3 billion lei in current prices in 1950 to 27.6 billion lei in 1960, nearly 80 billion lei in 1970, 210 billion lei in 1980 and a maximum of 249 billion lei in 1986, and then until 1989, when it was of 236 billion lei (*** - Anuarul 1990: 526-527).

Source: Madisson Angus – *the World Economy: Historical Statistics,* Paris, Development Centre of OECD, 2003, p. 101 (Murgescu B. – *România şi Europa. Acumularea decalajelor economice (1500 – 2010),* Editura Polirom, Iaşi, 2010, p.396)

The energy policy of the authorities took a leading role in the failure of haynie in the 1980s. The dynamics of the national economy in the context of the European Communist bloc is presented in table no. 1. It is characterized by poor economic growth in the Communist bloc. The whole block is observed that only Poland and Romania have had a declining economy. Starting from this situation Silviu Brucan appreciated that the industrialization policy of Romania (of those years) was an "underdevelopment" policy (Brucan 1990: 47) sending country to the third world. (Brucan 1990:38).

The failure of industrialization policies of outliers is given by the over consumption of production goods obviously accompanied by a substantial increase in spending on maintenance and repair (from 21.7 billion lei in 1975 to 80 billion lei in 1985), which inevitably leads to a very reduced productivity (Hitchins, 1996: 420). The volume of unused industrial production capacity increased from 358,4 billion lei in 1985 to over 400 billion lei in 1989 (Ionete 1993: 76).

Meaningful is the comparison of normate service term of production equipments in Romania and in other countries. In developed countries this term was under ten years (in the United States of America was 6 years in Japan was 5-6 years), while socialist countries was less than ten years (in the Soviet Union was 12,5 years, in the German Democratic Republic for 16 years, while in Romania it was 20-30 years) (1993; 90 Ionete).

The industrialization conceit, the megalomania and the anomaly thinking of the Romanian leaders stands out by the organization of the educational system. The first step leaded to this situation was taken in 1974 by the provision that the unambiguous party "in schools of all grades, in the process of education will organize the effective participation of teachers and students in productive activity", so it has been used as a cheaper work labor (students who were entitled to 20% of the value of work done) (Murgescu 2010: 388).

In 1977 the network of highschools has been restructured, being dismantled high real-humanities and replaced with narrower profiles (mathematics-physics, philology-history, science of nature, etc.), but redistribution of seats in favour of industrial profiles (table no 2).

Table no. 2- The weighting of the various types of highschools by the number of students enrolled(%)

Period / Type of high school	1968/1969	1978/1979	1988/1989
Math-Physics	80,1	11.4	3,1
Science of nature		1,3	0,6
Philology-history		4,4	0,6
Pedagogy	3,5	1,0	0.4
Sanitary	0,1	1,2	1,0
Art	0,7	0,4	0,1
Economics	5,3	4,1	3,8
Industriale	4,4	67,7	71,1
Agricultural and silvan	4,7	8,5	19,1

Source: Constantinescu N.N. (coord.) – *Istoria economică a României, vol. 2, 1939 – 1989,* Editura Economică, Bucureşti, 2000, p. 336

Another unmatched anomaly in any country (Sadlak 1990: 60) happened in the last Communist decade when the students of the weight in the engineering field consistently exceeded 50%: 56,1% in the academic year 1978/1979 and 68.8% in 1988/1989 (Constantinescu et al. 2000: 336).

Conclusions

The insustrialism introduces an order which is removed from the knowhow and alienate us from where we were born. He applied the same methods and technologies in any country. Thus, the industrial economy is inherently aggressive. Causes a wreckage in order to enrich the above measure to another location.

Introspection development of national economy in the Socialist period indicates that this was a "forced", specifies all the Soviet bloc economies (Kornai, 1992: 197). In Romania the Communist leadership ambitions led to a linking of decisions which have not achieved the ultimate goal, the improvement of social life. The Romanian economy was a demand-driven economy, particularly the offer of prodfactori at the expense of consumer goods production, and much less a demand-driven economy, which would have its connection to national consumption requirements.

The Communist regime relies on a long book as evidenced by losing: chaotic accumulation intensively (common plan of dictatorial regime) and also autarhic of the capital. It was pursued classical industrialization rejecting   purposely the development of the capitalist countries. And when this fact was obvious, Romania has not actually changed the siding. This shows that the authorities were frozen and lacking in vision. Normally would have had to act on the directions in which the gap was not so high and the chance of recovering the gap was larger.

The foreign debt payment ought to mean economy and social life ungridle, but it was not like that. Despite its ambitious programmes, of the efforts made by the Romanian society as a whole and of religious sacrifice imposed on the population, the Communist regime has failed to solve the problem of relative undevelopment of Romania in the European context.

Notes:
 (1) It is about the analysts of Polish Embassy in Bucharest
(2) According to Burakowski Adam, who had access to notes and of the Polish Embassy in Bucharest of that time, in 1970 only 7.7% was obtained.

ENERGY CRISIS IN COMMUNIST ROMANIA

Părean Mihai–Olimpiu *
West University of Timisoara, Romania Faculty of Economics and Business Administration

If during the interwar period Romania has managed to move from an agrarian economy to an industrial-agrarian one, after the 2nd world war in Romania, as in other communist countries, has monitored the further development of the industry. It wanted to be a true industrial revolution.Over time one can identify several types of industrial revolutions, each giving impetus to a given development cycle, which had its beneficiaries and the losers. At first it was steam power, and then use the internal combustion engine, which used oil instead of steam. While other countries developed would increase of production capacity of nuclear power, a higher stage of economic development, in Romania continued the industrial development on the same grounds as in the inter-war period. This has had very serious tracks for the Romanian economy and society, since before and during World War II, the German war machine operated within the national resources of energy. The time and manner in which each country is part of this race are defining the social welfare. Unfortunately, Romania has failed to take advantage, each time losing the start. Creation of some production capacity and the development of industries (metallurgy, chemical industry, iron and steel industry), which consumed significant energy amounts was the wrong decision for the future well-being of the country. Oil impacts which have affected the world economy, hit also Romania. The first oil shock (impact) was more easily broken because of the continued use of internal resources (oil, coal, natural gas), but the second shock was catastrophic. It was too much for Romania after being forced to use those resources in the last decades (including the interwar period). Romanian leaders probably had in mind that Western countries were developed by enhancing industry of this type, but they did it in a different historical period when also the prices of such resources were much smaller and the lack of them was not a possibility. The outphasing of economic policies have resulted in a major negative impact on the population. In order to cope with the shortage of energy has been passed to the rationalization of energy products for the population consumption (from public lighting and restaurants program to heat and hot water rationalisation).
Perhaps the crisisof energy resources necessary to support an antiquated economic system was one of the major causes that resulted in social complaint from the Communist Romania.

Keywords: energy resources, communism, Romania, oil shocks (impacts), rationalization of domestic energy consumption

JEL Code: N 54, P 26, Q 32, Q 34

Introduction

Along with the first division of labour and human awareness of the importance of their needs and obtain a larger welfare as far as possible, resources have been converted to factors of production. The largest global energy problems and, by default, in the last century have been caused by the oil crises.

1973 is considered on worldwide the end of accelerated growth and the beginning of a economic hardship period for most countries of the world. Usually, entry into recession in the world economy is linked to the oil shock from 1973, when the producers group within the organisation of Petroleum Exporting Countries (OPEC) have increased the price of oil a few years apart followed the second oil shock (1981-1983). The oil price increases have marked on the worldwide the transition from an era of cheap oil to one of the expensive oil and volatile in price

terms and conditions of purchase. The world prices from 1980-1981being in real terms by about five times higher than in the first half of the year 1973. (1)

Still after the first oil shock the world economy has suffered, being very involved developed countries which were important industries based on consumption of petroleum. In many countries the European capitalist annual average rate of inflation over the decade between 1973 and 1983 surpassed the 10% (champion being Portugal with an annual inflation rate of 22.6%, while at the opposite pole were Switzerland with 4.3% and the Federal Republic of Germany with 4,9% annually). (Maddison 1995: 84) Many States were faced with budget deficits and considerable rises of public debt. Obviously that U.S. economy was strongly affected, cracking significantly also the dollar.

But the impact of the two successive recession of the years 1974-1975 and 1981-1983 on the gross domestic product was rather moderate (Murgescu 2010: 321).

The Situation of Romania

Oil shocks for Romania have had a significant negative impact to the economy because since the late 1950s was enhanced industrial development (lacking a rationality and maintaining a relatively acceptable proportions between sectors) based on a high energy consumption (2).

Domestic production of oil was overstates (extraction of oil in the country has not exceeded 15 million tonnes), giving evidence of an exaggerated and unfounded optimism. During the first oil crisis Romania has tried to compensate the international crisis by national oil extraction. Domestic production has reached a historic maximum between 1975-1977, with levels of around 15 million tons of crude extracted oil, after which the stocks accessable began to show signs of exhaustion relative, what did that in subsequent years the production to fall (Ivănuş 2004: 469-471).

It followed the second oil shock. In the 1930s, Romania was based on economic and political relations with Iran as the main supplier of crude oil to the national economy. In early 1979 he triggered the revolution in Iran, and over a year was irakiano-iranian conflict began. Thus, Iran crude oil production has been reduced from levels of around six million barrels daily before the revolution at levels below four million barrels in 1980 and less than two million in 1981-1982 (Murgescu 2010: 393). In this case the main international oil supplier since 1980 but was Iraq, and Iraqi production after the start of the war has subsided considerably, Romania was obliged to purchase crude oil prices in the worldwide.

The situation of the consumption and production of crude oil in Romania is observed in tabel no.1.

Tabel no.1 Energy consumption, production and imports of crude oil in Romania 1960-1989

Year / Indicator	1960	1970	1975	1980	1985	1989
Electricity consumption, including losses in networks (billion KWh)	7,6	32,7	?	67,9	75,0	83,7
Crude oil extract (million tonnes)	11,5	13,4	15,0	11,5	11,3	9,2
Crude oil imported (million tonnes)	-	2,3	5,1	16,0	14,6	21,8

Source: *** - Anuarul Statistic al României 1990, p. 472-473, 500-501, 626-627, Ivănuş Gh. – Istoria petrolului în România, Editura AGIR, Bucureşti, 2004, p. 470

A significant proportion of imports was produced according to special agreements. In consideration of the benefits of services and/or exports of goods, petroleum and the cost of the invoice is very hard to determine. However in the 1980s it was higher than the average of the years 1985-1989, representing a heavy burden for the balance of payments of the Romanian Socialist (Murgescu 2010: 393). But, these imports were made only for the putting into service of

immense refining capacities and other industrial compound built by weather authorities. The regime's bid on the grounds that the production of fuels and refined chemicals in order to allow recovery of the amount of imports and of course to reduce the trade deficit, but Romania was losing about 25 bucks for every tonne of refined products sold in the West, compared with the price paid on importation of crude oil (Turnock 1986: 272).

For Romania the biggest problem was in the period of the second "oil shock" whereas on the first pass using the domestic resources that it has supraexploatat from beneath Kings. The avings program established in 1982 on measures culminated in the production of energy and the development of the energy base until 1985. Energy production has been covered in coal power plants. Because of the defavorable evolution of crude oil, a solution would have been the substitution of crude oil with other energy sources. The most appropriate remedy would have been natural gas, but domestic production of methane gas was much in demand in the past (Ionete 1993: 81). According to the official national gas production increased from less than 20 billion cubic metres in 1970 to nearly 28 2 billion cubic metres in 1980, it reached a maximum of 29,26 billion cubic metres in 1981 and then it was gradually reduced to 27,2 billion cubic metres in 1985 and 22.2 billion cubic metres in 1989 (*** - Anuarul 1990: 472 - 473). This situation has led to increasing the share of consumption of coal, but which involved the extraction of coal with low energy value (the share of coal in the production of electricity increased by only 5.7% from 26,5% in 1980 to 32.2% in 1989, and the failures in relation with the plan were very high, contributing to the usage of installed capacity and to the Romanian's economy distortion) with harmful effects on the environment (Murgescu 2010: 395).

Industry consumption continued to grow both in absolute terms (from 43.7 billion kWh in 1980 to over 49,3 billion kWh in 1985 and almost 55.6 billion kWh in 1989), and in relative terms (from 64.3% from total expenditures in 1980 to 66,4% in 1989) (*** - Anuarul 1990: 500-501). Dynamics of energy resources exploitation in socialist period is shown in table no. 2.

Table no.2 Dynamics of energy resources exploitation in Romania during 1950-1989

Energy resource type	1950	1960	1970	1980	1989
Electricity (billion kWh)	2,11	7,65	35,09	67,49	75,85
Extracted coal (thousand tonnes)	3,89	8,16	22,83	37,81	66,46
Extracted crude oil (thousand tonnes)	5,05	11,50	13,38	11,51	9,17
Gasoline (thousand tonnes)	1,50	2,79	2,79	4,76	6,07
Extracted methane gas (billion cubic metres)	2,06	6,70	19,97	28,16	22,22

Source: Murgescu B. – *România şi Europa. Acumularea decalajelor economice (1500 – 2010),* Editura Polirom, Iași, 2010, p. 341

In the early years of communism the greatest efforts have been made in the energy industry and energy industry for the extraction of fuels (Cucu, Jordan 1984: 226-238) which have absorbed over 50% of industrial investments in the quinquennial 1951-1955 and, although their share has declined since then, stayed in first place until the mid-1970s, when they were overcome by investments in machinery construction industry (3). These investments have allowed the extraction of crude oil rise (5 million tonnes in 1950, 11,5 million tonnes in 1960, 13.4 million tons in 1970), coal (2,7 million tonnes in 1950, 4, or 5 million tonnes in 1960 and 8.1 million tons in 1970), lignite (0,8 million tonnes in 1950, 3.1 million tonnes in 1960 and 14 million tonnes in 1970) and methane gas (2.1 cubic metres billion in 1950, 6.7 cubic metres billion in 1960 and nearly 20 billion cubic metres in 1970). New hydro electric power stations were put into service, which led to growth of electricity production from 2.1 billion kWh in 1950 to 7.6 billion kWh in 1960, 35.1 billion kWh in 1970 and 67.5 billion kWh in 1980. On the other hand, the potential growth of the energy industry began to collapse in the 1970s-1980s.

Thus, the extraction of crude oil reached a peak in 1975 and subsequently decreased in spite of efforts to maintain; It also increases the production of coal and methane gas and they slowed, which forced Romania to use as growing fuel with lower calorific value (lignite, shale), so the less economically efficient and more environmentally destructive; the project of building a central power stations at Cernavoda was delayed too much, work began in 1982, and their slow pace in terms of restricting imports made as the first reactor to be put into service until 1996. Under these circumstances, production of electricity, although it has continued to grow, has not coped increase in consumption, especially of industrial consumption. Romania in 1970 export 2.4 billion kWh (6.9% of its energy production) and in 1989 reached to import 7.8 billion kWh (over 9% of consumption) (Murgescu 2010: 344).

Social implications
In 1978-1979 the problems have worsened. To the seriousness of the national economy and the adiministrativ chaos was added also the fuel problem is scumpeau more and more and thus serious problems have arisen in the supply of energy products (for example, in the case of electricity, public lighting has been drastically reduced, and in winter between the two years have made many calls to the public to limit heating of dwellings. The fuels were rationalized; It has reached a crisis, the most affected tourism and foreign tourists, especially from „neighboring and friend countries" who have not hesitated to trenchantly express the disagreement with such measures, which eventually turned out as expected, very unprofitable for Romania's tourism.

At the end of the 1970s in order to improve the condition of the population have taken some measures, but which failed to solve the problem altogether because energy rationing was far too drastic: ended some investment in this industry (refinery from Borzeşti, mining Rogojelu, a new probe in Ploieşti and determination to change to daylight saving time – on 19 May 1979). But they could not solve the problem which was very delicate. Later it was switched to a clear reduction in domestic energy consumption (it is well-known that Ceauşescu developed a bauble for the industrialization of the country). In July 1979, the State Council has decided a series of measures to reduce the consumption of fuel and the use of electricity, heat and gas (Păiuşan, Ion, Retegan 2002: 243 – 244).

Energy consumption of the population has been reduced, including the supply of domestic hot water and heating in homes under the slogan irritating and revolting „Take an extra coat"(Păiuşan, Ion, Retegan 2002: 275). In the winter of 1984 and 1985 was adopted a new plan of „rational use" of electricity (the restaurants were closing at 21.00, the artistic cultural activities – should be conducted so that the consumption of electrical and heat energy, to be as small as public lighting, the reduction of businesses and housing at 50% from the previous winter) (Giurescu 2003: 717 - 718). The winter of 1986-1987 was not gentle with Romanians, being the most glacial of last century (Stoenescu 2004 – 2005: 7). On 7 February 1987 was issued a decree by which it was reduced by 20% of energy consumption in the production units, which led to a brief outburst of social complaints (Giurescu 2003:726).

It was developed the industry of mechanical engineering intended for the general public, but for the production of cars with little consumption were produced Oltcit and Dacia 500. In 1989, the electricity consumption of the population had fallen to less than the losses in electric networks of transport and distribution (Ionete 1993: 79). In relation to the beginning of the period of Communist Romania in 1989 produced 25 times more electricity per capita (over 130 3.276 kWh kWh in 1950), 18 times more than steel (623 kg per capita compared to 34 kg in 1950), 2.5 times more grain (794 kg per capita compared with 316 kg per capita in 1950), have considerably greater number of dwellings with modern facilities, and infant mortality had decreased by over 4.3 times (the children of deceased 116,7 until a year to 1,000 live births in 1950 to 26.9% in 1989) (Postolache 1991: 469 - 471).

Conclusions

The progress measure consisted of global production and per capita and, especially, its speed of growth. Any other evaluation criterion was secondary. But once the product has increased and the degree of exhaustion of resources. On the horizon appeared the „rare economy”.

The Romanian economy was built on an energofag calapod; because of the beginnings country's industrialization due to the fact that it coincided with a relative abundance of resources, and when the world prices are modificau hard, were relatively stable. All this in combination with a centralized decision-making arrangements have resulted in a reduction of the ineluctable savings and a susceptibility to an inefficient use of resources.

In the early 1980s, due to the appreciation of the energy imported resources (prices of delivery requested by the Soviet Union were close to world levels) and tightening credit conditions on the world market, socialist countries have experienced serious problems in repayment of debts and ensuring the continuation of economic processes. In most countries have been reductions in the investment level, which has reduced and more possibilities of adaptation to the new economic conditions.

You can appreciate that the energy policy of the authorities took a leading role in the failure of haynie in the 1980s. Eventually, Romania was not only a victim of the big energy problems of mankind, but was the victim of its own improvidence (managers' improvidence) and the wish to strongly impress the international economic and political environment. The solving of these problems tried to be made almost exclusic, battening on the population.

Acknowledgement

Notes:

 (1) The world oil price has increased during 1973-1974 from approximate 3 dollars/barrel to over 12 dollars/barrel, has fluctuated in the next years to around 14 dollars/barrel, and during the second oil shock increased to levels above 30 dollars/barrel, reaching occasionally 38 dollars/barrel.

(2) It has been produced, in particular, after the Council for Mutual Economic Assistance (CMEA) , Romania was assigned a minor role in the vision of Romanian leaders since then by the fact that you wanted to become an agro-alimentary main source, as opposed to the German Democratic Republic or Czechoslovakia that were to follow the path of a strong industrialization.

(3) According toTurnock D. – *The Romanian economy in the twentieth century, Croom Helm,, Londra, 1986, p. 161,* the investments in the energy sector and fuels accounted 50.7% of industrial investments in 1951-1955, 40.5% in 1956-1960, 34.3% in 1961-1965, 30.9% in 1966-1970, 26.2% in 1971-1975 and only 24.3 % in 1976-1980.

This article aims to propose a case study analysis in order to confirm literature assumptions and to provide suggestions for future improvement of the company presented.
Often, management has to take decisions about business process reengineering or outsourcing in order to maintain firm's viability and growth. We focus on the relevance, difference and usefulness of outsourcing and business process reengineering to support organizational change in the managerial function of the firm analyzed. We show BPR success and the need to embrace BPO principles so as to have a relevant content that could and should be the basis for imprenditorial change and innovation. According to literature, our objective is to propose the outsourcing paradigm – in its form of cosourcing - as a future solution which would help the firm's management to concentrate resources on the core processes, redeploying key personnel to more strategic roles.

1. Introduction

We live in a world of inexorable change, where the network of economic, political and social processes that form the social Kosmos described by Ken Wilber (1995; 1996) and the economic one (Mella 2008) is continually being redesigned; traditional processes are abandoned while other processes are added, spurred on by the *new technologies*, which change the way organizations operate (Hayes and Jaikumar 1988).

Not only do the cultural bases of the individuals and the cultures of the organizations change, but the organizations also evolve through modification of their structures, processes and output, in the attempt to loosen the old restraints while setting new objectives and rewriting the programmes for their achievement.

A good *change management process* is conceived of as a *"systematic approach and application of knowledge, tools and resources to deal with change. Change management means defining and adopting corporate strategies, structures, procedures and* technologies to deal with changes in external conditions and the business environment"* (SHRM). This process becomes physiological, for individuals (Lewin 1951), social groups, or organizations (Senge 2006), and it represents the natural approach for dealing with change both at the individual and organizational levels for all types of organization. (Hiatt 2006).

> Hammer and Champy (1993) believe that having the correct product and service at the right time encompasses a form of obsolete thinking in a *change* environment, due to the limited life span of products. The decision managers have to take is whether to adopt a

radical reengineering approach or to outsource, in order to stimulate firm's performance (1).

The most successful corporations today are those that continually search for new and innovative processes and technologies that will allow them to adapt to the ever-changing business environment. Those that do not embrace change, nor have a strategic vision of opportunities for operational and product improvements, most likely will experience a loss of market share, revenue and profit margin.

In a period of change an organization needs to reinvent it's competitive advantage (Jaworski and Kohli 1993) and to do this the firm should:

- consider strategy not only linked to vision, but continuously questioning what is being done, why it is being done, and how can it be done differently,
- analyze top management commitment, vision, strategy and objectives both at the organisational and functional levels,
- individuate where change is necessary and set up clear goals, with projects broken down into manageable parts,
- promote cross-functional activities, shared objectives, and externally oriented thinking, and
- decentralize decision making to a point as close to the customer as possible.

While improvements can be made to pick up or maintain best practice, to get ahead requires radical breakthroughs in performance, i.e. the reengineering of business processes (Earl and Khan 1994) or outsourcing (Hammer and Champy 1993).

The pages that follow illustrate some empirical evidence related to an applied research project that has been done with the main objective of strengthening the role of guidance and support to the business of the Management and Finance of an Italian medium - large firm in the field of intermodal transports.

The article aims to illustrate the current and therefore the usefulness of Business Process Reengineering (BPR) to support the processes of change in the management function and to understand the necessity to outsource the activities too costly to be reengineered, in a view of organizational viability and performance.

2. Framework

In our case study, the paper discusses BPR implementation and our suggestion to go towards a process of outsourcing involving one function of the firm. Therefore, we will start our article presenting literary reviews on BPR, the case study as an application of BPR, and our suggestions towards a business improvement, through outsourcing. The analysis presented don't want to preserve the status quo, but to change, fundamentally and radically, what is done: it is a dynamic approach.

3. Business Process Reengineering

The term Business Process Reengineering (BPR) was first introduced by Hammer (1990), Davenport and Short (1990), as an approach to management processes involved in raising performance.

Since initiation, it has become a popular management tool for dealing with rapid technological and business change in today's competitive environment. BPR evolved from the experiences of a few US-based companies in the late 1980s (Martinsons and Hempel 1998).

The aim of reengineering is to facilitate the match between market opportunities and corporate capabilities, and to ensure corporate growth (2).

Several authors have provided their own interpretation of the changes being applied to organizations, for example Davenport and Short (1990) have described BPR as the analysis and design of work flows and processes within and between organizations. Other authors such as

Talwar (1993) have focused on the rethinking, restructuring and streamlining of the business structure, processes, methods of working, management systems and external relationships through which value is created and delivered. Hammer and Champy (1993) have promoted the fundamental rethinking and radical redesign of business processes to achieve dramatic improvements in critical, contemporary measures of performance, such as cost, quality, service, and speed.

Petrozzo and Stepper (1994) believe that BPR involves the concurrent redesign of processes, organizations, and their supporting information systems to achieve radical improvement in time, cost, quality, and customers' regard for the company's products and services. While Lowenthal (1994) describes the fundamental rethinking and redesign of operating processes and organizational structure, the focus is on the organization's core competencies, to achieve dramatic improvements in organizational performance, as BPR's essential components.

Particularly interesting is the comparative analysis carried out by O'Neill et al. (1999) who highlight the focus on the processes and change made by different authors on the topic (see table 1).

Analysis perspective	Authors
Business process improvement	Harrington (1991)
Core process redesign	Kaplan e Murdoch (1991)
Process innovation	Davenport e Short (1990)
Business process transformation	Burke e Peppard (1993)
Breakpoint business process redesign	Johanssen et all. (1993)
Organizational reengineering	Lowenthal (1994)
Business process management	Duffy (1994)
Business scope redefinition	Venkatraman (1994)
Organizational change ecology	Earl et al. (1995)
Structured analysis and improvement	Zairi (1997)

Table no 1 – BPR different perspectives' - our elaboration from O'Neill et al. (1999)

Table 1 illustrates that the main objective of the BPR, whatever definition adopted for it, is to support organizations in achieving significant improvements in critical business processes.

According to Day (1994), we want to point out two distinctive principles according to which we elaborated our case study and successive analysis in order to undertake a change management process (BPR or Outsourcing):

1) setting the objectives: they must involve customers' satisfaction, and

2) coordinating the organization's activities in order to generate a learning process: it's a complex horizontal process that will require definition of boundaries and horizontal connections amongst culture, change, and unfiltered information that is readily available to all team members (Senge 1990a).

