The solutions are obtained by solving the system of linear inequations. From the domain of solutions, were chosen  $a = 8$  and  $b = -8$  although any solution should work for the purpose of the analysis. The index variable becomes  $Z = 8vol - 8val$  and the new model is:

$$trans = 1006.55 - 0.17BET + 0.044Z \quad (10)$$

All the model parameters are significant at 5% level of significance.

In the regression model (10), multicollinearity was removed if looking at the VIF values from the below table.

**Table 4:** VIF values

Variable	VIF
Z	1
BET	1

As mentioned before, one of the effects of multicollinearity is that parameter estimates can have opposite signs. This was the case of  $val$  variable, which changed signs after multicollinearity was removed.

Although in this model the stock price is lower explained by the explanatory variables then in model (8), the problem of multicollinearity has been fixed. In this case, the

predictive variables help in explaining the number of closed transactions in a proportion of 40%, which increased from 6% when explained only by the stock index. Even though, in general, the method does not prove out an increase in the model quality, such results are expected.

## 6. Conclusions

The presented method is used to overcome the effects of the multicollinearity phenomena. The originality of this study consists of creating a new variable as a linear combination of the highly correlated ones. The linear combination coefficients are obtained by imposing specific constraints on the system of inequalities. The constraints under which the coefficients are computed are using strictly the covariances between the variables. Any pair of solutions from the solution domain will lower down the multicollinearity phenomena but the best pair can be chosen with the help of an optimization program. The best pair of solutions will lower down enough the correlation between the independent variables and increase the correlation between the independent variables and the response one. The multicollinearity will be lowered down and even fixed.

As further work, the method can be developed to apply to a set of several highly correlated variables and an optimization program that chooses the best set of coefficients will be of interest. Also, some work can be done in proving that the quality of the model increases when the highly correlated variables are replaced by the index variable.

*Abstract: After a period of studying a certain subject, students form an opinion about it and begin having certain expectations. These expectations and the degree in which, in the end, they fulfil, contribute to the reputation of the university. Consequently, a continuous evaluation of the quality of the educational process is needed. The present research presents a part of a more complex study made on a sample of master students in Audit and Financial Management in Romania. The goal was to evidence the main factors that affect students' expectations in what regards the grades they will obtain at the end of the semester. For this, a questionnaire of 20 questions was applied to 250 such students. After factor reduction procedures were applied, six most significant variables were kept in the analysis: the proportion of knowledge acquired, the perceived level of utility of the discipline in the professional career of the student, the proportion in which the subject could contribute to getting employed in the field it belongs to, the evaluation method and two variables evaluating through grades the didactic performance during the course and the overall performance of the tenure professor. The influence of these variables upon the grade expected by the student was assessed with the help of the OLS regression, both in the simple and multiple forms. Out of the six hypotheses formulated, only one proved to be false based on the simple regression analysis. When individually assessed, the evaluation method announced by the teacher at the beginning of the semester turned out to have no statistically significant influence upon students' expectations. For the rest of the variables, results were according to the assumptions made, i.e. all determine in a significant positive manner the students' opinion about the grade they will get. We have also constructed the multiple regression models. When putting all variables together, the significance changes. The level of difficulty of the evaluation method becomes significant, while from the rest of the variables only the proportion of knowledge acquirement still holds. The final conclusion is as expected: the higher the proportion of acquirement, the higher the grade expected at the end of the semester, while the more difficult the evaluation method, the lower the grade.*

## 1. Introduction

Students' expectations in what regards grades they will obtain at the end of the semester depend on a series of factors. In a complex analysis, they were asked to grade different aspects related to the teaching – learning process. The final goal was to evaluate the quality of the educational process and problems that may appear. Out of the results, the present study emphasizes the main factors that affect their expectations.

For an important educational progress it is necessary to know students' opinion on various aspects regarding the educational process. In literature we can find many studies on different factor influencing students' perceptions on education. Many researches were conducted on the importance of the education programs in finding a job after graduation (Phillips and Crain, 1996, Sellers and Fogarty, 2010). The way in which students prepare for the employment moment is reflected also in their implication in assimilating as much information and knowledge as possible during the years of study.

Cooper and Tom (1986) based on a study called Pygmalion in the Classroom (Rosenthal and Jacobson, 1968) demonstrated that the expectations teachers held for student performance influence student achievement. Others researchers conducted studies on the same relation between teachers and their students (Madon et al., 1998; Alvidres and Weinstein, 1999 etc), reflecting that the higher the teacher expectations were, the higher was the student achievement.

Later on, Periasamy et al (2012) conducted a study which reflected that the students' grades depend on their gender, financial status and study time. Other studies pointed out that without hard work students' performance cannot be achieved and their grades reflect that (Harb and El-Shaarawi, 2007).

Despite these internal factors, Jaggia and Hawek (1999) consider that the family background and the stability of a community are the main factors affecting students' performance.

As we can see there are many factors affecting the students' achievement of information and knowledge. Our study aims to develop a possible relation between some of these factors and the grades students expect to obtain, considering that the grades that students get reflect in a different proportion some of the factors described before.

The paper is structured as follows. In the first part, the Introduction, we present the reasons for this study and others researches identified in the scientific literature. The second one refers to the research hypotheses and the methodology we used to process the data we collected. Results are presented in section 3, followed by conclusions.

## 2. Research Hypotheses, Data and Methodology

In order to analyze the main factors that influence students' expectations, we have constructed a series of working hypotheses.

*H1: There is a direct relationship between the level of knowledge acquired by the students and the grade they expect to obtain.*

*H2: If the course is important for its future career, the student will learn and will get a higher grade.*

*H3: The higher the contribution of the course to finding a job in the field, the higher the interest of the student and, consequently, the grade expected.*

We expect students to be more interested in subjects that could increase their chances on the labour market, both from the point of view of finding a job and from the point of view of the type of job and level of salary.

*H4: There should be a negative relationship between the grade expected and the evaluation method announced.*

The tenure teacher was asked to inform the students at the beginning of the semester about the way they will be evaluated for the final grade. Obviously, we assume a low level of difficulty to be associated with high expectations of the students.

*H5: A positive relationship between the academic performance of the professor and the students' expectations for evaluation.*

Regardless of other factors, a bad academic performance may lead to a loss of interest of the students for that subject. Instead, the opposite should have as a final consequence a better performance of the student. Actually, this hypothesis was divided into two. Consequently, resulted hypotheses H5a and H5b. The first one evaluates the didactic performance during the course, bearing in mind that some of the classes were held by other persons than the tenure teacher. The latter assesses the overall performance of the tenure professor.

A complex questionnaire of 20 questions was applied on a sample of 250 students enrolled in the master courses in Auditing and Financial Management of the EU Funds. The master programme aims to develop a close relation between the higher education institutions and the entities from the practical environment that are already beneficiaries of programmes financed from the European Funds. Therefore, the master program management team decided that the involvement of the economic specialists experienced in the field of interest is very necessary. Therefore, the master classes and workshops for training will be held not only by the teachers, but also by the experienced practitioners in the master program field (Nistor et al, 2011).

After the validation process, the volume of the final sample was of 236 students. Factor reduction procedures (Buiga, 2000; Buiga, 2011) were applied and 6 exogenous variables were finally left in the analysis. The variables are:

- GRADE (endogenous variable) – the grade students expect to obtain at the end of the semester for the course under discussion. The minimum value is 1 and the maximum is 10.
- PROP\_KNOWLEDGE (exogenous variable) – the proportion of knowledge students consider they have acquired for the discipline under discussion.
- CAREER\_UTILITY (exogenous variable) – the perceived degree of the discipline's direct utility in the professional career of the students.
- EMPLOYMENT (exogenous variable) – the extent to which the knowledge assimilated during the course will contribute to finding a job in the field of the programme students are enrolled in.
- EVALUATION\_METHOD (exogenous variable) – the perceived level of difficulty of the evaluation method announced by the tenure teacher at the beginning of the semester.
- DIDACT\_ACT\_PERF (exogenous variable) – the grade given by each student for the performance of the didactic activity during the courses.

- OVERALL\_PERF (exogenous variable) – the grade given by each student for the overall performance of the tenure professor.

The first four exogenous variables were initially measured in proportions from 0% to 100%. For analysis purposes, they were transformed on a scale from 1 to 10, just as the endogenous variable.

In the case of the teaching performance two variables were considered. The reason is that all tenure teachers invited practitioners during the semester for practical lectures. Consequently, we have evaluated, on one side, the didactic activity as a whole, for all the persons that made presentations for a discipline, and, on the other side, only the overall performance of the tenure teacher.

In order to test the hypotheses made, we have employed the correlation coefficient and the OLS regression method, in the simple or multiple form (Dragos, 2008), with constant term. The endogenous variable was, in all cases, the grade each student has declared to expect at the end of the semester. The regression models were validated through the common regression diagnosis procedures based on residual values.

### 3. Results

The goal of the present study is to assess the factors that influence students' expectations in what regards grades they will obtain at the end of the semester. To do this, first we have asked the students in the sample to give the grade they anticipate to get. The average value for the sample is 8.95 (see table 1). Results show that students are very optimistic. On a scale from 1 (lowest) to 10 (highest), most of them declared the value 9. Moreover, no grade lower than 6 was encountered and more than 25% of the students are expecting to be graded with the highest value – 10.

**Table 1:** Descriptive statistics for the grades students expect to get at the end of the semester.

		What is the grade you expect to obtain for the course?
N	Valid	227
	Missing	9
Mean		8.95
Median		9.00
Mode		9.00
Std. Deviation		0.96
Minimum		6.00
Maximum		10.00
Percentiles	25	8.00
	50	9.00
	75	10.00

Source: own calculations using SPSS 17.0.

To test the hypotheses we have run simple linear OLS regressions. The results are synthesized in table 2. We can conclude that the highest dependence is between the grade expected and the level of knowledge acquired by the student.

The first hypothesis tested the existence of a direct relationship between the level of knowledge acquired by the students and the grade they expect to obtain. The positive coefficient of 0.372 accepts this hypothesis at a 99% confidence level. Actually, all the hypotheses that were accepted by the analysis had a significance level of 0.000, so a confidence level of 99%. Consequently, only the sign of the coefficient remained to be inspected.

**Table 2:** Regression analysis: the grade expected versus factor – synthesis.

Hypothesis	Factor var.	Coef.	Sig.	Beta C.	Adj. R <sup>2</sup>
H1	PROP_KNOWLEDGE	0.372	0.000	0.627	0.391
H2	CAREER_UTILITY	0.208	0.000	0.397	0.154
H3	EMPLOYMENT	0.193	0.000	0.370	0.133
H4	EVALUATION_METHOD	- 0.035	0.236	-0.080	0.002
H5a	DIDACT_ACT_PERF	0.350	0.000	0.393	0.150
H5b	OVERALL_PERF	0.290	0.000	0.290	0.080

Source: own calculations using SPSS 17.0.

In the regression model between the grade expected and the proportion in which the course is important for a future career, the coefficient is 0.208. Thus, we can state that the hypothesis made is true, the higher the importance of the course for a future career, the higher the grade.

In other studies (Mare et al., 2012, Span et al., 2012) we have seen that students are more interested in courses with a direct utility on the market. So, their main goal is getting employed in a certain field. That is why we expected a direct relationship to be found between the grade and the contribution of the knowledge taught during a specific course to finding a job in the field of interest. The positive coefficient sustains this assumption. However, when comparing the results for hypotheses 2 and 3, we can see that the importance of the course in a future career has a higher influence than the direct utility of getting employed in a certain field. H2 and H3 were constructed from the idea that students will try to learn as good as possible for a course that has practical utility. And the most important aspect is the contribution on the labour market. Consequently, the direct relationship should be first between this contribution and the level of knowledge acquired. Only afterwards, the grade expected and, finally obtained. That is why we have also tested the level of correlation between the above mentioned variables.

Both correlation coefficients have values between 0.3 and 0.7, showing a medium intensity relationship. Moreover, this relation is positive, as expected. Again, the second variable has a lower coefficient, meaning a lower influence (thing already evidenced by the above mentioned results) (see table 3).

**Table 3:** Correlation coefficients between the level of knowledge acquired and the contribution of the course for a future career.

	Value	Approx. Sig.
What is the proportion in which you consider the course has a direct utility for your future career?	0.510	0.000
The knowledge acquired during this course will contribute to finding a job in the field of study in a proportion of...	0.473	0.000

Source: own calculations using SPSS 17.0.

The fourth assumption is related to the evaluation method. The coefficient has the right sign (negative) – the more difficult the evaluation method, the lower the grade expected to be obtained. But the significance value is much higher than 0.05 (0.236). We can conclude that there is no significant relationship between the grade expected and the evaluation method announced by the professor.

Our last assumption is related to the performance of the professor. A good academic and didactic performance should be accompanied by higher expectations from the students. To test H5 we have used two variables. In H5a the students were asked to grade the performance of the didactic activity during the courses. In the H5b case, the grade was given for the overall performance of the professor. In both cases the hypotheses made were accepted – the coefficients are positive and statistically significant. However, the performance seen strictly from the point of view of the course has a higher influence on students' expectations in what regards their final examination results. An increase in the grade for the didactic activity with 1 unit would lead to an increase in the grade expected by 0.35 points, while the same increase of the evaluation vote for the overall performance has as a consequence an expected higher grade by 0.29 points. An explanation of this could be the fact that for the entire sample, the tenure professor invited specialist to the courses that explained the applicability of the notions taught.

Up to this point, individual influences were assessed. We were curious to see what happens when all these factors are analyzed together – do they all remain significant and if changes occur in the degree of influence. The multiple regression analysis shows that almost all the factors considered become statistically insignificant (see Table 4). Consequently, we have re-estimated the regression with the two significant factors.

**Table 4:** Multiple regression model – coefficients and significance tests.

Model	Unstandardized Coefficients		Standardized Coefficients	t	Sig.
	B	Std. Error	Beta		
Constant	5.848	0.563		10.396	0.000
PROP_KNOWLEDGE	0.349	0.046	0.588	7.538	0.000
CAREER_UTILITY	0.021	0.047	0.041	0.448	0.654
EMPLOYMENT	-0.017	0.046	-0.032	-0.359	0.720
DIDACT_ACT_PERF	0.070	0.068	0.077	1.036	0.301
EVALUATION_METHOD	-0.050	0.024	-0.115	-2.083	0.039
OVERALL_PERF	-0.004	0.068	-0.004	-0.060	0.952

Source: own calculations using SPSS 17.0.

Finally, the best model for explaining students' expectations in relation with their final evaluation is based on two factors – the proportion of acquirments for each subject and the level of difficulty of the evaluation method announced by the professor. This is the model with the best fit –  $R^2 = 0.407$  and adjusted  $R^2 = 0.401$ . This means that the two predictors explain 40% of the variance of the endogenous variable. Additionally, the ANOVA analysis returned a value of 75.4 for the Fischer test, at a significance value = 0.000. Table 5 presents the coefficients and the significance tests for the model. Moreover, the signs of the coefficient are the ones expected – positive for the share of knowledge acquired and negative for the difficulty of the evaluation method.

**Table 5:** Best fitted regression model – with two factors.

Model	Unstandardized Coefficients		Standardized Coefficients	t	Sig.
	B	Std. Error	Beta		
(Constant)	6.330	0.298		21.231	0.000
PROP_KNOWLEDGE	0.375	0.031	0.635	12.184	0.000
EVALUATION_METHOD	-0.056	0.023	-0.128	-2.458	0.015

Source: own calculations using SPSS 17.0.

#### 4. Conclusions

The goal of the present research was to assess the factors that influence students' expectations in relation to the grades they will obtain at the final exams. After a complex judgment, based on statistical methods, six main factors remained in the analysis. Their individual evaluation confirmed the hypotheses in 5 out of the 6 cases considered. We demonstrated that the grade expected by a student to be obtained at the end of the semester is positively influenced by the degree in which the discipline was assimilated and it could influence the personal career in general

and the employment in that specific domain, in particular. A relationship of the same kind was also found with the performance of the didactic activity, through both the proxies used. Even though the sign of the coefficient returned as expected, the influence of the degree of difficulty of the evaluation method announced by the professor did not prove to be statistically significant. However, the low  $R^2$  values show there other more important factors influencing the grade students expect for the final evaluation.

Things changed when multiple regression analyses were made. The most significant model consists in two exogenous variables – the proportion of knowledge assimilated and the difficulty of the evaluation method. The signs of the coefficients were as presumed – positive in the first case and negative in the second. All other exogenous variables turned to be insignificant.

In conclusion, the higher the proportion of knowledge accumulation, the higher the grade. In the same time, the less difficult evaluation, the higher the grade expected.

**Abstract:** European Structural Funds have been created with the clear goal to redistribute money among European Union members in such a way as to help poorer regions diminish the gaps between them and the richer ones. The present study assesses this problem for the Structural Operational Programme Environment in Romania. Using spatial econometrics methods, we evaluate two issues on the sample of 42 Romanian counties. The first one is if any clusterization process takes place in what regards contracting funds through ESF for environmental protection projects. The second one is intended to test whether the main principle of the ESF is satisfied – helping the poor in a sustainable development process. Using the quartile maps and the spatial Moran's I autocorrelation coefficient we show different results for the clusterization topic. When considering the budget value of the projects implemented through SOP ENV, both as total and as eligible share, Romanian counties group based on a positive global spatial autocorrelation. This means that counties with approximately the same budget levels are neighbours. Transylvanian counties have gained the most out of the projects on environment. When the number of contracts is assessed, the distribution of the counties proves to be random and no global spatial autocorrelation was found. Moreover, the map analysis shows that, in general, there is a negative relationship between the value of the budget and the number of contracts. The spatial regression analysis shows the violation of the ESF principle. The coefficients of the GDP are positive. This implies a direct relationship between the richness of the county and the projects implemented through the SOP ENV. Thus, instead of being used by the poorer regions, money goes to the richer ones. The higher the GDP, the higher the value of the budget for the environmental protection programmes financed through European funds. The GDP also positively influences the number of contracts scheduled or signed, but the only at a 10% significance level.

**Keywords:** SOP ENV; sustainable development; environment; Romanian counties; spatial distribution; spatial regression model.

**JEL classification:** C31; Q56.

## 1. Introduction

The present paper combines two of the main issues of interest nowadays – European Structural Funds and the environment. For a young member state as Romania, financial aid in the form of the Structural Funds is the main entrance channel for investments. It helps the receiving country modernize its infrastructure

and improve the skills of the labour force in order to diminish the gap between it and the older members. But the efficiency of such programmes depends on the capacity of the receiving country to absorb these funds.

Environmental protection is the subject of continuous concern internationally. Economic activity and the lifestyle have affected environment in a great manner. Problems such as pollution, global warming, etc are now intensively discussed worldwide and solutions are sought. Companies are required to improve their production plants to become more environmental friendly. In the same time, governments search for methods to reduce pollution. Dragos and Dragos (2013) consider the environmental quality of a country as a specific factor for this field, accomplished through adequate governmental politics and population self-awareness.

Considering all these, we have decided to combine the two issues by assessing the projects on environment financed in Romania through the European Structural Funds.

The goal of the ESF is to help poorer members of the European Union reduce discrepancies that exist between them and the richer ones. However, practice has shown that it is not always true. There are many cases in which such projects were implemented by the latter group as they also had the financial resources necessary for the contribution of the beneficiary. Is it also the case of the environmental protection programmes in Romania? In order to reach a pertinent conclusion we have employed spatial econometrics methods to evaluate the budgets and the number of contracts of the projects implemented in the Sectoral Operational Programme ENVIRONMENT. The spatial distribution based on counties was assessed through different kinds of maps fated to emphasize whether any clusters appear or there is a random distribution of values in the sample. Afterwards relationships between variables were studied through different spatial econometric methods, including spatial autocorrelation and spatial regression.

Sectoral Operational Programme Environment (SOP ENV) is one of the seven operational programmes under the "Convergence" objective of the European Union for the period 2007-2013.

SOP is the most important financing program for municipal environmental infrastructure and continuous investment in the pre-accession programs (Phare, ISPA and SAPARD). SOP is based on the objectives and priorities of EU environmental policies, reflecting Romania's international obligations and national specific interests.

The overall objective of the SOP ENV is to improve the living standards and environmental standards and at the same time to contribute to the achievement of the European accession commitments and environmental regulation compliance. To achieve this overall objective, the SOP ENV finances investments for the following sectors:

- The water/wastewater sector – is allocated 60% from EU SOP funds to this sector;
- Waste management sector/rehabilitation of historically polluted lands - investments in the sector aim to create integrated waste management systems at regional level, in parallel with the closure of non-compliant landfills;
- The heating sector – the funds allocated for the sector aim to reduce the

- emissions from municipal heating plants;
- The nature protection sector – the objective is to ensure an adequate management of the protected areas and to prevent the degradation of biodiversity and natural resources;
- Flood protection and coastal erosion reduction aim to protect people and goods from the devastating effects of flooding;
- Technical Assistance. Activities financed from the technical assistance are intended to increase the absorption capacity of EU funds by financing the project preparation and monitoring activities, evaluation and control of projects, publicity and information actions regarding the SOP Env.

The program is financed by two funds:

- European Regional Development Fund (ERDF) –for the waste sectors, nature protection and technical assistance;
- Cohesion Fund (CF) - for the water, heat and flood protection sectors.

The SOP ENV is created to reduce the gap between the EU and Romania regarding environmental infrastructure both in terms of quantity and quality. This should be reflected in effective public services, taking into account the principle of sustainable development and the principle of "polluter pays".

Analyzing the objectives above, we can mention that what follows the SOP ENV program is the development and maintenance of sustainable development, the economic sustainability of the beneficiary countries and the social empowerment of all the people.

Sustainable development is perhaps the key element of the humanity in the XXI century (Ienciu, 2009). Sustainable development became a very important element once with the advent of Brundtland Report in 1987 and with the awareness of the greenhouse effect. The most widely accepted definition of sustainable development is the one proposed in this report. Brundtland Report defined sustainable development as meeting the current needs without compromising the ability of future generations to meet their own needs (WCED, 1987).

Sustainable development does not concern only with the environmental issues. The reference document of the World Summit on Sustainable Development in 2002 (WSSD, 2002) speaks of the independence and mutual support pillars of sustainable development as economic development, social development and environmental protection.

Closely related to sustainable development is the concept of sustainability. Sustainability is a concept that refers to a fair allocation of resources on a global scale. Equity or fairness comes from a responsible and rational distribution of resources and opportunities between the present and future generations (O'Dwyer and Owen, 2005; Dragomir, 2008: 2).

So far, sustainability can be seen as the ultimate objective that an entity/country wishes to attain, a status or a desired condition, while sustainable development is the process by which the human activity is moving towards sustainability and maintains this status (Hibbitt, 2001).

Social responsibility is interpreted as the social dimension of the sustainable development concept. In this case, the entity encompasses social responsibility, economic responsibility and environmental responsibility (Zwetsloot, 2003, Desjardins, 1998).

SOP ENV program is an important step in achieving these objectives so necessary

for the economic growth and social development during the globally crisis we face with.

Our analysis is thus based on two main ideas:

- Is there any spatial clustering process in respect to contracting environmental protection projects through ESF?
- Is the main principle of the ESF respected in reality in the case of the Environment Sectoral Operational Programme, i.e. more funds for the poorer counties to help diminish the gap between them and the richer ones?

The paper is structured as follows. In the first part, the Introduction, we present the reasons for this study, emphasizing the importance of the main concepts included in the general objectives of the SOP ENV program. The second one is the methodological part, where the spatial econometrics methods used and the data are explained. Results are presented in section 3, followed by conclusions.

## 2. Methodology and Data

To evaluate the performance of Romania in attracting structural funds through the Environment SOP programmes considering the two basic ideas, we have employed Spatial Econometrics methods. The easiest way to analyze spatial distributions is through maps. They emphasize the existence of clustering processes. For the present analysis were used the quartile maps, that divide the sample into 4 equal groups based on the values of the variables. Deriving from the map distribution, were constructed the rest of the analyses. But before that, the spatial weights matrix was constructed. In this case, the most suitable proved to be queen contiguity matrix (it had the lowest Moran value). The Moran's I statistic (Moran, 1950) was employed to test the existence of global spatial autocorrelation. If clustering processes exist, than spatial autocorrelation should be found, too. It can be of two types: positive, when similar values concentrate in a certain area, and negative, when regions with dissimilar values are neighbours. The Moran's I statistic is computed based on the following formula:

$$I_t = \frac{z_t' W z_t}{z_t' z_t}$$

where  $z$  is the observation vector in year  $t$  seen as deviation from the average and  $W$  is the standardized weights matrix (Upton and Fingleton, 1985). The null hypothesis is the absence of spatial autocorrelation. Moreover, positive/ negative spatial autocorrelation exist when the value of  $I_t$  is larger/ smaller than  $E(I) = -1/(n-1)$ . The stability of the spatial autocorrelation was tested with the randomization procedure with 999 permutations. The result is a histogram with the  $I_t$  value as a yellow bar and a pseudo-significance level.

The relationship between the projects financed through SOP ENV and the level of richness of each county was dealt with using spatial regression. The first step is to estimate a classical OLS model and then establish whether it is the most suitable one or it has to be re-specified in the form of a spatial lag model or a spatial error model. For this are used the Lagrange Multipliers. In the study were constructed four models in which each of the variables related to the projects (TOT\_VAL, ELIG\_VAL, CONTRACTS, CONTR\_SIG) were endogenous and the county's GDP was de exogenous variable. In the case of the first two models, that assessed the relationship between the GDP and the budget value, the most suitable proved to be

the spatial autoregressive model (spatial lag). It is characterized by the addition of a spatially lagged variable that transforms it into a non linear model. Its general form is (Anselin, 1999):

$$y = \rho W y + X \beta + \varepsilon$$

The third and the fourth model, assessing the impact of the GDP upon the number of contracts are simple OLS models.

They were all tested for significance and validity using the spatial econometrics procedures.

The sample is made up of the 42 counties of Romania. They were evaluated from the point of view of the following aspects:

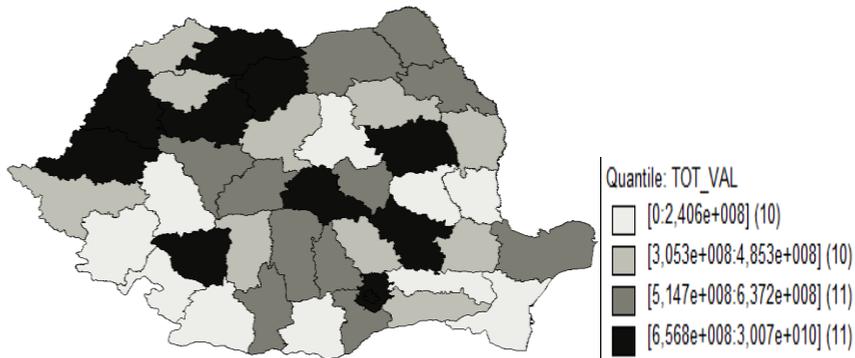

- The total budget value of the projects financed through the Environment SOP for each county (TOT\_VAL);
- The total eligible budget value for the same kind of projects (ELIG\_VAL);
- The number of contracts in general (CONTRACTS) and the number of signed contracts (CONTR\_SIG) for the environmental protection programmes per county;
- The county GDP – as there were no significant changes in the value of the NUTS 3 GDP during the period of implementation of the SOP ENV financed programmes, we have employed the average annual value for entire period.

Data was collected from the site of the Romanian National Institute of Statistics and the national authorities for the management of the European Structural Funds, for the SOP ENVIRONMENT.

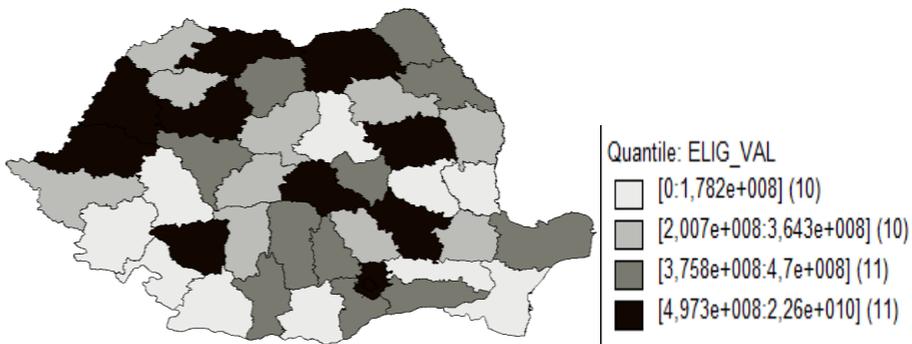

### 3. Results

The first objective of our study was to reveal if any clustering process takes place in Romania, at NUTS 3 level, in respect to programmes financed through the Environment SOP for a sustainable environmental protection. The first step was to construct the maps. Where the maps showed possible existence of spatial autocorrelation, the latter was assessed with the help of the spatial autocorrelation tests.

Figure 1 shows the total budget value of all projects financed through SOP ENV in a county, while figure 2 is constructed for the total eligible budget value per county from the point of view of the environment protection programme. In both cases, using the quantile distribution, we can see that, except for Bucharest and the Ilfov County, most of the upper values are concentrated in the North-West part of Romania, in Transylvania. A closer analysis shows there are 4 upper outliers: Bucharest, Ilfov, Bacau and Maramures, regardless of the type of budget considered.

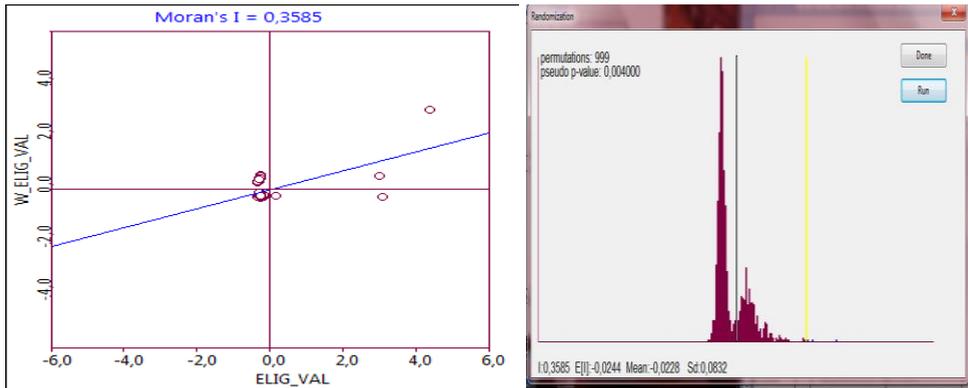

**Figure 1:** Spatial distribution based on quantiles of the Romanian counties based on the total budget value financed through SOP ENV.  
Source: own calculations using OpenGeoDa 1.0.

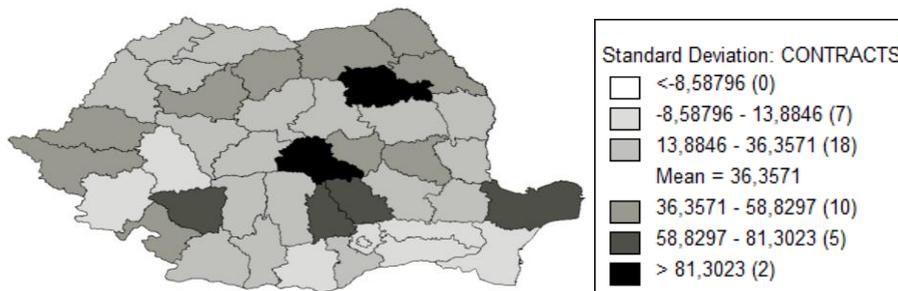

**Figure 2:** Spatial distribution based on quantiles of the Romanian counties based on the total eligible budget value from the point of view of the SOP ENV.  
Source: own calculations using OpenGeoDa 1.0.

Other clustering processes are also evidenced on the two maps. Consequently, we have tested the statistical existence of spatial autocorrelation, using the Moran I statistic and scatter plot. For the total budget, the Moran's  $I = 0.357$ , showing a positive spatial autocorrelation. This implies that counties that gained more projects on environment protection are neighbours. In the same time, counties with lower values bound on counties with approximately the same values attracted. The same type, positive spatial autocorrelation, was also to be found for the eligible value per county, with almost the same coefficient value – Moran's  $I = 0.358$ . In both cases, the statistical significance was evaluated using the randomization procedures. As an example for the analysis, figure 3 presents the Moran scatter plot with the randomization procedure for the eligible budget. Using 999 permutations, the randomization procedures shows the stability of the autocorrelation - the standard, yellow line is on the right side of the plot while the pseudo p-value =  $0.004 < 0.05$ , rejecting the null of no autocorrelation.

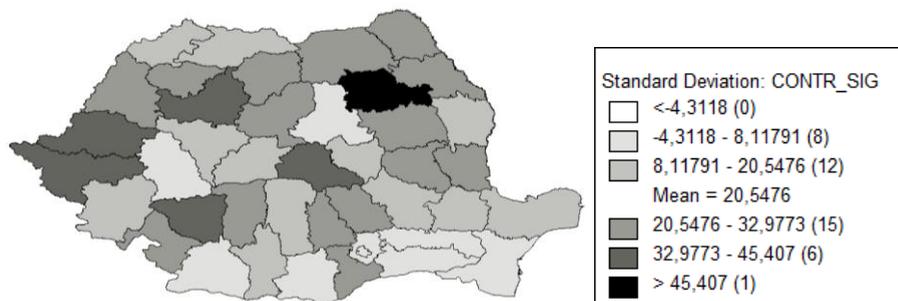

**Figure 3:** The total eligible budget value - univariate Moran's I - scatter plot and randomization procedure.

Source: own calculations using OpenGeoDa 1.0.

**Figure 4:** Standard deviation map based on the total number of contracts.

Source: own calculations using OpenGeoDa 1.0.

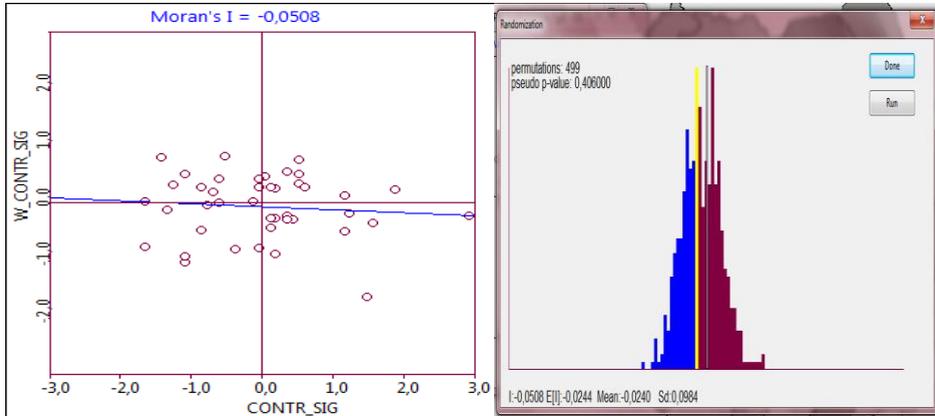

**Figure 5:** Standard deviation map based on the number of contracts signed.

Source: own calculations using OpenGeoDa 1.0.

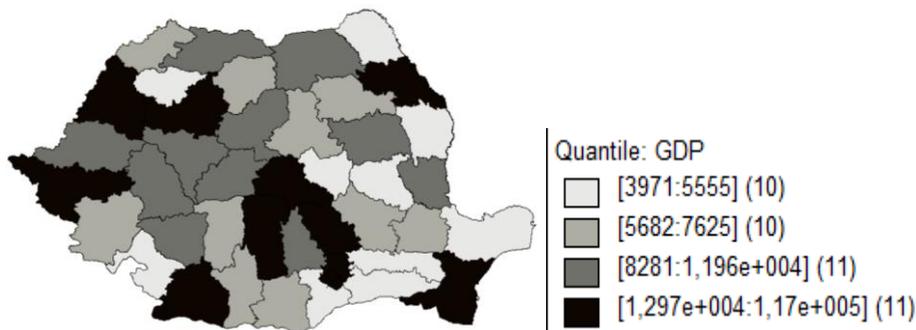

Things change considerably, when assessing the number of contracts scheduled and the number of contracts actually signed. An average of 36.36 contracts per county were scheduled, out of which the average number of contracts signed was 20.55. Figures 4 and 5 show that the distribution changes, counties with high budget values having lower number of contracts. This implies that in these regions, the level of the budget per contract was much higher. This result is presented in the form of standard deviation maps. There is only one upper outlier evidenced by the box plot

– the Neamt county with 57 contracts signed. No evidence of spatial autocorrelation was found, for neither of the variables involving the number of contracts. For example, for the number of contracts signed, a coefficient of -0.05 was obtained, with a pseudo p-value = 0.41.

**Figure 6:** The number of contracts signed - univariate Moran's I - scatter plot and randomization procedure.  
Source: own calculations using OpenGeoDa 1.0.

In the second part of our analysis we wanted to see if the fundamentally principle of the European Structural funds stands on or not. To assess this aspect we also introduced in the analysis the GDP/county. The quartile map shows a random distribution (see figure 7). In the same time, the Moran's I test validated this assumption with a value of =0.0166 (almost inexistent) and a pseudo p-value = 0.17.

**Figure 7:** Quartile distribution of the Romanian counties based on the average GDP value in the period under analysis.  
Source: own calculations using Open GeoDa 1.0.

When comparing figure 7 with figures 1 and 2, we can see that there are richer counties that benefitted from high amount of money through the SOP ENV. Consequently, we expect to obtain a direct relationship between the two, instead of a negative one. The best way to evaluate this aspect is the regression method. We have considered as endogenous variable both types of budgets evaluated – the

total one and the eligible part from the SOP ENV point of view. The positive sign of the GDP's coefficients in both cases (see table 1) validates the assumption made based on map analysis. We can thus conclude that the main principle of the ESF is not satisfied in this case, as on average, the higher the GDP, the higher the value of the projects financed through the SOP ENV. Obviously, the same results in what regards the number of contracts. The coefficients of the regression models are presented in table 1. We also present the best fitted model for each case. The Moran test found the existence of spatial autocorrelation for the two variables related to the budget and none for the number of contracts. Consequently, we expected spatial autoregressive or error models in the first two cases and the simple OLS model for the last two. The results confirm our expectations.

**Table 1:** Spatial regression analysis – GDP as exogenous variable.

Endogenous variable	Coefficient	Std. error	z-value/ t-statistic	Prob.	Type of best fitted model
TOT_VAL	216350	40681.94	5.318	0.000	Spatial lag
ELIG_VAL	161664.8	30212.4	5.351	0.000	Spatial lag
CONTRACTS	0.00039	0.0002	1.974	0.055	Simple OLS
CONTR_SIG	0.0002	0.0001	1.842	0.072	Simple OLS

Source: own calculations using GeoDa 1.0.

#### 4. Conclusions

We have based our study on two issues.

The first one, the clustering process, was to be found in the case of the values of the budgets for the projects implemented through the SOP ENV. Counties group based on the amount of money gained for environmental protection through ESF. Results have shown a positive spatial autocorrelation, with the highest amount in Bucharest, Ilfov, Neamt and Maramures. As a group, Transylvanian counties have attracted most of the money.

In respect to the number of contracts, things change. The distribution reverses, in the sense that counties with high budgets have low contract numbers. This means that in these counties, the value/contract is high in comparison with the others. Could this be an efficiency indicator? We intend to assess this in a future study. Moreover, the distribution of counties based on contracts is random, no significant spatial autocorrelation being found.

In the case of the second issue analyzed, we can conclude that the principle of the ESF is not respected in this case. The positive value of the coefficient of the GDP in the regression model shows that an increase in the GDP would lead to an increase in the amount of money obtained through the SOP ENV. Thus, instead of being used by poorer counties, the programme is much more used by the richer ones. An explanation could be the fact that the beneficiary has to support part of the expenses and, obviously, a poor region cannot afford to do that.

# HUMAN CAPITAL: CAUSE AND EFFECT OF THE ECONOMIC GROWTH. AN EMPIRICAL ANALYSIS

**Neagu Olimpia**

*"Vasile Goldis" Western University of Arad, Romania*  
*olimpian2005@yahoo.com*

**Abstract** *From the birth of the human capital theory, economists were interested to find evidences showing the impact of the human capital on the economic output, discussing and debating more or less the effect of economic growth on the accumulation of human capital in the economy and the association between education and health.*

*The paper aims to test several econometric models to explain the relationship between human capital and economic output. Using World Bank data, 17 countries with the fastest economic growth rate during 1960-2010 were selected. Four econometric models are tested to explain the accumulation of human capital as input and as effect of economic output. Correlation coefficients were calculated to highlight the association between education and life expectancy.*

*The paper demonstrates that human capital, in his two components (education and health), in countries with a fast growth rate, are positively and strongly related to the economic output, in both senses, human capital being input and output of the economic growth. On the one hand, the economic growth adds to the resources available in the economy for improvements in health and education and, on the other hand, human capital is influencing significantly the economic output. Education and health are interrelated, being positively and strongly associated.*

**Keywords:** *human capital, education, health, economic growth*

**JEL Classification:** J 24, I 25, I15, O40

## 1. Introduction

The relationship between human capital and the economic output is intensively investigated in the literature of human capital. Several cross-country evidences supports the idea that human capital development is an important element in explaining variations in growth rates and level of per capita income.

Educational and health capital are the two main components of the human capital (Neagu, 2010). There are several studies analyzing the effects of the education and life expectancy on the economic growth. But there is less studied the explanation of human capital (health and education) evolution as a dependent variable on the economic output.

The aim of the paper is to explore the relationship between human capital and economic growth, in its both senses, by testing how the two components of human capital: educational and health capital are associated with the economic output (as cause and as effect of economic growth).

The paper is organized as follows: after a short literature review in section 2, the theoretical approach and the methodology of the study is described in section 3. In the section 4 are presented the main findings of the study and the section 5 contains the final conclusions and further research.

## **2. Human capital and growth: a short literature review**

The studies of Paul Romer (1990) regarding the effects of the human capital investment on economic growth concluded that the human capital stock determines the rate of economic growth, meaning that an economy with a higher human capital stock will evolve faster. The model of economic growth developed by Romer explains the fast economic growth of the developed countries in the 20th century, emphasizing that the low levels of human capital explain why are unobservable the progress of the underdeveloped countries, as they could benefit from their integration in the world economic network. He concluded that the rate of return in education can explain the rate of economic growth, through cross country regressions.

Robert Lucas (1988) developed growth models with human capital accumulation and specialized human capital accumulation, through activities like learning by doing and in the job training.

Nancy Birdsall, Thomas Pinckney and Richard Sabot studied the economic growth and education in countries with abundant resources and concluded that these countries expend less for education, in average, than other countries. The explanation resides in the "virtuous growth circle", in which education, as investment in human capital, has direct and indirect effects on the economic output. In rich countries the yearly increase by 1,4% of the enrollment rate in primary and secondary education has lead, in 25 years, to a difference of 40% in GDP per capita. Hanushek and Kimko (2000) concluded that the results to mathematic and science in 31 countries are positively and strong related to the growth of the macroeconomic output. Hanushek and Woessman (2009) conceived a methodology for estimating the human capital quality and its effect on macroeconomic output.

The international organizations and several economists are suggesting that the investment in education have to be a priority of the governments in the developing countries (Becker, 1994 Hanushek, 1995, UNDP, World Bank).

Barro and Lee constructed data sets, several times (2000, 2010), on educational attainment in the world, to investigate how output relates to the stocks of human capital measured by average years of schooling and as well as by the composition of educational attainment of workers at various education levels. They found a significantly positive effect of schooling on output.

In the OECD countries, several studies highlighted the positive impact of the human capital on the GDP per capita growth. The absolute value of the differences between the human capital stocks in rich and poor countries is the right factor determining the convergence of the poor countries towards the rich countries (Cohen and Soto, 2001).

Several studies explored the relationship between the accumulation of human capital and the economic output. Schultz (1961, 1962a, 1962b, 1963, 2003), Barro (1991), Bils and Klenow (2000), Mankiw et al(1992) identified a significant contribution of human capital (measured by the schooling rate) at the GDP growth. Barro and Sala-i-Martin (1995) found that the average schooling years have a significant positive impact on the economic output. Mamuneas, Stavides and Stengos (2002) concluded that the sensitivity of the human capital to the economic output is differentiate between countries, is positive for developed countries and for developing and underdeveloped is lower or zero.

Factors accumulation, inclusively, human capital accumulation, can explain the income differences across countries. In a panel regression of 83 countries, Soto (2009) found the coefficient of schooling as highly significant.

The literature of human capital is less focused on health and its impact on the economic output. There some studies carried out by Grossman (1972, 1999), Schultz (1962), and Gary Becker (2007) which are considering health as a form of human capital. Bloom, Canning and Sevilla (2001) found that a good health has a positive, sizeable and statistical significant effect on aggregate output. In 2004, Bloom, Canning and Sevilla argued that life expectancy effect in growth regressions appears to be a labour productivity effect.

Several studies, using WHO Data, concluded that health is an important determinant of income (i.e. Weil, 2005). But there are a number of indirect channels through which health affects a country are output. Several of these indirect channels, such as the effect of better health in encouraging the accumulation of human and physical capital, could have positive impact on income that are as large as the direct channel.

### 3. Theoretical approach and methodology

The assumptions of the study are: (i) the economic output positively influences the accumulation of human capital in the economy, (ii) the human capital has a positive impact on the economic output (iii) as two expressions of human capital, education and life expectancy, are strongly interrelated.

From the World Bank statistics I extracted time series for the period of 1960-2010 of the following data regarding world countries: GDP per capita, growth rate, life expectancy, enrolment rate in secondary education. Then, I selected countries that fulfil simultaneously the following criteria: (i) the level of economic growth rate (above the average world level (4,2%) for 1960-2010), (ii) data availability for all years (growth rate, GDP per capita, life expectancy, enrolment rate in secondary education), (iii) a standard deviation of the growth rate between 1960-2010 under the value of 7,5. The final number of selected countries was 17.

For each of the 17 countries, I used four regression equations. First, I assumed that life expectancy as a proxy of health capital is dependent on economic growth and the dependence is quadratic. This assumption is inspired by the findings of Hicks (1987). Second, I used the same assumption for the rate of enrolment in secondary education as a proxy of educational capital. Third, I assumed that the economic output, measured by GDP per capita, is a quadratic function of education, using the findings of the same author. Fourth, I assumed that economic output is dependent on education and life expectancy.

For the  $i$  country, the estimated 'life expectancy'  $LE_i$  can be obtained through the equation:

$$LE_i = a_i + b_i y_i + c_i y_i^2 \quad (1)$$

where:  $a_i$  is a constant parameter for the  $i$  country;  $b_i$ ,  $c_i$  are the regression coefficients and  $y_i$  is GDP per capita for the  $i$  country.

For the  $i$  country, the estimated 'rate of enrolment in secondary education',  $ER_i$  can be obtained through the equation:

$$ER_i = d_i + e_i y_i + f_i y_i^2 \quad (2)$$

where:  $d_i$  is a constant parameter for the  $i$  country and  $e_i, f_i$  are the regression coefficients and  $y_i$  is GDP per capita for the  $i$  country.

Then a regression equation was used to verify how the effect of education is reflected in the economic output:

$$y_i = m_i + n_i ER + o_i ER^2 \quad (3)$$

where:  $m_i$  is a constant parameter,  $n_i, o_i$  are regression coefficients and  $y_i$  is GDP per capita for the  $i$  country.

Finally, we can estimate the effect of both forms of human capital (education and life expectancy) through the equation:

$$y_i = k_i + h_i ER_i + g_i LE_i \quad (4)$$

where:  $k_i$  is a constant parameter for the  $i$  country,  $h_i, g_i$  are regression coefficients,  $y_i$  is GDP per capita for the  $i$  country,  $ER_i$  is enrolment rate in secondary education and  $LE_i$  is life expectancy.

There were calculated, for the selected countries, the coefficients of partial correlation between growth rate, GDP per capita, on one hand, and enrollment in secondary education rate and life expectancy on the other hand and finally, the correlation between the two types of human capital (education and life expectancy).

## 4. Results and discussion

### 4.1. Life expectancy and economic output

In all countries included in the survey, except Botswana, the quadratic model of life expectancy as function of GDP per capita (equation 1) is statistically validated (Table 1), for a significance threshold of 95%. In a graphic representation, the function is a flattened  $\cap$ -curve, meaning that life expectancy has limited growth when GDP per capita increases and after the maximum point, the economic growth cannot produce positive effects on the life expectancy. The evolution of the indicator 'Life expectancy' is explained in proportion of 40-97% by the evolution of GDP per capita, in selected countries, if all other factors are constant. Furthermore, life expectancy is positively associated with the evolution of GDP per capita, except Botswana and Lesotho (Table 2).

### 4.2. Education and economic output

In most of the selected countries (16 of 17), the correlation between education (expressed by the rate of secondary enrollment) and GDP per capita is strong and positive (0,8-0,94). In India the association of the two variables is moderate (0,4). The increase of the enrollment rate in secondary education, in selected countries, during 1960-2010, could be explained by the dynamic of the income per capita, in proportion of 45-94%, if other factors are constant. The graphic representation of the function is a flattened  $\cap$ -curve. The model of quadratic function (equation 2) is statistically totally validated in 12 countries of 17 and in other 5 could not be validated for all coefficients, for a significance threshold of 95%. Therefore, this model has to be treated with precaution in further studies.

In reverse, I tested if the evolution of GDP per capita is significantly influenced by education. In the table 2, we can see that in a quadratic model (equation 3), the coefficients of multiple correlation show a strong association between ER (enrollment rate) and  $y$  (GDP per capita) and  $y^2$ . But the model is statistically totally validated only in 5 countries and, in other 11, cannot be validated for all coefficients of the regression equation.

#### **4.3. The effect of human capital accumulation in the economic output**

The fourth model (equation 4) tests the effect of human capital (expressed by life expectancy and enrollment rate in secondary education) in the dynamics of GDP per capita. In all countries, the increase of GDP per capita could be explained in proportion of 69-94% by the increase of life expectancy and of enrollment rate, if other factors are constant, the multiple correlation being very strong. For 7 of 11 countries the model is totally validated and for 10, the model is only overall validated (not for all variables), for a significance threshold of 95%.

#### **4.4. Life expectancy and education**

As we can see in Table 2, for the selected countries, these variables are strongly and positively associated, except for Botswana and Lesotho, where life expectancy is negatively correlated with economic output.

As two components of human capital, life expectancy and education are interrelated and supportive for each other. A healthy and long life is an incentive for more education and more educated people are preserving their health status and have a longer life.

### **5. Conclusions and further research**

In fast-growing countries, economic growth, expressed by GDP per capita, positively influences life expectancy and enrollment rates in secondary education. On the other hand, the assumption that human capital determines economic growth is verified. Both expressions of human capital, the enrollment rate in secondary education and the life expectancy, have a positive impact on GDP per capita. Education and life expectancy are positively and strongly associated in most countries.

For a significance threshold of 95%, a quadratic dependence of life expectancy on GDP per capita is validated for all regression variables. The rest of the models are overall validated, the validation for all variables being under discussion.

Based on these findings, other research can be conducted, for groups of developing and developed countries, by testing log models of aggregate income. Further researches are needed as well, to explore all the channels of economic growth through which accumulation of human capital can be stimulated in economy.

**Abstract:** *The traditional analysis of unemployment in relation to real output dynamics is based on some empirical evidences deducted from Okun's studies. In particular the so called Okun's Law is expressed in a linear mathematical formulation, which cannot explain the fluctuation of the variables involved. This paper deals with an introductory study about the role of non-linearity in the investigation of unemployment dynamics. The main idea is the existence of a non-linear relation between the unemployment rate and the gap of GDP growth rate from its trend. The macroeconomic motivation of this idea moves from the consideration of two concatenate effects caused by a variation of the unemployment rate on the real output growth rate. These two effects are concatenate because there is a first effect that generates a secondary one on the same variable. When the unemployment rate changes, the first effect is the variation in the level of production in consequence of the variation in the level of such an important factor as labour force; the secondary effect is a consecutive variation in the level of production caused by the variation in the aggregate demand in consequence of the change of the individual disposal income originated by the previous variation of production itself. In this paper the analysis of unemployment dynamics is carried out by the use of the logistic map and the conditions for the existence of bifurcations (cycles) are determined. The study also allows to find the range of variability of some characteristic parameters that might be avoided for not having an absolute unpredictability of unemployment dynamics (deterministic chaos).*

**Keywords:** *Unemployment; Economic growth; Logistic map.*

## 1. Introduction

The phase of the economic cycle has strong implications on the employment levels of a Country through different channels. Business decisions on investment and employment depend on several socio-economic variables. The aggregate demand influences the level of utilization of the productive factors, and this in the long term also means investment decisions and capital accumulation. The capital incorporates technology, affects the productivity of workers and contributes to the formation of the human capital. Furthermore the transfer of labour force from a declining sector to another may be a thrust which affects its size and its allocation.

Structural changes in the economic environment can cause profound changes in employment that may prevent from returning to levels recorded before a downturn.

In this case the potential public support, in addition to its being a guide for the general upturn, can move towards the retraining of workers or the facilitation of their transition from a declining industry to a rising one.

Among the instruments to analyze these complex relationships, there is the quantitative relation between the unemployment rate and the *GDP* gap studied by the economist Arthur Melvin Okun (1962) for the U.S. economy in the 60s.

The so-called *Okun's Law* originated from the observation of some regularity in the dynamics of specific economic variables. It was conceived by the economist Okun in 1962, and represents an instrument to compare the current output and the potential *GDP*, starting from the difference between the gap of current unemployment rate and its natural level.

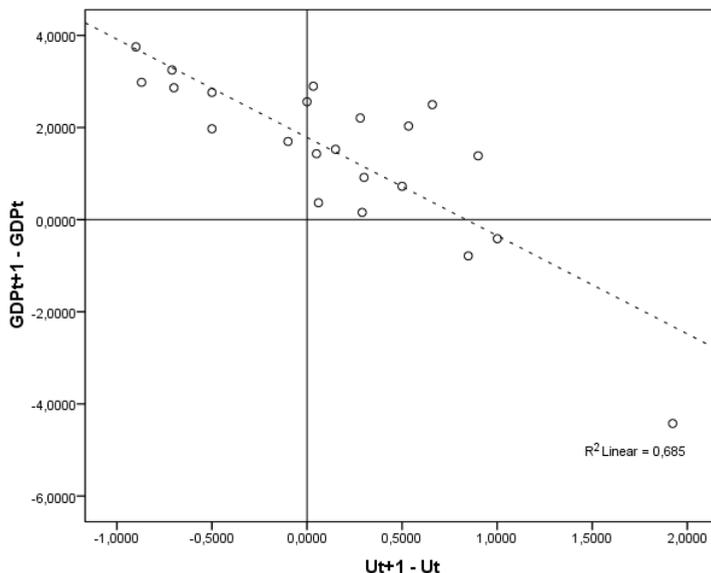

The output gap, that is the difference between the current *GDP* and the potential one, may be positive or negative. In the first case the aggregate demand is greater than the aggregate supply, and this situation tends to increase inflation. In the negative case the economic system operates at a lower level than the optimal one. Okun observed an empirical evidence of the U.S. data, considering how the higher level of current unemployment respect to the natural one, could be considered a cause of an increasing gap between the current level of *GDP* and the potential one (trend). The *Okun coefficient* has been estimated several times in economic studies adopting the different reformulations of the original relationship (see, among many contributions, Smith, 1975; Gordon, 1984; Knoester, 1986; Kaufman, 1988; Prachowny, 1993 and Weber, 1995). Initially it was verified that an increasing of unemployment rate by 1%, originates a drop of 2-3% of the real *GDP* from its potential value. The economic explanation for this empirical regularity is due to the fact that, during periods in which there is expansion of output, more workers are employed or work hours are extended.

The *Okun's Law* can therefore be seen as an instrument of economic policy to control the unemployment level and the trend of *GDP*. Of course, the employment level depends on characteristics of the national system and the local labour market and then the value for other Countries may be different from the final effect in the United States. The aim of bringing unemployment close to the natural level could be reached by a support to the aggregate demand, also by public aids that could sustain the output level. With the increasing of output level, it becomes necessary to increase the number of the labour force in the system. Obviously the number of newly employed workers must be greater than the natural variation of population, because over time, thanks to knowledge and new technologies, the productivity of labour increases, implying the decrease of the number of workers necessary for an unchanged level of output.

Economic studies (see Silvapulle et al., 2004) have highlighted an asymmetry in the relation of Okun. The positive turns in the economic cycle are less influential on unemployment respect the negative ones. This condition should be valid in all the Countries like the U.S. that have a labour market with few restrictions that implies the possibility of a rapid decrease of the labour force.

Most recent determinations of the coefficient of Okun have confirmed the trend found in the 60s from empirical regularities, at least for U.S. and Canada, while the relationship is weaker in Europe and Japan (see, for an analysis on G7 Countries, Moosa, 1997). In many European Countries labour regulation and the role of trade unions prevent firms from adapting the number of workers promptly to the needs dictated by the economic cycle.

The following chart shows the relationship between one-period (annual) changes in *GDP* and in the unemployment rate in the *Euro Area* (17).

**Figure 1:** Relationship between one-period (annual) changes in *GDP* rate and in the unemployment rate for the *Euro Area* (17), 1992-2013\* (\*estimates)  
Source: Our elaborations on *IMF* data

Even by the comparison between the annual variations of the two variables is clear the inverse relationship. This evidence is confirmed over time, though with obvious distinctions, and it is more evident in the largest economic contexts such as the *U.S.*, the *E.U.*, the *Euro Area* and the *G7* group, nonetheless remaining valid even in the single national contexts (see, among others, Mattoscio and Odoardi, 2012).

## 2. Unemployment non-linear dynamics and real output growth

The dynamic model that funds the analysis contained in this paper moves from a generalized version of *Okun's Law* that links the behaviour of real output growth and changes in unemployment over time. In this generalized form *Okun's Law* states that the unemployment rate  $u$  declines by  $\gamma$  percentage point for every 1 percentage point of annual real output growth  $g$  above trend. But the same law establishes that, if output growth were 1 percent below trend, unemployment would rise  $\gamma$  percentage point.

A mathematical form of this version of *Okun's Law* can be expressed in the following way (Dornbush and Fisher, 1985, p. 483):

$$u_{t+1} = u_t - \gamma (g_{t+1} - g_{t+1}^e) \quad (1)$$

where  $u_t$  is the unemployment rate at time  $t$ ,  $g_{t+1}$  and  $g_{t+1}^e$  respectively are the growth rate of real output at time  $t+1$  and the expected one (trend);  $\gamma$  is a real positive

number (parameter).

The *Okun's Law* is an empirical relation between growth and unemployment, but its generalized form can be integrated by a theoretic hypothesis about the non-linearity of the relation itself.

In fact it has much significance to hypothesize the dependence of real output growth gap ( $g_{t+1} - g_{t+1}^e$ ) on unemployment of the previous period as a quadratic function, in consequence of the presence of two interconnected effects on real output growth dynamics coming from a change in unemployment rate. We think to the double effect (direct and indirect) of a variation in unemployment rate on the real output growth: a direct effect, linked to technological aspects, is the variation in the level of production in consequence of the variation in the level of the labour factor; an indirect effect is the change in the level of production in consequence of the variation in the aggregate demand due to the different individual disposal income caused by the previous variation of production itself.

The analytical form of this type of quadratic relation can be written in the following way, according to the double effect described above and considering the algebraic signs of the coefficients  $\alpha$  and  $\beta$  not predetermined:

$$g_{t+1} - g_{t+1}^e = -\alpha u_t - \beta u_t^2 \quad (2)$$

(the negative signs in the second member of this equation are opportune for the following calculations).

By the simultaneous consideration of equalities (1) and (2) it is possible to obtain the following dynamic equation of the time path of the unemployment rate:

$$u_{t+1} = (1 + \alpha \gamma) u_t + \beta \gamma u_t^2 \quad (3)$$

If we use an opportune linear transformation of variable  $u_t$  in (3), we can write an equation equivalent to (3) itself, that acquires the analytical form of the logistic map (May, 1976).

The transformation is:

$$u_t = -[(1 + \alpha \gamma) / (\beta \gamma)] U_t \quad (4)$$

The logistic map so obtained is:

$$U_{t+1} = (1 + \alpha \gamma) U_t (1 - U_t); \quad (5)$$

$(1 + \alpha \gamma)$  is the characteristic parameter of the map itself and equation (5) is the time path equation of the supporting variable  $U_t$ .

### 3. Steady states, stability analysis and conditions to avoid chaos

The discussion of the possible time paths of the variable  $U_t$  and consequently of the variable  $u_t$  that expresses the unemployment rate, with respect to the variation of the characteristic parameter  $(1 + \alpha \gamma)$  leads to the conditions of the existence of bifurcations and periodic cycles and therefore to those related to the onset of deterministic chaos.

These latter in particular are important because they allow to know how to "avoid

the chaos” that is inherent in the dynamics of the system. This result is consistent with a very true statement: chaos must be “known” in order to “be avoided”, since it is a phenomenon more close to everybody than one might think.

The first important considerations are to be referred to the conditions of existence of a stable steady state: the convergence of the unemployment rate to a stable steady state is conditioned by the variability of the parameter  $(1 + \alpha \gamma)$  in the open set of real numbers  $(1,3)$ , according to the stability analysis that is usually made in relation to the logistic map. On the other hand, for the existence of a stable steady state, the same condition, interpreted as the double inequality  $1 < (1 + \alpha \gamma) < 3$ , leads to impose that the parameter  $\gamma$  should vary in the open set of real number  $(0, 2/\alpha)$ , that is:  $0 < \gamma < (2/\alpha)$ . For the coherence of the algebraic signs in this inequalities,  $\alpha$  would be positive, since  $\gamma$  is a positive parameter. The sign of  $\beta$  would be either positive or negative.

Analyzing the equation (3), that is the time path of the variable  $u_t$ , there are two values of the unemployment rate that could be interpreted as steady states:  $u^*_1 = 0$  and  $u^*_2 = -\alpha/\beta$ , both of them determined by imposing  $u_{t+1} = u_t$  in (3) itself. The two potential steady states so determined coincide with the values in which the gap  $(g_{t+1} - g_{t+1}^e)$  would be equal to zero, in consequence of the relation expressed by equation (2).

But  $u^*_1 = 0$  (corresponding to  $U^*_1 = 0$ ) must not be considered, being the equation (3) an identity in this value. We observe the coherence of this mathematical result with the economic significance: the steady state corresponding to an unemployment rate equal to zero is a trivial result.

Moreover  $u^*_2 = -\alpha/\beta$ , corresponding to  $U^*_2 = [(\alpha \gamma) / (1 + \alpha \gamma)]$ , is the only steady state to be considered; it exists and is stable if  $0 < \gamma < (2/\alpha)$ , according to the general results of the stability analysis of the logistic map.

Our analysis becomes more useful in relation to the aim of avoiding chaos that is the aim of avoiding the absolute unpredictability of unemployment dynamics. We summarize the main results by referring to three different ranges of values of the characteristic parameter  $\gamma$  of the logistic map. Another useful result of our study is the possibility of evicting cycles in unemployment rate dynamics.

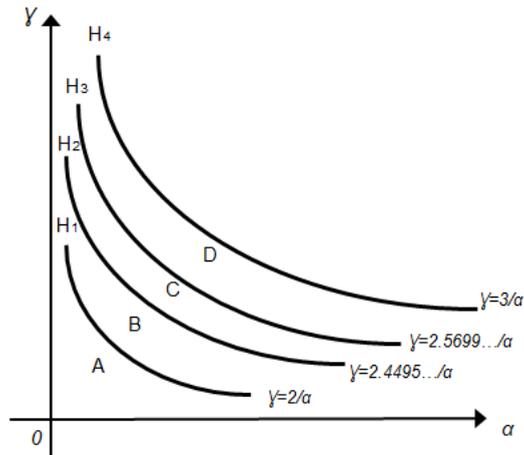

When  $(2/\alpha) \leq \gamma < (2.4495.../\alpha)$  the time path of the variable  $U_t$ , and consequently of the unemployment rate  $u_t$ , undergoes a first bifurcation (2-frequency cycle).

When  $(2.4495.../\alpha) \leq \gamma < (2.5699.../\alpha)$  bifurcations of the time path of the variable  $U_t$ , and consequently of the variable expressing the unemployment rate  $u_t$ , successively double themselves ( $2^n$ -frequency cycles).

Finally, when  $(2.5699.../\alpha) \leq \gamma \leq (3/\alpha)$ , the time path of the variable  $U_t$ , and consequently of the variable expressing the unemployment rate  $u_t$ , evolves with the presence of cycles characterized by “infinite frequency”, that is with the presence of the absolute uniqueness of any value of the rate itself, whose evolution “appears” stochastic, but it is only absolutely disordered, in other words the deterministic chaos occurs. The last closed set of real numbers should be “avoided”, and consequently it should be avoided that the parameter  $\gamma$  of the generalized form of Okun’s Law (1) varies in the interval of real numbers:  $[(2.5699.../\alpha), (3/\alpha)]$ .

#### 4. Graphical representations

The discussion about the numerical consequences of the variability of the parameter  $\gamma$  can be visualized by a simple graphical representation.

**Figure 2:** Sets of  $(\alpha, \gamma)$  pairs.

The four hyperbola branches in the Figure 2 correspond to the four cases related to the following four equalities:

$$\gamma = 2/\alpha, \quad \gamma = 2.4495\dots/\alpha, \quad \gamma = 2.5699\dots/\alpha, \quad \gamma = 3/\alpha;$$

these hyperbola branches form four regions in the first quarter, named A, B, C, D.

If  $(\alpha, \gamma)$  belongs to the open region A, there is a potential convergence to the stable steady state  $u^*_2 = -\alpha/\beta$  that is equivalent to  $U^*_2 = [(\alpha \gamma) / (1 + \alpha \gamma)]$ .

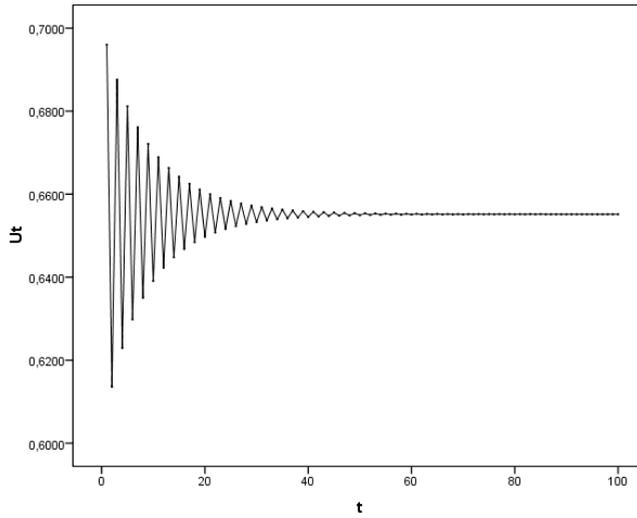

If  $(\alpha, \gamma)$  belongs to the open region B, there is the first bifurcation and a 2-cycle.

If  $(\alpha, \gamma)$  belongs to the open region C, bifurcations double over time and there are cycles characterized by increasing periodicity.

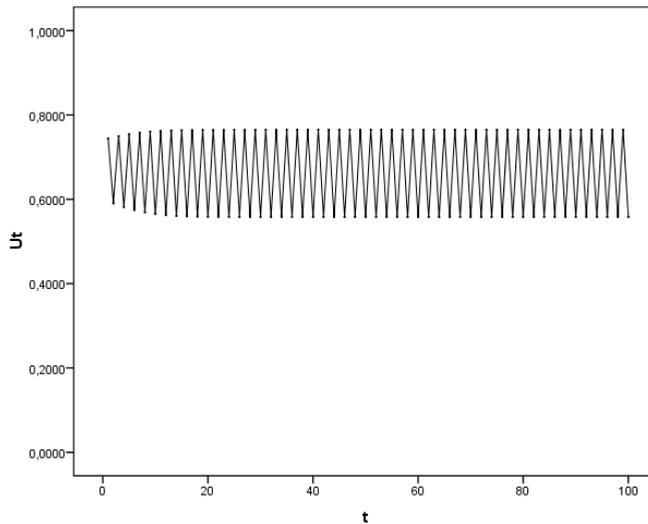

If  $(\alpha, \gamma)$  belongs to the open region D, there is the onset of deterministic chaos.

If  $(\alpha, \gamma)$  belongs to the branch  $H_1$ , there is one bifurcation; if  $(\alpha, \gamma)$  belongs to the branch  $H_2$ , there is a first doubling of bifurcations; if  $(\alpha, \gamma)$  belongs to the branches  $H_3$  and  $H_4$ , there is deterministic chaos.

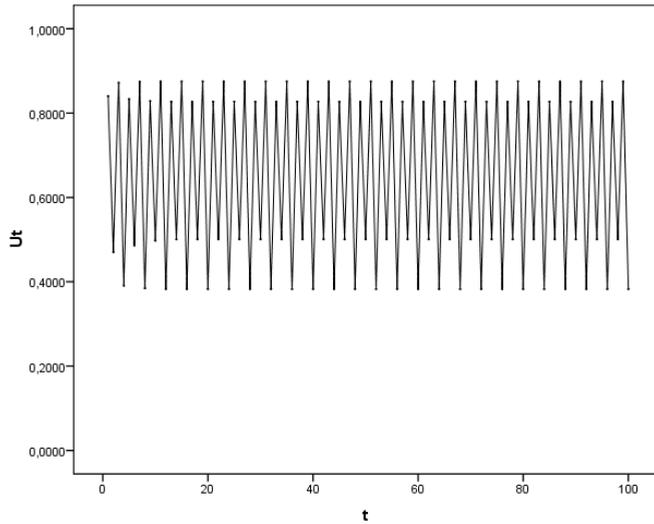

The following four graphs represent different cases corresponding to four values of the parameter  $(1 + \alpha \gamma)$ . In these graphical representations the axis variable is time and the ordinate is the supporting variable  $U_t$ .

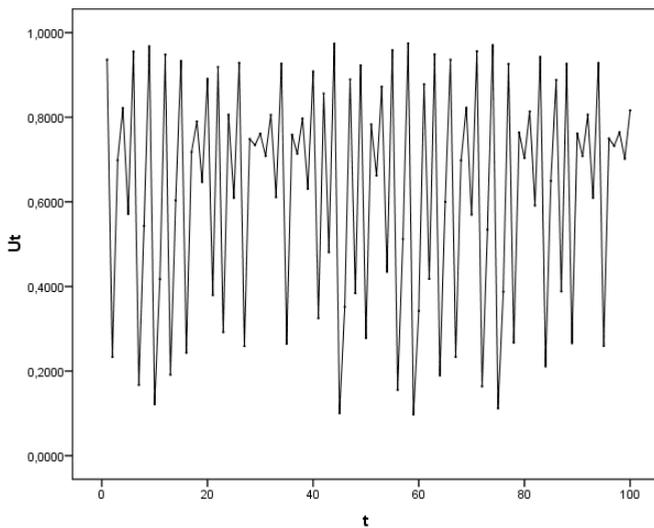

**Figure 3:**  $U_0 = 0.4$ ,  $U_1 = 0.696$  and  $(1 + \alpha \gamma) = 2.9 \leftrightarrow \gamma = 1.9 / \alpha$   
 (convergence to the only stable steady state  $U^* = [(\alpha \gamma) / (1 + \alpha \gamma)] = 0.655$ )

**Figure 4:**  $U_0 = 0.4$ ,  $U_1 = 0.744$  and  $(1 + \alpha \gamma) = 3.1 \leftrightarrow \gamma = 2.1 / \alpha$   
 (one bifurcation – a cycle of periodicity 2)

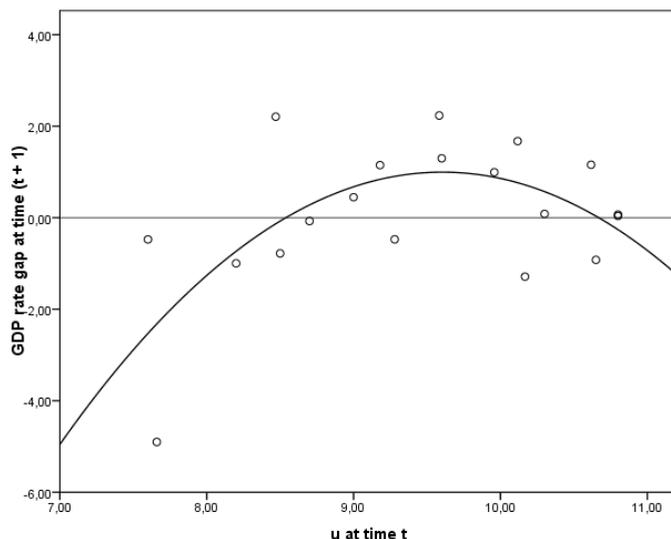

**Figure 5:**  $U_0 = 0.4$ ,  $U_1 = 0.84$  and  $(1 + \alpha \gamma) = 3.5 \leftrightarrow \gamma = 2.5 / \alpha$   
*(a first doubling of bifurcations)*

**Figure 6:**  $U_0 = 0.4$ ,  $U_1 = 0.936$  and  $(1 + \alpha \gamma) = 3.9 \leftrightarrow \gamma = 2.9 / \alpha$   
*(deterministic chaos)*

The main contribution contained in this paper is the proposal of a method for reviewing *Okun's Law*, moving from the observation of real data that often show a non-linear relation between the GDP growth rate gap and the unemployment rate of the previous period, according to the hypothesis expressed by equation (2). The following graph represents this type of relation for European aggregate data.

**Figure 7:** Relationship between *GDP* rate gap and the unemployment rate of the previous period for the *Euro Area* (17), 1994-2012

Source: Our elaborations on *IMF* data

## 5. Conclusions

The study contained in this paper is the theoretic step of the analysis aimed to formalize the relation between unemployment rate and real output growth.

The main contribution of this work is the method used to examine this link.

The analytical approach moves from the idea of the existence of an economically significant non-linear relation between the gap ( $g_{t+1} - g_{t+1}^e$ ) and the unemployment rate.

Another important result of this paper is the individuation of conditions to avoid the onset of the unpredictability of the unemployment rate. The relevance of these conditions is due to the following equivalence: unpredictability is equivalent to uncontrollability because of the total absence of information about the future value of the variable to be controlled.

The study itself has to be completed by the econometric determination of the coefficient  $\alpha$  and  $\beta$  of the quadratic relation (2) which expresses the dependence of the *GDP* growth rate gap on the unemployment rate of the previous period.

## **1.Introduction**

Today, in many countries, the tourism industry fall within government priority, which is why there are numerous national and international projects of large scale and offer stimulation programs for economic development. In this situation is that the program and Romania join the European Union had the priority areas agriculture and tourism.

From the literature we can draw a number of necessary conditions for the development of rural tourism and a number of motivations for its support. Implementation of policies and plans tourism is the responsibility of both governments and private sector entrepreneurs.

The public sector is responsible for policy formulation, research and planning, development of basic infrastructure, the development of certain landmarks, establishment and management of service delivery standards, establishing management measures and recovery planning and environmental protection, setting standards for training and improve employment, maintaining public health and safety.

The private sector is responsible for the development of accommodation services, travel agency operations, the activity of commercial tourist enterprises, development of landmarks and advertising through specific marketing activities, all based on existing infrastructure provided by public administration.

In general need to implement tourism, was deduced from the experience of countries that are considered to have pioneered in the field, such as Montana in the U.S.A, where the employment rate in tourism, in 2000 was 7% compared to only 1.5% in agriculture, and if we refer to the UK in 2001, tourism income were double those obtained by livestock, according the same sources (Sharpley, Craven, 2001).

We believe that a revision of an important part of approaches that have appeared in the literature in terms of the concept of rural tourism, in terms of methods of analysis of tourism activities and, not least, requiring the use modern techniques for foresight indicators by which to make assessments on these activities.

The role of those involved in tourism is to seek to better meet the diversified demand of tourists given increasingly broad range of desires and experiences desired by them (experience or desire to explore, experience biotic, social experience and experience optimized).

In this paper we try to show as well the main factors of the emergence and development of rural tourism in order to establish priorities in the joint action of local people, entrepreneurs, tourists and local and national administrations.

## **2. Materials and methods**

For analysis of several aspects of rural tourism research was conducted by scientific reading, organization and systematization of information and ultimately benchmarking data, performed both in theory and in practice.

## **3. Results and discussions**

### **3.1. Factors appearance of the rural tourism**

The appearance decline of traditional rural occupations, such as agriculture, mining and forestry, since three or four decades, rural communities determined to explore alternative means to strengthen their economic base (Byrd, Bosley, Dronberger, 2009).

As a result, rural communities approached alternative activities or industries to strengthen and diversify their economies. Tourism has been identified as one of the primary industries with potential to support local communities in developing economic diversity. However, tourism is a cure, but it is only cure for the economic downturn because it induces both positive and negative effects. For tourism

development all activities must be coordinated as well constructed strategic plans and management and then managing to do with maximum responsibility.

Rural areas have a special attraction for tourists because of the distinct characteristics associated with mystical, cultural, historical, ethnic and geographical (Wilson, Fesenmaier, Vanes, 2001). Rural tourism is less expensive than traditional tourism and therefore can more easily establish development strategies and to attract tourists with more modest incomes. But this kind of tourism can not develop without the participation of local small businesses, and can not be totally independent companies outside of the community.

New attraction holiday is oriented to satisfy desires of the potential tourists addressing four different areas of life experience, the desires of tourists that are required but offered sometimes simultaneously (Snack, Baron, Neacsu, 2001):

- experience or desire to explore (from an ordinary walk into a geographic area known or unknown to participation in some agricultural work) that reaffirm the need for travel, it does come back, it causes regeneration;

- experience biotic (the tourist is finding himself unknown skills or capabilities in rural areas);

- social experience (integrated in social manifestations of a rural tourist location, together with individual satisfactions experienced in different small communities created spontaneously);

- experience optimized (it has a tourist complex expected satisfaction and intended to create a feeling of self, feeling it was "good" and that recent experiences have added value to its existence).

The fundamental components of a tourism product that is offered for sale through a distribution network can be considered as follows:

- a. equipment (structures) for receiving and restoration: reception, accommodation and catering - is the primary component of the touristic product and premise of retaining the visitor stay. In addition to the investments required to build new structures of renovating existing ones is imperative to achieve minimal civilized standards (Wilson, 1999). Our opinion is that the use of the term "restoration" isn't best used in this case, even if accepted by the experts who made the DEX according to which "restoration (in cooking) recently word, used more often in the literature the term instead catering for the activity including culinary production (preparing culinary, pastry and confectionery) and distribution, and drinks, activities in the specialized economic units. - In fr. Restoration ". We believe that simply catering structures would be more appropriate:

- b. elements of attractiveness: climate, landscape, historical, cultural, quality tourist services, strong reasons to return to a destination;

- c. communication infrastructure: access roads, transportation, telecommunications, transport services - that can be included in the package or left to customer choice. A constant affecting tourism activity and the choice of rural tourist destinations is transport infrastructure (Gartner, 2005) whose role was and still is ignored in the regions of Eastern and Southeastern Europe. Almost all studies showed the transport in these regions its weaknesses, so negative impact on tourism activity (Dickinson, Robbins, 2008);

- d. human elements: civic education, technical, professional and cultural knowledge, aesthetic education, hospitality (tourism is known as a "hospitality industry"). During the last three decades have established a lot associations and NGOs whose main object of supporting tourism and organizing conferences to

discuss research works results and their implementation (Pforr , 2001). Our opinion should not be ignore human resource training for the preparation and implementation of projects to attract EU funds reimbursable or partially reimbursable. For countries that joined the EU in recent period these funds could be the most important financial resource.

e. additional equipment: permanent: recreational, sports and cultural facilities, own facilities of holiday center for spending a varied and attractive leisure; occasional: cultural, artistic or commercial activities (fairs, expositions, festivals). In many cases(Wilson, 1999; Gorz, Kurek, 1999), even if it was not too rich sightseeing, tourists have expressed a desire to spend time in some rural areas for desire to exploit the opportunities for outdoor recreation (biking, walking, horse riding, climbing, rafting or walking with rafts).

To implement tourism in general and rural tourism so, conditions need to be met, such as:

- action program in the first stage of development, generally the first five years of the plan is done as part of the whole process of programming tourist then periodically, updated and adapted to the new socio-economic conditions. Action program must include public and private projects including infrastructure, attractions, facilities and services necessary to ensure that development is integrated, comprehensive and coordinated as possible. A comprehensive action program must describe each project, indicate the estimated costs of each development project area have all logical steps and their sequence and indicate the factors responsible for each stage of the project;

- zoning, is important for the implementation of land use plans for all tourist facilities in areas of attraction. The rules of zoning requires the existence of standards development such as tourism density, the upper and lower levels. They can be separately adopted for each tourism sector. Zoning must be made to develop areas near tourist areas, so that they are compatible with tourism development;

- administration of sites, architectural and landscape design must be made by a panel of architectural analysis. This committee should consider and make changes, if necessary, all tourism development proposed projects to ensure compatibility with natural resources and harmonize with the environment and local architectural traditions;

- according to some authors (Mccool, Moisey, Nickerson, 2001), the review of quality life showed a number of problems when you want to implement sustainable tourism. Here, the views of residents on quality of life are often critical in implementing tourism development policies. Economic development activities such as tourism, are seen more as a tool than as an purpose;

- establishment of tolerance limits of an area or region presents other problems. For example in the Czech Republic government policy was to establish several tourist routes and where investments were concentrated (Holland, Burian, Dixey, 2003). This strategy has determined to overcrowding of these areas. We present the Prague metropolitan area, which, according to the same source, record 60% of the national tourism receipts, phenomenon imposed disperse tourists to other adjacent areas, and perhaps just as attractive, but obviously with other specific, so they imposed new development projects in other areas. Growth limits, however, may be difficult due and only some appropriate policies at the right time can reduce negative effects (Saarinen , 2006);

- also the idea of harmonious development and dispersal of tourism activities can remember that often invest in less sought by tourists or high demand areas, but investment remained one step behind. We call here a study done on the correlation between supply and demand of accommodation of tourists in NV development region of Romania (Barbu, Olah, 2010).

Supporting promote European village in international tourism, and the country's internal rural heritage special is supported mainly by the following:

a. knowledge and promoting heritage items that arouse of tourists interest and curiosity to enjoy living and civilization other than those that are used daily, have these great possibilities the increasing number of tourists in tourist areas with low weight tourism;

b. system fragmentation holidays and school holidays for a stay of 4-5 days in rural areas;

c. choice of tourist destinations in neighboring or distant countries, as a result of border crossing facilities, customs formalities and getting some original tourism products;

d. continuous development of cultural tourism and support new forms of manifestation, which has increased interest to cultural values of the villages;

e. increasing request of accommodation with modest comfort and low prices, especially in rural guesthouses;

f. diversification of rural leisure activities which include some adventure sports activities and desire to know of natural biodiversity.

After all, how forms of services taking place in the Romanian rural area now demonstrates the need to strengthen alternative activities as:

- there is growing aging rural workforce;
- migration intensifies from rural to urban;
- required increasing participation of women in economic activities;
- emerges slowing and even loss artisan-crafted skills;
- skills and management of rural services are not clearly strengthened in a form-legislative methodology;
- diminishing role of agriculture is found, a manufacturer of raw materials (less than 10% of PIB in developed areas, compared with 30%, on average, in the developing countries);
- is more visible development of farms under the impact of technological and managerial revolution in the rural areas.

### **3.2. Factors that determine the development of rural tourism**

Rural tourism has developed due to revenue growth (Botezat, 2003) (it is mostly discretionary income), due to increased leisure life and diversification motivations and desires of tourists. Then it's about other factors that may favor the development of rural tourism, namely:

- ✓ growth levels of education, asserting the originality and authenticity of the tourism market of cities or regions with tourism potential developed or expansion;
- ✓ Improved quality of transport and communications;
- ✓ increasing demand travel offers customized according to the wishes of tourists and funds that they are willing to spend;
- ✓ increasing interest in health maintenance;

- ✓ pronounced development of sports equipment industry and tourism;
- ✓ increasing interest from global, national, district and local administrations;
- ✓ development of telecommunications. Mobile telephony, which has grown exponentially I might say, led to an increase in demand for trips or holidays spent in tourist areas, but also helped pensions owners to organize their work better, skin showed by the mass media in some economic issues.

Tourism development is favored by improving infrastructure, historical monuments and architectural restoration and promotion of environmental conservation. This is why tourism should be considered an important factor in social and economic development of a country and rural areas in particular.

If we consider the types of rural tourism (cultural, curative, religious, adventure, rest and recreation, for winter sports, for hunting and fishing, transit, etc.) we can say that the demand is influenced by the situation overnight stays a number of factors such as seasonal calendar of religious holidays, restrictions on hunting or fishing, planned vacations periods of pupils and students and not least infrastructure and weather conditions.

Addressing rural tourism sector like any other economic activity to progress together with profit for those involved, it requires several components: attractions, investment, appropriate infrastructure, services and diversified hospitality promotion (Wilson, Fesenmaier, Vanes, 2001). To run this set of factors need to join entrepreneurs and public administrations.

In our opinion, this list of components required for tourism to progress plans should be completed with some very well documented and carried out by experts in the field and, most importantly, a strategy for medium and long term development of tourism, strategy must be an integral part of the general development strategy of the area.

Development of rural tourism and implementation travel plans requires long-term efforts and sometimes consistent investments. Modalities of implementation are:

- approval policy and tourism plan, as an official document of the tourism development in the region and managing development for a longer period than five to ten years;
- planning development projects and necessary actions and efficient organization of public and private sector;
- adoption and implementation of relevant legislation and regulations for tourism development and measures such as environmental protection and development standards;
- efficient and systematic funding of individual tourism projects and public sector to develop attractions and infrastructure tourism;
- preparing and training staff in all tourism activities - human resource development in tourism and local community involvement in tourism development;
- tourism marketing and efficiency advertising of tourism across the region and private firms;

During 1990-2000 in South America and the Caribbean Islands a number of factors have marked losses in the tourism industry (Strizzi, Meis, 2001): economic and financial instability, structural unemployment, inflationary pressures, unequal income distribution, urbanization underway, risks safety and security, health threats, limitations in aviation infrastructure and political uncertainty.

Occurrence of diseases or epidemics also determine to lower demand for tourism. Mad cow disease in the United Kingdom (Sharpley, Craven B, 2001), for example, had a strong impact economic on losses to farmers. In particular, the tourism industry

had losses between 140 and 500 million pounds only to England and worldwide about 5 billion euro only in 2001.

In Romania, more than ten environmental organizations in the Apuseni Mountains battle with local administration to reduce pollution and deforestations (Abrudan, Turnock, 1999), important factors in the development of rural tourism. Apullum Zlatna enterprise polluted Ampoiu river, from Zlatna to the confluence with Mures, using old technology. Then dust polluted 30,000 ha of agricultural land and 49,000 ha of forest. Abusive deforestation for two centuries determined to soil erosion and higher frequency of floods and flood threatening. Excessive use of grazing by large areas of grasslands rental owners sheep from Sibiu area, determined to damage to the ecological balance. We have not found statistics by which to observe a decrease in the activity of rural tourism in these cases, but we believe that the affected areas were less visited by tourists.

According to specialists opinion in the field, shared view of new human resources has an important place in all tourism activities, thus developing human resources for tourism should be a priority in providing quality services expected by the tourist. This requires a systematic approach to design personal needs and establish training procedures necessary to provide qualified personnel both in the public and private sectors.

Chaotic, unscheduled development or without serious pre-feasibility studies of rural tourism sector has determined to competition in the job market between agriculture and tourism (Fleischer, Tchetchik, 2005).

It is also essential to use techniques and methods tourism marketing, targeting and marketing strategies and implementation of a promotional program. Marketing activities must take place in the government tourism offices, local tourism office and the private sector for the development of a positive image of the new potential tourism markets tourism sector is very important.

In a study about students has shown that inappropriate behavior on trips and camps, they have determined parents to not allow them free vacations for keep under observation (Mattila, Apostolopoulos, Somnez, 2001). This determined the touroperators and tourism service providers to address more carefully the behavior of pupils and students.

#### **4. Conclusions**

The concept of rural tourism had a series of additions based on socio-economic development of society, increasingly diversified demand of tourists, but also to a change in the great mass tourism resorts established.

We conclude that factors that stimulate more sustained affirmation of rural tourism are:

- increasing time assigned for recreation, which is generally an important factor in the development of rural tourism. A particular issue that has implications for rural tourism is multiplying short periods of time allocated to leisure. To these are added the possibility to make a staggered holidays. Correlating this with other factors such as reduced duration of transport, cost of stay, the deficit of short term tourist solutions, that rural selecting prospects holiday as space is increasing, at least for short periods of time;

- increased interest in maintaining the health, aspect recorded a spectacular growth. Although currently in our country, how to obtain food is less artificial than

industrialized countries, it is also true that stressors generated by economic instability, failures and pollution of the big cities, affecting increasingly health of the population. Orientation more obvious purpose of stay for leisure activities, sports, daily release from tension is natural and part of a strategy more or less deliberate health maintenance. Rural areas are excellently placed to provide satisfying the most diverse and sophisticated options, from walks in fresh air, biking, climbing or hiking, the quiet fishing parties to the satisfactions offered drinks and traditional food tasting;

-authenticity is increasingly required or sought by tourists. Coming mostly from an saturated with audiovisual environment, dominated of products by highly industrialized, districts of blocks dull, impersonal collective relations, more and more tourists appreciate authenticity, naturalness of country life, warmth specific to small rural communities. Sociological surveys conducted so far show that the quality is ranked second by the quality of landscapes, between motives underlying the option for stay in the country;

-peace and wellbeing are more elements sought by many tourists, which is not surprising, given the level of stress, specifically most workers. Mechanisms underlying the displacement of the tourism activity are diverse and often subtle. Voluntary aspiration occurs frequently leaving the city life. The idea of escaping into nature is found almost universally among today's urban desires, and her realization often occurs in rural areas. The man wants usually alternating calm with animated emotions and, therefore, not surprising leave home for the possibility of being able to find the pleasure in the quiet, unpolluted, far from the constraints of urban activities, rural areas being the that can answer all these needs;

-assertion of individualism on market. Systematic and persistent promotion of certain products to earn a stable segment of consumers is a practice commonly used to impose various tourist consumer products markets. Rural tourism is able to capitalize on this opportunity can be particularly beneficial in circumstances where there is motivation and competence for advertising and sale offer, or receive tourists. Needs to develop a profitable rural tourism are based transformations on should take place in rural areas to meet the ever-increasing and diversified demands of modern tourists (Glavan, 2003):

-civilization and comfort standards development of households according to their originality and typological diversity;

-change the mentality, giving up a way of thinking summarized by the words "anything goes" or "go anywise" and understanding the requirements and the need for professionalism and performance in the tourist activities. As generous as offer some components, it does not prove to be profitable only if it manifests in a system that integrates all the factors that define the tourism product (accommodation, pension etc.);

-tourist movement, animation, various activities, services, friendliness, cleanliness exemplary, attention for detail, etc.);

-entrepreneurship and entrepreneurial development among the natives.

The future looks promising for rural tourism due to a increasing interest to spend time in the countryside and outdoor activities and due to increase free time and duration of holidays. This we consider promising future and because the entrepreneurs are not required to invest too much money, but most important condition is that governments make available infrastructure.

# SUSTAINABLE TOURISM AND ITS FORMS – A THEORETICAL APPROACH

**Băc Dorin-Paul**

*Department of Economics, Faculty of Economic Sciences, University of Oradea, Oradea, Romania  
dbac@uoradea.ro*

**Abstract:** *From the second half of the twentieth century, the importance of the tourism industry to the world economy continued to grow, reaching today impressive figures: receipts of almost \$ 1,000 billion and direct employment for over 70 million people (WTTC 2012), without taking into account the multiplier effect (according to the same statistics of WTTC, if considering the multiplier effect, the values are: \$ 5,990 billion in tourism receipts, and 253.5 million jobs). We can say that tourism: has a higher capacity to generate and distribute incomes compared to other sectors; has a high multiplier effect; determines a high level of consumption of varied products and services. In this context, voices began to emerge, which presented the problems and challenges generated by the tourism activity. Many regions are facing real problems generated by tourism entrepreneurs and tourists who visit the community. Therefore, at the end of the last century, there were authors who sought to define a new form of tourism, which eliminated the negative impacts and increased the positive ones. As a generic term they used alternative tourism, but because of the ambiguity of the term, they tried to find a more precise term, which would define the concept easier. Thus emerged: ecotourism, rural tourism, Pro Poor Tourism etc.. All these forms have been introduced under the umbrella concept of sustainable tourism. In the present paper we will take a theoretical approach, in order to present some forms of sustainable tourism. During our research we covered the ideas and concepts promoted by several authors and academics but also some international organizations with focus on tourism. We considered these forms of tourism, as they respect all the rules of sustainable tourism and some of them have great potential to grow in both developed and emerging countries. The forms of sustainable tourism we identified are: ecotourism, pro-poor tourism, volunteer tourism and slow tourism. In the second part of this paper we presented both the pros and the cons of each of the identified forms.*

**Keywords:** *sustainable tourism; ecotourism; slow tourism; pro poor tourism; volunteer tourism*

**JEL classification:** *L83; Q56;*

## **1. Introduction**

Sustainable tourism has emerged in response to the increasingly negative impacts of the tourism industry in the destination-regions. So, sustainable tourism has emerged as a reactive concept, which seeks to eliminate the negative impacts (economic, social, cultural and environmental) that might outshine the benefits tourism brings to host- communities.

Since the early '90s, the concept of sustainable tourism began to be used more often in academic and, to a lesser extent among tourism entrepreneurs. Although

some early forms of the concept have been used earlier, the birth of sustainable tourism was the publishing of the first issue of the *Journal of Sustainable Tourism* in 1993 (Weaver 2006:10; Hunter 2002:3; Dodds and Butler 2009:43).

This new form of tourism involves small companies and entrepreneurs, with the stated purpose for community conservation and protection of local culture. One of the most important voices of the alternative tourism, David Weaver, thought that "the main difference between the old and new forms of tourism is the glide of the focus from the wellbeing of the tourist to the welfare of the community" (Weaver 1998:31).

At that time, the concept was highly debated and it was received with hostility by the tourism industry, dissatisfied to put any limits to growth. It was considered by many an "ivory tower" unrelated to the real market. Sustainable tourism was also considered "intellectually arrogant, expensive, elitist and useless" (Lane 2009:20). This attitude was not limited to the tourism industry. Governments and local authorities have not taken the concept seriously, the classical model of tourism bringing them significant benefits. Conventional mass tourism, generated jobs and wealth transfer from developed countries to developing ones. The mass - media did not pay very much attention to the concept of sustainable tourism, noting that it is much easier to denigrate than to explain it. There were academics and researchers who considered sustainable tourism "an impossible dream" (Lane 2009: 21). This was best explained by Wheeler: "on one hand we have the problems of mass tourism, which is growing steadily and uncontrolled. And what is our response? The development of small, slow and controlled. It is simply impossible! (Wheeler in Miller and Twining-Ward 2005:32)

There are many definitions of sustainable tourism and/or the sustainable development of tourism, and we believe that this multitude of opinions is just a sign of the lack of a global consensus.

Hunter (2002:4) believes that although the concept of sustainable tourism is derived from sustainable development, sometimes it is considered as an independent and distinct concept from other sectors of the economy.

Some authors (Hunter 2002:5, Swarbrooke 1999:18) believe that "tourism development should provide economic benefits to all partners (stakeholders), provided they do not adversely affect the resources available for future generations." Weaver (2006:10) defines sustainable tourism as "a form of wise exploitation, so you can conserve it for the long-term."

According to another definition, sustainable tourism represents "all forms of tourism (conventional or alternative) that are compatible with and contribute to sustainable development" (Liu 2003:461). In the context of this definition, development does not necessarily imply growth, being essentially a process by which specific social and economic objectives are achieved. Achieving these goals may involve stabilization, increase, reduce, change or loss of product quality, existing firms or industries.

From the perspective of the World Tourism Organization, sustainable tourism is defined as: "Tourism that takes full account of its current and future economic, social and environmental impacts, addressing the needs of visitors, the industry, the environment and host communities" (<http://sdt.unwto.org/en/content/about-us-5>).

We can say that, although there is no uniform definition of sustainable tourism, there are some common points in each of the above: benefits for the entire community, protecting resources and the environment, reducing negative impacts etc. Thus, sustainable tourism should harmonize and balance three elements: economic,

social and environmental.

Initially, sustainable tourism focused mainly on protecting natural resources, the main reasons for this are the following: the high interest of environmental organizations, evidence of environmental degradation due to tourism, the dependence of tourist destinations on global environmental condition, the relative ease of counteract the physical impact of tourism on the environment, compared to the socio-cultural, which is much more difficult to annihilate, and the advertising that can benefit a destination by showing interest in environmental protection (Butler 2000:339).

After 2002, with the launch of World Tourism Organization's ST-EP (Sustainable Tourism – Eliminating Poverty) program, the attention was focused on social issues, especially considering the fact that this initiative was based more on the general development of the country and not just protecting natural tourism resources.

There are many authors who argue that sustainable tourism is a form of tourism which is in contrast to mass tourism, aimed at a relatively narrow niche of people interested in the negative impact that tourism can have. This is an extremely dangerous point of view. It should be clearer that sustainable tourism is defined as tourism based on the sustainable development principles and it has a fundamental objective: tourism as a whole must be sustainable. The term should reflect a condition of tourism and not just a form. Mass tourism, properly organized and controlled, can and must become sustainable.

In this context, we identified four independent forms of tourism, which respect all the principles of sustainable tourism: ecotourism, pro-poor tourism, volunteer tourism and slow tourism.

## **2. Research methodology**

The objective of our paper was to identify specific forms of tourism either sustainable or mass, which respect the principles mentioned in the introduction. Also, after identifying them, we presented the main pros and cons that these forms face.

There are many forms of tourism, identified by some authors as being sustainable or alternative. According to the place of destination we have: ecotourism, urban alternative tourism and nature based tourism. According to the type of accommodation we have: guesthouse tourism, farm-based tourism and backpacking. Our concern is that these forms of tourism are not very strict, and raise many concerns regarding the respect of the principles of sustainable tourism. This is the main reason our focus was on forms of tourism based more on motivation. This is why, the most important forms of tourism we have identified are: ecotourism, pro-poor tourism, volunteer tourism and slow tourism.

As we can notice, they have no limitations regarding the accommodations and/or the place of destination.

The tourists that choose these forms of tourism can use, for accommodation, a tent or a guesthouse, as their focus is on the activities involved.

At the same time, these forms of tourism can be practiced in both remote natural areas and in the middle of cities.

## **3. Findings**

Although the literature and the practice offer numerous examples of sustainable tourism packages, we have chosen four forms of tourism which represent the best examples of putting theory into practice. The four forms of tourism we identified are:

ecotourism, pro-poor tourism, volunteer tourism and slow tourism.

### **3.1. Ecotourism**

Ceballos-Lascurain, the father of ecotourism, considered it a philosophical and multidimensional concept, a component of eco-development that requires planning based on strict rules. He suggested that the ecotourists have an enormous amount of information about the natural and cultural resources they visit, and were involved in the conservation and protection of resources. Also, Ceballos-Lascurain identified a number of differences between people who practice mass tourism and ecotourism in terms of natural resource usage. Both types of tourists are interested in natural resources, but mass tourism practitioners have a passive role in the relationship with nature, practicing activities such as water sports, jogging and cycling. Ecotourists, on the other hand, are attracted to natural resources and try not to abuse them, practicing photography, botanical studies and observing wildlife (Ceballos-Lascurain in Diamantis 1999:96). We conclude that, from the perspective of Ceballos-Lascurain, ecotourism is essentially passive and must be practiced in protected areas, thus having a positive impact on the environment.

Ziffer has a different perspective on ecotourism: "ecotourism is a form of tourism inspired primarily by the natural history of an area, including existing indigenous cultures. Ecotourists visit underdeveloped regions, in a spirit of appreciation, participation and sensitivity. Ecotourism uses without consuming natural resources and contributes directly through employment or money, and preserve the welfare of the local people (Ziffer in Diamantis 1999:98).

In turn, the International Ecotourism Society gives us a different definition of ecotourism: "responsible travel in natural areas of environment and enhance local welfare "(TIES 2006).

As you can see from the above definitions we can conclude that ecotourism is a form of tourism in the natural environment that oscillates between passive or active attitude of the tourists regarding conservation and nature protection.

Laarman and Durst (in Orams 2001:28) described in 1987 the hard and soft dimensions of ecotourism. The terms hard and soft cover how interested are the ecotourists in the natural resources of a destination and the physical effort they are willing to do. A hard ecotourist is willing, or even wants to benefit from reduced comfort and to travel longer in difficult conditions in the wild, in order to truly experience nature. By comparison, a soft ecotourist has a casual interest in natural resources and wants to experiment on a superficial level within a relatively short time span.

It is quite difficult to assess the ecotourism market, because of the confusion stemming from its definition. According to some authors (Diamantis 1999: 29), the segment of tourists visiting natural resources and wildlife generates between 20 and 40% of total tourism receipts. The most important ecotourism destinations in the world are: Alaska, Amazon, Antarctica, Blue Mountains (Australia), Borneo, Botswana, Costa Rica, the Dominican Republic (Caribbean Sea), the Galapagos Islands, Himalayas (Nepal and Bhutan). With regard to these destinations we can see some common features: are located in relatively remote areas with poor accessibility; are located in countries with a lower level of development; provide a high concentration of plant and wildlife species; are not traditional destinations for mass tourism.

Due to the increasing demand for ecotourism, classification criteria or eco-labels

began to appear for the accommodation units, different from the standard (number of stars). Although there are several classification systems worldwide, the International Ecotourism Society (TIES 2007:12) established some common components: voluntary registration facility; well-defined standards and criteria; • analysis and audit; grant and permission to use a logo; regular audit for certification renewal; continuous improvement; transparency; defining standards through participatory mechanisms.

In 2007, the World Ecotourism Conference was organized in Oslo, Norway. According to the Oslo Declaration on Ecotourism, international agencies, governments and all those involved in ecotourism planning must take into account the following courses of action (TIES 2007): 1. recognizing the important role that ecotourism plays in sustainable local development; 2. maximizing the potential of well managed ecotourism as an economic factor, central to natural conservation and cultural resources; 3. support the performance and activities of the ecotourism businesses through effective marketing and through education and training; 4. control of critical issues to strengthen its sustainability.

### **3.2. Pro-poor tourism**

This form of tourism has emerged in the UK, from the initiative of the Overseas Development Institute, and it considered that tourism can play a major role in eradicating poverty (Beeton 2006:200-201).

Pro-poor tourism (PPT) is defined as "a form of tourism that results in net benefits for the poor" (PPT 2004a). PPT is not a very well defined tourism product but rather an approach to management and tourism development. A key element is that, in many cases, the poor are the owners of the tourism resources: natural resources and cultural festivals and so on, and in the past, unfortunately, their role was ignored. By accepting this reality, governments, development agencies and tourism organizations can develop strategies to help communities (Beeton 2006:202).

Although the benefits mentioned above are important, Sofield et al. (in Beeton 2006:202) identified a number of issues that must be taken into account in the future: exposure to operational risk - poor communities lack the education and skills to prevent exploitation of the tourism industry; negative impact on traditional structures, leading to instability in the community (old vs. Youth, women vs. Males); negative impact on cultural elements due to mass production of souvenirs, modification and alteration of festivals and traditions for the entertainment of the tourist; materialism and individualism that could replace community-based organization; total or partial loss of access to natural resources (coastal, water, forests, etc.) which, for some communities, represents the main source of income.

From the above mentioned ideas, the UNWTO created the ST-EP Initiative created (Sustainable Tourism - Eliminating Poverty). The main implementation modalities of this program are: 1. Employment of the poor in tourism enterprises; 2. Providing the poor tourist firms goods and services; 3. Direct sales of goods and services to tourists, by the poor; 4. Establishment and administration by the poor of tourism agencies; 5. Differential taxation of income or profits that help the poor; 6. Support or donations from tourists and the tourism industry; 7. Investment in infrastructure stimulated by tourism, which will benefit the poor (<http://step.unwto.org/en/content/overview-st-ep-activities-0>).

Although it seems that many strategies are presented, they are focused locally, without involving changes at national or global level, where they might have a

stronger effect. As Scheyvens says, "for example, it is relatively simple (and good for public relations) to pump money into community tourism initiatives, but it is more difficult and controversial to support trade unions and workers' rights in tourism or to contest control that foreign companies and local elite have on the tourism sector "(2007:135).

### **3.3. Volunteer tourism**

Volunteer tourism is defined by Weaver (2002:45) as "a framework in which tourists are involved in voluntary work for social or environmental protection without receiving financial remuneration". Weaver believes that tourism is for people who "want, for whatever reason, to volunteer in an organized framework and to spend their holidays helping a community, restoring the natural environment and participate in research on society and the environment" (in Higgins-Desbiolles 2009:334).

In general, volunteer tourism is a chance for destination regions that will benefit from the help of volunteers, but also for tourists who will enjoy their work. A distinct feature of this form of tourism is related to the association with religious and environmental NGOs, located in the regions of origin of the tourists.

Another difference between mass tourism and volunteer tourism represents benefits. In the former, benefits are calculated as the number of tourists arriving or total receipts, which will be felt, to some extent, by the local population. Volunteer tourism generates direct benefits for local people: the construction or renovation of houses, medical or educational services (Weaver 2002:45-46). For this reason, sometimes, volunteer tourists are not perceived as tourists by the host community or themselves (McGehee and Andereck 2009:47).

Volunteer tourism focuses on two areas: improving the living conditions of the target community and the environment.

One of the most important organizations in volunteering is Habitat for Humanity, founded in 1976 by Linda and Millard Fuller. Habitat for Humanity is a Christian, non-profit organization, that aims to build homes and shelters in poorer regions of the world. Their projects are carried out on all continents, in 90 countries and 3,000 communities ([http://www.habitat.org/eurasia/learn\\_about\\_habitat/who\\_we\\_are.aspx](http://www.habitat.org/eurasia/learn_about_habitat/who_we_are.aspx)).

For environmental protection, "Conservation Volunteers" in Australia have listed what are the main benefits for tourists who decide to get involved in their projects: opportunity to make a real contribution to conservation in Australia, through effective programs; the opportunity to travel in regions with numerous natural, cultural and historical attractions, which are not on the main routes of Australia; opportunity to learn new practical techniques for conservation; social and cultural exchanges between participants from different cultural backgrounds; opportunity to learn about the visited regions, through active participation and conservation; transportation, accommodation, food and guide or project leader (Davies 2002:172).

In recent years, volunteer tourism took a new form: volunteer tourism for justice. It reflects "active partnerships in the fight against injustice of any kind and is based on the idea that partnerships need to overthrow situations of power imbalance present in many places in the world" (Higgins-Desbiolles 2009: 337). This global resistance movement crystallized due to numerous cases of social, economic or environmental injustice, caused by globalization and capitalism. Visible results of this type of tourism are demonstrations - some very violent - taking place at all international

meetings with economic issues: WTO conferences, World Economic Forum, G20 meetings etc.

Although it is difficult to criticize this form of tourism because of the extremely noble goals, there are authors who believe that some non-profit organizations involved in volunteer tourism behave like firms, are increasingly more interested in their public image, lobbying and bureaucracy at the expense of the initial target (Holmes et al., 2010: 257; Weaver 2002:47). There are even authors who raise questions about the motivations of the tourists. We cannot be sure whether such a motivation is fuelled by empathy and altruism or simply improving ones personal image and CV (Higgins-Desbiolles 2009:335; Coghlan and Fennel 2009:377-378).

### **3.4. Slow tourism**

Slow tourism stems from the slow food movement, which emerged in 1986 at the initiative of Carlo Petrini. He founded the organization Arcigola to protest against the opening of the first McDonald's in Rome (Myhrvold et al. 2011:23). The slow food movement emerged as an antithesis to fast food, representing an intersection of ecology, gastronomy, ethics and pleasure. The movement opposes the standardization of taste and culture, and unregulated corporate power in the food and agricultural industry. The movement promotes a return to cooking and to avoid the "curse" of the fast food restaurants, using local ingredients and information about the food we eat.

The principles and philosophy of slow food are easily adapted to tourism. The central idea of slow tourism is to get some quality experiences, reduced in number and to avoid holidays, where the emphasis is on quantity (Heitmann et al. 2011:117). As sustainable tourism and ecotourism, slow tourism was defined in several ways. From the perspective of Dickinson (2009:2) slow tourism represents "holidays involving shorter trips and longer stays, air transport is not used, but other forms of transport, which are more environmentally friendly, and become part of the tourist experience".

Heitmann et al. (2011:117-118) believes that slow tourism "is characterized by the joy of discovery, study and sharing, and the holiday slowdown will create opportunities to interact and establish links with local people and places at a deeper level."

Lumsdon and McGrath (2011:265) believe that essentially slow tourism means "driving a short distance and enriching experience, both on the road and the destination."

Slow tourism relies on deceleration at the expense of speed, so that the journey to the destination becomes a relaxing time, not a stressful interlude imposed between home and destination (Gardner 2009:10-11).

Slow tourism can be considered a return to the past, to pilgrimage and the Grand Tour, which largely respected the principles of this form of tourism (Dickinson et al. 2011:282).

Activities during the holidays are not much different from the other forms of tourism, but the key features - immersion and slowness - are central to the philosophy of slow, requiring more integration, research and spending more time in a particular environment, to form stronger memories. However, not all attractions have been designed to provide such experiences and many of them are forced to give a quick (fast) tour because of the popularity and pressure that a large amount of tourists generates (Heitmann 2011: 118-119).

From an economic perspective, slow tourism strategy is based on a slow growth by reducing capital flight, at the expense of rapid growth, based solely on the number of tourist arrivals. This will increase efficiency by increasing the quality. This focus on quality at the expense of quantity will increase the resilience to external shocks (Timms and Conway 2011:13).

Since slow tourism promotes the use of other means of transport, rather than air, we can ask some questions about the solutions for countries or regions at some distance from tourist generating markets (Caribbean, Maldives etc.) .

Unfortunately, Bramwell and Lane (2011:419), the editors of the *Journal of Sustainable Tourism*, believe that there is very little evidence to show that policy makers should be interested in developing a new paradigm of tourism based on the de-growth or slow tourism.

## Conclusions

In the following years, sustainable tourism will face numerous challenges from the industry, governments, local authorities and even tourists. The forms of sustainable tourism we have presented in this paper are well established on the tourism market, maybe with the exception of slow tourism, which is still in a discovery period. The only task at hand remains the marketing and advertising of these forms of tourism, in order for a larger number of persons to become involved.

From our point of view, in order for sustainable tourism to become an umbrella for all forms of tourism, significant steps should be taken in the direction of education. Through education, information can reach individuals from a very early stage in their development, and can change their attitude to become more focused on what sustainable development in general and tourism in particular, really deal with. Education is one of the few fields that transcend governments, local authorities, academics and entrepreneurs, thus it can change the attitudes of exactly the people who might represent obstacles in the future development of sustainable tourism.

# THE EVOLUTION OF TOURISM IN THE NORTH – WEST DEVELOPMENT REGION (DURING 2009 – 2011)

**Borma Afrodita**

University of Oradea, Faculty of Economics, Oradea, Romania  
aborma@uoradea.ro

**Abstract.** Fourth year PhD candidate at the University of Oradea, under the guidance of Professor Mrs. Alina Bădulescu in the doctoral research project entitled: "Doctoral studies and Ph.D. candidates for competitive research on a knowledge based society", a co-financed project by the European Social Fund through the Operational Program for Human Resources Development 2007 - 2013, Priority Axis 1. "Education and training in support for growth and development of a knowledge based society" I chose to present this subject in order to demonstrate the connection that exists between tourism and development regions of Romania. Having as research topic "Tourism and development in the Euro regional context" I felt it would be appropriate to devote a subchapter in presenting the evolution of tourism in developing regions of Romania. The research methodology that was used consisted in documentation from the specialised literature and statistical data collection from the site <http://www.insse.ro/cms/rw/pages/index.ro.do> in order to gather representative data on the evolution of national tourism for the 2009 – 2011, in each districts of North-West. The first part of the paper presents the foreign visitors who come to Romania, hence the largest number of foreign visitors and how it evolved from 2009 to 2011 the number of foreign tourists in Romania. The second part deals with the existing tourism potential in the North-West region and the opportunities offered by the region. The three part deals with the main touristic indicators in the six counties of North-West and the differences between them. The analysis is based on the comparison of main tourism indicators showing the tourist activity in the development regions of Romania, namely: the number of arrivals, number of nights and existing tourist capacity. The last part presents the steps that should be followed to overcome the losses caused by the crisis of 2008-2009 and to ensure a positive growth of the indicators analyzed.

**Keywords:** districts of North-West; tourism potential; touristic indicators;

**JEL classification:** L83

## 1. Introduction

Romania presents a touristic potential of great diversity, which offers the tourist the possibility to choose a tourist destination in order to spend leisure time in any time of the year.

Tourism creates opportunities for regional and local economic growth, contributing all the same in creating new jobs. Thus, capitalizing tourist attractions in different parts of the country can contribute to the economic recovery of some declining urban and outlying rural areas by favouring the emergence and development of local firms,

making areas with low economic competitiveness in areas that are attractive to investors.

The indicators through which is characterized the tourist activity in Romania, in the eight regions of the country are: the number of arrivals (tourists' lodging), the number of overnights, existing tourist accommodation and the operating accommodation capacity.

Following the evolution of foreign visitors in Romania, during 2009 - 2011, it can be noted that in 2009 the global crisis also reflected upon Romania's tourism, registering a decrease of 15% compared to 2008, and in 2010 and 2011 a slight increase was recorded but without reaching the values recorded in 2008.

**Table 1:** Arrivals of foreign visitors in Romania on continents and origin states

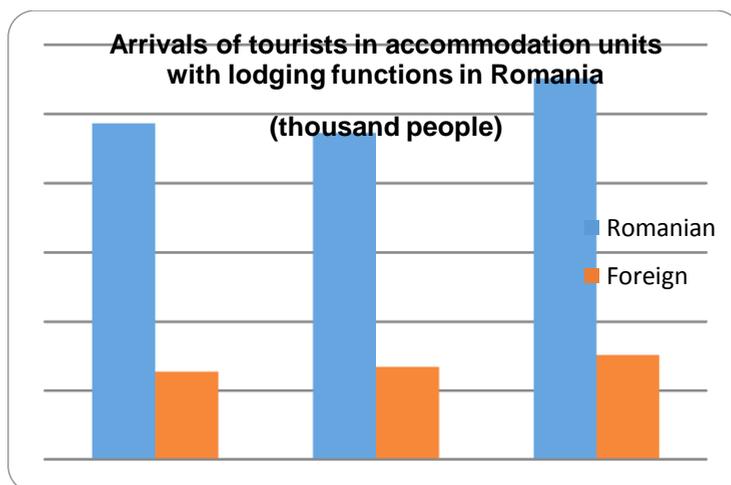

Continents and origin states of foreign visitors	Arrivals of foreign visitors in Romania (thousand people)		
	2009	2010	2011
Europe	7.203	7.098	7.180
Africa	17	21	22
America	169	171	182
Asia	171	195	211
Australia and Oceania	14	13	15
Unspecified countries	1	:	1
TOTAL	7.575	7.498	7.611

Source: made by the author based on data obtained from National Institute of Statistics, [Online], Available: <https://statistici.insse.ro/shop/>

According to the statistical data given by INS, in 2011 the highest weight of foreign visitors was represented by those from Europe with 94.3%, Asia by 2.77% to 2.39% America.

If we extend the analysis by countries located in Europe, we observe that between 2009 - 2011 the situation is almost constant, that is the largest number of foreign visitors to Romania was registered by two neighboring countries with Romania, respectively Hungary (1.546 thousand visitors in 2011) and Bulgaria (797 thousand visitors in 2011).

If in 2010 in comparison to 2009 the arrivals in the lodgings registered a slight decrease of approximately 1%, in 2011 the situation changed, the number of arrivals increasing with almost 16% in comparison to 2010.

**Figure 1:** Arrivals of tourists in accommodation units with lodging functions in Romania

Source: made by the author based on data obtained from National Institute of Statistics, [Online], Available: <https://statistici.insse.ro/shop/>

In 2011, the arrivals of Romanian tourists in accommodation units with lodging functions represented 78.4% in the total number of arrivals, in comparison to foreign tourists that represented only 21.6%.

In 2011, three regions of the eight development regions in Romania (Center-20.4%, București–Ilfov-18.25% and South – East -16.14%) represent over 50% in the total of registered arrivals in accommodation units with lodging functions.

The North – West region ranks fourth (among the 8 development regions) registering 11.38% in the total of arrivals in accommodation units with lodging functions.

## 2. The North – West Region of Romania

The North – West (Northern Transylvania) is one of the 8 development regions of Romania and includes the following counties: Bihor, Bistrita-Năsăud, Cluj, Maramureș, Satu-Mare, Sălaj. The surface of the region is of 34.159 square meters, representing 14.32% of the surface of the country, with a total population of 2.744.914 inhabitants. The region includes 421 administrative and territorial units: 6 counties, 42 cities of which 15 municipalities and 398 communes and 1.823 villages. The region has a strategic geographical position, it borders with Hungary and Ukraine as well as the Central Region, West and North - East of Romania (Regional Development Agency North West).

**Figure 2:** North-West development regions

Source: <http://www.runv.ro/harta.html>

### 2.1. Tourist Attractions in the North – West Region

The most representative types of tourism in this area are:

- Balneal and treatment tourism;*
- Mountain tourism;*
- Cultural tourism;*
- Urban and rural tourism;*

*Balneal and treatment tourism* in the region is based on the existence of thermal waters and disused salt mines. The North - West region has a rich potential of thermal waters, the most famous resorts in the region are: Băile Felix and 1 Mai (10 km from Oradea) and Sângeorz Băi. Promising potential is present also in the following localities: Tinca, Tășnad and Marghita. Also, the existence of salt mines (unfunctional) and of salt lakes from Ocna Dej, Turda, Ocna Șugatag, Băița present a special attractiveness for the tourists of the region as well as from the nearby regions.

*Mountain tourism* focuses on winter sports and extreme ones. Maramureș Mountains and the Apuseni Mountains represent excellent opportunities for the development of mountain tourism. Thus, if we take into consideration the entire region we can notice the existence of a representative number of mountain resorts: Stâna de Vale and Băișoara (Apuseni Mountains), Borșa, Piatra and Fântânele (in the Northern part of the Oriental Carpathians).

*Cultural tourism* is distinguished by popular culture and ethnographic heritage, fortresses and monuments (Oradea, Bistrița), fortified churches and monasteries of

wood in Maramureş (monuments Unesco). Also in this region are more than 170 protected areas, two national parks and two nature parks included in tourist circuits.  
*Urban and rural tourism*

In the region one can also find traditional urban areas (Oradea, Baia Mare, Bistriţa etc.) with a rich historical and cultural heritage that are (or can be) included in the tourist circuits.

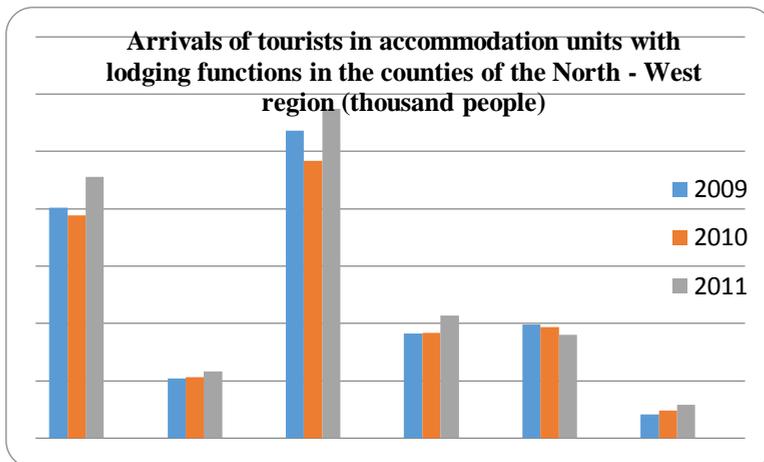

Tourist areas in the Apuseni Mountains, Transylvania, Maramureş Mountains and Transylvania Plain represent real touristic attraction for tourists eager to spend their free time in nature.

### 3. The Evolution of Tourism in the North – West Region

#### 3.1. Arrivals of tourists in accommodation units with lodging functions in the counties of the North - West region

In comparison to 2009, arrivals in accommodation units in the North – West region in 2010 registered a decrease of 4%. In 2011 we can observe a 13% increase in the number of arrivals compared to 2010. The counties that registered the highest number of arrivals in the North West were Cluj (35.9%) and Bihor (28.1%) the two counties comprising 64% of the total number of tourists in the region. On the last place is Sălaj (29,012 tourists), with a weight of only 3.62% of the total arrivals in the region.

In 2011, arrivals of Romanian tourists in accommodation units with lodging functions in the North West region represented 84% of the total arrivals, in comparison to the foreign tourist arrivals which were only 16%.

**Figure 3:** Arrivals of tourists in accommodation units with lodging functions in the counties of the North - West region

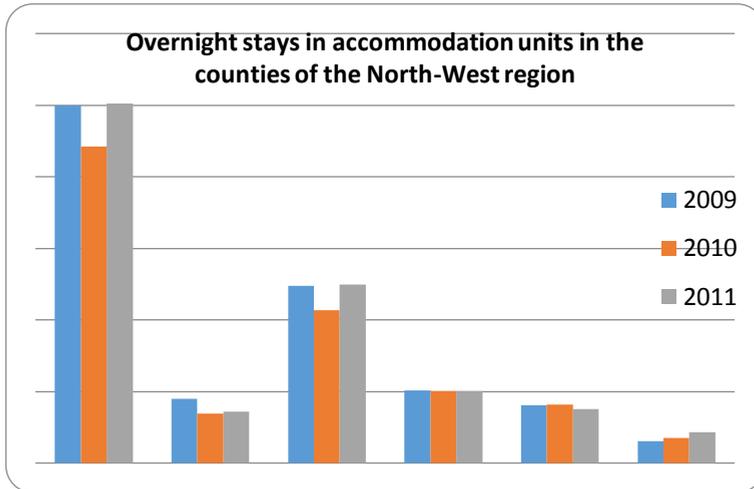

Source: made by the author based on data obtained from National Institute of Statistics, [Online], Available: <https://statistici.insse.ro/shop/>

According to INS, in 2011, the destinations chosen by foreign tourists were those of Cluj (5.75% of the total tourists) and Bihor (4.50% of the total tourists) probably due to existing tourism potential in the two counties. Romanian tourists' preferences were

identical with those of foreign tourists; the largest number of arrivals was recorded in Cluj (24% of all tourists) and Bihor (48.15% of the total tourists).

### 3.2. Overnight stays in accommodation units in the counties of the North-West region

Overnight stays in tourist accommodation units decreased in 2010 (1.885 thousand overnights) of 11% compared to 2009 (2,099 thousand overnights). In 2011 (2.085 thousand overnights), according to the figure below, can be observed a positive change, registering a value similar to that of 2009.

**Figure 4:** Overnight stays in accommodation units in the counties of the North-West region

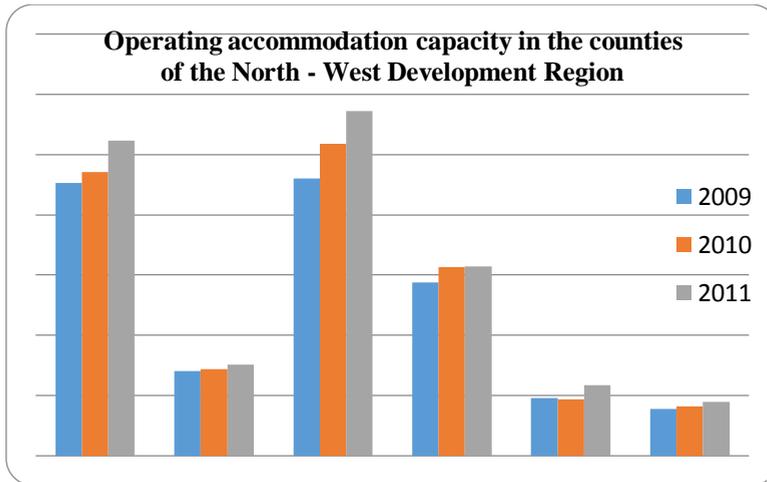

Source: made by the author based on data obtained from National Institute of Statistics, [Online], Available: <https://statistici.insse.ro/shop/>

Romanian tourists' overnight stays in accommodation units in 2011, represented 86% of the total of overnight stays, while the overnights of the foreign tourists represented 14%.

During these three years, the highest number of overnight stays in the region was registered in Bihor County representing 48% of the total of overnight stays.

### 3.3. Tourism Infrastructure in the North – West Region

In 2011, in the North – West Region there were a total of 8,831 thousand lodging places (12.90% of the total of tourist accommodation units in Romania) being placed second among the 8 regions, the first place being occupied by the Center Region which holds 12,867 thousand lodging places (18.81% of the total tourist accommodation units in Romania).

**Figure 5:** Operating accommodation capacity in the counties of the North - West Development Region (Units: places-days)

Source: made by the author based on data obtained from National Institute of Statistics, [Online], Available: <https://statistici.insse.ro/shop/>

Operating accommodation capacity showed an upward trend during the analyzed period.

Following the figure 5, between 2009 -2011, there is a relatively continuous upward trend of operating accommodation units in most counties.

In respect to the operating accommodation capacity, the most impressive growth is recorded in Cluj County, where the number of accommodation units increased in 2011 (2.858.256 number - places), 24% more than in 2009 (2,303,416 number - places). If we analyze the distribution of tourist accommodation units according to the counties in the North – West region it can be observed that most of them are in Cluj (32.36% in 2011) and Bihor (29.58% in 2011) and they withhold the largest accommodation capacity with a number of 5,471 thousand lodging places, which represents about 62% of the accommodation capacity of the North-West region and the fewest are in Satu Mare (6.63%) and Sălaj (5%).

The net use index of the lodging places in 2011 was 23.60%, in the total number of operating accommodation units, decreasing with 3.97% compared to 2009 (27.57%). This was due to the increase of the tourist accommodation capacity in 2011 to 16.57% compared to 2009, while the number of overnight stays in 2011 decreased by 0.67% in comparison to 2009.

#### 4. Conclusions

2011 (compared to 2010) represented a positive year in the evolution of tourism in the North – West region, registering an upward evolution for all indicators in comparison to 2010. Thus, in 2011 we witness a 13% increase in the number of arrivals in tourist accommodation units and in the case of the number of overnight stays and that regarding the accommodation capacity we can notice again an upward trend.

To ensure positive growth in the coming years should keep in mind the following:

Although the region has a diverse tourist potential (geothermal resources, cultural heritage etc.) is needed to develop the intervention the intervention of accessibility in the main tourist areas in the region. Certainly the lack of an international airport in Oradea prevent foreign tourists wish to visit this town and spa resorts (Băile Felix, Băile 1 Mai) located near the town.

To attract foreign tourists in this area is needed tourism infrastructure and tourism services adapting their requirements.

To ensure quality service needed hiring of specialized personnel in the tourism sector.

Seasonality is also a problem facing North-West, as one of the main strategy should be to channel on finding ways to extend the tourist season.

Another sensitive point refers to the low level of promotion of tourist areas in the region. It would be ideal to create a regional brand with which to identify that region.

# EXPLORATORY RESEARCH REGARDING ROMANIANS' PERCEPTION ABOUT THE REGIONAL BRAND "MARAMUREȘ"

**Drule M. Alexandra, Chiș Alexandru, Dunca G. Adina**

**Abstract:** *In recent years, the expansion of touristic activities confirmed the importance of marketing activities in touristic regions. In tourism as well, globalization implies an unlimited number of options, and the traditional elements regarding competition and differences related to price or quality are no longer sufficient in efficiently differentiating the touristic region. A key factor in this sense is represented by the notion of place branding or, to be more precise, regional branding. Theoretical studies on this subject are relatively recent, and fewer compared with studies on traditional brands, for example. A practical research regarding a touristic region can thus provide a series of utile information that marketers can use in elaborating marketing strategies and, specifically, in the branding process. The study's main objective aimed at shaping the regional brand "Maramureș" using mainly projective techniques, scarcely used in studies of this kind in Romania, based on a sample of more than 200 respondents. The information obtained focused on the respondents' perceptions regarding the region of Maramureș as a touristic brand, the associations made, the values attributed to the region in terms of touristic potential, of touristic infrastructure, of weak and strong points of the touristic brand Maramureș, but also elements of the regional image and identity (at this point were considered certain associations with visual elements but also with its personality). By highlighting respondents' subjective and diverse opinions, it was aimed to point out some directions that would eventually guide a new approach of the brand for this touristic region. Also, the results of this study could represent a starting point for a program of regional development, funded through various local or European funds. Furthermore, based on the information obtained from respondents, it has been proposed a new logo of the region, as a first step in running a promotion campaign of Maramureș as touristic destination.*

**Keywords:** regional brand; regional marketing; tourism destination; tourism brand's personality; Maramureș.

**JEL classification:** M31; M38; L83.

## 1. Introduction

The study of brands designed for touristic regions is relatively recent and, according to Dumbrăveanu (2010), Ryan and Mizerski (2010) or Ashworth and Kavaratzis (2010), the number of materials in which it is discussed in detail being rather small. Among researchers who deal with it can be mentioned Lucarelli and Berg (2011), who focus on time evolution of specialty studies regarding city branding, highlighting

their growing importance. Kotler et al. talk about place marketing for the first time in 1993. But this subject became more and more popular, discussed 'as a result of the growing competition between places, cities and nations (...). Moreover, place marketing is not limited only to touristic activities, but plays an important role in urban and regional development, the positioning of the region and/or country within international relationships, as well as maintaining a constant development of economy and infrastructure.' (Maheshwari et al., 2011:198). Zenker (2011:41) affirms that in recent years the focus was increasingly more on the process of *regional branding*, as element of regional marketing: 'regions are motivated to obtain positive associations in consumers' minds in order to develop and promote the brand continuously'. However, Anholt (2005) states that the brand is a very powerful tool in the process of economic development, having a significant contribution to *regions' development*. Touristic destinations are extremely varied, this category including cities, countries, regions or any other element that is perceived as touristic objective. Regions, however, are much more diverse destinations, and the branding process highlights their complexity. So, for some authors, the destination brand is equal with the competitive identity, and represents the destination's essence and characteristics or, in other words, it is the DNA that defines that destination (Buncle and Keup, 2009).

## **2. Tourism Destination Branding**

The branding process of the destination surprises very complex elements, the main purpose being that of guarantying touristic a positive experience, from the moment they come in touch with the destination to their return home (Buncle and Keup, 2009). Nyseth and Viken (2009) stress the importance of the cooperation between the public and the private sector in the process of creating an image/an identity for the touristic destination. Many authors who have studied the problematic of *destination branding* (Hall, 1999; Buhalis, 2000; Prideaux and Cooper, 2003; Zevedo, 2004) but also that of national branding (Szondi, 2006; Rausch, 2008; Pike, 2010) underline the importance and the practical utility of the brand as a very powerful strategic process specially created for developing competitiveness and economic development of regions and countries.

According to Buncle and Keup (2009), *complexity* is a base attribute of touristic destinations' brand. Pike (2005) highlights the complexity of destination brands with the following arguments: destinations are multidimensional, the interests of various groups on the market are heterogeneous, and the theory cannot be applied due to the politics of taking a decision across all the people involved.

As an aspect associated to this complexity, *brand architecture* is very important (Hankinson, 2010), because of identities correlations at a regional level, and of choosing brand alliances (between cities or regions with different or complementary traits).

According to Morgan et al. (2004), the 5 phases within the process of building a destination brand are: (1) market research, analysis and strategic recommendations; (2) development of brand identity; (3) brand launching and introduction: communicating the concept; (4) brand implementation; (5) monitoring, evaluation and verification. According to Buncle and Keup (2009), the stages of this process are: destination audit, segmentation analysis, SWOT analysis, shareholders' commitment, competition analysis, models of brand building, brand's integration in marketing activities, global campaigns versus local campaigns, brand

global versus target segments. Moilanen and Rainisto (2009) present the model of developing the destination brand- DEBRA, based on ideas regarding brands in services belonging to de Chernatony and Segal-Horn (2003).

Balakrishnan et al. (2011) classify *the components of a destination brand* in several categories: functional elements refer to the basic function/purpose of the brand associated with tourists' immediate, practical needs; symbolic or emotional elements are those situated above the basic product, referring to attributes regarding intangible aspects; elements related to experiences include the relationship between the brand and the consumer, its intuitive preferences, the ability of the brand to communicate an exclusivity feature, a particular lifestyle.

### **3. Identity, Image and Personality of the Brand of Touristic Destination**

*Identity* captures the internal dimension of the brand, while *the image* surprises the external one (Saraniemi, 2010). *The image of the destination* contributes to the formation of the destination's brand and to its success. There are two different types of images involved in the branding process: the image projected (promoted by marketers) and the image perceived (received by tourists) (Tasci and Kozac, 2006). For Hildreth (2010), the brand is the visual representation of an entity (the brand's identity) and the collective perceptions of the entity in people minds (the brand's image). The images of the touristic destination can be classified in: organic images made on long term from a multitude of sources (mass-media, novels, and geography), induced images made from exposing to the projected image of the destination an induced modified image or a complex image, based on the interaction of touristic experience with organic and induced images (Fakeye and Crompton, 1991). *Brand's personality* is part of the branding process of a touristic region (Avraham and Ketter, 2008). Go and Govers (2009) state that the personality of the brand and that of the destination are correlated concepts, which sustain the idea that regions, especially through the process of branding, can be attached to human's personality traits. Forristal (2009) analyzes the personality of the brand in respect to Aaker's model. Aaker (1997) presents the five dimensions of the brand's personality: sincerity, enthusiasm, competence, refinement and strength, which, at their turn, have other subcategories.

Ashworth and Kavaratzis (2010) also stress the importance of *brand's personality*, suggesting that the places in competition should be associated with famous persons, such as artists, persons, celebrities.

Morgan et al. (2004) surprise two side of the personality, namely the rational side and the emotional side: the first refers to the logic traits of the brand, and the second refers to its emotional benefits and associations. Using only one slogan or logo is not sufficient but, according to Hankinson (2005), Hildreth (2010), Maheshwari et al. (2011) many campaigns rely solely on these elements.

### **4. Regional Branding**

Creating a *regional brand* is the core element in promoting local competitiveness, especially when regions and cities try to compete for external resources, using their brand. So, it is not an unusual thing to notice a national brand playing the role of umbrella-brand for its regions, and the regions to have the role of umbrella-brand for the cities (Boisen et al., 2011). Region's branding is seen as a 'process that permits a place to develop through its strong points, to find the sense adequate to its complex and multidimensional traits, as well as the variety which characterizes

its past, present and future identity' (Maheshwari et al., 2011: 201).

According to the authors Ashworth and Kavaratzis (2010), the brand, whether it's national or regional, must be seen as a multidimensional concept, with functional, emotional, relational and strategic elements, which create a unique set of associations in the mind of the public. Regional brands must be distinct, but still to have similarities, to integrate within the national brand. The difficulties of coordinating activities arises from the fact that regional brands cannot be controlled by one entity or organization, but they are developed and offered through a complex network of public and private actors (Dinnie, K., 2009). Another feature mentioned by many authors is the similarity and the comparison of regional touristic brands with corporate brands. Anholt (2005, 2010) compares the nation with a corporate brand, and Moilanen and Rainisto (2009) states that regional brand resembles with the umbrella-corporate brand.

In creating *region's identities*, an important role is held by symbols (names, logos, customs, etc.) (Mueller and Schade, 2011). Kotler et al. (1993) argue that the image of a place or a region can be positive and attractive, negative and weak, mixed (with both negative and positive elements) or contradictory (when the region's image is positive for some tourists and negative for others). The diversity of the actors involved in the creation and development of a regional brand is very high. Destination's marketing organizations (DMO) represent an important active element in the branding process. Dinnie (2011) underline the participation of residents and tourists. Taking into consideration the region's inhabitants has numerous advantages, these being the first that should know, understand and share the values of the region they live in. *Regional identity*, as an element of the regional brand, is perceived as a sustainable competitive advantage" (Go and Govers, 2009: 49), and for long term sustainability, regional brands need a strategic management (Ryan and Mizerski, 2010).

## 5. Research Methodology

The importance given to the process of development of the regional brand and to the marketing programs thoroughly sustained by all active participants depends on the extent to which each country understands the positive effects brought by a powerful touristic brand. It was chosen the analysis of the touristic regional brand Maramureş because it is a representative area for Romania's tourism. However, the methods used for promoting the area have a low degree of efficiency, are not fully adapted to the target audience, promotion campaigns are not very well-known even among residents, and market research to highlight deeper the opinions of those involved and affected by touristic activities are practical inexistent.

The *main objective of the research* is to analyze the perceptions and the opinions people have about the touristic region of Maramureş, as a touristic brand, but also of the values assigned to it. Starting from this general objective, there were established *several derivate objectives*, as following: the analysis of the elements which form the image of the touristic region and those which determine its identity (visual elements, as well as personality traits), respectively identifying weak and strong points of the touristic brand Maramureş.

*The research hypotheses* focused on the fact that:

1. Respondents have generally positive opinions on the touristic region Maramureş.
2. Respondents associate the region with tradition, folklore and less with modern

elements.

3. Respondents consider that touristic promotion is poorly implemented.

As *data collection method*, it was chosen the survey (punctual among a judgmental sample of the studied population) combined with a series of indirect methods, namely projective tests. Besides the types of tests mentioned above, there were included also several response matrices through which was followed the association of the regional brand with a series of personality traits. The population studied was formed out of people who knew the region of Maramureş, either personal (residents or tourists), or indirect (based on information provided by mass-media, friends, family or acquaintances). *The size of the sample* studied was of 248 respondents.

## 6. Research Findings and Discussion

Opinions regarding *tourism generally practiced in Maramureş* reveal both positive and negative elements: the majority of the respondents (67.7%) highlight the touristic potential of the region, because of particular natural elements, Maramureş's traditions but also the openness of the residents and of the hosts towards tourists. If 12.9% consider satisfying *the level of touristic services* in the region, a higher number of respondents (19,4%) consider them unsatisfying.

Approximately a third of the persons interviewed (32,3%) claim *that tourism promotion is insufficient*, even though there are many development opportunities through concrete measures ('creating more info-points for tourists', 'lack of promotion abroad, among foreigners'). 19,4% from the respondents highlighted a series of region's traits through their own experiences as tourists in Maramureş ('it is a unique touristic experience, but I get informed and I asked around as a tourist, from Internet sources').

12,9% of respondents presented more forms of tourism specific to the region of Maramureş (rural tourism, religious tourism, cultural tourism, agritourism, ecologic tourism). Through *several association tests was aimed to identify what is the opinion of the respondents regarding the current situation of tourism in Maramureş*. The answers reveal even more complex aspects: the majority (87,1%) believes that there isn't enough promotion and exploitation of the region's touristic potential.

Other options have been manifested in lower proportions: the lack of online promotion campaign (32,3%); authenticity, uniqueness through traditions, people and landscape (29%); poor participation of local authorities and residents, lack of investments, lack of coordination between the traditional environment and the appearance of touristic hostels or poor promotion within foreign tourists (22,6%); poor infrastructure which lades tourists' access (12,9%); an optimist vision of the regional tourism, which is still developing/ improving (9,7%).

As for *Maramureş's touristic potential*, the first aspect mentioned by respondents was the diversity and the uniqueness of the region (41,9%), but also the traditions specific to the region (38,7%). In addition, 22,6% of respondents expressed their dissatisfaction with the way in which the potential touristic is exploited (inefficient and insufficient), while 19,4% stressed a defining element: wood art, represented by the specific gates and the wooden churches. Only 9,7% from the respondents mentioned agritourism as the most important aspect of touristic potential.