In fact, we embrace Schaffer and Thomson thinking (1992) who highlighted how focusing on results rather than just activities makes the difference between success and failure in change programmes.

Put into strategic context, Senge (1990b) and Deming (1993) advocate for BPR a systems outlook involving customers, suppliers, and the future in order to achieve long-term corporate objectives. According to Gulden and Reck (1991), we believe that the success of a designed process don't lie in what it is performed today, but rather in thinking about how to reshape it for tomorrow.

The case study presented in this paper fits with Hammer and Champy's identification of three motivations that lead companies to undertake an analysis of organizational change (1993):

- companies find themselves in deep trouble: if a company's costs are higher than profits or than its business model will allow, if its product failure rate is higher than the competition's, if in other words, it needs productive, economical and financial improvement, that company clearly needs business reengineering,

- companies that are not in trouble but whose management expects a trouble coming,

- companies that are in peak condition and see an opportunity to develop to a leader position (over their competitors).

Numerous researchers and practitioners believe that top management commitment is the most important factor for a successful BPR effort (Davenport 1993; Janson 1993). They argue that BPR never happens bottom-up, and a reengineered process alone will not change the way people work. Champy and Arnoudse (1992) identify the role, attitude, vision, and skill or knowledge of leaders as necessary for successful BPR. Especially, they state that BPR must be more top-down driven than a quality improvement plan because of its radical change requirement.

We believe, according to Senge (1990), that BPR focuses on processes that are inherently cross-functional, leadership by those who have comprehensive perspectives and the authority to coordinate different interest groups is essential.

Hammer and Champy (1993) also emphasize the importance of measurement and rewards for reengineered process performance. They argue that employees must be paid on their performance and ability. Measuring the performance of a process and people is important for evaluating BPR, but the way of measuring is sometimes inadequate. To get employees to operate productively in teams, share information, take initiative, and display other behaviors that are now important, top management must devise new rewards and management processes, in order to evolve towards a learning organization model (Senge 1990).

To review more concrete factors of BPR success we can go to Bashein, Markus, and Riley (1994) who argue that financial conditions and human resource specialist involvement are critical to BPR success. According to this perspective Janson (1993) adds that clear, honest, and frequent communication is also important for successful BPR implementation and can help minimize employees' resistance.

Furthermore, we remember that to create a complete winning BPR, it's necessary to have a successful team made up of people from different interests (Katzenbach and Smith 1993). The size of a BPR project team, its members level of skill, a shared goal, and mutual accountability among team members are important factors for successful project team management.

4. Case Study: CEMAT SPA

This study is an illustrative case analysis (Yin 1989). Any claims about the broader view of BPR or outsourcing being typical and beneficial to industry should not be taken as statistically significant or empirically substantive. Our task, for future research, is to increase this research with an empirical one where data will be collected from a representative sample of many companies.

The results of this study provide anecdotal evidence for the plausibility of our claims and serve to illustrate the application of the framework of analysis and proposal we have provided.

Being an applied research project, we took as a reference model, the one proposed by Zuber-Skerrit (1991) and from which we derived the following four main phases:

1 - *Planning stage*. This phase analyses clearly the problem as belonging to a business environment, both from a scientific point of view, both from a practical point of view. With reference to this project, we analyzed the creation of a governance structure for the project, the formalization of the objectives and strategic directions, including the preparation of a detailed plan of the project;

2 - *Action phase*. This phase involves the execution of the provisions in the planning stage and it has been crucial the knowledge of the available literature. For this reason, the project, and therefore this paper, has provided an analysis of national and international literature. Among the activities, during this phase, particular importance went to the direct observation and conduction of workshops with staff directly involved in the project and indicated, in order to provide a comprehensive view of activities within the area considered;

3 - *Monitoring period*. We organized data collection for review and critical processes analysis (i.e., flow of activities, curves of presentation, processing time, criticality, etc.).

4 - *Being prepared*. Data has been collected in order to formulate feasible solutions to the identified problems.

4.1 General overview of Cemat: characteristics of the intermodal transport.

Intermodal transport is a particular type of transport carried out using a combination of different mediums such as trucks more trains or trucks and ships. Its characteristics are listed below in Table - 2.

Objective	Carry a unit from the sender to the recipient with the lowest possible consumption of resources
Environment	Demand for transport services
	The effects of policy decisions, such as laws, regulations, taxes and subsidies
	How to transport in competition
	The infrastructure
Resources	Trucks
	Machines to handle equipment in the terminals
	Railcars
	Ship
	Staff
Components	Conveyors
	Operators of railway structure
	Railway companies
	Shipping compagnie
Managers	Transport agents and logistics operators, even in the absence of formal power
Clients	Chargers directly or through agents who organize the shipment
Decisors	Formally no one, but forwarders and logistics operators play an important role
Planners	As described above, but with closer cooperation between the terminal operator and manager of the railway infrastructure and railway companies Planner

Table no 2 – Characteristics of intermodal transport of Cemat – our elaboration

The combined transport done by Cemat is composed, mainly, of unaccompanied combined transport (ferroutage) providing land transport semi-trailers, swap bodies and placement of containers. In Italy the market of railway transport is anomalous and underdeveloped compared to the rest of Europe, as a result of the strong diffusion of road transport. Among the domestic market and internationally there are significant differences, since Cemat manages alone traffic, direct customers and suppliers. It follows that, in Italian market, Cemat is solely responsible for

the final results. By contrast, the international market consists of, predominantly, by a set of axes managed in collaboration with partners. The results obtained in the international market must, therefore, be shared between partners and Cemat. This distribution can only generate strong implications both in commercial activities, both in the administrative and control.

In table 3 we can see some statistical data that represent Cemat activities in 2009.

Statistical data – year 2009	National market	International market
Transportation	138.626	469.994
Loading unit transported	179.666	655.846
Trains moved	7.673	19.827

Table no 3 – Our statistics on domestic and foreign market – source Cemat database.

4.2 Objectives of the project

The general objective of a *correct organizational development* has been translated into sub - objectives:

1) support the introduction of a *vision for processes*, through a clear understanding of both the activities within the firm and the main critical factors in the performance of the same. In fact, Barrett (1994) suggests that the key to successful reengineering lies in the development of a vision of the process. The key element is visioning the outcome (Goss et al. 1993).

2) exploit all *possible synergies* between the different organizational functions;

3) promote a greater *orientation to performance*;

4) promote the *cultural development of human resources* involved in the project: this will induce benefits in terms of motivation and productivity. Several authors (Harrington 1991a; 1991b; Lowenthal 1994; Duffy 1994) concentrate on the need to take account of the human side of reengineering, in particular during the change of organizational management.

Some authors (i.e. Mumford and Beekma 1994; Bruss and Roos 1993) suggest that the management of change is the largest task in reengineering. Kennedy (1994) on the other hand, incorporate the human element of reengineering due to the perceived threat it has on work methods and jobs.

Hammer and Champy (1993) pointed out some enterprise features more suitable for the application of a BPR project, namely: 1) the urgent need for change to recover low levels of competitiveness or to reduce costs, under penalty of exclusion from the market 2) the need for change to avoid having to deal with future problems but probable, and 3) the need for change to seize opportunities that will give the company a competitive advantage positions.

On departure of the project, Cemat needs to change in line with point 2 and point 3. In particular, with reference to point 2, the decrease in volumes in the domestic market and competitive pressures in the international market, have pushed Cemat to review its processes to make them leaner, faster and more effective, less expensive and where possible. With regard to point 3, however, Cemat has embarked on a path of renewal management, partly as a result of being part of the State Railway Group (Trenitalia), which provides for the introduction of SAP.

Since the intermodal business is very particular, Cemat has decided to undertake a project of change, departed from proper exploitation of the wealth of knowledge accumulated over the years, dictated by the desire to minimize the phenomenon of convergence towards industry averages, very frequent in the presence of integrated management solutions and standardized. This intention has justified in part the emphasis that the project has had during the AS-IS for detailed formalization of existing processes and their criticalities. The economic crisis, however, has emphasized the urgency for change more to resist the systemic decline in business volumes.

4.3 Methodology and analysis

Both Deming (1993) and Senge (1990) have written about the importance of *systems thinking* in understanding workflow, business processes, and the impact of feedback. In order to have a full understanding of the effects of what is being done, it is necessary to understand the whole process and how it fits into the organizational system.

Therefore, many authorities (Klein 1994; Grover and Malhotra 1997; Stoddard and Jarvenpaa 1995) recommend a thorough understanding of current processes before embarking on a reengineering project. Current processes can be understood and documented by flow-charting and process mapping.

With reference to the analysis of existing administrative and financial processes, the methodology has provided:

- an analytical mapping of the activities through causal analysis activities (the logic inputs / activities / outputs). This activity has been the most critical of the whole project due to the typical activities performed by Cemat, and due to the lack of adequately formalized documents to draw a clear representation of the activities and critical areas connected to each of them. We would like su underline that, except for the invoice manager, the employees profile of competences analyzed is low with a level of experience related, in most cases, only the activity in Cemat. This has made it a bit more complex, at least at the beginning of the project, the use of the methodology presented in this section.

- the definition of the job description;

- identification of critical issues associated with the activities carried out; this task is complicated due to the presence of some critical function unrelated to the managing of active and passive cycle. This involved a series of interviews with other business functions, including especially, the Sales Manager and Production Division.

- the consolidation and enhancement of knowledge gleaned by suitable instruments: 1) graphical representation of the processes through drawings in Microsoft Visio, 2) relational database created specifically (Process Activity Framework) for the collection of information gathered on the field and the production of reporting.

With reference to the improvement of existing administrative and financial processes we analyzed all activities carried out manually or mainly in manual mode. Each of these activities has been classified as follows:

1- *automatable activity*, in the case in which it is possible to automate business carried out in a manual or mostly manual way. Automatable activities were classified as follows:

a- *automated activities* (AS-IS improvement). This is the case with all those manual tasks that are predominantly manual or automated through the use of computerized procedures more or less complex;

b- *activities with automated rule* (AS-IS improvement). This is the case of all those activities predominantly manual or manuals that are now performed through the support of a file of personal productivity (usually Microsoft Excel) based on a set of rules are not codified but nevertheless necessary for the proper conduct of activities in question. In this case the use of computerized procedures must be done taking into account the implicit rules observed in the activities.

c- *tasks can be automated with condition* (AS-IS improvement). This is the case of all those activities predominantly manual or automated manual which involves a more or less significant impact on how the work of other business functions. The leverage information technology in this case can not be separated from that organization;

d- *tasks can be automated* (TO - BE reengineering). This is the case of all those activities predominantly manual or automated manual which would lead to rethink the logic of the process to which they belong. These activities have been reported separately as the primary objective of top management is to highlight, in a first instance, all those activities predominantly manual or

automated manual in the short term, according to a logical improvement and reengineering;

2- *activities to change without automation*, where we can improve the efficiency and / or efficacy of one or more activities without the use of procedures for computing facilities, but speaking about the organization and processes within the Administration Finance. Also in this case the logic of the work is directed towards an improvement and not to a process reengineering analyzed;

3- *activity not automotable*, in the case where it is impossible to automate an activity carried out in manual mode or predominantly manual;

4- *activities not automatable but eliminatable* by the Administration, Finance because they have a different organizational nature, almost always in the back office for marketing and / or production; for automated activities already in AS-IS (including those with rules and conditions), the methodology of the project involves the detection of worktime and frequencies, and the characteristics of the inputs and outputs generated.

5 Results

The results of this project are the product of an intensive work within the firm, summarized as follows:

- Identification and analysis of existing administrative and financial processes: 20 processes and 4 main support processes within the active cycle, 5 and 8 main processes supporting processes covered by the passive cycle;
- 551 business cards available by accessing a relational database created ad hoc;
- more than 600 factors input / output mapped to the activities;
- 76 between paper files and database analysis;
- identification of 78 critical issues, divided into strategic and operational;• 9 types of reports for a total of over 2000 pages and printable pages.

These values assume more sense especially if they are compared with the data available to the Administration and Finance at the beginning of the project, namely:

- Active Cycling:
- 10 procedures;
- 78 activities mapped;
- 13 files mapped;
- no match role / activity.

- Passive Cycle:
  - 7 procedures;
  - 56 macro activities;
  - 5 mapped files;
  - no match role / activity.

- Perception that something is not working properly without knowing exactly what and how much.

CRITICALITIES	WIDTH TO –BE	PURPOSE TO – BE	LEVERS TO - BE	TIME ORIZON
Strategic	*General vision (firm perspective)*	*Rengineering, strong impact on the processes and business model definition of*	*definition of new shared models to be introduced gradually in the firm*	*Medium – long*

		new models to be introduced gradually in the company		
Operative	*Focus on specific operational areas within administration and finance*	*local improvement with an incremental logic*	*Improvements involving I.T. and organizational (HR management) aspects*	*Short – medium*

Table no 4 – Criticalities found – our elaboration

During mapping process we found criticalities as described in table 4. There are two macro cathegories:

1) *strategic criticalities*, characterized by a high potential impact on future business performance. The resolution of these problems involves one or more projects of reengineering with reference both to individual business processes, and the business model as a whole. Projects of this magnitude often involve the introduction of new management models, on a medium-long term time horizon.

2) *operative criticalities*: their resolution promote incremental improvements and is, almost always, aimed at the recovery of efficiency in one or more business processes (i.e. recovery Full Time Equivalent), intervening both at the level of I.T. systems, both at organizational level on a short-medium term time horizon. We want to underline that the need, for Cemat, to restore the processes to efficiency involves, also and necessarily, the increase in duties and responsibilities of people employed.

> One of the Cemat strategic criticalities observed is the absence of a systemic vision (Senge 1990; Mella 2009) and synergy between different organizational business units. From fieldwork it was found that the business activities are strongly anchored to the personal initiative, based on formalized procedures, and less on the real business drivers. This indicates a lack of integration and coordination between the different business areas. Such situation reflects both the absence of automation in the field (RFID, Barcode, etc..), both of a smooth and timely administrative workflow. Moreover, procedures inside the Administration has been developed according to an incremental logic to deal with a number of exceptions arising from the lack of connection with other functions and with the various stakeholders.
>
> A possible evolutionary scenario (which will be discussed in the following paragraphs) is to promote a corporate culture oriented to the improvement of employers' skill, formation, recruitment, etc.

Interventions aimed at process improvement for resolving operative criticalities, include the informatization of some activities and review of certain organizational conditions, without altering the structure of the process and / or system that currently supports it.

In particular, these interventions were aimed at increasing the reliability of the calculation procedures of the management system (AS400 - pending the development of SAP system) to avoid manual control activities, as at present.

The priorities of intervention was addressed by top management to the improvement of the manual tasks or mainly through the use of manual IT procedures (78 activities) or organizational interventions (12 activities) (3).

According to Davenport (1993), this project has enabled the Cemat Administation to create the conditions for maximizing the benefits arising from the introduction of an ERP system. The

analytical mapping of processes and activities has allowed us to understand and discuss the successes of BPR and the possible evolutionary paths of the Cemat business.

The increase of automation and the saving of FTE, for example, involves the need to *qualify deeply* permanent staff in the company, in order to *improve processes in their totality*: both the standard ones (characterized by replacing men with machines) and both those where the HR component is crucial in the formation of a shared vision (Senge 1990) and critical to the business processes' success.

6. How to improve agility?

Our findings in this case study are a signal of how BPR can be considered a technique that can effectively support business change. As for all technical and managerial tools, even BPR cannot represent by itself a panacea for removing the obstacles that naturally occur in any situation of incremental or radical change. The latest is a necessary condition to compete and not just a simple distinguishing factor. Successful companies are those that are able to change and continuously innovate competences rooted in the company, at all levels of the organization, promoting a corporate culture focused on performance and value creation.

From evidence, undertaking a second phase would be significant for Cemat in order to implement our findings and applications of BPR with the advantages of a strategy of outsourcing.

As we see in this case study, staff management plays an important role in BPR, but it would become more stressing in the future. In our opinion, it would be important, for Cemat, to increase its *attention on human resource* (HR) *management* relation to business processes since it takes a combination of management leadership and employee participation and is also an enabler of social and organizational transformation, making it an integral part of an organization's strategy (Parker 1996). Its aim would be to improve training, attendance management, remuneration, recruitment and benefits to staff.

7. Towards outsourcing: from a make or buy decision to a strategic choice

The term outsourcing was used in 1982 (Van Mieghem 1999) to identify the decision by which one or more processes or activities necessary to obtain a product or a component, even an organizational function – originally undertaken in-house by a certain organization – are regularly entrusted by a firm – the outsourcee – to an outside organization, the outsourcer (supplier or provider), who carries out the activity and sells the results to the former.

The first feature of outsourcing, from the production point of view, is that the outsourcee "takes outside" the firm processes and functions already carried out internally and does not only acquire – "brings inside" the firm – factors or services that were until then produced by outside firms.

This feature is not always clearly explicit. For example, the Dictionary of Business (Collins 2005) defines outsourcing as the "purchase of components, finished products or services from outside suppliers rather than their production within the firm". "In some cases this is done because turning to outside suppliers lowers costs, because the outside suppliers have greater technical competencies, or because they offer a greater variety of products.".

The outsourcing process can occur physically outside the premises of the outsourcing organization or inside the organization.

In the first case, *outsourcing* can be viewed as service *contracting-out*: that is, as the outsourcing of services necessary for production (Domberger 1998). In the latter case it is service *contracting-in* – or *co-sourcing*: that is, the carrying out within the organization of processes with capital and know-how resources owned by others. We will focus our attention on this second aspect of outsourcing.

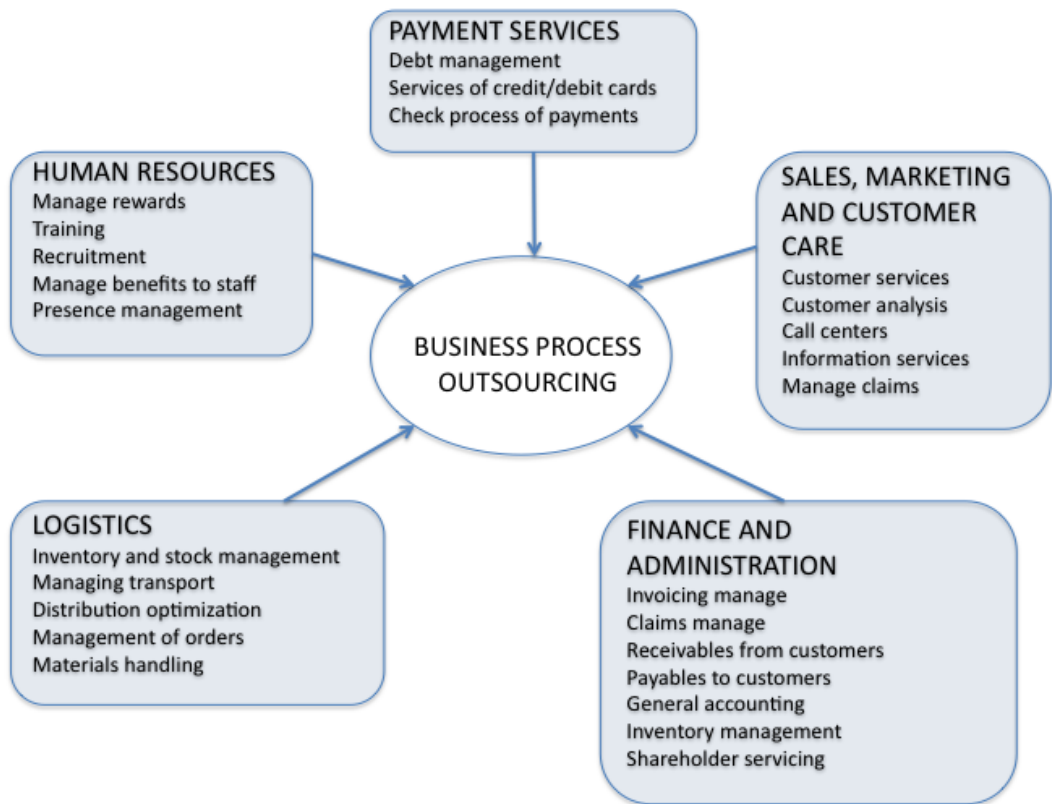
Outsourcing is a flexible phenomenon; in theory everything can be outsourced, with the exclusion only of business or managerial activity.


Fig. no 1 – The most typical processes outsourced. Our adaptation from Gartner (2004)

"Make or buy" specifically indicates the decision-making process to decide whether or not it is more convenient to produce in-house or to externally acquire activities "up the line" or down the line", even professional activities (Besanko et al. 2005; Espino-Rodriguez et al. 2008).

As Williamson (1989), Chalos (1995), and Roodhooft and Warlop (1999) indicate, from a theoretical point of view the propensity of firms to adopt outsourcing is a function of the difference between the price of the external producer (the marginal cost of the external service market) and the marginal cost of in-house production.

Along with this general motivation, other drivers spur on the decision to adopt outsourcing, with various studies attempting to indicate the most important.

Based on a survey of over 1,200 firms, Deavers (1997) identified five principal factors:

1. the need to increase the firm's focus on the core competencies;
2. guaranteeing access to world-class capacities and competencies;
3. accelerating the benefits from re-engineering (i.e. in the case study discussed), going so far as to rewrite the firm's processes from scratch;
4. sharing the risks between the outsourcee and the outsourcer;
5. the possibility of freeing up the firm's resources to focus attention on the management of the core competencies

According to Sharpe (1997), outsourcing arises to reduce the costs the firm faces in order to respond to economic change, and thus it is a means for creating flexibility; Abraham and Taylor (1996), on the other hand, believe firms adopt outsourcing for manufacturing and service transformations in order to give stability to production cycles and to benefit from the specialization of other firms.

Heshmati (2003) instead notes that the outsourcing decision is complex due to sunk costs, stating unequivocally: "The choice to continue production in-house or to undertake it externally through outsourcing involves considerations other than just the difference between production cost and supply cost", going on to claim that outsourcing should not be considered as simply a make-or-buy decision, based solely on a comparison of explicit costs, but also refer to previous investments that give rise to "sunk costs" for the firm. Without their total amortization, sunk costs can have a negative effect on the decision to adopt outsourcing for production.

In recent years outsourcing has moved from being a pure make or buy tactical decision to becoming part of a strategy for changing the way business is done.

In fact, by tradition firms originally considered outsourcing as a solution to short-term problems, such as a sudden or unexpected increase in demand, an interruption in plant or equipment functioning, or the launch of a new product.

Today firms consider outsourcing as a *network of stable aggreements* with specialized suppliers as part of a long-term *strategic perspective*.

According to Quinn and Hilmer (1994), from a *strategic perspective* outsourcing allows management to optimize the firm's resources in four principal ways:

1. by maximizing the output from internal resources by concentrating investment and effort on what the firm "does best;

2. by developing the core competencies by setting up barriers against present or future competitors who might try to enter the firm's areas of interest, thereby protecting its competitive advantages

3. by utilizing the investments of outside firms, as well as their innovations, skills and specializations, which could be maintained in-house only through continuous investments and innovation

4. by reducing the risks from rapidly changing markets and fast-evolving technology; an outsourcing strategy shifts the risks involving technological updating and R&D costs outside the firm, thereby shortening the production cycles and making responses to customer needs more flexible and rapid

It has never been easy to develop long-lasting competitive advantages, but in a competitive and technological environment that is vaster and more dynamic than in the past, firms, like Cemat, must deal with complexity – from globalization, new technologies, and the emergence of new competitors – by turning to new strategies.

8. Outsourcing decision in Cemat: competitive strategy model

Kedia et al. (2005) refer to Porter's (1985) generic strategies concept to assess the advantages and risks of outsourcing production, affirming that outsourcing can allow the firm to combine and obtain advantages from all three areas of generic strategies: cost leadership, product differentiation and focus.

The competitive advantages arise from cost leadership "*when the company manages to be the producer with the lowest costs in the industry*" (Porter 1985: 149). With the generic strategy of differentiation, the company builds a competitive advantage when it "*tries to be unique in the fields that the buyer appreciates*" (Porter 1985: 129).

Considering Cemat, the outsourcing of HR functions shown in Figure 1, according to literature, would allow management to concentrate resources and attention on the "core competencies" of the company, allocating cost savings obtained from outsourcing to increase the value added of the product by investing, for example, in Research and Development, with the opportunity to obtain benefits from new services or new productive processes.