*Elements that are mostly associated with Maramureş* in the mind of the respondents are: nature (51,6%), local people features (48,4%) and tradition (41,9%). Fewer people mentioned traditional food (29%), famous touristic sights (22,6%) or wood art (19,4%). Besides these aspects, respondents mentioned in their answers:

traditional clothing and music (12,9%), a feeling of retrieval (9,7%), authenticity (9,7%), famous people such as Paula Seling or the Rednic couple (6,5%), color (6,5%), hiking (3,2%) and the city of Baia Mare (3,2%).

At the question regarding *the image of Maramureş region*, more than half of the respondents described the landscape of the historical Maramureş (58,1%), followed by mentioning the traditional Maramureş gates (22,6%), as well as very famous sights such as ‘Mocăniţa’ or ‘Cimitirul Vesel’ (19,4%).

16,1% of respondents have thought of people dressed in traditional clothing, followed by churches and Sunday’s religious sermons or holiday days (9,7%), the image of a museum in open air (9,7%), persons singing traditional music (2,4%).

In order to discover *the personality traits associated with Maramureş*, it was used an open question, through which respondents had to associate the region with a person and to describe the way she or he would interact with it. A large number of respondents associated with the region an open, cheerful, lively, sociable and welcoming person (41,9%); a wise, empathetic, good-hearted, compassionate, hardworking and caring person (38,7%). Furthermore, approximately one-quarter of the respondents (25,8%) associate the region with a bold, intelligent, charismatic and sincere person. However, some respondents, besides the traits mentioned earlier, associated the region: with a caring mother or a grandmother in traditional clothing (25,8%).

*Applying the five-category brand personality Aaker model (1997):* excitement, sincerity, competence, sophistication and ruggedness (Table 1), respondents associated the region to a higher extent with a merry, honest, incorruptible, with a strong spiritual character, loyal and intelligent person, a charming person and into a higher degree with inventiveness and dearness, but less with a modern character.

**Table 1:** Regional brand Maramureş’s personality dimensions

Dimensions		Mean	Dimensions		Mean
Excitement	Daring	3.77	Competence	Reliable	4.06
	Spirited	4.48		Intelligent	4.06
	Imaginative	3.71		Successful	3.84
Sincerity	Up-to-date	2.42	Sophistication	Upper class	2.00
	Down-to-earth	3.03		Charming	4.00
	Honest	4.42	Ruggedness	Outdoorsy	2.87
	Wholesome	4.10		Tough	2.48
	Cheerful	4.69

Closely related to image and personality, identity is the central element on which marketers focus in creating and strengthening a regional touristic brand. The vast majority of the information obtained from respondents focus on the image these have already formed about Maramureş but also on the personality of the brand (Table 2).

**Table 2:** Maramureș's representative aspects

	Mean		Mean
Wood art	3.68	Museums	2.52
Wood churches and monasteries	3.61	Landscapes	3.55
Art clothing and fabrics	3.65	Baia Mare	2.81
Ornamental pottery	3.00		

Source: authors' calculations

In *creating a positive image*, many respondents (61,3%) support the importance of correlating well-organized touristic services with distinct elements of the region (traditions, folklore, wood art, landscapes). 54,8% consider that touristic sights must be efficiently valued at a local, national but also international level. 29% of the respondents believe that the brand must be sustained and developed through well done campaigns and actions, focusing on the necessity of developing touristic infrastructure.

*Campaigns of creating identities* are extremely complex and require substantial resources, in this case focusing on one of identity's components, namely proposing a logo. From all the general categories that determine in a lesser or greater extend the positive appreciation of Maramureș, the most representatives, according to opinions expressed by respondents are: wood art, clothing art and fabrics, wooden churches and monasteries but also Maramureș natural landscapes. These categories exposed to respondents broadly outline the traits of a region which still conserves unaltered and unchanged elements of culture, folklore and history.

## 7. Conclusions

From the prior set of assumptions, most of them have been confirmed, *so the image of Maramureș in the eyes of the respondents is a positive one, and these put a great accent on traditional elements that offer uniqueness and a distinct character of the touristic region and less on modern elements*. Descriptions and arguments offered by the respondents offered the image of a region with a huge touristic potential, mainly represented by traditions, customs and famous objectives. However, Maramureș brand requires a deeper, more profound analysis, but which, according to the study should be based on the following:

1. *Region's characteristics*: wood art and culture, customs and habits of the traditional village of Maramureș, the hospitality of the people, Maramureș's traditional clothing and fabrics, unique touristic objectives, nature, cultural and religious elements;
2. *Rational benefits*: unspoiled natural elements, especially outstanding mountain landscapes, accessibility, escaping from the urban space, an oasis of relaxation, new experiences;
3. *Emotional benefits*: reconnecting with the traditions and the culture of Maramureș, a feeling of freedom, openness, return to everything that means customs and elements of authentic folklore, spiritual peace correlated with natural landscapes, special memories;
4. *Values and traits of the brand's personality*: this regional brand reflects, according to the respondents, the idea of openness, sociability, courage, charisma but also wisdom and faith, a mix of resistance and fragility, all in correlation with traditions that define the touristic region and reflect its distinctive

character;

5. *The brand's essence*: tradition and nature, optimism and openness, continuity. As far as a possible logo of Maramureş is concerned, it must be representative for the region, with suggestive and defining elements, but in the same time simple and effective. Analyzing all the information obtained through this research, traditions and folkloric elements are definitely very suitable for creating the logo.

More precisely, wood art is one of the most distinctive elements through which it could be indicated at a visual level regional identity. The actual logo reflects the outline of a wooden church, however, an even more representative and fit element, which cannot be found in any other region of the country is the traditional Maramureş gate, conclusion which results from the study as well.

Among the motifs present on a traditional gate can be mentioned: the nods, the rope, the solar wheel that appears as a simple circle, of some concentric circles, sun with human face (the solar cult), the tree of life, the ear of corn, etc. Also, it is recommended to focus on the solar motif present on the gate as a dominant symbol. The solar disc in a simplified form combines traditionalism with the dynamism specific to the Maramureş region, through the nuance and the forms used. Also, the logo would convey an idea of continuity, optimism and openness.

These are only a few guidelines that could lead to a more precise outlining of the regional brand Maramureş, part of a much larger project of regional branding, which seeks to reinforce the touristic brand Maramureş at all levels.

liana.stanca@econ.ubbcluj.ro  
alexandru.chis@econ.ubbcluj.ro

**Abstract:** *The decision to purchase the tourism product is influenced by the information provided to the tourist. The Internet information, which is the primary source, is used. The tourists choose the company based on the information provided. The main purpose of an online agency is to sell vacations. On the other hand any online agency must respond to user needs even if they are not always commercial (obtaining impressions of a destination, documentary on cheap destinations, etc.). The purpose of our work is to analyze travel web-sites, more exactly, whether the criteria used to analyze virtual stores are also adequate for the Romanian tourism product. Following the study, we concluded that the Romanian online tourism web-sites for the Romanian market have the features that we found listed on similar web-sites of France, England, Germany, etc. In conclusion, online Romanian tourism can be considered one of the factors of economic growth.*

**Keywords:** *tourism; tourism on-line; ITC in tourism; quality of a web site; testing the consistency; usability rules.*

**JEL classification:** L86, M15, M31

### Introduction

“Tourism is one of the most important economic sectors in the European Union. Furthermore, tourism is the sector with the highest growth rate within the European economy. The European tourism industry will be marked by an important process of transformation, as more and more clients are interested in the attractive offers presented online. Tourists give up traditional services offered by airlines, travel agencies and tour operators to take advantage of the lower prices for packages available on the Internet”. [web1]

“According to a recent estimate of the main players in the U.S. tourism market, within at the most 5 years, online companies will have the majority, practically, tourism becoming the largest industry on the Internet. A forecast justified by the extent that the Internet has got worldwide, in the recent years, in the tourism industry, not just overseas. The United States are the leader in online tourism, mainly because of the higher Internet access rates, estimated at 90% for 2013”. [web1]

The information has become a commodity, an essential resource. Each information provider (hotel chains and associations, restaurants, car rental companies, travel agents, national tourist offices) should respond to this challenge: the provision and organization of information easily accessible and attractive, reliable and updated.

Online tourism has profits also in the crisis period. Among the ten trends noticed by ANAT regarding tourism in 2011: the importance of social media and online as a distribution channel has increased.[web2]

### **Related Work and Statistical study**

Considerations relied on analysis performed in this work were:

1. As the tourism product does not actually exist at the time of sale. Usually, upon purchase, the product represents the information on the booking paper or computer. The tourist buys the right on the product. Upon the selling, the tourism product represents only the information about the offer. The product may not be tested before being purchased. Thus, the decision to purchase the tourism product is influenced by the information provided to the tourist. Furthermore, the Internet information, which is the primary source, is used. The tourists choose the company based on the information provided. The holder of qualitative and updated information has priority.
2. The pace at which the Internet has grown is amazing and it transforms completely the online reservation domain. At present, there are hundreds of online travel agencies where one may choose and the market is consolidating around major distribution channels, allowing them to charge high commissions and impose inflexible terms; although online travel agencies exercise great power, the digital revolution has made customers have the control ... as it should be - stated in an online publication by horeca.ro
3. "Online tourism has grown in the recent years, so, in February 2011, there were 446 million visitors registered to travel sites, worldwide. As a result of the increased interest in tourism portals, in 2010, the international tourism operators assigned average budgets between 60,000 and 80,000 USD for online promotion, according to a study made by Cornell University. Of the preferred methods for online promotion, we noticed Facebook, Twitter and YouTube. In the recent years, Romania has also agreed with the international trends in the field of online promotion in tourism". posted by G. Stefan on his blog [web 3]
4. "Top 10 is selling very well". This is achieved through the desire to send information, etc., by various criteria. It is well accepted that there is no standardized system to which we and also the operators in the industry may relate when talking about how a business should be or should be managed, so that everyone does as they see fit. Further, we concluded that each type of web-site has a different type of analysis [web4]
5. Technologies; everyone knows W3C or RGAA, but the user has different needs and requirements in accordance with the ergonomic, loading speed or SEO. As shown by the researchers conducted in 2010 and 2011, the searching of travel web-sites is on the 5th place among the interests of the Romanians.[web5]

Articles and papers regarding the quality, ergonomics or an audit of web site that we had as a starting point can be summarized:

- a. a series of articles like "barometer" referring to the online tourism in Western European countries, which retain the following titles: "Le 1er baromètre de la qualité web des sites touristiques" available at [web5], "A chaque type de sites Web, sa méthode spécifique d'évaluation" available at [web6]

- b. analysis related of sites banks, ministries, insurance companies in Romania available at [www.tree.ro](http://www.tree.ro) [web7]
- c. analysis conducted by researchers from roumanian universities [web9], tourism specialists in online comments on blogs [web3], [web10], etc.
- d. analyses performed on Romanian online shops to illustrate the degree of development of e-commerce, competition authors used several criteria available at web13.

The research method used in this study is the survey and the data collection tool is the questionnaire. The questionnaire was made combining various quality analysis criteria of the virtual entities, taken from [web7, web8, web11, web12,web13].

The purpose of the questionnaire is to analyze travel web-sites, more exactly, whether the criteria used to analyze virtual stores are also adequate for the Romanian tourism product. The questionnaire obtained had to be structured into six main chapters / sections. Chapter / Section 1 contains 11 criteria (note from C1 to C11) with the purpose to verify the theory according to which for three clicks, one may get the desired information. Chapter / Section 2 contains two sub-criteria with the purpose to verify the existence of the information on Legal & Trust. Chapter / Section 3 contains 27 criteria with the purpose to verify the existence of classical but complex architecture of the web-site (ergonomic organization of the information on the company policy, products and services). Chapter / Section 4, suggestively called easy Sign-up, verifies the existence of 4 classical elements for the achievement of this activity. Chapter / Section 5 measures the existence of 10 elements necessary / important / vital for the process of booking the tourism product in the virtual environment. In our opinion, these 10 elements should be present on all tourist web-sites. Chapter / Section 6 verifies the possibility of online booking and the use of electronic payment instruments. In this section, we wanted the evaluators to determine how well this tool is developed on the web-site by giving marks from 1 (very poor) to 5 (very good).

The questionnaire was filled in / reviewed by 16 people, aged between 20-30 years old, with average to good knowledge related to the use and development of software products. As this is the first phase of our research, we thought that it was important that the persons who made the evaluation to have high knowledge in order to achieve the quality coherence of this instrument (questionnaire) for the analysis of Romanian tourist web-sites. The tourist web-sites analyzed were found for several months in the top of the surveys conducted by various online publications.

Study hypothesis: The chapters of the questionnaire are a tool for the validation of the web-site quality, in terms of user perception and satisfaction. The Romanian tourist web-sites comply with the usability rules, criteria and principles available in the virtual space. [web5, web7,web8, web11,web12,web13]

Hypothesis 2. According to Nielsen's theory, web-sites allow one to obtain the information within three clicks.

Hypothesis 3. The web-sites include complete information on their legitimacy and confidence as legal entities.

Hypothesis 4. The web-sites have an ergonomic organization of information (in terms of quantity and quality).

Hypothesis 5. The web-sites present easy sign-up

Hypothesis 6. The web-sites present a complete procedure to acquire the tourism product

Hypothesis 7. The web-sites include electronic payment instruments.

The applied statistical analysis is that specific to dichotomous data that the evaluators used in order to specify the existence (value 1) or non-existence (value 0) of the criteria that make up the first 5 chapters of the questionnaire. The results of the analysis are presented below:

To test the second hypothesis of the study, we applied the test for measurement of the ratio rate (REA) which measures the probability of fulfillment / failure to fulfill the criterion. In this context, the analysis required the tracking of the users' responses who graded 1. The purpose of this analysis is to determine if there are inconsistent criteria. The result is drawn in Table 1.

**Table 1.** Achievement of the analyzed criteria

Parameters-Criteria	C1	C2	C3	C4	C5	C6	C7	C8	C9	C10	C11
<b>P</b>	<b>0.775</b>	<b>0.75</b>	<b>0.77</b>	<b>0.563</b>	<b>0.663</b>	<b>0.775</b>	<b>0.825</b>	<b>0.613</b>	<b>0.88</b>	<b>0.788</b>	<b>0.9</b>

Source: : own calculations

The analysis results show that the 11 criteria as determined by evaluators are consistent and present in all the 5 web-sites evaluated. The criterion having the lowest consistency is c4 and the criterion c11 obtained the best score. So, it is required that the owners of the analyzed web-sites to improve the web-site as related to the criteria studied, paying more attention to the criteria having  $p < 0.6$ . Please note that the value of  $p = 1$  means that all evaluators gave the maximum score to the said criterion.

The research hypothesis shows differences between the score obtained by the 5 companies studied regarding the Home Page criteria. To verify this hypothesis, we applied the Kruskal-Wallis test (Chi-Square = 13.479,  $p$ -value = 0.009) and we noticed differences between the scores obtained by each company.

**Table 2.** Statistically descriptive

Web sites	Mean	Std. Deviation	95%CI for mean		Min	Max
Site1	9.06	1.389	8.32	9.80	6	11
Site2	8.88	1.708	7.96	9.79	4	11
Site3	6.38	2.849	4.86	7.89	1	11
Site4	7.81	1.721	6.90	8.73	5	10
Site5	8.63	2.029	7.54	9.71	5	11

Source: : own calculations

To determine which web-sites generate differences in terms of scores, we applied the Mann-Whitney test. According to the Mann-Whitney test, the score obtained by web-site 1 is not significantly different from web-site 2 ( $p$ -value = 0.838) and from web-site 5 ( $p$ -value = 0.696), but it is significantly different from the average score obtained by web-site 3 ( $p = 0.004$ ) and the average score obtained by web-site 4 ( $p$ -value = 0.035). The study shows that the average score obtained by web-site 1 is greater than the average score obtained by web-site 5 and web-site 3. To determine

which of the five sites studied generate differences, in terms of scoring, we applied the Mann-Whitney test, whose result is: the score obtained by web-site2 is not significantly different from web-site5 (p-value=0.867), but it is significantly different both from the average score obtained by web-site3 (p = 0.007) and the mean score of web-site4 (p-value = 0.04). The study also shows that the average score obtained by web-site 2 is greater than the average score obtained by web-site 5 and web-site3. We applied the Mann-Whitney test to determine that the score obtained by web-site 3 is not significantly different from the one obtained by web-site 4 (p-value = 0.128), but it is significantly different from the score obtained by web-site5 (p= 0.021). The study shows that the average score obtained by web-site 2 is lower than the average score obtained by web-site5 and web-site 3. Next, we applied the Mann-Whitney test according to which the score obtained by web-site5 is not significantly different from web-site 4 (p-value = 0.184).

In the literature[Kuder 1937], [Cortina1993] [Feldt1989], [Webb\_Shavelson\_Haertel2006] there are several opinions regarding testing the internal consistency of dichotomous items. We have considered appropriate in the present study to use Kuder-Richardson (KR21, KR20) for them is analogous to Cronbach's  $\alpha$ , except Cronbach's  $\alpha$  is also used for non-dichotomous (continuous) measures[Kuder 1937].

The statistical analysis was continued by calculating the internal consistency coefficient of the dichotomous item called Kuder-Richardson (KR21), and the fidelity calculation is obtained through Kuder-Richardson coefficient (KR20). [Opariuc] The result of the Kuder-Richardson coefficient (KR20) is  $r_{KR20} = 0.65$ , so the degree of fidelity of the questionnaire items to measure the obtaining of information by three clicks is acceptable. The result of the Kuder-Richardson (KR21) coefficient is  $r_{KR21} = 0.60$ . So, *hypothesis 2* of the study is achieved. The web-sites allow the obtaining of information with three clicks, according to the Nielsen principle.

In this context, we applied the Cohen's kappa test to test the correlation between the evaluators and the result obtained is: between web-site 1 and web-site 2 Kappa = 0.253 with p <0.001 fair agreement; web-site 1 and web-site 3, Kappa = 0.378 with p <0.001, fair agreement; web-site 1 and web-site 4, Kappa = 0.430 with p <0.001, fair agreement; web-site 1 and web-site 5 Kappa = 0.357 with p <0.001, fair agreement; web-site 2 and web-site 3, Kappa = 0.364 with p <0.001, fair agreement; web-site and web-site 4 Kappa = 0.350 with p <0.001, fair agreement; web-site 2 and web-site 5, Kappa = 0.320 with p <0.001, fair agreement; web-site 3 and web-site 4, Kappa = 0.459 with p <0.001, moderate agreement; web-site 3 and web-site 5, Kappa = 0.492 with p <0.001, moderate agreement; web-site 4 and web-site 5, Kappa = 0.438 with p <0.001, moderate agreement. We have made the interpretation of Kappa results according to his theory (Landis & Koch, 1977).

We continued the study by testing the existence of the legal dimension of the studied web-sites. The evaluators marked 1 if the site provides information on the collection and processing of personal data (information, defining goals, individual rights) and zero, thus, the result is:

Web-sites	web-site 1	web-site 2	web-site 3	web-site 4	web-site 5
P	1	0.5	0.875	0.8125	0.875

Following the study, we obtained the following hierarchy: web-site 1 on the first place, followed by web-site 3 and web-site 5, followed by web-site 4 and on the last position, web-site 2.

We have also made a test related to the confidence of the evaluators in the existence of the trademark of the company name / web domain and its reference on the web-site. The result is:

Web-site name	Web-site 1	Web-site 2	Web-site 3	Web-site 4	Web-site 5
p	1	0.625	0.688	0.688	0.813

The evaluators decided unanimously that the web-site 1 presents both the trademark with the name / domain and this is clearly stated on the site. In the case of web-site 2, 19% of the evaluators decided that the information on this subject is absent. In the case of web-site 3, respectively web-site 4, 31% of the evaluators decided that the information on this subject is absent. In the case of web-site 2, 38% of the evaluators decided that the information on this subject is absent. So, hypothesis 3 of the study is moderately fulfilled.

Hypothesis 4 of the study refers to a possible agreement between the grades of the evaluators regarding the presence / absence of the basic elements of the architecture of the studied web-sites. To test this hypothesis, we applied the test of PHI associations for all 5 sites. The results are: web-site 1 is poorly associated with web-site 2 PHI = 0.236, p-value = 0.000; web-site 1 is moderately associated with site 3 PHI = 0.414, p-value = 0.000; web-site 1 is poorly associated with web-site 4 PHI = 0.395, p-value = 0.000; web site 1 is poorly associated with web-site 5 PHI = 0.394, p-value = 0.000; web-site 2 is poorly associated with web-site 3 PHI = 0.326, p-value = 0.000; web-site 2 is poorly associated with web-site 4 PHI = 0.307, p-value = 0.000; web-site 2 is associated with web-site 5 PHI = 0.299, p-value = 0.000; web-site 3 is associated with web-site 4 PHI = 0.451, p-value = 0.000; web-site 3 is poorly associated with web-site 5 PHI = 0.479, p-value = 0.000; web-site 4 is poorly associated with web-site 5 PHI = 0.444, p-value = 0.000. We may conclude – generally, there is a good agreement regarding the organization of information on the 5 web-sites.

We continued the study by determining the agreement between the evaluators. In this context, we had to calculate the Cohen's kappa coefficient and the results obtained are: between web-site 1 and web-site 2 Kappa = 0.503 with p <0.001, moderate agreement; web-site 1 and web-site 3 Kappa = 0.561 with p <0.001, moderate agreement; web-site 1 and web-site 4 Kappa = 0.674 with p <0.001, moderate agreement; web-site 1 and web-site 5 Kappa = 0.293 with p <0.001, fair agreement ; web-site 2 and web-site 3 Kappa = 0.351 with p <0.001, fair agreement; web-site 2 and web-site 4 Kappa = 0.503 with p <0.001, moderate agreement; site 2, and site 5 Kappa = 0.264 with p <0.001 so fair agreement; web-site 3 and web-site 4 Kappa = 0.451 with p <0.001, moderate agreement; web-site 3 and web-site 5 Kappa = 0.227 with p <0.001, fair agreement; web-site 4 and web-site 5 Kappa = 0.237 with p <0.001, fair agreement. We have made the interpretation of the Kappa values according to his theory (Landis & Koch, 1977).

We have also calculated the coefficient of the internal consistency of the dichotomous items called Kuder-Richardson (KR21) coefficient and the fidelity of the evaluators according to Kuder-Richardson (KR20) coefficient. (Opariuc). The result of the Kuder-Richardson coefficient (KR20) is  $r_{KR20} = 0.845$  so, the fidelity degree of the questionnaire items for the measurement of the internal architecture of the Romanian travel web-sites is very good. The result of the Kuder-Richardson coefficient (KR21) is  $r_{KR21} = 0.72$  so, the internal consistency of the items measuring the architecture of the site is good. We may conclude that the 27 criteria for the testing of the ergonomic content of the web-site may also be used for other web-sites and the results are consistent with reality.

Hypothesis four of the study is fulfilled, in other words, there is an ergonomic organization of the information on the web-sites. We mention that these criteria for measuring the organization of the information have been validated for a study of web-sites in France [web5].

Hypothesis 5 of the study consists of an agreement between the marks of the evaluators regarding the presence / absence of the easy sign-up on the web-site. To test the association degree of the web-sites according to validation criteria, we calculated the PHI coefficient. The results are: web-site1 is moderately associated with web-site2 PHI = 0.524, p-value = 0.000; web-site1 is moderately associated with web-site 3 PHI = 0.570, p-value = 0.000; web-site 1 site is moderately associated with web-site 4 PHI = 0.674, p-value = 0.000; web-site1 is poorly associated with web-site 5 PHI = 0.313, p-value = 0.000; web-site3 site is poorly associated with web-site 3 PHI = 0.392, p-value = 0.000; web-site 2 is moderately associated with web-site 4 PHI = 0.524, p-value = 0.000; web-site 2 is poorly associated with web-site 5 PHI = 0.267, p-value = 0.000; web-site 3 is moderately associated with web-site 4 PHI = 0.459, p-value = 0.000; web-site 3 is poorly associated with web-site 5 PHI = 0.263, p-value = 0.000; web-site 4 is poorly associated with web-site 5 PHI = 0.244, p-value = 0.000. We may say that, generally, there is a good agreement regarding organization of the information on the 5 web-sites.

The study also includes the determination of the agreement degree between the evaluators. In this context, we had to calculate the Cohen's kappa coefficient and the result obtained is: between web-site 1 and web-site 2 Kappa = 0.502 with  $p < 0.001$ , moderate agreement; web-site 1 and web-site 3 Kappa = 0.571 with  $p < 0.001$ , moderate agreement; web-site 1 and web-site 4 Kappa = 0.684 with  $p < 0.001$ , moderate agreement; web-site 1 and web-site 5 Kappa = 0.294 with  $p < 0.001$ , fair agreement; web-site 2 and web-site 3 Kappa = 0.352 with  $p < 0.001$ , fair agreement; web-site 2 and web-site 4 Kappa = 0.503 with  $p < 0.001$ , moderate agreement; web-site 2, and web-site 5 Kappa = 0.274 with  $p < 0.001$ , fair agreement; web-site 3 and web-site 4 Kappa = 0.451 with  $p < 0.001$ , moderate agreement; web-site 3 and web-site 5 Kappa = 0.237 with  $p < 0.001$ , fair agreement; web-site 4 and web-site 5 Kappa = 0.238 with  $p < 0.001$ , fair agreement. We made the interpretation of the Kappa values according to his theory (Landis & Koch, 1977)

The analysis of chapter 4 of the questionnaire refers to the measurement of the sign-up within the 5 web-sites. The statistical analysis necessary to test hypothesis 4 consists of the calculation of the internal consistency coefficient of dichotomous items called Kuder-Richardson (KR21) and the calculation of fidelity is done by Kuder-Richardson coefficient (KR20). The result of Kuder-Richardson coefficient (KR20) is  $r_{KR20} = 0.784$ , so the degree of fidelity of the questionnaire items to

measure the sign-up on the Romanian travel web-sites is good. The result of Kuder-Richardson coefficient (KR21) is  $r_{KR21} = 0.75$ , so the internal consistency of the items measuring the architecture of web-site 1 is good. So, the four criteria designed to test the sign-up on web-sites representative for Romanian tourism may also be used for other sites and the results are consistent with reality. So, hypothesis 4 of the study is fulfilled, meaning that the studied web-sites have an easy sign-up. We mention that these criteria for measuring the organization of information on web-site 1 have been validated for a study of web-sites in France [web5].

Chapter 5 of the study is designed to measure the existence of the booking procedure. The hypothesis of the study is that there is an agreement between the grades given by the evaluators regarding the presence / absence of the basic elements of a web-sitte1. To test this hypothesis we applied the PHI associations test, whose result is: web-site 1 is moderately associated with web-site 2 PHI = 0.597, p-value = 0.000; web-site 1 is moderately associated with web-site 3 PHI = 0.460, p-value = 0000; web-site 1 is moderately associated with web-site 4 PHI = 0.434, p-value = 0.000; web-site 1 is moderately associated with web-site 5 PHI = 0.604, p-value = 0.000; web-site 2 is moderately associated with web-site 3 PHI = 0.401, p-value = 0.000; web-site 2 is moderately to well associated with web-site 4 PHI = 0.616, p-value = 0.000; web-site 2 is moderately to well associated with web-site 5 PHI = 0.730, p-value = 0.000; web-site 3 is moderately associated with web-site 4 PHI = 0.565, p-value = 0.000; web-site 3 is moderately associated with web-site 5 PHI = 0.442, p-value = 0.000; web-site 4 is moderately associated with web-site 5 PHI = 0.470, p-value = 0.000.

To test the agreement between the evaluators, we applied Cohen's kappa and the result obtained is between web-site 1 and web-site 2 Kappa = 0.596 with  $p < 0.001$ , moderate agreement; web-site 1 and web-site 3 Kappa = 0.423 with  $p < 0.001$ , moderate agreement; web-site 1 and web-site 4 Kappa = 0.418 with  $p < 0.001$ , moderate agreement; web-site 1 and web-site 5 Kappa = 0.601 with  $p < 0.001$ , moderate agreement; web-site 2 and web-site 3 Kappa = 0.376 with  $p < 0.001$ , fair agreement; web-site 2 and web-site 4 Kappa = 0.601 with  $p < 0.001$ , moderate agreement; web-site 2 and web-site 5 Kappa = 0.729 with  $p < 0.001$ , good agreement; web-site 3 and web-site 4 Kappa = 0.545 with  $p < 0.001$ , moderate agreement; web-site 3 and web-site 5 Kappa = 0.421 with  $p < 0.001$ , moderate agreement; web-site 4 and web-site 5 Kappa = 0.463 with  $p < 0.001$ , moderate agreement. We made the interpretation of the Kappa values according to his theory (Landis & Koch, 1977).

The statistical analysis continued with the calculation of the internal consistency coefficient of the dichotomous items called Kuder-Richardson (KR21) and the fidelity calculation is done through Kuder-Richardson coefficient (KR20). The result of the Kuder-Richardson coefficient (KR20) is  $r_{KR20} = 0.95$  so, the degree of fidelity of the questionnaire items to measure the acquisition procedure of the tourism product on the Romanian travel web-sites1 is very good. The result of the Kuder-Richardson coefficient (KR21) is  $r_{KR21} = 0.90$  so, the internal consistency of the items measuring the booking procedure of the tourism product is very good. So, hypothesis 6, the web-sites present a complete procedure for the purchase of the tourism product, is fulfilled. We mention that these criteria for measuring the booking procedure of the

tourism product have been validated in the case of a study on web-sites in France [web5].

The last chapter is dedicated to the determination of the existence of electronic payment instruments on the 5 web-sites. To test hypothesis 7, we calculated the average value of the marks given by the evaluators for each web-site studied in terms of this dimension. The result is:

**Table 3:** Descriptive Statistics

	Mean	Std. Deviation	Minimum	Maximum	Percentiles		
					25 <sup>th</sup>	50 <sup>th</sup> (Median)	75 <sup>th</sup>
Site1	4.63	2.062	0	6	3.25	6.00	6.00
Site2	4.00	2.221	0	6	2.25	5.00	6.00
Site3	3.56	2.128	0	6	1.50	4.00	5.75
Site4	4.00	2.268	0	6	2.00	5.00	6.00
Site5	3.81	2.228	0	6	2.25	4.00	6.00

Source: : own calculations

We continued the study by applying the Kruskal Wallis test for the verification of the differences between the marks given by the evaluators for the web-sites. The result is shown in the table below .

**Table 4:** Kruskal Wallis Test

	Web1	Web2	Web3	Web4	Web5
Chi-Square	15.000	15.000	15.000	15.000	14.000
Df	15	15	15	15	14
Asymp. Sig.	.451	.451	.451	.451	.450

Source: : own calculations

The analysis results show: according to the average value of the marks given by the evaluators, there are no significant differences between the average value of the marks give to the web-sites. However, the fact that the average value of the grades given by the evaluators is different from zero indicates that the instrument is present on each web-site, so hypothesis 7 is fulfilled. In this context, we mention that the implementation of online payment instruments was done with hard work and in time. Given this reality, their existence on the studied sites is a step forward in this area and time will allow their improvement.

The fact that all study hypotheses are met reveals that the general hypothesis of the study (chapters of the questionnaire is a tool for validating the quality of the web-site in terms of user perception and satisfaction) is fulfilled.

## **In conclusion**

As a corollary: the study shows that the Romanian travel web-sites exist, and in addition, they comply with the rules, criteria and principles of usability available in the virtual space.

The results provided as a result of testing the questionnaire on five web-sites that were the pioneers of the Romanian tourism, on the 16 evaluators with average knowledge of IT allows us to continue applying it on other sites.

Following the study, we concluded that the Romanian online tourism web-sites for the Romanian market have the features that we found listed on similar web-sites of France, England, Germany, etc.

Now, at the beginning of the 21<sup>st</sup> century, the new technologies change the traditional situation. Any time, a new competitor may upset the value chain. Competition becomes "global", at the same time, global and local. Each tourism company may address equally the entire world, but adapting to local travel markets.

In addition, changes of the global social, economic and public policies force many institutions to begin to benefit from new technologies. We may say that the entire world is undergoing a fundamental change related to the way in which the "interaction" is made; a change led by the almost unanimous acceptance of Web 2.0 technologies, such as "wiki" sites, social networks and blogs.

In spite of cost and efficiency benefits arising from the use of the new technologies in service delivery, traditional attitudes of ownership of information and organization of companies are still barriers in the modernization process.

In the near future, the main activities will be not only B2B (business to business) and B2C (business to consumer), but also S2S (services to services): a virtual network of specialized companies that will provide value-added services. The result will be a complete customization for the consumer and the use of one to one marketing (individual tourist or travel company) and more general access to all tourist information in the world.

# THE PERFORMANCE OF TOURISM AS A TOOL OF DEVELOPMENT FOR BRASOV REGION

**Sălăgean Liana Ramona**

*Faculty of Economic Studies „George Barițiu” University, Brașov, Romania  
lianaugb@yahoo.com*

**Abstract:** *Tourism is a strategic economic activity in Brasov, its importance in the local and national economy being likely to grow in the next few years. Tourism is now one of the world's largest industries and one of its fastest growing economic sectors.*

*This paper is aimed at analysing the tendencies in tourism over the past five years in Brasov, observing the evolutions and suggesting some viable solutions for this region to become and remain a successful tourism destination in the future.*

*The measurement of tourism activity from the perspective of the consumption of visitors entails the estimation of the observation units – trip, visitor and travel party – and their corresponding characteristics. Tourism is a consumer of cultural and natural resources, direct and indirect services, being a source of services in turn. A significant part of the Brasov region abounds in natural and anthropic tourism resources, which makes it possible that an increasing flow of both national and international travellers should be drawn by tourism development, while new towns may appear and flourish as tourism resort.*

*In the case of Brasov region, the main reflection topic should be focused on the difference between the expected performance – the regional resources and the geographic position. As an absolute and also relative value in GDP, in the last few years, the Romanian tourism achieved performances which place it in the second half of the classifications related to Europe.*

*The contribution of tourism activity to the general economic development in Romania shows that tourism may act as in impetus for the global economic system. This implies the specific demand of technologies, goods, and services produced by various economic branches should be met.*

*Brasov area has a diversity of natural tourist resources and cultural assets of a great historical, architectural, and artistic value, those distinguish it from other areas. An accurate estimation of tourist potential elements requires a qualitative and quantitative system of criteria. Tourism favours the local utilization of several resources, of the labour market, for instance, contributing to its stabilization by diminishing the migration process towards the urban areas.*

**Keywords:** *tourism, system of indicators, accommodation, performance, analyse.*

**JEL Classification:** *M 10, M 20.*

**1. Introduction** Tourism is a service sector with a particularly complex product which depends on an extremely fragmented supply. Each link in the chain (hoteliers, travel agencies, tour operators, restaurateurs) offers one element in the overall product. Together, these components determine tourists' experiences and their appreciation of the quality of the service. (Tassiopoulos, 2008).

### **The industry and services in Brasov**

After the industrial decline in 1999, similar with the national tendency an industry relaunching happened in the year 2000. The industrial output has dropped in the last period due the following factors:

- The low capacity of adaptation to the modifications occurring in the structure of the home and foreign markets
- Strong undercapitalization due to inflation rise, sharp devaluation of the national currency, low investments volume, etc.
- Slow rate of privatization and restructuring
- Unsteady and incoherent legislative framework that did not stimulate foreign and home capital investment.

The construction sector is well represented at regional level. The industrial building sites have proven their experience in the framework of broad projects, by building dwellings, commercial centres, hospitals, education institutions, etc. A similar ambitious project was started in Brasov in 2011, called Airport Brasov.

In the field of services we can identify a decrease tendency that can be notices both at regional and national level in the recent period of time, with the mention that in the region the lowering rate has decreased from year to year. The weight of occupied population in services against region total is 29,60%, value that is extremely low when reported with the weight owned of this sector in UE regions.

This sector is characterized by:

- a strong concentration in the developed centres of the region, while in the rest of the territory it has a very low weight;
- Focusing on commerce and restaurant activities, and the services supplied directly to the population are insufficient and of poor quality.
- Tourism services that are not capitalized at the level of the existing potential;
- The advisory services that are insufficiently promoted;
- The health and social assistance services that are under the quality standards;

The activities concerned to ware and passenger transport have followed two baselines:

- Railway transport is still under state ownership and was subject to restructuring at the level of regional subsidiaries, to update the existing infrastructure;
- Road transport has particularly developed in the private sector, as ware and passenger transport companies were established and organized in an up-to-date and efficient manner.

Taking into account that tourism activity influences the use of the labor force from other sectors of the economy such as agriculture, food industry, light industry, construction, and that each job in the tourism generates one to three indirect and induced jobs, it highlights the need to develop stronger tourism activity in Romania and increasing its role in the national economy (Mihalache, 2011).

### **2. The evolution of tourism in Brasov during 2007 - 2011**

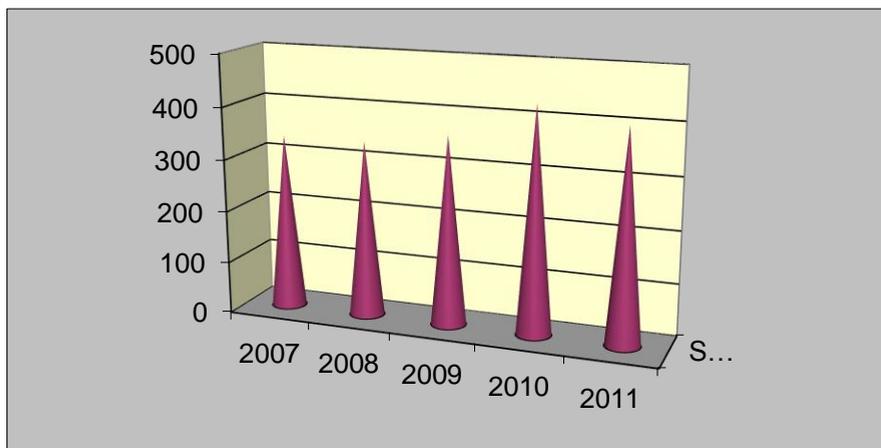

Brasov County is one of the counties with an enviable heritage and natural history, but that is not valued as it should be. Although the largest share of total tourist accommodation capacity in operation in the Romania, over the five years, has the Constanta County, Brasov County is following the share of total accommodation capacity in the country. Its advantage is that the accommodation capacity can be used in all seasons. It is interesting to follow the evolution of the accommodation

capacity and the number of tourist facilities, the types of units in order to determine a prognosis closer to reality as the development of tourism in Brasov.

**Table 1** Establishments of tourist reception with functions of tourists' accommodation

<b>Tourist accommodation structures</b>	<b>2007</b>	<b>2008</b>	<b>2009</b>	<b>2010</b>	<b>2011</b>
Hotels and motels	42	37	42	47	55
Tourist chalets	27	24	19	21	13

Villas and bungalows	60	59	52	64	67
Camps for students and preschool children	7	7	7	3	1
Urban guesthouses	84	87	119	82	107
Rural guesthouses	114	121	121	211	155
Holiday villages	1	1	1	1	2
<b>Total</b>	<b>337</b>	<b>338</b>	<b>362</b>	<b>431</b>	<b>403</b>

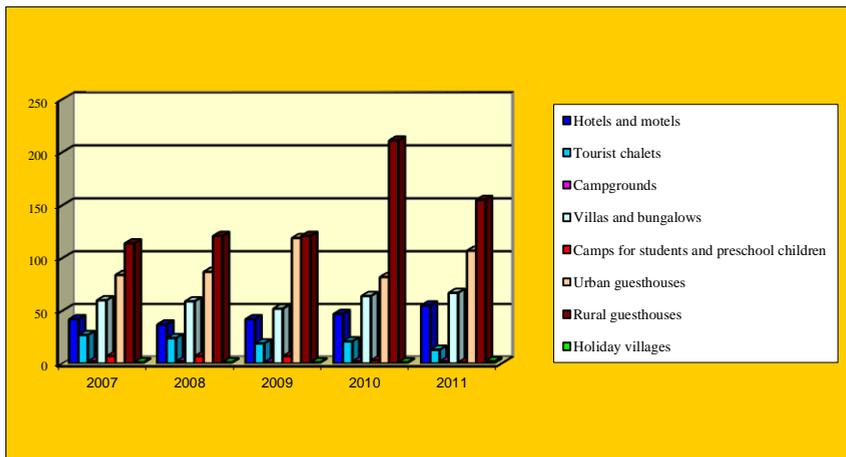

Source: National Institute of Statistics

**Figure 1** - Evolution of the total number of tourist accommodation – Made by the author

Source: National Institute of Statistics

It can be observed that in the years 2007 – 2011, in Brasov, the overall number of tourist accommodation structures with functions of accommodation had an increasing trend (with 66 units), their number decreased in the last year by 28 (403 in 2008 compared 431 in 2010). Were put into operation new hotels, motels, villas and bungalows, increased number of urban hostels, however, the number of guesthouses, after a steep increase from 114 in 2007 to 211 in 2010, in 2011 a decrease from 155 to 56 units. Also it is noted a decrease in the number of tourist chalets (from 27 in 2007 to 13 in 2011) and camps for students and preschoolers. However, increasing the capacity of accommodation in Brasov in 2011 compared to 2007 is approximately 20%.

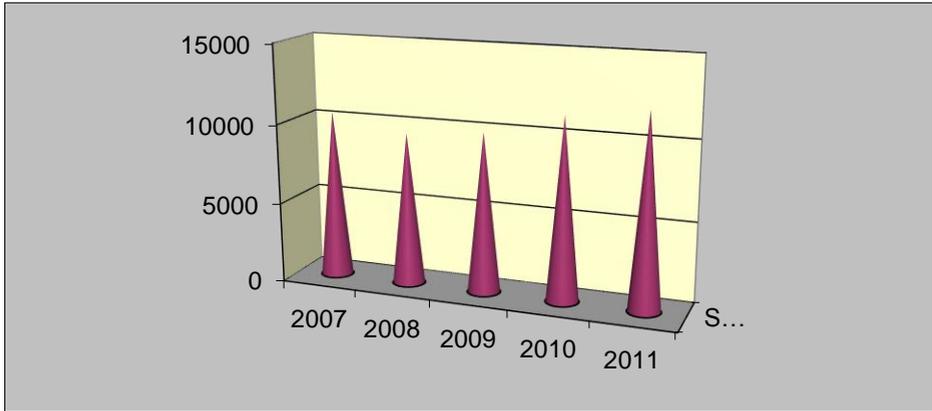

**Figure 2** - The evolution of the types of accommodation in Brasov, during 2007 – 2011 – Made by the author  
Source: National Institute of Statistics

Accommodation capacity has fared similar to the tourist reception structures, an increase of 14.5% in 2011 compared to 2007. There was a decrease during the period in 2008 when the number of accommodation decreased from 10.513 to 9.528 (a difference of 985), but the following year began to rise again, reaching a total of 12,037 in 2011.

**Table 2** - Evolution accommodation capacity in Brasov during 2007 – 2011

Year	2007	2008	2009	2010	2011
The accommodation capacity	10.513	9.528	10.007	11.380	12.037

Source: National Institute of Statistics

**Figure 3** - Trend of accommodation during 2007 – 2011 – Made by the author  
Source: National Institute of Statistics

It can be observed the same trend of growth and in terms of arrivals in tourist accommodation structures, with a decrease in 2008, followed by an increase in the next years. From 2008 to 2010 there is an increase in the number of arrivals by 45,5% and in 2011 came to 36,6% more tourists than in 2007.

**Table 3** – Arrivals in the establishments of tourists' reception with functions of accommodation

Year	2007	2008	2009	2010	2011
Number of persons	328.000	290.000	325.000	422.000	448.000

Source: National Institute of Statistics

**Table 4** - Number of overnight stays in the establishments with accommodation functions in Brasov during 2007 – 2011

Year	2007	2008	2009	2010	2011
Number of persons	885.000	779.000	823.000	961.000	1.000.000

Source: National Institute of Statistics

Number of overnight stays, according to statistics, in the period under review increased by 13%, had a period of decline in 2008, as the number of arrivals. Overall, the net use index of tourist accommodation capacity, determined as the ratio between the number of nights and number of places-days tourist capacity was in Brasov in the 2007 – 2011 lower than the national average (and so pretty lower) and lower than the average in the region VII Centre. This is a real warning to taking action for revival of tourism in Brasov.

**Table 5** – The net use index of accommodation places (%)

Year	2007	2008	2009	2010	2011
Brasov County	23,1	23,6	22,5	24,6	23,7

Source: National Institute of Statistics

The biggest tourist capacity utilization index in operation was recorded in 2010 (24,6%) compared to previous years (23,1% in 2007, 23,6% in 2008, 22,5% in 2009 and 23,7% in 2011).

### 3. The accommodation structures in Brasov

Made by the author

The analysis of the degree distribution of the stars we can see that classification most hotels in Brasov are classified with the 3 – star levels (53%). This reality actually pursues European tourism market trends and national default. Most hotels in major cities have a high three-star comfort, a trend that is reflected in the evolution expected for the next years. That kind of hotel has as tourist's model: businessmen, tourist groups, middle class families, etc.

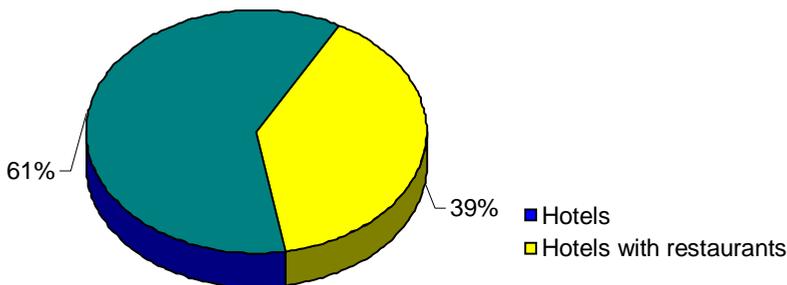

The distribution of hotels in Brasov

**Figure 4** – The distribution of hotels in Brasov – Made by the author  
Source: National Institute of Statistics

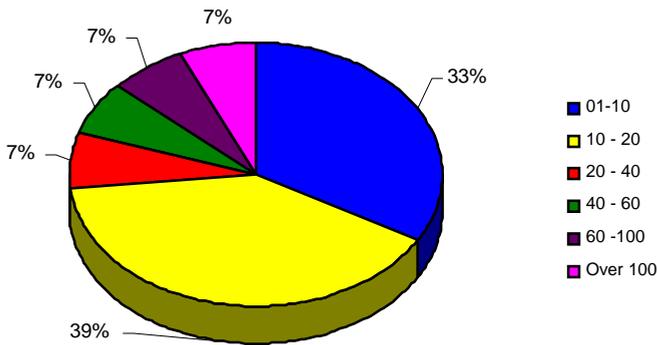

Regarding the distribution of the conference rooms in hotels, it can be notice that about a quarter of them have conference rooms equipped properly. The trend at the level of providers is to create such spaces considering that the business tourism is in full development. This form of action in tourism is becoming more profitable because of their high load hospitality, services ordered and consumed (conference rooms, catering, entertainment, etc.). In generally conference participants personally do not support the costs of accommodation and meals; those are paid by companies, who sometimes have impressive budgets for these events.

Analyzing the distribution of accommodation units that have their own restaurants, it is observed that about 40% of them have dining rooms. This is a normal situation, considering that many of the accommodation units have a limited number of rooms, which do not justify setting up catering facilities. Hotels with more than 20 rooms have catering facilities.

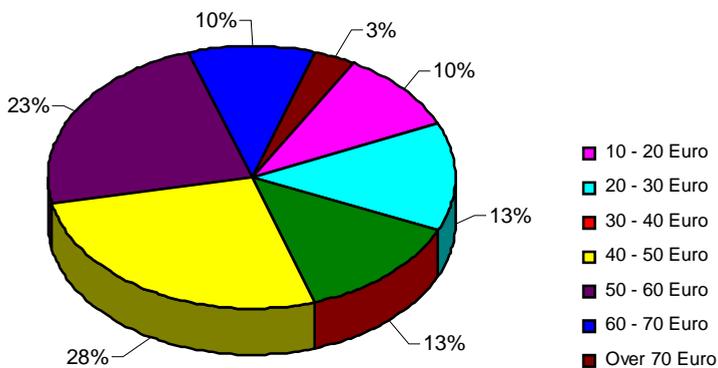

**Figure 5** - The distribution of hotels with restaurant/ hotels in Brasov – Made by the author  
Source: National Institute of Statistics

By analyzing the size the accommodation units of Brasov *are withdrawn* the following conclusions 33% of them are sized up to 10 rooms, 39% between 10 and 20 rooms. The rest are units with no more than 20 rooms. This shows that 72% of accommodation units in Brasov are small size, generally family hotels. Relatively low capacity of the accommodation is generally particularly high value of the investment in the hospitality industry. As a positive factor sizing to a small number of rooms allows for better adaptation to market requirements. Underdimensionnement for accommodation capacity creates inconvenience, especially in the case of larger groups.

**Figure 6** - Percentage representation of the size of the accommodation units in Brasov – Made by the author  
Source: National Institute of Statistics

**Figure 6** – Percentage representation of charges in hotels – Made by the author  
Source: National Institute of Statistics

Analysis applied tariffs at the reception show off those overall margin price 3-star establishments in the range of 40-60 Euro price / night for double room. This is an acceptable price by consumers being practiced within both national and European level.

#### **4. Conclusions**

Brasov tourism market is growing, so one could say the same about the types of tourism products, so investment in this area are welcome and can be effective. The tourist offer should be based on developing a marketing mix to be based on a correct segmentation of the target market; a complex product policy and adapted to expectations of potential customers; attractive pricing strategies, standard distribution policies and especially communication and promotion policy aimed at achieving direct feed-back communication with the target market. Prices / rates should take into account, on the one hand, the specificity and the financial interests of companies and, on the other hand, the strategies adopted by companies / travel agencies competing both directly and indirectly. It required a special approach market for individuals because it particularities both domestic and foreign markets, while improving market approach where the majority of business customers are more features. It is necessary to enhancement of the positive image that has the Brasov area, including the external market, while trying to create loyalty for the significant customers by using public relations techniques.

**Abstract:** *This paper seeks to relate a strategy of diversification to innovativeness and to the performance of a hotel. Due to the more increased competition within the area of tourism e.g. hotel sector, the need of analyzing the variables mentioned in the title of the paper has become more and more obvious. The first part of the article regards the literature review for the three variables and thus, like an outcome four hypotheses are stated. The second part consists of developing findings for the studied region of Cluj County based on the presented research methodology. The results show that hotel performance is influenced by customer orientation and hotel innovativeness, while the latest one is associated in a positive manner with learning orientation. The three chosen variables could be considered real driven forces for competitiveness in the hotel sector. Thus, any management team should be aware of the results of this study and should create an appropriate environment within the organization able to sustain an expected performance level by focusing on the mentioned variables. Making a deeper analysis about the performance indicators, the results demonstrate the actual development stage of the hotel sector for Cluj County: above the national average, but with potential of growing, mainly from the perspective of efficiency. At this point, management should be aware about how significant could be innovativeness and learning orientation for creating or improving services and delivering processes. In the hotel sector it is very obvious that due to the increased role of employee the awareness is more valuable than in other sectors. Due to the most relevant market segment e.g. business tourism, the studied county is customer oriented and has a good mean value for sales goal achievement, also. In order to improve the profit goal achievement value, innovativeness and learning orientation have to be considered powerful instruments for management team. Taking into consideration the potential of growth in the Romanian hotel sector, we consider that the three chosen variables - customer orientation, learning orientation and innovativeness, should be further analyzed in respect with other performance indicators. Thus, we consider the study being valuable and relevant because it can be expanded not only to other regions - which gives it practical value, but also by including other performance indicators - for academic value.*

**Keywords:** hotel; customer orientation; learning orientation; innovativeness; performance; competitiveness

**JEL classification:** L83; L25; M10

## **1. Introduction**

In order to compete in this turbulent, unstable and globalized marketplace, hotel managers have to consider differentiation as a necessity. This differentiation can be understood in terms of innovative and/or personalized services, qualified human resources, brand, social responsibility, information and communication technology implementation or proactive managerial orientation towards customer, organizational learning or innovativeness. To sustain a competitive advantage, hospitality businesses have to exploit these opportunities.

Tajeddini (2010:221) suggests that hotels need to place customer orientation at the heart of the hotel's competitiveness. At the same time, Hult, Hurley and Knight (2004) say that a key component in the success of hotels is the extent of their innovativeness. Farrell (2000) suggests that once a hotel becomes customer-oriented, it begins to adopt and implement a learning orientation.

Consequently, the past few years have witnessed great interest in these constructs, their interrelationships and their implications on hotel performance, by scholars across marketing and management disciplines (Nasution et al., 2011; Tajeddini and Trueman, 2012; Leekpai and Jaroenwisan, 2013).

The article is structured as it follows. Firstly, a literature review on customer orientation, learning orientation and innovativeness provides a clear and accurate outline of these issues. This is followed by hypotheses statement. We then discuss the research methodology: sample, data collection and procedures. In the end, the results and discussion are presented followed by the conclusion of our study in terms of implications for hotel managers and academics.

## **2. Conceptual framework and research hypotheses**

### **2.1. Customer orientation**

Many studies provided evidence that being customer-oriented leads to obtaining a competitive advantage and high performance. In order to obtain these goals, hotel management have to consider customer orientation like a key element of current decision making process. Ruckert (1992:228) defines customer orientation as the degree to which the hotel obtains and uses information from customers, develops a strategy which will meet customer needs, and implements that strategy by being responsive to customers' needs and wants. Thus, a hotel should be able to answer and deeply analyze the following question: "What exactly do tourists want and value?". The first step a hotel must take to find the answer is to closely monitor its tourists. A large number of studies have focused on Front-Office employees from hotels (Tajeddini, 2010:222) like a primary resource through which hotels can gain a competitive advantage. For a better respond to this challenge, we consider that employees should have the following characteristics: ability to clearly identify and focus on relevant information and objectives, to develop appropriate and/or new solutions to certain types of problems, active listening and interacting with tourists, task orientation, responsibility, feedback oriented, organizational commitment and flexibility. Developing a sufficient understanding of tourists in order to deliver attractive, personalized and competitive hotel services is not enough. Hotel management must understand that, tourists' needs, expectations and perceptions of services' benefits change over time. Therefore, hotel management has to

systematically and continuously adjust the hotel offerings in order to deliver a memorable experience, not a simple hotel service.

Thus, the customer orientation is considered an important tool for achieving high performance in hotels, whether customer orientation is viewed from the perspective of product or service delivery (Tajeddini, 2010:222). Hence:

**H1:** Customer orientation is positively associated with hotel performance measured by: (a) profit goal achievement; (b) sales goal achievement; (c) occupancy rate.

## **2.2. Innovativeness**

Distinctions have been drawn among the concepts of innovation and innovativeness. In our initiative to pursue the concept of innovation in hotels we concluded that there is no precise definition, no consensus on its meaning, resulting in many interpretations. Moreover, this area is not enough researched (Peters and Pikkemaat, 2005, Rodgers, 2007), which prompted Ottenbacher and Gnoth (2005:206) to state that because of this deficiency, hotels managers use "intuition, assumption and experience" when trying to achieve innovation. Even though innovation and innovativeness in the academic research are not yet thorough, in practice they have evolved a lot (Hjalager 2010:1) due to their benefits.

In an attempt to define innovation in hotels, we appreciate that this is the process by which new services are obtained or enhanced current services or delivery processes, with positive effects on hotel performance and tourists' satisfaction. Also, we consider that related to the complexity of the hospitality sector, it is necessary to develop a definition of innovation in respect with the research objectives and the development level of the hotel sector from the analyzed region/country.

In order to understand the relationship between innovation and innovativeness, we mention this opinion: whereas innovation is typically an outcome-oriented measure, innovativeness captures the firm-level orientation toward innovation (Leekpai and Jaroenwisan, 2013:167 after Hurley and Hult, 1998). In other word, innovativeness represents the openness to new ideas as an aspect of a hotel's culture (Nasution et al., 2011 after Hurley and Hult, 1998), the initiation process of innovation (Hult, Snow and Kandemir, 2003).

Innovativeness has become an imperative for hotel's competitive advantage (Deshpande et al. 1993) and key determinant for hotel performance and survival (Van de Vrande et al., 2009). Thus:

**H2:** Hotel innovativeness is positively associated with hotel performance measured by: (a) profit goal achievement; (b) sales goal achievement; (c) occupancy rate.

## **2.3. Learning orientation**

Sinkula et al. (1997) conceptualize learning orientation as consisting of commitment to learning, shared vision and open-mindedness (Nasution et al., 2011:338 after Sinkula et al., 1997). Calantone et al. (2002) defines learning orientation as the activities of the organization to adding and using knowledge to enhance competitiveness. Furthermore, learning orientation is reflected in increased efforts by the employee to actively expand his or her existing repertoire of technical and social skills, thus learning new and better ways of interaction with customers (Hennig-Thurau and Thurau, 2004). Therefore, learning orientation is considered one of the most valuable resources, allowing hotels to address issues of

globalization and economic uncertainty. Many studies found that learning orientation has a direct and positive effect on organizational innovativeness (Hult et al., 2004). Thus:

**H3:** Learning orientation is positively associated with hotel innovativeness.

#### **2.4. Customer orientation, learning orientation and innovativeness**

We observe in literature that the relationship between customer orientation and innovativeness is a subject to debate. Some scholars show that customer orientation facilitates hotel innovativeness (Sandvik and Sandvik, 2003). Furthermore, Baker and Sinkula (1999) suggest that market orientation is necessary and sufficient in the creation of an optimal environment for innovation (Nasution et al., 2011:339 after Baker and Sinkula, 1999). Deshpande et al. (1993) suggest that, to understand the role and importance of customer orientation, the concept should be related to the innovativeness of an organization's culture. With regard to the relationship between learning orientation and innovativeness, Hurley and Hult (1998) suggest that learning orientations is one of innovativeness dimensions, which represent organizational cultural characteristics. These arguments and findings have led us to formulate the following hypothesis:

**H4:** Customer orientation and learning orientation are positively associated with hotel innovativeness.

### **3. Research methodology**

The samples in this study were hotel managers. In order to achieve our objectives, all classified hotels from Cluj County (one of the most developed counties from Romania) were included. The research method used in this study was the survey through a self assisted Web questionnaire. There were validated 35 questionnaires, resulting in the response rate of 66.04%.

The questionnaire was designed to ask hotel managers for their opinions on the following variables: customer orientations (9 items), learning orientation (7 items) and innovativeness (9 items). This information was collected using a five-point Likert scale (1-strongly disagree to 5-strongly agree) in response to statements about mentioned variables. The second part of questionnaire deals with the assessment of 3 performance indicators, namely profit goal achievement, sales goal achievement and occupancy rate. Each respondent was asked to evaluate performance in relation to primary competitors, using a five-point Likert scale (from 1= "worse than", to 5= "better than" the other company. This approach is used in many research papers (Hooley et al., 2000; Kirca, Jayachandran and Bearden, 2005; Tajeddini and Trueman, 2012). The last part of the questionnaire contains factual questions that capture respondents' demographic characteristics as well as their organizational characteristics.

### **4. Results and discussions**

The adequacy of the measurement model was assessed through examining construct reliabilities. As the coefficient alphas of all constructs exceed the 0.70 level recommended by Nunnally (1978), the reliability of the measurements is achieved. In fact, the coefficient alphas for customer orientation, learning orientation and innovativeness are 0.82, 0.86, and 0.77, respectively (Table 1).

**Table 1:** Cronbach's coefficient alpha

Variable	Number of items	$\alpha$
Customer orientation	11	0.82
Learning orientation	5	0.86
Innovativeness	11	0.77

Source: Authors' calculations

Results concerning the research samples revealed that the first three market segments targeted by hotels are: business tourists, with a percentage of 26%, transit tourists, with a percentage of 22% and leisure tourists, with a percentage of 18%.

If we analyze the three variables that influence performance, we observe in Table 2 that studied hotels in Cluj County have a high level of customer orientation (Mean=3.98) and medium levels of learning orientation (Mean=3.41) and innovativeness (Mean=3.39).

On the other hand, the performance indicators reveal the best mean value for occupancy rate (Mean=3.42), while the lowest one is for profit goal achievement (Mean=2.28). Cluj County is characterized by an intensive tourism flow due to the representative market segment-business tourists. As a result, the mean value for sales goal achievement is an appropriate one. This is not the case for profit goal achievement because of the low efficiency of the internal operations within the studied hotels.

**Table 2:** Correlations among variables, and shared of measures (N=35)

Variable	Mean	Standard deviation	1	2	3	4	5	6
1.Customer orientation	3.98	0.715	<b>1.00</b>					
2.Learning orientation	3.41	0.681	0.77	<b>1.00</b>				
3.Innovativeness	3.39	0.837	0.88	0.82	<b>1.00</b>			
4.Sales goal achievement	3.17	0.821	0.71	0.43	0.92	<b>1.00</b>		
5.Profit goal achievement	2.28	1.152	0.61	0.42	0.72	0.84	<b>1.00</b>	
6.Occupancy rate	3.42	0.948	0.82	0.50	0.85	0.83	0.72	<b>1.00</b>

$p < 0.05$

Source: Authors' calculations

Also, in Table 2 we observe positive correlation coefficients between studied variables, suggesting that the relationships are in the same direction. The lowest correlation coefficient was between learning orientation and profit goal achievement (0.42), while the highest correlation coefficient was found in innovativeness and sales goal achievement (0.92).

As Table 3 shows, customer orientation in studied hotels has a positive and significant impact upon sales goal achievement ( $\beta=0.688$ ,  $p<0.01$ ) and profit goal

achievement ( $\beta=0.503$ ,  $p<0.01$ ) providing support for H1. Similarly, innovativeness has a significant and positive impact upon occupancy rate ( $\beta=0.723$ ,  $p<0.01$ ) supporting H2.

**Table 3:** Hypothesis testing of H1–H2 standardized parameter estimation.

Variables	Sales goal achievement		Profit goal achievement		Occupancy rate	
	Beta	t-value	Beta	t-value	Beta	t-value
Customer orientation	0.688	1.420	0.503	1.890	0.535	2.778
Learning orientation	0.243	2.161	0.061	1.199	0.215	1.092
Innovativeness	0.638	1.796	0.325	2.395	0.723	1.039

$p < 0.05$

Source: Authors' calculations

Moreover, the study found that the interaction of customer orientation and learning orientation is positively related to innovativeness ( $\beta=0.854$ ,  $p<0.01$ ) leading to the acceptance of hypothesis 4, and learning orientation has a significant impact on innovativeness ( $\beta=0.817$ ,  $p<0.01$ ) providing support for H3.

## 5. Conclusions

The main goal of this study was to develop a more complex research in which to determine the extent to which each different variable could positively influence the hotel performance. In this particular paper were selected the three variables customer orientation, learning orientation and innovativeness based on the literature review and considered significant by the previous analysis.

Customer orientation is a primary variable and the most studied one when referring to its correlation with the performance of the company. If we consider the hotel sector, there are not so many studies with the above mentioned subject and we appreciate this one like a good start for the Romanian hotel sector. If we look at the Beta estimations for this variable, there are definitely the best values. We appreciate it like an expected situation because among the three selected variables this is the most available way for managers in order to improve their performances. Also, the more intensive correlation with sales goal achievement supports the same idea, while the profit goal is in the opposite situation. Managers could analyze the results of the study and to improve the internal aspects of the hotel business in order to get a more intense correlation. It means more focus on process innovation. This can be achieved by sustaining the other two variables.

Innovativeness has the highest value from all the correlation (0,723 – occupancy rate) which leads us to the idea that in the studied county, the managers are already concerned with developing adequate organizational culture for sustaining the innovation processes. We consider this process being in an early stage because it has not yet revealed the possible favourable influence on the other two factors. The management should have a proactive approach in respect with innovativeness and to push it to the other employees. Every employee should be aware about his/her role within the process delivery and to be encouraged to have a proactive attitude in every assigned task.

Learning orientation has the lowest values when referring to the estimated correlations. We believe that a flexible management attitude toward the directions already mentioned will enable to get more intense correlations with the performance.

We appreciate that the hotel organization of the 21<sup>st</sup> century would be more able to improve its performances if managers will have a better approach to the three studied variables and thus, the traditional trade-off between short term – financial performances and long term approach – competitiveness ones are no longer so valuable.

## **6. Limits of the study and future directions**

The three chosen variables are significant but the study could be more developed by adding new relevant variables. Also, the performance indicators could be extended by adding other financial or even nonfinancial ones for the future studies. We consider both the two possible extensions of the initial study like having a potential academic value.

Another perspective is to extend the geographical area of the research by comparison between the initial area and another one, already selected- Braşov County or to develop a national study where considering the most important touristic areas within Romania. This approach could have a significant importance for practitioners or managers within the studied areas.

# CONSUMERS' PERCEPTION ON INNOVATION IN THE TOURISM VALUE CHAIN

**Răvar Anamaria, Iorgulescu Maria-Cristina**

*Department of Tourism and Geography, Faculty of Commerce, Bucharest University of Economic Studies, Romania*

[anamaria.ravar@gmail.com](mailto:anamaria.ravar@gmail.com)

[cristina.iorgulescu@yahoo.com](mailto:cristina.iorgulescu@yahoo.com)

## **Abstract:**

*In the current economic environment, innovation is considered critical by the majority of tourism companies that are increasingly willing to spend more to become more innovative. This tendency is visible in all segments of the tourism value chain: accommodation services, transportation, intermediaries – travel agencies and tour-operators – as well as entertainment and leisure facilities. The final aim of innovation in tourism enterprises is to increase customer satisfaction and thus secure the enterprises' competitive advantage on a continuously changing market. Thus, consumers' perception on innovation is relevant not only to academics and researchers, but especially to organisations in the business environment, which use customer feedback in order to develop innovative products which are better suited to the individual needs of tourists. The purpose of this article is to determine how consumers of tourist services perceive innovation in the various segments of the tourism value chain. The results will indicate the perceived intensity with which innovation is implemented in the tourism industry as well as the sectors in which innovation could bring additional benefits to tourists. To this aim, it was conducted a literature review on the main types of innovations in hospitality, airline transportation and travel intermediaries, as well as a pilot questionnaire-based study on 120 regular consumers of tourist services. Results indicate a discrepancy between the importance tourists give to innovation and the actual perceived level of innovation in the tourism value chain. Furthermore, the research shows the importance of innovation in different segments of the tourism value chain in the purchase decision of a tourism product. Unfortunately, results indicate that Romanian tourism operators' perceived innovativeness is lower in comparison with foreign tourism operators. The study is exploratory, representing a starting point into a more comprehensive research into the means through which innovation can be enhanced in the various sectors of the tourism industry.*

**Keywords:** innovation; tourism; hotel industry; travel agencies; transportation; technology

**JEL classification:** L83; O14; M10

## **1. Introduction**

Tourism is an industry which is subject to a great variety of internal and external influences, being characterised by continuous transformation (Orilla-Sintes and Mattson) and generating new economic and social relations between people and

businesses. In order to maintain its competitive position, a company must strive to develop new products and services, new management instruments, new ways of organizing its function and structure and new means to communicate with partners and customers. Although a company's position is measured according to its revenue, profitability, market share and customer satisfaction, these elements cannot „point the way to the future” (Kim and Maubogne, 1997). Longterm success in the tourism industry greatly depends on an organisation's capacity to innovate and adapt to its changing environment. Innovation in particular is regarded one of the main determinants of competitiveness in tourism as it allows firms to achieve lower costs and higher quality outputs (Orfila Sintes and Mattson, 2009).

The study follows the rationale of Johannessen et al. (2001), which suggests that innovation in the tourism industry should be assessed by asking three questions – “What is new”, “How new is it” and “To whom is new”?. The current article aims to answer the first question – „What is new” – providing an overview of innovation in the various segments of the tourism value chain – accommodation, transportation and intermediates.

## **2. Innovation in tourism**

Innovation in tourism was largely neglected until the end of the 1990s, when mass tourism proved its incapacity to ensure the satisfaction of customer's changing needs and was replaced by what Poon defines as “new tourism”, a tourism focused more on the depth of the travel experience and the individual satisfaction of the tourist rather than on service standardisation (Poon, 1994, cited by Tigu and Rávar, 2012). The importance of innovation in tourism has increased ever since under the influence of both demand and supply factors. Thus, the increasingly complex needs of tourism consumers are continuously forcing tourism enterprises to “develop new products, services and experiences” (Pikkemaat and Peters, 2006). On the other side, new production factors such as information and communication technologies determined a profound change in the management of tourism enterprises. Several criteria may be used to classify innovations in the tourism industry. Based on its intensity, innovation may be classified as incremental and radical (Thorburn, 2004) or, according to Hjalager (2002) as regular, niche, revolutionary and architectural. Generally, incremental innovations consisting of continuous adjustments and improvements are regarded as typical to the tourism industry (Mointeiro and Sousa, 2011).

Based on the object dimension of innovation, a diverse typology has been put forward in the literature: product and service innovations, process innovations, management innovations, logistics innovations, institutional innovations (Hjalager, 2002), social innovations, human resource innovations, technological innovations (Pikkemaat and Peters, 2006). Other authors (Vila et al., 2011) also address market innovations, which include distribution channels, web-based communication, customer loyalty, information sharing and marketing innovations.

Innovations may also be classified based on the market they are addressed to. Executives appreciate as most important innovations leading to new offerings for existing customers, followed by new offerings that allow expansion into new customer groups. However, innovation leading to different changes in existing products and services also tends to become a priority (Andrew et al., 2010), together with innovations which make use of information and communication technologies (ICT) and which tackle environmental issues.

Since a tourism product encompasses a multitude of services, each provided by companies operating in different sectors – transportation, accommodation, leisure, and intermediation – the intensity and centrality of innovation also differs across the industry. In fact, tourism may be viewed as an integrated value chain of services (Bieger, 2001, cited by Pikkemaat and Peters, 2006), with different innovation patterns at each level of the value chain. Jong and Marsilli (2006, cited by Meneses and Teixeira, 2011) classify innovative small firms as

follows: the transport sector is “supplier-dominated” (as a consumer of technology externally developed by the manufacturing industry), while hotels and personal services are considered “resource-intensive” (a similar category to “supplier-dominated”, but with a higher degree of innovativeness). We will proceed to analyze the degree to which innovation is present in each of the main sectors of the tourism industry and, respectively, on each of the levels that make up the tourism value chain.

### **2.1. Innovation in the hotel industry**

In comparison to other industries, research and development expenses and the number of patents registered remain relatively low in the hotel industry (Pikkemaat and Peters, 2006). However, this does not mean that innovation is absent or scarce. In fact, it seems that most entrepreneurs in the hotel industry recognize the importance of innovation (Volo, 2004, cited by Pikkemaat and Peters, 2006).

Although the hotel industry is relatively homogenous, the innovation behaviour of enterprises varies considerably according to a multitude of factors. Innovation varies according to the size of the enterprises operating in the market, as the innovation capacity greatly depends on the organisation's size and this influences its ability to initiate research activities or to acquire and implement externally developed innovations (Hjalager, 2002; Orsila-Sintes and Mattson, 2007; Pikkemaat and Peters, 2006).

Although enterprises in the hotel industry are currently accustomed to a large variety of innovations, these innovations are generally developed by external suppliers and rarely developed internally (Pikkemaat and Peters, 2006). Some authors (Hjalager, 2002; Orfila-Sintes et al., 2005) define innovations in the hotel industry as being supplier-driven and not science based. This aspect is particularly valid in what regards ICT technologies (reservation systems, property management systems, new media applications). Other new innovative products include loyalty and environmentally sustainable programmes. As far as loyalty programmes are concerned, they are generally developed in integrated enterprises such as hotel chains, allowing customers to be accommodated in any establishment part of the chain at preferential tariffs. Process innovations are also frequent in the hotel industry, as property management systems are implemented in both individual as well as chain hotels in order to reduce costs and increase operational efficiency. A study conducted by Vila et al. (2011) indicates that market innovations and process innovations are among the most critical as they facilitate and regulate internal operations but most importantly relations with the hotel's customers.

### **2.2. Innovation in other sectors of the tourism value chain**

The expansion of Internet use had a visible impact in the tourism industry, significantly changing the way customers allocate knowledge about hotels, flights or even destinations (Grisseemann and Stokburger-Sauer, 2012). This impact is probably more visible in the travel agencies sector, considering the development of online travel agencies or online travel portals. Travel-related products are the largest category of goods sold on the Internet (Yu, 2008, cited by Castillo-Manzano and López-Valpuesta, 2010; Kim et al., 2007). In order to survive competition, traditional travel agencies must use the new technologies in order to not only create their own websites (Tsai et al, 2005; Yu, 2008, cited by Castillo-Manzano and López-Valpuesta, 2010), but also provide greater added value to the information and advice they offer clients (Alamdari, 2002; Cheyne et al., 2005, cited by Castillo-Manzano and López-Valpuesta, 2010). Moreover, travel agencies have to face a “re-intermediation process”, meaning they have to reassert their intermediary role by enhancing human interaction and consumer trust (Kracht and Wang, 2010, cited by Grisseemann and Stokburger-Sauer, 2012). Increasing co-creation activities enable travel agencies to provide travel arrangements tailored to each customer's individual needs (Grisseemann and Stokburger-Sauer, 2012).

In the airline industry, innovation is increasingly becoming a formula to regain profitability, along with massive cost cuts and mergers and acquisition activities (Franke, 2007). According to Franke (2007), innovation is induced through three main levers: new business models, advanced customer segmentation and new technologies. New technologies include new next generation aircraft such as regional jets (Brueckner and Pai, 2009), advanced information technology – wireless surveillance networks, integrated data bases and host systems - and new distribution systems, such as Amadeus, Sabre and Worldspan (Franke, 2007).

In particular, the airline industry has been deeply influenced by the expansion of Internet. The changes are very visible in the airline distribution sector (Alamdari and Mason, 2006, cited by Castillo-Manzano and López-Valpuesta, 2010), where companies started using websites for offering lower fares for price-sensitive customers (Muthitacharoen et al., 2006; Alamdari and Mason, 2006, cited by Castillo-Manzano and López-Valpuesta, 2010).

The expansion of Internet, however, has its disadvantages, as it increases competition by allowing customers to compare fares in order to select the best choice for them. The use of online travel services has become the most popular choice for purchasing travel tickets and other related conveniences, travel agencies being ranked last in customer usage (Kim et al., 2007).

### 3. Research methodology

Considering the fact that most studies focus mainly on innovation in the hotel sector, the aim of this research is to highlight the use of innovation in mostly all the firms of the tourism value chain. In order to analyse customers' perception on innovation in the tourism value chain, a pilot study was conducted on Romanian tourists. The research instrument was a questionnaire, specifically designed (in Romanian) and administrated to tourism services customers. The questionnaire was created using Google Docs and published online, the data being gathered via an Internet survey, conducted from March 24 to April 7, 2013. Approximately 400 persons received the invitation via e-mail to participate at the survey. During the 2 weeks dedicated to the study, participants were able to respond at any time to the online questionnaire by simply accessing the URL provided in the e-mail received. From the 400 persons involved in the study, 120 completed the questionnaire, resulting in a 30 percent response rate.

The first and the last 6 questions of the questionnaire were designed to obtain the respondent's demographic characteristics (Table 1). The other 7 questions (with a total of 33 items to be answered) were aimed to identify respondents' perception on innovation in different segments of the tourism value chain: hotels, travel agencies, transport, restaurants, entertainment. These questions were created with a 5-point Likert scale, measuring frequency of using different tourism services, innovation intensity and importance in the tourism value chain. As it can easily be observed in the demographic profile of the respondents (Table 1), age was measured using a categorical scale. More than 80% of the respondents are under 35 years old, while the gender distribution of the respondents is more balanced: 60% of them are female and 40% are male. Considering the distribution of respondents on age groups, the distribution based on the monthly income is not surprising: 65% of the respondents earn less than 2500 lei. The study focused on highly educated people (97% of the respondents have a bachelor or a master degree) who are (self) employed (55% of the respondents are working and 23% run a business).

**Table 1: Demographic profile of the respondents**

Variable	Percent	Variable	Percent
Age (years)		Education level	
18-24	33	High school	3
25-34	49	Bachelor's degree	33
35-44	9	Master's degree	64

45-54	5		
Over 55	4		
Gender		Occupation	
Female	60	Student/Master's student	20
Male	40	Employee	55
Monthly income (lei)		Manager/Entrepreneur	23
< 1000	22	Inactive	2
1000-1500	15		
1500-2000	12		
2000-2500	16		
> 2500	35		

The study has its limitations since different market segments have different travel experiences and are thus prone to make subjective judgements about specific services (Pikkemaat and Peters, 2006). Assessing the intensity of innovations at different levels of the tourism value chain should also include a research among providers from various branches which contribute to the creation of a holistic tourism product – accommodation, restaurants, transportation and entertainment.

#### 4. Results and discussion

The first question was designed to obtain the frequency with which respondents use to travel to tourist destinations from Romania and abroad. Responses show that 20 percent of tourists usually travel once a year, 62.5 percent – 2 to 3 times a year, 10 percent on a monthly basis, while 7.5 percent travel more than once a month. The result indicates that respondents are regular consumers of tourist services and therefore in a relevant position to make personal appreciations regarding innovation in the tourism industry.

The second question sought to determine the frequency with which tourists consume services provided by operators in the various segments of the tourism value chain: accommodation facilities, food and beverage, entertainment facilities, transport companies, travel agencies and tour-operators. The frequency was measured on a 5 level Likert scale: 1 „never”, 2 „occasionally”, 3 „medium frequent”, 4 „frequent” and 5 „always”. Results (Figure 1) show that the services provided by accommodation and dining facilities are frequently consumed by the vast majority of tourists, with a weighted average of 3,89 and 3,6 respectively, while the services provided by travel agencies and tour-operators are consumed occasionally. Transportation and entertainment services are consumed medium frequent.

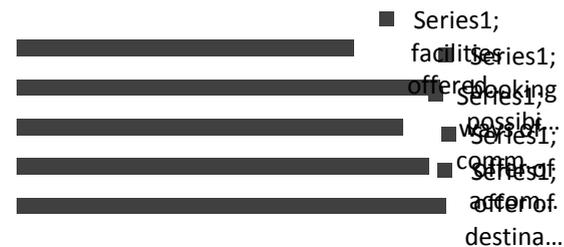

**Figure 1:** Tourism services – frequency of use and consumption

The purpose of the third question was to determine tourists' perception on the intensity of innovation in the different segments of the tourism value chain. Respondents' perception was also measured on a Likert scale from 1 "very low" to 5 "very high". According to the questionnaire results, the respondents perceive accommodation facilities as the most innovative in the tourism industry, with a weighted average of 3,63, while travel agencies are perceived as least innovative, with an average of only 2,28. Surprisingly, transport operators (2,91) are perceived as less innovative than food and beverage facilities (3,01), and entertainment facilities (3,4) although transportation is a capital-intensive sector which is in close connection with technology and ICT.

**Figure 2:** Perceived innovation intensity on various providers of tourism services

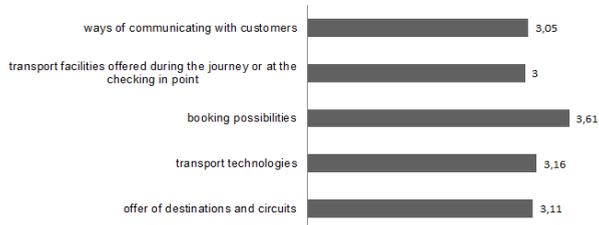

The fourth question was designed in order to determine tourists' perception on innovation intensity in travel agencies, organisations which act as intermediates between the final consumer and other providers of tourist services.

**Figure 3:** Perceived innovation intensity on travel agencies and tour operators

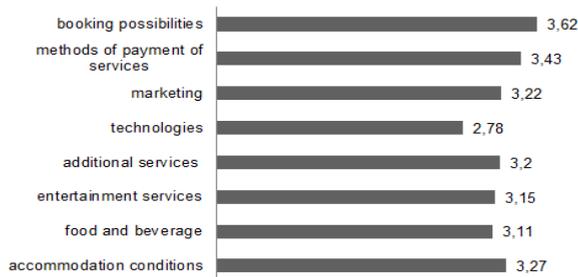

Results show that the reservation/booking possibilities are perceived as most innovative, with an average value of 3,26 on the Likert scale (from 1 "very low" to 5 "very high"), followed by the offer of destinations and circuits, with a weighted average of 3,31. Facilities offered at the agency's headquarters are perceived as least innovative (2,6), while the ways of communicating with customers (2,98) and the offer of accommodation and transportation

services (3,18) are perceived as medium innovative. The fifth question was aimed to identify the perceived innovation intensity (measured on a Likert scale from 1 “very low” to 5 “very high”) on different items concerning a specialized transport company activity (including airline companies).

**Figure 4:** Perceived innovation intensity on transport companies

As seen in Figure 4, according to the weighted averages computed for all the respondents (with values from 3 to 3,61), transport companies are perceived as medium innovative. The highest score was obtained for the booking possibilities (3,61), which indicates that customers consider that transport companies are highly innovative in this concern. The lowest score (3) was obtained for the transport facilities offered during the journey or at the checking in point, followed by the item concerning the ways of communicating with customers. Furthermore, respondents perceive transport technologies and the offer of destinations and circuits as only medium innovative. These results could have been influenced by the fact that the respondents do not have very high incomes and probably tend to choose low cost transport companies. The next question was aimed to highlight the perceived innovation in the hotel industry. Similarly to the previous questions, the respondents were asked to grade from 1 (“very low”) to 5 (“very high”) the innovation intensity in different aspects regarding a hotel’s activity.

**Figure 5:** Perceived innovation intensity in hotels

Unfortunately, the hotel industry is also perceived as only medium innovative, according to the weighted averages (with almost all values lower than 3,5) based on all the responses obtained in the survey. The highest score (3,62) was registered, similarly to the case of transport companies, for perceived innovation in booking possibilities, followed by the perceived innovation in methods of payment offered to clients. Accommodation conditions (e.g. great architecture, personalised rooms, new types of rooms) are also perceived as only medium innovative, closely followed in score by innovation in marketing (promotion ways utilised by hotels) and in additional services offered (e.g. spa, laundry, beauty salon). Entertainment services are, in turn, considered only medium innovative, similarly to the food and beverage services offered by hotels (weighted averages slightly higher than 3). The lowest score was registered for perceived innovation in utilised technologies (including “green technologies”), considered low to medium. As mentioned before, the results may have been influenced by the scale of accommodation units preferred by the questioned customers.

Furthermore, the research was aimed to identify the importance of innovation in different segments of the tourism value chain for choosing a vacation destination and for purchasing tourist services. Respondents were asked to award a grade from 1 (“not important at all”) to 5 (“very important”) for innovation importance in 5 sectors of the tourism industry: travel agencies, transport companies, accommodation units, restaurants and entertainment companies.

**Figure 6:** Importance of innovation in different segments of the tourism value chain in choosing a vacation destination and in purchasing tourist services

As it can be observed in Figure 6, according to the weighted averages computed based on all the customers questioned, innovation in accommodation units and in entertainment companies is important in choosing and purchasing tourist services (the weighted average, with a value of 4,08 in both cases, places these two value chain segments first in the top of most important sectors in tourism). Innovation in restaurants (weighted average of 3,94) is also important for the respondents, while innovation in transport companies is only medium important. The lowest weighted average was registered by the importance of innovation in travel agencies, which, according to the customers questioned, is medium important in purchasing tourist services. The last specific question of the survey intended to identify customers' perception on Romanian tourism operators' innovativeness, in comparison with foreign tourism operators. Results show that 81% of the respondents state that foreign tourism operators are more innovative than Romanian ones, while 12% believe that Romanian tourism operators innovativeness is relatively equal to the one of tourism operators from outside the country. Only 1% of the customers questioned believe that Romanian tourism companies innovate more than the ones outside, while 6% of the respondents were not able to make a comparison due to the fact that they had not travelled outside Romania. These results definitely conduct to further research ideas on innovation in tourism.

## 5. Conclusions

To conclude with, results show that the importance given by respondents to innovation in the various sectors of the tourism value chain is higher than their actual perception of innovation intensity in these sectors. Thus, although tourists feel that innovation in accommodation facilities, entertainment companies and restaurants are important to their decision to travel, they perceive these facilities as being medium innovative, which may signal an unsatisfied demand for innovation on the tourism market.

Furthermore, it is surprising that tourists view the food and beverage sector as more innovative than transport and intermediates and place a relatively high priority on the importance of innovation in restaurants. This indicates that although the literature on innovation in tourism is primarily focused on the hotel industry and transportation technologies, other segments such as dining and entertainment should not be ignored as they play a vital importance in the decision to travel.

Last but not least, although travel agencies and tour-operators have been described in the literature as open to innovation through the expansion of Internet and ICT, they seem to be perceived as little to medium innovative. Moreover, the importance of innovation intensity in travel agencies is regarded as lower than in the case of other sectors.

The results call for further research into the impact of innovation in the different sectors of the value chain on tourists' satisfaction and behaviour, as well as into the means through which innovation can be enhanced. A more comprehensive research based on this pilot study should also take into account the differences among providers operating in the same sector, since each of the industries playing a role in the tourism value chain – hospitality, food and beverage, intermediates, transportation and entertainment – are highly heterogeneous.

# WHAT MOTIVATES CULTURAL TOURISTS? AN ANALYSIS OF BUCHAREST INHABITANTS' MOTIVATION TO VISIT THE CENTRE REGION

**Răvar Anamaria, Mahika Cristina**

*Department of Tourism and Geography, Faculty of Commerce, Bucharest University of Economic Studies, Romania*

[anamaria.ravar@gmail.com](mailto:anamaria.ravar@gmail.com)

[cristinamahika@yahoo.com](mailto:cristinamahika@yahoo.com)

**Abstract:** *Cultural tourism is currently one of the main driving forces of the tourist phenomena, accounting for a significant part of the world's tourist flows. Cultural tourism may take many forms, according to the motivation behind tourists' impetus to travel to a certain destination. Cultural heritage and historical sites, dance, music and theatre performances, art galleries, museums and exhibitions, religious and worship sites and ethnic traditions are the main attractions for tourists motivated by knowledge seeking, self-development and the desire to experience other cultures. Although cultural motivations play an important role in the generation of tourist flows towards cultural tourism destinations, a tourism experience is rarely generated as a result of a single motivation. The act of choosing a specific destination and tourism product is influenced by multiple motivations, not only cultural but also connected to relaxation or family. Furthermore, tourism products are rarely homogeneous – a single holiday may include experiences with cultural content as well as leisure time, sports, adventure or entertainment. Thus, culture is not always the main motivation behind cultural tourism and may in fact be less central to the decision to travel than other factors. This is particularly true in the case of destinations which dispose of various cultural assets, but whose natural tourist resources – such as landscape, climate, access to the sea – also makes them attractive for other types of tourism. The aim of this article is to show that in the case of tourist destinations where cultural attractions represent the vast majority of the areas' tourist heritage, cultural motivations remains central to the decision to travel. Furthermore, we will seek to identify the main types of cultural attractions that motivate cultural tourism in Romania by investigating Bucharest inhabitants' perception of the Centre Region, a cultural destination par excellence in light of the latest statistics and developments. The article is based on the findings of an exploratory survey-based research carried out in the first three months of 2013 on more than two hundred tourists and potential tourists in Bucharest.*

**Keywords:** cultural tourism; tourist motivation; Centre Region; cultural attractions; cultural destination

## **Introduction**

Among the forms of the „new tourism” defined by Auliana Poon (1994) is culture and heritage tourism, an industry which is both fast-growing as well as influential in what regards its capacity to change and improve life, knowledge and human relations.

Due to the fact that cultural tourism is often complementary to other forms of tourism, being practiced as a secondary activity, the nature and complexity of motivations influencing the travel decisions of cultural tourists still remains disputed among

scholars. Thus, apart from cultural motivations, the decision to travel to destinations disposing of cultural heritage assets also depends on factors associated with family, entertainment, relaxation and even business opportunities. However, cultural motivations – such as the desire to improve one’s knowledge, to discover and experience other cultures, to learn and develop – still remain important to cultural tourists.

### 1. Theoretical considerations on cultural tourism

Cultural tourism is currently „one of the most significant and fastest growing components of the tourist phenomena” (Alzua, O’Leary and Morrison, 1998). In fact, WTO estimates that cultural tourism currently accounts for almost 40 percent of all tourists trips worldwide (Isaac, 2008).

A study conducted at European level shows that 20 percent of tourists visiting Europe respond to cultural motivations, while 60 percent of travel flows in Europe include activities with cultural content (Nedea et al, 2011). In the former communist countries in Central and Eastern Europe in particular, cultural tourism has been regarded both as a new growth market as well as a means to produce, maintain and promote a favourable image of these countries (Hughes, Allen, 2005).

The terminology related to cultural tourism has been subject to confusion in the last decades (Hughes, 1996, Alzua, O’Leary and Morrison, 1998). According to Hughes (1996), cultural tourism includes „visits to historic buildings and sites, museums, art galleries and also to view contemporary paintings or sculpture or to attend the performing arts”.

The great variety of cultural attractions has lead to a classification of the many forms of this phenomenon. Thus, Hughes (1996) distinguishes between several forms of cultural tourism – **historical or heritage tourism**, which includes visits to historical sites, **arts tourism**, which refers to visits focused on museums, galleries and performing arts, and **ethnic tourism**, when the main motivation is to experience other cultures.

Regardless of the nature of the attractions which are subject to cultural tourism flows, culture and its forms of expression are generally considered the primary motivation behind cultural tourism. According to Lawrence (2008, cited by Ozel and Kozak, 2012), experiencing cultural assets is a major motivation in the decision to travel.

However, the centrality of culture as a motivation for travelling varies among consumers of tourism products (McKercher and du Cros, 2003). Opportunities for learning, cultural experiences and self-explorations are not always major motivations for cultural tourists (Hausman, 2007, cited by Ozel and Kozak, 2012).

Therefore, in an integrated tourism product, culture may be either a main motivation or a secondary activity, according to the structure of the destination’s heritage and the needs and interests of the tourist. Often, groups involved in cultural tourism also include people with little knowledge of the significance of the cultural asset that they visit (Hausman, 2007, cited by Ozel and Kozak, 2012).

In fact, a study conducted by Özel and Kozak (2012) shows that knowledge and experience – which are associated with cultural motivation – are rarely central for the decision to travel, being less important to tourists’ decision than rest, relaxation and experience. Still, the study has its limitations since it is conducted exclusively among Turkish tourists in the context in which Turkey is mostly regarded as a sun and sand destination, cultural motivations thus being secondary to leisure and relaxation. Thus, it would be possible for motivations to vary not only to the individual

profile of the tourists, but also according to the structure of a destination's heritage and particularly to the proportion of cultural attractions in the destination's overall heritage.

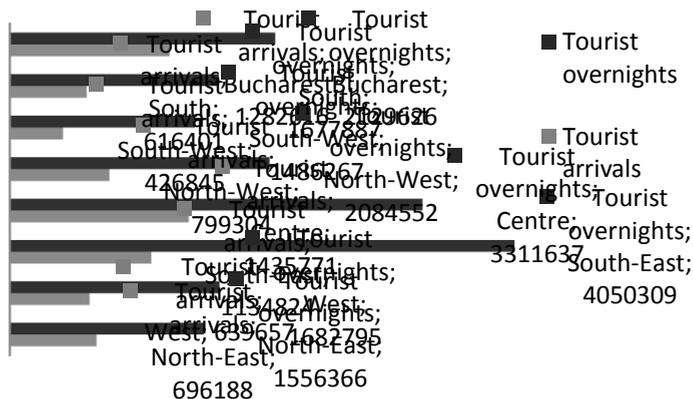

## **2. The Centre Region as a destination for cultural tourism**

The Centre Region is situated in central Romania, covering the vast majority of the historical province known as Transylvania. The region comprises 6 counties: Braşov, Sibiu, Alba, Covasna, Harghita and Mureş, which, over the course of the past eight centuries, have been home for various ethnic groups and communities – Romanian, Germans and Hungarians.

The multicultural character of the region has been reflected in the variety and multitude of cultural sites and attractions, which make up a rich and extremely valuable heritage, both material as well as intangible. These cultural attractions may be grouped in several categories:

- Medieval urban citadels, which are nowadays an integral component of many urban centres, such as Braşov, Sibiu, Sighişoara, Alba Iulia;
- Peasant fortresses - such as Feldioara, Rupea, Râşnov, Saschiz – and fortified churches, such as Prejmer, Biertan, Viscri or Călnic;
- Castles from various time periods, such as the Bran castle, the Bethlen Haller castle in Cetatea de Baltă (Braşov county), the Apafi Manor in Mălâncrav, the Bethlen castle in Cris (Mureş county), the Kalnoki castle in Micloşoara or the Arcuş Castle in Covasna county;
- Museums and exhibitions, such as the Astra Museum or Rural Civilisation in Dumbrava Sibiului, the Bruckenthal museum in Sibiu (Sibiu county), the National Unity Museum in Alba Iulia (Alba county);
- Religious edifices, such as the Şumuleu Monastery near Miercurea Ciuc (Harghita county), St. Stephen's cathedral and the Coronation Cathedral in Alba Iulia (Alba county), the Black Church in Braşov, the Brâncoveanu monastery in Sâmbăta de Sus (Braşov county)
- Rural areas which have maintained a rich intangible heritage, such as traditional dances, music, clothing, food and handicrafts; the region comprises several such ethnographic areas: Mărginimea Sibiului, the Bran-Moeciu-Rucăr corridor, Țara Făgăraşului, the Târnava Mare area etc.

According to the National Institute of Statistics, since 2010, the Centre Region has been the development region with the highest number of tourist arrivals – 1.13 million in 2010 and 1.44 million in 2011 respectively (Figure 1). Furthermore, together with Bucharest-Ilfov, the Centre Region has been the only development region registering an increase of the number of tourist arrivals in 2010 and 2011, thus recovering from the severe decline in the 2008-2009 period. In fact, since 2010, the Centre Region registered a higher number of tourist arrivals than Bucharest-Ilfov – the main destination for business tourism – and the South-East region, the only region with access to the seaside and where sun and sand tourism is possible in Romania.

**Figure 1:** Number of tourist arrivals and overnights in Romania, per development regions

Source: *The National Institute of Statistics, 2013*

Despite of the fact that the Centre Region comes second – after the South-East region – in what regards the number of over-nights spent in accommodation facilities this is however natural since stays in regions which are fit for leisure and sea-side tourism are generally longer than in the case of cultural tourism or business tourism destinations.

Although data regarding the proportion of cultural attractions in the Region’s tourist heritage are not yet available, there are several studies discussing the proportion of cultural tourism in the overall tourist flows in the Centre Region. For example, a study conducted by Dulău and Coroş (2009) indicates that approximately 50 percent of foreign tourists visit the region for cultural purposes and that cultural sites in the area are highly appreciated by visitors. In fact, Dulău and Coroş (2009) determined that foreign visitors’ favourite activities while travelling in Transilvania are visits to churches and monasteries, and visits to historic and archaeological sites respectively.

Thus, we may state that cultural assets do play an essential role in tourists’ decision to travel to the Centre Region, the area being considered the most representative cultural tourism destination in Romania, together with Bukovina (Dulău and Coroş, 2009).

### 3. An analysis of Bucharest inhabitants’ motivation to travel in the Centre Region

The statistical indicators published by the National Institute of Statistics (2013) show that the Centre Region was in the 2010–2011 period the development region with the highest number of tourist arrivals in Romania and the second highest number of overnights spent in accommodation facilities, being exceeded only by the South-East Region. These statistics indicate that tourists in general are highly interested in the Centre Region, both those coming from within the borders of Romania as well as foreign tourists. Taking this into consideration, the present study sought to identify the motivations of Bucharest inhabitants to visit, but most importantly, to practice cultural tourism in the Centre Region.

### 3.1. Methodology

To analyze the extent to which cultural motivations remain the main factor in the decision-making process of travelling in the Centre Region for those who live in Bucharest, we conducted an exploratory research based on a pilot study. To this aim we developed a 16 questions questionnaire, both multiple choice as well as open-ended questions, which were sent via e-mail to more than 500 Bucharest inhabitants. The questionnaire was posted online on Google Docs and was available for completion in the first quarter of 2013. The only criterion respondents needed to fulfil in order to fill in the questionnaire was to currently live and work in Bucharest.

The research is exploratory, as it represents only a starting point for further research into the motivations of Romanian cultural tourists. Limitations are imposed by the relatively small sample – approximately 200 cultural tourists - as well as by the fact that the research is restricted to tourists residing in Bucharest, with previous experience in cultural tourism activities in the Centre Region.

The observation unit is the tourist. The decision to analyze cultural tourist flows originating in the Bucharest Region is not arbitrary. The distance between Bucharest and the Centre Region can be easily covered by train or car in approximately 3 hours (on the routes Bucharest-Braşov and Bucharest-Sibiu), the region thus being relatively accessible to tourists in Bucharest.

At the time being, Bucharest is the largest cultural, industrial, commercial and academic centre in Romania. Bucharest is also Romania's capital and the largest city in the country in terms of both area and population, with approximately 1.67 inhabitants according to the Population and Housing Census in 2011 (National Institute of Statistics, 2013). Therefore 8.8% of the Romanian population lives in Bucharest.

Furthermore, statistics show that Bucharest-Ilfov is the only development region in Romania with a gross domestic product higher than the average GDP per capita at EU level (Adumitroaei, 2013). As cultural tourists are generally characterised as well-educated and earning an income above average (Busuioc, 2009), Bucharest may be regarded as one of the most important emission areas for cultural tourist flows.

The gross sample value was computed based on the formula  $n = \frac{t^2 * p * (1-p)}{\Delta w^2}$ , where n is the sample value, p is the ratio between the number of subjects possessing the studied characteristics and the total population, t is the coefficient corresponding to the guaranteed confidence probability, and  $\Delta w$  is the maximum accepted error level. The value of "p" is estimated based on studies in what regards the proportion of cultural tourists in the total number of tourists. A research conducted by Stăncioiu et. al (2011) shows that approximately 24 percent of Romanian tourists travelling to Transylvania practice cultural tourism. Thus, p will be considered equal to 0,24. The value of " $\Delta w$ " will be considered 5 percent (0,05) for a guaranteed confidence probability of 90 percent ( $t=1.645$ ). Based on these values, we concluded that, in order to be statistically relevant, our study must include at least 197,4 people.

The sample included 200 respondents, of which 36% men and 64% women. As far as age is concerned, 86% of respondents are 19-35 years old, 9% between 36-55 years and 4% over 55 years. In what regards the level of education, 11% finished high school, 40% have a university bachelor's degree, 45% a master's degree and 3% are PhDs.

### 3.2. Results and discussion

The first question was designed to obtain information regarding the frequency to which the respondent travels for cultural purposes in the Centre Region. Answers show that 20% of respondents travel visit the Centre Region approximately 2-3 times a year, 29% annually, and 26% less than once a year.

The second question was aimed at determining the main destinations that are chosen when traveling in the studied area. 43% of respondents travel predominantly to destinations in urban areas, but occasionally in rural areas, 19% choose only urban areas, while 8% only travel to rural areas. 17% of respondents travel to destinations which are situated both in rural as well as urban areas. Thus, it can be seen that respondents prefer urban destinations in the Centre Region, but do not ignore the rural destinations.

The third question refers to the importance of six factors – architecture and monuments (1), festivals and concerts (2), museums, galleries and exhibitions (3), local communities’ lifestyle (4), folklore and culinary traditions (5), other motives including leisure, entertainment, business tourism, visiting relatives and friends (6) - in the decision to practice cultural tourism in the Centre Region. To this aim we used a semantic differential five-level scale where 5=„very important” and 1=„not important” factor. Results were interpreted with the use of the Likert scale.

A weighted average was computed for each of the listed factors. As shown in Figure 2, the three main factors influencing the decision to travel in the Centre Region are, in order: architecture and monuments (4,069), other motives (3,875) and cultural events (3,76). Factors related to customs, traditions and museums were considered neither important nor unimportant: folklore and culinary traditions (3,68), museums and exhibitions (3,63) and local communities’ lifestyle (3,53).

The responses show that while cultural motivations remain important, respondents also place great emphasis also on other forms of tourism in the area, such as mountain tourism, business tourism or visits to relatives and friends, which confirms once again that tourists prefer to blend several forms of tourism during a trip.

**Figure 2:** Importance of various factors in the decision to practice cultural tourism in the Centre Region

Source: Data compiled by the author based on research results

The answers to the question regarding the time of the year when tourists prefer to travel to the Centre Region show that July and August are the most popular months

for such journeys, this period being chosen by 50% of respondents, while 27% of respondents opted for the May-June period, 9% for September-November, 9% for December-January. Only 5% stated that they prefer the February-April period for travelling in the Centre Region. The fact that 77% of respondents prefer to travel in the Centre Region from May to August leads us to the idea that Bucharest inhabitants prefer the warm summer months to practice cultural tourism in the area, seasonality being relatively high.

With regard to the average length of stay, an overwhelming share of 64% devotes a weekend for this kind of journey, 33% prefer to stay from 3 days to a week in the Centre Region, while only 4% spend more than a week in cultural destinations.

The sixth question is open-ended and invites respondents to indicate 1 to 5 cultural destinations where they prefer to travel in the Centre Region. 141 of the respondents indicated Brasov, 125 - Sibiu, and 82 – Sighișoara. Bran-Moieciu received 43 responses, the Făgăraș area - 38, Alba Iulia – 29, and Târgu Mureș - 20 responses. A quarter of respondents stated that they had visited one or more villages with fortified churches. It can thus be seen that the most popular areas for tourists coming from Bucharest are rich in cultural heritage. However, they also allow tourists to practice other forms of tourism such as mountain tourism, business travel or visits to relatives and friends.

Question 7 was aimed to determine the most frequent activities conducted by tourists in the Centre Region. We interpreted responses by using a semantic differential scale with 5 levels, where “1=never”, “5=always”. The respondents were given a list of nine activities and 5 variants of answers: never, occasionally, relatively frequently, often and always.

A weighted average was computed for each of the following 9 activities – spending time in nature (1); visits to relatives and friends (2); interaction with local communities (3); cooking, painting, photography, traditional art classes (4); attending music, film and theatre performances (5); attending cultural events, including festivals (6); visits to museums, galleries and exhibitions (7); visits to places of worships such as churches and monasteries (8); visits to historical sites (9).

**Figure 3:** Frequency of different tourism activities practiced in the Centre Region  
Source: Data compiled by the author based on research results

As shown in Figure 3, the most frequent activities undertaken by respondents are, in order: visits to historical sites and vestiges (3.4) and to places of worship (3.04). A mean of 2.92 was obtained for visits to museums and spending time in nature. Cooking classes, photography, painting classes received the lowest score (1.65), which indicates that respondents place a lower importance on learning activities.

The answers to questions 3 and 7 show the importance given by tourists from Bucharest to visiting historical sites in the Centre Region. This is not surprising, however, as the Centre Region concentrates a significant percentage of Romania's cultural and historic heritage, including 8 UNESCO Heritage sites, Sighișoara and seven villages with fortified churches.

In what regards the travel preferences of respondents, results show that 66% of respondents prefer to be accommodated in guesthouses, 13% in the homes of relatives or friends, 12% at hotels, 8% in camping facilities, 2% in hostels, while only 1% choose the rental of an apartment. As far as transportation preferences are concerned 81% of respondents stated they prefer to travel by car, 16% by train, 2% by bus or minibus and only one respondent by plane.

Asked about who they are travelling with when visiting destinations in the Centre Region, 55% of respondents answered they prefer to travel accompanied by friends, 33% accompanied by family members, 9% prefer travelling in a large group and only 3% travelling alone.

The last two questions were designed to determine the person responsible for the decisions regarding the destination and travel plans. Results show that 98% of respondents prefer to organize their own leisure activities and only 2% use a travel agency for this purpose. 62% of those who completed the survey stated that they are the ones who usually decide on the holiday destination and visited attractions, while 23% claim that the friends they are travelling with are responsible for this decision. 13% stated that their life partner decides on the destination, while 2% indicated that family members other than their life partner generally take this decision.

Regarding the average budget spent per day per person when travelling in the Centre Region, 47% of the respondents spend less than 100 lei, 44% spend between 101-300 lei, 7% spend between 301-700 lei per person and only 1% over 700 lei.

#### **4. Conclusions**

The purpose of this article was to analyze the importance of cultural factors in the decision to travel by studying Bucharest inhabitants' motivations to travel in the Centre Region, a region which occupies the south, eastern and central parts of Transylvania and is characterised by a highly diverse and rich cultural heritage. It also aimed to determine the main types of cultural attractions that motivate cultural tourism in the Centre Region and to assess the extent to which cultural tourism is complimentary to other forms of tourism, such as mountain tourism and business tourism.

The exploratory research revealed that architecture and monuments are considered more important in the decision to travel than the opportunity to spend time in nature or visit friends and relatives. Furthermore, local folklore and culinary traditions, festivals cultural events and visits to museums were indicated as relatively important by most respondents.

Thus, our analysis indicates that cultural motivations remain central to Bucharest inhabitants' decision to travel to the Centre Region and that cultural assets such as historical sites, places of worship and museums exert the highest attraction to tourists from Bucharest.

It seems however that other types of tourism such as mountain tourism, business tourism or visiting relatives and friends are also of great interest to tourists travelling in the area. This shows that culture and heritage are the main but not the only motivations for tourists travelling in the Centre Region. Furthermore, the study indicated that cultural tourism is often complimentary to other forms of tourism or part of a more comprehensive tourism product which can include both leisure as well as cultural activities.

The study has its limitations as it investigates tourist flows generated in one development region and oriented towards a single tourist destination, namely the Centre Region. Furthermore, the findings contradict other similar studies (Özel, Ç. H., Kozak, N., 2012) which show that cultural motivations play a secondary role in the decision to travel to a certain destinations. However, these studies were mostly conducted in areas in which natural resources such as landscape and climate play a more significant role in the generation of tourist flows than cultural factor and which are renowned as destinations for leisure tourism. In this context, we believe there is much need for more comprehensive research into the correlation between the centrality of cultural motivations and the structure of a destination's tourist heritage.

# THE CURRENT STATUS OF ACADEMIC EDUCATION FINANCING IN ROMANIA

**Avram Marioara, Drăgușin Cristina-Petrina**

*University of Craiova, Faculty of Economics and Business Administration, Craiova, Romania*

marioaraavram@yahoo.com

cristina\_dragusin29@yahoo.com

**Abstract:** *At the moment academic education is imperative for any society based on knowledge or which tends to it. Academic education can be treated as the "engine" of the society development as it contributes to the individual development of citizens and the development of the community as a whole. Therefore, the amounts for academic education should not be treated as burdensome expenses, but as true long-term investments for the community development. However, the Romanian academic education funding has always been a sore spot and a highly controversial topic of debate for members of the political class and civil society. For a long time it has been searching for the optimal solutions in university funding as an essential lever for shaping and sustaining a high quality education system. Over time, academic education has been funded from multiple sources: not only from public funds and financial resources from individuals or companies, but also from its own resources. Although efforts have always been made to sustain academic education from public funds, the recent research in higher education funding reveals a decrease of the amounts allocated by the state. The economic and financial crisis has clearly made its mark even on public funding of state universities. In this pessimistic context, in order to carry out their missions, universities have been forced to find new sources of funding. In this paper we propose, by a persuasive presentation from a theoretical perspective, to illustrate key aspects of current funding of academic education in Romania. In this purpose we will analyze the funding mechanism for state universities and private universities and we will try to provide answers for the following questions: To what extent could the current system of financing academic education in Romania be improved and what can we do to improve it? Could new sources of funding be identified as to support the educational process?*

**Keywords:** *academic education funding; basic funding; additional funding; complementary funding; own incomes; financial university autonomy.*

**JEL classification:** *H52; I22.*

## 1. Introduction

Academic education is particularly important in the development of any society because it creates long-term effects both in terms of human resources development and in the creation and dissemination of knowledge.

At the moment, in our country education is being considered and treated as a priority of national interest and its development is a public responsibility (Eurypedia, n.d.). Higher education is organized in state universities and in private universities. In

2012 in Romania were operating 57 state higher educational institutions and 51 private institutions of higher education accredited or provisionally authorized (CNFIS, 2013: 7).

For strengthening and upgrading the academic education, investments in higher education should be a priority for each state. Investments in academic education refer to *the process of financing higher education institutions*, namely all the ways in which universities get their resources and funds necessary to carry out the educational and research activities.

In time, higher education institutions from our country have been funded from public or private sources, but mostly from mixed or public-private funds. The adherence of Romania to the European Union has brought significant changes within each sphere of activity and implicitly in education. Regarding higher education, the rallying to the European Higher Education Area Standards was compulsory.

Universities funding, regardless of their type, is settled by the National Education Law (2011: 79). The current system of financing the Romanian higher education combines the traditional version in which the allocation is based on input (such as the number of students, number of ranking domains) with funding in relation to qualitative criteria such as excellence index, which depends on the class which are positioned in the hierarchy the curricula offered by each university. Higher education institutions enjoy *financial autonomy* in that the universities have the right to manage resources, but in compliance with applicable law.

## **2. Objectives**

Through this paper we intend to present an overview on Romanian academic education funding and to provide answers to the following research questions: To what extent could be improved the current system of financing academic education in Romania and what can we do to improve it? Could new sources of funding be identified as to support the educational process?

## **3. Methodology**

The research methodology that we used to develop this paper was not only the study of national legislation and specialized articles and studies, but also the study of reports and views issued by professional bodies regarding Romanian academic education and its financing. The scientific instruments used in elaborating this article were: data and information analysis, the synthesis, the interpretation and the deductive reasoning. Also, we used comparative analysis for comparing, in terms of financing, higher education institutions from public and private sector.

## **4. Financing public higher education institutions**

Analyzing the case of public institutions of higher education, the financing system represents the essential lever by which the government pursues its strategic objectives and ensures the implementation of national academic education policies. The academic education funding methodology is developed by the Ministry of National Education, in accordance with the methodological recommendations of the National Council of Higher Education (abbreviated CNFIS) as an advisory structure (CNFIS, n.d.). In turn, CNFIS is assisted by The Executive Agency for Higher Education, Research, Development and Innovation Funding (UEFISCDI), through the Directorate for Funding Higher Education (UEFISCDI, n.d.).

In terms of financing are mainly pursued the following objectives: the continued growth of the academic education quality, ensuring the efficient use of the allocated resources, respecting university autonomy, ensuring the compatibility with the European Area, ensuring equal opportunities for all citizens in academic preparation, satisfying the requirements of the labor market and of the society in general.

The annual budget of state universities consists of incomes from: budget financing and own incomes (extra budget incomes and incomes from other sources).

*Budgetary funding* of public institutions of higher education consists of amounts allocated from the Ministry of National Education and includes: institutional funding and complementary funding.

*Institutional funding* is allocated according to the institutional contract, signed annually for the current year between the Ministry of National Education as a financier, and each higher education institution, as beneficiary of funding. As can be seen in Figure 1, the institutional funding includes:

- *Basic funding* which is allocated on the three cycles of higher education (Bachelor's, Master's and Doctorate), depending on the number of unitary equivalent students and on the number of doctoral grants. This source of funding is multiannual in that it is provided throughout the entire cycle of study (Bachelor's, Master's and Doctorate). Basic funding is granted to cover the main categories of expenses related to teaching such as: personnel costs (not only wages of teachers, auxiliary teaching staff and research staff and related contributions, but also internal or external displacements), material costs (maintenance costs, costs for materials, for inventory, for functional services, for current repairs, books and publications, labour protection, staff training, protocol, etc.) and overheads (*The Methodology of Budgetary Allocation for Basic Funding and Additional Funding for Public Higher Education Institutions in Romania*, 2012: 1).

In order to determine the allocation for basic funding for each university, it is necessary to establish firstly the financing per student. Therefor, taking into account the above-mentioned allocation methodology, the next steps are followed: firstly, we determine the number of equivalent students for each hierarchy domain of an university; secondly, we determine the number of unitary equivalent students for each university; thirdly, we determine the total number of unitary equivalent students (overall universities funded); fourthly, we determine the allocation (financing) per unitary equivalent student as follows:

$$fb_s = \frac{FB}{SEU}, \text{ where}$$

$fb_s$  = the allocation per unitary equivalent student;

FB = the allocation for basic funding;

SEU = total number of unitary equivalent students.

At this point, we can determine the basic funding allocation for each university, as follows:

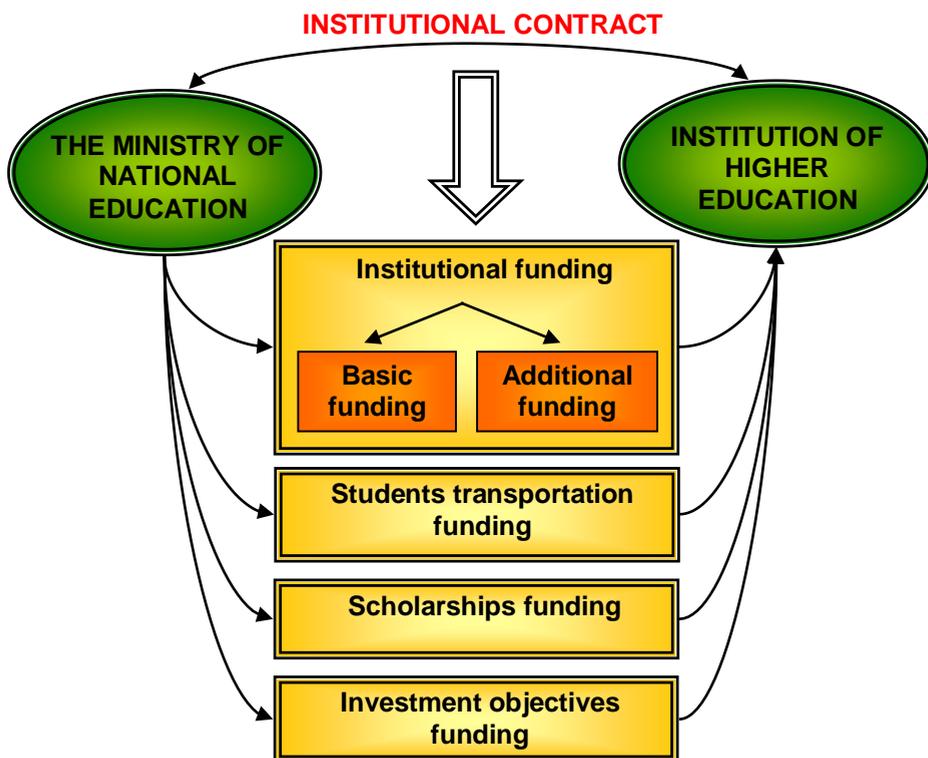

$$fb_U = fb_s \times SEU^U, \text{ where}$$

$fb_U$  = the basic funding allocation for the university U;

$fb_s$  = the allocation per unitary equivalent student;

$SEU^U$  = the number of unitary equivalent students of the university U.

- *Additional funding* which is allocated to stimulate the excellence of the universities and the study programs within them, depending on the fulfillment of the quality criteria and standards established by The National Council for Financing Higher Education. At national level, additional funding is allocated in quantum of at least 30% of the amount allocated as basic funding for public higher education institutions.
- *Scholarships and other forms of social protection funding* such as: scholarships for Romanian students and PhD, scholarships for students who live in rural areas, merit scholarships for international Olympians, scholarships for foreign students and PhD scholars of the Romanian state.
- *Students transportation funding* allocated according to the number of unitary equivalent students - full time students, on funded places.
- *Investment objectives funding.*

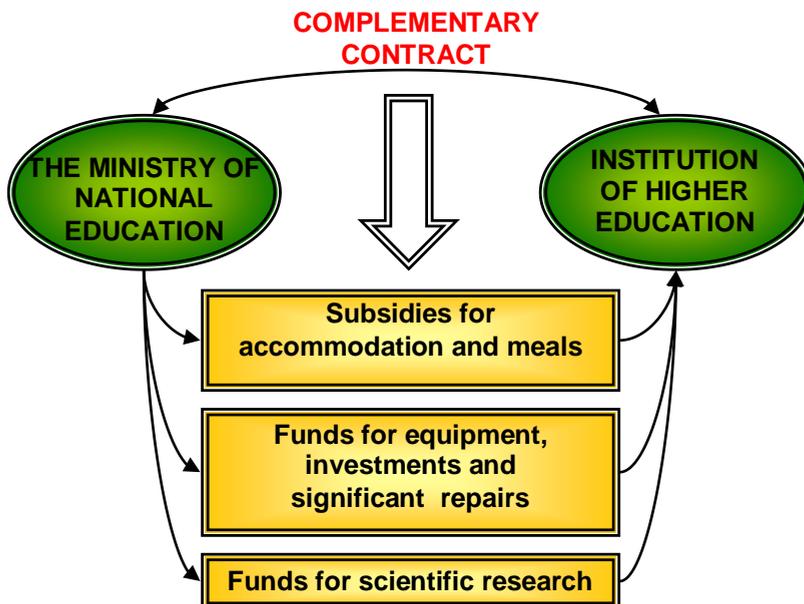

**Figure 1:** The scheme of institutional funding for public institutions of higher education

Source: Own processing of the National Education Law

By analogy, *complementary funding* is also allocated according to a contract, but this is the case of a complementary one, signed simultaneously with the institutional contract, between the Ministry of National Education as a financier, and each higher education institution, as the beneficiary of funding. Complementary funding is allocated for covering the overhead expenses of the teaching process, as can be seen in Figure 2, and it can take the form of: subsidies for accommodation and

meals, funds for equipment and other expenditures for investments and significant repairs, funds for scientific research.

**Figure 2:** The scheme of complementary funding for public institutions of higher education

Source: Own processing of the National Education Law

In fact, universities sign the institutional and the complementary contract early in the first quarter (usually in March) for the current year and then at the end of the year (in December) the renegotiated contracts will be signed.

Concerning the two previously mentioned funding sources (institutional funding and complementary funding), the National Education Law expressly stipulates the fact that by the agreement signed with the Ministry of National Education, *rectors of state universities are responsible for allocating the resources with priority to the most performant academic structures.*

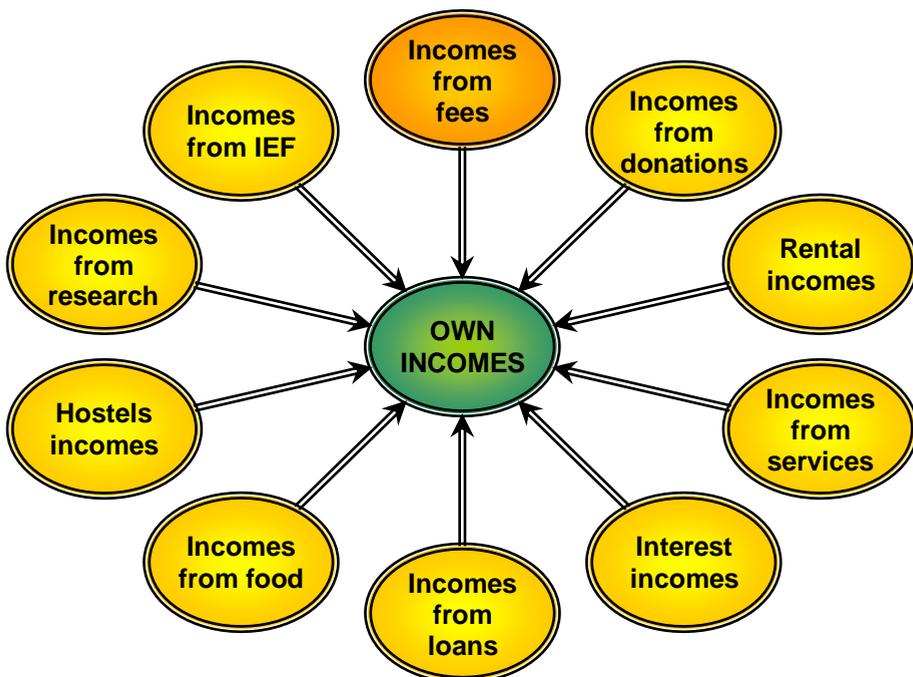

However, for Romanian universities, obtaining the necessary funds to carry out their activities has become a matter of financial management, aiming to identify the most efficient methods of using these resources. The autonomy of the universities in financial management has increased, especially regarding the collection and use of *own revenues*. Public institutions of higher education can obtain their own revenues from multiple sources.

The most important source of own revenues is represented by *the tuition fees* collected by the universities from the students who aren't funded by the Romanian state. Also, state universities may collect fees not only for admissions, registrations, exceeding the tuition time established by the law, re-examinations and backlogs, but also for other activities not included in the curriculum. The amount for the tuition fees is approved by the Senate of each university depending on the faculties proposals.

Schneider and Cosma (*The Current System of Financing Public Higher Education in Romania*, 2011:393) identifies also other financing sources from private funds, such as: donations and sponsorships, amounts obtained by renting properties, amounts obtained from services (various courses, organising different events, consultancy services), interest income, amounts obtained from loans or overdrafts. In the category of own revenues we can also find *the irredeemable external funds* which can be classified according to their origin in: amounts received from the European Union (through European Regional Development Fund and European Social Fund) and amounts received from the state budget. In 2007-2013, academic education in our country has benefited from structural funds through three financing programs: POSDRU, POS CCE and Regio.

Another source of own revenues for universities are the *revenues from research contracts* signed between them and various private entities. Scientific research is an integral part of the mission of universities and aims to contribute to the overall development of higher education. The scientific research is based on: projects won in national competitions (research contracts excluding VAT) and projects financed by third parties (research contracts including VAT - business contracts).

State universities can also obtain financial resources not only from revenues in the form of taxes for accommodation in student hostels, but also from the canteens activity. The suggestive presentation of the main own sources of funding is shown in Figure 3.

**Figure 3:** The origin of own incomes of public institutions of higher education  
 Source: Own processing after the financial statements of the University of Craiova as a public institution of higher education

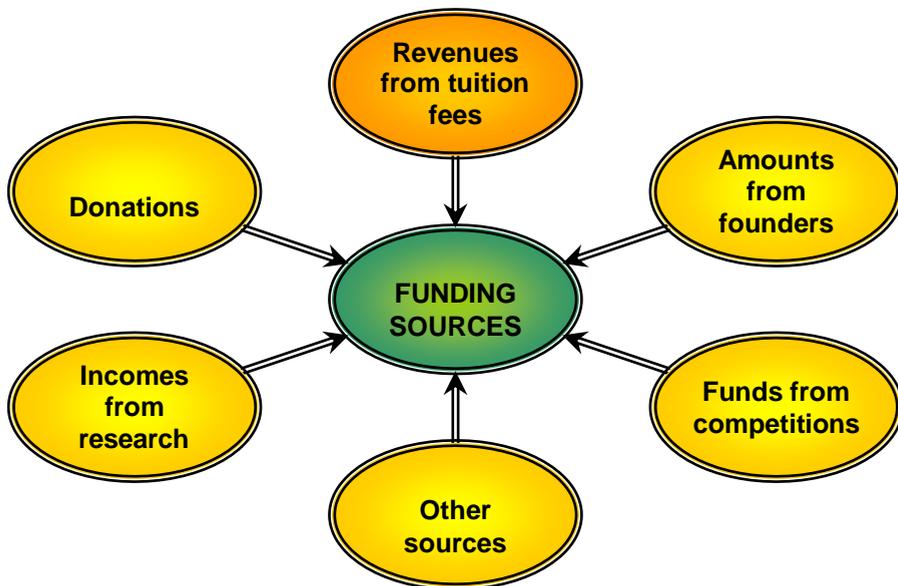

## 5. Financing private institutions of higher education

Concerning private institutions of higher education, firstly it should be noted that they operate as private legal persons and they are funded on the initiative and with the resources of a foundation, association or other education provider.

These institutions also benefit from university autonomy according to the National Education Law (2011: 82), but they also have economic and financial autonomy under private ownership.

The private universities may be financed from the following sources, as shown in Figure 4:

- revenues from tuition fees and other school fees;
- amounts from founders;
- national and abroad donations and sponsorships;
- funds obtained from competitions;
- amounts from exploitation of the results of research, innovation and development;
- other sources.

**Figure 4:** Funding sources for private and confessional institutions of higher education

Source: Own processing of the National Education Law

## 6. Conclusions:

The strengths of the current system of financing are mainly the following:

- it provides transparency in budgetary allocation for higher education institutions as a result of the existence of a clear methodology in allocation based on a formula uniformly applied;
- it supports university financial autonomy;
- it encourages an integrated management in universities, based on strategic management and careful planning;

- it efficiently stimulates the use of funds, giving priority to the most advanced structures that contribute to achieving the strategic objectives.

However, it would be too much to say that the current system of financing Romanian academic education is efficient. Certainly, we must admit that the National Law of Education significantly improved the current system of financing universities from our country in the attempt to rally on the principles recognized and adopted by most EU countries, but it is still far from being fully efficient.

The main problems which the current system of academic education funding is faced with are:

- the chronic underfunding. For the academic year 2012-2013 Romanian Government allocated for education only 3.43% of GDP. Insufficient public funds allocated for academic education hinder Romanian universities to become competitive at Community level, even worldwide, and undermines the quality of the system and the development of the Romanian society;
- the impossibility to compensate the reduction of state funding by increasing the number of students with fees;
- the annual budgetary allocation per student is extremely low and scholarships are insufficient to support and stimulate the desired performance;
- the increase of the VAT percentage and higher utility prices were not taken into account to increase the subsidy for hostels and canteens, but on the contrary these increases have led to higher taxes of accommodation in hostels, despite the fact that, in recent years, investments in student hostels and canteens have not achieved the standards.

Although the current system is functional, obviously there are necessary additional measures to improve and modernize it, especially in terms of finding new sources of funding.

Our proposals for optimizing financing Romanian academic education are:

- increasing the absolute level of funding by increasing the budget allocated for education as a percentage of gross domestic product (GDP);
- increasing resources efficiency by prioritizing funding lines to academic structures considered important (for example: investments in research, libraries modernization and last but not least investments in hostels and canteens rehabilitation);
- identifying new funding sources.

In order to improve the current system of funding academic education, we support, firstly, the combination of funding by input criteria with funding based on outputs, such as number of graduates (as a quantitative element) employed during the year under specialization that followed (as qualitative element). This performance indicator would highlight the ability of universities to teach capable and well prepared graduates. Universities whose graduates are unable to access the labour market according to their specialization should receive lower budgetary funds in the next academic year.

Secondly, as a new source of funding, we support legislating the participation of employers in academic education funding (Schneider and Cosma, 2011:395). The university should be rewarded, once for each graduate employed according to his specialization, with the equivalent of a minimum wage. This amount would be paid 50% by the employer and 50% by the recent graduate employee from his wage. The amount paid would not be a burden neither for the employer nor for employee

since it involves reducing the wage for one month and the payment would be made once in a lifetime. But, for every university, this contribution would be very significant because it allows the funding of other students and the orientation of accumulated surpluses to finance other investments in academic education. Introducing this demarche would have the effect of encouraging universities to improve the quality of education in order to receive the proper reward after hiring trained and qualified graduates.

Another proposal that we support is introducing funding through *the system of educational vouchers*, a proceeding that respects the basic principle of funding "the resources follow the students". This financing system consists in providing vouchers to students that will decide in which university they will study. The vouchers could be used in any accredited higher education institution. The problem in this case refers to choosing which students may benefit from these vouchers and setting the methodology of allocating the vouchers. At the moment, we believe that the baccalaureate is not a criterion by which it could fairly distribute these educational vouchers, even if it is organized nationally. Therefore, we believe that the transition to educational voucher system should first be made for master's and doctoral cycles because in these cases it could be taken into account the results obtained during university years.

Given all the above mentioned considerations, we believe that the current state of academic education funding in Romania still needs significant improvements to complete the improvements brought by the National Education Law, followed by orientation to support private higher education only after the public higher education reform will be stabilized.

**Abstract.** *The budget is a multiannual tool for financial forecasting both at micro and macro level. In this sense, regional and local government budget is a financial instrument that connects resources to use local funds in order to ensure the prosperity of the community concerned. Construction and especially budget execution highlights the effectiveness of local and regional government. Using a system of correlated indicators it reveals income, expenditure and budgetary outturn.*

**Keywords:** *budget, budget execution, cash flow, revenue collection level, primary deficit*

**JEL classification:** *H72*

## 1. Literature review on local government budget

The term budget with its multiple meanings is specified in the content of the public finance law. Thus, legal rules provide that the budget means the document that is provided and approved each year concerning revenue and expenditure or, where appropriate, only the costs, depending on the system of financing public institutions (\*Law no. 500/2002, on public finances, published in Official Gazette 597 of 08.13.2002).

Public financial resources are established and managed by a single system of budgets, namely the state budget, social insurance budget, local budgets, special funds budgets, state treasury budget and the budgets of other public institutions with autonomous character under the conditions to ensure budget balance.

The national budget is the main financial instrument of the state, which serves the size of financial resources to establish their destinations and to substantiate the financial balance over a given period, usually one year.

The main external influences that may affect the budget, are grouped in the following areas (Brookson, 1997, pp. 30-31): the economy (inflation, interest rates, taxes etc.). Population (type, number, mobility and future trends ) workforce (number, availability, demand, expectations), law (labor law, consumer protection, health,

safety), governments (types, fiscal and monetary policy, industrial policy, incentives, initiatives).

Some experts consider that the budget function reflects the monetary expression of the quantity of each public utility (Niskanen, 1976, pp. 617-643), while others believe that the budget constraint expresses that require voters about the usefulness of certain purchases or public works. (Moesen & Cauwenberge, pp. 207-224)

The budget is the most important act of public life, it is the financial expression of the state action program for the period of one year.

## 2. Method and results

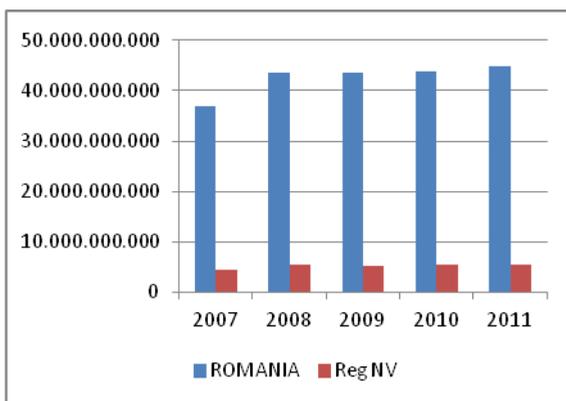

The regionalization of Romania, in terms of territory took place in 1998, when they founded 8 regions (North - East, South - East, South - Muntenia, South West, West, North West, Central, Bucharest Ilfov).

Like all developing regions, the North West has no administrative powers, its main functions are coordinating regional development projects and absorption of EU funds.

North West Development Region comprises 6 counties. In each county local authority structures are the County Councils, Local Councils, municipal, town and community.

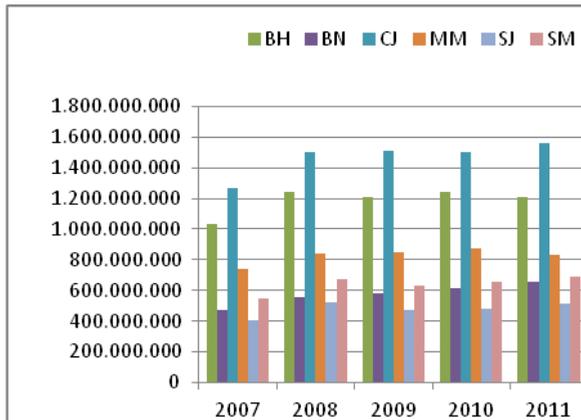

### 2.1. Analysis of the budget revenues in the northwest region

Indicators of income - are indicators that reflect a certain level of income and the extent to which local and regional government holds control over regional and local revenues.

**Graphic 1:** The evolution of total revenues in Romania and North-West region

Source: The budget and the financial statements of county administrations in the North-West region

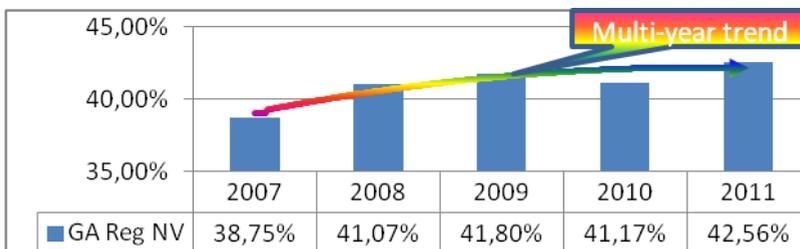

**Graphic 0:** The evolution of total income in the counties in the North-West region  
 Source: The budget and the financial statements of county administrations in the North-West region

The first indicator is the degree of self-financing of local government (GA), which represents the ability of local government to cover the total costs of revenues (tax and non-tax revenues for local government where authorities are responsible for establishing, monitoring, control and collection):

$$GA = \frac{CT}{VP} \times 100$$

where:

- CT represents the total expenditure;
- VP represents own income.

**Graphic 3:** Evolution of the self-financing in the North-West region  
 Source: The budget and the financial statements of county administrations in the North-West region

We consider that as this indicator is 100% a way for the self-financing local government projects is ensured. From the graphic notes above we observe that the funding needs of local governments is around 50% of own funds, the rest being used for investment resources.

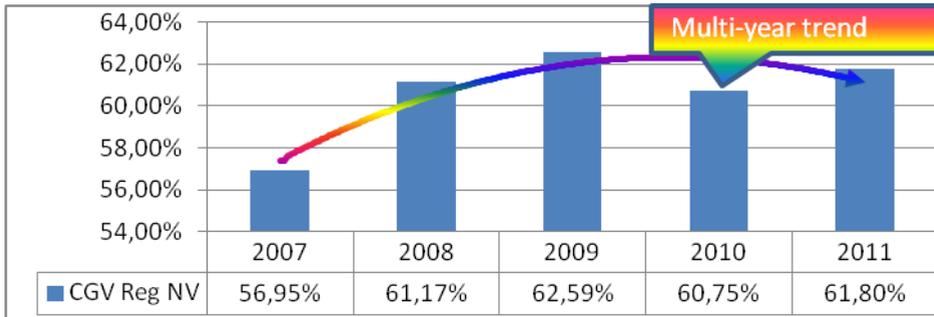

**Capacity of local authorities to generate revenue (CGV)** is another important indicator that can be defined as a share of own revenues (tax and non-tax revenues that are under the control of local authorities and rates of income tax collected in the

territorial administrative unit) - which reflects the development of local economy - the total budget revenue for local authorities.

$$CGV = \frac{VP + \text{shares IVG}}{TV} \times 100$$

where:

- VP + shares IVG represents own income and share of income tax collected in the territorial administrative unit;
- TV represents total income.

**Graphic 4:** The evolution of local government capacity to generate revenue in North-West region

Source: The budget and the financial statements of county administrations in the North-West region

The indicator reflects the credit standing of local government units, its financial autonomy is all the greater as this indicator tends to 100%. From the above plot it is observed that the own funds of local governments representing are over 60% of total funds with remaining resources being provided from other sources.

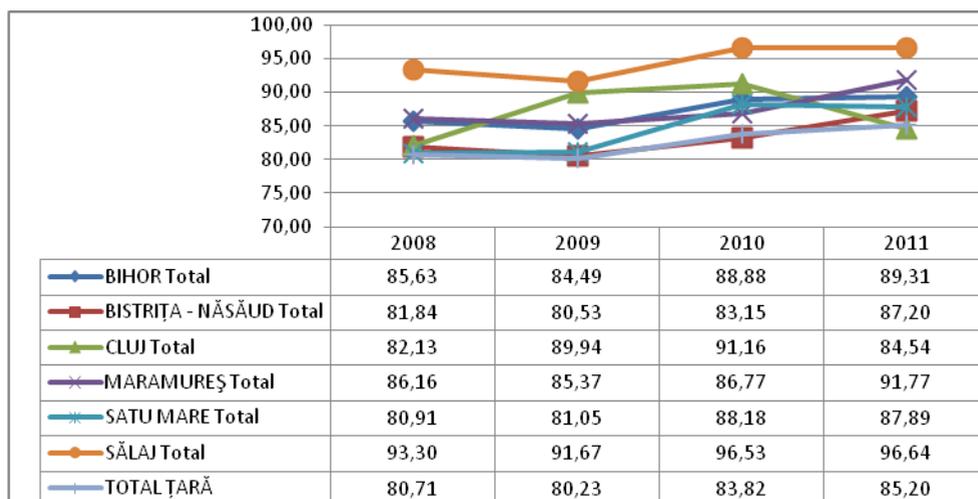

Local authorities should exercise strict control over their own income, but can not control the source of the income tax rate, power tracking this source of income is through deconcentrated central government. The more developed the administrative territorial-unit is in terms economic term the higher the indicator is.

**Degree of own revenue collection (Gr.CVp)** is the collection of own revenues in a given period, compared with the corresponding period's budget.

$$Gr.CVp = \frac{RV_p}{PVP} \times 100$$

where:

- RVP represents the achievements of their income;
- PVP represents the program to achieve their income.

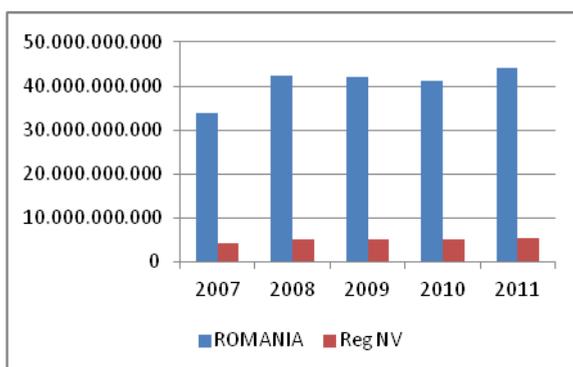

**Graphic 5:** The evolution on counties of the collection of own revenues in the North-West region

Source: The budget and the financial statements of county administrations in the North-West region

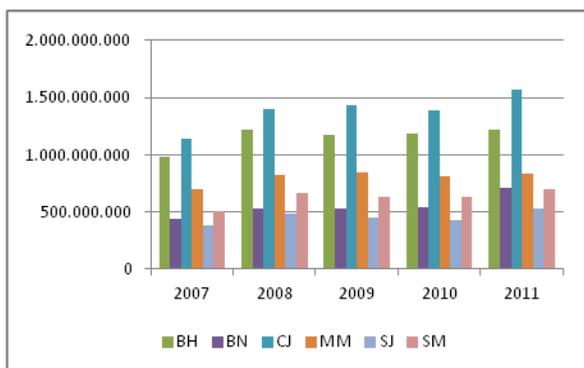

The indicator reflects the ability of local authorities to collect and properly establish their own income. The indicator tends toward 100% so one can say that the level of own revenue collection is optimal and it is more efficient in financial management. From the above plot it is observed that the highest level recorded is in Cluj County, and the lowest in Bistrita-Nasaud. Comparing the data with the country's is noted that the whole north-west region's values are superior to it.

## 2.2. Budgeted expenditure in the north-west region

Specific indicators are indicators that reflect the degree of expenditure flexibility in allocating resources to different destinations.