Our analysis, moving from the the need of Cemat's future business improvement, integrates what we said above about outsourcing and BPR and emrbraces the concept of value chain, introduced by Porter. He says that value chain "disaggregates a company in its strategic relevant activities in

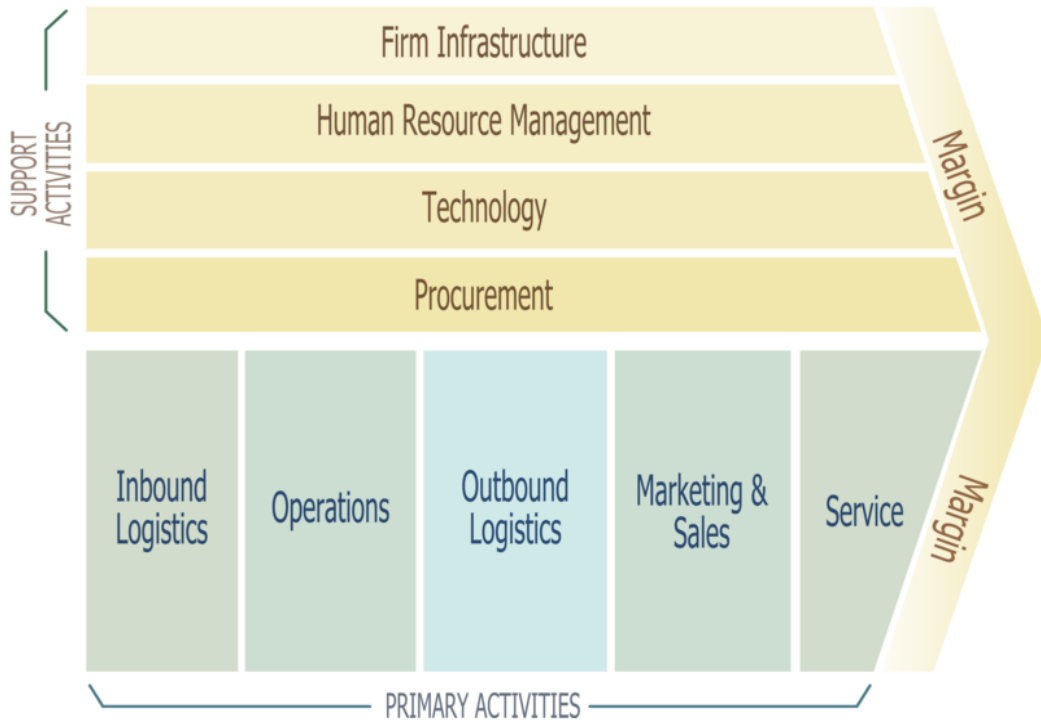
order to interpret costs behavior and current and potential sources of differentiation" (Porter 1985: 150). It includes five primary activities and four support activities (see figure 2).


Fig. no 2 – Value Chain – our elaboration from Porter (1985).

The value chain - precisely as it represents the links between the various activities and expresses the potential synergies between products and services - allows to express the value of a given product or service in terms of assets needed to produce it, just distinguishing between primary activities and support activities.

It is essential, for Cemat, identifying the nature of competitive advantages and to identify strategic actions to protect and strengthen them.

Kedia et al. (2005) suggest to analyze each primary and support activities in sub-activities and groped to identify: 1) what contribution each sub-activity leads to the competitive advantages of the company, 2) what contribution each sub-activity leads to the "core competencies". 3) what sub-tasks should be outsourced in order to maintain and / or achieve a competitive advantage.

To implement this analysis, the sub-activities identified in the value chain can be placed in a matrix "competencies / competitive advantages" (Kedia et al. 2005) - which could take the form shown in Figure 3 - to examine how each contributes to the core competencies and competitive advantages of the company.

We suffest that the combined examination of the value chain and the matrix provides the elements to decide which sub-activities or activities give in outsourcing.

The ones that are in the low-down position are potential candidates for outsourcing because their contribution both to the "core competencies" both to the competitive advantages appears modest. These activities consume unnecessary resources without giving the company a competitive advantage. These considerations are opposed to the sub-activities which, high-high ranking in the matrix, are the main sources of competitive advantages, they should therefore be kept inside, protected and enhanced.

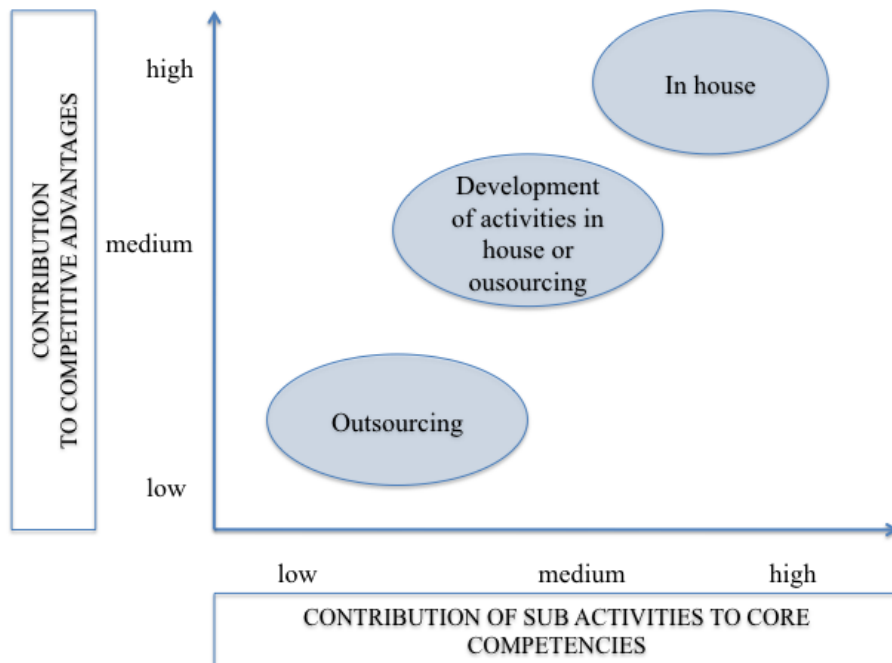
The central position is represented by sub-activities that do not contribute significantly either to the "core competencies" or to the competitive advantages of the company, for them there is a choice between development, through investment, so as to become strategic resources in the long term, and placed in the high-high position of the matrix, or being considered as candidates for outsourcing.


Fig. no 3 – Matrix "competencies / competitive advantages". Our elaboration from Kedia et al. (2005).

The use of technical analysis of the value chain and the construction of the matrix has been crucial in defining which activities are to be recommended to outsource, this analysis must necessarily be accompanied by the activity of management who must locate, even with other accurate analysis, what are the sources of "core competencies", the sources of competitive advantages, and the links between these sources.

We would point out, for completeness, that the changes in the economic and competitive environment require, often, reviews of decisions regarding outsourcing. Outsourcing is not a decision "once for every" (one-off).

These tools identify current positions of a firm, while each competitive strategy must be the result of a projection of future needs and also consider the probable response of competitors.

8. Conclusion

In many cases, outsourcing offers companies a low cost, low overhead and quickly implemented solution that helps rid them of paperwork, as well as mundane mailroom and data-entry functions.

> BPR is a typical "insourced" (in-house) process, often stretching corporate resources and requiring significant financial investments and intellectual capital.
>
> Cemat managers has expressed the need to improve internal control and productivity but, in a first phase (approximately 2008-2011), cannot expend the needed resources in HR improvement, ongoing formation and HR management.

> For this company, in a second, suggested, phase (approximately 2012-2015) a better solution could be to *cosource* business functions involving HR management in order to reduce costs and to benefit of all the outsourcing advantages.

Remembering that cosourcing is a business practice where a service is performed by staff from inside an organization and also by an external service provider, we believe that Business Process Cosourcing (BPC) is an innovative approach, offering organizations, such as Cemat, a new and highly effective "total" business solution plan to improve productivity, efficiencies and costs.

The HR team's cosourcing will be designed to assist Cemat in putting together a total solution that will behave similarly to an in-house services center. And, much like an outsourcer, a cosourcer will handle all, or many, of the front-end processes such as helping selecting staff, people knowledge improvement, while operating under a service level agreement that defines quality and turnaround time.

According to Porter's Value Chain (1985 – see fig. 2) and still discussed above, Cemat should think to cosource the support activity specified in the HR management, and specifically, management remuneration, recruitment and training (see figure 1).

In this way it would be possible to obtain the production of data stream relevant to the business starting from field (i.e. stations) and, therefore, a real-time connection with the processes of business (sale, production, etc..).

Cemat and its management is increasingly being pushed to invent new ways to increase performance, productivity and profitability in today's highly competitive business environment. In a changing world, executives continually search for solutions that will reduce the expenses while expanding market share.

We have deeply seen the looking to an in-house solution or contracting with an outside supplier, is not an easy choice. A company must take decisions about company policies, resource availability, working capital and time.

> The suggestion of cosourcing, for the future of Cemat, has the main objective to combine all the key elements and benefits of outsourcing, discussed above, with the additional advantage of the service provider becoming an integral part of the client's value-added relationship with internal and external customers and stakeholders.
>
> Utilizing the latest technologies, a cosourcing provider system, in Cemat, can offer a better channel of communication which involves all the areas of the organization management.
>
> All the benefits of outsourcing are realized, but in addition, functionality is increased to an even higher level, since cosourcing ends and the internal process begin.
>
> The cosourcing paradigm we propose allows Cemat to lower transaction processing costs, increase control and reporting having the advantage of a minimal or no capital expense; this approach could redeploy key personnel to more strategic roles.

9. Notes

 (1) The choice depends on the magnitude of the needed change, the feasibility of it, and the resources required to accomplish it (Davenport, 1993).

 (2) It's necessary to point out that outsourcing could be a product of reengineering, even if it do not define reengineering (Lowenthal 1994).

 (3) For manual activity we mean an activity carried out without (or reduced) use of information technologies and an activity whose effectiveness depends on checks carried out by the operator and not by technology.

ENVIRONMENTAL IMPLICATIONS OF THE INCREASING DEMAND FOR ENERGY

Perțicaș Diana
Assistant, Phd. Student West University of Timisoara Faculty of Economics and Business Administration

During human society's development on large geographical areas, a series of cultural systems have appeared and have determined a certain approach concerning the environment and social relations. These systems of thought persist even today and they are strongly influenced by individuals' thinking and approaches in that society, thing that requires a specific approach for the implementation of these relatively new concepts (e.g. sustainable development, pollution, ecological approaches on social life). Furthermore, the continuous growth of the demand for energy in the world is seen as an alarm. Between 1970 and 1997 world energy consumption has almost doubled and it is projected to grow by about 57% during 2004-2030 and the thing which should be mentioned is that with the increasing energy demand, pollution levels will increase too. But we must not forget that electric and thermal power represent one of the basic needs of mankind, and when the fulfilment of this need started to affect the climate and implicitly human health this problem turned into a hardly manageable one. We must not forget that the world's population is growing rapidly and the level of pollution per capita increased we might even say in direct proportion. In many cases, increased pollution has its explanation in the growing number of individuals at global level and also the increasing needs, desires, aspirations, standard of living, of these.
This paper intends to objectively analyse the interconnections that arise between the environment and the growth of the demand for energy, emphasizing the devastating effects of pollution created by burning fossil fuels in order to obtain electric and thermal power as well as the current and future possibilities for the replacement of these energy reserves with renewable energy reserves. The whole analysis will be accompanied by case studies and will follow strictly imposed goals by sustainable development.

Key words: energy, environment, pollution, sustainable development, fossil fuels.

JEL codes: Q32, Q42, Q57

"The control of nature" represents an expression full of arrogance born during the Neanderthal age when it was supposed that nature exists for human convenience. ". (John Barry, 2010:5) If those in the Neanderthal era believed that nature exists for human convenience, today it is clear that humans have for the first time the ability to destroy the planet as they wish: with a single action, or gradually, but is the first generation that can not consider nature as something given for free, which exists for its mere convenience and that will be in the same way forever. So therefore, the environment has become a topic increasingly debated in time, occupying a central place in the social theories and political practices.

Starting from the question "what is the connection between social theories and political practices", John Barry first defines environment as the place where he will age, where his children and grandchildren will be born and raised. He continues then the analysis of the medium in different stages: during his childhood, adolescence, the present and ending with an exercise of imagination on what his grandchildren and the generations to come will see.

Electric and thermal power represent one of the basic needs of mankind, and when the fulfilment of this need started to affect the climate and implicitly human health this problem turned into a hardly manageable one.

The continuous growth of the demand for energy in the world is seen as an alarm. Between 1970 and 1997 world energy consumption has almost doubled and it is projected to grow by about 57% during 2004-2030. The total worldwide energy consumption is projected to increase from 447 quadrillion Btu thermal units in 2004 to 702 quadrillion Btu in 2030. In less developed countries energy consumption is expected to grow three times, as fast as in OECD countries. Together with the increase of the consumption of energy pollution will increase too. United States for example, use approximately a quarter of the energy produced worldwide. (Hill K. Marquise, 2010:80)

An interesting thing to note is that about half of world's population does not purchase fossil fuels, or even if they do, the sums they are spending in this respect are very small, because poor people are part of "those who do not contributed to fossil fuel pollution", they use wood in the same manner as their ancestors, using it both for cooking and to provide light and heat. Even today over 60% of consumed wood in the world is used as fuel.

In China, people burn coal to ensure thermal and energetic comfort, but the quality of it is often poor and as consequence it is responsible for much of the recorded human poisonings and environmental diseases. In addition, mining and recovery operations and / or burning oil can have a disastrous impact on the local environment polluting it very much.

Coal is responsible for producing half of the required energy in the United States of America. In Europe, its large scale use began in the seventeenth century, when wood became less and less available. Coal use increased almost 500 times per year in the strongly industrialized Western economies. But the biggest problem encountered in using / burning of coal is that like most products it does not take into account the impact it has on the environment. In addition, due to the fact that coal is part of the exhaustible resources, and they will be exhausted in the not too distant future, under the action of the laws of supply and demand, its price is constantly rising. (Hill K. Marquez 2010:80)

Figure no. 1 - The structure of global pollution. Pollutant substances and their weight
Source: Hill K. Marquez, *Understanding Environmental Pollution*, Third Edition, Published in the United States of America by Cambridge University Press, New York, 2010, pg 204

Increasing energy demand seems to be endless. For the first time in decades, energy demand has fallen, but as expected not by much, due to the recession of world economy. After the industrial revolution began, cities without precise limits started to emerge, cities with developed industrial areas in the suburbs and with a continuously growing population. Cities always adapt in order to cope with supply problems of the population (in those places self-consumption is fairly low) and industry, waste and industrial disposal, transportation, insuring of both electrical and thermal energy and thus start to appear more severe pollution problems.

Figure no. 2. - The percentage of global emissions in various domains
Source: Hill K. Marquez, *Understanding the Environment Pollution, Third Edition*, Published in the United States of America by Cambridge University Press, New York, 2010, pg 205

The registration in the WHO Charter of such a goal is not a casual matter. Elementary logic leads anyone to conclude that between the economic development and environmental conditions on one hand, and human health, on the other hand, there is a strong interdependence relationship. An important aspect for our theme is for the economic development to be social and to positively influence the environment, and in this way, to provide support to human health. (Pohoata Ion, 2008:45)

Figure no. 3. - Carbon emission trends between 1750 and 2010
Source: *Carbon Dioxide Information Analyses Center*, available online at: http://cdiac.ornl.gov/trends/emis/glo.html accessed on 29.10.2011

As it can be observed from the presented graphic, the level of pollution rose constantly from 1880 to 2010. And during 1750-1880 pollution levels have had an upward trend but a smaller one than that corresponding to the last 50 years.

Even if world population is increasing continuously, we might even say that the level of pollution per capita increased in direct proportion with it. In many cases, increased pollution has its explanation in the growing number of individuals at global level and also the increasing needs, desires, aspirations, standard of living, of these.

Table no. 1. – The analysis of the carbon dioxide (CO_2) concentration between 1751 and 2008

Year	Total	Gas	Liquids	Solids	Production of cement	Inflammable gas	/ Capita
1751	3	0	0	3	0	0	
1771	4	0	0	4	0	0	
1870	147	0	1	146	0	0	
1886	281	2	5	275	0	0	
1928	1065	23	143	890	10	0	
1951	1767	115	479	1129	20	24	0.69
2000	6750	1288	2818	2370	226	48	1.1
2001	6916	1311	2827	2494	237	46	1.12
2004	7782	1431	3027	2971	298	55	1.21

2006	8350	1519	3080	3333	355	62	1.27
2007	8543	1551	3074	3468	382	68	1.28
2008	8749	1616	3095	3578	386	73	1.3

* (All data are expressed in million metric tonnes of carbon. In order to convert them in tonnes of carbon dioxide you should be multiplied by 3.667)

Source: *Carbon Dioxide Information Analyses Center*, available online at: http://cdiac.ornl.gov/ftp/ndp030/global.1751_2008.ems accessed on 29.10.2011.

Before 1950 the calculation per capita of pollution could not be performed due to lack of information. Since 1751 approximately 347 million tonnes of carbon were released into the atmosphere from fossil fuels and cement. Half of these emissions were produced by mid 1970s and in 2008 emissions from burning fossil fuels were of about 8.749 billion metric tonnes of carbon, with 2.7% more than the amount released in 2007. (*Carbon Dioxide Information Analyses Center*)

Another effect of global warming is the increasing ocean temperatures. Described climate models indicate the fact that these will warm before the atmosphere. Previously there have been few measurements of the water temperature evolution of the oceans but the information provided by oceanographers found an increase in average temperature of the water in the Pacific, Atlantic and Indian Ocean both to north and south in the period 1955-1995 by 0.6 °C between the surface of the ocean and the depth of 1.86 miles (3000 meters). This difference seems to be small, but given the fact that the oceans play an important role in capturing sunlight, we can deduce that an increase in ocean water temperature would lead to a less solar radiation capture. (Marquise K . Hill, 2010:188)

In the American state of Alaska, the average temperature increased by 3 °C over the past 30 years, this increase being four times higher than the global average. This fact led to the melting of icebergs in the area much faster than was anticipated in previous years. The research team consisting of experts, professors and researchers from the University of Alaska conducted a series of measurements. Their conclusion was that the melting of the icebergs is faster than ever in that area in comparison to anyplace else, and thus contributing with at least 9% to the increase of Bering Sea level analysed in the twentieth century. (Marquise K. Hill, 2010:196)

The rapid increase of the temperature in Antarctica has affected human and animal life of the region. For example, the number of polar bears has dropped dramatically. That is the reason why in May 2008, United States of America have taken the decision to protect polar bears under the "Endangered Species Act".

Measurements in respect to icebergs' melting began 30 years ago achieved by satellite. Since then, the arctic region has lost more than 20% of the ice. The loss rate began to accelerate in 2002 to the extent that, in the summer of 2007, the Canadian Northwest Passage became fully navigable. In the situation in which the annual growth rate of icebergs' melting continues to increase, studies show that the Antarctic by the summer of 2030 will be completely free of ice.

But not only the icebergs in Antarctica began to melt but those on mountain peaks too. For example, Kalis Peru Quori glacier in Peru decreased 33 times faster between 1998 and 2000 than it did between 1963 and 1978. In Nepal and Bhutan many lakes around glaciers are dangerously full. If they continue to rise they will flood nearby valleys causing much destruction especially among people living nearby.

Another worrying phenomenon is the rising sea levels. This accelerated growth rate caused the raising of the level of these by 20 inches in the last 100 years. The measurements made by the satellite called "Jason" especially built for this purpose, highlighted some of the negative consequences of this phenomenon. The biggest concern is in Bangladesh where a billion people could become homeless if the sea level would rise one meter. (Marquise K. Hill, 2010:196)

In regards to Romania's situation on the generation of wastes resulted from economic activity in 2008, this is the first among EU countries in this respect. In 2008 it produced an amount equal to 17031486 tonnes of waste arising largely from agriculture and deforestation. Whether this amount would be used as biomass, Romania's indicators such as: economic growth, dependence on imported energy, deforestation, and energy intensity would certainly achieve many more favourable results.

In a similar situation but not so disastrous is Spain which in 2008 produced an amount from economic activities of 11322154 tonnes of wastes, with almost 6 million tonnes less than Romania, given that this country is part of developed ones.

Table no. 2. Emissions of air pollutants per capita, kg, 2009.png

Source: Eurostat, available online at: http://epp.eurostat.ec.europa.eu/statistics_explained/index.php?title=File:Emissions_of_air_pollutants_per_capita,_kg,_2009.png&filetimestamp=20111004100800 on 21.10.2011

The above table represents a ranking made in 2009 in respect to the emissions of air pollutants calculated per capita of EU countries and the EU27 average. We can note with displeasure that Romania, in three out of four categories is in the top of the countries that are heavily polluted. For example, in terms of air pollution with ammonia (NH3) Romania ranks 5 among EU countries, with a value of 8.7 kg per capita compared with 7.6 as is the average EU-27 so it exceeds the average by more than 14 %. We have to mention that ammonia according to the Explanatory Dictionary of the Romanian Language is "a colourless gas with a pungent odour, stifling, obtained from combining hydrogen with nitrogen, and it is used in the manufacture of nitric acid, nitrogen fertilizers, of explosives etc." (the Explanatory Dictionary of the Romanian Language)

Current perspectives of environmental development whether it is maintained or increased the rate of current pollution are unimaginable. In order to flatten the ascending curve of the

environmental destruction, currently it is recurred to a range of measures including the analysis in this paper is the reduction of fossil fuels to provide the required heat and electricity. If in the 1970s for mankind was questioned the replacement of fossil fuels for reasons related to depletion of these energy resources at present the situation is far more serious with a focus on reducing fossil fuels consumption for survival reasons. As an alternative would be to use nuclear energy but that has several disadvantages and more dangerous implications than current fuels.

From the environmental development current point of view the emphasis is put on the large scale use of renewable energy that has a low rate of pollution and restoration of large flora on the on vast regions.

With all the energy resources disadvantages respectively geographical areas, season, ore, etc.., there can be addressed a global vision of a world energy system (solar panels in desert areas, hydro plants on major water courses, wind fields in areas with potential, geothermal plants in areas with considerable ores and the widespread use of heat pumps in order to capture and use of geothermal energy - geothermal energy that is stored by earth's crust as a follow up of the solar energy activity on the crust).

THE ANALYSIS OF POPULATION MORBIDITY RATE DUE TO INCREASED ENERGY DEMAND

Perțicaș Diana
Assistant, Phd. Student West University of Timisoara Faculty of Economics and Business Administration

Florea Adrian
Assistant professor University of Oradea Faculty of Economics Oradea

Sustainable development as general acceptance is that form of ensuring the bio-socio-economic needs of the present generation without affecting the existence and development opportunities for the generations to come. Secondary, the concept refers to the protection of the environment that is at present greatly affected by externalities of the socio-economic activity of previous and present generations. As it is shown in this paper the negative effects of the environmental pollution records higher and higher values in a short period of time of which we analyze their impact on population health, focusing on the situation of Romania.

I started the analysis from the assumptions that the health of an organism is a normal physical and physiological state, being the opposite of the concept disease. The most common diseases are: hereditary, infectious, internal, infantile, autoimmune, allergic, socio-professional, tumorous, degenerative diseases etc. Of these infant, allergic, tumorous and autoimmune diseases are mainly generated by environmental pollution. Extremely special, regarding the incidence of harmful environmental factors, are the socio-professional diseases or of civilization that are represented by those diseases that are more common in industrialized countries than in the so called third world. In respect to air pollution-generated illnesses with products resulting from burning fossil fuels are highlighted respiratory diseases, immunological diseases, benign and malignant neoplasm of the airways and also dermatitis.

Most activities follow sooner or later to increase welfare. Economic growth, environmental protection as well as fulfilling social needs of individuals are only a few elements that lead to the increase of population welfare. If we accept the above mentioned things, then it means that promoting the realisation of sustainable development based on clean and renewable resources and the rationally using the conventional ones is an objective to be supported and of course achieved.

Key words: sustainable development, population morbidity, fossil fuels, energy,

JEL codes: P48, Q56, Q32

The environment has also suffered a lot of change mainly due to increasing production. In a report realised by Millennium Ecosystem Assessment, conducted by a group of 130 experts from 95 countries, it was demonstrated that 60% of the ecosystem is essential to maintain life on Earth. This ecosystem is in constant decay. Specialists have been trying to quantify the exact figures, from economic point of view of the impact pollution has on the environment, but this objective is almost impossible to achieve. For example, the extinction of some plants and animals that man has not consumed for food and used for some purpose has no direct implication on humanity but none the less represents a loss to the ecosystem. And considering all these World Bank annually estimates that environmental degradation costs ranging between 6 and 10% of the annual GDP. (Millennium Ecosystem Assessment, Climate and air pollution)

Table no.1 Review of air polluters resulting from burning fossil fuels

Produced pollutants	Responsible fossil fuel
Global climate change and oceans' acidification Carbon dioxide (CO_2)	Burning coal produces more CO_2 than oil and more oil than natural gases
Methane	Methane that arises from the use of fossil fuels derives from retrieving coal and oil and gas pipe leaks.
Acid deposition Sulphuric acid and sulphate Nitric acid and nitrates	The sulphuric acid and sulphate are formed in the atmosphere from SO_2. Nitric acid and nitrates are formed in the atmosphere from NO_x.
Ambient air Sulphur dioxide (SO_2)	SO_2 is emitted in large quantities by coal burning plants and in smaller quantities from burning oil and natural gases
Nitrogen oxide (NO_x)	NO_x forms - not from fuel but from a reaction between nitrogen and oxygen during combustion at high temperature. From motor vehicles predominantly in urban areas and also power stations.
Carbon monoxide (CO)	CO is a product of incomplete combustion. In urban areas up to 90% is from burning diesel oil.
Ozone (O_3)	O_3 isn't a primary pollutant but is formed from precursors. Motor vehicles are the main source of NO_x and VOC_s that lead to O_3.
Particles	Particles are emitted from burning coal and to a lesser extent from burning oils. Metal particles are emitted as particles except elementary mercury.
VOC_s	Hydrocarbons are most of them VOC_s emitted from burning diesel by motor vehicles.

The toxic effects on the developing embryo or foetus during development are of deep concern. Beyond the obvious congenital malformations, scientists express their concern for mother's exposure during pregnancy to certain toxic substances in the atmosphere that can have a negative impact on the health of the child. Then, infants and young children, often but not always present a higher sensitivity to toxic substances in the atmosphere than adults, this being due to the fact that their immune system is incompletely developed thus being less protected against these harmful substances.