**Graphic 6:** Evolution of total expenditure in Romania and the North-West region  
Source: The budget and the financial statements of county administrations in the North-West region

**Graphic 7:** The evolution of total spending by county in North West region  
 Source: The budget and the financial statements of county administrations in the North-West region

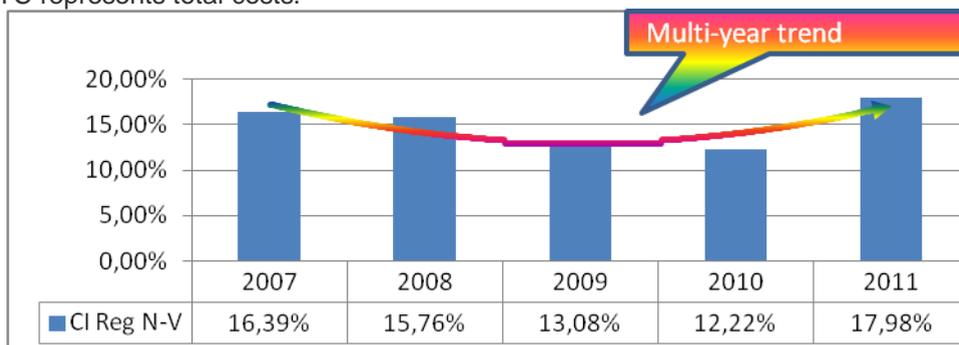

**Investment capacity (CI)** is an important indicator which is calculated as a ratio of capital expenditures and total expenditures allocated and highlights how a local authority local development in a budget year.

$$CI = \frac{C_c}{TC} \times 100$$

where:

CC represents capital expenditure.

TC represents total costs.

**Graphic 8:** The evolution of investment capacity in the North-West region  
 Source: The budget and the financial statements of county administrations in the North-West region

From the graphic above we note that investment is maintained low during 2008-2011 and the growth is in 2007 and 2011. Use of this budgetary practice can provide useful and necessary information for setting policy and long term budget and expenditure prioritization. At the same time, while using other indicators, the tendency or expenditures can be controlled at the expense of development.

The indicator can be used in two ways, namely:

► To determine the ability to invest using resources from its own budget; in the formula expenditures made from funds raised (external grants, loans, etc.) will not be introduced.

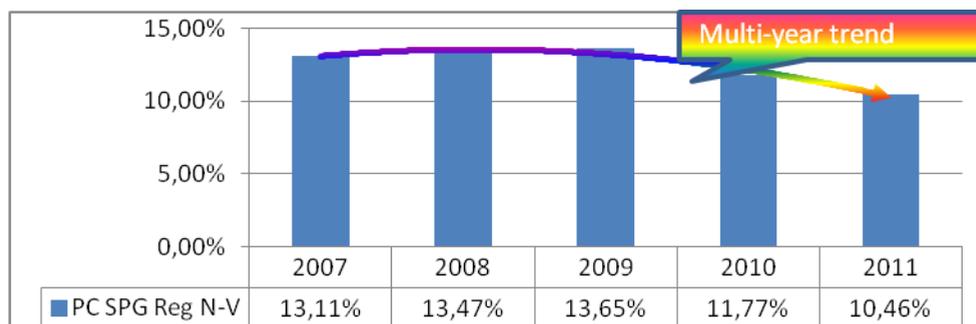

► This indicator is intended to measure the quality of government management so far that in the formula can be entered expenditures made from funds raised.

**General public expenditure share in total expenditures (PC GSP)** is an indicator that can be calculated as the ratio between the total expenditure and budgeted expenses.

$$PC\ SPG = \frac{SPG}{TC} \times 100$$

where:

- GSP represents spending general public.
- TC represents total costs.

**Graphic 9:** Trend in share of overall public expenditure in total expenditure

Source: The budget and the financial statements of county administrations in the North-West region

From the graphic above is noted that this indicator remains at a low level during the period 2009-2011 and the growth is in 2007-2009. The indicator reflects the local government's policy to manage the funds at its disposal to ensure its smooth functioning.

### 2.3. Budgetary performance of North-West region

Results and performance indicators on the one hand reflect the financial management capacity of local governments and on the other hand provide a clear picture of participation in economic activity in the community. The most suggestive indicators are presented below.

**Financial management capacity (CMF)** can be defined as all resources mobilized locally compared to the total expenditure incurred on the basis of the principle of local autonomy:

$$CMF =$$

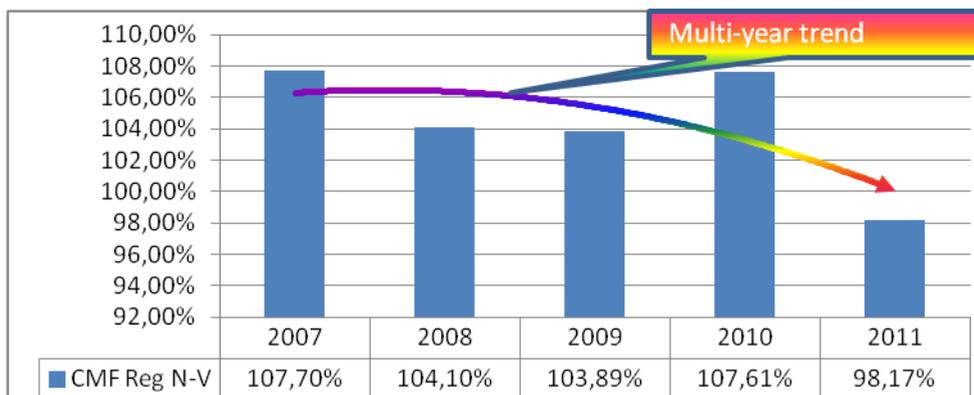

where:

- VR represents income;
- CR represents achieved expenses.

In public finance practice we are confronted with a growing demand for balancing funds, in detriment of developing the quantity of own revenues (taxes on individuals and businesses).

Financial practice of local government is faced increasingly often with a balancing overload of funds in detriment of development in the amount of funds collected from its own funds for the local government which has the power of setting, tracking and collections.

The issue of insufficient financial resources allocated from the state budget should not be neglected while decentralization of responsibilities. The result of this measure, which takes into account how the foundation budget (income and expenditure) and the fulfillment of the approved budget (revenues and expenditures) is met gives a measurable quality regarding the financial management adopted by the authorizing officer and the institution that coordinates.

**Graphic 10:** The evolution of financial management capacity in municipalities in the North-West region

Source: The budget and the financial statements of county administrations in the North-West region

From the graphic above we note that local government covers all costs of income except in 2011, when the coverage is 98.17%.

**Fiscal effort of local government units (EF)** can be defined as the percentage of public revenue local community generates itself, under its elected administration of total local government revenue collected both for themselves and for society.

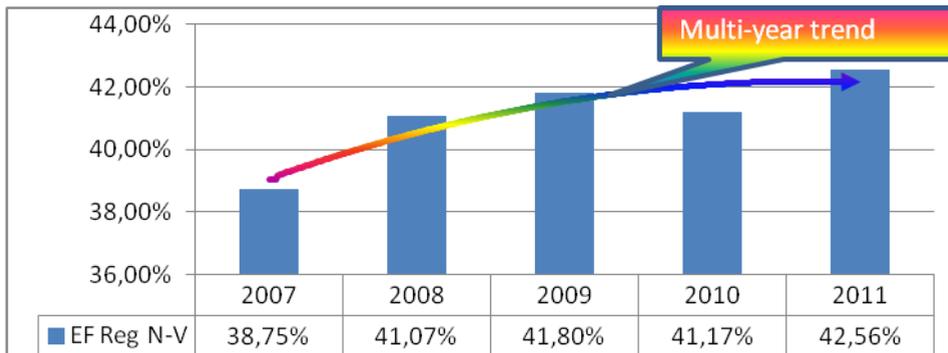

EF

where:

- VGL is locally generated revenues (own income + share split);
- VIL is locally collected revenues (revenues earned + own + share amounts deducted and subsidies, transfers, loans, grants).

In this model considered local revenues are those revenues for establishing competence, tracking and collection belonging to the territorial administrative unit (local taxes for individuals and businesses, revenues from rental and leasing, revenue from the sale of goods).

Local earned income is in this model, all income derived by an administrative territorial unit from all sources during legislation for which the analysis is performed (own income, allowances deducted from certain state income taxes, amounts deducted from certain budget revenues State special purpose or balancing subsidies and transfers, donations and sponsorships). The result of this indicator helps, along with other indicators and local government in particular -the financial management capacity, a pragmatic analysis of effort the local community makes for local economic development and the provision of public services . This indicator can be taken into account and in the preliminary analyzes of stabilising the buget of local communities.

**Graphic 11: The evolution of fiscal effort for territorial administrative units in the North-West region**

Source: The budget and the financial statements of county administrations in the North-West region

From the graphic above we note that the fiscal effort of local governments is about 42%, compared to the income earned by them.

### 3. Conclusions

From the investigations we drew the following conclusions:

- financial autonomy underlying the development of local budgets causes, or - as outlined in the legal literature - has the effect of preserving the individuality of each local budget and local budgets as overall configuration of the budgets of all municipalities, cities and counties in Romania;
- budgetary process, manifested in local government autonomy, means all actions and measures taken by competent state institutions for realization of the financial policy implemented by the government. On the other hand budgetary process assumes the existence of financial resources and their allocation to provide the public goods and public services;
- in local budgets meet, on the one hand, revenues and on the other hand expenditures of administrative - territorial units to satisfy local need;
- In our opinion, the budget process should be evaluated using a system of indicators of income, expenditure and budget execution as to assess the effectiveness of local administration. The analysis undertaken at the local

government in the Northwest region found that financial resources were used by local budgets effectively.

**Abstract:** *Higher education system occupies a special place in the policy of each nation. Regardless of geographical location, socio-economic or cultural differences, the need to improve the education offered for population by facilitating access to higher education becomes more and more important. Providing a suitable framework for the personal development of each student is expensive and involves high amounts of money. From the analyses carried out we couldn't identify the substantial differences between the way it is structured and organized education system worldwide. However, we were able to identify a number of common elements that create a global University System. The need to invest in human resources through structural reforms in each country is present, and therefore a higher indention to pay greater attention to the development of the higher education system. In our work we decided to analyze education systems in countries like United States of America (USA), United Kingdom (GB), China (CHN), Germany (DE), France (FR), Russian Federation (RU), Japan (JPN) average values recorded for EU-27 and last but not least Romania (RO). Although the investment in the University system is hard to quantify, it is unanimously acknowledged that a country can achieve a competitive advantage in international relations through a very well prepared and trained personnel. The countries reviewed in this paper have different policies when it comes to financial support of the University System. If Germany and France have decided to get involved directly in supporting the system by allocating the necessary funds from the State budget, another European country, the United Kingdom, decided to apply a policy diametrically opposite, similar to that existing in the USA and cover in a lesser degree the needs of universities in Government funds. Regardless of the policy adopted the results are intended to be the same: facilitating access to university education, a high quality of teaching and research process, greater mobility among teachers and students and last but not least, scientific and academic recognition worldwide. However, these reforms, even if they are creating value in an initial stage, over the long term can negatively affect the social situation of the country.*

**Keywords:** *university system; quality; financing; unemployment; perspectives;*

**JEL classification:** H52, H75, I21, I23

## **I. The importance and evolution of higher education system**

A long time to subject of the importance of having a competitive and performant higher education system for a country. Human resource has become an important tool in becoming an important country in the world economic system, moreover to the discussion regarding globalization. As Czech President Vaclav Havel stated "We live in an era in which everything is possible and nothing is certain." (Issues in global education 157: 2000)

The global higher education system undergone a large number of changes and is still suffering reforms in a lot of the countries ever since the second half of the 20th century. As Ulrich Teichler also stated, there are some key facts in this development such as: advanced countries adopted the idea that expansion of higher education system would lead to economic growth and also increasing diversity is desirable by stronger concentration of resources, growing differentiation of the research role, diversity of talents etc. ( Teichler: 2004:11). The importance of this aspect was surprised in 1999 by Altbach „The future is also happening faster than any of us can imagine. These conditions predominate in world politics largely because power is being dispersed not only across nations but across cultures. Education is the medium of that exchange” (Altbach, Peterson, 1999: 6).

The increase of tuition fees, and thus increase the quality of the University system, could lead to an exodus of young people to the countries which are offering a competitive educational system but with much lower costs. On the other hand, a system that enables high school graduates to attend the courses of faculties, without imposing large financial strain, will lead in the long run, to an over qualification of the population and thus leading to the disappearance of some basic careers that do not require higher education. It has not yet been identified a viable education model that can meet all the needs of the market.

We appreciate that the Bologna educational system, involving a very large number of national States, could generate a balanced system from all points of view. However, even if the idea of this process is viable in theory, in practice it is very difficult to implement because the countries which have accepted these reforms are far too different from one other, both culturally and socio-economical. These discrepancies makes the Bologna process to suffer mutations at the level of each country and the long-term impact of education over the social environment cannot be quantified.

## **II. Towards a global higher education system?**

This analysis will present a compared series of qualitative and quantitative indicators which define to a large extent the American, British, Chinese, French, German, Japanese, Russian, Romanian and European education systems. This analysis is based on data supplied by the national statistical institutes of each country, data provided by UNESCO, the World Bank, IMF and EUROSTAT.

**Table 1.** The structure of Higher education in 2012

Country	The structure of higher education and the length of studies (years)			The year of last reform
	Bachelor	Masters	PHD	
USA	4	2-3	3-6	1970

RU	4	2	2-4	2009
RO	3	2	3	2011
UE 27	3	2	3	1998

Source: Authors calculation based on mentioned databases

In recent years, each university system has undergone major changes, designed to improve the system from all points of view. At first, it was identified the need for a change at the structural level. In this regard, all countries surveyed have adopted a system based on three cycles of study: bachelor, master and doctoral. This grading is beneficial especially for students as they can more easily obtain the equivalence of diplomas when they decide to study abroad. At the same time this structure is beneficial for the authorities in relation to the plan adopted for the development of human resources because it may encourage punctually each level of study. From the structural point of view, Romania was folded tertiary structure required by the Bologna Declaration.

Even though the structure of studies is similar, their duration varies from one country to another. These differences are attributed to the ancient structures of the system. However, even though the implemented reforms have a quantitative impact on higher education, the impact upon quality should be pursued as well. It is not enough to impose reform just to change the form of studies but also to impose a change in curricula, methods of teaching or teacher-student relations. A bad example is Russia, that, even if the country has reformed the University system structure, the quality of the studies has remained unchanged.

Once these reforms are applied, correlated with the impossibility of the Governments to financially support from the State budget the tertiary system, the number of private institutions and the various degree programs with fees from the State universities have seen a sharp increase.

**Table 2.** Total number of higher education institutes in 2009

Country	Type of institution			Access of population to higher education (inhabitants/university) (I/U)
	Public	Private	Total

UE 27	n	n	4000	125925 I/U

Source: Authors calculation based on mentioned databases

\* According to French law, only the State institutions may hold the title of universities.

\*\* Only two private institutions are holding the title of University, the rest being residential institutions of higher education

Note: n = unreported

Worldwide there are tens of thousands of institutions that provide higher education. However, depending on the country of origin, they have different titles. Whether in Germany or Japan there are only private or public universities in countries like France, the United Kingdom and the United States, in addition to the institutions that have obtained the title of University, there are a number of institutions offering diplomas recognized as higher education but who have other titles.

The majority of the institutions that offer higher education are in America, followed closely by the EU 27 and China. A special case is France, where, under the law, only State institutions may be called universities. Thus there are no private universities, but only public or private institutions providing higher education diploma. In many cases these institutions are more internationally ranked than State universities. The same case is registered in the United Kingdom, where only two private institutions have obtained the title of University. However, compared to France, where there are 85 universities and over 3,400 private institutions, in the UK the difference is much smaller, from 165 higher education institutions 115 are universities. Romania is the country with the lowest number of institutions of higher education, but which nonetheless has the most balanced ratio between the number of State institutions and private ones.

It must be considered that this indicator should be directly correlated with the population. In order for a system to be able to make a difference on an international level it should be able to give the population equal opportunities for access to education. Thus, dividing the number of inhabitants of each country to the number of institutions providing higher education we noted that the wider system is present in France, where for every 18806 inhabitants there is such an institution. At the opposite side rests the British system, where each University must cope with a possible influx of more than 375806 people.

In order to be creator of value, the University system must be competitive both nationally and internationally. For this purpose it is necessary to undertake a direct comparison between the University systems reviewed.

**Table 3.** The university's international rankings (Academic Ranking of World Universities) in 2012

Country	The best occupied positions	Total numbers of institutions in 500 top
SUA	1,2,3,4,6,7,8,9	151
GB	5,10,20,38	37
CHN	151-200	28
FR	40,41,48	21
DE	47,53	39
JPN	21,27	23
RU	80	2
RO	0	0
UE 27	-	197

Source: Authors calculation based on Academic Ranking of World Universities

According to data provided by the Academic Ranking of World Universities, the best universities in the world operate in America. In top 10 positions, 8 of them are occupied by American institutions. The total number of institutions of this country in this top is 151. Highest ranked European University stands in fifth place and comes from the United Kingdom. The weakest position in top is occupied by Chinese system this even though it has 28 institutions in the top 500. The country with the fewest universities present in this ranking is Russia, which even if it has a representative on the 80 position, only two institutions have managed to enter the top 500. Romania is the only country subject to analysis that was unable to have an institution in this international ranking.

A criteria taken into account at the time that these tops are created is the number of students currently enrolled in the studies. However, as we could see, it is not sufficient for the system to have a large number of students if this is not in conjunction with qualitative study programs.

**Table 4.** The total number of enrolled students (thousand persons); the share of students in total population; the share of graduated in total population\* (2009)

Country	Total number of enrolled students (thousand persons)			The share of students in total population (%)	The share of graduated in total population*
	Bachelor	Masters	PHD		
SUA	19,948	479	20,427	6.47%	94,8%
GB	2,394	85	2,479	4.00%	58,52%
CHN	22,317	n	22,317	1.65%	25,94%

UE 27	n	n	19,847	3.94%	61.4%

Source: Authors calculation based on mentioned databases

\* as proportion of total population aged up to five years after graduating

Note:  $n$  = unreported

Worldwide a consistent number of persons is involved in a program of higher education. Although in China more than 22 million people attended the courses of the faculty, they represent only 1.65% of the total population, while in the U.S.A this percentage rises to over 4%. The highest percentage of graduates with higher education also can be identified on the North American continent, and the lowest, less than 25%, is identified in China.

At the same time, thanks to a system based much more on the Bachelor level than master's license, both Germans and China does not report specifically the number of students enrolled in this type of program.

Although the number of students is the main criteria for a university system to survive, this variable must be closely analyzed with the absorption capacity of the markets. In order for an economy to be viable, the result generated by the investment in the University system, the graduates, must be creators of value. To be able to do that, first they must be integrated into the labor market

**Table 5.** The share of unemployment with tertiary education in total unemployment (2009)

Country	Total unemployment	The share of unemployment with tertiary education in total unemployment
SUA	7,9%	9%
GB	7,9%	14,3%
CHN	4,1	14%
FR	10%	18,3%
DE	6,5%	11,4%
JPN	5%	19%
RU	6,5%	32%
RO	7,3%	6,7%
UE 27	9,7%	14%

Source: Authors calculation based on mentioned databases

Market capacity to integrate graduates is essential in order for an economy to thrive and to compete in the world market. Among the countries analyzed the largest share of unemployed is registered in France, 10%. However, the largest number of unemployed persons with higher education lies in Russia, 32%, followed by Japan with 19%. The lowest share of higher education graduates who failed to find a job is recorded in Romania. The percentage of our country lies far below the European average, and could be based on the account of a small percentage of the share of higher education graduates in the total population.

These percentages can be attributed to several factors. Among them we can mention in particular the economic situation of the country concerned. Depending on the economic situation of each country, unemployment is directly influenced by the market's ability to hire specialists with higher education and also to remunerate them in correlation with preparation and expectations. Another determining factor could be the number of graduates reported to total working population. If in an economy, the University system is based on a large number of students and to graduate is relatively easy, both in terms of academic preparation and financial point of view,

then the number of those who completed the courses of the faculties will be increased. Thus, they will encounter difficulties in the hiring process, both because of their poor academic preparations and higher financial expectations.

In order to create value the state must be able to efficiently combine socio-economic policies with financial and educational ones. High school graduates should be encouraged to follow university courses, but only those who prove to be competitive to be able to obtain the diploma of specialist. The example offered by USA, and to some extent United Kingdom, through the implementation of very high tuition fees, in medium and long term it might be able to provide the expected results. Such a system would discourage people who wish only to obtain a diploma to pursue university programs. Instead those with notable results, obtaining financial aid from the State, will be able to bring the added value that both universities and labor market need.

Regardless of the academic system, one thing is certain; the universities require a consistent share of the expenditure from the State budget. For this reason, one of the chapters where governments worked steadily has been reforming the financing sources by reducing universities dependence on the State budget.

**Table 6.** Expenditure with higher education at national level (2009)

Country	Total expenditure on education (% of GDP)	Total expenditure at tertiary level (% of GDP)	Total expenditure per student (% of GDP)	Total expenditure per student (USD)

As stated, education in general and higher education in particular requires special attention from the Government because the huge amounts needed from State budget. From the analysis undertaken we can see that of all countries, the United Kingdom allocated some of the largest sums for the education system, 5,6% of GDP. However the University system received only 0,81% of GDP, a percentage similar to that of Russia or Japan, countries which allocated much less to the education. This is due to the reforms implemented in recent years. This reform aims at a reduction of contributions allocated to the universities, in the same time correlated to a massive increase in the amounts coming from extra-budgetary sources, mainly from tuition fees. France, the country with the highest percentage of GDP allocated to education, and Germany, countries where the tertiary system education is almost free, generates nearly double expenses by comparison with the United Kingdom.

Analyzing this problem in terms of gross domestic product per capita, we note that the most significant expenses are registered in China, 85 % of GDP/capita and this even if the State spends only 3,3% of GDP on the education system. This is due to

the very low value of GDP/capita in conjunction with an increased amount of funds needed for higher education. This phenomenon is present also in developed countries, Germany and France, which allocates more than 40% of GDP/capita to higher education. Instead, the United Kingdom and America, systems that generate consistent income from tuition fees, the financial effort on the part of the State is much lower, only 20% of GDP/inhabitant.

So, the amounts allocated to education can reach up to \$ 15,000 annually. As comparison, Chinese State is spending four time less than the German State on higher education. In these circumstances it is very difficult to talk about equity and equality of opportunities between students or university systems. These major differences are affecting the students, the direct beneficiaries of the University system, by the fact that, in countries with financial difficulties, the largest amounts are directed towards meeting the costs of personnel and administrative and not towards the investment in creation of adequate conditions for study and training

From one country to another the financing policy of University system differs. Whether in Germany it is mostly free of charge, in USA, there are no higher education programs financed entirely from State sources, students being obligated to pay a tuition fee that can oscillate between a few hundred dollars on semester up to a few tens of thousands of dollars.

**Table 7** the level of tuition fees and the aid granted to students from the State (2009)

Country	Tuition fees	Financial aid (% of total expenditure with higher education)
SUA	5000-50000 USD	19,6 %
GB	1000-9000 GBP	37,5 %
CHN	1700-8400 USD	n
FR	177-584 EURO (1500-6000 EURO - private system)	7,4 %
DE	1000 EURO	20,7 %
JPN	6500-14000 USD	27,5 %
RU	1500-3500 USD	n
RO	500-2000 EURO	7%
UE 27	0-11000 EURO	17,4%

Source: Authors calculation based on mentioned databases

Most significant tuition fees can be found in the universities on the North American continent. The fee for some study programs can reach 50,000 dollars annually. At the opposite pole, the lowest tuition fees are in the European countries, which allocated huge sums from the State budget to finance this system.

In direct connection with these tuition fees should be analyzed the system of student aid granted by the State. In order to be fair and non-discriminatory, the State must give equal opportunities to all those who wish to follow courses at prestigious institutions. Because financial pressure is high, Governments must help the top students with limited financial resources by offering them the opportunity to access funds on advantageous conditions in order to finance their studies. Note that the

countries with the highest tuition fees have the most developed financial aid system. In countries like United Kingdom over 37% of the expenditure on University system can be found in the financial aid offered to students. However, the case of Germany is an exception due to the fact that the percentage allocated to the financial aid of students, as percentage of total expenditure with higher education is roughly equal to the percentage allocated by the U.S. We conclude that Germany puts great emphasis on academic preparation, facilitating access to education to all those interested in attending an academic program.

Funding of the University system is not an easy matter for any country worldwide. Because of the amounts involved, this system is one of the most expensive part of an economy. Because results can be quantified only on medium and long term, in situations of financial crisis and economic instability, universities are among the first that have to suffer from financial cuts. These funds allocated to higher education system are directly influenced by a number of factors, among which the most important is the economy and the growth of gross domestic product.

\* I. Evolution of the annual expenditure on University System

\* II. Annual evolution of GDP

This analysis was carried out without taking into account China, due to the lack of consistent data on the amount of annual spending with higher education.

In terms of the coefficient of correlation of high intensity for the entire period under review, the two indicators are currently following the same trend. An increase in the GDP lead to a growth regarding the amounts allocated to higher education. This assumption is natural, in the conditions under which, a functional market economy, with a consistent and stable national wealth, would be able to finance the University system, when an underdeveloped country will seek to fund other sectors of the economy, which could generate in short-term more visible effects.

### **III. Conclusions**

Each country must be able to develop a university system, as far as possible independent of the macroeconomic oscillations, because only by applying a viable long-term strategy, they can be creative. In 2009, once installed the economic crisis, all countries surveyed had to reduce budgetary expenditure, generating a consistent cutting of funds allocated to higher education.

From the analyses carried out it is observed that, by applying a policy diametrically opposed, University systems can become competitive at an international level. There is no successful policy that could be applied globally. If considered the international university rankings, the U.S.A. system has proved to be the most viable, constituting the foundation for developing prestigious educational institutions. In recent years, although the Bologna system was adopted the reforms adopted by the United Kingdom are strikingly similar to the structuring of the overseas education. In light of the fact that in Europe and also in Asia, in contrast to U.S.A., the higher education system is regulated at constitutional level, and is an issue in direct subordination to the Governments, makes the U.S. system impossible to be applied with success on the old continent.

The University system is complex and requires massive public funding. The reforms must relate to the need of the markets, to the possibilities of institution and not least with the needs of students and teachers.

The challenges ahead for the global education system in the terms of globalization is therefore increasing mobility of students and movements of academic programs, the impact of innovation and technology, the increasing number of students and the challenge to increase quality to name a few. The future is opened to changes as Le Bras stated "Shifting demographics, technological breakthroughs, and the volatility of international political and economic condition make it unlikely that patterns of the past will easily or reliably predict the future" (Le Bras, 2008).

**Abstract:** *Financial liberalization process and its implications on financial emerging markets have been multidisciplinary research since 1970. Reform of financial liberalization is a complex and long phenomena. This implies that the impact of this reform on financial markets should not be immediate, but rather gradually during a long time period. It is also important to note that liberalization does not occur in the same way on all financial markets. Each country, according to his specification regarding the economic climate and the specificity of financial markets, has differently set its progress of liberalization process. It is generally accepted that the process of financial liberalization is not composed of a single event, but a series of events. The idea is that market reform is a gradual process where the data identified above only refers to the most significant events. Regarding the effect of liberalization reform on emerging markets has been shown; on the one hand, that liberalization helps to reduce the cost of capital, helps to integrate the emerging markets in the global market, enhances economic growth and allows emerging markets to become more mature. On the other hand, financial liberalization process has a very ambiguous and inconclusive impact on informational efficiency and volatility in emerging markets. Launching liberalization reforms provided an analytical framework for studies that attempt to investigate the effectiveness of emerging markets and empirical links between liberalization and efficiency. The first reason is that with liberalization, the authors believe that emerging markets have become more speculative and more competitive. So there is a chance to see if the weak form market efficiency is verified. The second reason is that the authors explore the relationship between liberalization and efficiency. Researchers and regulators seek an answer to the fundamental question: financial liberalization helps the stock market become more efficient? Financial liberalization is not a riskless process.*

**Keywords:** financial liberalization; stock market; capital

**Jel classification:** O16; G10; G32

### 1. Introduction

Financial liberalization process is not a contemporary phenomenon. For decades, Western countries and companies were operating in a free economy. Thus, it is difficult to identify the beginnings of financial liberalization process. It is sufficient to recall the role of bankers in Europe Italian Renaissance in the nineteenth century in

order to illustrate the importance of English and French capitals in the world, especially in the colonial empires in Russia, and the influence of American capital movements following the crisis in 1929.

Financial liberalization includes several elements; it reflects a variety of restrictions that were imposed. This may includes: capital account liberalization, financial sector liberalization and capital market liberalization (Table 1).

**Table 1:** Elements of financial liberalization

<b>Capital account liberalization</b>	<b>Financial sector liberalization</b>	<b>Liberalization of stock markets</b>
<b>Criteria for liberalization</b>		
<i>Bank loans and foreign companies</i>	<i>Interest rates</i>	<i>Acquisition by foreign investors</i>
Banks and companies are allowed to borrow abroad. They should inform the authorities, however, a license is granted almost automatically. Required reserves are less than 10%. The minimum maturity is not more than two years.	There are no controls on interest rates.	Foreign investors are allowed to hold domestic equity without any restrictions.
And	And	And
<i>More exchange rates and other restrictions</i>	<i>Other indicators</i>	<i>Repatriation of capital, dividends and interest</i>
There are special exchange rates for both current account transactions, but not for capital account transactions. There are no restrictions on capital outflows.	There are no controls on lending (subsidies for certain sectors or certain credit allocations). Deposits in foreign currencies are allowed.	Capital, dividends and interest can be repatriated freely within two years of the initial investment.

## 2. Literature review

Many studies have been made to highlight the impact of financial liberalization on the financial sector and the overall economic performance of emerging economies. Thus, some authors praise the benefits of financial liberalization. There has been shown that financial liberalization contributes on the one hand, to strengthen the functioning of financial systems, improving the competitiveness of the banking and financial sector and the transformation of savings into funds available for financing the economy. On the other hand, helps to promote international diversification and access to global capital markets. For example, Kim and Singal (2000) argue that abandoning controls on the financial sector leads to more efficient capital markets in

emerging economies allows guiding existing funds and national economies to the most productive investments. Levine and Zervos (1998), Stulz (1999) and Mishkin (2001) argue that liberalization will improve transparency and reduce liquidity problems in developing countries. Other authors, such as Bekaert and Harvey (2000) and Henry (2000) claim that, particularly, in emerging markets participants can enjoy new gains from international diversification and cost reduction capital after liberalization. Also, Bekaert et al. (2001) argue that economic growth tends to be improved as a result of financial liberalization.

Financial crises of the 1990s show that financial liberalization is not a process without risk. Indeed, the banking system was fragile and collapsed in many emerging economies. Economies where there were high growth rates have become characterized by severe recession. Also, a negative phenomenon is to increase the risk of financial instability, which is caused by the free movement of capital. This is why, after the Asian crisis, many authors have found that financial liberalization took place too quickly and expanded too far, so there was a request for resetting up controls on the financial sector. Stiglitz (2000) suggest that there must be set some limits on capital flows to moderate excessive capital inflows and outflows due to problems of over-reaction to the shock and herding behavior of investors in periods of high uncertainty. Krugman (1998) considers that the free movement of capital flows was one of the causes of the Asian crisis, and recommends implementing controls to reduce the adverse effects.

Empirical financial literature, despite its abundance, failed to reconcile this conflict of opinions. Empirical results highlighted in the literature on financial crises suggest that financial markets have in center financial turmoil. Proponents of the theory of the occurrence of crises especially emphasized the destabilizing nature of financial deregulation [Corsetti et al. (1999), Kaminsky and Reinhart (1999)]. Instead, the financial literature suggests that removing controls from financial markets and capital flows are beneficial to emerging economies because they keep them most liquid and substantially reduce the cost of capital (Bekaert et al. (2002), Henry (2000)]. For Kaminsky and Schmukler (2003), the difference in views on the expected impact of liberalization on emerging economies could result from the fact that some articles are focused on short-term effect of liberalization, while others are focused on its effect on long term. The authors point out further that in most cases, empirical studies neglect the idea that liberalization is dynamic and progressive, for which should not be allowed to reach definitive conclusions.

### **3. Advantages and disadvantages of financial liberalization**

#### **3.1 Arguments in favor of financial liberalization process**

In the early 1970s, the economic environment was very different from today. Many national economies were characterized by financial repression. This means to set constraints on financial system, such as taxation of bank reserve requirements (often large), to put barriers on the free movement of capital flows and restrictions on the access of foreigners in domestic industries. All these are the main obstacles to economic development, because they impeded the international exchange. The situation was even more critical as domestic resources were insufficient to finance the economic development. To avoid different crisis, all countries were subsequently forced to open its stock markets to foreign investors in order to seek external funds.

Liberalization was thus created and it started by removing regulations that constrain the international flow of capital (Stiglitz, 2000). Initially, this financial process was adopted by the largest economies in the world, like Germany in 1973, followed by United States in 1974. Emerging countries waited until the early 1980s, when the governments understand the role and importance of financial liberalization process. The main reason was that the loans granted by foreign banks in favor of emerging markets, which were the only source of external financing, fell sharply following the debt crisis in Latin America during the period 1982-1983 (Richard, 2002).

Among the arguments that favor the adopting the financial liberalization process, we can include monetary measures, namely: (i) the economic growth, that is driven by demand factors of production (capital and labor) and the rate of productivity growth, (ii) the currency supply, it is an exogenous variable of the system and it can be controlled by monetary authorities and (iii) inflation, it is attributed to an excessive increase in the money supply relative to the actual rate of production increase and it can be moderated by reducing the growth rate of money supply.

These arguments did not present a clear relationship between money growth rates and inflation, on the one hand, and real output growth on the other. The monetarist argument is based on the assumptions that are related to the degree of employment and aggregate money supply that is driven by macroeconomic policy. Neither of these assumptions is valid, because in a world of financial innovation, quasi-money can be created, global liquidity in the system cannot be rigidly controlled by the monetary authorities. Thus, we can say that the actual liquidity in the system is determined endogenously. Therefore, the real monetary variable that is in "government hands" is the interest rate.

There are some negative economic and social effects of financial liberalization, which are often so large that they outweigh any benefit that regards the access to more capital inflows. This refers to both financial markets and the economy. This means that financial liberalization creates exposure to the following types of risk: a trend towards financial crises, both domestic and foreign; a deflationary impact on real economy and limited access to funds for small producers. This in turn has major social effects in terms of job loss.

### **3.2 Disadvantages of financial liberalization process**

#### *Financial fragility and the tendency towards crisis*

It is now widely accepted that financial liberalization has led to increased financial fragility in developing countries, which conduct them to periodic financial crises. These refer to the domestic banking crises and currency crises. The origin of many crises can be traced through the transition to a more open and liberal regime in financial terms, because it unleashes a dynamic that pushes the financial system to a poorly regulated and oligopolistic structure, with a corresponding increase in fragility. Greater freedom to invest, including in sensitive sectors, such as real estate and stock markets, the ability to increase exposure to certain sectors and individual clients and increase regulatory tolerance, all lead ultimately to increased cases of financial crisis.

Financial markets are known to be predisposing to crises, due to their public characteristics of information. Agencies must acquire and process all these information. They are characterized by insufficient monitoring by market participants. Individual shareholders tend to refrain from investing time and money in the

acquisition of information regarding the management, hoping that others will do so, and they may benefit from the obtained information (Reinhart and Smith, 2002). Thus, it appears to inadequate monitoring information, which will lead to risky decisions and malpractice. Financial firms that want to reduce or avoid monitoring costs, they can simply follow the investment decisions of other financial companies leading to what we call "herd instinct", a feature of the market players. This does not limit the access to finance for some agents, but could lead to over lending entities whose failure could have systemic effects.

#### *The effects of deflation and development*

The strongest criticism of financial liberalization process refers not only to the increased possibility of occurrence of crises, but the argument that it has a clear bias against deflationary macroeconomic policies and force the state to adopt a deflationary position to appease financial interests (Patnaik, 2003). To begin with the need to attract international capital means that there are limits to the possibilities of intensifying taxation, especially on capital. The financial liberalization process has reduced indirect tax revenues of states that were under the financial liberalization. This imposes new limits on government spending because financial capital is generally opposed to large fiscal deficits. This affects the economic growth or development activities of the state.

Covering the deficit is seen as increase liquidity in the system and therefore is regarded as being potentially inflationist (Prasad et al, 2003). Inflation is the anathema to finance because erodes the real value of financial assets. However, government expenses are "autonomous" in character, so that the use of debt to finance such autonomous spending is seen as placing a arbitrary player in financial markets, which is not driven by profit reasons, whose activities may cause differences in rates interest, so further financial profits become more unpredictable. If the deficit leads to a substantial increase in debt, it is possible for the government to intervene in financial markets to reduce interest rates that can have an impact on financial returns.

#### **4. Internal liberalization versus external liberalization**

Financial liberalization refers to measures aimed at eliminating or reducing direct regulated controls on institutional structures, instruments and activities of agencies in different segments of the financial sector. These measures may relate to internal or external regulations [Chandrasekhar (2004)].

*Domestic financial liberalization* refers to financial reforms and involves, in particular, banking reforms and privatization policies. In theory, domestic liberalization should allow free-floating interest rates and central bank policy to manage credit and loans. However, fluctuations in interest rates are expected to depend on the currency demand and supply of traders.

Internal liberalization typically includes some or all of the following:

➤ Reduction or elimination of controls on interest rates and fees charged by financial agents. Of course, the central bank continues to influence or manage rate structure by adjusting the discount rate and its own market operations. But usually, deregulation eliminated interest rate ceilings and encourages competition among financial companies, which aimed to attract depositors, on the one hand, and to tempt the potential lenders in the loan contract, on the other hand. As a result, price competition limited expansion and forced financial firms (including banks) to depend on the volumes traded for ensure profits.

- Withdrawal of the state from financial intermediation by converting "developing banks" in regulated banks and privatization in the banking sector. It is usually accompanied by the decline of direct loans and eliminating the requirements for special credit allocations for priority sectors (whether they are public), agriculture, small producers, and other sectors regarded as for strategic priorities or economic development.
- Relaxing the conditions for the participation of both companies and investors on the stock market by eliminating or reducing listing conditions, by providing freedom in fixing the prices of new stocks, by allowing a greater degree of freedom to intermediaries such as brokers.
- Reduce controls on investments can be undertaken by financial agents. Most regulated financial systems have tried to keep separate different segments of the financial sector, such as commercial banks, mutual funds and insurance companies. Agents from one segment to another segment can not invest for fear of conflicts of interest which could adversely affect business. Removing the "wall" between these sectors leads to "universal banks". This means an increased interdependence of financial structures.
- The liberalization of the rules governing the various types of financial instruments that may be issued and purchased in the system. It transforms the traditional role of banks in the main intermediate that introduce the risk in the system. Conventional, banks have agreed liabilities with short maturities of small entrepreneurs who were highly liquid and involved lower costs and reduced risk capital, respectively that have made large investments, relatively illiquid and risky on the medium and long term. *External financial liberalization* typically involves changes in the exchange rate regime. Usually full convertibility for current account transactions were accompanied by trade liberalization reforms either consecutively or simultaneously, which are then filled with different degrees of capital account convertibility. External liberalization is interested in policies that facilitate foreign capital inflows on domestic markets, and in this way, in the participation of foreign investors. This type of liberalization involves the following, but with a wide variety of implemented models:
  - Measures allow foreign residents to hold domestic financial assets in the form of debt or equity. This may be associated with greater freedom for domestic firms to undertake external commercial borrowings, often without government guarantee. It may also involve the reduction or elimination of controls on the entry of new firms in the stock market.
  - Measures allowing domestic residents to hold foreign financial assets. This is usually seen as a drastic liberalization method, because it facilitates capital flows to domestic residents in times of crisis. However, some countries that receive excessive capital inflows have resorted to such measures as a measure to reduce pressure on the exchange rate.
  - Measures that allow to foreign currency assets to be held and traded freely in the national economy. This is the most extreme form of external financial liberalization, which has been implemented in a few countries.
  - Expanding resources and tools through which businesses or financial agents can access funds .This leads to the proliferation of instruments, such as commercial papers and certificates deposit issued by domestic market and allows access of offshore products on secondary market such as ADRs (American Depository Receipts), and GDRs (Global Depository Receipts).

Financial literature focuses on external liberalization in general, and in particular, the policy that facilitates international investment portfolios (Nguyen and Bellalah, 2008). The purpose of these policies is to ensure that in a liberalized market, foreign investors hold, without having to be subject to restrictions, listed financial assets in emerging markets and domestic investors to hold the right to trade securities issued on foreign markets. Therefore, all deregulations that aimed the opening of national markets for non-resident investors are seen as the first elements characteristic of external liberalization process.

### 5. Indicators of financial liberalization process

Financial liberalization can be recognized by official data and the effects of liberalization occurred, such as the introduction of ADR and investment funds, or a significant increase in U.S. capital flows. To better understand this reform is important to study the shown effects (Arouri et al, 2010).

#### *Foreign capital flows*

Foreign capital flows to emerging markets reflects the effects of financial liberalization and is thus the first actual indicator of reform. These streams comprise mainly foreign direct investment flows (FDI), portfolio investment flows (international equity portfolio flows), cash deposits and bank loans (table 2).

**Table 2:** Capital inflows and outflows on emerging markets during 2000 - 2007

<b>Capital flows (bil. \$)</b>	<b>2000</b>	<b>2001</b>	<b>2002</b>	<b>2003</b>	<b>2004</b>	<b>2005</b>	<b>2006</b>	<b>2007</b>

Source: Arouri et al (2010)

#### *American Depositary Receipts (ADRs)*

The introduction of ADRs is considered as an important event of the liberalization process. In many cases it may precede the official date of liberalization of the local

market. ADRs were first introduced to Morgan Guaranty Bank in 1927 to help U.S. investors to purchase securities listed on foreign markets, these markets are closed to foreign residents. An ADR is a negotiable certificate of deposit issued by U.S. banks and represents a specified number of shares of a foreign market that are traded outside the United States. ADRs are denominated in U.S. dollars and traded on U.S. stock markets like New York Stock Exchange (NYSE) and American Stock Exchange (AMEX).

#### *The introduction of closed funds*

A closed-end fund is an investment company that issues shares in national markets and use various procedures to invest in shares of companies that are in a foreign country. Thus, investing in a closed-end fund allows exposure to local markets and international diversification. Before the liberalization of stock markets, unit trusts funds provide a measure for investors to gain access to some emerging financial markets where investors have no right, legally speaking, to deal with domestic stocks.

## **6. Conclusions**

The impact of financial liberalization can be properly assessed only if the following aspects are considered:

- The market could have immediate reactions to the information disseminated;
- Market participants might anticipate and react before the event of financial liberalization process. Indeed, the market can be informed before deciding the financial reform, the rumors or the time lag between the announcement and effective liberalization date;
- The market could have delayed reactions to the events of financial liberalization. This idea comes from the fact that financial liberalization is not complete after the first event, and there are other subsequent events that follow;
- Financial liberalization is a part of economic and financial reforms from a package, which simultaneously affects the national financial system, the stock exchange market and capital account;
- Changes in the behavior of emerging markets are not only because of financial liberalization process. It is important to simultaneously monitor the impact of reforms;
- Country-specific factors such as political and economic conditions, could significantly influence changes in the banking and financial sector. Many countries have opened their stock markets to foreign investors in times of economic prosperity, to avoid selling securities at discount. These factors must also be controlled.

## MEANS OF ESTABLISHING CHURCH PROPERTY AND FUNDING SOURCES

**Cricovean Mircea**

*West University Of Timisoara, Romania*

*cricovean@yahoo.com*

**Abstract** *Regarding the administration of goods, the Church finds guidance in the laws of the State to which it belongs (Stan, 1952) but taking into consideration the fact that the Church cannot “have its special principles and rules contradicted”(Floca, 1990: 448). However, the church, in fulfilling its purpose - the salvation of believers, needs wealth or heritage. This is not to understand that the Church can “lose its essential character, supernatural character, because, for the Church the earthly possessions and temporal happiness are not an immediate end” (Floca, 1990: 451-452). To understand the Church’s sources of financing it is necessary to take account of its properties. Along the time the church was holder of ownership rights. Its property had to be maintained, at least, so it needed funding. The Church’s canonical and statutory provisions are those governing the Church’s source of funding. They cannot conclusively be understood without observing the principles and rules specific for the ecclesiastical wealth management. Noted should be that previously there were no generally accepted rules on the management of financial resources of the church. The canonical, legal and statutory establishments have become customary in time, making it possible this way, by the dioceses supervisors, that sources of funding should be directed towards the maintenance of the Church, of the worship and of social activities.*

**Key words:** *sources; financing; Church; patrimony; canons; principles.*

### **1. Judicial means for Church property configuration**

A question has to be asked: how did the Church manage to possess property and financial resources before the promulgation of the Edict of Milan by the Emperor Constantine the Great? This comes especially for that before enjoying religious freedom throughout the Empire, the Church had in its property cemeteries and sacred buildings. Also it had productive land assets. We can say that religious buildings were more modest at first, but since the 3<sup>rd</sup> century “we witnessed the building of churches, private homes, these not being used anymore as places of gathering and prayer. The basilica discovered at Dura Europos in Mesopotamia was set up at the beginning of the 3<sup>rd</sup> century. In the year of 202, at Edessa, the Christian basilica was severely damaged by flood. Under the ruling of Emperor Alexander Severus (222-235) the community of Rome would register a trial against the leister association due to a piece of land located within the town, the King’s decision favoring the Christians.” (Hertling, 2003: 79)

In the past, for instance, a man of wealth was preferred to be in charge of a diocese, for the local Church “to profit from his wealth, even if it only concerned the building of places of worship or the refurbishing of the existing ones, all at his own expense” (Bernardi, 2002 :53). It should be mentioned that “these practices did not come as a

shock to the masses, who were quite far from having the perception of equality the way it is perceived by the modern society. In fact, everyone prefers a bishop from among the great lords, for the simple reason that he would be a social protector for the ones of his own. He would know the judges and tax agents; provincial governors and generals, even ministers who were old comrades during their studies, his friends or relatives. Such a bishop could be counted on for lending a helping hand when needed. These family burdened bishops tended to leave their position as inheritance for their sons so as to place their family among the clergy. Their daughters would marry priests or bishops. More so as the bishops and priests are exempt from tax, as it was settled before for the pagan clergy. Very soon there would be set up true Episcopal dynasties. The modern observer, taught against nepotism, will have a prompt reaction. Contemporaries, however, from Diocletian onwards, being accustomed to seeing sons following their fathers' steps, did not feel at all spiteful" (Bernardi, 2002 :53)..

It is assumed that previous to the Edict of Milan, patrimonial goods belonged to individuals, the Roman citizen, and not to legal entities, in this case the Church (Hertling, 2003: 80). From another perspective, however, "in ancient times, not only could someone become legal entity without much difficulty, but they could also easily buy, possess and sell, inherit or donate without legal title issued by the State. This way the existence of a collective heritage was possible". This way only can be found an explanation for the vast property which the Church possessed in the 4<sup>th</sup> century, referring to establishments for social protection, homes for the poor, hospitals, homes for the elderly, small children's swing (Stan, 1957: 267-277) all of these witnessing a main charitable work performed under the protection of the Church set up by the followers of Christ.

The Edict of Milan in 313, enacted by Emperor Constantine the Great, entitles the Church the right to possess properties, formally. But the one who cared in a very exceptional manner for the administrative organization of the Church was Emperor Justinian (527 - 565). Without changing any of the principles inherited by the Church from the Holy Apostles, he put them in order and allowed their clear development (Gerostergios, 2004: 234) understanding that the property of the Church is especially needed in terms of philanthropic activity.

It is worth noting that every local Church – according to the law – enjoys the privilege of being the subject of law and due to its legal character it can receive goods through legal channels and thus having the right to increase its wealth. If there are to be found testimonies regarding helping Christians since ancient times from a rich Church directing material aid towards a poorer local church, this fact was based on "the virtue of love" (Floca, 1990: 472) superior to any other human laws. Ownership is offered recognition also in the case the other establishments operating under the blessing of the Church – the asylums for the poor, orphanages and all charity organizations of religious character.

If this way property rights are regulated for the Eastern Church, in case of the Western Church property rights are offered recognition not in the case of local Churches but in the case of the Roman Catholic Church, as a whole, represented by the Pope who grants local churches only a right of usufruct, disrupting property rights.

Regarding the Church, it indulged variety in the forms of ownership. According to conciliar decisions (Jubilee Bishops' Council of the Russian Orthodox Church, 2002: 217), it was considered that any form of property may lead to sinful manifestations

such as theft, accumulation, unjust distribution of the results of labor as well as to an appropriate and justified use of material goods.

Currently, in the case of the Romanian Orthodox Church, the main sources for financing practiced by its establishments are:

- contributions from parishioners;
- the funds from the state budget for salaries and investments;
- the funds from its own incomes for the remaining costs;
- sponsorship
- donations;
- domestic loans;
- foreign loans (Greceanu-Cocoș, 2010: 6).

### **1.1. Donations**

This form of aid was practiced by Christians ever since the time of the Apostles, “and no one among them was left out, because the ones who possessed land or houses and sold them brought in the sums they received” (Acts of the Apostles 4, 34). Bringing goods together “in the Jerusalem community was not a mass phenomenon and it was practiced only by some who were free to preserve their property or sell it.” (Preda, 2002:119). Christians showed willingness towards donating based on the idea of faith solidarity with their fellows in need.

Of the goods collected then emerged the charitable actions of the Church but “this was rather spontaneous and personal, where the help was granted according to everyone’s need and degree of poverty”(Preda, 2002:119). The representatives of the Church focused not exactly on external communion of the goods but more on the inside one. The Christian conception was based on a limitation of property rights that the parishioner had on a certain good so that he could exercise his attributes of possession, use and disposition of that property without any obstruction from the Church.

If in the early times of the Church Christians jointly used material goods, this proved effective for this type of property relations contributed to the strengthening of the believers’ spiritual unity in many cases, as in monasteries, it turned out to be cost-effective. It is worth adding that sharing material goods in the Church was of a purely voluntary character and it was triggered by people’s own spiritual option when joining the Christian community.

Among donations there can be mentioned:

- agapes; (Acts of the Apostles, 7,1- 7)
- firstfruits;
- tithe;
- offerings to the altar.

The Agapes were Christian meals that followed immediately after the Sacred Mass (Acts 7.1 -7) (<http://www.teologie.net/2009/12/12/agapele-mesele-fratesti-ce-insoteau-euharistia-in-primele-veacuri/> 30. 11. 2012).

Regarding the firstfruits, the Church received the first produce gathered by the Christians and derived from agricultural activities. Tithing is constituted as a share of the total product of owner’s labor and harvest of the respective land. Once harvested the farm produce were then offered to the Church (Soare, 1948:59). It should be noted that the Church did not accept donations obtained through ill-gotten activities. Preferred were only those gifts that came from “honest labors” (Soare, 1948:59). The

offerings at the altar were formed either by cash or by natural goods (Soare, 1948:59).

The Church rewarded those who donated various material goods through prayer and remembrance through aloud reading of the names by the religious servicemen. When the remembering of the dead was performed by prayer, the offerings brought were distributed among the poor.

If priests proved worthy in the administration of material goods the Christians did not hesitate in providing the Church with ever more material goods. It should also be noted that donations came also from the Christians entering the monastic life of the Church, which was another way of increasing the Church's heritage (Soare, 1948:64).

### **1.2. Regular contributions of parishioners**

Expenditures for maintenance of religious establishments and for the development of ecclesiastical activity is financed (Greceanu-Cocoș, 2010: 18) from own revenues that have to be managed in accordance with the statutory provisions of the Romanian Orthodox Church.

A very important source of funding is made up of the contributions of parishioners embodied in the form of collections that are undertaken during the public and private religious services. Collection was practiced since the time of the Apostles: "If we have sown unto you spiritual things, is it of any importance if we reap yours earthly?" (I Corinthians 9.12).

Collections can be divided into regular or occasional. These were organized usually on Sundays but they were also undertaken in the proximity of fasts. Every parishioner put in a box what he considered to be for charity (Soare, 1948:69), keeping the box inside his home.

In very exceptional cases, other collections were organized. Some collections were stimulated by Church ministers and others occurred spontaneously on the initiative of parishioners.

### **1.3. The gifts of the kings**

Wealthy Christians offered the Church various goods or real-estate to support charitable undertakings. We remember hereby the courtesy of deaconess Olimpiada.

Impressive details on the deaconess Olimpiada we may gather from the story of her life. The research (Saint John Chrysostom, 1997:73-84) making comprehensive reference to her life was put forward, apparently, by Heraclid of Nyssa. Thus, we learn about the Olimpiada that she descended from the lineage of the vicar Avlavie and for a short period of time, she was married to Nevridie, vicar in the fortress of Constantine. All assets held by this pious woman were given to the Church once she became widow. Considering it to be her duty to entrust the Church with all her belongings, and considering St. John the Chrysostom, patriarch of Constantinople, the deaconess Olimpiada gives to the community "all her other real-estate property located in all provinces together with the rights held on public procurement, and she also ordained as deaconesses of the Holy Church three of her relatives, Elisantia, Martiria and Paladia, so that the monastery founded by her should forever celebrate the four ministries" (Saint John Chrysostom, 1997:77).

Kings would pass different laws in the support of legacies and donations (Soare, 1948:64). For example, Emperor Justinian saw that there were some Christians who

signed wills by which they donated money without indicating any individual person or legal entity as recipients, so he decided that these goods that were subject to donation are to be left to the church where the testament was written. The treasurer of that respective church had the duty to manage the assets in accordance with the law and to direct them towards their proper destination (Soare, 1948:65).

Also, emperors granted certain tax opportunities for the Church. Moreover, the taxes owed to the State would be reduced or the emperor himself would intervene so that the benefits registered by the Church of Constantinople should be directed towards the Church's charitable activities, reducing the number of ministers in Constantinople (Soare, 1948:65).

#### **1.4. The contract for sale and purchasing**

Property and its three attributes – possession, use and disposal – is a vital thing for the being of an individual or a legal entity. Regarding the ways of acquiring property (Hanga, 1977: 269-277) by natural right these could be: occupation (occupatio), tradition (traditio), accession (accessio) mixture (confusio) and specification. We cannot ignore that property acquisition could be made by the judiciary and by the rule of law.

As the dismissal of property rights, although of entire and perpetual character, the property may become extinct in case the object (work on which the holder has ownership) has been lost or in case of slaves when they died or were simply released.

## **2. Canonical and legal provisions related to the sources of the Church's financing**

State laws may help the Church as long as these edicts not always contradict the teachings of the Church. If we were to define the term “canon” then we could rally our opinion to the one on an author who defines the canon as the sum of faith-related teachings settled by the Church “in the true image of the Holy Spirit, in the ecumenical or local councils or by its great Fathers” (Phidas, 2008:22 ).

Noteworthy is that these statements called canons should not be taken out of the context of the time they were issued. There must be taken account of the era in which they were written because “it is clear that separating the specific content of the canons from their historical context, it would be difficult, if not impossible, to recognize the true intention of many canons and the message the Church wanted to highlight through them” (Phidas, 2008:25 ). It should be borne in mind that, regardless of the authority that issued the canon, collective or individual, that guidance or that canon “does not express the mystery of the Church only if the content relates clearly and on spiritual level to the fullness of the content of Christ's revelation and to the fullness of the spiritual life of the faithful” (Phidas, 2008:39 ).

In the same vein, we should add that “not the letter, type, shape, material structure of canons are an absolute essential element of the Orthodox canonical tradition, but that their historical liaison with the Holy Spirit, they became authentic carriers of an essential element in Christ's saving message. This way, the Orthodox Church will never accept to turn to absolutism the force of the historical form of canons, nor has it tried to marginalize them within the religious life. The Church feels free to explain and update the content of Christ's revelation according to the spiritual needs of the faithful, whether within administration or in the pastoral mission, but maintains the

strength of the canons as a reliable criterion, on which its legal power should ceaseless rely on. The correct use of canons does not imply, of course, their unconditional or anachronistic application of historical issues in the modern era, as the canons would then become an object of worship, but their pastoral spirit, for the genuine continuity of the Church's mission in the world of today" (Phidas, 2008:102-103).

The Church did not promulgate canons led by the thought of providing a legal or judicial tendency for the Holy Fathers' settlements. The laws left to the Church by the Holy Fathers were directed towards healing the fallen ones in grave sins. Therefore, the canons of the Church are of curative and therapeutic character (Yannaras, 2002:189).

### **2.1. The Apostolic Canons**

*The 3<sup>rd</sup> Apostolic Canon* and *the 4<sup>th</sup> Apostolic Canon* refer to offerings, gifts that believers bring to the altar or for the clergy. The 3<sup>rd</sup> Apostolic Canon prohibits the bringing of gifts to the altar and was similar to pagan rituals but the next canon provides that products brought by Christians are to be used for the maintenance of the church and for the clergy. In the early period of the Church clergy maintenance was the responsibility of the community they served (Floca, 2005:9-10)

*The 38<sup>th</sup> Apostolic Canon* states that the bishop is the main treasurer of the Church's property. It should be noted that this canon "shows the bishop's full competence in all ecclesiastical matters, he being obliged to care for the Church's property and the right of administration according to the needs of the Church" (Floca, 2005:31)

On the other hand, the bishop as spiritual leader of his diocese is only an administrator characterized by responsibility regarding the diocese's management. Therefore he would not deal directly with any economic or financial problem but rather delegate this task to another cleric.

The Canon leaves it to the bishop to consider if it is necessary to grant aid for someone of poor condition, to be offered backing by the parish or from the Church's funds. In the early periods the "property of the Church was also called the fortune of the poor, because along with the salvation of souls, the main concern of the Church was to drive away the suffering of the deprived and ensure human living conditions for all believers, even of the poor among the ones who did not believe. This was always the concern of the Church especially when the suffering of the poor got worse" (Floca, 2005:31)

*The 41<sup>st</sup> Apostolic Canon* requires the bishop to define his own wealth from the one of the the diocese he leads (Floca, 2005:33).

The destination of funds and the maintenance of the Church's property were allotted to the Church, the service staff and also having social-humanitarian purposes.

*The 59<sup>th</sup> Apostolic Canon*, also, states that the resources of the Church are sacred and it is not allowed to anyone their appropriation for personal benefit. The Church has always had a well-organized social welfare activity (Floca, 2005:41).

*The Apostolic Canons 72 and 73* indicate a barrier to stealing the sacred. The sacred belongings of the Church are aimed to serve the public divine worship.

## **2.2. The canons of the ecumenical councils**

Canon 17 of *the First Ecumenical Council of Nicaea* prohibits those who are part of the church to practice interest or usury. Therefore, among funding sources, the Church did not have the possibility of promoting the loan with interest (Floca, 2005:67).

Canon 2 of *the Fourth Ecumenical Council of Chalcedon* states that the administrator of the Episcopal wealth would be the treasurer who is not to be granted this position by him offering money in order to achieve this (Floca, 2005:86).

Canon 3 of *the Fourth Ecumenical Council of Chalcedon* allows those of the clergy to care for the well-being of the social institutions that are in the care and supervision of the Church (Floca, 2005:87).

Canon 22 of *the Fourth Ecumenical Council of Chalcedon* helps identify another possibility for the establishment of ecclesiastical heritage. Thus, the bishops' inheritance remained in the care of the Church and also to their legal successors (Floca, 2005:98). The person put in charge of this was the treasurer, according to Canon 26 of *the Fourth Ecumenical Council of Chalcedon* (Floca, 2005:100).

Canon 9 of *the Sixth Ecumenical Council of Constantinople* prohibits as funding source for the clergy and the Church to register revenues that come from "taverns or bars which trade alcohol" (Floca, 2005:120). Also, Canon 9 of *the Sixth Ecumenical Council of Constantinople*, sets a restraint – for the Church and clergy – from registering revenues coming from loans or interest.

Canon 97 of *the Sixth Ecumenical Council of Constantinople* established the right of religious authorities to dispose of buildings, real estate, which they administer (Floca, 2005:176).

Canon 4 and 5 of *the Seventh Ecumenical Council of Nicaea* condemns the gain of dishonest financial revenue in the case of the heads of the Church (Floca, 2005:183).

Canon 11 of *the Seventh Ecumenical Council of Nicaea* states the need for appointing Church treasurers and for the right of devolution. The right of devolution indicates "high Church authority intervention in the competence of the Church authorities lower down the hierarchy" (Floca, 2005:189) in many cases explicitly provided by the ecumenical law by which church authorities lower down the hierarchy refuse to perform their tasks. Among these tasks there is also to be found the institution of the treasurer.

Canon 12 of *the Seventh Ecumenical Council of Nicaea* states general rules on the estrangement of church property. The sale of church property by worldly rulers is forbidden. In case a need requires it, the Church's real estate may be sold only to clerics who perform agricultural activity (Floca, 2005:191).

The church disposed of many sanctuaries, establishments that were designed to promote the ecclesiastical activity. It is forbidden by canon 13 of *the Seventh Ecumenical Council of Nicaea* as the real estate should not be used for other purposes than established by the Church.

Canon 19 of *the Seventh Ecumenical Council of Nicaea* provides as general source of the Church's funding the possessions brought in the monastery by the ones who joined the monastic life (Floca, 2005:195).

## **2.3. The canons of Local Councils**

Canon 15 of *the Local Council of Ancyra* in 314 year states that the possessions of the Church enjoy a particular legal status. Thus, movable goods or real estate y belonging to the Church may be transferred only with the approval of the bishop. If

it were to be alienated, the asset may be claimed by the bishop or retain the sum due to the selling of the respective good confirming this way the the documentation set up by the treasurer (Floca, 2005:209).

*Canons 7 and 8 of the Local synod of Gangra* in the year 340 identify among the funding resources of the Church the altar offerings brought by the parishioners. These offerings were divided up among the ones in need (Floca, 2005:221), after the respective blessing. Particularly important are the rules of the canons 24 and 25 of the Synod of Antioch which distinguish between the belongings of the Church and the personal possessions of the Bishop. Canon 8 of the Council of Gangra against those who, at their will, “divide up among themselves the goods and gifts brought to the church” (Phidas, 2008:73) states that these acts are not to be committed “without the blessing of the bishop” (Phidas, 2008:74).

Canon 24 of *the Local Synod of Antioch* in 341 based on the apostolic canons states that the property of the Church “is entitled to be administered based on the judgment and ruling of the bishop to whom the entire population is entrusted ... [...] nothing should be hidden ...” (Floca, 2005:236). The following canon emphasizes the outstanding duty of the bishop as administrator of the belongings of his diocese. If there should happen that “the administration of the Church was secretly brought to a loss, the respective person would be held accountable before the council of that diocese. And if in another way the bishop or his presbyters would be liable for blame, by appropriating the belongings of the Church, either land or other dealings of the Church, so as to inconvenience the poor and thus cover with slander and disgrace the Church administration, and those who settle this way, these should be called upon and the Holy Synod would decide on the appropriate actions to be taken” (Floca, 2005:237) .

Canon 26 of *the Local Council of Carthage in the year 419* states the way some property of the Church could be sold, ones that are not profitable, as well as the procedure to be applied by the Bishop administrating the property: “if a belonging of the Church does not register revenue and a great need would require it, this is to be dealt with by the one who is the head of that diocese and jointly with a determined number of bishops should decide what there is to be done. Should there arise such great need of the Church that they cannot consult before selling, then the bishop would call neighboring ones to witness, making sure to show the council all circumstances proper to that respective church; if these requirements are not met, the seller will look guilty before God and before the foreign council regarding estrangement of his own dignity” (Floca, 2005:279) .

Canon 34 of the same council provides that the wealth gathered by the clergy accumulate after joining the monastic life belongs to the Church: “bishops, presbyters, deacons or any clergy, who have not possessed anything previously, in case they should be appointed to a position and would purchase land or other estates during their episcopate, these properties should be regarded as God’s belongings, but being admonished, they would deliver them up to the Church. And if anything were to return to their possession, especially in the case of gifts or inheritance from relatives, it would be up to them what to be done with that respective property...” (Floca, 2005:282). The 35<sup>th</sup> Carthaginian Canon puts an end to the abuse against Church property, in case the bishop or the priest would happen to act this way in exercising his position.

*Canon 1 of the local Council of Constantinople in 861* monasteries established that the wealth of the monasteries cannot be passed on to the benefit of individuals.

Professor Floca shows that this canon “regards the abuse on the part of some who, building monasteries and equipping them with wealth, donated these to the church, but further considering themselves as owners and behaving this way, establishing the abbot or even selling the property” (Floca, 2005:337).

*Canon 2 of the Local Council of Constantinople in 861* explains how to regard the poverty vote, thus in agreement with Novell 123 of Emperor Justinian if the situation is as such that the monk has children, the wealth due to the latter will be provided and the share of the monk will be given to the monastery (Floca, 2005:341).

### **3. Statutory provisions**

*The Status for the organization and functioning of the Romanian Orthodox Church* has some amendments regarding the succession rights of bishops and monks. Thus, art. 192 states that the Dioceses have a calling on all goods of succession of their bishops. Similarly, art. 193 refers to the belongings of monks and nuns brought with them or donated to the monastery upon their entry into the monastic life, as well as those acquired in any way while living in the monastery. They will totally remain within the monastery they belong to. They may not be subject to further claims. Regarding the retired bishops, the Holy Synod will govern their rights under the statutory and regulatory provisions of the Church as observed in art 194 of the *Status on the organization and functioning of the Romanian Orthodox Church*. Thus, we note that the dioceses have exclusive rights as legal heirs of the bishops' wealth. In the case of a testament, the succession, which is rightfully of the diocese, is materialized in half of the decujus patrimonial. Thus the Church becomes – through the diocese – the only legal heir of the bishops, removing by civil law the legal heirs that might distinguish themselves as having inheritance vocation (Harosa, 2011: 327-328).

Article 41 para. (1) of the *Status regarding the organization and functioning of the Romanian Orthodox Church* states that “the Patriarchate, Archbishops, Bishops, vicariate, deanery, convent and parish are legal entities of private law and public interest”. The listed legal entities, “are entitled to two single tax registration codes, both for the economic and for the non-profit activity”, according to art. 41 paragraph (2).

As one author notes, “the organization and administration of ecclesiastical property of the ROC and ROC Statute provide that the canonical means of acquiring wealth can only be allotted to ecclesiastical legal entities of public utility within the Church, identified by art. 41 para. (2) in relation to art. 40 of the Statute of the Romanian Orthodox Church, in order to request the parishioners various contributions, as well as various ways of acquiring property through purchase, inheritance or pious will. For the most part, the Orthodox canonic law makes reference to the Romanian civil law, reminiscent of liaisons between the oriental religious right with the rules of the state.” (Harosa, 2011:260)

In accordance with art. 41 of the Status, art. 191-193 refer to the church expenditure and state aid. Thus, art. 191 of the *Status regarding the organization and functioning of the Romanian Orthodox Church* states, “expenditures for maintenance and operation of facilities for worship, as well as for repairs and new constructions, will be covered by the voluntary contributions of the parishioners, from religious establishments' revenues derived from their own activities and contributions from the

state budget, from the local government authorities and other institutions, according to the law". According to the article, we identify the following sources of funding:

- voluntary contributions of the parishioners;
- revenues by church entities from their own activities;
- contributions from the state budget;
- contributions from the local government budget;
- contributions from other institutions' budget.

Regarding the right of the Church to receive contributions from parishioners, it has its origins in the "ecclesiology of the communion, which allows concrete contributions to church authorities from parishioners, whenever necessary, as in these cases, any gift from the parishioners as well as any tax is a sign of the communion with the Church and is manifested in the service of the ecclesial community" (Harosa, 2011: 267). Thus, the citizen who expressed adherence to a religion the support shown to the respective cult becomes both a right and an obligation.

### Conclusions

Before the year 313, the Christian religion was forbidden. In these circumstances, the Church could increase assets under disguised contracts of sale, donations, wills or other means which were under the right of individual property and not of the Church as a recognized legal entity. Only starting with the Edict of Milan in 313, the Church was granted the opportunity of becoming the subject of civil rights and obligations.

From the above we can say that the funding sources or the path "by which the goods become in time Church property, may be governed by natural law, the canonic law, the civil law (civil law canonization) or mixed, or may be of origin (occupation, accession or incorporation, the prescription) or derivatives (acts of disposal of intervivos free title, mortis causa, legal or testamentary succession, contracts, legal acts, mergers, spin-offs and extinctions of legal entities, etc) as well as public law (taxes ) or private law" (Harosa 2011: 260).

The Church understands the value of property as a means by which the parishioners should enjoy its appreciation by running religious assistance which is not cold or impersonal, but warm, having a deep philanthropic character.

## CIVIL LIABILITY OF DOCTORS AND THEIR INSURANCE (MALPRACTICE)

**Gârbo Viorica Irina**

*The Department of Finance and Accounting Computer Science, Faculty of Economic Sciences, "Bogdan-Voda" University, Cluj-Napoca, Romania  
vioricagarbo@yahoo.com*

**Abstract:** *Malpractice insurance of medical staff is probably the oldest professional liability insurance underwritten in the insurance market in Romania. The aim of our research is to theoretically examine in a qualitative inquiry the usefulness of insurance completion by the practitioners from the Romanian health system at both state and private, in order to improve a best practice medical insurance. The medical profession is practiced in Romania under the Code of Medical Ethics 30 March 2012 prepared in code that complies with international standards contained in the Geneva Declaration of 1948, as amended by the World Medical Association and the International Code of Medical Ethics. The forms of medical liability are: disciplinary, administrative, civil and criminal and only the civil liability can be taken into insurance because only it meets the conditions of insurability. Once we explain in general and the insurance liability in particular we show articles of the Romanian Civil Code which establishes the obligation the one that caused an injury to a third person for the repair or indemnify and conditions provided by the Civil Code as an act to be considered liability. Then we refer to situations where the patient may be damaged through the fault of the doctor or the doctor unit operates. The object of malpractice insurance is loss of money that the insured would have to pay a patient whom he caused injury as a result of acts or deeds of negligence committed to, during and in relation to professional activity. Risks taken in the insurance are personal injury, illness or death of the patient and / or moral damages. Regarding the excluded risks we have presented an overview of the more common contracts underwritten by Romanian insurance companies. We show the way of underwriting, the insured sums of the standard insurance and the additional one which subscribes moral damages, to companies in Romania agreed by bodies which organize and supervise the Romanian medical system. The current procedure for determining the guilt of a doctor and his patient complained of the amount of damages is a long and difficult. The procedure for determining the guilt of a doctor reported by his patient and the amount of compensation is a long and arduous one. In conclusions we have shown that along with the reform and reorganization of the Romanian medical system, the civil liability insurance of the medical staff, the way of contracting, the way of establishing the guilt of the applicant and the amount of compensation need to be reformed.*

**Keywords:** *doctors, liability insurance, malpractice, indemnity, compensation.*

**JEL Classification:** *G22, I14, I19*

## 1. Introduction

Any healthy person is exposed to the risk of injury or illness and being treated by a doctor in a medical facility. Every person hopes the service he will receive will be one of a good quality and will go home healthy. But unfortunately, doctors as other professionals, there are persons better or lesser prepared. Even the best trained can have a bad day and the case to be a medical failure.

The noble profession of doctor, practiced from ancient times, certainly under different names is done in order to protect the physical and mental health of human beings (Article 1 of the Code of Medical Ethics 30 March 2012). The professional act and all the work the doctor will perform without any discrimination based on age, sex, race, ethnicity, religion, nationality, social status, political ideology, or for any other reason, including the state of health or patient's chances of recovery (Article 2 of the Code of ethics).

The new medical ethics code developed by the College of Physicians from Romania on 30 March 2012 and published in Official Gazette No. 298 of May 7, 2012 comply with international standards contained in the Geneva Declaration of 1948, as amended by the World Medical Association International Code of Ethics and medical.

## 2. Short History and Malpractice in Other Countries

In terms of malpractice history it must be said that the oldest malpractice case described in history took place in 1375, in the United Kingdom (Văduva, 2010) at Royal Court John Cavendish. Agnes of Stretton has broken her hand and turned to Dr. John Swarlord for care and medical treatment. Because after a few days the hand had not healed, Mrs. De Stretton turned to another doctor who told her that Dr. John Cavendish had treated her incorrect, the patient taking action and suing first doctor who treated her. The process had been canceled due to a technical error.

In the United States, the first case of malpractice occurred in Connecticut, before the American Revolution, 1775-1776. Mrs. Cross had a problem with one of the breasts and consulted Dr. Guthery for diagnosis and treatment. Diagnosis was scrofula and amputation of the breast was recommended. After the patient's consent, the breast was amputated but after surgery the patient had a hemorrhage and died. Dr. Guthery expressed sympathy to the husband but after a few days sent him the bill. The husband, angry, sued, and in the process, the doctor had to pay substantial compensation (*Medical malpractice*, 2013).

Over the years, patients' demands have reached higher, so that more and more patients are suing medical staff, especially doctors who treated during illness or accidents, requiring substantial benefits. The amount of compensation that patients receive varies according to the legislation of the country in which the patient was treated.

Regarding the legislation of European states it should be noted that most of them do not have special legislation for malpractice cases. Instead of punishing medical professionals that were wrong, preferring compensation for the traumatized patient. In most states the provisions of the Civil Code and the Penal Code are applied (Perețianu, 2009).

In Germany, malpractice insurance is not mandatory in most provinces. But the majority of those who practice medicine prefer to ensure because insurance premiums cover the risk of paying compensation to a patient dissatisfied with the services received. Every medical practitioner ensures the sum he considers

abundant to indemnify the dissatisfied patients. It should be noted that allowances granted are only measurable (sick leave, prosthetic devices, etc.), not related allowances suffering, pain, or to reward a person sentenced to confinement due to infirmity caused by medical error - moral damages.

Netherlands was the first country where medical special provisions have been introduced in the Civil Code. This solution was necessary because health system characteristics such as the need to keep medical records, consent is requested, using patient information in research.

In the U.S., the country with the most cases of malpractice in the world, 10 times more than in Canada (*Medical malpractice*, 2013), healthcare providers, healthcare professionals and medical facilities are not required to enter professional indemnity insurance but nobody could afford to practice without malpractice insurance because of frequent complaints and the high volume of claims required by those who consider themselves injured by medical acts.

In New Zealand, there is no professional liability insurance, because there is also law that employers are required to compensate employees who are injured, including medical malpractice. Therefore there are no compensation processes requesting medical institutions or doctors (Perețianu, 2009).

In Romania, the first time reminiscent of professional liability insurance for healthcare in Law 145/1997 on social health insurance, which in art. 41 was stated: "The health insurance funds are obliged to organize a system of civil liability for providers of the security system. The provision was ambiguous and was never implemented."

Above-mentioned law was replaced by Ordinance 150/2002 on the provision and operation of the social health insurance system, and they requested the doctors to practice freedom of contract concluded with Health Insurance to provide liability insurance professional indemnity.

Currently under Law 95/2006 - Title XII, physicians exercise their profession based on the certificate to the College of Physicians of Romania approved annually based liability insurance for mistakes in work, valid for the year.

### **3. Medical Personnel and Civil Liability**

According to Article 642 of Law 65/2006 in the name of health care are included: doctors, dentists, pharmacists, nurses and midwives. We will deal only with the responsibility of the accused doctors when a patient was not treated properly and calls for material and moral damages.

As we have shown the medical profession is one of the oldest in the world. Although he had many names: Doctor, medicine man, healer, the purpose of their activities was defending physical and mental health of community members in which they worked.

Etymology of the word "doctor" is in ancient Greece. Archiatros or archiater (after latinization), mean person considered primary healer or one who deals with prevention, recognition (diagnosis), treatment and follow-up of diseases and accidents.

"A medical career begins long before they enter a college field, somewhere in childhood told a reputed surgeon. Once you begin to understand which way to go through what steps to climb and that you learn all your life, you feel like giving up but then true professionals are sieved. "

Although the steps of a medical profession are numerous, from a fresh faculty graduate to the primary specialist in a branch of medicine, not all have the same

degree of training. The degree of training is an essential condition to achieve performance. Skills is vital, but it is, in any case, the only ingredient for success. Equally important are solid preparation, compassion, correct reasoning, communication skills, clinical sense, theoretical knowledge and exemplary professional conduct to successfully meet the needs of patients.

Successes and failures in treating patients can be had by those Well and less trained. Perhaps the better prepared have many numerous successes and the others failures. Liability in case of failures have each of those who treated the case. As shown in our work on ensuring civil servants in art. 75 of Law no 188/1999 on the Statute of civil servants, and now the doctors are public servants, stated that the violation by the guilt of their duties and the rules of professional conduct and civic prescribed by law and constitutes a disciplinary offense and attracts liability (disciplinary, administrative, civil and criminal), as appropriate. Forms of liability does not exclude each other, if the deed meets the various forms of liability, they may apply simultaneously. Therefore, the doctor may be sanctioned with specific forms of accountability measures.

We define the forms liability (disciplinary, administrative, civil and criminal) of the doctor because we want to show which of them may be subject to insurance.

- *Disciplinary* - are deviations from the Code of Medical Deontology / 30.03.2012. Acts of misconduct are reviewed by the College of Physicians and disciplinary sanctions are applied (reprimand, warning, suspension of work, sales employment contract);
- *Administration* - are deviations from the Labour Code. Is instrumented by the employer (the Board of Directors of the hospital, office, clinic, etc.). Penalties are administrative (Law 95/2006 are called all disciplinary related internal regulations of the employer) and consist of demotions, reductions in salary, moving to another department, etc. (Article 263 of Law 95/2006);
- *Criminal* - when there is injury and / or death. Is determined by the courts under the Criminal Code and instrumented by the Prosecution;
- *Civil* - is established and dealt with by the courts under the Civil Code and the penalties are pecuniary damages awarded to the injured.

None of the three forms of liability set could not be taken in an insurance contract because the risks to be insured must meet several insurability criteria (Ciurel, 2011):

- to be calculated, can be probabilistically calculated,
- cannot be avoided,
- they may not be acknowledged,
- be bearable,
- to be compensatory, that insurer to compensate the financial loss resulting from their production,
- Be consistent with the regulations in force, moral and insurer profitability.

The first two forms of legal liability (disciplinary and managers) not meet the conditions a, b and c and criminal liability does not meet the last condition of insurability, that is inconsistent with applicable law, the moral and social ethics.

We left the medical professional liability for last, because it may be subject to an insurance contract, as we will show.

#### **4. Civil Liability of Medical Staff and Its Insurance**

The fundamental role of insurance is to protect the financial compensation of the losses caused by the occurrence of a risk, compensation provided from the insurance fund established by adding and fructification of the insurer, the insurance premium that the policyholders pay (Pintea, 2011).

Liability insurance (Ciurel, 2011) covers all sums which the insured is obligated to pay by law for property damage, moral and / or injury caused by him to a third party. In most contracts court fees are added. The interest of the insurance is to avoid the lowering of the insured patrimony as a result of his civil liability to injured persons.

In a terminological approach civil liability is a legal obligation that the person who caused an injury to another person shall repair the damage to the product (Bistriceanu, 2001) and under the obligation of responsible for causing injury to the repair from the provisions of the new Civil Code or rather its two key institutions namely crime and qvasicrime.

In matters of tort, the new Civil Code governing the civil liability of those who harm others injured, giving art. 1349, that "every person has the duty to respect the rules of conduct imposed by law or local custom and do not affect by actions or inactions of its rights or legitimate interests of others, who with discretion, violates this duty responsible for all damages, being obliged to fully compensate them. "Art 1350, states that" the borrower is obliged to repair the pecuniary damage caused to the creditor contractual nonperformance, defective performance or delay in benefits to which he is indebted under a valid contract ended "

Articles 1357 and 1359 of the same Code Civil concerning liability for his own deed, provide that "he who causes harm to another by an unlawful act committed with guilt, is obliged to pay compensation" and "illicit offender is obliged to repair the damage and when it is caused because of the damage of another's interest if the interest is legitimate, serious, and how that manifests itself, creates the appearance of a subjective right"

Theory of civil law specifies that there are two types of liability: tort and contract, their common element consisting in that both are based on the idea of repairing damage caused to another by an unlawful act.

Tort involves a person's obligation to repair the damage caused to another through an extra contractual unlawful act or the damage for which he is called by law to answer for.

Contractual civil liability of a debtor assumes duty obligations arising from a contract to repair the damage caused to the creditor or by non-performance due to delay its execution or improper execution of them.

Since between the two forms of liability there are no major differences, the legal classification of the liability situations both tort and contract envisages the cumulative meeting of the three following target conditions:

- contractual unlawful act consisting of non-contractual benefits owed by the debtor;
- damage caused to the creditor;
- the causal link between the wrongful act and the injury to third persons

Proof of damage caused to the creditor (the patient) or the causal link between the wrongful act and the injury must be demonstrated by the third person who has suffered damage. Proof of illegal act (if tort) or non-enforcement, inadequate or delayed execution of contractual obligations (in case of contractual liability), all of the

damage back to the person who suffered the damage, using the bodies granting sanctions - College of Physicians and courts of Romania.

The doctor must feel safe when practicing, his whole capacity should focus on the medical act and not be altered by the fear of error. To achieve this goal the notion of malpractice and the way they protect themselves from the error repercussions through professional insurance liability-malpractice must be understood.

Etymologically, the word malpractice, consists of the Latin word "mal", "malus" - evil and word of Greek origin "praxis" - practice. Therefore the meaning of malpractice is bad practice, poor practice, the wrongly practice of medicine.

Definition of malpractice law is quite specific meaning. Malpractice is the professional error committed in the exercise of the medical act or medical-pharmaceutical, generating harm to the patient involving civil liability of medical personnel and healthcare provider, healthcare and pharmaceuticals (Art. 642). Basically, Law No. 95 of 14 April 2006 on healthcare reform, (published in Official Gazette 372 of 28 April 2006) with its numerous amendments provides that medical personnel, including doctors, dentists, pharmacists, nurses and midwives providing care patient liability for damages caused by error. The error may appear in the prevention, diagnosis or treatment and causes of error are cited by law: negligence, carelessness, and insufficient medical knowledge in the profession through individual acts in the framework of the prevention, diagnosis or treatment.

Also, health care and civil liability for damages of error arising from non-compliance on the patient's informed consent and mandatory medical assistance when they exceed the limits of its competence, except for emergency cases where competent medical personnel is not available.

It should be noted that not only the doctor's unlawful act may cause the patient injury. There are clearly situations specified in the law, which may cause harm to patients and the doctor is not responsible. These are the following:

- when they are due to working conditions, insufficient endowment equipment diagnosis and treatment of nosocomial infections, adverse effects, complications and risks generally accepted methods of investigation and treatment, addictions hidden sanitary materials, medical equipment and devices, substances medical and sanitary use;
- He acts in good faith in an emergency, respecting the granted competence.

For damage to the patients by these circumstances, the medical unit in which the physician works will be responsible and will have to compensate the injured patient with appropriate monetary compensation.

Like any profession, medicine is carried out under the control of a professional body (the College of Physicians, National Health Insurance) to which the doctor's membership is mandatory. When the doctor as a professional, making a gesture unintentionally detrimental to someone, the state provides the citizens it protects that injured patient will not remain uncompensated.

Professional liability insurance (malpractice) addresses individuals possessing the degree of doctor issued by a medical university institution in Romania or abroad, equated by law and authorized by the Ministry of Health, according to medical staff status. It also can provide other health professionals: nurses, lab technicians and other professionals with specialized secondary education, and health care facilities: hospitals, maternity hospitals, clinics, dispensaries, nursing homes, private clinics and so on, on behalf and for their servants.

The object of professional liability insurance for doctors and health professionals is the financial loss that the insured would have to bear whenever a patient caused his injury as a result of acts or acts committed by negligence to the during and in relation to professional activity, within the jurisdiction conferred by permit free circulation, for which he is liable under special laws, rules and the profession, the rules of ethical conduct and professional ethics, and is required to repair.

Damage may consist of personal injury, illness or death of the patient situations where the patient receives an allowance and / or moral damage, the amount of all benefits and compensation as determined by the courts. There are cases expressly provided (specific exclusions) in most of the companies that underwrite such insurance, it is not possible to award damages, namely:

- damages arising from plastic surgery / cosmetic, unless it is provided only as a necessity of correcting the consequences of an accident and / or congenital deformities;
- treatments / services provided to cause pregnancy, surgery to produce sterility, sex change operations, in-vitro fertilization;
- personal injury (including emotional distress or psychological trauma or phobia) damage that is caused or claim to be caused or are in any way related to AIDS or hepatitis;
- treatments (including medication and diet) to reduce weight;
- manipulation / genetic damage;
- Carried out by dental general anesthesia or any work done under general anesthesia unless they occur in special clinics with specialized assistance.

Compensation by insurance companies in Romania may represent, as appropriate:

- costs of the proceedings made by the applicant for legal formalities in order to oblige the insured to pay compensation if the insured was required to pay their final and irrevocable court judgment;
- costs of the proceedings made by the insured in the lawsuit if he was forced to compensation by the final and irrevocable court decision, including where prosecution is not driven costs and remain civil action in criminal courts;
- costs and expenses incurred by the insured, the insurer's written consent and for investigations, tests, surveys, and so on;
- Value to pay moral damages which the insured was bound by the final court decision.

Premiums paid for malpractice insurance (liability in case of medical mistakes) are tax deductible. Maximum size depends on the amount and type of compensation provided under the contract (property damage, injury and possibly moral damages) In recent years the College of Physicians of Romania and Health Insurance have signed agreements with leading insurance companies, only contracts with such companies being agreed by the bodies mentioned above.

According to the College of Physicians of Romania for 2013 professional liability insurance medical insurance cover ends on the following:

- General practice / family medicine - 15,000 euro
- Laboratory medical specialties -20,000 euro
- Clinical medical specialties - 37,000 euro
- Medical and surgical specialties - 62,000 euro

Amounts provided are related to damages and personal injuries, known by most insurers at standard conditions. Insurance premiums vary by subscribing insurance company and the insured specialty.

Those who want the insurer to pay injured patients as potential moral damages, most insurance companies are limited to a certain maximum amount secured more than € 20,000, an amount too small to moral damages set by the court of malpractice cases in Romania. The first additional insurance coverage related to underwriting and moral damages is 4-5 times higher than corresponding insurance premium standard.

Prerequisite for a company to pay damages for the harm in case of poor medical practice is to fit the object of insurance / risk insured and the injured person to prove entitlement to compensation. The hardest thing to prove is that the doctor was wrong and that the patient's right. Medical negligence is established by a committee for monitoring and professional malpractice cases. Between the years 2006-2011 there was a total of 725 notified cases of malpractice (Report Romania/2011 Medical College) and a total of 916 doctors were accused of malpractice, of whom only 198 were sanctioned and punished and only 11 have been prohibited from practicing medicine. These figures do not indicate the number of cases that were not reported, which could reach several thousand thanks to the difficult system of establishing guilt of the applicants and the amount of compensation. In Table 1, we show how the number of doctors accused of the sanctioned and the number of final decisions issued by the disciplinary committee of the Medical College evolved, and in Figure 1 we show graphically the same.

Table 1- *Evolution of the number of reported doctors, the sanctioned and the decisions of the CSD in the 2006-2011 period*

years	2006	2007	2008	2009	2010	2011
Reported doctors	112	135	171	157	154	187
Sanctioned doctors	19	16	51	48	38	26
Nr of CSD decisions	123	118	148	95	106	135

Source: Report Medical College of Romania / 2011

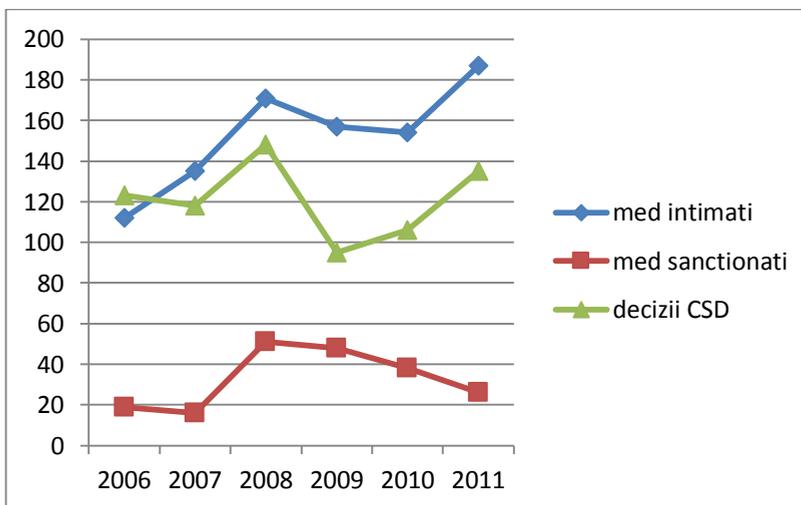

Figure 1: *Graphic evolution of the number of doctors reported, sanctioned and decisions of the CSD in the period 2006-2011*

The Commission will appoint malpractice before a panel of experts and the review will determine whether or not it is a malpractice case and will communicate its decision to all interested parties, including the insurer. The size of compensation is determined only by the courts of Romania. The period of establishing the degree of guilt of a doctor accused of malpractice is very long, to which the trial period known to process in Romania are added, known to be very long. So from bringing charges of malpractice and to compensate the injured it reaches a period of 5-6 years.

## 5. Conclusions

Romanian health system is in an unacceptably long crisis. This is manifested in all sectors: financial, material and human resources but perhaps the most difficult is the organizational.

Given that more and more patients dissatisfied with the services they received in medical institutions in Romania addressed the Disciplinary Board of the Medical College to claim malpractice cases and to filing the complaint and to collect damages for an extended period of time passes conclude that along with the reform and reorganization of the Romanian medical system needs to be reformed and liability insurance to medical personnel, the way of contracting, the way of establishing the guilt of the applicant and the amount of compensation.

In terms of how liability insurance must be reformed we conclude that it should include more types of insurance cover for standard ensuring every medical specialty and different types of insurance cover for any compensation for moral damages, the potential provided to able to choose the subscription according to any damages which it believes will be required next year insurance and insurance premium they can afford to pay.

Regarding the malpractice insurance we will show that it should be contracted with all insurance companies licensed to underwrite risks in the Romanian market, not just those approved by certain protocols and due to competition between insurance companies insurance premiums would decrease more.

Perhaps the most important change would be made to establish the guilt of the applicant and the amount of damages awarded. College of Physicians territorial area in which the complaint was made to determine whether the applicant is guilty in a fixed period determined malpractice law and then the amount of compensation to be established by direct negotiation between the insurer of the guilty doctor and the harmed patient.

Only when malpractice insurance will work in a reformed health system performance in the presented form or close to it will be a reliable aid to medical personnel in Romania.

**Abstract:** *The main objective of our research is to make extensive analysis on the budgets of EU member states in order to emphasize the main trends within the period 2000-2011. We are using common measures such as: data in millions of euro, percentage of GDP, fixed base index, chain based index, percentage of total revenues or total taxes. Through this study case, we aim to create a good presentation of the EU. State members, an image of the percentage modification related to a base year, achieved by the main budgetary components from year to year. On our case study we are focusing only in indirect taxes since these are, for many EU countries the main budgetary revenues. Another important reason for focusing on indirect taxations is the fact that most countries during the financial crises consider readjusting of these taxes on of the main tool to adapt to the lack of public resources. Our research is based on data extracted from EUROSTAT and our calculation and compilations. Our working hypothesis is that despite huge differences in tax policy among all 27 European countries there are some common trends and Romanian tax policy must adapt and must follow them. Another important element is that trends in fiscal policy may vary due different elements such as: level of development, social policy issues, systems of financing different public expenditures, number and structure of populations, regional and local objectives and many others. The VAT, the main important indirect tax is extensively annualized since most of the trends of taxation are dictated by the trends of VAT. Romania is a special example, not the only one., where VAT has significance importance for budgetary revenues and was the main element of fiscal adjustments during the financial crisis.*

**Keywords:** *fiscal policy; indirect taxes, VAT, European Union, fiscal harmonization.*

**JEL classification:** *E62; G28; H20; O52.*

### 1. Introduction

The purpose of our research is to analyze the budgets of the E.U. countries compared to the budgets of Romania during 1999-2010 period, highlighting the evolution of the budgetary incomes especially indirect taxes. After studying the literature regarding the budgets of the E.U. member states we had done the analysis of their budgets. Our study also aims at analyzing the main trends and budgets of

the E.U. states, which are done through the calculation of some indices, reported both income and expenditure of the extracted data: indices with fixed base, chain-based indices, minimum, maximum, mean values recorded at the level of states, weights and values of total GDP. The data needed for analysis were processed from the European Union website (<http://epp.eurostat.cec.eu.int>), in compliance with the standard classification. These data were extracted and processed in March 2012. Our analysis is according with the European Union standards ESA. Our approach begins with the analysis of the most important categories of taxes, the tax on production and imports (D2). ESA standard define this kind of tax who is achieved through cash payments or in nature, that are collected by the public institution or by the E.U. institutions, in what concerns the production and the import of goods and services, workforce or land owning or other goods utilized in the process of production. These taxes are payable without taking into account if there is a profit or not,

The taxes on production and imports include the following categories: Taxes on products and Other taxes on production. The category taxes on products are including: V.A.T., taxes on products excluding V.A.T. and the import duties on products;

Taxes on products include those taxes paid per unit of good or service produced or transacted. The tax may be formed from a sum of money paid per unit of a good or service or may be calculated ad valorem as a percentage of price per unit or value of goods and services produced or traded.

The Value Added Tax is a type of tax that falls on the goods or services collected in stages by enterprises and ultimately borne entirely by consumers.

The taxes and duties on imports excluding VAT comprise compulsory payments levied by general government or the EU institutions on imported goods, excluding V.A.T., in order to allow free movement within the economy and the services provided by unit's resident and resident units to buyers.

The taxes on products excluding VAT and import duties (D214) consist of taxes on goods and services that become payable as a result of production, export, sale, transfer, leasing or delivery of such goods or services, or from the use of these goods or services for own consumption or own capital formation.

Other taxes on production consist of all taxes that enterprises incur as a result of employment in production, regardless of the quantity or value of goods or services produced or sold. These types of taxes can be paid on land, fixed assets or labor employed in production or in certain activities or transactions.

D2 Taxes on production and imports

D21 Taxes on products

D211 Value added type taxes (VAT)

D212 Taxes and duties on imports excluding VAT; D2121 Import duties:

D2122 Taxes on imports excluding VAT and import duties; D2122A Levies on imported agricultural products; D2122B Monetary compensatory amounts on imports; D2122C Excise duties; D2122D General sales taxes; D2122E Taxes on specific services; D2122F Profits of import monopolies;

D214 Taxes on products, except VAT and import taxes; D214A Excise duties and consumption taxes; D214B Stamp taxes; D214C Taxes on financial and capital transactions; D214D Car registration taxes; D214E Taxes on entertainment; D214F Taxes on lotteries, gambling and betting; D214G Taxes on insurance premiums; D214H Other taxes on specific

services; D214I General sales or turnover taxes; D214J Profits of fiscal monopolies; D214K Export duties and monetary compensatory amounts on exports; D214L Other taxes on products.

D29 Other taxes on production; D29A Taxes on land, buildings and other structures; D29B Taxes on the use of fixed assets; D29C Total wage bill and payroll taxes; D29D Taxes on international transactions; D29E Business and professional licenses; D29F Taxes on pollution; D29G Under-compensation of VAT (flat rate system); D29H Other taxes on production.

## 2. Taxes on production and imports

As we can observe, the indirect taxes are represented at the E.U. 27 budgetary classification level by the D2 code. The maximum amount of the indirect tax revenue in the E.U. 27 was 1,666,408.9 million Euros in 2007. The minimal amount of the budget revenues (from this tax) in the E.U. 27 was recorded in 1999 and was 1,174,391 million. Regarding the average, we can say that it was 1,426,687.82 million Euros in the period under review for E.U. 27. The country that recorded the maximum values of the indirect taxes was Germany, which recorded a maximum of 305.460.00 million Euros in 2007. The main reason for this maximum was recorded in indirect taxes, in Germany, was due to the increasing of the V.A.T. rate from 16% to 19%.

<b>Table 1</b>			
Indirect taxes, state ranking, mil. Euros			
Maximum values		Minimum values	
Germany	305.460 (2007)	Malta	454 (1999)
France	288.571 (2008)	Estonia	627 (1999)
England	256.471 (2007)	Latvia	933 (1999)
Italy	225.928 (2007)	Lithuania	1405 (1999)
Spain	122.779 (2007)	Bulgaria	1.663 (1999)
Source: Personal processing of the data from the Eurostat			

Table (Indirect taxes, state ranking) shows the minimum and the maximum values of the European Union. All the maximum values are recorded in 2007, except France (2008) by the old European Union member countries, while minimum values are found in countries that joined recently the European Union. France also has quite high values of the maximum indirect tax revenue in quantum of 288.571 million Euros in 2008. The main cause of this increase was the lowering of the indirect tax rates leading to a high degree of their collection. Britain also reached high values of the indirect tax revenue in this period, namely a maximum of 256,470.5 million Euros in

2007. The main cause of this increase was due to a higher fiscal pressure of the indirect taxes from 37.6% to 38.3%.

Italy also recorded in 2007, in this area, a maximum of 225.471 million Euros. Germany in 2007 had a maximum of 305,460 million Euros from indirect taxes. In all these countries where there have been significant increases in the indirect tax revenue we could observe an increase over the period, the maximum being reached in 2007. Thus, compared to 1999 in Germany was an increase from 1999 to 2007 of 1.26 times, 1.31 times in France, in the U.K. of 1.38 times and 1.34 times in Italy. In Estonia there was also a considerable increase of 3.36 times. As we can remark, the average percentage of the indirect tax revenues, at the E.U. level, in total incomes, is exactly 29.68%. The highest percentage of the revenues from this tax was almost 49%, and it was registered in Bulgaria (2006).

If in the Nordic countries, the highest indirect tax revenues were recorded, we see that the indirect taxes are exactly the opposite, Finland registering, for example, the minimum of the percentages in total incomes of the indirect taxes. We noted that the maximum percentages of the indirect tax revenue in total income were in Bulgaria. High percentages appear in former communist countries such as Romania, Hungary, Poland, Slovakia and other countries such as Slovenia, Latvia, Ireland, Portugal, and Lithuania.

<b>Table 2</b>		
<b>The minimum and the maximum of the indirect taxes, percentages in total income</b>		
Maximum indirect tax, percents in total income		
Indirect tax:	48,98%	Bulgaria
Minimum indirect tax, percents in total income		
Indirect tax:	24,02%	Finland
Source: Personal processing of the data from the Eurostat		

In Romania, the absolute amounts of revenues from the indirect taxes increased greatly between 1999 and 2007, from 4,114.5 million Euros to 16,379.5 million Euros. Thus, we realized that there was an increasing in the amounts of 3.98 times in 2008 compared to 1999. The trend in the indirect taxes can bring out the base and chain indices analysis. It is noted that in 2005 over 2004, these revenues have increased 1.44 times. It should be noted that the mentioned increase of 1.44 times, the largest increase from one year to another, was registered in the E.U. 27. As you know, Romania is among the countries where the average percentage of the indirect tax revenue in total revenue is 34.11%, compared to 18.07% from the average of the direct tax revenues. In terms of G.D.P. the percentage average of the indirect taxes recorded in Romania, is 11.99%, average close to the percentage average of the

G.D.P. registered in the Netherlands (12.18%), Latvia (13.93%), Lithuania (11.83%), Germany (11.74%), Spain (11.13%).

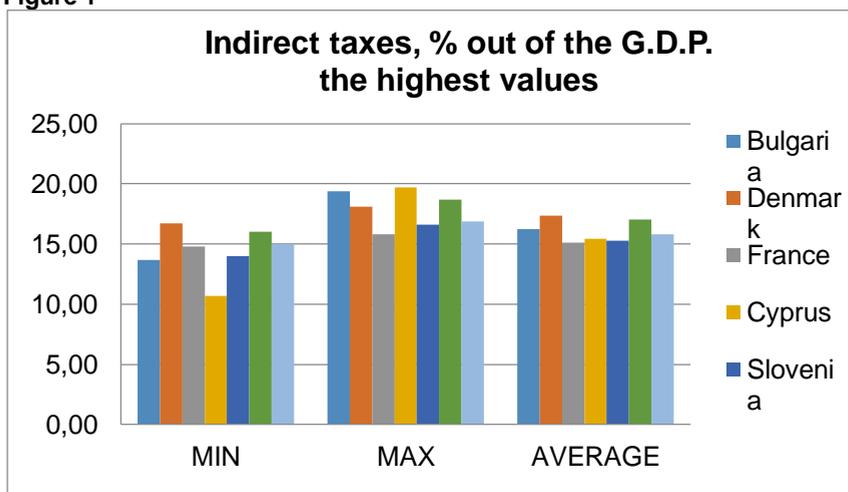

Further, considering the percentage of the G.D.P. of the indirect taxes for all countries analyzed, we find that it varies between 8.80% - 19.70% for the entire period (1999-2007). The maximum percentage in the G.D.P. of indirect taxes was recorded in Bulgaria (19.4% in 2006), and the minimum in Spain (8.8% in 2009). We noted that in Germany, Spain, Italy, Netherlands, England, the maximum percentage in G.D.P. of these taxes had minimum values and the average of the period analyzed had a very close level to the minimum, which suggests that the indirect taxes have been a slow evolution for the entire period considered in this study.

The indirect taxes are divided into taxes on production and other taxes on production.

### 3. Taxes on production

The revenues from the taxes on production represent over 80% of the revenues from taxes on production and imports, with an average share of the total income of 24.70% and an average share in G.D.P. of 10.96% (of the U.E. 27). These revenues, in the U.E. 27 had a maximum value of 1,380,088.2 million Euros in 2007 and a minimum value of 966,185.6 million Euros in 1999. Among the countries that have high levels of incomes from taxes on production, are to be named: Germany, England, France and Italy. This is due to an improvement in services, namely the production of the goods in those countries, so that the amount of revenues from taxes on products increased proportionally with them.

Figure 1

Source: Personal processing of the data from the Eurostat

The taxes on production are divided into: a) value added tax (V.A.T.), b) Taxes on imports excluding V.A.T., c) taxes on production, excluding VAT and customs duties.

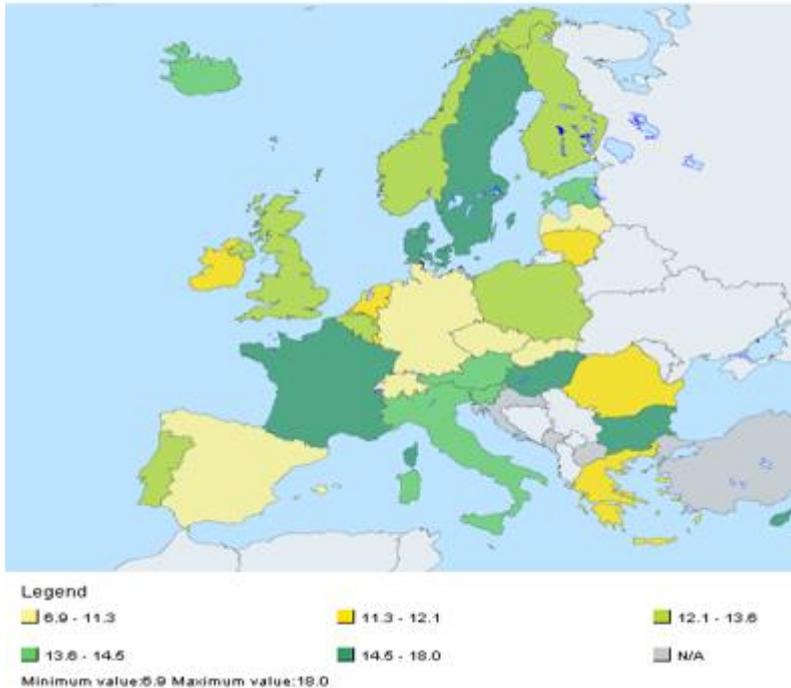

### 4. V.A.T.

The V.A.T. is the most important component of the taxes on production and it represents about half of the taxes on production and imports, accounting for 15.18% of the total revenues, and accounted for 6.73% of E.U. 27 G.D.P. The revenues of the value added tax in the E.U. 27 recorded a maximum of 856,510.1 million in 2007, and the minimum value, 568,410 million, was recorded in 1999. If we analyze the evolution of the income from V.A.T., we can see that these revenues are evolving in the analyzed period from 568,410 million in 1999 to 856,510.1 million in 2007, and then, in 2008, 2009 and 2010, the values registered were below the peak recorded in 2007. The countries with the highest values of V.A.T. revenues are: Germany (178,460 million Euros in 2010), France (134.744 million Euros in 2008), England (131,047.4 million Euros in 2007) and Italy (131,047.4 million Euros in 2007). The lowest values of the V.A.T. revenues in the countries of the E.U. 27, appear in Malta, Latvia, Cyprus, Estonia. From the available data we can see an increase in the V.A.T. revenues in absolute terms in all through 27 countries over the period we analyzed. The share in total revenues of the V.A.T. revenues ranged from 10.97% (Slovenia 1999) and 31.38% (Bulgaria 2006). In 2007, the V.A.T. in England had an increase of more than 1.39 times compared to 1999. In Romania, the total amount of the V.A.T. revenue is between 12.74% in 1999 and 25.03% in 2005, but will decrease to 23.53% in 2007 and then in 2010 to drop to 22.60%. Romania ranks seventh E.U. 27, in terms of total share's average of the V.A.T. revenue in total revenues at a rate of 19.92%. Bulgaria is just ahead of Romania with a share of total V.A.T. revenues of 27.25%, 23.09% Estonia with 23.09%, Ireland 19.99%, 20.61% Cyprus, Latvia 20.96% and Lithuania with 21.73%. Analyzing the share in the G.D.P. of the V.A.T., on all the countries surveyed, we acknowledged that it ranged between 4.8% and 12.4% for the entire analyzed period.

## **5. Taxes on imports**

In what concerns the chapter of taxes and payments on imports excluding VAT, is of less importance in our analysis because they accounted for 3.37% of the total budget and 2.2% from the income tax on production. With respect to these taxes, it should be noted that the taxes on imports excluding V.A.T. had an interesting development in the period 1999-2011. The revenues from this tax were 28.285 million Euros in 1999, after that, they grew up in 2001 to 32,271.2 million, then they decreased in 2002 to 30,700.2 million, in 2003 they increased again to 31.35,9 million, after which they decreased in 2004 to 30,245.2 million and in what concerns the last year we analyzed, in 2010 they reached 29,506.9 million Euros, value similar to that from 2007. We note that their level is low in almost all E.U. countries in the entire analyzed period. Romania has an average of the taxes on imports excluding VAT of 1.86% out of the total revenues during 1999-2010.

**Figure 2**  
**Taxes on production and imports**  
**% of GDP - 2010**  
**General government**

Regarding the section of the taxes on products excluding VAT and customs duties, it is worth noting that they accounted for 8.80% out of the total revenues in the E.U. 27 and other current taxes have accounted for approximately 5%. The revenues from the taxes on products excluding V.A.T. and customs duties have higher values than those mentioned above. This type of incomes recorded an average in the E.U. 27 throughout the analyzed period of 436,129.74 million Euros. The highest value occurred in England (93,947.5 million), Germany, France, Spain and Italy, and the minimum values are registered in Estonia, Malta, Cyprus, Latvia and Luxembourg. Romania has an average of these taxes in quantum of 2768.08 million in the analyzed period. The largest share of the G.D.P., regarding this duty, belongs to Slovenia in 1999 (8.3%) and the lowest proportion in Estonia in 2000 and 2001 (0.1%). The percentage average of the tax revenues on products excluding V.A.T. out of the total incomes in Romania is 10.22%. The percentage average of the G.D.P. of this tax are low, ranging from 0.1% to 8.3%, in the member countries while in Romania, the value recorded as a percentage average from the G.D.P. is 3.57%.

## 6. In conclusion

The maximum amount of the indirect tax revenue in the E.U. 27 was 1,666,408.9 million Euros in 2007. The minimal amount for the E.U. 27 was recorded in 1999 and was 1,174,391 million.

The country that recorded the maximum values of the indirect taxes was Germany, (305.460.00 million Euros in 2007), due to the increasing rate of the V.A.T. from 16% to 19%. All the maximum values on Indirect taxes, are recorded in 2007, except France (2008) by the old European Union member countries

Minimum values on Indirect taxes are found in countries new members of EU. The biggest increases in the period 1999 – 2007 were in: Germany, 1.26 times; 1.31 times in France, in the U.K. 1.38 times and 1.34 times in Italy.

The average share of the indirect tax revenues in total incomes, at the E.U. level, was 29.68%. The highest percentage of the revenues from this tax was almost 49%, and it was registered in Bulgaria (2006). If in the Nordic countries, indirect tax revenues were the lowest. Finland registering, for example, the minimum shares in total incomes of the indirect taxes.

in former communist countries are recorded the maximum shares of the indirect tax revenue in total income: Bulgaria, Romania, Hungary, Poland, Slovakia, Slovenia, Latvia, and Lithuania.

In Romania, the absolute amounts of revenues from the indirect taxes increased greatly between 1999 and 2007, from 4,114.5 million Euros to 16,379.5 million Euros. It should be noted that the mentioned increase of 1.44 times increase, was the biggest registered in the E.U. 27.

In Romania the average percentage of the indirect tax revenue in total revenue is 34.11% (18.07% average of UE). In terms of G.D.P. the percentage average of the indirect taxes recorded in Romania, is 11.99%, average close to the percentage average of the G.D.P. registered in the Netherlands (12.18%), Latvia (13.93%), Lithuania (11.83%), Germany (11.74%), Spain (11.13%).

The maximum percentage in the G.D.P. of indirect taxes was recorded in Bulgaria (19.4% in 2006), and the minimum in Spain (8.8% in 2009)

The revenues from the taxes on production represent over 80% of the revenues from indirect taxes, with an average share of the total income of 24.70% and an average share in G.D.P. of 10.96% (of the U.E. 27). The highest levels are recorded in Germany, England, France and Italy.

The V.A.T. is the most important component of the indirect taxes; it represents about half of the taxes on production and imports, accounting for 15.18% of the total revenues, and accounted for 6.73% of EU 27 GDP. The revenues of the value added tax in the E.U. 27 recorded a maximum of 856,510.1 million in 2007, and the minimum value, 568,410 million(1999). The countries with the highest values of V.A.T. revenues are: Germany (178,460 million Euros in 2010), France (134.744 million Euros in 2008), England (131,047.4 million Euros in 2007) and Italy (131,047.4 million Euros in 2007). The lowest values of the V.A.T. revenues in the countries of the EU27, appear in Malta, Latvia, Cyprus, Estonia.

The share in total revenues of the V.A.T. revenues ranged from 10.97% (Slovenia 1999) and 31.38% (Bulgaria 2006).

In Romania, the total amount of the V.A.T. revenue is between 12.74% (1999) and 25.03% (2005), 23.53% (2007) and then in 2010 to drop to 22.60%.

Regarding the section of the taxes on products excluding VAT and customs duties, it is worth noting that they accounted for 8.80% out of the total revenues in the E.U. 27 and other current taxes have accounted for approximately 5%. The revenues from the taxes on products excluding V.A.T. and customs duties have higher values than those mentioned above.

## THE INFLUENCES OF CHANGES IN TAX LEGISLATION

**Morar Ioan Dan**

*Department of Finance Accounting*

*Faculty of Economics*

*University of Oradea*

*morar\_id@yahoo.com*

**Abstract:** *Taxation is a fairly important field in the relationship between tax payers and tax authorities, especially given the frequent changes in specific legislation.*

*Legislative changes affect the patrimonial position of the tax payers, but also their behavior, therefore this phenomenon is important to advise those interested and also to analyze the changes resulting from changes in tax legislation.*

*This paper aims to meaningfully present the latest legislative changes and to analyze their influences on tax payers and on budget revenues from taxes subject to change. The research methodology is based on comparison and inference, based on previous analyses for such studies on the tax system.*

*In the literature there are known ways and methods of increasing the tax burden and, based on the variables, in the present paper we will highlight the particular influences on the tax payer's, loaded by weight imposed by the official distribution of the tax burden.*

*The implications of legislative changes in tax matters should be sought in the innermost chord of tax payers and also in the increasingly large and patched pockets of the modern state.*

*In the first place, we will point out the implications on changing tax procedures, in terms of the workload for the tax payer and the tax collectors.*

*By accurately and relevantly analyzing the influences generated by such changes, the author aims to demonstrate the harmful influences of some changes in terms of discouraging investments and honest labor.*

**Keywords:** *corporate tax, budget revenues, social contribution, deductibility;*

**JEL classification:** *H30, G18;*

Tax legislation reflects the doctrinal orientation of the executives even in conditions of economic crisis when fiscal measures some times seem to be saving or enslaving. The substantial changes as well as those related to conjuncture directly generate influences on budget revenues, and indirectly through their pressure on the taxpayers, which in turn will adjust the fiscal behavior.

Our legislation has been amended and this year by GO.6/2013 with direct influence on corporate tax, on the tax on the microenterprises' income, also there are changes on personal income tax, non-residents' income tax, then there are changes of VAT, and some small additions to the tax base of compulsory social contributions.

In terms of corporate tax there are some changes in the preparation of the Tax Audit Register in connection with research and development expenses, in connection with the depreciation rules and for certain non-deductible expenses, then, in terms of tax on the microenterprises' income, there was a change in the definition of microenterprises and, also, the right to choose to be a microenterprise was eliminated.

A spectacular and debatable, in the same time, change is that on imposing personal income made from agricultural activities. The personal income tax changes also in terms of deductibility of some expenses.

VAT amends the definition of liability of registered tax payers to register in terms of VAT with some adjustments referring to the harmonization with Directive 112/2006/EEC.

The influences of the legislative changes are measurable on a postoperative basis, still we have available some time projection models based on changes in the tax base, with indirect effects on budget revenues.

We will follow the changes in legislation in the following points depending on the tax that affects it, as follows:

a) The corporate income tax. First, since February this year we can speak of the implementation of the obligation of income tax payers to explicitly maintain the Tax Audit Register, for each income and expense in turn.

Regarding the deductions from the tax base, the R&D spending deduction ceiling is increased from 20% to 50%, thereby beneficially influencing the research.

Regarding the non-deductibility of expenses, there are additions to the legislation in force for the introduction of non-deductible expenses in the calculation of expense taxes later found to be associated with acts of corruption.

Also in the same context, it is better defined the notion of borrowed capital for determining the indebtedness in the calculation of the ceiling for deducting interest expenses and foreign exchange rate differences.

The deductibility of depreciation of commercial means of transport is limited to a level of 1500 lei/month.

Another change in determining the taxable base at corporate tax refers to the intangible assets with indefinite recovery period, which will be considered current expenses, so a simplification measure of exceptions when conciliating the net income result with the fiscal law.

b) The tax on microenterprises' income, the main change of this tax is the obligation to pay it, eliminating the right to choose the option between being the payer of this tax or the payer of the income tax. This change negatively affects businesses with activity based on prices with low added value, such as, for example, small middlemen who rely on minimum margins disadvantaged in favor of large networks. This measure is completed with the reduction of the turnover ceiling from 100,000 Euro to 65,000 Euro, the exchange rate at the date of the accession to the EU and the measure to eliminate the mandatory use of work force, (from 1 to 9 employees).

The changes regarding this tax are officially justified by the need to reduce fiscal evasion in the field of microenterprises with activity in agriculture, tourism, constructions and other services, but it seems that the negative influence is felt on the intermediaries as we have outlined above and another limitation on these businesses is the result of the reduction of the turnover limit.

c) The tax on personal income. The changes to this tax concern tax payers who have incomes from non-agricultural activities and non-resident individuals that have incomes from various sources in our country.

Regarding the taxation of the individuals' incomes which derive from crop farming, animal husbandry, beekeeping, the exploitation of forests and other such activities,

they will be taxed starting with February this year in fixed taxes on the cultivated surface for what exceeds the limit surface according to the crops obtained, in fixed amounts per animal for what exceeds a certain threshold on animal species, the number of bee families, etc., the introduction of this tax being justified by the elimination of this tax evasion in agriculture. I, however, believe that tax evasion should not be sought in the peasant households that carry out a subsistence farming, but in large farms and large tenants, some being in the state's ownership. These people will also owe the mandatory social contributions for income from agriculture, forestry and fisheries.

The taxation of income of non-residents are taxed in the country where they obtain these incomes, following that based on the conventions of the avoidance of international double taxation, the tax residency certificate and the tax certificate from the country where they obtain the incomes. The changes on the jurisdiction of this tax target the incomes of non-residents in Romania, but also abroad, regardless of the place of supply, less the international transport services its complementary services. Also, we introduce a new tax rate of 50% for revenues obtained in Romania and destined to a country with which Romania has signed an international double taxation convention.

d) The Value Added Tax. It is known that the consumption taxes are the object of the harmonization with EU regulations, namely Directive 112/EEC/2006, and this harmonization process is a continuous process.

In this context, the GO No 6/2013 clarifies the submission to taxation of the operations carried out at the market value between related parties, and also clarifies the lack of management and taxation of goods that are subsequently charge as stolen, being subject to taxation.

Regarding the VAT-collection system, there are provisions on granting the right to deduct VAT on purchases conducted by the beneficiary that do not enforce the collection of VAT from taxable persons applying this system.

Also there are changes and clarifications related to VAT payers registered in the Register of Intra-Community Operators (RIO), meaning that people in that register will be required to submit to the fiscal district body of the new administrators or associates within 30 days after the change, and, otherwise, take a tough measure namely, the payer will be removed from this register.

### **Conclusions:**

The changes to the fiscal code are officially justified as being necessary in the context of harmonization of consumption taxes to European directives and the need to reduce the level of tax evasion, but the explanations should be extended also to the effect of changes on the budget revenues in future periods and on the patrimonial influences and on the taxpayer's fiscal behavior.

In terms of budget revenues, it seems that the changes will not bring major budget solutions in terms of stability and elasticity of the tax system; such measures appear to be minor repairs to a mechanism burdened by the overweight of the load.

A real reform of the tax system would mean changes related to the alignment of the labor taxation to capital taxation, an adjustment of social security contribution in order to optimally distribute the tax burden between income taxation and income

taxation with the se contributions and social contributions.

Then, it would be necessary to set back again the distribution of amounts between the central budget and the local budgets, according to simple and transparent criteria regarding such redistribution.

Last but not least, it would be required adjustments on granting tax deductions for individuals' expenses made in certain useful tax purposes to encourage and select the consumption.

The author of this work has set the objective of summarizing the changes in tax legislation and presenting them in a form accessible to the analysis of the overall tax system, an analysis needed to understand the mediate effects in the fiscal procedure and, also, the structure effects of the tax system.

**Abstract:** *Because of the fact that specialty agricultural assistance is not always available when the farmers need it, we identified expert systems as a strong instrument with an extended potential in agriculture. This started to grow in scale recently, including all socially-economic activity fields, having the role of collecting data regarding different aspects from human experts with the purpose of assisting the user in the necessary steps for solving problems, at the performance level of the expert, making his acquired knowledge and experience available. We opted for a general presentation of the expert systems as well as their necessity, because, the solution to develop the agricultural system can come from artificial intelligence by implementing the expert systems in the field of agricultural insurance, promoting existing insurance products, farmers finding options in depending on their necessities and possibilities. The objective of this article consists of collecting data about different aspects about specific areas of interest of agricultural insurance, preparing the database, a conceptual presentation of a pilot version which will become constantly richer depending on the answers received from agricultural producers, with the clearest exposure of knowledgebase possible. We can justify picking this theme with the fact that even while agricultural insurance plays a very important role in agricultural development, the registered result got from them are modest, reason why solutions need to be found in the scope of developing the agricultural sector. The importance of this consists in the proposal of an immediate viable solution to correspond with the current necessities of agricultural producers and in the proposal of an innovative solution, namely the implementation of expert system in agricultural insurance as a way of promoting insurance products. Our research, even though it treats the subject at an conceptual level, it wants to undertake an attempt to present the necessity and importance of implementing expert systems in agricultural insurance as a solution of development of the Romanian agricultural sector since insurance play an important role in the stimulation of investments in agriculture and in the stabilization of agricultural producers incomes. The results of the study, at a conceptual level, confirms the necessity of applying expert systems in agricultural insurance because of the benefits which would be created (informing agricultural producers about the existence and importance of agricultural insurance, the development of the insurance market which would lead to the development of agriculture, creation of new insurance products adapted to the needs of the farmers).*

**Keywords:** agricultural insurance; expert systems; agriculture.

## **1. Introduction - The Necessity of Implementing Expert Systems in Agricultural Insurance**

There are many reasons why the financial domain is so popular for expert system applications. The majority of problems from the finance domain can be split up into quantity and quality parts, and in a sense they can be formulated under some rules, facts, cases, forms or semantic networks. Thus, the financial domain can benefit from the application that uses the technology of expert systems. (Liebowitz, 1998) (Ganesan, 2006) believes that agricultural production has evolved into a complex business requiring the accumulation and integration of knowledge and information from many diverse sources. Unfortunately, agricultural specialist assistance is not always available when farmer needs it. In order to alleviate this problem, expert systems were identified as a powerful tool with extensive potential in agriculture.

The implementation of expert systems in the agricultural insurance domain could represent an encouragement of development towards agriculture and agricultural insurance because in view of the accomplishment of a modern agriculture, the need of maintaining the financial possibilities in the required conditions of the particularity of agricultural production is necessary. To this effect, the use of expert system in insurance represents a primordial tool for the protection of agricultural producers and farmers, fact why our agricultural sector need to be developed, all the more so that recently new risk have been shown as a result of climate change.

A study realized by Ciurea I.V., Paveliuc-Olariu C., Ungureanu G., Mihalache R. in 2011, which followed the agricultural consultation case from the North-East Region of Romania, 12 years after its establishing using the questionnaires method which were filled by a number of 80 specialists in agricultural consultation from the 6 counties of the North-East Region, emphasizing the following aspects: "All the persons that ensure consultations develop activities with a general character from all agricultural domains. There is an acute lack of specialists, a single person ensuring his services for thousands of farmers... A lack of interest is developed by the local authorities for consulting activities. Specialists are unhappy about their pay level, their limited possibilities of improvement, the high volume of work, the lack of equipment and transport, as well as political interference\_in the personnel recruitment process.

The conclusion of this study are other arguments that highlights the necessity of implementing a new informatics system in promoting agricultural insurance, the application of expert system technology within agricultural insurance is as well needed as it is useful due to the informing of agricultures about their existing insurance products and the reproduction of human expert reasoning in a form easy to understand, thus the user, regardless of his level of training, can take a decision that suits him the best in the respective moment.

Before utilizing expert systems in agricultural insurance, in view of following their efficiency, it is necessary to raise a few questions present in Figure 1.

Browsing Figure 1, we can easily find the necessity of implementing expert systems in agricultural insurances because of the high potential of insurance development, the simplicity in its use, but this imposes an initial investment (material and organizational) which implies the involvement of insurance agencies as well as the state, which is not always prompt.

**Who will be interested in using the system?**

- Agricultural producers, animal breeders

**What will be the finality of the system/the possible benefits?**

- A better awareness of farmers about the benefits of insurance will lead the way towards a better development of agricultural insurance and agriculture. The aim of the system is not that to replace specialists, it is do offer information to help getting a better understanding about the risk at which agricultural exploitation/animal effectives are exposed to and to offer solutions, according to the particularities of every case.

**Who needs to be involved to create the system?**

- Insurance agencies need to make data systems related to the creation of an agricultural insurance contract available to the engineer.
- Experts from related domains of agriculture: veterinarians; agricultural consultants; agricultural tools providers; seed providers; The National Institute of Meteorology and Hydrology to make available data's about temperature, humidity, precipitations as well as the implication of the Office of Soil Science and Agro Chemistry in view of stabilizing the soils hydro physicals parameters (fading coefficient and soil humidity).

**How much will it cost?**

- The costs of purchasing data, studies, system and maintenance engineers need to be taken in consideration.

**What is the necessary training level needed to use this system?**

- It doesn't need speciality knowledge, the system being designed to be able to be used easily by everybody.

**Where will be the system accessible?**

- A strategically place would be at the Town Hall, so it can be accessible to every farmer.

**What are the impediments of implementing such a system?**

- The lack of involvement and mobilization of insurance agencies, The Ministry of Agriculture and Rural Development, The National Institution of Meteorology and Hydrology, the Office of Soil Science and Agro Chemistry to provide complete data's in view of creating a decent knowledge base.

**Figure 1:** Useful questions before implementing expert systems in agricultural insurance

## 2. Expert system structure

For a better understanding of the working mode of expert systems, next we will describe, briefly, the sequences that need to be gone through to develop the system as well as its components.

Expert systems are composed from two main parts: de development environment which is used to create the components and introduce the knowledge in the system containing elements (the purchase of knowledge module, the inference motor and the knowledge base) which will facilitate the creation of expert system, as well from the consulting environment which is used for counseling and for obtaining specialty knowledge, facilitating the use of the model and offering its users the advice of

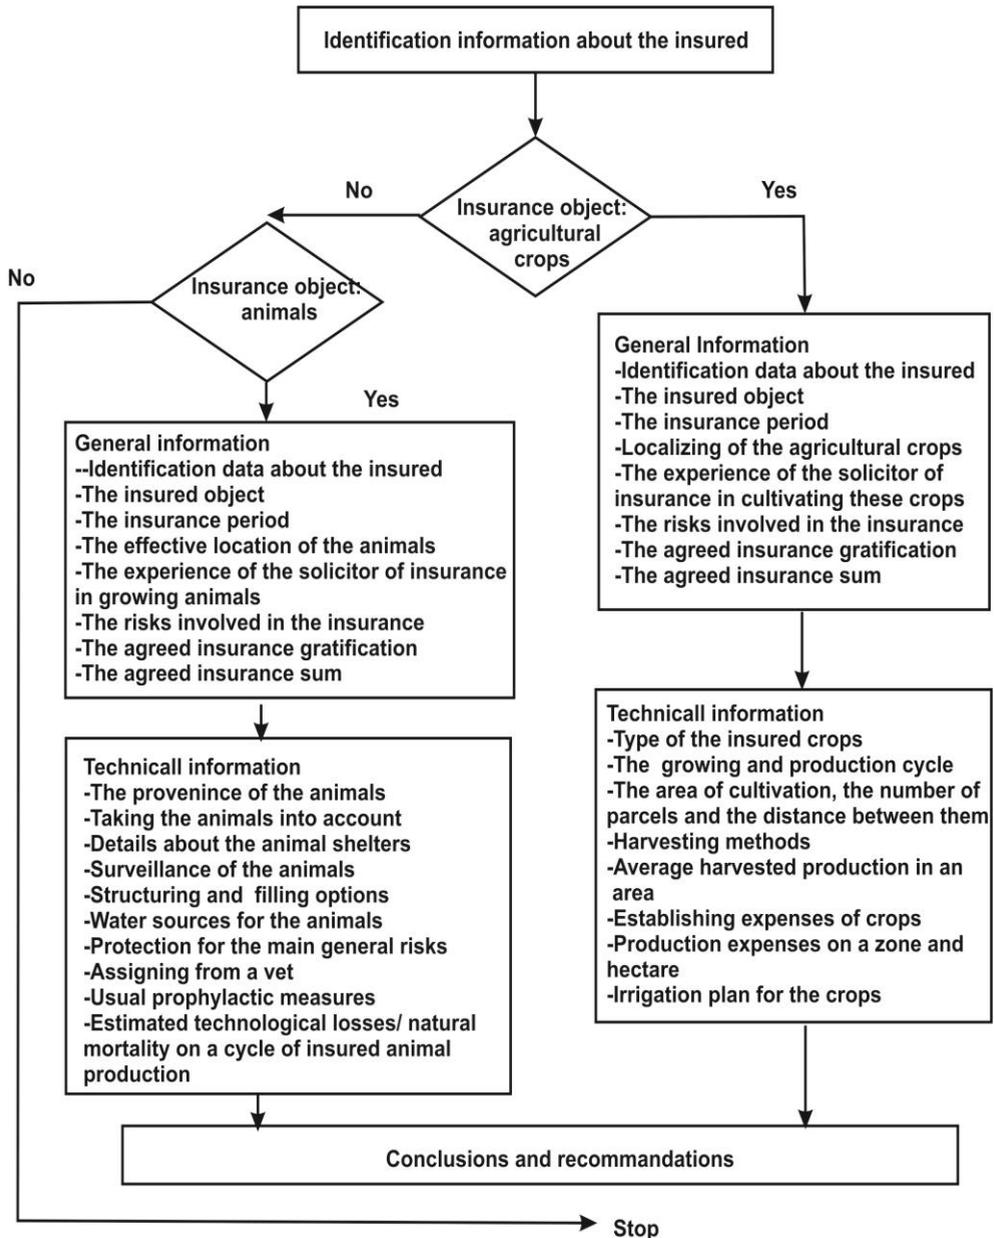

experts and answers to their questions (Turban, et al., 2011). Thereby, an interface exists that facilitates explanations as well as facilitating the recommended action. The architecture of expert system is composed of 3 base components:

- ❖ *knowledge base, which is formed from 2 parts;*
- ❖ *the rule base which contains the biggest part of the necessary knowledge to solve the problem which is specified;*
- ❖ *the facts base formed especially from knowledge specific to the problem that will be solved (formulation of the problem) as well as the resulting facts from a process inference from an inference motor (it contains all of the users data), representing the working memory. Because the systems rules are being created on the base of known fact, the decision process is influenced directly by the availability of the relevant facts. So, it is important that the facts base reflects perfectly reality and show exactly the modifications made.*

In view of preparing a very complex knowledge base, which will be included in the system, official documents or diagrams are being used, using specialty information from experts from within the agricultural insurance field (data related to the creation of an agricultural insurance contract) as well as experts from agricultural related environments. These need to contain in-depth knowledge in the domain, good communication abilities, experience and reputation so that the information offered would offer credibility. The acquired knowledge from experts and other sources will be communicated to the knowledge engineer (specialist in computers), he will be an intermediary between computers and human experts, which will process the information in such a manner that it will be applicable on a computer, creating a database. After the knowledge acquiring, their validity will be checked and a final, coherent database will be generated.

Thus, the expert systems consist of organizing information on different main levels. In Figure 2, we outlined the logical scheme of agricultural crops insurance and animal insurance within expert systems, where every level represents an integrated assembly of sublevels. For example, the level “The risks involved in insurance” from agricultural crops contains the sublevels: hailstone, hoarfrost (the late spring freezing and the early autumn freezing), downpours, storms, hurricanes, landslides, fires started from lightning, from which the farmer picks an option, based on his necessities.

We opted for a simplified schematic representation (on a single level) of the model of perfecting the expert systems in agricultural insurance for a better understanding of its functioning manner, where the system informs the user about the existing insurance conditions and offers an alternative based on the picked options.

**Figure 2.** Logical diagram of how an expert system works in agricultural insurance  
Source: compiled by the authors

*Inference engine:* it is a structural control component which picks from the knowledgebase the facts utilized for creating the reasoning in view of obtaining a decision option. The inference engine controls the mode and succession in which the knowledge from the rule base is applied on data from the facts base being a

computing program which applies new rules to facts to generate using induction, new facts which are being added to the knowledgebase or confirming/infirming a hypothesis, or the solution of the problem. Thus, the rule base is being run, searching for the identification of a correspondence between the facts from the conditions or the consequences of the existent rules and information in the knowledgebase. When such a correspondence is identified, the respective rule is used to produce a new knowledge or to confirm a hypothesis. This follows a series of major objectives, the elaboration of the problem solving plan after its necessities, commuting from a control strategy to the next one, the execution of actions provided in the solving plan, depending on the knowledge that we have at our disposal (<http://iota.ee.tuiasi.ro/~mgavril/Simpe/L2.htm>).

If the reasoning is done well, it can be transposed into the system with the help of the <<IF, THEN>> type rules, this being the most frequent, but we can also find rules which have an <<ELSE>> component which has the meaning to generate, at the end of the logical algorithm the best solutions for the user (agricultural producer) or to formulate a conclusion. Many expert systems have the capacity to explain to the user *why?* (by using motives that were at the base in the process of making an action) and *how?* (by explaining the inference process) reached by using their reasoning to their proposed solutions.

*Interface with the user:* it ensures the dialogue between the user and computer in an enthralling and easy to understand mode. For the interaction with the user, most systems use graphs or a texts with questions and answers, but they can be more complex by integrating dictionaries. In general though, an imposing scenario which interacts with the user can contain the next additional components (Turban et al, 2011): the subsystem of acquiring of knowledge, the working place (blackboard), the subsystem of explication generating, the subsystem of auto learning (knowledge-refining system).

*The subsystem of acquiring of knowledge* ensures the communication with the database interface, allowing the user to introduce new knowledge for creating or extending a database.

*The subsystem of explication generating* allows the following of the systems reasoning and issuing justifications for the obtained solutions, highlighting in this mode the cause of the mistakes or the failure motives, following the behavior of the system and answering question as: How did we get to a particular conclusion? or Why was a particular alternative rejected?

*"The working place"* is used to record the intermediary results, hypothesis and decisions. Three types of decisions can be recorded on a blackboard: a plan (for example how to approach a problem), an agenda (for example the actions while waiting for the execution potential) and a solution (for example, hypothesis and alternative routes of action which the system generated until now).

*Knowledge-refining subsystem* needs to be able to analyze motives for the programs' success or failure taking into account the obtained results which can make the knowledgebase better using a more efficient reasoning. Having the capacity of auto learning, the system can improve its behavior in a short time, by changing the rule base.

*Such a behavior of the commercial expert systems is experimented at several universities and research centers. But currently it's not mature enough to be used.*

After picking a proper tool (the most popular is the Corvid System) the attention shifted to the coding of the knowledgebase, the major concern in this stage being if

the coding process (defining variables, creating the logic blocks and constructing command blocks) is efficient and appropriately operated, to avoid errors. In what concerns the system evaluation, this implies the checking (by ensuring the fact that the knowledgebase contains the acquired data from experts and that no errors appeared in this stage of coding) and validation of the system (by confirming the fact that the system works correctly).

### 3. Study Case Regarding the use of Expert Systems in the Insurance of Agricultural Crops

After going through the questionnaire made by the expert systems the following information has been obtained: an agricultural producer from the Cluj-Napoca country, Cojocna parish, wants to solicit insurance for his wheat culture on an surface of 2 hectares, the average production obtained that wants to be insured consists of 3.500kg/ha, for the 21.01.2012- 31.08.2012 period. The average obtained production to a hectare in the last 5 years for the agricultural culture that wants to be taken into insurance is presented in table 2.

**Table 1.** Average production for a hectare (kg) obtained in the last 5 years for wheat

Nr. crt.	Type of agricultural culture	Years				
		2011	2010	2009	2008	2007
1.	Wheat	3.900	3.700	3.500	3.800	2.900

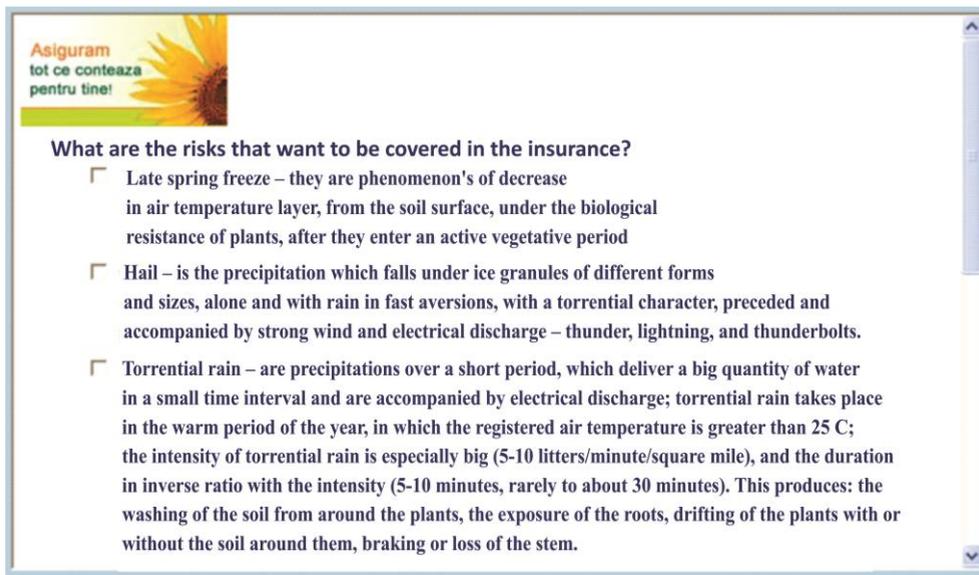

Source: Author processing's

For the agricultural culture insured no damage has been recorded in the previous agricultural year and the risks contained in the insurance are: direct effects of downpours, storms, hurricanes, collapses, landslides, fires started from any reason, the agricultural producer is willing to allocate a budget of 100 lei, not wanting to pay for deductibles.

In view of finding the insurance gratification and the gratification, the expert system will use the data communicated by the user to find the best possible option of insurance on the market taking into consideration his needs, going through a logical algorithm. The system will pick first price quota (%) of the respective culture taking into consideration the tariff group of the culture (wheat), the risks contained into the insurance (direct effects of downpours, storms, hurricanes, collapses, landslides, fires started from any reason) and the grouping of the counties on tariff groups (Cluj) which it will be applied to the cost of the harvest of the entire planted surface, the insurance gratification being obtained.

The expert system will be conceived in such a manner that it will be able to be used with ease by agricultural producers, offering additional explanations where it is required and argumentations for the recommendations it makes.

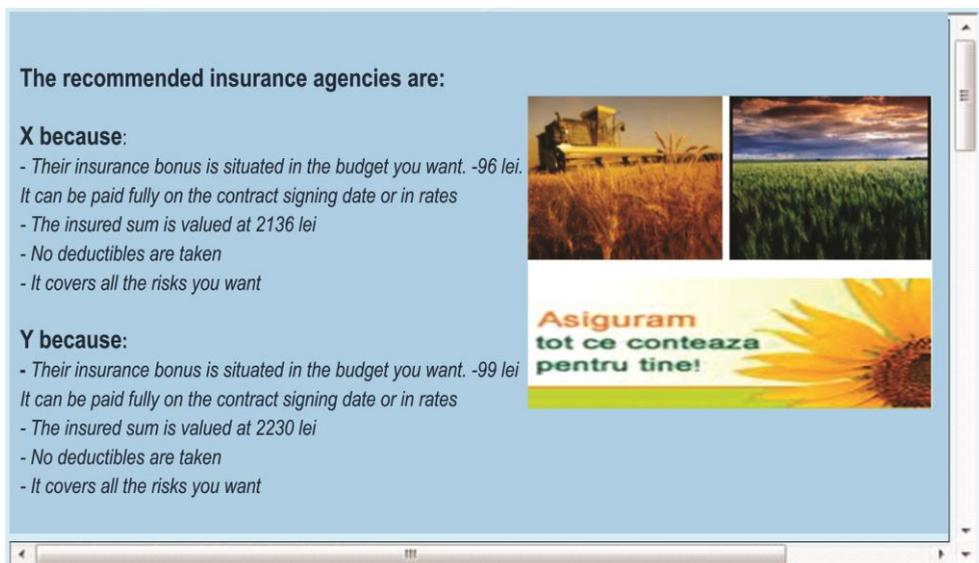

For example, referring to the risks contained in the insurance, the system offers a clear and explicit definition, compliant with figure 3, thereby so that the agricultural producers can identify the correct risks at which their agricultural exploitations are exposed.

**Figure 3:** Online questionnaire

Source: screen capture while running the application (Exsys, 2013)

In respect of the results, the expert system will recommend the first 3 insurance agencies which fit the farmers' necessities, arguing the choices made and offering the possibility of sending a solicitation to create an insurance contract on the website of the respective society, pursuant with figure 4.

**Figure 4:** The recommendation of the system

Source: screen capture while running the application (Exsys, 2013)

#### **4. Conclusions**

After running through the steps followed by the expert systems, we can easily see the efficiency of implementing artificial intelligence in agricultural insurance, the main benefits being the development of agriculture and insurances by removing the lack of information and the trust of farmers towards insurance so that they will have at their disposal solutions and newly improved information based on the previous experience of the users. Specialty literature from the studied expert systems area, highlights the benefits of implementing expert systems in all the areas of the socioeconomics activity, amongst them agricultural insurance, but, it doesn't deal with the agricultural insurance segment alone, in spite of its importance in the development of agriculture. This fact confirms the added value brought up by the existent article from specialty literature.