Another explanation of this phenomenon is given by the fact that underage individuals, breathe faster than adults. So, if the air is polluted, they inhale a larger amount of emissions. For example, a child in an industrial city inhales on average of 110 ng benzopyrene, an amount equivalent to smoking three cigarettes a day. Thus, statistical data strongly highlight the evidence that pollution is a significant cause in increasing asthma and allergies rates especially among children in urban areas of the developed countries. (Hill K. Maquita, 2010:80)

In order to demonstrate those stated above in the following we will analyse the evolution of health situation in Romania, respectively we will see how the evolution of main diseases caused by air pollution is.

Table no. 3. Number of patients discharged from hospital suffering from tumours

It can be noticed that the number of these has increased almost constantly since April 1994 until 2009. Specifically by 2001 the number of patients affected by tumours has increased constantly. An explanation can be the fact that Romania was an industrialized country until 1989, but unfortunately these were also highly polluting industries mainly due to existing technology of the time. Then, after 1989, step by step some of them were closed because they were considered unprofitable, thing that can be seen in the evolution of the number of patients that were recorded, evolution which registered a downward trend during 2001-2006. When Romania's situation began to recover, specifically to record significant economic growth the number of patients began to grow.

The same phenomenon can be encountered in the case of the individuals with nervous system disorders. Even in this situation can be observed the same trend in respect to evolution of the number of patients.

Most frequently encountered theories in the specialised literature are those that argue that economic progress is the one that increases life expectancy. But what they don't support is that this life expectancy does not coincide with the increase of life quality, welfare because reality shows (we talk about the situation of Romania) the number of people suffering from various diseases mainly caused by pollution is continuously growing and furthermore this increase ranges between 50% and 300%.

Asthma is one of the most widely spread diseases and is considered to be a barometer of the level of pollution in the world. It represents a chronic disease of the lungs that manifests by heavy breathing due to airways inflammation. When they present irritations, the muscles of the airways' walls narrow causing a respiratory failure. During an asthma attack, airway cells secrete more mucus than normal, thus causing their blockage; they inflame causing the airways to swell and the muscles around them to tighten. People with asthma suffer the most exacerbations during the night and not only, this way limiting certain activities or causing them some deviations from the family routine.

It is known that asthma is an incurable disease, but there are some drugs meant to control the disease, drugs such as inhalers or steroids tablets that help prevent or improve attacks.

The number of days of hospitalization due to asthma in France per year is of an average of 840000, which represents an expense that ranges between180 to 210 million Euros. This figure does not take into account the expenses for drugs and those for sojourns in climatic and thermal cures, neither the induced costs (loss of a work day, absenteeism, etc.). The overall cost claimed for asthma is assessed each year in France to one billion Euros. (Grimfeld Alain, Dusser Daniel, Eveillard Anne, 2007:12)

In Great Britain an extent study was done on this disease, which showed that at present far more children die because of asthma than ten years ago, although the overall infant mortality declined by almost one quarter. In Great Britain, there are over 3 million asthmatic children. More than a half of the children hospitalised suffer from asthma and their hospitalization costs the British health service around £ 107 million annually. Hospitalizations for severe cases of asthma have tripled, but in the case of children these have increased five times. (Ridgway Roy, 2009:8)

Asthma is one of the most common diseases that affect people of all ages and it is also the most common chronic diseases (long term). In Great Britain, in 2005, there were over 5 million people (about 8% of the population) who were treated for asthma, and 8 million (about 12% of the population) were diagnosed with asthma at some point in their lifetime. It is a disease that

expands constantly and increasingly more people become asthmatic, and patients with asthma have more and more crises. Nowadays, the incidence of asthma is four times higher in adults and six times higher in children than it was 25 years ago. Only in Great Britain over 1500 people die of asthma each year.

In England and Wales (country with large oil reserves), of all cases presenting to the doctor, almost 70% are children under the age of 5. For comparison, for the population between the ages of 45 and 65 this figure is only 22% (to mention is that this figure may slightly be exaggerated when one considers that parents take their children to the doctor more frequently than older patients go to the doctor). (Youngson Robert, 2005:12)

The toxic effects on the developing embryo or foetus during development are of profound concern. Beyond the obvious congenital malformations, scientists express their preoccupation for mother's exposure during pregnancy to certain toxic substances in the atmosphere that can have a negative impact on the health of the child. Then, infants and young children, often but not always present a higher sensitivity to toxic substances in the atmosphere than adults, this being due to the fact that their immune system is incompletely developed thus being less protected against these harmful substances. Another explanation of this phenomenon is given by the fact that underage individuals, breathe faster than adults. So, if the air is polluted, they inhale a larger amount of emissions. For example, a child in an industrial city inhales on average of 110 ng benzopyrene, an amount equivalent to smoking three cigarettes a day. So, statistical data strongly highlight the evidence that pollution is a significant cause in increasing asthma and allergies rates especially among children in urban areas of the developed countries. (Hill K. Maquita, 2010:80)

Another example is the Tower Hamlets district in East London. Children in this area are exposed to high levels of air pollution and the hospitalization rate for asthma in the local hospital was 80% higher than the national average. Pollution comes mainly from motor vehicles and the industrial area nearby. The reason for which these pollutants affect asthma prevalence is becoming increasingly clear, many of these substances released into the atmosphere, together with ozone under the action of sunlight destroys the cilia on the surface of the air tubes. (Youngson Robert, 2005:12)

Figure no. 1. Asthma morbidity degree at national level

Source: The Global Burden of Asthma, available online at: http://chestjournal.chestpubs.org/content/130/1_suppl/4S.long, accessed on 30.10.2011

In United States, the situation is similar. According to US National Heart, Lung and Blood Institute, asthma affected in 2009, 12.4 million of Americans, a number that was almost the double that was registered in the 1980s, when 6.8 million persons were registered. (Ridgway Roy, 2009:8)

In conclusion we can say that the economy has developed and specialized in various domains of activity and great economists were able to observe the pollutant effects of human activity. The damaging influences of environmental pollution in the recent decades are reflected on both

biodiversity and the human individual; harmful influences on the human individual can be seen in the biological conditions (diseases with an increasingly rapid evolution and death), in the disruption of the psychosocial framework and last but not least all the major economic implications due to the extremely high costs needed to cover health expenses, the costs of maintaining a balanced social structure and of an individual psycho-activity as close to mental health. For Romania, I noticed that the negative effects of pollution on the population register an upward trend, which is a heavy burden not only for the Romanian economy but also for each individual.

INNOVATION– AN INFLUENCE FACTOR OF CYCLICAL FLUCTUATIONS. STUDY CASE FOR ROMANIA, BETWEEN 1995 AND 2009

Pitorac Ruxandra Ioana
Faculty of Economics and Business Administration West University of Timişoara

Cismaş Laura Mariana
Faculty of Economics and Business Administration West University of Timişoara

The study of influence factors of cyclical fluctuations is of major importance for a country's economy. In the present context, of the new economy, where the emphasis is on new technologies, and information is the main product and resource of the economy, innovation is one of the most important factors among the ones which influence the economic activity fluctuations.

As part of a larger paper, this study is set to emphasize and explain the influence of innovation on the cyclical fluctuations in Romania between 1995 and 2009.

The following analysis indicators were used: the 'innovation' factor is represented by Research & Development expenses and by the number of people with internet access, whereas the economic activity fluctuations are represented by the fluctuations in the real GDP.

The research starts with the conceptual boundaries regarding innovation, with an emphasis on Joseph Schumpeter's theory, then, the influence of innovation on economic activity fluctuations is underlined through a quantitative analysis of the three indicators mentioned above and through an econometric model.

The results of the research underline Romania's economic status, the scale on which new technologies have entered the Romanian market and the way in which the fluctuations of the economic activity are closely linked to innovation.

Key words: cyclical fluctuations, innovation, Schumpeter, GDP, internet

JEL codes: E32, O31

1. Introduction

The impact of technological changes on the economy represents one of the current and representative subjects in economic research. Information and communications, including scientific and technological information have become a primordial component of the production forces.

The reduction of physical consumption is accelerated in favor of using information and knowledge, while investments in human capital are intensified, compared to investments in fixed assets. Moreover, the respective technologies have contributed to the improvement in productivity of the capital and work factors, which lead to a rise and diversification in production. Thus, they make up an important source for the creation of new products, services and jobs, first within their own sector, and then, through the expansion of production and exchanges, in other economic activities as well.

New technologies feature increasing efficiency (many products have a very high initial development cost, and then the respective products are sold at very low marginal prices; for example, the initial development of a computer program might be very expensive, but the cost of its copies is very low – in the case of the medium cost on which the software is recorded: CD, DVD, or sometimes zero – in the case of the internet), and this efficiency represents the engine of economic growth.

For all these reasons, the goal of the paper is to underline these innovations and the way in which they influenced the fluctuations in economic activity in Romania, between 1995 and 2009.

In the first part of the paper it is presented the importance of studying this influence factor and in the second part it is made a short theoretical review, with an emphasis on Schumpeter's theory of innovation, and identified the five Kondratieff cycles, with their great innovations. In the third part it is presented the work methodology and the descriptions of the data series, creating a multifactorial model that shows the influence of the studied factors on the real GDP.

2. Innovation – Conceptual Boundaries

J. Schumpeter considers that innovation is the fundamental factor that explains the evolution of economic life, it is at the basis of cyclical fluctuations, and without it the economy would work as a simple circular flow. A new idea inserted into the economy gives extra efficacy and progress and economic growth. Its curve peaks when the technical progress is mass spread, a point in which the technological mode of production based on past innovations has exhausted its capacity to create progress. This moment of tension is the descending phase of a cycle. The moment of crisis imposes the identification of new technological, economic and organizational possibilities. (Cismaş, 2000)

Innovation must be funded before the entrepreneur can benefit from its results, and funding is ensured, usually, through loans given by banks. Its effect spreads from field to field and one innovation generates another, influencing each other. Another feature is unpredictability, which means that not all the anticipated innovations will be successful and there will be a time when loans will have to be paid: if the companies will not be able to pay them, a wave of pessimism and chain bankruptcies will be created and there will be a recession which will effect a great number of sectors of the economy. (Schumpeter, 1939)

Schumpeter continues the ideas of the Russian economist Nikolai Kondratieff concerning long waves, according to which each cycle corresponds to a major innovation and thus the following cycles can be identified: (Valery, 1999)
- the first Kondratieff cycle (1785-1845) would correspond to the first industrial revolution, marked by hydraulic energy, the textile industry and the iron industry;
- the second Kondratieff cycle (1845-1900) would correspond to the innovations in the steam, railways and steel industries;
- the third Kondratieff cycle (1900-1950) would encompass the chemical industry and the internal combustion engine;
- the fourth Kondratieff cycle (1950-1990) would encompass the petrochemical and electronics industries and aviation;
- the fifth Kondratieff cycle (1990-2020) corresponds to digital networks, software applications and new means of communications.

As we can see, the Kondratieff cycles become shorter as they succeed one another. The first one lasted for 60 years, then the following ones for less and less: 55, 50, 40 and 30 years respectively. This 'acceleration' effect can be explained in three ways:
- we are experiencing a 'learning effect': companies and consumers pay attention to new innovations and adopt them immediately;
- the most recent innovations are network innovations, these have a tendency to develop exponentially, affecting all fields and causing a drop in unit costs due to scale economies;
- the nature of innovations is mostly immaterial, they spread rapidly, irrelevant of distance; in a global economy, innovation has no borders.

Innovations are accompanied by that which Schumpeter called 'creative destruction', a sort of 'economic storm' that engages the brutal disappearance of many jobs, while simultaneously creating an equal or greater number of jobs in other fields. This phenomenon is present in an economy with a high degree of flexibility. (Schumpeter, 1939)

Currently, the phenomenon of globalization, of Earth flattening under the influence of these new innovations is predominant. Thomas Friedman (Friedman, 2007) identifies ten forces which lead

to flattening: *(1)* the fall of the Berlin Wall, the birth of computers and the development of the Windows operating system, *(2)* the birth and development of the internet, through the concept of World Wide Web and the Netscape platform, *(3)* the development of workflow automation software, *(4)* the development of uploading, through blogs and open-source programs, *(5)* the birth of the outsourcing phenomenon, *(6)* off shoring, market liberalization, *(7)* the development of supply chains, *(8)* internalization, *(9)* getting information, through the more and more pronounced development of the internet, especially in the case of the Google, Yahoo and MSN platforms and *(10)* the development of the rural environment, of mobile phones, the birth of the iPad and the inclusion of new technologies into these devices.

3. Analysis on the influence of innovation on the economic activity fluctuations in Romania

In this paper, the period between 1995 and 2009 was chosen in order to ensure the compatibility of data, taking into consideration the change in the Romanian GDP calculation method, which was set to 'ESA 1995' in 1995. The data series used are taken from the websites of the National Institute of Statistics, http://www.insse.ro and of the World Bank, www.worldbank.org. Indicators: the gross domestic product and the research & development expenses are expressed in millions of lei and a conversion was made from current prices to constant prices (with the aid of the GDP deflator and the CPI - Consumer Price Index), and the number of internet users is expressed in millions of people.

Table nr.1. GDP and its influence factors

Year	Real GDP (mil lei)	R&D expenses (mil lei, constant prices)	Internet users (mil people)
1995	5781.5	4336.11	0.02
1996	6199.5	4215.63	0.05
1997	5456.3	3110.09	0.1
1998	4977.7	2439.08	0.5
1999	5085	2034.02	0.6
2000	5121.1	1894.82	0.8
2001	5545.3	2162.66	1.02
2002	5834.4	2217.08	1.45
2003	6571.8	2563	1.95
2004	7358.5	2869.82	3.27
2005	7885.9	3233.2	4.68
2006	8826.8	3972.07	5.35
2007	10162.5	5284.48	6.12
2008	11658.2	6761.77	7
2009	10683	5020.99	7.88

Source: drawn-up by the authors on the basis of data of the INS (www.insse.ro), and of the World Bank (www.worldbank.org)

In Table 1 we can see that the real GDP reaches its lowest level in 1998 (4977.7 million lei), after which it registers a slow increase, a recovery towards the value that it had before the drop, recorded in 1996. This happens only in 2003, after which the real GDP starts to rise, until it reaches its peak in 2008. The Romanian economy entered recession in the third quarter of 2008, along with the drop of the Gross Domestic Product and keeps registering falls in 2009.

The highest level of Research & Development expenses was recorded in 2008 (6761.77 million lei), and the lowest in 2000 (1894.82 million lei). Between 1995 and 2000 we can see a decreasing expense trend, and after 2000, an increasing one. Also it can be seen the boom of the

internet; the number of people with internet access rose exponentially since 1999, when only 20,000 inhabitants had access, to 7.88 million people in 2009.

Further on, we calculated the GDP Index, in order to emphasize the change of the indicator compared to the previous year. We performed the same operation for the R&D expenses and for the number of internet users.

Table nr.2. The dynamics of the real GDP and its influence factors (previous year=100)

Year	Real GDP Index	R&D Index	Internet Index
1995	100	100	100
1996	107.23	97.22	250.00
1997	88.01	73.78	200.00
1998	91.23	78.42	500.00
1999	102.16	83.39	120.00
2000	100.71	93.16	133.33
2001	108.28	114.14	127.50
2002	105.21	102.52	142.16
2003	112.64	115.60	134.48
2004	111.97	111.97	167.69
2005	107.17	112.66	143.12
2006	111.93	122.85	114.32
2007	115.13	133.04	114.39
2008	114.72	127.96	114.38
2009	91.64	74.26	112.57

Source: according to Table nr.1

A decreasing trend in the research & development expenses can also be seen (R&D Index < 100). From 1996 to 2001, the highest drop was recorded in 1997, 16.22% compared to the previous year. Similarly, in the same year, the real GDP registers the highest drop, of 12%.
Source: according to Table 2
Fig. nr. 1. The dynamics of the real GDP and its influence factors

The internet index has an ascending trend throughout the analyzed period, which can be seen in Table nr.2 and Figure nr.1. The highest rise was recorded in 1998, 400% compared to 1997. Afterwards, the rises were not as high, but they were constant, averaging 50% each year.

After each influence factor was interpreted separately, we will create a model that will show the influence of both factors on the real gross domestic product.

The way in which the economic activity fluctuations are influenced by research and development expenses and by the number of people with internet access, between 1995 and 2009 were calculated with the aid of a regression, through a multifactorial econometric model with the following form:

GDP = α + β1 * R&D Expenses + β * Internet Users + ε (1)

	A	B	C	D	E	F	G	H	I

Source: made by authors
Fig. nr. 2. The Multifactorial model of the influence factors of the GDP

In the econometric model we can see that:
- Multiple R is 0.99, which shows a very strong link between the GDP and the research & development expenses and the number of people with internet access;
- R Square is 0.99, meaning that 99% of the GDP variation can be explained by the influence of research & development expenses and of the number of people with internet access;
- the resulting F value is 628.7, much higher than the critical F value (2.483), which means that the econometric model is correct;
- the estimated value of α is α is 3638.9, the estimated value of β1 is 0.56 and of β2 is 567.38;
- the t Stat value associated with α is 20.85, higher than the critical t value of 2.144, the t Stat associated with β1 is 9.29 and of β2 is 18.15; all the values are higher than the critical t value, which means that all the mentioned factors are in the model.

This model shows a strong link between the real GDP and the factors taken into consideration. Thus, the multifactorial econometric model in the case of Romania between 1995 and 2009 has the following form:

GDP = 3638.91 + 0.564*R&D Expenses + 567,382*Internet Users + ε (2)

4. Conclusions

The internet plays an important role in the spread of knowledge in economy (Choi, 2009) and as an indicator of innovations it has an effect on economic activity fluctuations.

This research was made for the period between 1995 and 2009, during which the Gross Domestic Product was analyzed in correlation with the innovation influence factor, represented by the following indicators: Research and Development expenses and the number of people with internet access in Romania.

The main results were: *(1)* identifying the economic activity fluctuations by studying the real GDP in relation to the other factors, thus two periods during which the GDP dropped were noticed: 7% and 9% in 2009 and 1998 respectively; *(2)* interpreting the influence factor 'innovation' through internet users, noticing that in 1998 their number recorded the highest increase, of 400% and that throughout the studied period it had a rising trend, and through Research & Development expenses, which had an decreasing trend until 2000, then started to rise and *(3)* the correlation of the real GDP with the two studied indicators in an econometric multifactorial model, having as a result a strong link (0.99), thus an influence of innovation on cyclical fluctuations.

THEORETIC INCURSION IN THE IDENTIFICATION OF DETERMINANTS AND E-GOVERNMENT STRATEGY. EMPIRIC STUDY OVER THE GRADE OF IMPLEMENTATION OF E-GOVERNMENT IN BIHOR COUNTY

Pop Cohuţ Ioana
Faculty of Economics
University of Oradea

Abstract
We are currently witnessing an unprecedented development of new technologies, that offers great opportunities for the modernization of the society, it changes radically the way governments, businesses and citizens have the opportunity to obtain goods and services, the way in which public services are provided that become increasingly important for citizens, the way of obtaining and transmitting information, the way in which business connections are done, the interaction between different communities, etc..
From this point of view we research the way in which public strategies of achievement and implementation of model of e-government are shaped, model which can exploit the opportunities offered by new technologies and can implement roles for the citizen and public policy makers and implicitly of local and regional development. How the public sector should support the implementation of strategies of e-government, to polarize at the highest level all communities of interest, to provide a framework for planning and action across the board, covering local administration, institutions, organizations and government agencies, to empower appropriate training for implementation of IT strategies, can lead to stimulation of generators factors of local and regional development.
We also, intend to identify, from carrying out an empirical study in Bihor county, by analysis of 30 public institutions, the degree of implementation of new technologies in public administration, human resources readiness for appropriate use of IT facilities and what level of implementation of e-government in these institutions, in order to outline the main characteristics and determinants of e-government implementation.
The present paper is of interest to policy-makers, researchers, local communities through analysis how the introduction of new technology development in developing and implementing public policies, particularly by networking government and e-government, can cause local and regional development and change perceptions about the relationship and the interaction between citizens, communities and local and national authorities.

Key Words: networking government, e-government, regional and local development, public policy, new tehnology

JEL Codes: O38, D78, D85, R58

Theoretic incursion in e-government

E-government represents the process of transformation of the relationship that the government/administration has with the citizens and the business environment, through using the information technology for improving the efficiency, effectiveness, transparency, responsibility and the supply of public services (Kraemer and King, 2003).

The main determinants with positive impact over the assimilation and implementation of e-government are: the information technology expertize – the grade of specialisation and organisation of IT that to be able to assure constantly support and adapt to the needs of organisation; the support for top management, that sustains the implementation of some new technologies and to motivate and direct the employees behaviour to participate at the assimilation of e-government; organisation compatibility, that refers to the extent to which the IT technology is perceived as being compatible with current practices; regulations regarding the environment and competition that can exercise coercive pressures to adopt innovation and assimilate e-government (Pudjianto, B. and Hangjung, Z. 2007).

The EU strategy in the field of e-government is created in the „E-government Action Plan", plan created to offer a support to governments / public administrations to respond to the services demand came from the citizens and from the business environment, in the direct purpose of reducing bureaucracy and increasing the transparency of information and services offered to the population. The „E-government Action Plan" is focused on five priorities as can be seen in Table nr. 1. **EU's E-government Main Policy Strategies Strategy Description**

Table nr.1 EU's E-government Main Policy Strategies Strategy Description

1. Inclusive e-government
Governments at national, regional and local levels, together with their agencies and other intermediaries (NGOs, civil societies, volunteer associations, and the third sector in general) which deliver public services, are increasingly integrating ICTs into their processes, both behind the scenes and in their interfaces with the public. Whilst e-government services should reduce the complexity of citizens' and businesses' dealings with government and its intermediaries, there is a danger that people without easy access to ICTs could find it even harder to deal with government.
2. Efficiency and effectiveness
E-government significantly contributes to high user satisfaction, transparency and accountability, a lighter administrative burden and efficiency gains. Improving efficiency and effectiveness in any kind of activity requires knowledge of the current situation and specific targets for improvement, often set by comparison with counterparts seen to be "doing better" in a particular area. In e-government, the EU is taking a leading role in developing measurement techniques and benchmarks against which organizations can judge their performances. The EU fosters the deployment of efficient and effective e-government services with a two-pronged strategy. It promotes co-operation and exchange of best practice and technical standards through the benchmarking and impact assessment of services.
3. High-impact key services for citizens and businesses
The Action Plan aims to make high-impact services for citizens and businesses more widely available, such as electronic procurement services for businesses, services for mobile citizens, or social security services. E-government will be critical to enable service providers to take advantage of market opportunities outside their home country.
4. Key enablers
The plan also seeks to put in place key enablers which provide the foundation for e-government systems to work together, and to build the connections between ICT systems in different public organisations and countries. Interoperable systems, electronic identity management, document authentication and archiving technologies are all critical for public services to co-operate and share data. Open Source Software can provide a cost-effective method to support such interoperability and co-operation.
5. E-participation
In order to reinforce governance in Europe, the Action Plan will help to strengthen citizen participation and democratic decision-making (e-participation) by using new technologies to develop interfaces between democratic institutions, public bodies and citizens.

Source: *E-government factsheet European Union (November 2008 Edition 1.0) http://epractice.eu*

Every EU member state implements the European strategy in a particular context. The studies referring to the implementation of e-government in EU, realised especially for developed countries as Austria, Great Britain, France, Sweden, Norway, Germany, Spain, Portugal, Holland and Italy, reveal the fact that the most usual services offered on-line to the citizens, monitored by the European Commission to measure the grade of growing of the offer of on-line public services are (European Commision, 2008): Income Taxes, Social Contribution for Employees; Job Search,

Social Security Benefits, Personal Documents, Car Registration, Application for Building Permission, Declaration to the Police, Public Libraries, Birth and Marriage Certificates, Enrolment in Higher Education, Announcement of Moving, Health-related Services, Corporate Tax, WATT, Registration of a New Company, Submission of Data to the Statistical Office, Custom Declaration, Environment-related Permits, Public Procurement.

The maturity level of the implementation of e-government can be quantified after the model proposed by the European Commission (European Commission, E-Commission, 2005), a model that includes four levels as follows: *the first level* – a simple site, that indicates the institution's online presence and provides some information about public policy; *the second level* - on-line government, characterized by the emergence of simple forms of interaction between citizens and institutions; *the third level* - integrated government associated with the automation of some parts of the administration and rethinking processes and administrative structure so that electronic components are embedded, not only adapted to the day to day activity; *the fourth level* - government transformed phase in which "there is no need for printed forms and administrative processes are automated from end to end ".

Studies realized on the subject of the adoption of e-government have been concerned with measuring the implementation of e-government principles and the impact it has upon providing online services, both for governments and for citizens and businesses (Brown, 2007, Moon and Norris, 2005, West, 2004). The impact of new technologies in the administrative sector helped not only to improve the way of offering services to citizens, but also to increase the information transparency and reduce corruption and increase business competitiveness (West, 2004; Von Haldenwang, 2004).

Also, studies undertaken on the degree of digitization of public institutions providing online public services revealed that there is considerable heterogeneity between different EU countries (Caldas et al, 2005, Torres et al (2005), Capgemini, 2007). Also, significant differences have been identified at the level of regions within the same country. In other words, not all institutions have the same degree of implementation of e-government, even if we speak of the same country.

Empirical Study on the degree of implementation of e-government in Bihor County
The research methodology

To emphasize the role of e-government in the implementation of local and regional development strategies we considered significant as a first step in our analysis, to identify the degree of computerization of local institutions, more exactly, were analyzed a total number of 30 public institutions in Bihor County and the degree of the e-government principles implementation. In this respect has been conceived a questionnaire answered on one hand by the employees of public institutions and on the other hand by managers of the public institutions analyzed. The main issues we wanted to highlight in our study on information system were the skills of employees using IT equipment and their participation in specialized training courses, degree of novelty and diversity of software that employees of public institutions use in daily activities that are ongoing activities for which they use the IT equipment in the institutions, insofar as it uses its website to disseminate the information of public interest, which is equipped with the IT equipment available to the public institutions, which are services offered online to the citizens.

Working assumptions

To analyze these issues were established the following assumptions:
- Endowment with IT equipment (hardware and software) of municipalities is poor especially in terms of the software used;
- Reduced training of staff into the proper use of IT facilities in public institutions;
- Poor digitization of information available to citizens especially in rural areas;
- Achievement of only the second level of maturity of e-government system.

Interpretation and validity of the working hypotheses

As results of carrying out our research, the data obtained was analyzed and interpreted, the working hypotheses were validated and were verified and the conclusions were outlined.

Regarding the assumption that the *"endowment with IT equipment (hardware and software) of municipalities is poor especially in the software used"*, this hypothesis was not confirmed, especially in terms of endowment with computers. Public institutions are equipped with IT equipment from a minimum of 7 computers to a maximum of 280 computers, all with Internet access. As it regards the configuration of the software used on computers, this part of the hypothesis is confirmed, because the configuration of the computers is good, 55% are equipped with Pentium 4, Windows XP 38%, 7% have a poor configuration, while 33.62% do not give their configuration. With respect to the software that employees of public institutions use daily, the answers show that programs with the highest frequency of use are Word and Excel. In addition they also use special characteristics of each post. 30.32% of respondents use only Word, while 33.61% use both Word and Xcel, and a share of 36% use other special programs: FoxPro, Mozilla, Firefox, SOBIS (accounting, taxes, welfare , register agriculture), Saga (accounting), mapping programs, programs for calculating taxes, registration and licensing software transport, registration certificates, etc.

The assumption that *"the human resource readiness on the proper use of IT facilities in public institutions is reduced"* – was not confirmed - the managers of public institutions claim that subordinated employees that use IT equipment at a rate of 67.79% have taken specialized training course, have qualifications in the use of IT equipment, 22.03% have even ECDL certification, 3.38% attended special courses and only 6.77% have no training in the field of use of equipment and courses. Regarding current activities in public institutions employees using IT equipment, showed that almost half (49.18%) of respondents use the computer daily for writing documents, reports, record keeping, administrative, accounting for 17.21% is used for correspondence, documentation Internet, sending and receiving data, 17.21% use it for payroll, monitoring, statistics, statements, setting local taxes, record keeping, 16.39% is used in public relations, preparing reports of social services, essays, social problems.

The assumption according to which the *"digitization of information available to citizens is poor, especially in rural areas"* - is confirmed. Information available electronically to citizens is relatively low. Almost half of respondents (44%) say they recommend the institution's website to download documents, 7% do not recommend this option to access printed documents, and 4% said that the website of the institution does not provide to citizens such documents.

The hypothesis regarding the *"achievement of the second level of maturity (four levels by the European Commission) of the e-government system"* - is confirmed. Analyzing the maturity level of implementation of e-government model proposed by the European Commission, the information collected through the questionnaire applied to the 30 public institutions confirms that the maximum level of e-government achieved in Bihor County is level two. All 30 municipalities included in the sample presentation have a site of the institution and provide general information about projects and services. A number of 12 have forums or section meant for problems notification, 25 have electronic bulletin board, 13 municipalities' web pages offer the possibility of downloading document templates, 12 have links to institutions, 26 have functional mail address, and on 19 web pages can be found activity reports and the budget of the institution. Of the 30 institutions analyzed 5 offer online services. Although they exist, are relatively small in urban areas (online payments, fees, taxes, filing petitions, petitions filed verification stage, download forms, programming marriages and identity documents10.2%, the possibility of on-line payment of taxes is found on 6.8% of the municipalities questioned, 1.7% use it for correspondence, 1.7% for information, 1.7% for their own page, 1.7% for checking the situation regarding the payment of taxes) and almost nonexistent in rural areas.

Conclusions

Using the data obtained from 30 public institutions from Bihor county, we evaluated the grade of IT endowment, the endowment with software necessary for processing and analysing the data, the grade of human resource training as well as the grade of development and implementation of e-government. In this process, we noticed that the number of public institutions that offer on-line services to citizens is small, and the services offered are generally speaking: on-line payments, taxes, contributions, petition, the checking of the stage of petition, form downloading, marriages appointments and identity cards, correspondence, etc. Our brief study over the grade of implementation of e-government in public institutions in Bihor county reveals the significant discrepancies in the endowment and utilisation of new technologies for offering citizens service, especially between public institutions from urban areas and those in rural areas, between small urban areas and the county residence.

The data obtained confirm that the development of e-government in Bihor county is at an early stage, and this gradual process can be implemented using the current IT structure and endowment within public institutions, but must be completed by the implementation of an overall strategy, led by managers with a global vision who can motivate and coordinate employees in the principles of e-government. By the other side, this process can be accelerated by the direct demand of citizens and of business environment, which ask more frequently for this type of services in this period. The higher the efforts and pressure from citizens and business environment are for the extension of online services, the greater are the required skills and investment of government in new technologic equipment. These actions will also require increasing concerns for human resource training at all levels, improving quality and accessibility of digital networks by increasing expertise, growing concerns for improving efficiency of public services and transparency of information which will determine the reduction of bureaucracy and corruption in future.

CONSIDERATIONS REGARDING ROMANIAN HIGHER EDUCATION GRADUATES

Popovici (Barbulescu) Adina

West University of Timisoara Faculty of Economics and Business Administration Contact address: Strada J.H. Pestalozzi, Nr. 16, 300115 Timisoara, Romania E-mail: adinap_12@yahoo.com Telephone: +40 256 592506

The paper aims at analyzing the dynamics of in Romanian higher education graduates in the 2006-2010 period, both in Romania and by the Romanian development regions.

After highlighting the importance of human capital and its education, the paper analyzes the dynamics of Romanian higher education graduates in the targeted period, at both of the above-mentioned levels.

The conclusions reveal that, during the analysed period: 2006-2010, the number of female, and, respectively, male higher education graduates, as well as the total number of higher education graduates, continuously increased in the 2006-2010 period at the whole country level and registered an increase trend, as well, by the eight development regions of Romania in the 2006-2010 period, with very few exceptions in some years of the period, in some of the the eight development regions of Romania.

Therefore, the Romanian higher education system must correlate the graduates number with the number of work places in the Romanian economy, and take into account the necessities imposed by the participation at international competition.

Key words: knowledge-based society, economic growth, human capital, education, higher education graduates

1. Introduction

Throughout the modern history, all countries of the world have been focused on economic development. Contemporary world comes back to the real purpose of economics, the human being, assuring his welfare and security, both at individual and social level. Thus, it appears on the ideas level a new conceptual paradigm, that of human development, which accompanies and motivates the economic one. This new paradigm has obviously not manifested itself instantaneously, but has developed as a slow, difficult and deliberate process. The rapid rhythm of changes has convinced both the business people community, and the nations, that labour force flexibilization is necessary. Each sector of activity, including the agricultural one, needs a permanent qualification up-date, combined with the accumulation of action knowledge and competencies. This irreversible trend represents a proof of the increasing importance of some ''intangible'' points in the investments field – such as education – while the effects of the ''intelligent revolution'' are being felt. In this case, investment in education becomes a strategic investment (Popovici 2011: 193). As Jacques Delors, the president of the International Commission foe Education states: ''*In the 21st century, educational systems must educate in an innovating spirit, promote the capacity of evolution, adaptation to a fast changing world, that each individual should be capable of assimilating*'' (Ciobanu 2003: 15).

2. The Importance of Investments in Education and Health

Human capital consists in those people's skills, which are characteristic to them and remain the same in any social environment and can be used on the labour market, in exchange for economic resources of any type. Practically, *the human capital* is composed of:

- *the educational capital*, represented by the skills acquired by individuals during and outside the education process, and

- *the biological capital*, represented by the individuals' physical skills, the most often synthesized by their health state.

Human capital has developed itself as a concept in economy, where it is mainly regarded as "estimation of a person's ability to produce income by labour".

The human capital treatment as investment has generally imposed itself, the abilities human capital is composed of could practically be used anytime, in function of the social and economic environment, in which individuals could place themselves at a certain moment. More, this investment is continuous, aiming either the development (the perfectioning courses or continuous education, for instance), either the maintenance of the capital stock (periodical medical consultancies, for instance) (Cismas and Popovici 2011: 57).

The importance of education and health for the economic growth and development is due to the returns from investments in the two variables. These are two forms of human capital, the improvement of which should enhance worker's productivity. Several studies show that better health, special early in life, is associated with higher educational attainment. Conti et al. (2010) argue that more educated individuals, in turn, have better health later in life and better market prospects. According to the authors, education has an important causal effect in explaining differences in many adult outcomes and health behaviours (Conti, Heckman and Urzua: 2010; Carlei et al. 2011: 174).

Economic growth during the transition period had a particular pattern in CEEC. Capital has provided a certain positive contribution to growth, while labour had a small or even negative contribution (IMF, 2006). In this respect, CEEC stand out among other emerging countries, where labour input has typically contributed substantially to growth. Most of the growth during the transition period was actually accounted by the increase in total factor productivity (TFP). Even though the classical source of TFP growth is technical progress and innovation, growth during transition was mostly explained by efficiency improvements in the use of capital and labour (Havrylyshyn, 2001; Jude and Pop Silaghi 2011: 72).

Starting in the late nineties, CEEC experienced a return to the classical factors determining growth, with an increase importance for innovation and technical progress. Once the transition period completed, the growth process in CEEC should be sustained by factors like capital intensity, innovation, human capital and competition (OECD, 2003; Jude and Pop Silaghi 2011: 72).

3. Romanian Higher Education Graduates in Figures in the 2006-2010 Period

Professional insertion of young people has lately become, both in Romania and in the European Union, a difficult process, which requires an increasing period of time from the moment of finalizing the last form of education, until the moment of finding a work place (Popovici 2011: 194).

Today exist in the world about a billion young people with the age ranging between 15 and 24 years old, 85% of them living in developing countries. The participation rate on the labour market among young people has decreased at a world level from 59.3% to 54.4% during 2004-2010, mainly because of the prolonging of studies among young people. In the European Union currently live about 62 million young people, which represent 12.7% from the total population. According to the data supplied by the National Institute of Statistics, there is a decreasing trend with regard to the evolution of young population until 2025. This evolution may

be explained by the decrease in the birth rate, the increase of the period and level of education, the social mobility, women's emancipation (Popovici 2011: 194).

The statistical data show that Romania, like other EU countries, faces a major problem of the labour market, i.e. young people unemployment. The unemployment rate among young people is three times higher than the average rate (20.8% as compared to 6.9% in 2009). The high level of employment among young people should be an important reason in applying some active policies that should aim at this vulnerable category. Within this group of unemployed people we usually find people who are not involved in training activities, graduates from high school, occupational schools, as well as graduates from university immediately after graduation (Herman and Dalalau 2011: 343).

Romanian Development Regions have no legal personality, being not subject to administrative law, but the result of concentration achieved at intercounty level, corresponding to NUTS II division of the European Union. By agreement of the local councils and county councils four macroeconomic development regions have resulted, in conformity with NUTS I division of the EU, each of them being composed of two regions, so there are 8 development regions across the country. The main objective for establishing these regions is to access EU funds in a unified manner and to achieve an integrated development of infrastructure projects at regional level (Avram anf Pociovalisteanu 2011: 46).

Table no. 1. The Number of Female Graduates in Romania and by the Romanian Development Regions in the 2006-2010 Period

Region / Year	2006	2007	2008	2009	2010
Romania	462740	520709	595369	618096	671696

Source: Eurostat
Fig. No. 3 The Total Number of Graduates in Romania and by the Romanian Development Regions in the 2006-2010 Period in Romania

Source: Eurostat

As Table no. 3 and Fig. No. 3 highlight, the total number of graduates:

- continuosly increased in the 2006-2010 period at the whole country level;

- registered an increase trend, as well, by the eight development regions of Romania in the 2006-2010 period (with very few exceptions in some years of the period, in some of the the eight development regions of Romania).

4. Conclusions

The conclusions reveal that, during the analysed period: 2006-2010, the number of female, and, respectively, male higher education graduates, as well as the total number of higher education graduates, continuosly increased in the 2006-2010 period at the whole country level and registered an increase trend, as well, by the eight development regions of Romania in the 2006-2010 period, with very few exceptions in some years of the period, in some of the the eight development regions of Romania.

Therefore, the Romanian higher education system must correlate the graduates number with the number of work places in the Romanian economy, and take into account the necessities imposed by the participation at international competition.

Knowledge-based economy requires both in Romania and internationally, the presence of intelligent organizations, with advanced management capabilities of their collective skills, as sources of performance. As a result, worldwide, more than ever, knowledge is accepted as one of the main sources of competitive advantage.
Small and medium sized enterprises (SMEs) are the most dynamic and vital factor of progress in the contemporary society, main generator of economic performance and substance in any country, employment opportunity provider for most of population, major contributor to the national budget, and engine to improve the living standard of the population.
SMEs represent 99% from all enterprises, drawing up the main human resource agglomeration. In this context, knowledge-based management approaches are inevitable, arising from systemic complexity that goes beyond the rigid hierarchies and traditional practices and entails the emergence of non-hierarchical organizational structures.

Keywords: knowledge-based management, small and medium enterprises, managers, tourism

The article's JEL code: M3, M31, L81

Introduction

Research shows that learning activities, carried out individually, are not transferred, with ease, at the organizational level (Garratt B. 1999, pp.202-207). On the other hand, new technologies available inside the organizations allow their employees to work, think and act globally (Massey C., Walker R. 1999, pp.38-47), but also to innovate, at a scale and pace out of reach until now (Carroll J.S. 2008, p.57). Today, worldwide, all great managers recognize that in order to collaborate and to lead effectively, we need a completely different type of management (Bar-On R., Elias M.J. 2007, p.64), different from the one based on the authority that comes from the hierarchical scheme of the company (Torbert W. 1994, pp.57-70).

To develop tools, techniques and systems capable of allowing organizations to overcome these limits and to fully benefit from a performing management (Reuchlin M. 1989, p.19-32), adapted to the global knowledge economy era (Pemberton J., Stonehouse G. 2000, pp.184-193), all these organizations need complex research, adapted to the cultural and economic reality (Osborn A.-F. 1999, pp. 113-129), research integrated with a solid theoretical basis (Simonin B. 1997, pp.1150-1174).

As a result, worldwide, more than ever, knowledge is accepted as one of the main sources of competitive advantage (Harvey, Denton J. 1999, p.897-918). In this context, the ICT spectacular development influenced decisively the capacity of organizations (Daft R., Weick K. 1994, pp.284-295) - regardless of their size - to acquire, store, use and disseminate knowledge (Palmer J. 1999, pp.34-56).

Like the knowledge-based economy, the knowledge-based management is a relatively recent concept in the vocabulary and mental models of practitioners (Swieringa J., Wierdsma A.F.M. 1992, p.45-68); it appeared in response to the many challenges of the organizational change (Pedler M. 1999, pp.537-540).

Since the 90s, the learning organization has become synonymous with performance and sustainable success (Vygotski L. S. 1998, pp.41-43), being a model for an organization continuously concerned about knowledge-based management and adapting to the environmental changes and shaping its internal structure depending on this external environment (Hedberg B. 1999, p.3-27).

The Romanian organizational environment has not taken exception from the global trend of orientation towards knowledge but due to the lack of strategic options (Addicott R., Mcgivern G., Ferlie E. 2006, p.87-94), the tendency manifested unsystematically (Elkjaer B. 2001, pp. 437-452), and especially in the informal plan.

To ensure feasibility of organizational learning projects in the Romanian context requires joint efforts of the information technology (Landau S., Everitt B.S. 2004, pp.234-256) together with an adequate managerial and educational support (Ferry G. 2005, p.59-73). In this context, at national level, the following are very important:

(1) Form and train the human resources with skills in the knowledge-based management and related fields (Uit Beijerse R.-P. 2000, pp.94-109);

(2) Official recognition of new professions and occupations related with the knowledge-based management and organizations (Dibella A., Nevis E. 1997, pp.178-257).

Knowledge-based management requires both in Romania and internationally, the presence of intelligent organizations, with advanced management capabilities of their collective skills, as sources of performance (Chivu et al. 2009, p.36-78).

SMEs represent the most numerous and important category of enterprises, with multiple economic, technical and social functions (Popa et al.2009). SMEs are the most dynamic and vital factor of progress in the contemporary society, main generator of economic performance and substance in any country, major contributor to the national budget, and engine to improve the living standard of the population. Representing 99% from all enterprises, SMEs are drawing up the main human resources agglomeration. Furthermore, SMEs generate the most of Gross Domestic Product (GDP) in every country - usually 55%-95%, provide employment for most of population (Popescu et al. 2010, pp.46-50).

In the context of The European Union forming a group of countries with the most intense concerns and performance in supporting and encouraging SMEs (Bancroft N.H. 1996, pp.41-57), knowledge-based management involves an uniformity of managerial practices and organizational behaviours (Smith-Easterby M., Lyles M. A. 2006, pp.145-153).

Investigating the correlation between managers approach to motivating the human resources and organizational activity performances, represents the start-up of a research that could lead us to results to be developed afterwards (Moilanen R. 2005, pp.71-89). For instance, the influence of superior-trained and well-motivated human resources on the SMEs outcomes (Leleu P. 1995, pp.178-235), can be extended to the influence upon the economy service sector.

Main objective of the paper:

The present paper aims to analyze, as a consequence of managers opinion regarding the knowledge-based management concerning the compatibility between positively motivated employees and superior performances of the SMEs they belong to.

Research Methodology

The methodology used is a logical consequence of the research questions applied within the survey, representing a first step in choosing the qualitative/quantitative approach. For our research, the key question is: In what measure managers from the SMEs that activate in the field

of tourism consider that positively motivated employees determine highly organizational performances (as a result of knowledge-based management practices)?

We have chosen the qualitative path as it refers to managers opinion upon employees motivation-employees performance connection.

Acknowledging the importance of knowledge-based management and SMEs performances, we realized a study on a sample of 117 respondents that belong to SMEs from tourism domain, both in Romania and Spain: Accommodation, Restaurants, Passenger Transports, Travel Agencies and Cultural Tourism Organizations, from different regions of the two countries taken into consideration, measuring 19 variables. The results are based on a study performed in September and October 2010 in different regions of two European Union's Country members (Romania and Spain) and confirm the research hypothesis regarding the knowledge management and its contribution to SMEs performances.

Research design: in fundament the research, we have taken into consideration the numerous answers received from the 117 respondents. Each question was formulated in order to answer, directly or indirectly to the research hypothesis. The questionnaire includes general, easy-to-answer, closed questions, in order to make the tasks easier for the respondent. A second part is reserved to issues regarding the SMEs profitability and economic performances and the third part refers to human resources performances. The main purpose of the research is strongly connected to the answers received from the second and third part of the questionnaire.

The first set of questions (1-6) is indirect ones, related to the purpose of the research. They refer to organization size, tradition and other factors that may influence the basic features of the organization dimension and activity. Their purpose is to fix the analyzed entities into a specific, determinate area of investigation. In this context, we appreciate those basic factors as market experience, number of employees or field of activity, may influence, in different ways, the quality and the work results of the employees.

The second part (questions 7-14) aims to get indirect answers in order to establish human resources work outcomes within the organization (expressed by the productivity evolution).

Third part of the questionnaire (questions 15-20) is directly related to human resources practices (which is the managers opinion about the motivation alternatives) and to material and non-material stimulants and facilities given to employees.

First, the authors obtained the validity of the questionnaire on core values employed in this study. The initial version of the questionnaire was sent as a pilot survey to Spain SMEs in order to ensure the accuracy of questions relative to the core values. After completing the questionnaire, feedback was asked to managers for improving questions precision. Afterwards, a revised version of the survey was sent to Spain and Romanian SMEs.

The data was analyzed using Statistical Packages for Social Scientists (SPSS) 16.0 and yielded multiple results that are presented synthetically in the present paper. Therefore, the most significant results are highlighted, with a focus on the profile characteristics, and the detailed secondary correlations.

Work method: Primary data, through structured questionnaire, were collected from a sample of 117 respondents (response rate of survey: 56,80%), randomly selected from among the SMEs engaged in tourism types of activity. The survey elaborated by the researchers group consisted of 20 items. The research adopted a survey method to collect data on the SMEs general characteristics (field of activity, form of property, market experience, geographical position, legal form of organization), organization performance (turnover and profit evolution, tangible assets contribution, average number of services, organization's turnover structure, first three clients and suppliers importance), human resources performance (employees level of motivation, education, average number of training days, average wage, facilities for employees).

Results obtained

Some of the significant findings of the study tested under the Pearson chi-square assumptions are given below.

The importance given by managers to employees' social activities tends to decrease as the size of the organization becomes larger.

The importance given by managers to Social Processes is not distributed similarly across different Size of the organizations and small size enterprises are more likely to give importance to employees' social activities than bigger ones (Table 1).

The number of employees	Importance given to employees' social activities			
of the organization	Low	Average	High	Total
1-9	14.5%	61.3%	24.2%	100.0%
10-49	26.0%	64.4%	9.6%	100.0%
50-249	66.2%	21.5%	12.3%	100.0%
Total	35.5%	49.5%	15.0%	100.0%

Table 1: Importance given by managers to Social Processes

The use of planning techniques and knowledge-based management approaches in the organization is not correlated with the level of educational background (Business and Social Sciences – Other types of study). This dependent variable proved to be associated with the independent variable Specific Managerial Studies. The chi-square significance test measures the likelihood that the observed association between the independent variable Specific Managerial Studies Undertaken and the dependent variable Use of Planning Techniques is caused by chance and yielded a result of 0.001.

The information is provided in Table 2.

			Use of planning techniques		
			Yes	No	Total
Specific Managerial Studies	yes	Count	28	18	46
		% of Total	23,5%	16,0%	39,5%
	no	Count	28	43	71
		% of Total	22,0%	38,5%	60,5%
	Total	Count	54	63	117
		% of Total	45,5%	54,5%	100,0%

Table 2: Specific Managerial Studies and Use of planning techniques

A similar result was obtained for the dependent variable Use of career plan for employees, which has a chi-square significance test result 0.011 indicates in correlation with the independent variable Specific Managerial Studies. As in the previous case, the use of a career plan in the firm is significantly higher in the case of the entrepreneurs who benefited from some sort of managerial studies and trainings, beside their academic background (Table 3).

			Use of career plan for employees		
			Yes	No	Total
Specific Managerial Studies	yes	Count	12	34	46
		% of Total	10,5%	29,0%	39,5%
	no	Count	9	62	71
		% of Total	7,5%	53,0%	60,5%
	Total	Count	21	96	**117**
		% of Total	18,0%	82,0%	100,0%

Table 3: Specific Managerial Studies and Use of Career Plan

It was tested also the correlation of this dependent variable with the level of Academic Education of the managers and with the Field of the Educational Background, but the results were also not significant, which indicates that the use of knowledge-based management approaches linked to organizational strategy is influenced by another variable which can not be captured by a qualitative research and requires an individualized quantitative approach.

According to these definitions of the concept the main characteristics of *knowledge-based management* and their compatibility with the result of our study are the following:

- Provides continuous knowledge opportunities for its employees in the form of training or other employee development activities. 45% of the interviewed entrepreneurs said they offer some kind of internal or external training to their employees and there is an increasing trend in this direction, sustained by the entrance on the Romanian market of several international consultancy and recruitment organizations.

- Is continuously aware of and interacts with its environment, feature that can be translated into the acknowledgement of the importance to collect data from the environment and the interest for innovative information technologies. Although 56% of the organizations do not collect external data on a regular basis, 95% of the entrepreneurs are aware of the importance of the new communication and information technologies to the development of the firm.

- Links individual performance with organizational performance. In terms of Planning and Strategy, SMEs from Romania are still in an incipient stage. Planning is used to a higher extent in 45.5% of the cases, but a career plan for employees exists in only 18% of the firms and there is a small declared linkage of the human resources recruiting strategy to

organizational objectives. The management of the organization is in these conditions mainly intuitive and does not apply the rules and rigors found in large companies. By their nature, SMEs nurture with their reduced dimensions and small number of employees, the existence of a less rigid business work frame.

- Develops collective as well as individual knowledge approaches. This characteristic is also sustained by the fact that 75% of the entrepreneurs encourage the employee's involvement in other areas than those specified in their job description. A less favourable characteristic revealed by the study is that in SMEs the predominant way of working is still very individualist, the majority of the respondents (45%) neglecting the benefits of team work for the organization.

Conclusions

The international work experience provides the scientists with the opportunity of expanding their know-how and know-who, which in turn could bring important benefits for their organization and country of origin. Such benefits may consists in enhancing research productivity and quality, better connecting the internal research activity to the international scientific circuit and, ultimately, stimulating the national economic development, in general.

Considering the current problems in Romania's knowledge-based management approaches, any action plan directed towards scientists' repatriation may have limited impact. Therefore, in the short term, we recommend to stimulate and facilitate temporary, short-term collaborations between researchers and academic personnel in the country and their peers abroad. This can be done by: creating part-time jobs in universities / research laboratories for scientists residing abroad; organizing international conferences, symposia and workshops in the country concerned; inviting highly skilled migrants (and their foreign colleagues) to collaborate in projects in that country and so on.

In the medium to long term, a more radical approach should be adopted, for a better integration of the national academic and research system in the international scientific circuit. For a maximum efficacy, this approach should have both a financial dimension (adequate investment in research) and a "cultural" dimension (changes in mentalities, attitudes, criteria used for performance assessment, promotions, compensation etc.). Based on the participants' input, this is extremely important for enhancing the research sector and attracting scientists (both national and foreign scientists) towards Romania (and other countries faced with similar challenges).