Using expert systems in agricultural insurance can contribute to the development of the agricultural sector, bringing immediate and long term benefits, whereas the behavior of the agricultural producers can be followed, their aversion towards the risk and the frequency and intensity of the risks in various regions, making the creation of better insurance products possible which will responds to the needs of the farmers, approached based on the different types of risks specific to agriculture, as well as the extending of the coverage of this products at the full level of the farmers inheritance, these having the role of sustaining in time, the development of the economic sector and maintaining the financial circuit in agriculture.

In point of the future research directions of this area, we can say that the success of applying expert systems in the agricultural insurance domain depends on the understanding of this systems importance, the availability and the capacity of the insurance agencies to support this domain, as well as the involvement of the Commission of Surveillance of Agriculture and the Ministry of Agriculture.

# EMPIRICAL STUDY REGARDING SUSTAINABILITY OF ROMANIAN PENSION SYSTEM

**Oprean Delia, Podoabă Lucia**

*Bogdan Vodă University, Cluj-Napoca, Romania*

*opreandelia@yahoo.com*

*lucia.podoaba@yahoo.com*

**Abstract:** *This paper is part of a broad, applied scientific research, based on popular empirical procedures (such as natural observation). Positivistic and constructive research methodology used was based on the consensual-inductive system (Locke), which is why we studied the different views of specialists on sustainability of pensions in Romania, necessary to formulate the problem of generating relevant information. Research strategies used were the comparative and longitudinal ones, as we analyzed the time evolution of qualitative indicators VUAN (unitary value of net asset) specific to pension funds Pillar II and Pillar III of Romania, concomitant with the number of participants in these funds, as to determine their direct relationship with the need for sustainability in this area. The hypotheses regarding causal relationship efficiency – participants - sustainability and needed measures for pension reform were built in this paper inductively (by analyzing the sustainability issues of pensions in time), causally (by explaining the cause and effect phenomenon studied), deductively, logically and subjectively (due to the existence and perpetuation of conflict premise between generations and social inequality between employees and pensioners). The qualitative approach of the phenomenon studied by collecting information (using mediated data collection technique) has allowed the relevant findings and practical solutions necessary for all those involved in this concerted action of pensions, which affects us all. Evolution of pension systems has been studied from the general to the particular, from the national to the European level. SWOT analysis of the public pension system was expanded with the pension scheme for private and voluntary. The role of this analysis was to highlight the weaknesses of the pension systems, as all have an absolute need to real stability. Relevant conclusions of our paper outline the characteristic perspectives and limits. In fact, these limits generate our actions for future study in this exciting area of research that concern us all.*

**Keywords:** *sustainability, public pensions, private pensions, SWOT (analysis), reform, VUAN (indicator)*

**JEL classification:** *Q01, H55, J32, O11, P41, P47*

## **1. Introduction**

Both on international and on national level, the pension system administration was a major challenge on the last decades for everyone involved in the process. The large number of retirees relative to the falling number of employees seriously threatens the sustainability of this system. Existing demographic problems (Vasile V. et al, 2011), and the increase of redistributed financial resources cause problems of sustainability of the budgetary deficit when the economic activity falls in a period of economic recession (Socol et al, 2010). Differences between pension systems

were analyzed by specialists in the field (Draxler, 2009), especially after pension reforms (Van Vliet et.al, 2011), to highlight the importance of private pension funds, to remove existing social inequities. In addition, it was found that the vulnerability of the pension system, supported by characteristic factors, constitutes a serious impediment to its future sustainability (Bouchet, 2003). Outlining of relevant models of sustainability for pension systems, tailored to specific developments corresponding to each country, were concerns of specialists in the field (Grech, 2010; Zeisel V.,2010/2011; Marotta, 2011) to provide solutions to sustainability problems arising in the process of pension reform. Regarding our country, pension reform must be rigorously implemented by substantially increasing the number of taxpayers to ensure specific sustainability (Beju, 2007). To this end, for the Pillar II pension fund (Coca-Cozma, 2012), in the future, there has to be some legislative stability, without affecting the relative balance between the interests and obligations of participants, administrators and government institutions. Instead, for the Pillar III pension funds (Coca-Cozma, 2012) is necessary to achieve, in the future, the simplification of procedures and streamline of the accession process, collection and administration system.

## **2. Hypotheses and data sources**

Taking into account the statistical data published on the website [www.csspp.ro](http://www.csspp.ro), opinions of specialists in the field and pension interests of participants (employers, employees, contributors, state), we think it is necessary to conduct this study (without analysis of the impact factors), so proposed and tested hypotheses are:

*H1: There is a causal relationship between VUAN values-the number of participants - the sustainability of the pension system?*

*H2: Which are viable and necessary measures (particularly for public pensions) to be applied in the reform of the pension system in Romania?*

## **3. Pensions: introductory approach**

As part of the contemporary public policy for the elderly, social policy programs have a special place, whose implementation measures vary from country to country, according to the degree of diversification of benefits, the level of resources allocated as volume and proportion of GDP. In this context, financial resources for pensions may come from the public budget, from insurance and savings or combinations of these resources.

### **3.1. Pension systems: general aspects of the EU**

Pension schemes (public or private) must provide income to pensioners, so that the sole criterion for assessing is in the terms of performance in sustainability conditions. Financing of pension systems is a challenge of the XXI century, on the background demographic aging, increasing of life expectancy and declining birth rates. Hence, the major concern in recent years of European countries has resulted in the development of strategies, whose implementation must ensure achieving adequate retirement living, financially sustainable, adaptable to socio-economic conditions and labor market changes. Specifically, some states have reformed their public pension systems as "Pay As You Go" (with mutual aid between generations), while others have promoted legislative provisions to improve the legal framework for supplementary pensions, privately managed, based on capitalization. The share of private pensions in EU Member States in the total income of pensioners is variable

depending on the degree of participation and the funds' assets and on the inclusion or non-inclusion of some redistributive elements in these systems. Traditionally, private pension systems in the EU Member States are of three types:

- regulated pension schemes (normatively defined) - represented by the privately managed public pension system component, including pensions, mandatory in some countries (the case of Spain, Slovakia, Latvia, Slovenia, Denmark) or optional in others (such as in the Lithuanian case);
- occupational pensions (unregulated) - established by contracts of employment, participation in these being subject of the work place, practiced in countries such as the Netherlands, Denmark, Sweden, Germany, Italy, Belgium;
- individual pension plans – on which both employees and employers can contribute (as the case of Slovakia, the Czech Republic, Estonia).

### 3.2. Pension system in Romania

The pension system in Romania is characterized by the presence of two components:

- public pension system – Pillar I, publicly administrated, redistributive, based on solidarity between generations;
- private pension system, privately managed, with contributions records of participants' individual accounts, based on capitalization, consisting, in turn, of two components:
  - privately administered pension - Pillar II, similar to that in other EU countries such as Poland, Lithuania, Slovakia, Slovenia and Latvian Republic;
  - voluntary private pension - Pillar III, similar to the one in the Czech Republic, Estonia, Slovakia.

According to the World Bank classification, private pensions implemented in Romania belong to Pillar II - privately administered pensions, mandatory, with defined contribution (DC) and Pillar III - privately administered pensions, voluntary, based on individual accounts. Implementation of the private pension system aimed primarily at providing additional income in retirement to lead, to a rate as high, to adequacy and sustainability of pension income. Reaching this objective depends on the development of the parameters influencing the accumulation of assets (such as: the level and dispersion of system coverage and contribution levels and yields). But the private pension system in Romania is a young one, in full process of implementation and expansion, which has suffered many transformations over the years. To identify the real problems that the public pension system is facing and to shape viable solutions to address these difficulties, we have developed a SWOT analysis of this system, shown in the table below (Table 1):

**Table 1:** SWOT analysis of the public pension system

<i>Strengths</i>	<i>Weaknesses</i>
<ul style="list-style-type: none"> <li>▪ Addressing the social issue of general interest;</li> <li>▪ The high level of awareness of entitlement among the population, due to advertising campaigns supported by CSSPP;</li> <li>▪ Taxes collected for social purposes, and the taxes per income from employers and / or payers going directly to CNAS and properly managed;</li> <li>▪ There is a guaranteed minimum wage and minimum guaranteed social pension that ensures the survival of workers and pensioners;</li> <li>▪ The equal access to pension rights is ensured;</li> </ul>	<ul style="list-style-type: none"> <li>▪ Major difficulties in planning, fundraising and managing the pension scheme;</li> <li>▪ Substantial inconvenience to cover the current pension budget amount;</li> <li>▪ Inequity created between different categories of pensioners' income (is the case of "privileged" pensions or "service" pensions provided to certain categories of professions) as the major discrepancies between income and consumption of retired population;</li> <li>▪ Annual indexation of pensions in percentage size increases the difference between small and large pensions;</li> </ul>

	<ul style="list-style-type: none"> <li>• Application of different methods of calculating pension income for different categories of people;</li> <li>• Maintaining chronic budget deficit the State Social Insurance Fund (SSIF) due to ongoing debt of CNAS through bank loans to achieve monthly payment of pensions;</li> <li>• Payment of current pensions as a result of the redistribution process of income collected by BASS;</li> <li>• Non-transparency of the social pensions fund;</li> <li>• Regulatory decisions and monitoring social pension fund are not always supportive of the proper risk management in the current pension system.</li> </ul>
<i>Opportunities</i>	<i>Threats</i>
<ul style="list-style-type: none"> <li>• Existence of young population in the working structure in high percentage, due to the acquisition of a high level of education;</li> <li>• Increase of the retirement age with a direct effect on reducing pressures on social fund;</li> <li>• Implement and development of long-term strategies that allow optimization of internal labor market performance, due to the use of EU funds by stakeholders in the national economy.</li> </ul>	<ul style="list-style-type: none"> <li>• Economic and financial crisis;</li> <li>• The decrease of the population, on the aging demographic characteristics;</li> <li>• Further perpetuating aging of population coupled with increasing dependency ratio of the elderly to those that are active;</li> <li>• High degree of poverty of the elderly;</li> <li>• Keeping impediments on domestic employment work market amid the high development of specific informal activities;</li> <li>• Existence of intense and lengthy processes specific to active population emigration, due to the reduction in the number of contributors to BASS;</li> <li>• Existing impediments to social security mechanisms of migrants and in the transmission of the incurred contributions to social funds among states under interstate agreements;</li> <li>• Asymmetric approach perpetuation of gender (women, men) of the basic conditions for entitlement to retirement;</li> <li>• Legislative and political instability, sometimes corruption.</li> </ul>

Taking into account the information contained in the above table (Table 1), we outline the following general recommendations for public pension reform:

- achieving and maintaining financial sustainability of the pension system
- fulfillment of social equity between generations, due to the principle "equal pension for equal contributions";
- the transparency reform the pension system.

Along with the public pension system, in Romania pension funds of Pillar II and Pillar III coexist, whose SWOT analysis (based on the annual financial statements and information published on the website [www.csspp.ro](http://www.csspp.ro)) we present in the tables below (Table 2 and Table 3):

**Table 2:** SWOT analysis of mandatory private pension system (Pillar II)

<i>Strengths</i>	<i>Weaknesses</i>
<ul style="list-style-type: none"> <li>• Increased of average annual return on pension funds (since its inception) and the number of participants;</li> <li>• Increase of total asset value of the funds in this sector due to profits made annually and the correlation between contributions paid and future benefits;</li> <li>• Contributions to these funds are tax exempt (excluding pensions above 1,000 lei) and do not impose additional financial obligations for participants.</li> </ul>	<ul style="list-style-type: none"> <li>• Payment of premium contributions to these funds only in May 2008, due to low level of financial literacy of population and minimal efforts to promote this system to stakeholders;</li> <li>• Diminishing of profits from these funds as a result of the current economic and financial crisis.</li> </ul>
<i>Opportunities</i>	<i>Threats</i>
<ul style="list-style-type: none"> <li>• Continue opportunity to educate the population amid its confidence in the system;</li> <li>• Increase of the percentage of contribution to the system through appropriate legislative changes.</li> </ul>	<ul style="list-style-type: none"> <li>• The high rate of elderly poverty amid rising unemployment and cross-border migration of the active population of the country;</li> <li>• The close relationship of dependence between the effects of the global recession and the financial markets among developing this system and existing political situation, due to aging.</li> </ul>

**Table 3: SWOT analysis of voluntary pension funds (Pillar III)**

<i>Strengths</i>	<i>Weaknesses</i>
<ul style="list-style-type: none"> <li>• Introduced in May 2007, it has recorded since the establishment an average annual return greater than the annual average inflation rate;</li> <li>• There is the prohibition of investment in toxic and dangerous assets;</li> <li>• Voluntary participation of contributors and tax deduction for employers;</li> <li>• Recorded positive investment results (most funds) for the increase of the number of participants and volume value of net assets.</li> </ul>	<ul style="list-style-type: none"> <li>• Reduced development of market on such funds on account of low interest for the population;</li> <li>• There are funds that have experienced negative returns on the market, with direct consequences on reducing participants' confidence;</li> <li>• Poor transparency in fund management.</li> </ul>
<i>Opportunities</i>	<i>Threats</i>
<ul style="list-style-type: none"> <li>• Establishing voluntary occupational schemes (direct contribution plans) by employers and trade unions;</li> <li>• Investment of financial resources of funds investing in money market instruments, deposits, current accounts, securities and other instruments with low risk;</li> <li>• Importance of involving institutions with legislative skills in regulating this system for citizens.</li> </ul>	<ul style="list-style-type: none"> <li>• Relatively high poverty rate of the elderly population, amid the financial crisis.</li> </ul>

During 2005-2011, the development of the pension system in Romania was characterized by:

- constant and solid evolution amid a climate unfavorable labor market and the positive trend of participants in voluntary pension funds;
- implementation of major projects in the private pensions market legislation (the guarantee of the rights of the private pension system);
- regulating the accounting frame required (in 2011) for the implementation and operation of the pension system in Romania (more specifically for the funds of guarantee of the rights of the private pension system), which will provide the appropriate framework for the implementation, in 2012, of the rules on investing and evaluation of private pension fund assets, of the disposal of the assets of private pension funds, risk management, technical provision;
- increasing of the role committed to the Private Pension System Supervisory or CSSPP (replaced in March 15, 2013 by Financial Supervision Authority) in the field of pensions.

These changes have resulted in further developments of pension funds from Pillar II and Pillar III in the period 2007-2011, characterized by:

- changes in the structure of administrators and private pension funds in the period analyzed due to changes in specific primary and secondary legislation have generated merger, dissolution or withdrawal from the Register CSSPP of those that do not assure the protection of the interests of participants in these funds;
- effectiveness of prudential supervision of entities in the private pension system by blending CSSPP action of "off-side" (embodied in the collection, verification and analysis of information collected through reports submitted by entities in the system) with the "on-site" action (evidenced by own checks performed), due to the elaboration of the "manual of good practice" in this area, organization of occupational pension system, risk monitoring through internal audit reports, analyzes and impact studies conducted on the development of assets of private pension funds.

In the extent of formulating conclusions and proposals that are relevant, we analyzed the evolution of a qualitative indicator of efficiency of pension funds respectively VUAN indicator compared to changing the number of participants in the pension

system (Pillar II and Pillar III). Increasing in this quality indicator VUAN favors the sustainability of the pension system. Data on these indicators were taken from the site CSSPP and their highlighting evolution, with necessary explanations during the period 2008-2011 is presented in the following tables. Before performing our analysis on the information provided in all tables presented in this paper, we point out the following:

- informative data are extremely limited in the area of public, private and voluntary pension funds, in Romania, due to limited bibliographic sources;
  - data analysis was done during the period 2008-2011, because they are fully completed financial years for which we can test the veracity of the information published in official addresses of Romania bodies involved in this area;
  - not to disturb the results of analyzes conducted, those pension funds for which there isn't complete data on previously the established period (2008-2011) were excluded from the interpretation of results;
  - informative data contained in various specialized papers, whose authenticity could not be verified on the official websites of Romanian authorities were not considered.
- We initially present the evolution of the VUAN indicator and the number of participants in private pension funds Pillar II (Table 4), and then the related pension fund Pillar III (Table 5), with corresponding explanations.

 CSSPP or PPSSC = Private Pension System Supervisory Commission

Analyzing the data in the table above (Table 4) we can conclude the following:

- FPAP OTP, FPAP Omniforte and FPAP Prima Pensie were absorbed by BCR FPAP and Interamerican FPAP, FPAP KD and FPAP BANCPOST were absorbed by FPAP Eureko, which is why we removed them from our analysis;
- in 2009, 2010 and 2011 we can observe the increase of VUAN indicator as opposed to 2008, but the growth was well below of the average percentage of 30.6% on all funds (in 2009) to 14.3% (in 2010) and 3,6% (in 2011), due to removal from the analysis of private pension funds Pillar II above mentioned, of the evolution of different specific value of the assets from one fund to another, of methodological changes to the rules relating to rates of return on these funds (Norm no.7/2010 of CSSPP), of reduce actual contributions paid by participants and their tax deductibility, even with aggressive advertising funds made for changes in purchasing, of power of buy of nominal pensions and inflation rate, of the movements of currency, of the central bank interest rates (ex. interest rates on the interbank market in 2010 showed a downward trend, due to excess liquidity), of changes in stock market indicators;
- in 2009, 2010 and 2011 there was a positive development specific to the number of participants compared to 2008, which is superior to the average of medium percentage of all funds of 5.7% (in 2009), 13.1% (in 2010) and 30,6% (in 2011), on account of financial specific changes to each fund, aggressive advertising conducted by some funds.

Examining the data in the table above (Table 5) we can conclude the following:

- FPF OTP Strateg and FPF BRD Primo were absorbed by FPF Stabil and FPF BRD Medio, FPF Eureko Confort and FPF Stabil appeared only in 2009, so we removed them from our analysis because their development was done on a too short period of time;
- in 2009, 2010 and 2011 we can remark the favorable trend of increase of VUAN indicator compared to 2008, but these rates were significantly lower than the average percentage of 834.7% on all funds (in 2009) to 10.8% (in 2010) and 1.6% (in 2011), due to the removal from the analysis of Pillar III pension fund mentioned above, of different developments specific value of the assets from one fund to another, of reducing actual contributions received by the funds;
- in 2009, 2010 and 2011 there was made a favorable trend specific to the number of participants than in 2008 (some funds having diminished values to the average percentage of all funds of 24.2% in 2009, 18.4% in 2010 and 17,5% in 2011) due to aggressive advertising specific to each fund.

#### **4. Conclusions, limits and perspectives**

Analyzing the tables above (Table 4 and Table 5) that comprise the index data on VUAN evolution and the number of participants, we draw the following conclusions:

- the number of participants in pension funds Pillar II and Pillar III has changed from one year to another, for the purposes of registration of the upward trend to some, but to others (which were absorbed) transfers took place amid alarms "drawn "by the Social Protection Committee on the high amount of management fees in total contributions maturity funds;
- the number of participants in Pillar III is significantly lower than the one under Pillar II, which shows the "reduced appetite" for optional insurance;
- the evolution of the number of participants in private administrated pension funds and voluntary ones was influenced by changing the number of employees, of

material benefits (in the form of grants or reduce payable contributions) offered to employers by law, of unemployment rate, of average wage value gross on economy, of EU funds absorption or non-absorption in the Romanian market designed to create and maintain jobs for the contributors to the pension.

Following the analysis performed and presented, we consider that there is a direct relationship between the sustainability of pensions – VUAN value - the number of participants, as meaning that the increasing the number of participants (implicitly the values of contributions) and VUAN value, represents real evidence of sustainability for pension system in Romania. So, *our first hypothesis (H1) is verified completely*. The current economic and financial crisis that we all go through generated considerable decrease in public confidence in financial institutions, whose direct repercussion was seen in subtracting the finance accumulated assets to retirement. If the answers of various government authorities were varied from country to country (ex. the Bulgarian Financial Supervision Commission reduced the technical interest rate from 3% to 2.8%, the Supervisory Commission Pension Funds COVIP in Italy relaxed the maximum liquidity for investment, etc.), CSSPP allowed (by additional legislation) investing pension fund assets in 100% in government bonds issued by Romania and other EU countries, due to exemption from compliance of managers to minimum limits and exposure on a bank guarantee of up to 5% of the fund assets. To achieve these goals, CSSPP reformed the current pension system in Romania. This reform is a major concern of the "actors" involved, particularly specialists in the field. In this respect, we agree with the certified specialists' opinion (Vasile et al, 2012) which proposed:

- maintaining public pension pillar (Pillar I), in the conditions of deep reform and strengthening its own private component, with capitalization, or
- waiver of Pillar I applicable to insurance programs for youth and operation on a transitional period, in parallel, of two pension systems - one in liquidation (due to state ownership on support services dedicated to elderly) and a new one with significant a private component.

The second variant listed above we consider to be less expensive for the state and national social assistance system, although current EU guidelines are for the former.

- additional taxation in tranches, with the share of 16%, of wages that exceed the average level of the tax rates and targeting this fee to reduce the deficit and balance the public pension Pillar I gradually would be an important action in the reform, along with the outsourcing of the minimum pension to the state budget, assessed as income from social assistance. This type of minimum pension could be supplemented by a system of benefits in community work. More specifically, the municipalities can create centers for the elderly, where specific activities will be carried through volunteering by them amid increasing interest active aging for additional revenue (through grants to employers when hiring elderly) and declining the number of the assisted;

- for the sustainability of the private pension system, reevaluate the active period (retirement age going upward), encouraging additional contributions (through the development of appropriate incentive for calculating pension contributions above the ceiling contributory) would be an effective measure aimed at allowing further tax deduction policy (which would increase companies' interest in providing employee benefits in the form of contributions to a voluntary pension fund);

- updating the purchasing power of nominal pensions by indexing for inflation the value of the pension point and reconsidering the relationship between pensions and the average wage by periodic reviews dependent on economic performance;
- calculation of the contribution in pension funds to ensure a decent income by including the amount of the pension financial simulation and risk number for annual fluctuations in investment markets, thus ensuring the guarantee of nominal capital invested;

Considering the presented conclusions, in order to achieve a strategic objective (protection of participants and transparency in the private pension system) of CSSPP mission in its work, we propose the creation of a record of administrators, custodians and marketing agents in the private pension funds on the site of the supervisory authority, which has to:

- include all necessary information about them (including action taken on them, after controls);
- be accessed by any individual and / or legal person and any institution in the country or abroad.

Relevant proposals presented in this paper *determine the final confirmation of our last hypothesis (H2)*. However, we know that this paper presents both scientific limits (caused by lack of information regarding pension system from Romania) and practical (materialized in the interest of decision makers and the application of presented solutions). The existence of these limits leads us to further deepening of this interesting and actual topic, because the treated subject affects us all.

**Abstract:** *The central researched element in our paper is the local budgets, the basic component of local public finances. Local budgets, like any other budgets, are the most important tool for the management (of local governments) planning, forecasting, implementing and monitoring the results of administrative-territorial units activity, also being an appropriate tool for enhancing performance. A budget is the government's plan regarding the use of public resources to meet the citizens' needs. The aim of this paper is to realize a research on budget transparency in local governments from the Nord-West Region of Romania, regarding the availability of the budget information on the websites of the county councils and the county residences. The key element of good governance in today global economic environment is transparency that can be defined as the openness of public authorities (central and local) regarding their policy intention, formulation and implementation. For local governments budget transparency is an important issue, due to the growing role of administrative-territorial units, confirmed over time by the economic reality. The importance of local budgets has increased in recent years due to the need to improve management efficiency and accounting at the level of local governments. Not only policy makers but also the citizens need information regarding local government current activities, expenditures, development projects and policies. In this context of a growing need for information, the transparency of local budgets is a mandatory condition for any local government. The combination of budget transparency and public participation in budget processes has the potential to combat corruption, foster public accountability of government agencies and contribute to judicious use of public funds. In this context, budget transparency represents the mean through which ordinary citizens and civil society organizations can access information about the allocation and use of public resources, so that they can assess how government officials manage public funds. Budget transparency needs to be implemented due to the benefits it brings and the most important one is obtaining better budgetary outcomes.*

**Key words:** *budget, budget transparency, local public finance, local governments.*

**JEL classification:** *H60, H72.*

## **1. Introduction**

The national public budget is the financial plan of the state which provides income and expenses for a specific period of time, in this case a year. The national public budget includes: state budget, local budgets and social insurance budget.

Therefore, in accordance with territorial administrative division of our state, local budgets are made up of counties' budgets and Bucharest budget, the budgets of cities, towns and villages. As part of the national public budget, local budget activity is circumscribed to national budgetary activity, knowing the same steps and is carried out on the same principles, but seen through the specificity of local government activity.

Local budgets are only one of the important aspects regarding the local public administration and any discussion regarding this issues must be placed in the context of the institutional framework taken as a whole (Ichim, 2010:243). Local public finances refer to the economic relationship through which the territorial-administrative units constitute and use their cash resources in order to provide public services to meet economic, social, cultural and public requirements. Due to the diversity of the public services that must be provided by the territorial-administrative unit and the complexity of economic and socio- cultural activities local public finance play an important role within the public finance (Onet, 2005).

The concern regarding budget transparency is an older one for the researchers. The meaning of this notion evolved over time from a simple norm in governmental accounting to "a tool for facilitating a relationship between public budgeting and market requirements, civil society demands and citizen participation" (Alegre et al, 2011:2). Different international organizations that promote budget transparency consider that new systems for public finance should first be tested on local governments before they are implemented at higher levels. Transparency is needed because local budgets reflect strategy, planning and content of a public administration.

## **2. General Aspects Regarding Budgets**

Voinea (2002) defines local budgets as being the programs through which are provided and approved annual revenues and expenditures of territorial-administrative units, in order to accomplish the administrative tasks of local governments and to fulfill the local public's needs. So, we can define local budgets as operational plans according to which the administrative unit guides its activity in the next fiscal year and is also the optimal standard for financial reporting to the local council.

Local budgets are prepared by every territorial-administrative unit due to the principle of autonomy, assuring the decisional autonomy of local governments and the improvement in the use of local funds and financial resources. Local budget can be interpreted in various ways as Ichim mentions in his paper "Changes in the structure of Romanian local budgets", such as: "A document..., a law..., a system of financial flows..., and a fiscal policy instrument of local administration." (Ichim, 2010:245).

The importance of local budgets arises from their role in assuring effective management of local government that determines the ultimate objective, the local development, a priority in the context of the new economic and social conditions.

Each administrative-territorial unit has well established tasks and the local budget is the financial instrument for resource mobilization and redistribution at local levels

and connects the public expenditure decisions with the real cost of resources. For local development a key factor is the local resources that can be optimized to the community needs. According to Ichim (2010) there are two conditions for the budgeting process to be efficient: (1) to take into account the significance of numbers and (2) to recognize this annual process as an opportunity to: evaluate local government services and facilities offered by them; establish priorities; consider possible changes; plan services and future needs and review and amend the income sources of the local budget (Ichim, 2010:245).

### **3. Legislative Aspects Regarding Local Budgets**

The general legal framework of the local public administration in Romania is provided by the Constitution of 1991, revised after the 2003 referendum, that states in Chapter V, Section 2 the basic elements and principles for local public administration, public finance Law 500/2002, the State Budget Law, the law on public local administration 286/2006 which sets out the consecrate principles of the previous law number 215/2001 and Law 273/2006 on local public finances. Regarding the public access to public information the legal framework is constituted from Law 544/ 2001 on free access to public information with ulterior supplements (Law 371/2006, Law 380/2006, Law 544/2001 published in Official Monitor 425/2007 and Law 188/2007) and Law 52/2003 on transparency in public administration completed by Law 242/2010. To all these we should add OMPF nr.1917/2005, on Accounting of Public Institutions, Published in Official Monitor No. 1186 from 29.12.2005 with ulterior amendments and supplements.

Budgetary procedure regarding local budgets is conducted on the principles stated by the named laws. So, according to Law 286/ 2006 with ulterior completions public administration in territorial-administrative units is organized and operates under the principles of decentralization, local autonomy, devolution of public services, local governments' eligibility, legality and *consultation of citizens* in solving local problems of special interest." Regarding the *principle of consultation of citizen* we can say that it requires that the public to be consulted in the design and adoption of local budgets. Law no.273/2006 on local government finance establishes the following principles: universality, *transparency and publicity*, unity, monetary unity, annuality, budgetary specialization and balance. The principle of transparency and publicity requires that the budget process is an open and transparent one, this being achieved by: (1) publishing in the local press, on the website of the public institution or by displaying at the local public administration authority the draft of the local budget and annual account of its implementation; (2) public discussion of local budget draft, during its approval and (3) presentation of the annual account of local budget execution in public meeting.

Procedures for advertising and publishing the budgets of territorial-administrative units are presented in Law 273/ 2006, article 76, with ulterior modification. According to this article the principal officers of local public institutions have the obligation to publish on the websites of territorial-administrative units the following documents and information: budgets' draft stipulated in art. 1 paragraph. (2) subjected for public consultation, including their annexes, within two working days of the submission to the public consultation; communications such as quarterly and annual are prepared financial statements on the budgetary execution, within 5 working days of their receipt; budgets stipulated in art. 1 paragraph. (2) approved, including their annexes,

within 5 working days of the approval; financial statements on quarterly and annual budgetary implementation for budgets stipulated in art. 1 paragraph. (2), including outstanding payments, within 5 business days after their deposit with the general directions of public finances; general budget of the public administrative unit, prepared according to the methodology approved by order of the Ministry of Internal Affairs and the Minister of Public Finance, within 5 working days of the submission of the council; register of local government debt and guarantees local registry, updated annually by 31 January of each year and public investment program of the administrative-territorial unit within 5 working days of approval.

The article 1 point 2 in the Law 273/ 2006 refers to: local budgets of communes, towns, municipalities, districts of Bucharest, counties and Bucharest; budgets of public institutions wholly or partly funded from local budgets, as appropriate; budgets of public institutions financed from own revenues; budget of external and internal loans for which repayment, payment of interest, fees, expenses and other costs are paid from local budgets and from: external loans contracted by state and sub-loaned to local authorities and / or operators and public service subordinated to them; loans to local government authorities and state-guaranteed, foreign loans and / or internal contracted or guaranteed by local authorities and external grants budget.

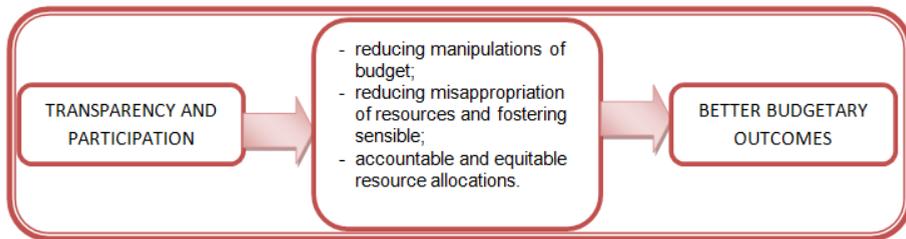

At the European level the Financial Regulation establish that the budget shall be established and implemented in accordance with the principles of unity, budgetary accuracy, annuality, equilibrium, unit of account, universality, specification, sound financial management which requires effective and efficient internal control, and transparency, information found on the website <http://ec.europa.eu>. According to Article 34, point 2 in the Financial Regulation the budgets shall be published within three months of the date on which they are declared definitively adopted. From these articles we see that the transparency of budgets is regulated at the level of European Union so the Romanian legislation must reflect the requirements of the European one. Thus, the Law on public finances (500/2002) is aligned with the Council Regulation on the Financial Regulation nr.1605/2002 on the budget of the European Community.

#### **4. Budget Transparency**

Around the world politicians and not only are realizing the existing relationship between good governance and increasing economic and social outcomes. The key element of good governance in today global economic environment is transparency that can be defined as the openness of public authorities (central and local) regarding their policy intention, formulation and implementation. It is obvious that the budget is the “governments’ key policy document”. Budget transparency is defined as the full disclosure of all relevant fiscal information in a timely and systematic manner. Budget transparency is a precondition for public participation in budget processes. The combination of budget transparency and public participation in budget processes has the potential to combat corruption, foster public accountability of government agencies and contribute to judicious use of public funds (OECD, 2002).

Budget transparency represents the mean through which ordinary citizens and civil society organizations can access information about the allocation and use of public resources, so that they can assess how government officials manage public funds. The lack of transparency and democratic control sustain a proper environment for graft and corruption, while citizen and civil society organizations can’t analyze

and monitor budget implementation and assess if the objectives established in the initial budget were obtained by the local government. Some of the benefits of transparency are presented below:

**Figure 1:** Benefits of transparency and participation in the local budgetary processes  
Source: own processing after Pekkonen and Malena

Regarding budget transparency there are a lot of initiatives and concerns at the international level resulting in guidelines or technical standards developed by international organization regarding data presentation and fiscal management procedures relevant to fiscal transparency. We can mention here the Organization for Economic Cooperation and Development (OECD) Best Practices for Budget Transparency, International Monetary Fund's (IMF) Code of Good Practices on Fiscal Transparency, United Nation's International Code of Conduct for Public Officials, International Budget Partnership's Open Budget Initiative, International Accounting Standards for the public sector (developed by the Public Sector Committee of the International Federation of Accountants), data dissemination standards (established by IMF and containing standards for providing economic and financial data to the public), fiscal reporting standards (included in the IMF' Manual of Government Finance Statistics), international accounting control guidelines (established by the International Organization of Supreme Audit Institutions (INTOSAI) regarding internal controls), international standards for government auditing (set by INTOSAI) and the fundamental principles of official statistics (set by the United Nations Statistical Commission regarding the integrity of official statistics). All this international movement regarding fiscal transparency determined, in the recent years, a reaction of civil society from developed countries for improvement of budget transparency. The OECD Best Practices for Budget transparency has three major pillars: budget reports, specific disclosure and ensuring integrity. Regarding the first pillar, budget reports, the OECD Best Practices states minimum content and specific periods when budget reports must be issued. The IMF's Code of Good Practices on Fiscal Transparency establishes a set of principles and guidelines for a sound transparency framework regarding fiscal policy. The IMF's Code is structured around four pillars (IMF 2007a, 2007b): Clarity of roles and responsibilities; **Open budget processes**; **Public availability of information and Assurances of integrity**. The last three pillars of the Code have multiple similarities with the OECD Best Practices and even go further in several aspects. Not only for public administration and political science the transparency in public financial management received increased attention but also for the economics research, that focused especially on testing the benefits of fiscal transparency such

as lower sovereign borrowing costs (Glennester and Shin, 2008), limited creative accounting (Alt, Lassen, & Wehner, 2012), improved fiscal performance (Alt & Lassen, 2006a, 2006b) and decreased corruption (Reinikka & Svensson, 2004). Authors such as Esteller-Moré and Polo-Otero (2008) explain fiscal transparency through combining political competition variables with tax pressure, while Hanssen (2004) checks the hypothesis according to which budgeting practices will be more transparent in systems marked by high political competition.

The International Monetary Fund (International Monetary Fund, 2007a:8) sustains that budget transparency “helps to highlight potential risks to the fiscal outlook that should result in an earlier and smoother fiscal policy response to changing economic conditions, thereby reducing the incidence and severity of crises.” According to International Budget Partnership “transparency means all of a country’s people can access information on how much is allocated to different types of spending, what revenues are collected, and how international donor assistance and other public resources are used” (OBI, 2012).

Also budget transparency can be seen as an indicator of quality of institutions and countries’ credibility, this idea being confirmed by articles regarding transparency and by rating scales based on transparency (Hameed, 2005). According to OBS 2012 the new evidence on the impact of budget transparency and accountability indicates: transparency can help attract cheaper international credit; opacity in fiscal matters can undermine fiscal discipline; transparency and public participation can help shine the light on leakages and improve efficiency in public expenditures and transparency and public participation foster equity by matching national resources with national priorities.

## **5. Case Study Regarding Budget Transparency in the North-West Region**

In this part of our paper we try to see if the procedures for advertising and publishing the budgets of territorial-administrative units that are presented in Law 273/ 2006, in article 76, with ulterior modification, concerning the obligation of principal officers of local public institutions to publish on the websites of territorial-administrative units the budgets’ draft, financial statements on the budgetary execution, the approved budgets, financial statements on quarterly and annual budgetary implementation for budgets, the general budget of the public administrative unit, register of local government debt and guarantees local registry and public investment program of the administrative-territorial unit. To do this we selected the North-West Region of Romania that includes 6 counties, 42 cities of which 15 municipalities, 398 communes and 1,823 villages.

We searched on the websites of the county council and of the municipalities (mayors) for public information regarding the budgets. The six counties are: Bihor, Bistrița-Năsăud, Cluj, Maramureș, Satu-Mare and Sălaj. The district’s residence for the counties mentioned are: Oradea, Bistrița, Cluj-Napoca, Baia-Mare, Satu-Mare and Zalău. Our analysis will be conducted only for the information published by the 6 County Councils on their websites and the 6 municipalities just mentioned. For the 6 counties the data was collected in 7<sup>th</sup> of April 2013 and for the municipalities on 29<sup>th</sup> of April 2013. The results of our analysis are presented in the tables below:

**Table 1: Available information on the websites of the County Councils from the North-West Region**

Source: own processing

From the table it is obvious that none of the six county councils has complete information on their websites as required by law 273/ 2006. Moreover, there are some of the documents stipulated by law that can't be found on the websites of the institutions or if they can be found, the documents aren't unitary published, such as quarterly reports on budget execution. From the analysis websites we found that there isn't a unified presentation of financial information at the level of the county council in North West and this type of information, in some cases, it is difficult to find on the websites because there isn't created a special page for this information. Of the six websites analyzed the best structured website and that included the most comprehensive information is the website of Satu Mare county council.

The same conclusions are applicable for the 6 municipalities taken in out study. What we can mention here is that the municipality of Cluj-Napoca has on its web site a page entitled "Participatory budgeting", this being an unique initiative in the studied Region.

The International Budget Partnership realizes the so-called Open Budget Survey that measures the state of budget transparency, participation, and oversight in countries around the world and it consists of 125 questions, being completed by independent researchers in the countries assessed. Ninety-five of the questions deal directly with the public availability and comprehensiveness of the eight key budget documents that governments should publish at various points of the budget cycle. The Survey does not reflect opinion. It measures observable facts related to budget transparency, accountability, and participation (OBS, 2012) In order to allow for comparisons across countries and over time, the IBP calculates the Open Budget Index (OBI), a simple average of the quantified responses for the 95 Survey questions that are related to budget transparency. Open Budget Index (OBI) score, a broad comparable measure of a country's budget transparency that can range from 0 to 100 as follows: Extensive Information (81-100); Significant (61-80); Some (41-60); Minimal (21-40) and Scant or No Information (0-20).

The OBI 2012 scores are not impressive because the average score among the 100 countries studied is just 43. Romania's OBI index is 47, this means that is greater than the average, but this means that there are only some information available to public. Even so, regarding changes in OBI scores over subsequent rounds of the Open Budget Survey for the period 2006-2012 Romania is framed at the worst performers (a decrease in the OBI score from 66 in 2006 to 47 in 2012). Regarding the study about changes in the publication of budget documents Romania appears among the countries that started publishing pre-budget statements and mid-year review. According to the survey the documents available to the public are: Pre-Budget Statement, Executive's Budget Proposal, Enacted Budget, In-Year Reports, Mid-Year Review, Year-End Report and Audit Report.

We consider that at the level of the county councils and residences from the North-West Region the budget transparency should be increased, this can bring lots of benefits, such as: more responsibly actions of the elected officials knowing that their decisions and actions are opened for public analysis; more equitable public spending; growing quality of public debate and more stable and predictable environment for investment decisions.

## **6. Conclusions**

Both political and citizens should be aware of the benefits of budgetary transparency, translated into better budgetary outcomes due to the opportunity to monitor and asses the government's financial management. All these are possible with the political will from public officials, who, as we know from experience, can have different interests in withholding information. If the will exists it must be accompanied by legal and institutional frameworks that sustain budget transparency. With all these there are some aspects that shouldn't be forgotten. One of these is the fact that the majority of citizens have low budgetary literacy level is hard to communicate lot of technical information (such the one written in budgets and reports) and this makes difficult the engagement of citizen to budgetary process because they can't identify at a personal level the budget impact. The solution for this is building budget literacy among citizens that determines a growing engagement of citizens in the budgetary process.

Transparency is a term hard to define from the point of view of governmental requirements. It shouldn't be understood as simple access to public information, it goes beyond this, requiring for public information to be understandable to external

stakeholders. In the current global context budget transparency is the major pillar of good governance of public funds and is a reference tool for budget practices and procedures.

# "THE KNOWLEDGE TRIANGLE" IN A KNOWLEDGE-BASED SOCIETY

**Rus Mircea-Iosif**

*Finance Department*

*Faculty of Economic Sciences and Business Administration*

*Babeş-Bolyai University Cluj-Napoca*

[mircearus2005@yahoo.com](mailto:mircearus2005@yahoo.com)

**Abstract:** *The knowledge-based society is the stage where mankind is found and aims to raise the living standards of population but also to increase the level of knowledge. To achieve this latter goal, the states of the world, and especially those in the European Union, must ensure an adequate funding for its realization, and therefore in 2011 it was decided at EU level the achievement of an Innovation Union, in which are to be involved all the European countries, while to stimulate and finance research and innovation the Horizon 2020 program was proposed. The results of the Program, an "Innovation Union" have begun to be felt, so in 2011, the major companies headquartered in the European Union increased their investments in R&D by 8.9% compared to 6.1% in 2010. This increase was almost equal to that of the U.S.A. companies (9%), higher than the world average (7.6%) and superior to Japanese companies (1.5%). The sectors that used the research-development activity have tended to have increases in employment above average. I believe this information highlights the fact that the European Union may become attractive for research-development and innovation investments even for businesses outside the UE, and this can result in jobs creation and increasing competitiveness of this field of the states of the European Union. In the introductory part of the article, I have briefly presented general notions of the three component activities of the "knowledge triangle", in the second part I presented the knowledge society with several features, in the third part, I showed some provisions of the program to stimulate research and innovation Horizon 2020, in the fourth part, I presented an innovation activity connection to private enterprise and entrepreneurial initiative stimulation in the field innovation, and the conclusions shows that research does not stop with achieving the objectives and finding the outcomes research, but is it the background for further research, especially in the context of a new economy", where innovation through knowledge is the most important.*

**Key words:** *research, innovation, financing, knowledge society.*

**JEL classification:** *E25, E26, O28, O31*

## **1. Introduction**

Scientific research is a creative activity, which aims to enhance the volume of knowledge, including knowledge of man, culture, and to use this knowledge to acquire new knowledge etc.

Nowadays the concept of scientific research is used under the name of research - development.

Research, development and innovation, together, form the 'knowledge triangle' and represent the engine of economic and social development. The common concerns of all countries, for scientific research and science, appear as recognition of their role in ensuring the welfare and human civilization.

In the current context, scientific research should, too, be seen in the light of globalization. In this area there are also real-world problems:

- science and research must take into account: the globalization of the economic life, the deepening of international division of labor, increased international relations, the limited resources and their uneven distribution across the globe, environmental protection and sustainable development of mankind;
- the need for scientific research is a serious problem and requires great efforts which sometimes cannot be supported by a single state;
- the sustainable development issues have to be solved from an international perspective. (Plumb I. *et al.*, 2007)

The innovation process requires specific skills, that is to seize market opportunities in conjunction with technological developments, to identify various technical solutions and so on, as well as abilities that are to be won by employees, managers or to be embedded into a business organization.

The success of a knowledge-base" society depends on the interaction with the business environment and the resources available in order to generate new products and processes. The mechanisms through which these objectives can be achieved are given by the innovation process itself.

Developed industrial countries have more or less from a "closed innovation system" to an "open innovation system". While the label "open" may include a number a factors (legal, economic etc.), developments of networks including public-private partnerships or university-industry links is a key element. (Maasen P. & Stensaker B., 2011)

## **2. The knowledge-based society**

Knowledge-based society is a formal association of people with common interests who seek to combine knowledge from specific areas of interest, thus contributing to knowledge. Knowledge as a result of perception, learning and reasoning, constitutes the major component of any activity and in particular, of the socio - economic ones. Activities in the spheres of economic, social, cultural and other human activities are highly dependent on information and knowledge, which represent results, but also raw material of these processes.

Society has always relied on knowledge, even if promoted by empirical methods such as observations and experiences that led to generalizations passed down from generation to generation. Mutations produced in contemporary society consists in the introduction of new technologies, which removes the barriers of space, transmission, storage, sharing and storing information and knowledge, providing a favorable environment for fertilization of ideas, leading to increased potential for knowledge generation and transformed it into the most important asset of contemporary society. (M. Muresan, 2011)

It is now a certainty that knowledge organizations emphasize, not only new phenomenology, but also induce a different view on how to conceive and practice management. Because new types of actors, but also roles, appear, because the typology of management practices is changing radically, it was found that the activities related to the production of knowledge (innovation), its dissemination (communication) and its acquisition (learning) are not compatible with an authoritarian leading or an hierarchical strict and comprehensive control.

On the contrary, their subtle character blurs the distinction between the formal and informal side, while, the outside official controls that became inoperative, are no

longer justified. In other words, the separation between management and execution is irrelevant because, as of now, the act of management focuses on developing problems of strategic vision and on facilitating coordinated action of relevant and cooperative actors, which are self-responsible, including in terms decision. (Popescu V.A. *et al.*, 2011)

The overall policy objective of the Lisbon strategy launched in a 2000 year was the transition of the European Union to a knowledge-based economy and society by a 2010 year. While this encompassing view implied a systematic approach, the European Knowledge landscape remains fragmented. The European Commission has been expressing the need to better integrate all the parts of the knowledge policy agenda for some time, noting in particular:

- the lack of innovation and entrepreneurial culture in research and higher education;
  - a lack of investment, in particular private investment, in research and development (R&D);
  - the difficulty Europe has in translating R&D results into commercial opportunities.
- (Hervás S. F. & Mulatero F., 2010)

Basic research is now carried out in a diversified institutional framework: universities, research institutes, companies and consortiums thereof. In some cases it can be transferred very rapidly in the correct application. On the other hand, it can lead to unexpected applications years later and in areas relatively distant from the original. Currently the private sector finances supports more than half and two thirds from research and technological development in Europe. Private investment in research and development in Europe, after a relative decrease, register again, an increase in the recent years. Multinationals and international investments have remained high and even increased. Due to globalization of the economy, these companies have developed strategies for research and development on an international scale, with alliances, mergers and acquisitions that have increased in each sector.

It follows that investment in research and development from the private sector in Europe is lower than that of competitors in the United States and Asia, due, in particular, to lower research efforts of SMEs. In Europe, these trends are essentially represented by the companies that make or use technology and whose future depends on their own capacity to develop. But, only a limited number of small businesses exploit the potential of high technologies, while establishing companies that sell the results of research and development is still at low levels in Europe.

On the other hand, European financial market did not sufficiently discovered the economic value of investment in knowledge. Even if it started to grow, the amount of venture capital focused on innovation is still limited in Europe. Such capital investment in the high-tech sectors and in the creation of such companies is much lower than in the U.S. So the climate for private investment in research in Europe needs, greatly, to be improved. (Popescu D.I. *et al.*, 2006)

The concept of knowledge society is used interchangeably with the knowledge-based economy (knowledge-based economy). The two concepts are related but not identical. Intensive use of knowledge, including knowledge generating, is the essence of some economic processes that have resulted. On the other hand, "society" is a more comprehensive framework than economy and progress towards the knowledge society will have, beyond the economic effects, the consequence of a better realization of the human personality. (Plumb I. *et al.*, 2007)

The relationship between Knowledge investments, innovation and competitiveness is an important topic in both academic research and economic policy and has been

studied extensively over the past decades. Nowadays, investments in private and public R&D are believed to make up the heart of a modern knowledge economy in a knowledge-based society. (Van Hemert & Nijkamp P., 2010)

### **3. „Horizon 2020” programme for research and innovation stimulation**

European Union in the context of the transition to the knowledge society aims to provide a framework for a smart, sustainable and inclusive growth. Knowledge society and innovation involves the integration of new technological infrastructure, the processes of research, development and innovations, as well as the educational ones, contribute directly to the development of intellectual capital, the main resource of current society. Knowledge generation, based on stimulating the use of intellectual capital is the key factor to increase competitiveness, to ensure sustainable growth and to increase social integration level. To achieve these strategic objectives, the European Union stated some precise targets. Because research and innovation targets set for 2020 includes the 3% of GDP for supporting this field, and for the field of education represents the diminishing school dropout to below 10% and the increasing number of tertiary graduates in the age group 30-34 years to 40% of the total population.

EU strategy provides better exploitation of the potential of economic growth, having as main priorities: research, development and innovation, as well as improving the educational process. The specific program for the research and innovation (Horizon 2020) provides:

- ✓ transforming the European Union into an Innovation Union;
- ✓ improving cooperation between the business environment the academic one by creating „Alliances based on knowledge ”;
- ✓ creating new partnerships between universities, research entities and companies in the business sector (communities based on knowledge and innovation);
- ✓ improvement of research and innovation systems, especially of private ones.

The strategic framework on research and innovation 2014-2020 is correlated with the Union Strategy for 2020, following: ensuring excellence in science, providing industry leadership (including active support for the SMEs), providing an adequate response to societal challenges. To finance the „Horizon 2020” program, funds worth 80 billion are provided to implement these policies, which demonstrates their importance. (European Commission, 2011)

### **4. Stimulating entrepreneurial initiative**

In times of rapid technological change, the need to prevent technological accidents at all stages (research, experiment, industrial use, consumption) should be well balanced with the need to maintain the pace of development and not to increase the already high costs of the more radical innovation.

Trade agreements between countries can have, also, lasting consequences for the locations of new industries. Mobilizing private finance for innovation system depends largely on the sophistication of financial market mechanisms for risk assessment of failures cost innovation and presentation. In most countries these market mechanisms are still immature. This creates financial bottlenecks that affect more advanced innovations that go beyond market borders, than the modest, incremental, innovations.

Resources released by these blockages can launch new businesses, so to resume the business cycle. This creates a challenge for governments, especially in countries where entrepreneurship in large business organizations and / or "governmental entrepreneurship" have traditionally played a leading role in the generation and exploitation of technological progress.

The main conditions that must be fulfilled for the entrepreneurial engine to operate efficiently are:

- A financial education;
- The proper functioning of the products;
- An appropriate regulatory framework for business: creating, trading, closing businesses,
- Development of entrepreneurial training and management skills;
- Facilitate SMEs' access to new technologies and information.

Financial markets can provide value and appreciation to the specific knowledge of the company, to a certain extent by share price, but this do not evaluate good the intangible assets. Labor market assigns value to knowledge embedded in individuals, certificates of education and training systems through awarded higher wages or business opportunities.

Another concern is the interactions between labor market and social esteem for determining long-term effectiveness, efficiency of human capital, regarding the formation and its allocation on the attractiveness of engineering or scientific careers. Government can intervene through its macroeconomic management: interest rate has an impact on the current value of knowledge embedded in capital goods and, more generally, on private investment in long-term research. Thus, when production is financed as a public good, is supported and researched as good for business and training, infrastructures that increase the profitability of some private investment in knowledge are achieved. (Popescu R., 2007)

## **5. Conclusions**

Scientific research should not be regarded as definitive completed once obtaining final results. They concern, as task, as achievement for the moment, only reaching the objectives pursued at the beginning of research. But beyond these targets are foreseen other matters, most of which are new, that appear as possible and / or necessary future research topics. Because of this, research results can be used either immediately applied in a practical sense or in a theoretically sense. In the latter case, they will be prerequisites for future research. (Gheorghe I. G., 2008)

At this point mankind is in the third revolution that is driven by THE knowledge-based service sector. Although, over time, the laws of economics have not changed, however, the economy itself has changed in a fundamental way. There are several important aspects of the knowledge economy, which is also called, „the new economy“, that are different and are marked differently from, „the old economy“. These differences between the two as „economies“ can be compared with the differences that led to the transition from the agrarian economy of the nineteenth century to the twentieth-century industrial economy. Thus, if in the industrial economy capital was more important than land, in „the new economy“ innovation through knowledge is the most important aspect. Currently most aspects of the economy are characterized by it. In the global knowledge economy, the advantage of some nations over others will result, not only from the use of natural resources

owned or by cheap work force, but also from their ability to assert their intellectual capital.

# THE PRO AND CONS OF THE NEW TREATY ON STABILITY, COORDINATION AND GOVERNANCE IN THE ECONOMIC AND MONETARY UNION

**Talpos Ioan, Avram Alexandru**

*Faculty Of Economics And Business Administration, West University, Timisoara, Romania*

*ioan.talpos@gmail.com*

*alex1avram@gmail.com*

**Abstract:** *In our study, using a descriptive research methodology based on survey and data interpretation, we are trying to state our opinion regarding the pro and cons of the Fiscal Compact, wheather our country made a step forward towards fiscal stabilization or a step backwards towards the space for manouver of the fiscal policy. Stability and Growth Pact, signed in Amsterdam in 1997, maintained the two limits set by the Maastricht Treaty, signed in 1992, namely those set within 3% of GDP for budget deficit and 60% of GDP for public debt, and established at the same time the regulatory framework for the coordination of national fiscal policies in the EMU. Medium-term objective, enshrined in the Stability and Growth Pact, is for the budgetary position of the Member States of the euro zone to be "close to balance or in surplus" – and to enable them to deal with normal cyclical fluctuations without exceeding effectively the 3% of GDP budget deficit. Achievement of the medium-term objective requires rapid evolution towards a sustainable situation, able to generate sufficient fiscal space for the promotion of discretionary fiscal policy measures - such as those embodied in the increase of budgetary allocations for investments in infrastructure.*

**Keywords:** *budget deficit, public debt, fiscal rules, restrictions, automatic fiscal stabilizers*

**JEL classification:** *E32; E62; H61.*

## 1. Introduction

Maximum limit of 3% of GDP for the budget deficit - included in the Stability and Growth Pact – is a limit that can not be reached every year, but the high level which can not be exceeded even in adverse economic conditions.

Thus, in periods of **economic expansion**, the total value of income taxes and social contributions mobilized at consolidated state budget increase - due to increasing the size of the base of calculation of tax or contributions, without implying any change in the fiscal policy or growth of the collection of taxes and social contributions. At the same time, the total volume of various monetary compensations and payments for unemployment allocations decreases and the result of these developments is that *the actual budget deficit is reduced or even a positive budget balance (surplus) is achieved.*

*Ensuring an adequate budgetary position, which is not dependent on cyclical fluctuations in the economy and can be capped at 3% of GDP for the actual budget deficit even during economic recession, becomes essential for compliance with the Stability and Growth Pact stipulations and achievement of a sustainable fiscal position in the medium and long term.*

Because of the extension of economic recession in many Member States of the euro zone, in order to strengthen the surveillance of budgetary positions and coordination

of economic policies, after several meetings of finance ministers, prime ministers and heads of state, on 2 March 2012 (i.e. after nearly 15 years of operation of the Mechanism of Stability and Growth), 25 of the 27 Member States of the European Union - with the exception of the United Kingdom of Great Britain and Northern Ireland and the Czech Republic - signed the **Treaty on Stability, Coordination and Governance in the Economic and Monetary Union (EMU)**. In the structure of this Treaty, the most important component is the **European Fiscal Compact** aimed at *strengthening fiscal discipline in Europe* by introducing penalties to be applied "in a more automatic manner" and a stricter supervision.

Unlike the **Stability and Growth Pact (SGP)** - medium-term objective of which was that budgetary positions of euro zone Member States to be "close to balance or in surplus", the new treaty includes the requirement that **national budgets "should be balanced or in surplus"**, and this requirement will be met if the annual structural deficit does not exceed 0.5% of GDP. This "rule of a balanced budget" should be introduced into national legislation, preferably at constitutional level, within one year of the entry into force of the Treaty - which will happen after it is ratified by at least 12 Member States of the Economic and Monetary Union, becoming afterwards mandatory for all members of the EMU. Other Member States of the European Union will come under the provisions of the Treaty on the adoption of the single currency or earlier if requested to do so.

If a member state has a public debt significantly below 60% of GDP and the risks to long-term sustainability of public finances are reduced, it is allowed to have a structural budget deficit of more than 0.5% of GDP, but not more than 1% of GDP. Failure to meet this requirement regarding the structural deficit will trigger an "*automatic correction mechanism*" – which shall be determined by each Member State on the basis of principles proposed by European Commission.

The authority responsible for monitoring compliance with this rule of a balanced national budget or in surplus is the **European Court of Justice**; its decisions are binding, and the failure to respect them can be followed by fines of up to 0.1% of GDP for Euro zone member states to be paid to the "European Stability Mechanism".

## **2. Structural Budget Deficit and the Impact of Discretionary Fiscal Policy on Aggregate Demand**

The real budgetary position or fundamental fiscal position, as stated in the Report of Fiscal Council of Romania for year 2011 (*Annual Report of the Fiscal Council for 2011. Macroeconomic and budgetary developments and prospects, 2012*) contains the data needed to calculate the budget balance adjusted cyclically or structurally, which is obtained by deducting from the actual budget balance the effects of the economic cycle on the general consolidated budget.

In this context, the structural deficit is defined as the size of budget deficit that would be recorded if GDP was at its potential level or could be recorded without the influence of the economic cycle.

Actual budgetary position has two components, depending on the factors causing them - temporary and permanent factors - and the determination of the structural budget deficit is based on the identity:

Actual Budget Deficit = Cyclic Budget Deficit (as effect of the action of automatic stabilizers) + Structural Budget Deficit (result of the discretionary fiscal policy)
--

Cyclically adjusted budgetary balance represents the most important reference point for defining the objectives of a state's fiscal policy, providing premises for action to reduce economic fluctuations due to automatic stabilizers' influence and, consequently, long-term sustainability of public finances.

Automatic stabilizers action points out that evolution of tax revenues and social security contributions is interrelated with their position in the economic cycle, to which the change of size of some categories of budget expenditures is added and the effect is abatement of cyclical fluctuations.

As mentioned above, in the event of economic expansion, budgetary revenues related to direct taxes (profit tax, dividend tax, income tax, tax on buildings owned businesses) and indirect taxes (VAT, excise duties) as well as social contributions collected by the state are increased, and the result is the relative decrease in the population and economic operators' level of income which reverberates on the solvable demand that goes down, effects being the mitigation of the economic growth and the return of GDP at its potential level.

Conversely, when economic recession is installing, revenues such as those mentioned above are smaller, and budget expenditures for support allocations, various monetary compensations for dismissed employees and unemployment payments increase, with positive impact on income remaining available to economic operators and population, favouring overcome of recession and return to economic growth and GDP reaching its potential level.

Undoubtedly, the effectiveness of automatic stabilizers' action depends on the size of government sector and the elasticity of budgetary incomes and expenditures in relation to the cyclical fluctuations of the economy. Thus, it is doubtless that the larger the dimensions of government sector, the more extensive is the variation in budgetary revenues and expenditures in relation to cyclical fluctuations of the economy and the dampening effect of these fluctuations like a result of the automatic stabilizers' action is higher.

In the last three years, the global economic crisis has highlighted that in terms of important shocks of aggregate demand, monetary policy is unable to respond with significant impact on economy, if the transmission mechanism is blocked by the conditions existent on financial markets. In this case, if there is an appropriate fiscal environment, is required to be promoted and expansionary discretionary fiscal policy, although some disadvantages are associated to it, with reference to: requirement for a relatively long implementation period; high intensity of political influences; lack of automatic reversal when the position in the economic cycle changes.

Automatic stabilizers do not have these disadvantages, but, as mentioned in some of the specialized literature (Cottarelli and Fedelino, 2009), (Baunsgaard and al., 2009), their effectiveness increases when the importance of government sector grows or if the progressive of taxation goes higher.

After reviewing the Stability and Growth Pact in 2005, the cyclically adjusted budget deficit has become the focus of fiscal surveillance mechanism of the European Union - in the sense that the key requirements imposed on EMU Member States in matter of fiscal policy are expressed in cyclically-adjusted and net values of temporary or single ("one-off") measurements.

Using the cyclically adjusted budget deficit concerns both the sustainability of public finances and the impact of discretionary fiscal policy on aggregate demand due to fiscal stimulus (which is calculated as the annual change/deviation of the structural deficit compared with the previous year's one). Thus, a positive fiscal impulse, corresponding to an increase in the structural budget deficit, reflects an incentive fiscal policy - embodied in reducing taxes and increasing the size of budgetary expenditures, while a negative fiscal impulse, which corresponds to a reduction of the structural budget deficit, indicates a restrictive fiscal policy - characterized by raising taxes and reducing the size of government spending. Taking into account the cyclical position of the economy, it can be assessed whether fiscal policy acts as macroeconomic stabilizer - to reduce pressure on aggregate demand during periods of economic expansion or to stimulate aggregate demand during economic downturns.

According to the identity mentioned in the first part of the paper, the budgetary deficit in structural year  $t$  (or CAB $t$ , "Cyclically Adjusted Budget  $t$ ") is obtained by subtracting the cyclical component (CC $t$ ) of the actual budget deficit (or budget balance - BB $t$ ), corresponding to the relationship:

$$\text{CAB}t = \text{BB}t - \text{CC}t = \text{BB}t - \varepsilon\text{OG}t \quad (1)$$

Structural budgetary deficit is the tax position in which the GDP is at its potential level, i.e. when the economy is midway between an economic "boom" economy and a recession in economy (Dumitru, 2012).

The size of the cyclical component of the actual budget deficit is given by the effective output - gap (OG) - which represents the percentage deviation of actual GDP from its potential level, multiplied by the cumulative sensitivity parameter of budgetary income and spending ( $\varepsilon$ ) at the change of economic activity's volume, estimated with econometric models.

For Romania, the sensitivity parameters were estimated as: 0.28 for revenues and 0.02 for budgetary expenditure, resulting a total sensitivity parameter ( $\varepsilon$ ) equal to 0.3 (Larch and Turrini, 2009). Estimating the structural budget deficit is made, either based on the Blanchard methodology (Blanchard and al., 1990) – consisting in the direct estimation of cyclically adjusted revenues and expenses by using regression analysis, or using the alternative methodology proposed by Carine Bouthevillain and all in 2001, which shows that estimation of budgetary components' elasticity is made by reporting directly to the relevant macroeconomic bases (GDP, private consumption, government consumption and so on) rather than output - gap, thus taking into account the changes that occur in the structure of aggregate demand and revenues.

### **3. Analysis of the actual deficit trend and structural budget deficit for Romania in the period 2006-2011**

In Romania, the actual balance of consolidated state budget for the period 2006 - 2011 was negative, registering an annual budget deficit, as shown in Table. 1.

**Table 1:** Evolution of Romanian GDP and budgetary aggregates, during the period 2006-2011

- Mil. Lei and % -

Nr	Name		2006	2007	2008	2009	2010	2011
1	GDP		344.651,0	412.762,0	514.654,0	491.007,5	511.582,0	563.100,0
2	Budgetary Revenues	abs. val.	106.975,3	127.108,2	164.466,8	156.624,9	168.674,2	181.566,9
		% of GDP	31,04	30,80	31,96	31,90	32,97	32,24
3	Budgetary Expenditures	abs. val.	112.626,3	136.556,5	189.121,5	193.025,5	202.282,0	210.054,0
		% of GDP	32,68	33,08	36,75	39,31	39,54	37,30
4	Actual Budget Deficit	val. abs.	-5.651,0	-9.448,3	-24.654,7	-36.400,6	-33.607,8	-28.487,1
		% of GDP	-1,64	-2,28	-4,79	-7,41	-6,57	-5,06
5	Cyclic Component of State Budget	% of GDP	2,10	0,70	3,80	-0,60	-0,83	-0,61
6	Share of Structural Budget Deficit in GDP	% of GDP	-3,74	-2,98	-8,59	-6,81	-5,74	-4,45

Source: Ministry of Finance reports on the consolidated general budget during the period 2009-2012, Convergence Programme 2009-2012 and own calculations.

As can be seen from the data presented in the Table, the evolution of budgetary revenues, in absolute value, is increasing during the period (excluding the drop in 2009) - from 106 975,3 million to 181566,9 million, with share in GDP ranging from 31.04% in 2006 and 32.24% in 2011 – which are some of the lowest percentages in the EU, as shown in figure 1. Increase in the absolute amount of budget revenues totaled 74591,6 million lei at the end of 2011, being with 69,73% over the revenues from December 31, 2006.

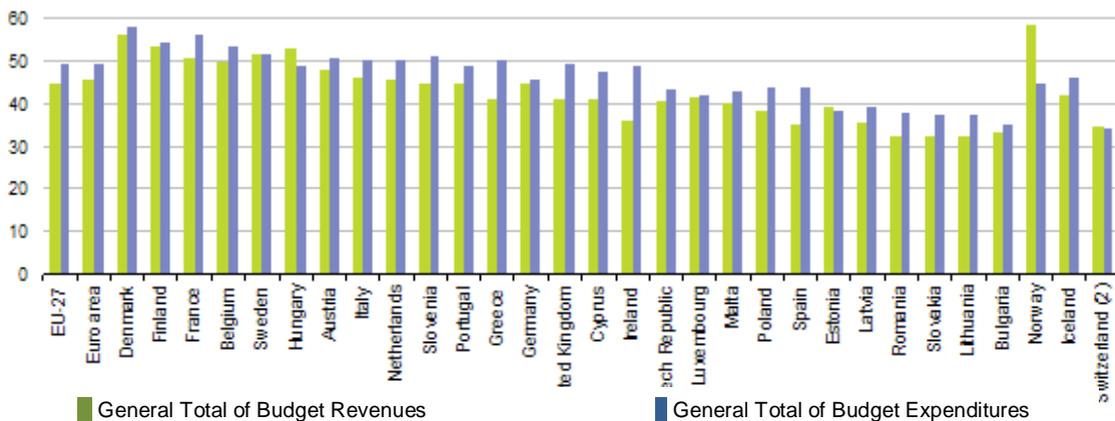

Budget expenditures increased constantly during the period - from 112626,3 million in 2006 to 210054,0 million in 2011 (with an increase in absolute amount of 97427,7 million, i.e. 86.51% ) and shares in GDP increased from 32,68% in 2006 to 39,54% in 2010 (the "top" period) and, respectively, to 37,30% in 2011. These percentages in GDP, as those revenues are among the lowest in the EU, as shown in Figure 1.

The size of the actual budget deficit has recorded significant annual increases, in nominal terms, during 2006-2009, with 67,2% in 2007 compared to 2006, with 160,94% in 2008 compared to 2007 and 47,64% in 2009 compared to 2008.

Most significant increase in the size of actual budget deficit was recorded in 2008, compared to 2007 (with +15206, 4 million, i.e. .160.94%), but the "top" of the actual budget deficit was recorded at the end of reporting period 2009 (-36400, 6 million, accounting for 7.41% of GDP - which is the highest of the period).

In 2010, under the impact of fiscal stabilization measures undertaken by government authorities, the budget deficit was stopped, being registered a decrease of 7.67% of it, in nominal terms, compared to 2009.

In 2011, the general consolidated state deficit fell to 28487,1 million lei, with 5120,7 million lei (15,24%) compared to 2010, reaching to 5,06% of GDP.

Data from 23.04.2012, arranged in descending order by total average of income and expenditure.

**Figure 1:** Share of budgetary revenues and expenditures in GDP, within EU-27, Euro Zone, and Member States of the EU-27, Norway, Iceland and Switzerland.

Sursa: [http://epp.eurostat.ec.europa.eu/statistics\\_explained/](http://epp.eurostat.ec.europa.eu/statistics_explained/)

Budget balance at the end of 2011, *is however distorted* by the impact of clarifying the statistical treatment of Romanian state obligations to several categories of employees in the public sector, which were decided by court rulings. Thus, in the implementation of ESA95 of the general consolidated state budget were included additional expenses in the amount of 6400 million lei (1,1% of GDP), with corresponding increases in the budget deficit - both in nominal expression and as a share of GDP. In the absence of this temporary measure, the general state deficit (according to ESA95) would have been significantly lower than the target set in the Convergence Programme 2009-2012, prepared by the Government and adopted in April 2011 (4,9% of GDP) and below the level included in the Memorandum of Understanding with the European Union (under 5% of GDP), reaching a level similar to cash basis (4,1% of GDP). Elimination of the ordinary differential cash-accrual is explained mostly by the fact that a significant proportion of payments made towards the end of 2011 were for settlement of the arrears belonging to state-owned companies and the public health sector. Under a negative cyclical component (-0,61% of GDP), 87,94% of the actual budget deficit in 2011 is structural, reflecting the spread of fiscal consolidation measures introduced in mid 2010 and a further reduction the number of employees in the public sector. As a percentage of GDP, the actual budget deficit recorded values in continuous increase in the period 2006-2009, from a low of -1,64% in 2006 to a level of -7.41% in 2009. In 2010, the budget deficit actually decreased compared to 2009, but remained at a considerable value, representing -6.57% of GDP.

The following year, 2011, the actual budget deficit was further reduced, but its share in GDP remained still high, being 5,06%.

Doubled by a "twin" deficit of the current account, deficit of the general consolidated state budget may represent in the coming period a factor with negative impact on overall macroeconomic stability of the country.

It must however be noted that *the level of budget deficit is strongly influenced by the position of the economy in relation to the business cycle.*

Even a low deficit can hide serious imbalances in fiscal position to the extent that is due to an increase of budget revenues obtained by over stimulating the economy.

Therefore, it is necessary to balance the public budget over the economic cycle.

In this respect, a particularly important indicator is **the structural budget deficit**, based on the assumption that the current size of the budget balance is the result of the influence of factors with both permanent and temporary action.