INFLUENCE OF THE INVESTMENT DECISIONS ON THE RETURN OF THE COMPANY

Pop Mugurel Gabriel Sorin
"Dimitrie Cantemir" Christian University Bucharest Faculty of Economic Sciences of Cluj-Napoca

We propose in this study, to make an analysis of the influence of the investment decision on the return of the company. The goal of our research is the quantification of the influence of investment activity on profitability. Fulfilling such a goal has forced us to research the existing literature in this field, both in our country and abroad, ascertaining the existence of a unitary meaning of the criteria for investment projects' evaluation.
Of course, the realization of such research was possible only after close consideration of the opinions expressed in the relevant literature on this area.
Our research aims to be a theoretical-applied one. It is based on comparisons we make between the two criteria for assessing investment projects namely: that of net present value (VAN) and internal rate of return (RIR). By creating a suite of phase calculations, based on information from economic and financial documentation of corporate investments, we separated the influence of the policy investment decisions on profitability. We are convinced that the most accurate determination of the influence of policy investment decisions on profitability helps the financial management, facilitating the process of adopting the most appropriate policy decisions that ultimately leads to the objectives formulated by the financial policy.
The result of our research is the quantification of the influence of investment policy decisions of the firm on profitability.

Key words: politics, investment decisions, evaluation criteria, updated net income, internal rate of return, influence.

JEL Code : G 31

1. Introduction

Investment activity always involves risk taking to achieve a certain gain in the future, called the expected gain. The gain is called expected gain for reasons of uncertainty, as we don't know for sure what the result of the investment will be tomorrow, or next year.

With respect to investments in real assets, productive, the gain recorded by these can appear as a gain rate (usually the internal rate of return) and as the absolute value of earnings such as the net present value of cash flows generated by investment project over its period of life.

Given the influence of time factor for the development of investment processes, we could not ignore the update on future value on quantifying the effects and effort of the investments.

Through the conducted research, we tried to answer the question: to what extent do the investments affect the company`s profitability and, ultimately, its fundamental purpose, which is the maximization of its market value.

The research results and the conclusions that we reached show that investments are the major route of modernization of business activities, to strengthen the position on the market in the specific field of activity, to increase investor's confidence in the company's activity.

2. Methods of evaluation of investment projects

Whether we face the situation to determine the rate of earnings or its absolute value for a specific investment to be made, the values we work with can only be expected or estimated, as we face uncertainty about the value of cash flows that the project will generate in the future. If we can

determine a set of states or possible events to occur in the future by attaching probabilities to each of them, estimating the obtaining of certain cash flows, we are in the position to determine the expected gain of an investment. In other words, we can move from a non-quantifiable situation, defined by uncertainty to a quantifiable one, defined by risk.

Reputable economists (Flouzat and Pondoven 2004: 313; Helfert 2006:251; Cistelecan 2002: 319; Binţinţan 2005: 105; Todea 2006: 52), both foreign and national authors argue that, theoretically and practically, the most well founded and robust criterion for the selection of effective investment projects is the one of net present value = VAN, respectively, the added value that new investment projects "promise" to bring to the existing value of the company. Selecting the best investment projects will be made in relation to maximizing the net present value.

The added return that the investment projects with maximum VAN bring in relation to the normal rate of return will help to maximize the enterprise value, the property of investors and therefore, the realization of the major objective of the company. Complementary to net present value, the most efficient investment projects have also internal returns (RIR) greater than the average money market return, chosen as reference.

The evaluation of selecting the most effective investment projects appeals to the following model for calculating the net present value (also known under the name of updated net income VNA (Binţinţan 2005: 105)):

$$VNA = \sum_{h=1}^{n}[V_h - (C_h' + I_h)] \times \frac{1}{(1+a)^h}$$

where: - VNA - updated net income;
          - V_h – income in year "h";
          - C_h - operating expenses (excluding depreciation) in year "h";
       - I_h - investment in year "h";

       - $\frac{1}{(1+a)^h}$ - the update factor.

The condition of efficiency provided by a project in terms of this indicator is to accept all project versions whose VNA> 0, at an appropriate update rate.

Internal Rate of Return (RIR) - is that update rate for which the updated value of revenues equals to the updated value of costs, so the ratio revenue / cost is equal to 1 and the updated net income is zero. RIR calculation is done by successive approximations in the sense that we determine the VNA at an appropriate update rate, considered as minimum rate for which, the VNA must be positive. Then, we determine VNA at an update rate higher than the minimum rate and high enough to obtain an updated negative net income. Finally, the exact calculation of RIR (Binţinţan 2005: 105) is achieved by interpolation, as follows:

$$RIR = R_{min} + (R_{max} - R_{min}) \times \frac{VNA_{(+)}}{VNA_{(+)} + |VNA_{(-)}|}$$

where: - R_{min} - the minimum update rate;
          - R_{max} - maximum update rate;
          - $VNA_{(+)}$ - positive updated net income obtained at the minimum rate;
          - $VNA_{(-)}$ - negative updated net income obtained at the maximum rate.

As the internal rate of return is higher, the project is stronger, more viable and the economic efficiency is higher.

The efficiency requirement of a project, seen in terms of RIR, is that it should be higher than the updated rate required by the efficiency level currently existing in the economy. If there are more project versions with different internal rates of return, we will choose that option which has the highest RIR.

3. Determination of the influence of investment policy decisions on the firm profitability

Given the reasons above and taking into account the fact that following the economic and financial analysis of investment projects, the company will retain in its portfolio only those elements that meet the used efficiency criteria, we intend to show how investment activity of SC Alfa SA has influenced its overall profitability.

A special place in the company's concerns is occupied by the development and implementation of a rigorous and structured investment program. Through the investments included in this program the company has tried to answer the most pressing and current needs of production and marketing of their domestic and export products. Throughout the period under review, in the investment program, there can be performed a number of shaped upgrading works to buildings with directly productive and administrative spaces. A special place is occupied by the purchases of machinery and technological equipment of high technical level, aimed at the upgrading of the production flow, at raising the quality of products, at the absorption in manufacturing of new products and upgrading existing products.

Such an investment program of the company had as purpose the increase of the physical volume of production and of the quality level of products in terms of relative stability in sales prices (even if in the analyzed period the cost of utilities increased).

Our research intends to highlight how this program of investment influenced the increase of the overall economic efficiency of the firm and in a direct manner, the positive influence on financial profitability.

For this purpose, we used the model of computation based on the VNA and RIR on which we made some previous considerations.

To determine the internal rate of return on investments made by SC Alfa SA, we used the information taken from the technical-economic documentation of investment projects, carried out within the analyzed period.

After we watched on each investment project the net present values and internal rates of return, sizes calculated with the occasion of the decision to implement those projects, we proceeded to the calculation of average size of VAN and RIR for all the investments included in the program for each year of analysis of activity.

We synthesized (Table. 1) the information on the ongoing of the investment process during the review period:

Table no. 1

Summary of information on accomplished investments

Source: own calculations made, based on technical-economic documentation

We included in the above table the information on calculating the rate of overall profitability for possible future comparisons between total expenditure and investment expenditure, which have the same economic content. We note that in the company's total costs there are included the investment spending each year of the analysis period. Consequently, in the total income, there are included the incomes generated by the operation of realized investment.

Separating the two figures of sizes, and attaching them the appropriate returns, we obtain the following data (table no. 2):

Table no. 2

Information derived from the decomposition of indicators

Source: own calculations based on information from economic and technical documentation

Analyzing the data in the table above we can conclude that without achieving the ambitious investment program to which we referred earlier, the company had achieved a much lower return. The fact that the performance indicators calculated by us on the basis of technical and economic documentation of investment projects have been implemented in practice, almost to the pre-calculated level, have led to increasing the overall efficiency of the company and have generated returns in years when, without the investment, the return would be lower.

Comparing the return on investment activity (row 12 in Table no. 2) with the internal rate of return on investment (row 5 in Table no. 1), we see a consistent size difference in favor of the

latter. This is explained by the fact that while the overall return on the investment activity is calculated annually, by taking into account the operating expenses generated by investment, the internal rate of return is calculated once in the implementation year of investment projects and it considers the entire economic life time of new capacity into operation. In the size of the internal rate of return on investment there can be felt the influence of the fact that during the years of economic life, the functioning capacities touching in a relatively short time the designed techno-economic parameters, the effects arising from the investment are greater than the effort involved in the productive exploitation of a completed investment.

The pieces of information taken from Table no. 2 strengthen our conviction that aside from the beneficial effect on profitability, induced by the accomplishment of investments, the quantitative, qualitative and other factors influenced their action on the evolution of company`s profitability. Sometimes, the action of these factors is so intense that it can diminish the positive effects of investment on company`s profitability.

In order to try to quantify the positive influence of investment on firm`s profitability, we proposed the following data analysis (Table no. 3):

Table no. 3

Evolution of return expressed in coefficient

No.	Indicators	Symbol / Method of calculation	UM	The period of analysis				
				2007	2008	2009	2010	2011 preview
1.	Return rate of investment activity	Rri = Pni/Cexpl.i	%	-	27,05	23,56	31,23	20,29
2.	General Return Rate	**Rrg = Pn/Cht**	%	12,07	9,06	7,23	5,62	5,74

Source: own calculations based on data from previous tables
Chart no. 1. Evolution of overall profitability, of overall profitability rate (exclusively investment-related) and the profitability in investment activity

Analyzing the data presented in Table no. 3 and following the Chart no.1 of the evolution of indicators throughout the analyzed period, we can highlight two phenomena, namely:

645

- the high rate of return on investment activity (row 1 of table no. 3.) can be argued through the fact that the company agreed to achieve and to fund only the projects that have gone through the "mesh" of financial analysis;
- by comparing the rate of the overall profitability of business activity, excluding the effort and the related effect of investments (row 3 of table no. 3) with the overall profitability rate (row 2 of table no. 3), which includes the coordinates of the investment activity (effect and effort), we find a higher level of the latter. By considering the differences between the two levels of profitability in each of the examined years, we accredit on the positive impact of the performance of the company's investment program.

4. Conclusions

As we previously stated, on the overall profitability of the firm (and hence on the financial return) aside from the investment program, there are other incidental factors, which may exercise a positive influence, such as: fluctuation of exchange rates, fluctuation of interest rate, fluctuations of rates of stocks and bonds on the stock exchange market etc., whose direct influence on the financial profitability of the company is very difficult to quantify through econometric models. Therefore, as required by the economic and financial analysis methodology, which provides the positive influence on the interaction of factors on quality factor, we also affirm that this part of the positive influence can be attributed to the company's investment program implementation.

The positive influence of investment programs conducted by the firm is also due to the fact that the decision to invest was substantiated thorough market studies and based on the consumer trend in relation to the products of the company.

We can draw the same conclusions if we analyze the evolution of positive cash flows emanating from the investing activity. It is argued once again that investments are the main way of boosting the activity of firms and to improve all indicators which reflect the efficiency of the company.

IMPLICATION OF DECISIONS OF FINANCING POLICY ON THE FINANCIAL PROFITABILITY AND STABILITY OF THE COMPANY

Pop Mugurel Gabriel Sorin
"Dimitrie Cantemir" Christian University Bucharest Faculty of Economic Sciences of Cluj-Napoca

Stâneanu Gheorghe
"Dimitrie Cantemir" Christian University Bucharest Faculty of Economic Sciences of Cluj-Napoca

The present study aims at analyzing the influence of decisions on financing policy of the current activity on profitability and financial stability of the company.
Of course, the realization of such a research is not possible without a pertinent analysis on the concepts expressed in the literature of this field. In relation to this matter, we find that each author has his own concept about the subject under review. These expressed views, based on previous research, are related to the domain under analysis.
Our research is in the current phase, a theoretically applied one. It is based on the comparisons we make between different means of financing the company's current activity. We are convinced that an accurate determination of the influence of decision on financing policy on the profitability and financial stability, helps the financial management, by facilitating the process of adopting the most appropriate funding decisions.
Our research results are outlined in the information provided on financial management of the company that will lead to a better substantiation for decision-making policy-related process on funding.

Key words: policy of funding, decision, modalities of financing own resources, attracted resources, self-financing, leverage ratios, influence

JEL Code: G 32

1. Introduction

In the structure of own and attracted resources we include the part of the net profit allocated to self-financing, amortization for tangible and intangible fixed assets in operation, undistributed profit for the financial exercise, legal and statutory reserves and provisions not yet incorporated in the capital, increase of own asset value from revaluation and certain operating liabilities. Such conception is found in the work of other authors (Chebac 2008: 406) with interests in financing arrangements for company activity.

Using a part of the net profit for the current financing and afferent amortization of tangible and intangible assets related operating that compose the resource, in which the economic and financial theory and practice (Brezeanu 2009: 208; Bistriceanu, Adochiţei & Negrea 2001: 229; Toma & Alexandru 2003: 112), is known as *self-financing*.

Self-financing is generally the pivot of firm's finance and for some of them it is the exclusive source of funding in critical phases of development. The fundamental nature of this resource holds to the fact that this is the item under which the external funding will be sought and attracted by the firm. This status of self-financing takes into two fundamental reasons, namely:

  − on one hand, its size (in absolute and relative value), which provides information about the company`s performance. A high self-financing assures the financial investors on

possible financial compensation and enhancement, by the company, of the funds that they have invested and will invest in the future;

− on the other hand, self-financing creates the company's debt repayment capacity and provides a measure of risk, which lenders of funds assume.

According to almost unanimously accepted opinion, self-financing capacity reflects the financial potential released by profitable business activity at the end of the reporting period, intended to pay for own capitals (in dividend payment) and to finance expansion investments (share of profits set aside in reserves and fund of development). At the same time, it shows us the way to use amortization as the main pathway for renewal of physical assets in future financial exercises.

In essence, self-financing capacity is an indicator that expresses the company's financial independence, reflecting a potential or actual flow of availability. Its size depends on one hand on the profitability of the company and on the other hand, on the firm's investment policy and methods of amortization of fixed assets. Regardless of the intensity of amortization process (resulting from the applied amortization methods), the amortization included in costs and recovered through sales entirely becomes a self-financing source.

2. Financing current activity

The whole economic and financial activity of the company, directed to reaching its goals, runs on a macroeconomic environment dominated by uncertainty and risk. Attitudes exhibited by macroeconomic decision factors have been copied almost faithfully by managers in the period of analysis to which we refer. Some reckless manifested by financial managers are explained by Mugur Isărescu because of two causes: "(...) first was that the decision makers felt that the "good times" came once and for all, which obviously means that the expansion of costs could be permanent. The second was the election year 2008, which boosted expenses even more. The lax fiscal policy of spending set the basis for an involuntary fiscal contraction in the event of economic downturn" (Isărescu 2010: 9).

It goes without saying that between gross profit and net profit there are differences as there are differences between total assets and own capital. To deepen the analysis of the current financing of the company Alfa we select (in the table no. 1) information based on data from the company's financial statements.

Table no. 1

Financing of the company's current activity

No.	INDICATORS	UM	The period of analysis			
			2008	**2009**	**2010**	**2011 (preview)**
1.	Global self-financing rate	%	13,90	14,19	14,14	14,88
2.	Indebtedness rate	%	22,06	14,16	12,87	1 3,48
3.	Financial return	%	8,44	5,80	5,10	5,56

Source: authors' own calculations.

Noting a decreased appetite of the firm for borrowing, we observe (according to the table of data) a timid growth to self-financing orientation. The phenomenon can be explained by the relatively low level of profit achieved by the company in the analyzed year and by the fact that all these years, the company has paid dividends due to previous administration periods. A slight recovery is expected for 2011 both on self-financing and on the access of loans appropriated to the exploitation cycle.

The findings can be presented graphically as follows:
Chart no. 1. The evolution of self-financing, debt and financial return

3. Resources of finance of current activity. Their structure

In the period under review, self-financing with debt were important resources to cover the company's current financial needs. If the company had not had stable own resources (positive net working capital) accumulated in previous years, its financial stability would have been affected. The current status of ruling the funding cycle of exploitation of the Alfa SA company is presented in the following table (Table no. 2):

Table no. 2

Resources for financing the current activity

No.	INDICATORS	UM	The period of analysis			
			2008	2009	2010	2011 (preview)
1.	The need for funding	%	100	100	100	100
2.	Global self-financing	%	13,90	14,19	14,14	14,88
3.	The degree of indebtedness	%	22,06	14,16	12,87	13,48
4.	Own stable resources	%	64,04	71,65	72,99	71,64

Source: authors' calculations performed by the information in financial statements.

The dynamic analysis of company`s financial resources for the period under study shows the great confidence manifested in its own stable financing resources of and in the current self-financing (or maintenance) ones. We must admit that, as it happens in reality, due to permanent resources, we cover permanent needs, most of which being represented by the fixed assets. Current operating needs for the exploitation cycle are represented by the size of circulating assets. Separating the two kinds of needs we can analyze to what extent the permanent resources of the firm have been used for the ongoing needs or cyclical needs. We consider here that the cyclical needs have to be covered by cyclical resources (mainly loans), and ongoing operating needs must be covered by the continuing financial resources (own net working capital). We attempt such an analysis presenting the information in the following table (table no. 3):

Table no. 3

Structure of own resources to finance current activity

No.	INDICATORS	UM	The period of analysis			
			2008	2009	2010	2011 (preview)
1.	Total fixed assets	thousand lei	98.217	93.492	81.726	93.985

No.		UM	2008	2009	2010	2011
2.	Total ongoing assets	thousand lei	32.358	30.804	36.972	42.518
3.	Total assets	thousand lei	130.575	124.296	118.698	136.503
4.	Total self-financing + loans	%	35.96	28.35	27.01	28.36
5.	Total need covered by self-financing and loans: - for fixed assets - for ongoing assets	thousand lei thousand lei thousand lei	46.955 35.319 11.636	35.238 26.505 8.733	31.790 22.074 9.716	38.712 26.654 12.058
6.	Own stable resources	%	64.04	71.65	72.99	71.64
7.	Total needs to fill from the stable resources of which: -for fixed assets -for ongoing assets	thousand lei thousand lei thousand lei	83.620 62.898 20.722	89.058 66.987 22.071	86.908 59.652 27.256	97.791 67.331 30.460

Source: authors' calculations performed by the information in financial statements

The analysis of data from the table above indicates that due to these ongoing resources the company needs to cover ongoing needs and a significant part of cyclical needs (current assets). Because permanent needs (mainly fixed assets) have some consistency over time, the variation of cyclical needs will entail variations in self-financing needs and current loan of the exploitation cycle.

4. Financial stability of the company

We will try to follow the extent to which the company's current financial stability was achieved at the expense of own resources (net working capital). For this we draw the following analysis table (Table no. 4).

Table no. 4

Achieving the financial stability of the company

No.	INDICATORS	UM	Symbol / Method of calculation	The period of analysis			
				2008	2009	2010	2011 (preview)
1.	Fixed assets	thousand lei	Ai	98.217	93.492	81.726	93.985
2.	Ongoing assets	thousand lei	Ac	32.358	30.804	36.972	42.518
3.	Permanent capital	thousand lei	Cperm = Cp + DTL	107.909	112.060	103.424	118.938
4.	Current liabilities (less than one year)	thousand lei	DTS	22.666	12.236	15.274	17.565
5.	The need for current funding resources (working capital needs)	thousand lei	NFR = Cperm - Ai	9.692	18.568	21.698	24.953
6.	Resources of coverage, from which: - own (working capital fond) - DTS	thousand lei thousand lei thousand lei	- FRP = NFR - DTS 	9.692 -12.974 22.666	18.568 6.332 12.236	21.698 6.424 15.274	24.953 7.388 17.565

The presented data show that in 2008, the company lacked sufficient resources to finance their current operating activity on the exploitation cycle. This prompted the call to attracted resources that are mainly represented by short-term loans. Call for debt is generated by the fact that in 2008 the company recorded a negative net working capital (a lack of own resources for funding). The size of debt is 22.06% of total necessary resources (according to table no. 2). In subsequent years, the company intensified the call for own resources (especially self-financing) gradually giving up debt (as shown in the data of table no. 2) which will lead to the restoration of financial balance. The information provided by the table no. 4 (row 6) shows that the company has its own resources to cover their financing needs that are growing and together with borrowed resources, it will result in a policy of funding the cycle of exploitation, which is to maintain the upward trend of the expected financial return for 2011 and onwards.

Our research (supplemented by a careful study of domestic and international bibliography specialized in the field) leads us to the possibility of formulating several conclusions about the basis for policy decisions to finance the companies with the development of complex financing process and the factors that stimulate or inhibit the employment of resources, attracted in companies' own circuit.

A first observation is that the economic *sector or branch,* to which the company belongs to, influences the overall risk of debt that is the sum resulted from the economic and financial risk.

A second finding regards the *taxation level,* which is manifested in the national economy and which is not neutral in relation to financial and fiscal situation of the firm (Chen 2004: 1349).

A third finding relates to the *economic situation* and *monetary policy* promoted by financial and banking institutions. As other authors state (Reinhart & Rogoff 2012: 235-236; Matiş 2010: 132; Manolescu 2005: 388), the credit cheapens or is more expensive as the institutions mentioned to promote an expansive or restrictive policy of credit, which directly influences the financial structure of the company.

Recent researches (Isărescu 2010: 10) have concluded that within the same sector of activity, the *size of companies* and their *asset composition* differs. According to some specialists (Reinhart and Rogoff 2012: 239-241, Rajan and Zingales 1995: 1438) these characteristics exert influences on leverage degree and ultimately on the financial return of firms.

As other authors state, (Rajan and Zingales 1995: 1439) *the company* influences the permanent or temporary resource level. By joining the assets, liabilities composition is not conditioned only by the distribution of assets in fixed or ongoing ones, but also on the liquidity degree of different asset positions. The banking financial institutions generally give more difficult loans to companies, which have a higher proportion of fixed assets, whose market value decreases with time, becoming lower to the accounting value, comparison that is made in case of reaching the insolvency (or bankruptcy).

Discussions with specialists (money managers) have created the impression that a debt rate with a higher value in the hands of competent managers may involve less financial risk than a significantly lower one managed by inexperienced managers. Competent managers will find solutions so that company can handle a high volume of loans, with beneficial implications on financial profitability. Top managers have a unique style in business administration of the company and superior ability to collaborate with banks and, at the same time, a unique way to convince them to grant new loans (respecting the allowed limits) for the financing of companies that they run. To this, we add the importance of achieving a profit large enough so that, on the basis of management decisions with a solid argumentation, it can support both self-financing and debt effects on the company.

4. Conclusions

Based on our research we found a similar behavior of companies on policy decisions to finance ongoing operations. There is established a specific correlation between the ratio of self-financing and leverage and technological and branch particularities of the companies. In conclusion, we can say that in the financing behavior of the analyzed firm, there are shown the same attitudes in the order of priority of the call made to funding resources. Thus, current funding is provided from retained earnings at first, then from own capitals and, ultimately, by calling on bank loans.

Regarding the restoration of financial balance (if needed) the firm calls for intervention of banks (using credit limits in the company's treasury), observing a slight tendency of development of business operations on the capital market through exchange operations.

THE CORPORATE GOVERNANCE AND THE OPTIONS BETWEEN EQUITY AND DEBT CAPITAL. CONSIDERATIONS ON ACCESS TO CREDIT IN ITALIAN REALITY (PART I)

Rangone Adalberto
University of Oradea and University "G.D 'Annunzio" of Chieti-Pescara

Abstract:
To conduct a business today one needs intuitive skills and, therefore, an ability to respond to the new and numerous challenges that the market requires.
These challenges are economic, but not only. A continuous and steady development involves actually the need to go beyond the limits, not only in the case of traditional companies, but also of those in the start up phase.
To be in a multilateral and global economic system - as the present one – supposes a continuous upgrading of production technologies within companies, sometimes by undergoing serious reengineering processes.
The updating of the company, however, cannot and should not be perceived as a simple and sudden initiative that is applied superficially just to conform to a market trend. It involves a certain difficulty, and especially the demand for new and ongoing investment in the sector of competence, therefore, it requires a careful process of analysis to relate multiple aspects of the company, including the availability of equity or the need to resort to foreign capital, such as to the bond market, to national or European facilitating tools or to foreign intervention of banking nature, on short or medium-long term, calibrating these interventions based on business needs.
It is this delicate "step" in the life of a company - which requires a coherent, appropriate and stable organization of the governance of the company – that we want to tackle within this paper, as well as its interaction with the banking system, which in our specific case is the Italian one, all these by a brief empirical analysis of the relationship that links corporate governance to the access to finances, in the current banking context.

Keywords: Corporate Governance, Banking System, Reengineering, Start up, Management

1. Start up, *Reengineering of the business and the resort to credit*

The corporate governance aims at the company's well-functioning or the fulfilment of its object of activity. This goal requires, besides fully technical management skills, several purely financial capacities as well. The latter can already be held by the enterprise from start, or need to be sought on the market, through external sources.

It is a well known fact, the principle by which foreign capitals generate a flow that should provide a *turnover* sufficient to recover the initial investment completely. To succeed in this task, the governance must perform a series of analyses of the company that shall allowing the company to adopt the most appropriate strategy. This is achieved by monitoring the state of the company before the investment, calculating its rate of return, thus evaluating the usefulness and opportunity of resorting to foreign capital. Normally, companies not so well equipped technologically do not experience too big difficulties in accessing foreign capital, while companies with a *high-tech* predominant in the productive organization do. With the latter we can notice a tendency to use less debt - at least in the *start-up* phase – favouring the venture capital. However, if this is not possible, they will also have to proceed to a careful management in order to make better use of the capitals obtained.

Depending on the financial goal to achieve, governance shall take into account the various possibilities to access capital.

There might be various types:

1.Venture Capital [Increase of equity by issuing new shares and / or self financing, resort to Venture Capital, investment funds interventions and / or Private Equity, Seed Capital]

2.Debt Capital [issue of debenture bonds, use of loans or medium-long term grants, national, regional or European financial facilities, operations of Operational Leasing, Finance Leasing, Shareholder Leasing]

3.Disinvestments of existing heritage items or Lease Back

4.Self-financing generated by revenue management

The choice would be based in this situation on the identification of appropriate financial solutions for the process of *reengineering* (1) being implemented or in case of *start up*.

As a first check, the governance will have to calculate what benefits can be achieved by the company and what time is needed to obtain them, in order to better determine the most appropriate financial coverage. Before proceeding to a brief review of the techniques commonly used in books on business economics, both to identify past performance and to calculate the best future investments, it must be said that these estimates should be seen as pure analyses *ex post* or as mere forecasts. This last observation arises from the fact that business management and market economy itself, par excellence, do not represent absolute certainties, but on the contrary, they are subject to different variables and conditions that reveal everything but the certainty of the context in question. A confirmation of this fact is: entrepreneurial risk as such, capital market and its own volatility, recurrent crises reminding of Schumpeter's theory, turbulences in the labour market, socio-political instability, diverging public policies arising from the need to address crises that, in our opinion, are no longer just economic or financial but gain the features of a true systemic crisis.

1.1 Break-Even Analysis

By *Break-Even* analysis we can make an estimate of the levels of *output* to be achieved in order to balance initial costs when an investment is planned. (2)

This analysis is called the cost-volume-outcome. Therefore, during programming it can be used in order to simulate the behavioural *trend.* of the firm. *Break-Even* analysis is usually considered among the preventive studies of typically economic nature.
The *break-even* point indicates the covering of the costs incurred at the beginning of the investment and, consequently, the initial point from which the investment begins to generate profit.

The cost-volume-outcome analysis aims to identify the effects of the variations in sales volume on economic performance, to assess the initiative of investment. In other words, we can say that

it emphasizes how much it needs to be produced and sold so as to begin to gain. *Break-Even Point* highlights the balance point where the gains from sales equal the cost of the products sold.

Assuming that:
   CF = fixed cost
   Q = volume of sales
   p = unit price
   cv = variable costs per unit

It is therefore expressed by the equality:

$$C = R$$

where: $C = CF + cv \cdot Q$
   $R = p \cdot Q$

However, this analytical principle - even if now it is a consolidated procedure together with *payback period* analysis - is considered by most researchers as insufficient for a comprehensive consideration on whether or not an investment is risky, regardless of the variability of the market prices and being applicable on short periods only.
In this respect it is customarily to corroborate it with indicators or indices.

1.2 Profitability indices and the Financial Plan
The analyses with indices are a resource observable from several points of view. By applying them, investors can assess the profitability of a firm, thus providing the quality of their investment, the financers can estimate the capacity of beneficiaries to cover the capital provided, or, simply, a company can carry out so-called "past" analyses - or on the previous management of the company - as well as "future" ones, on the administration of capital for specific investments. By this measure it would be possible to quantify the potential return on an investment.
Therefore, the areas of application of the above analyses are numerous:
-Patrimonial - when identification of the *stability* of the company's assets is desired
-Economic - when calculating of the firm's *profitability* is at stake
-Financial – when the identification of the firm's *liquidity* capacity is wanted
The patrimonial motivations tend to represent the characteristics of the patrimony or the latter's stability compared with the requirements of company management.
Considering the case of a company with an indisputable patrimonial stability, it may be outlined by the following equation:

$$\frac{PN}{C_{mi}} \leq 1$$

where:
   PN = net patrimony (contributed capital + reserves + retained earnings)
   C_{mi} = average capital invested along the period considered, represented by the sum $A_{c\,+}$
   A_i or the sum of circulating assets and fixed assets.
The equation underlines how and to what extent the net patrimony has financed the investments of the company. Also, the patrimonial solidity represents the financial independence of the company. The more the ratio tends to equal 1, the more capable is the company to act without the

conditionalities arising from the banking system or from the resort to the capital market of third parties on the medium and long term.

Because of the size limits imposed to this paper, we shall now move to profitability indicators.

There are several indicators of profitability.

If we consider the relations:

R_o = operating income

C_{mi} = average capital invested along the period considered

P_a = atypical earnings

P_f = financial earnings

Return on Investment

ROI: $\dfrac{\text{Net Income}}{\text{Invested Capital}}$

Return on Assets

ROA: $\dfrac{\text{Net Income}}{\text{Average of Total Assets}}$

Return Index

Return on Sales

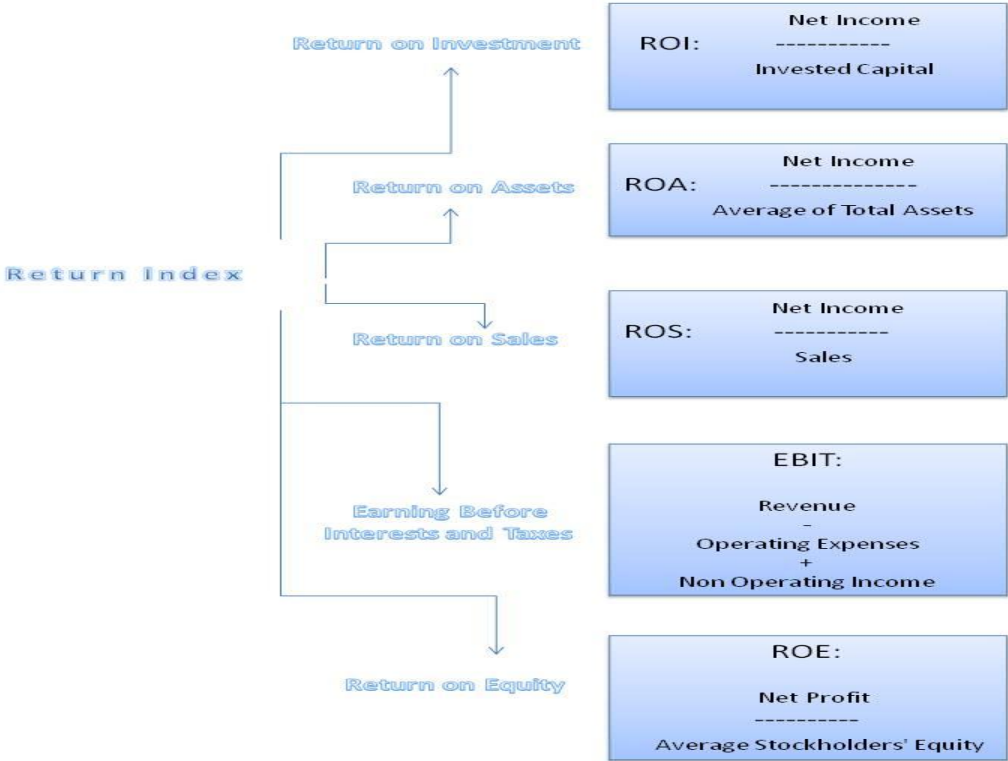
ROS: $\dfrac{\text{Net Income}}{\text{Sales}}$

Earning Before Interests and Taxes

EBIT:

Revenue
−
Operating Expenses
+
Non Operating Income

Return on Equity

ROE: $\dfrac{\text{Net Profit}}{\text{Average Stockholders' Equity}}$


We can summarize the indicators represented schematically in the table above:

Return On Investment. It is perhaps the most widely used way to calculate best the ability of a company to produce capital fully exploiting its potential. ROI is the indicator of the firm's capacity to recover the invested capital. It is expressed by the relation between the operating income and the average capital invested along the period considered.

Return On Assets. It is adopted when the financial profits or the atypical ones become "real"; with this indicator we can measure gross profit from the total investments. The company's operating income indicates the gross return of all investments, be they operational, atypical, extraordinary or financial. Therefore, it includes equity and debt capital. It is often identified in order to then apply ROI.

Return On Sales. The indicators mentioned above are then added a variation by calculating the ration between the total sales in the period considered and the operating income. This indicator is

the return on sales and it derives from the relation between operating income and net volume of business resulting from the administration of the given operations. If the value is "> **0**", it means that there is a further area of gains available after covering the total costs that arise from the company's administration proper, further gains thus usable to cover other costs of administration and to reward equity. If the report is "= **0**", the gains from the sale are barely enough to cover the operational costs. If the coefficient is "< **0**" we are dealing with a company administration insufficient to cover operating costs.

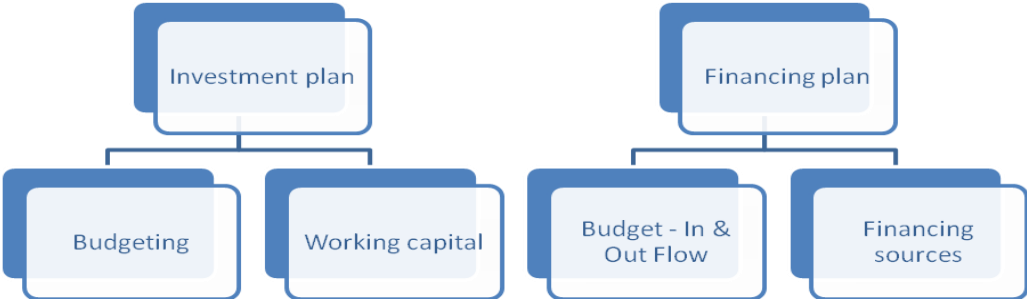
Return on Equity. ROE - understood as the ratio between net income and net patrimony – indicates a firm's profitability in relation to its risk capital. Although this indicator is very often subject to manipulation so that the company appears solid and promising to third parties, it remains a valid and effective tool for business management analysis. (3).

Earning Before Interest Taxes Depreciation and Amortization. Another indicator is the one referring to the gross operating margin. This indicator gives only a statement of business administration without consideration of the costs arising from depreciation, from other devaluations of the year and from fees.

We feel right again to confirm that these analytical methods constitute a source of research very important for defining a future investment plan. It is the very analysis on its own patrimonial stability and on its own profitability that guides the governance of an enterprise in its decision whether it is appropriate to make investments.

After the quick look at the key indicators of profitability, we will now consider the components more closely linked to the financial aspect of an enterprise.

When examining precisely its own financial situation, the corporate governance must take into account, above all, its own financial resources, to then calculate the structure that will shape due to the investments. The financial plan is certainly a viable help. This planning is developed through two different instruments:

Investment Plan and Financing Plan.


Through the investment plan the firm manages to develop a scheme that identifies all investments to be made both in durable goods or fixed assets (Capital Budgeting) and in goods of the circulating assets (working capital).

It will then be possible to undertake a range of analytical techniques – applicable in conditions of "safety", i.e. in the absence of inflation or of extraordinary financial constraints (4) - such as:

a) average rate of return

b) payback period

c) net present value

d) internal rate of return

e) current rate of return

As explanatory only, we considered it necessary to present a simple list, although we are aware of the importance of these techniques, they require indeed a deeper study that would fail to be integrated in the current paper.

Once drawn up an investment plan that can maximize production capacity able to satisfy the sales estimate provided by the business plan, the review of the financing plan will follow. By this, the governance identifies the sources and their use, this resulting in a fair allocation and distribution on the various units. Therefore, the estimates of *inflow*, i.e. input flows, and of *outflow,* i.e. the output flows, are identified. (5)

Next, we shall identify the techniques of the financial analysis of investments in progress, and the indicators useful for future estimations.

1.3 Financial research instruments

Concentrating in a short exposition the analyses that aim at verifying the financial needs of the company, we want to emphasize that the *ex post* analysis of a company's balance sheet, or the review of a business plan of a *start-up* must have the following objectives:

a) the study on the firm's capacity to meet at any time the payments necessary for its economic management;

b) As a consequence, this analysis implies returning a judgement on the relationship existing between funding and the uses of funds available or sought by the company;

c) the examination of the constraints that exist between the company's liquidity and the economic aspect of its administration.

We shall briefly see a series of financial indicators or ratios.

Relating the following elements:

$L_{i/b}$ = immediate and short-term liquidity

D_b = short term debt and other liabilities

we have:

$$\frac{L_{i/b}}{D_b} \quad <=> 1$$

This relationship is called *"quick ratio"* because it highlights the ability of the liquidity to meet short term debts quickly.

The degree of liquidity that marks the average capital invested is expressed in symbols by the following equation:

$$\frac{L_{i/b}}{C_{mi}} \quad \leq 1$$

The rigidity of funding sources can be expressed by the ratio of average invested capital and short term debt, in symbols:

$$\frac{C_{mi}}{D_b}$$

The liquidity index or cash coefficient, as called by some authors (6), has a function proportional to the degree of liquidity invested and a function inversely proportional to the degree of exigibility of the correspondent total capital acquired, regardless of the form and / or nature of the acquisition of capital.

We can highlight a further financial and patrimonial coefficient, called "*Net worth to fixed ratio*" which represents the ratio of self-coverage of the fixed, or immobilised, capital.
This index results from the relation of net patrimony and fixed assets.
Thus, we have:

$$\frac{PN}{A_i} \quad < = > 1$$

Assuming, instead:
V = sales made in a certain period
We have:

$$\frac{V}{C_{mi}}$$

that will be the average income per unit of operational investment.
This indicator may also capture some aspects of the financial dynamics and tends to measure the movement of the capital invested in the company analyzed.
Desiring in the second part of our analysis to make some considerations on the possibility of access to debt capital, mainly acquired from the banking system, we will consider one more very important indicator for the choices made by the firms that resort to external capital.
This is ROD, or *Return On Debts.*
This indicator is an important resource for companies that want to access external funding and, as long as the financial obligations that the company has to acknowledge to creditors usually have a massive influence on the remuneration of risk capital, they are values that should not be underestimated. (7)
The rate of return on third parties' financial means will be obtained taking into account the values:

I_p = passive interests
I_{fm} = average financial debt in a certain period

from which we obtain the ROD formula:

$$\frac{I_p}{I_{fm}}$$

Obviously, if you want to evaluate ROD value on a medium-long term, we will have to apply the long-term interest to the numerator and the debt values on a medium-long term to the denominator.
Also, if we want to obtain the value of ROD on short-term, we will need to apply the short-term interest to the numerator and the short-term debt values to the denominator.
When taking into account not only financial indebtedness, but the total debt - which highlights debts to suppliers and controlled companies - we get the RODT indicator.
It is calculated using the following formula:

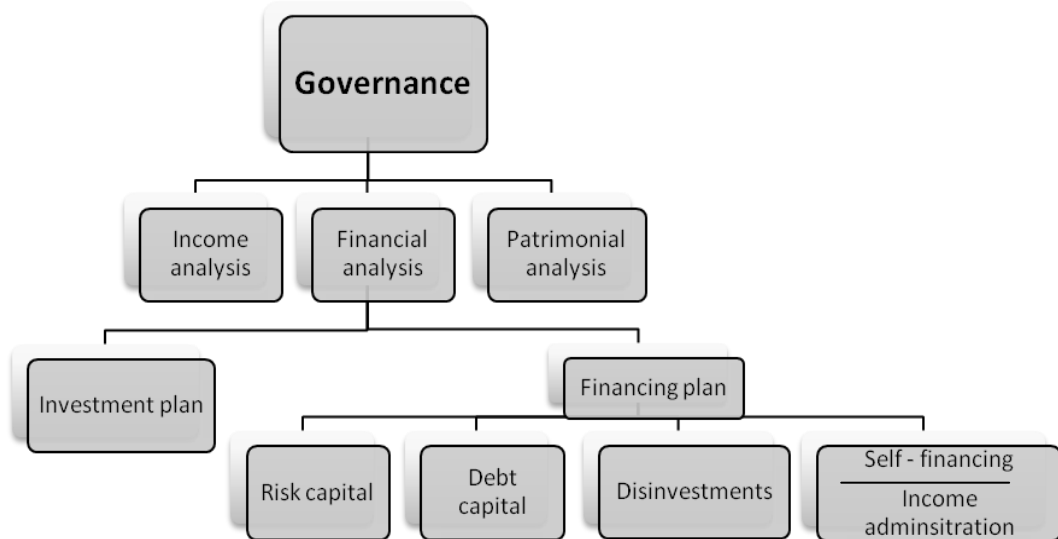
$$\frac{O_f}{I_{cm}}$$

with:

O_f = financial obligations
I_{cm} = average overall debt in a period

By use of these analytical principles the company will be in a position to be able to choose from the many forms of financing the one that best suits the project, either for *start up* or for *reengineering.*

We want to emphasize once again that the role of company management supposes a painstaking analytical process that extends from monitoring the historical evolution of the company, through the analysis of present management, to the forecast for the future, not forgetting perhaps the most incisive factor or the changing conditions imposed by the market.

Just explanatory, we shall summarise in the diagram below the decisions making process that is the attribution of the enterprise governance:


The diversity of the analytical techniques allows a support, not infallible, certainly, but at least effective, against the possible *default* (omissions) that a careless or unconscious management can encounter during its own investment. Obviously, we would like to illustrate the techniques without claims of completeness. Given these processes, typical to management, in the second part of our brief research we shall analyze the sources of companies' financing - mainly in Italy.

We will examine the countless possibilities of access to credit and through the data provided by Banca d'Italia it will be possible to outline a current view on the relationship between credit institutions and companies.

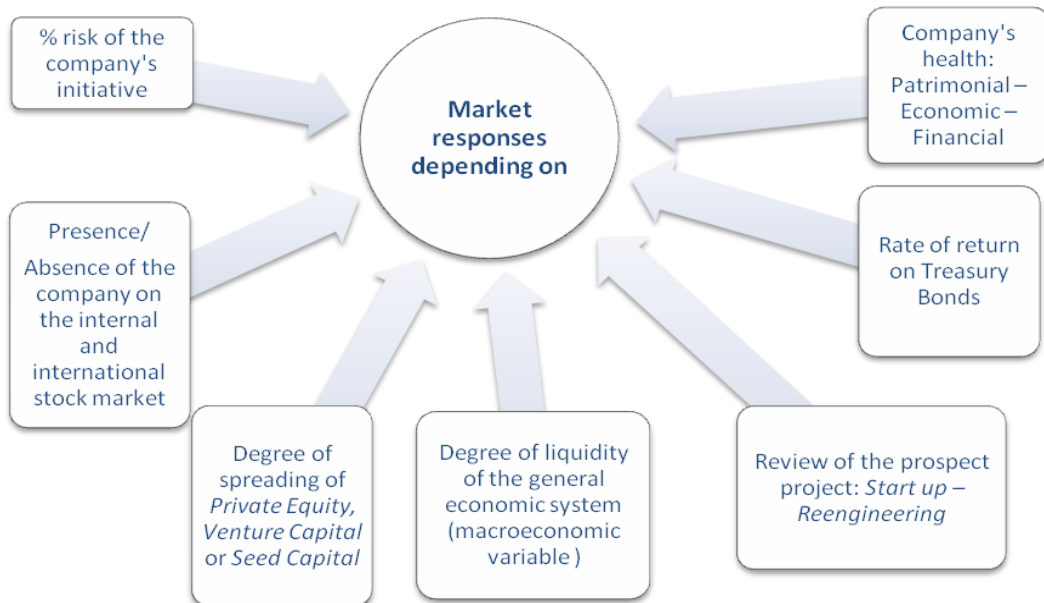
THE CORPORATE GOVERNANCE AND THE OPTIONS BETWEEN EQUITY AND DEBT CAPITAL. CONSIDERATIONS ON ACCESS TO CREDIT IN ITALIAN REALITY (PART II)

Rangone Adalberto
University of Oradea and University "G.D 'Annunzio" of Chieti-Pescara

1. Company needs and market offer

To make a careful and thorough research on future investments is certainly one of the most complex phases for the *governance* of the enterprise. Even the choice of the most appropriate financing has its importance for the success of the investment. The interaction company - credit institution can now benefit from its long history. Today the economic crisis of international proportions caused that relationship to be more labile and difficult, even if it remains always topical and important both for the local and international development. It is precisely therefore that we undertake to further identify, in addition to the requirements of the company, the offers as well as the market conditions which must be taken into account.

For the companies insufficiently prepared to make by themselves the investment chosen, the financial market offers a series of possibilities, so that these choices shall be identified based on the company's stability and balance.

The responses of the market and of the banking system - in particular - are linked to a number of factors that, without any pretence of completeness, we can summarize as follows:


- Different solutions are proposed, according to the degree of risk given by the enterprise's initiative.

The lowest percentage of return on an investment can make it less exciting on the market, thus less funded.

- The presence or absence of an enterprise on the stock market may have a greater impact in order to attract certain investments of a financial nature *(Back Up Facilities, Merchant Banking)* or to become attractive to prospective foreign investors.

■　　One should neither rule out the level of development on the market of certain financial solutions. The investment programs in support of the companies in the *start up* phase, such as *Seed Capital* or *Venture Capital* - are highly developed in the United States and less common on the European financial market.

■　　On the financial availability present on the market we will speak in due time, when we analyze data issued by Banca d'Italia.

■　　The state of health of a company is strictly related to the ability to receive funding or to be able to allocate new shares on the market. As we stated in the first part of this work, the historical development and the current situation of an enterprise, whether defined in patrimonial, income or financial terms, cannot be separated from the future investment - hence the choice of certain companies to improve their attractiveness, ROE, by "technical" changes brought to the analytical plans.

■　　The rate of return on money market (government securities market) is of considerable importance. The investments and the savings are clearly conditioned by the evolution of this rate. It is not appropriate here to emphasize the debate, still high, on the competition, sometimes sharp, between financing the debt and the public deficit and financing private companies.

■　　Last listed here, but not in terms of importance, is exactly the type of investment required by company, whether it is in the *start up* phase or it needs a *reengineering* plan.

This latter option is, more than the others, one that belongs mostly to the problems of *governance.*

First, the sector has to be restricted in accordance to the requirements of the company:
■　　*Investments in Real Estate or Fixed Assets or development of projects*

If at the basis of the investment is the need to purchase real estate, equipment or fixed assets useful for the operation of *reengineering* of business and also for starting the business, the company may use debt capital by Loan (predominantly Loan for Industrial Financing), Leasing (both Financial and Operational) or *Project Financing* (with the two expressions: *Project Financing* and *Project Management* where support extends to the very project - this last option is used mainly for investment in large projects).

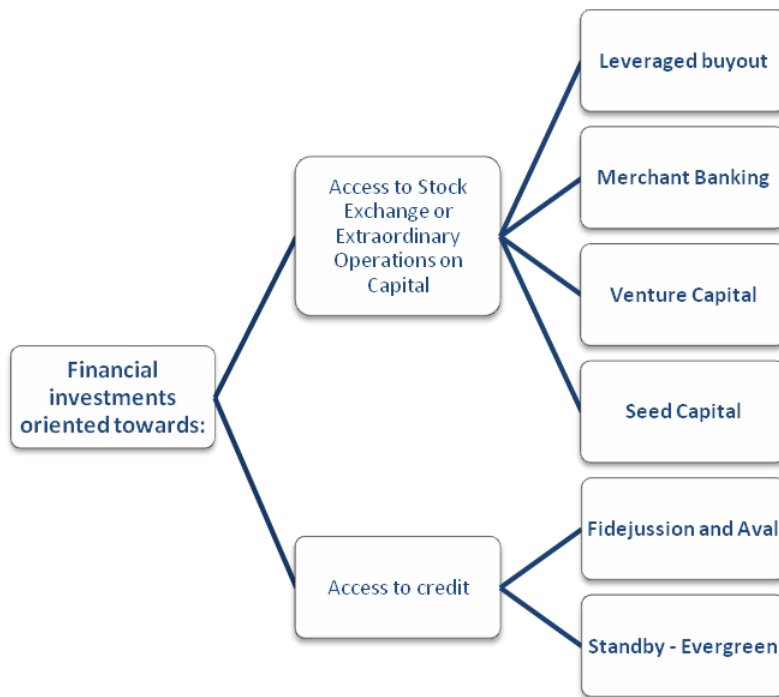
■　　*Financial Investments*

If the needs are primarily financial in nature, the range of opportunities available is more diversified and more widely.

In turn, the financial investments must be classified according to whether they refer to companies listed or unlisted.

If the governance of the company has to accede to credit, they can choose between the traditional bank credit line by the formalities of *Stand By* and *Evergreen Financing* and the warranties provided by the credit institutions (Fidejussion and Endorsement or Aval).

Financial investments oriented towards:

- **Access to Stock Exchange or Extraordinary Operations on Capital**
  - Leveraged buyout
  - Merchant Banking
  - Venture Capital
  - Seed Capital
- **Access to credit**
  - Fidejussion and Aval
  - Standby - Evergreen


If, instead, we refer to enterprises with a certain asset and income stability wishing to have access to stock market or initiate investments of incorporation and fusion, the governance will have the chance to choose between different financial products such as: *Leveraged By Out, Back Up Facilities, Shareholder Leasing, Merchant Banking, Venture Capital*; for *NewCo* a further solution has appeared in recent years, one able to provide sufficient financial instruments to enter the market. We here refer to the *Seed Capital*; By this practice - mostly developed in the U.S.A. – the companies in *start up* phase can have access to high-risk capital with a minority participation of an allocating institution. The investment does not special deadlines and allows the immediate launch of the company's investment project.

Therefore, the economic coverage to support the companies' investments - either in fixed assets or purely financial - has reached the level of sensitive development and specialization. Any requirement the enterprise might have, the market provides financial products coloured with the most appropriate and innovative hues. Well, once completed the enumeration of interventions, that, of course, is far from exhaustive, we ask a rhetorical , but necessary, question: is it, though, so easy for the enterprise to access the debt capital, i.e. different and more appropriate solutions provided by the banking and financial system? There are categories of companies for which the access to credit is more available and other that, on the contrary, suffer because of an endemic hardship to gain such access?

Looking into some statistics issued by Banca d'Italia we may give an answer to these problems.

3. Companies & Banks. Estimates on present, opportunities for future

The economic crisis, now of international dimensions, is rooted mainly in the exacerbated financial difficulties of the typical financial system. The efficiency of assistance given to companies by the credit institutions has forth undergone a slow but persistent decline. Simultaneously, enterprises - especially SMEs - have shown a rapid increase in the financing demand.

If we consider the year 2010, i.e. an intermediate year between the beginnings of the crisis - which, in the general opinion, is 2008 - and nowadays, we can notice a considerable increase in

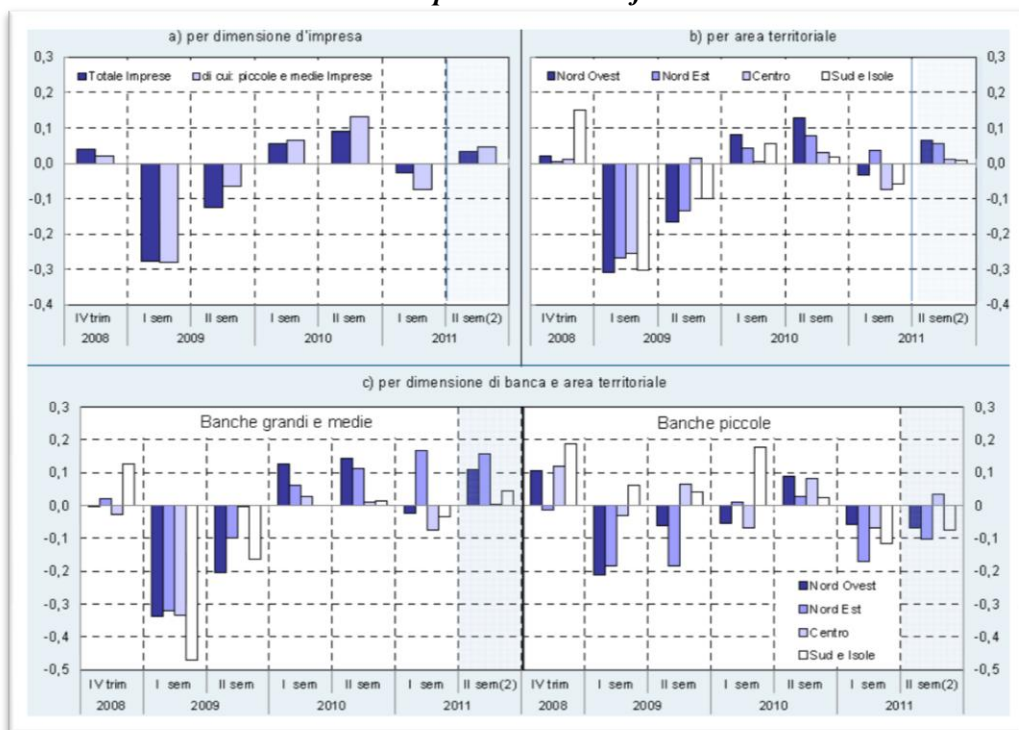
demand for bank debt, following a significant increase in gross fixed investment by 3.5% compared to 2009.

This process was the reflection of the modest growth in the industrial sector (0.7%, 0.4% only for manufacturing) and a faster increase in services (6.8%).

In the industrial sector this growth was stimulated by the acquisition of means of production, with firms achieving abroad more than two thirds of their turnover, thereby increasing investment by 6.3%, compared with a reduction of 0.4% with the remaining firms. Investment growth is perceived differently depending on the area: 3% in the North (over 4% in the Northeast) while a decrease of more than 3% is seen in the Centre and South. (1)

We must also note that 3.7% of them were related to the company's *re-engineering*.

This requirement for innovation and reorganization of the company increased consistently with that of the use of equity and with the growth of bank debt in a constant value of 7 percentage points. Considering the period between 2010 and 2011 we may see that there was a slight reduction in demand following a tightening of criteria for selecting the companies that should be financed.

b. 1 The companies' demand for credits


Source: Banca d'Italia, Regional economies. Credit supply and demand at the local level

The phenomenon was particularly felt by SMEs and even more in the areas of Centre - South.
The sector that was most marked by the recession was the construction sector, while services and manufacturing sectors remained mainly stable.

Tab. 2 Indicators of demand by sector

Therefore, it was noticed a more evident increase in the demand for circulating capital as well as a demand for restructuring the financing, with milder and simplified conditions, compared with the light decrease in investments both in the North and in Centre - South and also the limitation of mergers and acquisitions.

To make a comparison with the Italian companies' request, we can consider the proportion of offer promoted by the banking system. Banca d'Italia helps us in this analysis by examining a sample of 400 banks spread throughout Italy. In the first and second half of 2010 the offer of the banking system recorded normal percentage values. However, in the period between 2010 and 2011 there have been adopted several policies to raise the spread on the investments considered the most risky. Also, this principle of protection applied by banks has determined various types of companies, particularly in the *start-up* phase or with little risk capital in general, to use alternative funding sources. Indeed, a slight decrease has occurred mainly in the supply to small and medium sized enterprises. This may have depended on the growing competition of numerous credit and financial institutions that have developed throughout Italy to try to meet different needs of companies - even the smaller, so to say "risky".

It is observable that where it was seen a lower credit demand by firms in construction, the response in percentage of supply from the banking system was positive and growing. In contrast, the service and manufacturing sectors proved to receive a lower offer. However, it never exceeded the range between -1 and + 1 percentage points.

Tab. 3 Credit offer for enterprises

a) per dimensione d'impresa
b) per area territoriale
c) per dimensione di banca e area territoriale

Banche grandi e medie
Banche piccole
Source: Banca d'Italia, Regional economies. Credit supply and demand at local level

The crisis, from certain points of view announced and with systemic features (2) has become a global financial crisis and ultimately, as we are concerned, a crisis of the European debt, both of public nature and of the private sector, has involved businesses and banks as well. The graphs provide a better picture on the worsening of the situation of the credit demand from companies and of the banks' offer. Concerns and issues of the firms are confronted with and related to issues which show, more and more, macroeconomic features and dimensions.

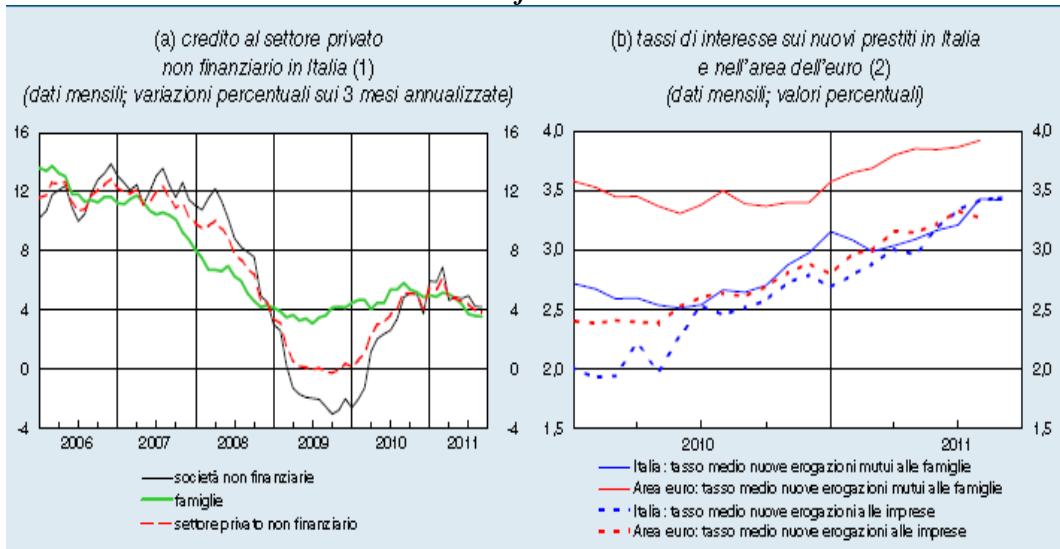
Tab. 4 Percentage of recourse to credit in the Eurozone
Source: ECB and national central banks: Financial Stability Report, 2011

Indeed, Italy is not alone in facing such critical conditions. Estimates of the use of credit in the European area show this clearly. Indecision of banks to provide credit to SMEs is parallel to the distrust of the firm to rely on the old *partners* - namely banks - to which it was always shown a deep respect and trust in order to receive economic support necessary to open the new activities, to improve existing ones, or simply to overcome times of shortage as the present one.

A European aid able to improve the company-bank relationship has come through improved and sustainable supply of liquidity both in euro and in dollars.

In conclusion, we can hear the echo of the famous warning, perhaps more than justified: *"save the banks!"*

The uncontrolled evolution of interest rates on bank loans in Italy and in the euro area is more than significant an indicator of the vertiginous bank collapse into the unknown.

Tab. 5 The evolution of credit and interest rates


Source: ECB and the Banca d'Italia in: Financial Stability Report, 2011

How can banks subsidize companies while they have no cash themselves?

Hiding behind the cautious choice of providing financial coverage to the investments of the firm, investments becoming more and more risky, the banks can conceal another truth, far more serious.

"It is so, if you think so!" Luigi Pirandello claimed in one of his theatre plays.

In this brief and modest work we do not intend to support the objective impossibility of knowing reality, suggesting a completely economic relativism of forms, conventions, and exteriority and especially of the objective impossibility of knowing the truth in absolute terms or, if we like it more, to the end.

On the contrary, there is a doubtless truth and the very data and statistics published by the Bank of Italy and ECB support it.

As proof of this hypothesis, there are then the numerous European financial measures designed for rescuing banks from collapse. The ROE of 14 major banking groups would have remained at 4.5%, maintaining a worsening of the interest margins (2.8%). (3)

But, in some ways, it is hard to admit or confess openly the wrong choices, or at least the highly questionable ones, operated in the past by States and Governments, Banks, Corporate Management and Governance.

We can make serious observations and can find a likely truth about what happens, and along this research we could find merits and faults to all. Without exception.

Conclusions

After outlining a general framework of conditions in which companies and banks operate, we try without any pretence of completeness and very modestly, to make a conclusive analysis.

"The Agency Theory", which tends to involve managers and governance in the structure of society in order to raise their accountability to shareholders, ended by constituting one of the elements of the systemic crisis of today. While until the midst of the last century, a company had to grow, create jobs, put good products or efficient services on the market and only then make profits, in the mid 70s and throughout the 80s and 90s, the imperative was to make profit, *"tout court"* to increase shares' value, at any price. By doing so, there have been stimulated behaviours oriented towards short-term profit, the long term investments being penalized. With *stock options*, which ended by representing simple positions of the management and governance of the company, there were added paradoxical situations such as: the dismantling of companies, in order to sell their assets, with consequent dismissal of employees, the often unjustified fever *"Merger and Acquisition"* and so on, all these only to support the shares' price without actually producing and reproducing true wealth.

Could the financial and banking system stay off this philosophy of behaviour? Of course not. So one can easily deduce what happened. If there were claims difficult to achieve, instead of being removed from the balance sheets and entered to losses, which would have smoothened the image of that bank, with the result of shares' price depreciation, debts were sold to specialized companies, responsible for their collection, or, even worse - through the financial engineering of derivatives – the liabilities transferred have been the basis for their subsequent estrangement. We can legitimately ask whether in this case there was created real wealth or a privilege to speculation, covering at the same time the previous inefficiencies of banking and financial management. Or, moreover, might the internal and international banking and financial system have escaped from the underwriting of issuance or the purchasing of debt securities, even beyond its natural capacity? It can very easily be inferred that if the banking system is undecided between the need to strengthen their own heritage, the need to underwrite bonds or to make more innovative finance, the traditional activity that characterized the original banking function of crediting and financial assistance for companies was reduced gradually.

Disregarding the choices of economic policy that each country has pursued favouring either a policy of *deficit spending* or a very strict policy of the debt-GDP ratio and deficit-GDP, the explanation of which would lead us away from our current specific research field, the author of the present paper wishes to emphasize that there was found however a sensible move from what can generally be recognized as legitimate *profit* for the economic organization, towards the position of *rent,* so a gradual transition from a capitalism of a production nature par excellence to a capitalism of a financialized economy, or if we like that more, to a *rentier capitalism*, with all the consequences that derive from it: oligopolies emerged and developed in the shadow of the state's commands; mainly speculative activities and operations on real estate assets; speculative finance - oriented towards short and very short term profits; lack of interest in medium to long term economic views; public sector that often removed resources from the private sector to finance current expenditure and often unproductive ones to the expense of non-reimbursable public investments, consisting of medium to long term investment that would have created a virtuous flywheel of growth and development.

Today, Italian companies - and not only them - see that their economic success depends on two main factors: improving European economic pressure and return to more satisfactory credit conditions.

In our opinion, until we will get back to a better understanding of the needs of small and medium size enterprises, no reliable support can be provided to critical economic situation, at least in the

Italian context. A more stable situation can be reaches through the cooperation between companies and credit institutions. This binomial has been since the dawn of Western economic the engine of economic development. This applies to the whole majestic analysis performed in quieter times by Schumpeter. This development process may look to the future through the victory over numerous technical challenges, but cannot escape the memory of the historic journey that had originated it.

A journey in which the small and medium enterprise was in the centre of progress also due to the fact that it was sustained economically by the various forms that credit institutions have taken over time.

Also, unless sudden and drastic reversals occur in the socio-economic system, the enterprise governance - in its various forms and manifestations - if they want to see their projects funded, should take more into account the numerous factors that may make their interests coincide with those of the credit institutions.

Finally, a closer link, almost inseparably, but a link that - given the upheavals brought by the crisis - will make less and less stable the international economic balance, if the banking system does not resume its classic function of credit provider, will mitigate the bias toward exclusive financial speculation or will continue to accommodate making comfortable investments in bonds, undoubtedly profitable and safe, but which in times of crisis consume the vital air of the real economy.

THE CAUSES OF ECONOMIC CRISIS. A BEHAVIORAL FOUNDATION.

Soim Horatiu
Western University Vasile Goldis Arad Faculty of Economic Sciences

The cyclical path of economy is a common place in the economic theory. The economic crisis that started in 2007 was not only one of the most severe since the WWII but it came unexpectedly. The cause of the crises and of the surprise consists in the economic models and theories that were founded on the rationality and maximization behavior of the economic actor. People lack the rationality the mainstream economics assume. This is why both economists and simple people do not act as theory predicts and finally economy does not tend toward equilibrium but suffers recurrent crises. This crisis started as a financial one, because of the subprime loans made in USA, but have spread in production sector because of credit frozen, is now in transforming into a social crisis because of austerity measures taken by governments. The paper analyzes the theoretical foundation of economic theory and how the facts that characterize the recent economic evolution fit with the non mainstream theories. It presents the figures of the economic evolution in the last 3 years and explains them based of the agent's behavior described by Herbert Simon and Daniel Kahneman. Their challenge of mainstream economics is based on an analyze of human behavior. Herbert Simon introduced the concept of bounded rationality as opposed to perfect rationality postulated by neoclassic economics and Daniel Kahneman realized experiments that proved that people cannot stick with the performances assumed by mainstream economics. Their conclusion permit to understand the approach of George Soros who says that people actions are bounded by reflexivity and as a consequences sometimes economy move not toward but far from equilibrium, creating bubbles that end in financial and economic crises. As Akerlof mention the cause of the crisis is the reliance of a false theory which said that we are safe. The conclusion is that we need new theories more close to the real life and an agent description that capture the limited characteristics of the human being despite the abstract "homo oeconomicus".

I. Introduction

The cyclical path of economy is a common place in the economic theory. Rarely, in the last century, we saw a period longer than 20 years without an economic crisis. The latest, which started in 2007, should not surprise us. A long list of disequilibrium's accumulated. This crisis started as a financial one, because of the subprime loans made in USA, but have spread in production sector because of credit frozen, is now in transforming into a social crisis because of austerity measures taken by governments.   The curious thing is that almost nobody predicted it. The large majority of economic analysts presented optimistic predictions even at the beginning of 2008, when the crisis already started. For instance
the forecast of the GDP growth and unemployment rate was missed by 101 out of 102 experts (1) (Morris 2010: 7). Thus it is not surprising that the crisis came totally surprisingly. With the Gary Gorton and Andrew Metrick's words "The financial crisis of 2007-2009 was the event which was not supposed to happen, but it did." (Gorton and Metrick 2011: 2)
The problem doesn't passesd unnoticed by the most important economists of the last century "What had people been thinking? Why did they not notice until real events - the collapse of banks, the loss of jobs, mortgage foreclosures - were already upon us?" (Akerlof and Shiller 2009: 2) After the events the facts that were seen as impossible became considered as inevitable.

And the explanation seems compeling and quite simple. People acted in a way that led to the greater disequilibriums after WWII, being sure that the economy is in a natural state of equilibrium, predicted by the mainstream teory. „There is a simple answer. The public, the government, and most economists had been reassured by an economic theory that said that we were safe." (Akerlof and Shiller 2009: 2) The reality shows that they were wrong and the effects may be are still to come, as the taken measures – mainly quantitative easing - relieved the pain but didn't cure the disease. At the local level pressed by the EU an IMF constraints, the government took austerity measures that deepened the crisis.

II. The foundation of economic behavior

There are an extensive literature about economic growth, business cycle and the behavioral foundation of these theories. The first is called mainstream economics that rely on the rational and maximizing behavior of the individual. It is based on several axioms. They are:
- For every individual A and any options x and y, is true one and only one of the following three statements: A prefers x for y, A prefers y for x, A in indifferent between x and y
       - The preferences of A between alternatives are transitive
- A tries to maximize his utility, where utility of an option x is bigger than the utility of an option y if and only if A prefers x for y. The utilities of two options are equal if and only if A is indifferent between them.
- If option x consists in getting the bundle of goods x', and option y in getting the bundle of goods y', and y' contains a quantity at least as big of every good as x', and at least for one good a bigger quantity, then all agents will prefer y for x.
- Marginal utility of a good x for an agent A is a decreasing function of quantity x which A dispose.
       - The behavior of any agent A is maximizing, the consumer maximizes his utility through consumption of goods, and the producer maximizes his profit.
       These axioms reflect a behavior that is perfectly rational and maximizing. The individual ("homo economicus") is an abstractization of the real individual, which doesn't influence the theoretical conclusions. But are they realistic? The critics of this model are very strong and are sustained by the results of other sciences: psychology, sociology, and biology. Ronal Coase, a Nobel prize winner agree that there are "a lot of
complaints about formalism in economics – the elegant but sterile reasoning and so on – but also talks about the lack of realism in economic discussion." Coase 2002: 5)
A consistent criticism to the concept of "homo oeconomicus" came from Herbert Simon. His main critics at the individuals' behavior considered by the mainstream economics consists in the following observations:
- people have major difficulties in gathering information necessary for decision making, in order to generate all the possible alternatives;
       - the human brain has a limited computing capability leading to difficulties in analyzing and comparing the alternatives;
- people have difficulties in getting aware of their our own preferences.
       - the values, needs and demands of the individual changes in time and are influenced by the environment;
- people haven't a consistent utility function (Simon, 1992)
As a solution to these shortcomings in the rational behavior Herbert Simon defines bounded rationality as a substitute for perfect rationality. He defined the concept of satisficing option, meaning that people don't maximize, but stop their decision process when arrive at a good enough solution. This along with the idea that human brain has computing limitation represent the core of the concept of bounded rationality.

In the attempt to save the concept of a rational maximizing behaviour, the mainstream economics extended the decision making area including information gathering. The individual is assumed to maximize his utility function, function that includes the cost of obtaining the necessary information. It was an promising approach but in this case the individual doesn't know if this worth the effort involved by this action, he doesn't know when to stop, when he has enough relevant information. Thus he doesn't know if his choice is optimal. Moreover the individual takes into account the expected benefits and not the the real ones, when he decides to stop the information gathering, because he don't know the latest.

Other criticism comes from experimental economics. In this field Kahneman and Tversky used relevant experiments in the area of rationality, arriving at the conclusion that there are many areas and situations when people don't act rationally, and the maximizing behavior is at best an desire. To name jus few of the heuristics and biases discovered: representativeness, availability, adjustment and anchoring. (Kahneman and Tversky 1974). Thus we cannot say that the people have a rational maximizing behavior. We can make an assumption that in certain conditions we can approximate the real behavior with the theoretical one. But if the theory works well in normal conditions it fails during the major crises because the markets are irrational, and largely overreact.

III. The relationship between behavior and economic evolution

The human behavior at the microeconomic level determine through aggregation the economic behavior at the macro level – GDP evolution, savings, investments, deficits etc. The ideology underpinning that specific behavior, the shared mental models, according to Douglass North play also an essential role. For instance the deregulating principles, based on the assumptions of efficient market, prevailed for about 30 years, starting from the Washington Consensus, at the beginning of '80. Their core idea is that the market is always better than government (people know always what is good for them better that others) and because of market efficiency is always in a near equilibrium point. Any adjustment will take place mainly smooth because the market is very vigilant. But is this correct? Are the markets efficient? The answer is mixed. They are efficient in conditions of economic normality when there are small deviations from the equilibrium, but inefficient when the economy is far from equilibrium. George Soros show, from real life facts, that future actions of people depend on the expectations they have, but their actions changes the reality and the expectations of the other actors. Thus the curves of supply and demand are not independent, but based on the people expectations. For instance "the decisions regarding buying and selling of stocks are based on the expectations about future prices, but the future prices depend on their actions of buying and selling." (Soros 2008: 58)

The people with their bounded rationality are often victims of the general ideology which lead to overreaction both positive and negative. This approach is consistent with Douglass North, mental models and ideologies. However according to North the performance of an economy is strongly related with the ideology and, based on it, the institutions a country develop through time. (North 1999: 107-117)

People believed the same ideology that markets are efficient, and have the same mental model that prices are going up because in the last 20 years, they do so. Thus when the prices go up creates an expectation for further rising, through a process of reflexivity, synonym of "self-fulfilling prophecy". The same is the case when the there is foreseen a pessimistic scenario. A decreasing of the incomes leads to reduced spending and creates the conditions for further decrease of the incomes.

A similar thing happened on the financial markets. After the massive deregulation in 80' and 90' many financial products were issued, like CDS and derivatives. The idea, based on perfect equilibrium theory, was to spread the risk by hedging and transferring it to other financial institutions. But while it could seem to be a solution at the microeconomic level, in fact it creates

a systemic risk that could not be calculated by a bounded rational individual, even if he dispose a huge electronic computational power. As Soros explained regarding the situations close vs. far from equilibrium the economic experts were right in periods of relative lull but deadly wrong in the time of rapid falling of the economy.

The government also acts according to the bounded rationality principles. The public decision maker suffers from the same shortcomings regarding rationality and computational power. Thus their decision can be suboptimal and this crisis proved that, through poor interest rate management of FED to mention just one item, it was actually the case.

IV. The economic crises and its behavioral roots

The current economic crisis is the worst from WWI. The magnitude of fall of GDP, and the level of unemployment, in many countries, is unprecedented since then. The worse is that the crisis in not finished yet. The measures taken by the governments and central banks didn't cure the disease but postponed the end. What happened? What were the measures used? What is the solution?

Let's see first the US example, the starting point of the crisis. The economic figures show that we had a bubble on almost all markets: real estate, stocks, and commodities. The plain facts are that after a long period of steady increase of GDP, in 2007 started a brutal fall of the values of assets, and incomes. The Dow Jones Index went down about 50% in less than a year, the Case Schiller index of real estate market lost about 20%, and the price of oil felt from 150 USD to 40 USD in the same period.

Suddenly people and economists started to talk about many major disequilibrium on different markets: real estate, stocks, derivatives, etc. What said economic theory about these facts? What was the mechanism?

If the market were efficient this could not happen. Efficient markets allow adjustments, but smooth ones. This kind of crisis is simply impossible. But they happen. Why? And we come to the question from the beginning: Are the markets efficient?

The real life conclusion, despite the theoretical appealing, is a clear NO. Where comes the discordance from? The problem is fundamental and come from the very foundation of economic theory, the rational maximizer "homo economicus". The real despite non obvious roots stems from the non perfect rationality and non maximizing behavior of the economic actor. "The idea that economic crises, like the current financial and housing crisis, are mainly caused by changing thought patterns goes against standard economic thinking. But the current crisis bears witness to the role of such changes in thinking. It was caused precisely by our changing confidence, temptations, envy, resentment, and illusions—and especially by changing stories about the nature of the economy." (Akerlof and Shiller 2009: 5)

An interesting and informed opinion has George Soros. He said that the economy follow a cycle of bubble creation and severe falling then.

The bubbles were created by the irrational behavior of the people, both specialists and simply people. FED kept the interest rate at 1% too long fostering credit and assets bubble. People were happy to borrow at a very low rate, believing that the prices will go up forever. Investors, who disposed from sophisticated models and huge databases, were wrong, too. And the reflexivity, the term described by a genuine speculator, George Soros, played for a time in their team. According to Soros prices can rise too much through a process of reflexivity, when people expect for the prices to rise and as a consequence they buy more thus the price rise even more enforcing the expectations.

Another effect was that people stopped to save conducting to disequilibrium between saving and investments, that had to be financed through external capital. The easy credit euphoria pressed also to prices increase toward unsustainable levels creating the illusion of wealth.

The same happened at the public authorities. Pressed by the increasing social expenditures they borrowed heavily in the hope that the future growth of GDP will allow them to repay the credits (public deficits). But the economy grew thus based on unsustainable stimulus, cyclical measures that leave a very small maneuver space for the government when the crisis hit.

The public authorities myopia is thus even more dangerous and non understandable taking into account that they benefit from huge research and analytical resources.