Considering the cyclical component of the budget balance, which had positive values in the years 2006-2008 and, respectively, negative ones in the next three years, except in 2007, it results that in the remaining five years of the period, the share of structural deficit in GDP exceed 3% of GDP, *indicating a relaxation of fiscal discipline.*

The increase of actual and structural budget deficit was due to an increase almost "exuberant" of public spending (which evolved increasingly from 32,68% of GDP in 2006 to over 39% of GDP in 2009 and 2010 and, respectively, 37.3% in 2011), and based on the relative stability of revenues that only in 2010 were close to 33% of GDP (32,97%). During 2008 and 2009, the structural budget deficit increased significantly from a level of -3,74% of GDP in 2006 to a high of -8,58% of GDP in 2008 and to -6,81 of GDP in 2009, *as a result of inadequate fiscal policy pursued by government authorities.*

This high rate of structural budget deficit in 2009 (-6,81%) is mainly the result of divergent evolution of revenues and expenditures. Thus, budget expenditures increased by 3.904 million from the previous year, reaching a share of 39,31% of GDP while revenues of 2009 decreased from the previous year with 7841, 9 million, representing 31,90% of GDP. These divergent developments of 2009 **led to recording the maximum effective budget deficit of that period**, with a percentage of -7,41% of GDP and a structural component of -6,81% (representing 91,9% of the actual budget deficit). Obviously, in 2006-2008, a period of expansion of the economic cycle, **it was necessary to promote a countercyclical fiscal policy and not a pro-cyclical expansionary fiscal policy.**

The efforts of fiscal consolidation undertaken by the government in 2010 caused the further downward trend in the structural budget deficit, reducing it to a level of -5,74% of GDP at the end of 2010 and -4,45% at the end of 2011.

These efforts should be appreciated in terms of the tolerance or indulgence that was shown by the employees in the public sector and pensioners who have been their incomes "cut"! But we should not overlook the fact that *European authorities have initiated the procedure of excessive budget deficit for Romania*, requiring that, by the end of 2012, the actual budget deficit to fall below 3% of GDP.

Structural budget deficit is a particularly important indicator regarding the sustainability of the fiscal policy implemented by government authorities.

Since the growth of structural budget deficit is likely to lead to growth of unsustainable debt (Talpos and al., 2007), (Talpos and al., 2009), the evolutions

presented above should be an interference signal for a proper intervention of government authorities.

The changes occurring in the structural budget deficit's size provide at the same time information on the extent of stimulating aggregate demand through fiscal policy, and on the degree of fiscal consolidation.

The analysis of the structural budget deficit's dynamics correlated with the position of the economy in the economic cycle allows assessment of the extent to which the fiscal policy acts as a stabilizer or, conversely, in the sense of exacerbation of imbalances.

In Romania, in the period of rapid growth before the financial crisis (2006-2008), the fiscal impulse was positive (+2.1, +0.7, +3.8) contributing to the over stimulating of the economy and thereby increasing the imbalances accumulated the economy (*Annual Report of the Fiscal Council for 2011. Macroeconomic and budgetary developments and prospects*, 2012).

In addition, the pro-cyclicality of fiscal policy during the pre-crisis economic upswing *has exhausted the fiscal space necessary to stimulate the economy during the recession that followed*, the and the need to reduce the budget deficit during the crisis (primarily due to funding constraints) has inevitably *led to maintaining the pro-cyclicality of fiscal policy*. Thus, the automatic, beneficial and stabilizing action of cyclical budget deficit (automatic stabilizers) *was canceled by the pro-cyclical discretionary fiscal policy*.

The structural budget deficit decreased from -6,81% of GDP in 2009 to -5,74% and -4,45% of GDP During 2010 and 2011, the rate of adjustment being a very fast one; at the same time, we must bear in mind that the starting level was high (-8, 59%), which required the rapid adoption of decisive measures to ensure the sustainability of fiscal policy.

Adjustment was made mainly on the expenditure side, the structural reforms being promoted particularly in the fields of budgetary personnel's remuneration, the public pension system and budgetary programming. In terms of budget revenues, the most important measure was the increase in the standard VAT rate from 19 to 24%, starting from July 2010. The estimated cumulative adjustment for 2009-2012, undertaken by Romania is considered *to be the third most ambitious in the European Union*.

#### **4. Conclusions**

We believe that the major con for the new Fiscal Compact is generated by the restrictions imposed thus contributing to the narrowing of the space for maneuver of fiscal policy by limiting structural deficits. Also, referring the means of financing the budget deficit, there has been *an increase in recent years of the relative importance of recourse to domestic financing in the short term*. High aversion to risk of commercial banks in the Romanian banking system has led to their substantial involvement in this process, with the immediate consequence of reducing the funds available for lending financial operators.

The important effect of crowding out of public credit on private investments is confirmed by the perception of economic operators who consider the problem of access to financing as the main constraint the Romanian business environment is facing, also, the consumption behavior of the households is being distorted by the premises of those changes.

We consider that by signing the Fiscal Compact, our country has made a statement towards fiscal discipline thus becoming virtuous in the eyes of the foreign investors, this being the most important pro that we can identify. The full impact of this gaining in the image and credibility chapters is yet going to be felt on a medium and long term.

## WEATHER DERIVATIVES: THE MOST COMMON PRICING AND VALUATION METHODS

**Botos Horia Mircea**

*Finance Department, Faculty of economics and Business Administration, Babes-Bolyai University of Cluj-Napoca, Romania  
Horia.botos@econ.ubbcluj.ro*

**Abstract:** *In recent years , weather derivatives have become a common tool in risk management for sectors as: agriculture, energy, sports, etc. This is based on the fact that there is no unique way to determine the value and price solutions that would be generally approved by all market-participant. Not as in the case of the Black-Scholes formula for options on non-dividend-paying stocks, thus weather derivatives valuation being the source for a constant debate between academics and practitioners. One looks for fair and truly correct prices that include all factors, while the others search every-day applicable solutions that help transactioning. To be honest... this is somehow like alchemy. This paper's purpose is the examination of statistical characteristics of weather data, data clearing and filling techniques. The study will be referring to temperatures because that is the best analyzed phenomenon, being the most common. This was also heavily influenced by energy companies and energetic interests, because the degree days were of interest ever before weather derivatives were put for sale. The main ideas are explaining what ways of pricing and valuation are put into perspective for this financial instrument, taking into consideration that the Black-Scholes Model is not suitable, mainly cause the lack of historically correlated and uniform data. Also here, we will present the pros and cons that we found for each method. The methods are: the Burn analysis, the index value simulation method (IVSM), the daily simulation method (DSM). On the hole, this paper wants to shed light the weather derivatives pricing methods that are a mix of insurance pricing method and standard financial modeling methods. At the end we will prospect the discounting problem, by means of the Consumption based Capital Asset Pricing Model (CCAPM). This is all done empirically due to the fact that on the Romanian market these products are not yet used for either insurance or investment purposes.*

**Keywords:** weather derivatives, pricing, valuation, burn analysis, DSM, IVSM

**JEL classification:** G22, G24

Weather derivatives are financial "means" that can be used by companies or/and individuals as part of a risk management strategy to lower risk of adverse or unexpected weather conditions. The difference from other derivatives is that the underlying asset (represented by rain/ temperature/ snow) has no direct value to price the weather derivative on [The use of the black-scholes model in the field of weather derivatives, Horia Mircea Botoș, Cristina Ciumas, UBB Cluj, IC. EMQFB 2012, Tg Mures].

It is natural to assume a mean-reverting model for the weather. As with interest rates, it is unlikely that the weather next year will be 10 times higher than the weather this year.

The most important difference between interest rate derivative models and models for weather derivatives is the calibration process. Interest rate derivative models are calibrated to the market prices of liquid instruments, while weather derivative models are calibrated to past data. So far, an mature, active and liquid market does not yet exist for weather derivatives. On the other hand, we have a wealth of historical weather data. We are determining the parameters for which the probability of having generated the observed data is maximal.

The most common methods put forward for a efficient process of pricing and valuating weather derivatives are: the Burn analysis, the index value simulation method (IVSM), the daily simulation method (DSM).

Description of these methods will show that the mix origin of weather derivatives, of insurance and financial instrument, manifests its self even in pricing. This puts into perspective the frequent use of the Consumption based Capital Asset Pricing Model (CCAPM), when addressing them.

### **Temperature statistical characteristics**

In my studies until this point an action that seemed logical but rarely took place is *natural* hedging. But when it comes to weather this imply the question if risk can be better foreseen by a diversification and spread of the geographical coverage of the business. In a try to record correct and adequate features of temperature, many papers and companies study correlations between cities and/or countries. Such a paper is the one of Cao and Wei in 2004, and the result were impressing. They stated that by widening the geographical coverage, the risk diversification is very low, almost null, when it weather phenomena's. Cao and Wei computed the numbers for the USA, and Ferrer Garcia and Sturzenegger for Europe, the result being the same. As an example the correlation of temperatures in New York and Philadelphia is of 0.9853, thus showing that only 2.9% of temperatures changes in New York are correlated with changes taking place in Philadelphia. There study show that the lowers correlation was of 0.8443, between New York and Dallas that was still high. The same study in Europe had similar results. Correlations between countries in Italy, Napoli- Milano was of 0.9536. General correlations between temperatures in France and the Swiss was of 0.99, while between Switzerland and Great Britain were 0.9671. A later study show that the correlation between New York and London was 0.9531. The conclusion arising from these figures is that temperature diversification can't be internationalized, this it is recommended that's markets the use of weather derivatives.

Given the basic temperature properties registered at different location and intervals (times), explains the use of the DSM, that incorporates an adequate track of these processes:

- a) Warming trend: Meteorological research shows that it is possible that climatic trends to be cooler or warmer over time. Weather stations, generally register just warming trend because of constant city expansion. This phenomena is called "the heat island effect" and caused by the heat-storing properties of construction materials. This means that CDD[Cooling degree days] levels will rise over time, while the HDD[Heating degree days] level

will decrease. The more energy-efficient are the building materials, the closer the two values will be.

- b) Seasons: Temperatures have a sinusoidal pattern, caused by the seasonal variations. This is visible without any data processing by just looking at the data
- c) Heteroscedasticity: temperature has a stochastic volatility, which is more visible in winter than in summer.
- d) Auto-correlation: temperature patterns are strongly auto-correlated. For short lags the correlation is near to 1, afterwards decreasing visibly. This auto-correlation is significant and visible for lags of 365 units or multiples of it.

All the points made until now show that the historical data describe future outcomes are at the basis of the process of valuation and pricing for weather derivatives, but this can cause problems for the dealer when data sets are incomplete or display errors.

Temperature data sets can be obtained from a large variety of providers, but we would recommend the ones obtained from the national meteorological institutes. This because the data is more objectively recorded and the institutes are incorruptible in their recordings. Raw data sets are more affordable and easier to be put into research structures, while the cleaned data are expensive and, some times, less relevant because of their alterations. The data cleaning methods for weather data are not made public, but the standard methods put into practice on the raw data also provides relevant information.

Scientists have put into perspective that the Principal Component Analysis (PCA) outperforms other techniques, the Fallback Methodology being the second method recommended. But practitioners, and also Chicago Merchant Exchange, prefer the Fallback method (results are also easier to be come across when there are values missing).

### **The Black Scholes Model**

There are a lot of reasons why the Black Scholes model does not work. Firstly, weather underlying factors are not tradable or storable, thus a riskless portfolio cannot be built. Another motive why the BlackScholes equation fails there is heteroscedastic nature of weather and, we must take into account that, indexes are summations of previous actual weather outcomes. The degree days indexes are an accumulation of average daily temperatures, making them similar to Asian derivatives.

More details about this subject can be seen in one of the authors previous works.

### **The Burn analysis**

This method is sometimes referred as actuarial pricing. The model starts from the assumption that future temperatures can be predicted using just historical series of recorded temperatures. Computing security paid in the past and averaging pay offs in the last years, the buyer can estimate the expected profits at maturity. To presume that future gains can be determined from past performances, we need a lengthy data set, the problem being that this is susceptible to frequent errors. Cao and Wei demonstrated in one of their studies that payoffs almost quadruple switching the data set from 10 to 20 years. This reassess the question: who do we determine the right historical length. Hard to answer.

An element that we must take into account is statistical power and representativeness. Long term data sets smoothes out extreme events and give more information, short or medium sized data sets distort trends. As in the case of any financial transactions, one has to try to see the potential indicators of change of local effects. This present raised importance when pricing short term derivatives. Predictions here should include forecasts and shorter data sets. The length of a data set is a matter of definition, but all industries prefer to study the last 10-20 years. After the payoff is foreseen, the next point of interest is the actual price adjusted with a discount factor, as seen the in formula:

$$P_t = \frac{E^P(F[WI [t_1, t_2]])}{(1 + r_f + RP)^{t_2 - t}}$$

where:

$P_t$  = price of the derivative in "t"

F = payoff outcome index function

$E^P(F)$  = Cash-flow at maturity under the P-measure

P = historical measure

$r_f$  = risk free rate

RP = risk premium

An investor can be compensated for the risk loading through the weather derivative, this not being diversifiable. this means that when 2 diametrically opposed positions meet, the risk is fully diversified and no risk premium will be covered. Risk premium has to be negative or zero, thus the writer of the security accepts the inherent risk of any temperature outcomes. Premium size depends on the margins put into discussion, plus the bargaining power of the two parties involved( these two manifest an information asymmetry that can tip the balance into ones favor). The risk premium helps with the determining of the price risk is hard to determine:

$$\lambda \cdot \sigma = \mu - r_f$$

where:

$\lambda$  - market risk price for weather indexes  
 $\sigma$  - volatility of the weather indexes

$\mu$  - drift term governing the index stochastic process

As we take into account the rate sensitive derivatives, which have a lot in common with weather derivatives, a risk free portfolio would have to contain only two derivatives, with the same maturity and the same underlying subject, same weather station, same phenomenon. This is high improbable to be possible to make, specially taking into consideration OTC-Market data.

Now that we explain the perspectives on the Black Scholes Model and the Burn Analysis, let's take a look, at the more complex IVSM and DSM methods.

### The index value simulation method

The index simulation method (IVSM) presumes that the underlying index distribution under the Q-measure is sufficient to determine the maturity price for weather derivatives. The core of the method is molding the historical data into a distribution having the form and structure like a normal distribution in order to determine future developments.

With enough data available, we can make the distribution of the weather index like a degree days graph. The purpose is to transform it later on into an risk neutral measure in order to determine the risk free rate as the discount factor when computing the expected payoffs.[ Schirm, A, "Wetterderivate - Finanzmarkt produkte fir das Management wetterbedingter Geschäftsrisiken". Finanz Betrieb 11/2000,2000]

The discount factor would no longer incorporate an impending risk premium, but revealing that it would contain only the risk free rate. The expressed price takes the form:

$$P_t = e^{-r_f(t_2-t)} * \int_{-\infty}^{+\infty} F[WI[t_1, t_2]] * dQ'[WI[t_1, t_2]]$$

where: Q` = density of Q

In the use of the normal distribution, books recommend the Jarque-Bera to be done. Plots can also be used to test goodness. The graphic tools are intuitive, they compare data sets CDF to the Empirical CDF (cumulative distribution function). What results is:

- the PP plot: in the comparing of the Empirical and resulting CDF and then make a graph manifest great problems due to its S-shape. This model takes into comparisons the CDFs by their graph form: is the model works, it manifests as a straight line, slope towards 1, and intersecting 0. If the line does not intercept 0, the mean is wrong; a difference from 1 of the slope indicates a wrong volatility.

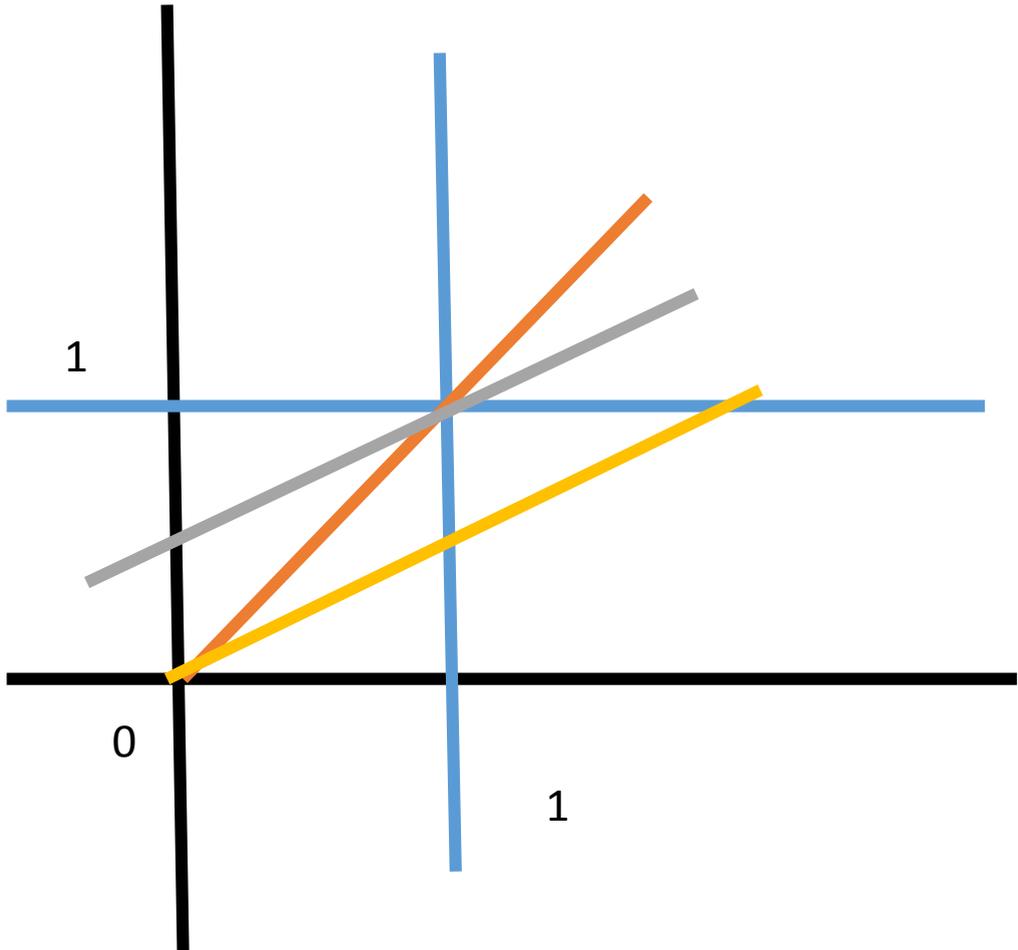

Figure1. Illustration of the PP Plot  
Source: made by Author

- QQ plot: The problem PP-Plot has is that presumes the CDFs start at 0 and end in 1. the extreme events take place in the tail of the distribution tend to straighten, even with a not proper fitting of the kurtosis. This plot overcomes this problem, because it compares quintiles. Also the optimal fit is a straight line , slope =1, interception point 0.

Other tests to check this are the Chi-square, Shapiro-Wilks, Kolmogorov-Smirnov or the Anderson-Darlings tests. The expressiveness is limited by the lack of available historical indices. We have to take into consideration that yearly only one degree day index value for season-contracts is catered, the number of values being limited. The shorter the data collecting periods, the smaller is the number of figures, nonetheless it exists.

The index value simulation method is more adjustable then the Burn analysis for the valuating the weather derivatives price tag. When normal distributions are present in

determining values or maturities, the IVSM can give closed form solutions for pricing weather derivatives. There are also some disadvantages, such as the normal distribution does not fit the degree days( it is to technical- degree days are positive or zero, while distributions can be negative, thus effects result on long periods, manifestances where a log normal or trimmed normal distributions). Another disadvantage is the computational power required for the data set new parameters being estimated for the maturities, thus making it very difficult the use of a single protocol in pricing weather derivatives. Probably the biggest inconvenience would be the lack of practicality due to the use of the Girsanov theorem ( that requires us to assume not transformation of the distribution). Thus by means of the Q-measure adjusted by the historic factor, the log normal distribution changes its form thus not being log normal any more. All this difficulties are reinforced by the fact that the risk free rate of returns does not have an equivalent for weather index, and the model does not permit switching to a neutral-risk.

### **The daily simulation method**

The limitation of the IVSM model, led to the creating of the daily simulation method that does not use the Girsanov equation, thus being easily applicable to different maturities, never the less manifesting its own complications. The idea tried was to generalize the Lucas model, thus doing a better pricing and valuation of weather derivatives (Cao and Wei). But while the largest number of papers explain the stochastic process adapted to weather derivative, Cao, Wei and Schirm thought that the "philosopher stone" would be found through the study if the discount factor under the P-measure.

The operation structure is: though a model that incorporates temperatures statistical characteristics we fit the historical data. Next step is a Monte Carlo simulation ran to show weather patterns, thus showing the possible scenarios of weather outcome. From the generated scenarios we determine the weather indexes, so being a step closer to finding the maturity payoff. This payoff is discounted by means of the equilibrium model, allowing a endogenous valuation (Cao and Wei present a endogenous price finding scheme, and Schirm a consumption based Capital Asset Pricing Model (CCAPM)) . Fully detailing this process is the primary idea of a future paper.

### **Conclusion**

Pricing and valuation of weather derivatives as not a task to be considered easy or approached without research-caution. As shown there are a variety of models, each with its set of obstacles. This sector is not standardized so, we can not point out an unique and perfect approach. The Burn analysis is intuitive, but may give large errors. The IVSM is the scientists choice, however by not being able to work in a fully risk-neutral environment, in practice is unreliable. The Daily Simulation Method works well, incorporating weather characteristics, discounting via the Lucas model adjusted with the consumption based capital asset pricing model. Despite the challenges it raises , the use of weather derivatives will prove to create suitable payoffs to compensate financial loss due to weather.

In my opinion, the finding of a generally accepted pricing and valuation model will cause a rise in the interest for this "insurance-investment" financial instrument.

# PROFITABILITY - CAPITAL STRUCTURE TRADE OFF: CASE OF PUBLICLY ROMANIAN COMPANIES

**Boțoc Claudiu**

*West University of Timișoara,*

*Faculty of Economics and Business Administration, Finance Department*

*Timișoara, Romania*

*claudiu.botoc@feaa.uvt.ro*

**Abstract:** *There is an increasing number of empirical works that test what drives firm profitability, since it is an objective and at the same time a frame of how a company is performing. The main aim of this paper is to test capital structure, noncurrent assets ratio and tax rate as determinants for profitability, with capital structure as main focus. Using a sample of 62 publicly Romanian for period 2001-2011 and panel data model the results suggest that financial statement variables considered are significant in gauging profitability. It was concluded that there is evidence for pecking order theory and firms with large amounts of noncurrent assets are under performing.*

**Keywords:** *profitability, capital structure, investment, taxation, financial statements.*

**JEL code:** *G30, G31, G32*

## 1. Introduction

Profitability is an important topic since it is an objective and at the same time a frame of how a company is performing. Not least, this effect has several implications for stakeholders, especially for listed companies.

There could be identified two major streams of research regarding determinants of firm profitability. First, economic tradition highlights the importance of external market factors in generating performance. Second, organizational approach is based on behavioral and sociological paradigm and suggests that organizational outcome is influenced by managers. In an integrated examination, factors from both streams seem to be as significant determinants for profitability. Furthermore, the results indicated that factors from organizational paradigm explain about twice as much variance in firm profit rates in comparison with factors from economic paradigm (Hansen and Wernerfelt, 1989).

Hirschey and Wichern analyze the accounting and market-value measures as determinants of firm profitability. Both types of measures can be used with caution as determinants of profitability, particularly R&D intensity, TV advertising, leverage and industry growth appearing to be important (Hirschey and Wichern, 1984). Using a simultaneous equation model, Brush et. al examine the relative influence of industry, corporate and business unit on firm profitability. They found that corporations have a larger influence over profitability in comparison with industry influence (Brush et al., 1999).

The main aim of this paper is to test the capital structure through debt ratio as determinant for profitability for Romanian companies, an emerging country. In order to improve the model two control variables were added, noncurrent assets ratio and tax rate. In this respect, the paper focuses on return on sales ratio as profitability measure and three variables that could influence it. In terms of methodology, panel

data model is employed by using fixed effects and random effects models. The results suggest that financial statement variables considered are significant in gauging profitability.

The paper is organized as follow. After this brief introduction, second section comprises a literary overview of empirical research regarding determinants of firm profitability. Section three describes the data collection, proposed model and the hypotheses for variables used in model. Section four reports data characteristics and empirical results. Section five concludes.

## **2. Literature review**

There is an increasing number of empirical works that test what drives firm profitability, according to specific areas from literature. For instance, in industrial economics literature there are two approaches, Structure-Conduct-Performance paradigm (SCP) and Persistence of Profit (POP) respectively. Traditional SCP paradigm approach states that profitability is determined by structural characteristics of the market such as concentration, economies of scale, barriers to entry and exit (Slater and Olson, 2002), while POP approach focuses on the time-series behavior of profitability, suggesting that any temporary deviation of firm profitability from market average is quickly adjusted through entry and exit effects (Goddard et al., 2006).

Another area of the literature, strategic management respectively, highlights the importance of internal resources as determinants of variations in firm profitability, since the main source of heterogeneity in profitability is considered management practices (Barney, 2001). The accounting and finance literature suggests the random walk hypothesis, i.e. the importance of a random walk model for time-series changes. Common measures for profitability such as return on assets, equity or sales were examined and similar findings with POP approach from industrial economics were reported (Callen, 2001).

However, it is well known that financing decision trigger important effects for company value since optimal capital structure lead to maximum level of profitability (Pirtea et al., 2010). At the same time, profitability depends on firm risk level, which can be measured in several ways (Anis et al., 2011).

A related strand of the literature has been examined financial statements drivers that could have an impact on firm profitability. Using a sample of 1384 firms from Belgium, France, Italy and UK, Goddard et al found that profitability is negatively related with size and gearing ratio and positively related with market share and liquidity (Goddard et al., 2005). In a multiple regressions model for Hindalco Industries Limited it was found that current ratio, liquid ratio, receivables turnover ratio and working capital to total assets ratio influence profitability (Singh and Pandey, 2008). A study over USA companies included in Standard and Poors Index suggests that variables such as sales, current ratio, debt-to-equity ratio, net profit margin, human capital investment, historical performance and industry diversification have influence on generating profitability (Nagy, 2009).

Few empirical findings with inconclusive results were performed for Romanian companies. In a sample of 18 companies, the results suggest that profitability is either negative or positive related with intangible assets, depending on profitability measure or industry sector (Purcărea and Stancu, 2008). Matiș et al. conducted a study in order to highlight the significance of Jones, Dechow and Kasznik models for 101 publicly Romanian companies that record a discrepancy between reported cash

flow and reported net income. They conclude that Jones and Dechow model appears to be significant at 10% level. In this respect, total accruals is positively related with changes in revenues, negatively related with property plants and equipments or change in revenues minus change in net account receivable (Matiş et al., 2010). In a time-series model for a chemical company it was found that profitability is positively related with the efficiency of inventories, debt level, financial leverage or efficiency of capitals and negatively related with fixed assets ratio (Burja, 2011).

### 3. Data and methodology

Data were collected from statistical department of the Romanian Ministry of Finance. This database provides accounts data starting from 1999 for all Romanian companies. Given the aim of the paper, it was decided to restrict the sample to listed companies at Bucharest Stock Exchange from tier 1, 2 and 3 for which ten years data were available. The reliability of financial statements was the reason for using publicly companies. In order to offer shares more attractive, listed companies have an incentive to present fair profit. As a comparison, private companies hide profit in order to avoid tax and thus it is likely that their financial statements do not reflect true results. Due to the specific nature of their activities, banking and financial firms were excluded from the sample. Finally, the sample was trimmed by dropping the outliers that could influence empirical results. Thus a balanced panel set of 682 year observations was obtained, with observations of 62 companies over the 2001-2011 period.

In order to capture profitability, various financial ratios can be used as a proxy. Among these, could be mentioned return on assets, return on equity and return on invested capital, each of them having pros and cons arguments. Instead of these frequently measures, it was used a measure for evaluating company's operational efficiency, profitability (PROF), calculated by dividing net income to sales.

Profitability could be affected by several variables at firm level. According to the purpose of this research, debt ratio (DR) expressed as total debts divided by total assets is used as a proxy for capital structure. The existing findings suggest that higher debt ratio generate higher costs and will lead to lower profitability.

*Hypothesis 1: "Capital structure and profitability are negatively related"*

Except capital structure, additional two control variables were used in order to improve the model. Investments could generate either scale economies or diseconomies of scale and thus noncurrent assets ratio (NCAR) expressed as noncurrent assets divided by total assets was used as a proxy for size.

*Hypothesis 2: "Size and profitability are either positively or negatively related, according to main driver of the growth"*

When companies perform better higher profitability means higher amount of tax payments and tax rate (TR) expressed as taxes paid divided by taxable income was included as a proxy for taxation

*Hypothesis 3: "Tax rate and profitability are positively related"*

The empirical model is estimated using panel data model, which allows controlling for variables one cannot observe or measure and for unobservable variables that change over time but not across companies (Baltagi, 2008). According to variables aforementioned, the empirical model is as follow:

$$PROF_{i,t} = \alpha + \beta_1 * DR_{i,t} + \beta_2 * TR_{i,t} + \beta_3 * NCAR + u_{i,t} \quad (1)$$

with  $u_{i,t} = \mu_i + \lambda_t + v_{i,t}$  where  $\mu_i$  denotes the unobservable firm effect to allow for unobserved influences on the profitability for each firm,  $\lambda_t$  denotes the unobservable time effect that control for the impact of time on profitability and  $v_{i,t}$  is the idiosyncratic error component.

It worth be noticed that Equation 1 is a static panel model with two way error component, in which a full set of individual firm effects,  $\mu_i$ , and time effects,  $\lambda_t$ , control for all cross-sectional and time series variation in profitability. In this respect, Equation 1 can be viewed as a model of the drivers of the short-run variation in profitability that would still remain unexplained after each set of effects. The availability of ten time-series observations requires data to be pooled and estimated with common slope. This procedure is in contrast with standard practice in corporate finance literature, in terms of time-series properties, but has the advantage of providing more accuracy coefficients.

#### 4. Results

This section exhibit the results for profitability empirical model described in previous section. Summary statistics for the variables included in model are reported in table 1. Particularly, there are 2 sections, panel A for descriptive statistics and panel B for correlation matrix.

**Table 1:** Summary statistics

<b>Panel A – Descriptive statistics</b>				
	<b>PROF</b>	<b>DR</b>	<b>TR</b>	<b>NCAR</b>
Mean	0.019	0.402	0.178	0.567
Median	0.035	0.374	0.171	0.557
Minimum	-3.555	0.005	-3.161	0.097
Maximum	1.247	1.698	2.552	0.981

NCAR	-0.024	-0.279	0.003	1

Source: Author calculation

It worth to be noticed that for publicly Romanian companies profitability is very low, with an average of 0.019. At the same time, investment policy is focused on non-current assets, since the average is higher than 50%. The average debt ratio (0.402) is similar with other emerging countries (Czech Republic) and lowers than in developed countries. Tax rate and profitability present some volatility, while skewness is observed for debt ratio and tax rate.

Correlation matrix highlights low correlations between variables, suggesting no multicollinearity issue. Furthermore, profitability is negatively correlated with debt

ratio and noncurrent assets ratio and positively with tax rate which is consistent with the literature review.

In order to test the model proposed two estimation methods were employed, fixed effects (FEM) and random effects model (REM) respectively. Table 2 reports the results for both methods, i.e. in column 2 are reported results for FEM and in column 3 are reported results for REM.

**Table 2:** Results

VARIABLES	COEFFICIENTS	
	FEM	REM
DR	-0.213*** (0.026)	-0.228*** (0.022)
TR	0.026* (0.013)	0.026* (0.013)
NCAR	-0.216*** (0.037)	-0.143*** (0.029)
CONS	0.259*** (0.026)	0.226*** (0.024)
R-squared	0.183	0.177
F-statistic	10.453	
p-value	0.000	0.000
Wald-statistic		164.904
p-value	0.000	0.000
Hausman test	13.350	
p-value	0.421	
Root MSE	0.089	0.089
Firms	62	62
Observations	682	682

Notes:

Standard errors are shown in parentheses.

\*  $p < 0.05$ , \*\*  $p < 0.01$ , \*\*\*  $p < 0.001$

Source: Author calculation

The results for both methods suggest the significance of debt ratio, tax rate and noncurrent assets ratio as determinants for profitability and have the expected sign. Additionally, a Hausman test was performed to select the most appropriate model. The test statistic is 13.350 with 0.421 p-value, suggesting that random effects model is preferred.

According to REM results, the relationship between debt ratio and profitability is negative and statistically significant. Firms with a higher debt ratio may tend to be affected, since the proportion of profits dedicated to servicing debt increase. This result is consistent with pecking order hypothesis which state there is a hierarchy in financing sources, first internal sources, second low-risk debt and third equity. Regarding control variables included in the model, tax rate is significant at 5% level while noncurrent assets ratio is significant at 0.1% level. The negative correlation with noncurrent assets ratio suggests that growth lead to diseconomies of scale, while positive correlation with tax rate suggests that high tax payment lead to higher profitability.

Overall, empirical results for Romanian companies are consistent with the findings from other empirical research. The relationship between profitability and debt ratio is negative, according to Goddard et al. (2005). Like Memon et al. (2012) tax rate is positively associated with profitability and like Burja (2011) noncurrent assets is negatively related.

## 5. Conclusions

This paper examines the impact of capital structure on corporate profitability for publicly Romanian companies. Limited studies have been conducted in this area so this empirical work will fill the gap in this field in Romania. On the basis of the estimation results and discussion, it is concluded that there is evidence for pecking order theory since profitability is adversely affected by capital structure. In addition, it worth to be noticed that firms with large amounts of noncurrent assets are under performing and rather generate diseconomies of scale, while firms with high tax rate perform better.

The results could have several implications for stakeholders, particularly investors and managers, since it provide a support in analyzing financial statements and making profitable investment decisions. Nevertheless, there could be implications for public policy and require further financial education. Thus, in a debt driven economy, a society can have an important role in generating economic prosperity and growth only if it can assimilate financial statements variables and is aware about their implications on firm profitability.

It can't be ignored that there are some limitations of the study, which require further research. Among these, the study could be improved either by using other estimation methods or additional variables. However, the results for the current model are significant and confirm the negative relationship between capital structure and profitability.

**Abstract** *The purpose of this paper is to test whether data from synthetic financial statements publically available in Romania can be employed within a logistic regression model to accurately predict the corporate bankruptcy probability over the economic crisis period.*

*The population initially subjected to our study included all the 26,980 companies from the Timis County that submitted financial statements for 2007 to the public authorities. As this population proved very heterogeneous, we focused on a more homogeneous group, composed of 4,327 companies. The target population was chosen by employing both economical and statistical criterions.*

*The data from the synthetic financial statements was used to build 12 ratios, 5 of which have proven to be significant within a logistic model for predicting corporate bankruptcy.*

*It was clear that other sources of information could help improve the accuracy of the predictions, but these sources are not easily accessible to most of the stakeholders. As the synthetic financial statements are publically available, evaluating their utility in the prediction of corporate bankruptcy was one of the main objectives of this research.*

*The proposed model offers an in-sample overall 70.3% accuracy in the prediction of the bankruptcy event over a 5 – year period, with an out of sample overall accuracy of 67.6%.*

*Under these circumstances, the model is considered to be of immediate practical utility, as it can represent a tool for performing a fast estimation of the bankruptcy probability of a company that fits the profile of the target population.*

*As theoretical contributions, the research proves that the companies that filed for bankruptcy during the crisis period showed signs of weaknesses before the beginning of the crisis. Financial ratios that show relevance in the prediction of corporate bankruptcy at local level have been identified and their correlation with the bankruptcy probability has been evaluated. The model is expected to maintain its accuracy with minimal or no additional calibration for companies from the entire Romanian economy that fit the profile of the target population.*

**Keywords:** *bankruptcy; financial statement analysis; economic crisis; logistic regression; accuracy rate.*

**JEL classification:** G33, C21, M41.

## 1. Introduction

At the present time, Romania has just over 1 million active companies. All statistics show that the occurrence of the economic crisis has increased the failure risks at corporate level. Reports of the National Trade Register Office show a growth in the number of corporate bankruptcies in the first 2 years following the acknowledgement of the economic crisis in Romania, with a moderate decrease in 2011 and 2012.

Reports of the National Bank of Romania reflect a continuous increase of the rate of non-performing loans in the corporate sector nationwide, placing Romania on the 4th position within the EU, and on the 5th position worldwide (in a list of only 70 countries published by the International Monetary Fund).

Accepting the idea that the economic crisis has increased the failure frequency, it was assumed that the companies for which the failure risks have materialised showed particular weaknesses. The current research was set to determine whether signs of such weakness were reflected in the synthetic financial statements of the future bankrupt firms before the beginning of the economic crisis.

The population initially subjected to our study contained all companies from the Timis County that submitted financial statements to the Public Finance Administration in 2007 (26.980 companies).

"Company failure" was defined as the declaration of bankruptcy according to the Romanian law of bankruptcy. In this research, the authors focused on the occurrence of bankruptcy during the crisis period (2008 – 2012).

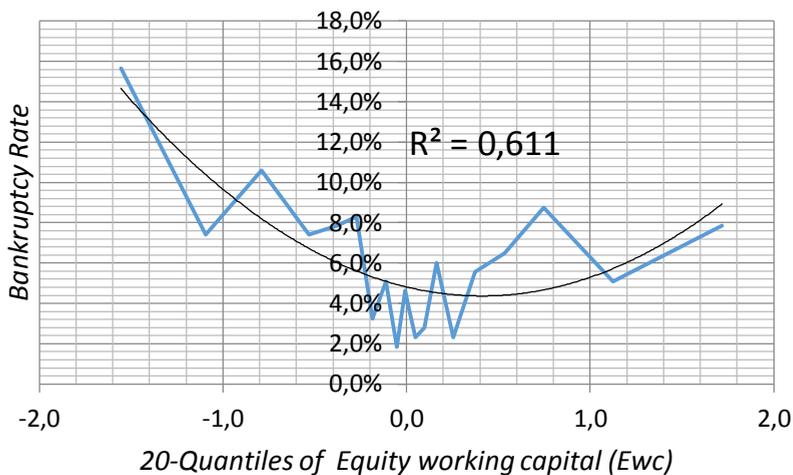

## 2. Methodology

The literature in the field of bankruptcy prediction offers a large variety of models after the elaboration methods:

- discriminant analysis (Altman E., 1968);
- hazard models (Schumway T., 2001);
- stationary financial distress models (Emel Kahya and Panayiotis Theodossiou, 1999);
- logistic regression (Mine Ugurlu and Hakan Aksoy, 2006).

Other models (Adnan A., Dar H., 2006) include artificially intelligent expert system models, univariate models, linear probability models, probit models, cumulative sums models, partial adjustment processes, recursively partitioned decision trees, case-based reasoning models, neural networks, genetic algorithms, rough sets models. The most popular statistical methods in the prediction of corporate bankruptcy (Hatem B. et al., 2005) are discriminant analysis and logistic regression.

In order to find a relation between available financial indicators in 2007 and the event of bankruptcy between 2008 and 2012, the method of logistic regression has been chosen (also known as logit). After scatter plot inspection of the relation between the 20-quantiles (vingitiles) of the independent variables and the bankruptcy rate, the variable *Ewc* (*Equity working capital*) was detected to present a u-shape relation. To count for this u-shape relation, both *Ewc* and its square should be entered in the model. All the other variables have been hypothesized to affect the bankruptcy probability linearly or, at least, monotonically. The relationship between *Ewc* and the Bankruptcy rate is described in Chart 1.

**Chart 1:** U-shape relation between Equity working capital (Ewc) and Bankruptcy Rate

### 3. Population

The population initially subjected to analysis included all companies in the Timis County (Romania) that submitted financial reports for 2007. Thus, data from 26,980 companies was evaluated, 1,933 of which would go bankrupt within the 2008 – 2012 period.

No new companies have been included over the crisis period, so specified numbers refer only to companies active at the end of 2007 which became insolvent in the following five years.

Of the non-bankrupt firms, 6,108 (24.4%) registered no sales in 2007 while 13,129 (52.4%) registered losses, thus consuming equity. Of the entire non-bankrupt population, 30.1% had no employees (7,549 companies) and 33.0% had public arrears (8,275 companies).

Of the bankrupt firms, 345 (17.8%) registered no sales in 2007 while 973 (50.3%) registered losses. Of the entire bankrupt population, 22.4% had no employees (433 companies) and 5.1% had public arrears (98 companies).

Preliminary evaluation of the data suggested important lack of homogeneity, which demanded for a more focused analysis.

After making adjustment for missing observations and unreasonable values, several filters have been applied in order to increase the level of homogeneity in the target population. Companies reporting values of *Atr*, *Fatr*, *Icr*, *Crcp*, *Far*, *Ewc* and *Roe* outside  $\pm 1.5^*$  interquartile range from Tukey's Hinges have been removed in order to reduce extreme and mild outliers which we consider to be standard procedure. However we think that the interval of  $\pm 3^*$  interquartile range also deserve much attention even if not analysed here. Companies with a negative *Ar* have also been removed. Regarding profitability, only companies with *Pr* between 0 and 50% have been retained. Even if this filtering procedure may be rightly criticised for keeping for estimation only a comfortable around mean population we think however that it

makes sense and useful insights may be obtained if further compared with other, more extreme, group of companies.

**Table 1:** Data selection process

Data sets	Description	Number of companies active at the end of 2007	Decrease - relative to the initial population	Number of companies insolvent in 2008 -2012
Initial Population	All companies from Timis county which submitted financial reports for 2007	26,860	-	1,907
Adjusted Population	Companies with missing observations and unreasonable values were removed	16,158	40%	1,315
Target Population	Fatr, Far, lcr, Crcp, Ewc and Roe within +/- 1.5* Interquartile Range; Ar>0; 0<Pr<50%	4,327	84%	266

#### 4. Explanatory Variables

The selection of the financial ratios that would be tested for their prediction of bankruptcy capacity was done considering the recommendations of the literature, as well as the limitations of the data available. In this matter, the attention of the authors was not focused on obtaining all data recommended by existing literature. The main purpose of the research was to test if the public financial data existent in Romania can be used efficiently in the estimation of the bankruptcy probability through a loggit model.

We thus used the financial data of the Timis County companies that was publicly available to build 11 ratios.

**Table 2** Ratios tested as explanatory variables

No	Ratios	Symbol	Formula
1	Fixed assets turnover ratio	<i>Fatr</i>	Sales / Fixed Assets
2	Inventory conversion ratio	<i>lcr</i>	(Inventory / Sales) x 360
3	Customer receivables collection period	<i>Crcp</i>	(Receivables / Sales) x 360
4	Fixed assets ratio	<i>Far</i>	Fixed Assets / Total Assets
5	Current assets ratio	<i>Car</i>	Current Assets / Total Assets
6	Autonomy ratio	<i>Ar</i>	Equity / Total Assets

N o	Ratios	Symbo l	Formula
7	Debt ratio	<i>Dr</i>	Debt / Total Assets
8	Solvency ratio	<i>Sr</i>	Total Assets / Debt
9	Equity working capital (100,000 RON)	<i>Ewc</i>	Equity - Fixed Assets
10	Profitability ratio	<i>Pr</i>	Net profit / Sales
11	Return on equity	<i>ROE</i>	Net profit / Equity

Our initial hypothesis was that a high total assets turnover ratio is associated with high return on assets (Liesz, 2002) and, as a consequence, with high profits, high autonomy ratio and low bankruptcy risks.

In addition, high total assets turnover ratios should have the potential of generating economies of scale, thus stimulating the profitability ratio, the second factor that determines the level of the return on assets in the Du Pont view.

First tests performed on the initial population suggested differently: the average total assets turnover ratio for bankrupt firms (0.99) was superior to the average total assets turnover ratio for the healthy firms (0.78).

The fixed assets turnover ratio is an indicator of the efficiency of the fixed assets management. Financing sources invested in fixed assets take a longer period of time until recovery, while their recovery is subjected to higher risks. We thus hypothesized that low fixed assets turnover ratios generate liquidity problems, and would therefore be positively correlated to the bankruptcy risk.

On the other hand, companies with financial difficulties would be expected to take different measures to regain proper liquidity, including the sale of fixed assets. From this perspective, low values of the fixed assets and high values of sales at low profitability ratios and long customer receivables collection periods could be positively correlated to the bankruptcy risk.

The inventory conversion ratio represents an estimation of the period that begins with the acquisition of raw materials or merchandise and ends with the sale of finished goods / merchandise. A high inventory conversion ratio forces the company to hold large values of inventory at each moment. This is expected to be correlated with a high working capital need, which could be financed from working capital or from short – term financial debt. We hypothesized that high inventory conversion ratios generate liquidity problems and involve higher debt ratios.

The customer receivables collection period is a ratio that attempts to estimate the average duration in which the receivables are being collected from customers. It is calculated based on the hypothesis of the uniformity of sales and collections throughout the duration of the year. A long collection period induces higher trade credit, thus affecting in a negative manner liquidity.

A study performed by Don B. Bradley III and Michael J. Rubach (Bradley III D., Rubach M., 2002) on 131 American companies filing for bankruptcy indicated that 66% of the studied population accused the difficulties in cashing the receivables as an important cause of their financial problems. The conclusion of the study is that failure to collect trade credit stands for an important factor of bankruptcy, alongside with general poor management of the working capital.

The literature (Bradley III D., 2004) mentions working capital problems as an important cause of bankruptcy, especially in the case of small and medium size companies.

The fixed assets ratio reflects the percentage of the fixed assets in the total value of the assets. Seen in the view of the financing process, this ratio shows the proportion in which the financing sources were invested in long-term resources. The long-term resources would be exploited for a long period of time and would release the financing sources gradually, over their economic lifespan.

We hypothesized that high fixed assets ratios would induce rigidity, making it for the company harder to adapt to changes that affect the volume of activity. In order for the financing sources invested in fixed assets to be fully recovered in the form of cash, the fixed assets need to be exploited at maximum capacity over their economic lifespan. A decrease in the level of activity (generated for example by a decrease of market demand) could keep a part of the financing sources invested in fixed assets from ever being recovered.

At the same time, fixed assets usually generate fixed costs, which increase the breakeven point and with it, the operating risks.

The current assets ratio reflects the percentage of the current assets in the total value of the assets. Ignoring the existence of prepaid expenses, the sum of the fixed assets ratio and the current assets ratio is equal to 1.

We believed that higher current assets ratios / lower fixed assets ratios would be associated with lower probabilities of bankruptcy, based upon the assumption of a higher flexibility of the investments made by the company.

The autonomy ratio shows the percentage of equity in total financing sources. The autonomy ratio and the debt ratio are perfectly correlated, as the autonomy ratio = 100% - the debt ratio. Under these circumstances, we decided to only use the autonomy ratio for further testing. Based on the principle of the financial leverage, a company should raise its debt ratio if it would have the capacity to generate a sustainable positive difference between its return on assets and the cost of debt. For an indebted company, the return on assets should allow the coverage of the cost of debt, while the liquidity of the assets in which the debt was invested should allow for sufficient cash flows to make the principal payments. We expected a lower autonomy ratio / higher debt ratio to be associated with higher bankruptcy frequency.

The solvency ratio shows the capacity of the total assets to cover the total debt. It is correlated to the autonomy ratio and the debt ratio and thus is expected to be lower for bankrupt companies.

The profitability ratio shows the capacity of the sales to generate profits. Low profitability ratios could be a cause for cash-flow problems, as the profit represents an important factor in the generation of cash. On short-term, we also take into account the possibility of cash-flow problems leading to low profitability ratios, as the company could reduce the profitability ratio in an attempt to boost sales. On a market that is significantly price-sensitive, low prices could be one of the main factors for increasing sales. Low prices would sustain low profitability ratios, but high sales could convert in scale economies (with positive impact on the profitability ratio).

## 5. Results

As the fixed assets ratio and the current assets ratio are strongly correlated, only the fixed assets ratio was put to further use in the research. In the same manner, from the autonomy ratio, the debt ratio and the solvency, only the autonomy ratio was retained.

The selection procedure of the significant discriminant variables is basically a one step approach. Firstly the logit regression is estimated including all the candidate variables *Fatr*, *Crcp*, *Far*, *Ar* and *Ewc* proved to be significant at the 0.05 significance level. On the other hand *Icr*, *Pr* and *Roe* fail the significance test at the 0.05 level and thus are excluded.

The estimated model has the following form:

$$P(\text{Bankruptcy} = 1) = \frac{1}{1 + e^{-z}}$$

Where:

$$Z = a + b_1\text{Fatr} + b_2\text{Crcp} + b_3\text{Far} + b_4\text{Ar} + b_5\text{Ewc}$$

The estimated coefficients, Wald test and  $e^b$  values for the estimation sample are presented in the following table.

Table 3 Variables in the Equation

	<i>b</i>	Standar Error	Wald Test	df	Sig. (p-value)	$e^b$	95% Confidence interval for $e^b$	
							Lower	Upper
<i>Fatr</i>	-0.031	0.013	5.563	1	0.018	0.969	0.944	0.995
<i>Crcp</i>	0.004	0.001	9.036	1	0.003	1.004	1.001	1.006
<i>Far</i>	-3.155	0.623	25.619	1	0.000	0.043	0.013	0.145
<i>Ar</i>	-2.198	0.474	21.495	1	0.000	0.111	0.044	0.281
<i>Ewc</i>	-0.302	0.153	3.885	1	0.049	0.739	0.548	0.998
<i>Const.</i>	-0.853	0.379	5.059	1	0.025	0.426		

Because *b* coefficients are difficult to interpret,  $e^b$  is computed. This value shows how many times the odds of bankruptcy are multiplied if the independent variable varies by one unit. The overall goodness-of-fit was tested by using the Hosmer-Lemeshow test. The test is chi-square distributed and is obtained by calculating the Pearson chi-square statistic on the observed and expected frequencies for ten groups of the predicted probability. The value of the test is 6.921 (p-value= 0.545) so the null hypotheses of equality between observed and predicted frequencies cannot be rejected. Another useful test is the difference between the values of -2Log Likelihood for the estimated model and a baseline model including only the constant. The value of the test, also chi-square distributed, obtained in our case is 109.99 (p-value =0.000) with five d.f.

The model may be further improved if the square of *Ewc* is added. As shown is Chart 1 *Ewc* has a U-shape relation with the probability. It follows that a quadratic transformation,  $Q(Ewc)$ , containing both *Ewc* and  $Ewc^2$ , will generate a new variable which will relate the probability in a monotonic fashion. Indeed by adding  $Ewc^2$

the pseudo R-square coefficient (Nagelkerke R-square) rise from 0.13 to 0.15. Another important change is that the *Ewc* loses significance, ( $p=0.89$ ), in favour of *Ewc*<sup>2</sup> which is significant at all levels, ( $p=0.000$ ).

An optimal cut-off point for the probability of 0.071 has been used. This value was estimated by optimizing the difference between sensitivity and the false positive rate (1-specificity).

The customer receivables collection period shows a positive correlation to the bankruptcy probability in the proposed model, which suggests that higher bankruptcy probabilities are associated to the companies with high customer receivables collection periods.

The fixed assets ratio, the fixed assets turnover ratio, the equity working capital and the autonomy ratio showed negative correlations to the estimated probability of bankruptcy, which suggests that high values of these ratios are associated with low bankruptcy probabilities.

In order to validate the model on a spatial out-of-sample basis, the companies from the target population have been randomly split in two approximately equal groups: estimation group (2165 companies) and validation group (2162 companies).

The model generated through logistic regression offers an in-sample overall 70.3% accuracy in the prediction of the bankruptcy event, with an out of sample overall accuracy of 67.6%. The accuracy rate on validation sample rises slightly to 67.9% if *Ewc*<sup>2</sup> is added.

**Table 4** Classification Table

Observed		Predicted					
		Estimation sample			Validation sample		
		Company State		%	Company State		%
		Healthy	Bankrupt		Healthy	Bankrupt	
Company State	Healthy	1432	592	70.8	1377	660	67.6
	Bankrupt	52	89	63.1	40	85	68.0
Accuracy Rate		70.3			67.6		

As reflected in Table 5, some of the explanatory variables are correlated, but their independent effects on the bankruptcy probability justified their inclusion in the model.

**Table 5** Correlations

Pooled Within-Groups Matrices									
		Fatr	Icr	Crpc	Far	Ar	Ewc	Pr	Roe
Correlation	Fatr	1.000	0.078	-0.067	-0.680	0.002	0.326	-0.129	0.118
	Icr	0.078	1.000	-0.058	-0.239	-0.266	-0.050	-0.278	-0.156
	Crpc	-0.067	-0.058	1.000	-0.200	-0.083	0.043	0.082	-0.051
	Far	-0.680	-0.239	-0.200	1.000	-0.001	-0.458	0.028	-0.101

	Pr	-0.129	-0.278	0.082	0.028	0.522	0.230	1.000	0.402
	Roe	0.118	-0.156	-0.051	-0.101	-0.173	-0.013	0.402	1.000

## 6. Conclusions

The fixed assets ratio, the fixed assets turnover ratio, the equity working capital and the autonomy ratio showed negative correlations to the estimated probability of bankruptcy, while the customer receivables collection period was positively correlated to the estimated probability of bankruptcy.

The negative correlation between the fixed assets ratio and the bankruptcy risk is contrary to our initial expectations. A high fixed assets ratio involves the investment of a high percentage of the company's financing sources in long – term assets, leaving a low percentage of financing sources to be invested in current assets. While current assets are either in the form of cash, or they convert to cash in a short period of time, the conversion of fixed assets into cash takes years and it can only fully happen in the current assets are being constantly used at full capacity.

Data analysis showed that for the group of companies with fixed assets ratios lower than 40%, the bankruptcy frequency was higher than the average, while over the 40% fixed assets ratio limit the bankruptcy frequency became lower than the average. A possible explanation could be that companies with high current assets ratios have higher working capital needs which are associated in the literature with high bankruptcy risks. We were not able to verify the correlation between the current assets ratio and the working capital need due to lack of data.

The fixed assets turnover ratios proved to be negatively correlated to the probability of bankruptcy. The hypothesis that low fixed assets turnover ratios generate liquidity problems and are therefore associated with high bankruptcy risks is sustained by the results of the analysis.

The customer receivables collection period is positively correlated to the bankruptcy probability, as initially suspected. The bankruptcy incidence is significantly lower than average for companies with customer receivables collection periods lower than approx. 30 days and higher for all the rest of the companies. In fact, the bankruptcy incidence is continuously increasing as the customer receivables collection period is becoming higher. This finding is consistent with the suggestions of the literature. From the financing point of view, high customer receivables collection periods lead to large values of the receivables, which makes necessary the investment of additional financing sources in the operating cycle. From the liquidity point of view, high customer receivables collection periods lead to the extension of the operating cycle, with negative impact on the cash-flows.

The customer receivables collection period is calculated based on the assumption of uniformity of sales and collections throughout the year. Still, in many cases, the customer receivables collection period is distorted by the existence of trade credits that are long overdue. Overdue trade credits artificially increase the customer receivables collection period, at the same creating cash – flow problems.

The economic crisis was responsible for important delays in the payment of trade credit, which led to increments in the customer receivables collection periods for many companies. Our findings show that companies with higher customer receivables collection periods from before the economic crisis were more vulnerable to the bankruptcy risk.

The autonomy ratio is negatively correlated to the bankruptcy risk. Companies with autonomy ratios lower than approx. 30% (which involve debt ratios higher than approx. 70%) show higher than average bankruptcy risks.

The correlation between the autonomy ratio and the bankruptcy risk proved to be as initially expected. The bankruptcy state is characterised through the company's

incapacity of paying its debt. Higher leveraged companies are subjected to higher bankruptcy risks. At the same time, through the leverage effect, companies with high debt ratios and low autonomy ratios should have higher potential in terms of returns on equity. The return on the assets financed from debt should cover the cost of debt and allow a supplementary remuneration of the equity holders.

Primary analysis of the correlation between the autonomy ratio and the return on equity confirms a tendency of the return on equity increasing with the decrease of the autonomy ratio (and the increase of the debt ratio).

The last explanatory variable (the equity working capital) is negatively correlated to the bankruptcy risk. The bankruptcy risk decreases as the equity working capital increases. Still, very high values of the equity working capital are associated with higher than average bankruptcy risks. For this reason, we expect a U-shape function to be a better estimate of the relationship between the equity working capital and the bankruptcy probability than a linear one. Such a function will be tested in future research.

The equity working capital represents the equity that exceeds the fixed assets and thus remains available (after the coverage of fixed assets) for financing current assets. High values of the equity working capital are associated with high autonomy ratios and low fixed assets ratios.

The bankruptcy prediction model proposed through the use of logistic regression is considered to be of practical utility, as it is capable to accurately predict the bankruptcy event over a 5-year period. The model only employs financial data from the synthetic financial statements publically available in Romania.

Further research should test the model for companies from the other departments of Romania. We expect the model to maintain its accuracy with minimal or no additional calibration.

**Abstract:** *This paper presents the emergence and evolution of catastrophe models (cat models). Starting with the present context of extreme weather events and features of catastrophic risk (cat risk) we'll make a chronological illustration from a theoretical point of view of the main steps taken for building such models. In this way the importance of interdisciplinary can be observed. The first cat model considered contains three modules. For each of these indentified modules: hazard, vulnerability and financial losses a detailed overview and also an exemplification of a potential case of an earthquake that measures more than 7 on Richter scale occurring nowadays in Bucharest will be provided. The key areas exposed to earthquake in Romania will be identified. Then, based on past catastrophe data and taking into account present conditions of housing stock, insurance coverage and the population of Bucharest the impact will be quantified by determining potential losses. In order to accomplish this work we consider a scenario with data representing average values for: dwelling's surface, location, finishing works. On each step we'll make a reference to the earthquake on March 4 1977 to see what would happen today if a similar event occurred. The value of Bucharest housing stock will be determined taking firstly the market value, then the replacement value and ultimately the real value to quantify potential damages. Through this approach we can find the insurance coverage of potential losses and also the uncovered gap. A solution that may be taken into account by public authorities, for example by Bucharest City Hall will be offered: in case such an event occurs the impossibility of paying compensations to insured people, rebuilding infrastructure and public buildings and helping the suffering persons should be avoided. An actively public-private partnership should be created between government authorities, the Natural Disaster Insurance Pool, private insurance companies, reinsurers, stock exchanges, institutions specialized in cat events modeling in order to develop and use alongside compulsory and facultative insurance of buildings new alternative risk transfer solutions as catastrophe bonds(also known as cat bonds).*

**Keywords:** *cat risk; cat model; earthquake; financial losses.*

**JEL classification:** *G22.*

### 1. Introduction

Catastrophes are extreme events, characterized by a low frequency but a high severity, currently being observed an upward tendency of both parameters. For example, during 1970-1980 the catastrophes frequency ranged around 150 catastrophes per year, while in the years 2000-2011 the recorded values were nearly 300 events each year, the maximum frequency being reached in 2005 when 397 catastrophic events were registered. In this context, special attention of all

stakeholders is required in order to find the most appropriate methods for managing catastrophic risk (cat risk).

In the past, buying an insurance policy seemed to be a complete solution for managing risk, but nowadays we can't say the same thing. Along with the economic development, the limits of traditional insurance could be observed, since new risks appeared and couldn't be covered by this. Among these are the weather conditions risk, terrorism and certain economic risks. Furthermore, over the last years the consequences of catastrophes were devastating in some areas.

There isn't just one class of stakeholders interested in an appropriate catastrophic risk management, but rather all the parties involved which can undergo losses as a result of the occurrence of such an event: property owners, insurers, reinsurers, mortgage banks as well as capital markets due to the call of traditional insurance market to them and the development of alternative risk transfer solutions offered by the market ART- *Alternative Risk Transfer*. Government's role in managing cat risk shouldn't be ignored, especially through some programs whose purpose is to control the consequences of such events by reducing the probability of occurrence of these risks or by establishing of some funds to be used for assistance immediately after a catastrophe has occurred.

Any risk involves a degree of uncertainty, but in the same extent the presence of some influential factors leading to situations entailing damages, so we can't suppose that these events have random consequences, but rather we should concentrate to have a better understanding of deterministic part of them.

## 2. Cat Risk and Catastrophes Modeling

At the base of risk assessment is situated the exposure, characterized by several elements: the resource at risk, also known as the object of risk; the random event or peril to which the object is exposed; the consequence, representing the possible impact on resource when the peril occurs.

In the next table we are going to illustrate these three concepts for some catastrophes:

**Table 1** Exemplification of the defining elements of cat risk

Exposure	Peril	Consequence
The number of houses	Earthquake	Financial losses Human casualties
The number of houses in the area affected by floods	Flood	
The number of houses in the region affected by storm	Storm	
The coast length	Tsunami	
The number of passengers	Terrorist attack	

Source: Authors' processing (Condamin et al., 2006:32)

Usually the resource at risk is quantified by values regarding the number of units, the acreage, and the volume. As regards the peril, knowing the probability of occurrence is an important thing. When it comes to the consequences, these can

be: financial or other, but in most of cases the goal is finding a model which results are shown as monetary losses.

Taking into consideration the complexity of catastrophic events the appearance of cat models can't be attributed to one area, but rather is considered that the first models emerged as a result of cumulative effort of insurance experts and those specialized in the science of natural hazard.

The beginning of catastrophe modeling is considered around 1800. Again are different opinions regarding the first steps in models constructing between experts from different fields. Therefore, on one hand, insurers consider that cat modeling lies in the earliest day of property insurance, at that time being used a rudimentary technique that consisted in the use of marks in order to see the concentration of their exposure. On the other hand, seismologists and meteorologists argue for the affiliation of cat modeling to modern science, when the nature and the impact of these extreme events are better understood.

In time there has been observed an evolution of these models, in the 1970's being published some studies theorizing the source and the frequency of events, so that, in the next step, along with the development of information technology systems, models provide estimations of losses in case of catastrophe. The first specialized companies that developed software which estimate the possible losses are: AIR Worldwide, Risk Management Solutions, EQECAT which later changed its name to ABS Consulting.

A positive impulse for the cat models development and also for a better understanding of the need for such models was given in the aftermath of two catastrophes that led to major losses: Hurricane Hugo and Loma Prieta Earthquake, both occurring in 1989. In the next period more and more insurers have turned to specialized companies in catastrophe modeling in order to improve their methods for pricing insurance policies. In addition, a signal to the public sector was given, U.S. Government being the first interested in using such models. So, in 1997 was launched the program Hazards U.S., also known as HAZUS. At first it offered only the possibility of determining potential losses in case of an earthquake, but lately also for losses due to wind or floods.

One of the problems in cat modeling is the lack of historical data. Since catastrophes are rare events large series of data can't be built and this explain the necessity of calls for the use of simulations through which similar results are obtained as in the case of real events occurrence.

### **3. Cat models components**

Models are tools used in order to have a simplified representation of the reality. A feature of catastrophe models is that these are built through the contribution of several disciplines, such as: physics, meteorology, statistics, insurance, engineering and others. Informatics contribution shouldn't be neglected because it offers us the use of simulation and thereby relevant results, even with smaller data series.

For all models there is a certain degree of uncertainty which can't be completely removed. So, it is necessary to distinguish between two different types of uncertainty: random and epistemic. Regarding random uncertainty we should mention that there is no way to reduce it by getting more information, but is associated with the impossibility to predict catastrophes. On the other hand, epistemic uncertainty emerges because of insufficient data or information for a specific catastrophe and in

this situation a better understanding on the phenomenon or additional information may lead to decrease of the uncertainty, which is the purpose when building a catastrophic model.

All cat models have some common components, or modules as these are called, regardless the type, or region where catastrophe occurs. In the following a detailed presentation of each of them will be offered. In addition it will be recorded the defining elements for each of them. (Born and Martin, 2006; Chávez-Lopez and Zolfaghari, 2010; Zimmerli, 2003; Grossi and Kunreuther, 2005)

### **3.1. Hazard Module**

Randomness characterizing natural catastrophes can't be eliminated with the help of certain models, as it is impossible to exactly predict their occurrence moment. If for certain natural catastrophes, for example floods, sometimes there are some warnings a few days before in the great majority of cases even this is impossible.

The ultimate goal of hazard module is identifying the locations most likely to be affected, the frequency of occurrence as well the severity, intensity of catastrophes.

In order to do this the specialists performing model follow next steps:

- Getting data from past catastrophes;
- Determining the probability distribution based on historical data;
- Generating, by computer, a large number of events similar with past ones, resulting a large scale of cat events that might actually produce;
- Calculating the intensity for each location considered.

Necessary information on past events include: localization of seismic zones and faults, geological properties of the region to observe the seismic waves propagation, in the case of earthquakes; coast length, barometric pressure, wind speed when it comes to hurricanes.

In order to achieve simulations, one of the most popular and used method is Monte Carlo. This is an iterative technique which consists in generating a number of scenarios based on a set of initial data when seeking more data and real observation is not possible, this being also the case of catastrophes. For achieving a similarity between real and simulated events it is necessary that the latter to follow the probability distribution of initially recorded data.

A very important element is the occurrence frequency of catastrophes, this aspect being characterized by a high level of uncertainty and at the same time by a major influence on the final outcome of model, the determination of possible losses. For determining the occurrence probability of an event should be taken into consideration certain representative parameters of that event. For example, in the case of earthquakes should be considered the pressure on faults.

The final step of this module, once all other requirements have been met consists in intensity quantification for each event resulting from simulations. Thus, for earthquakes, magnitude is the measure of intensity. If we consider a Richter scale we get a measure of intensity depending on the energy released by earthquakes, but in the case of Modified Mercalli scale the intensity is expressed by the potential losses. Another advantage is the fact that if an earthquake is characterized by a single level of magnitude, in case of potential losses, the distance from the epicenter is considered and as we move from the epicenter, the reduced losses will be observed.

### 3.2 Vulnerability module

This component of cat models is also known as engineering because the construction of damage functions, which is one of the main objectives of this module, lies with the engineers.

To notice the vulnerability, an analysis of the extent of one specific event is required. For this purpose, once the intensity is determined, for each simulated event resulting from the first module we move forward to apply these values on a portfolio of buildings. A database containing information about buildings and their contents is required, and through mathematical relationships the damages level is computed. The main features of buildings included in databases are: type of construction, building materials used quality of work taking into consideration also the labor force, building destination, occupancy, height, maintenance, age.

Numerical illustration of vulnerability module is realized through damage ratio. This should not be confused with compensation ratio determined as a ratio between the amount of compensation and the insurance premiums collected.

For different insured objects MDR (mean damage ratio) is determined:

$$\text{Mean damage ratio} = \frac{\text{Total losses}}{\text{Total value of insured objects}} * 100$$

One last step after determination of damage functions, through which we can have an image about expected damage ratio for different levels of intensity, is generation of vulnerability curves. These are built depending on the type of risk and also on classes of insured objects.

### 3.3 Financial losses module

Within this component the last step for finalizing the cat model is realized. It is to establish a relationship between the initial data, characteristic to each catastrophe, and the level of financial losses. At this stage a special attention is given to experts opinions about damage rate for different types of building. This is necessary because it is difficult to update too often damage functions to include all changes when new techniques of construction appear or other codes regulate constructing new buildings.

Then, having estimated the level of losses we can determine the value of insured losses, these being the share of entire damage after a catastrophe covered by the insurer. In this case, policy conditions have a major importance, being considered: existing deductibles, coverage limits, co-insurance, etc.

## 4. Illustration of the 3 modules of cat models for an earthquake in Bucharest *Hazard module*

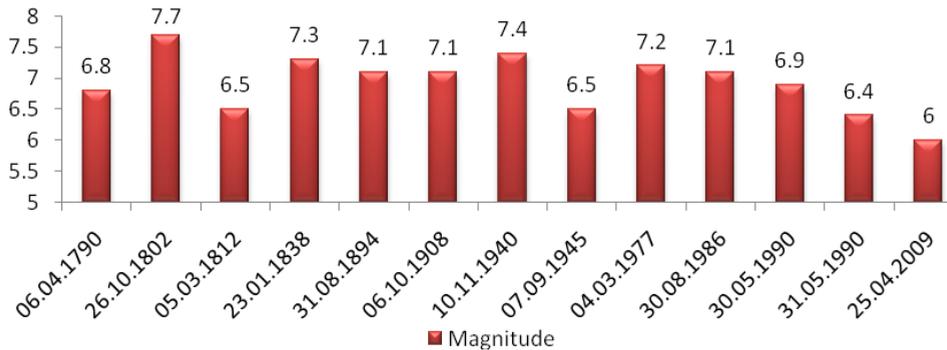

In Romania, the counties are classified into three zones, A, B and C based on earthquake risk exposure. Those from C zone are the most vulnerable, Bucharest being part of this class. According to the Natural Disaster Insurance Pool the three zones include:

- Zone A: Alba, Arad, Bihor, Cluj, Hunedoara, Maramureș, Sălaj;
- Zone B: Argeș, Bistrița, Botoșani, Călărași, Caraș Severin, Constanța, Dolj, Giurgiu, Gorj, Harghita, Iași, Mehedinți, Mureș, Neamț, Olt, Satu Mare, Sibiu, Suceava, Tulcea, Timiș, Vâlcea;

- Zone C: București, Bacău, Brăila, Brașov, Buzău, Covasna, Dâmbovița, Galați, Ialomița, Prahova, Vaslui, Vrancea, Ilfov

Vrancea is the most important seismogenic zone in Romania. Also, National Institute for Earth Physics defines all epicentral zones: Făgăraș-Câmpulung, Banat, Crișana, Maramureș and Dobrogea. Once identified, these are the locations most likely to be affected in case an earthquake occurs.

Regarding past earthquakes that occurred in Romania in Figure 1 can be observed the most important ones, with a magnitude greater than 6 on Richter scale.

**Figure 1:** History of Romania earthquakes with magnitude over 6 on Richter scale  
Source: Authors' processing based on data provided by [www.snas.ro](http://www.snas.ro)

Although the highest magnitude was recorded in case of 1940 earthquake, however in the classification of top 10 disasters in Romania in the period 1900-2012 conducted by Centre for Research and Epidemiology of Disasters (CRED) and made available through the database EM-DAT, the strongest effects were felt in the case of 1977 earthquake. The consequences were:

- 1641 deaths: rank 1 of 10
- 2000 million USD ,economic damage costs: rank 1 of 10
- 396300 affected people, rank 2 of 10

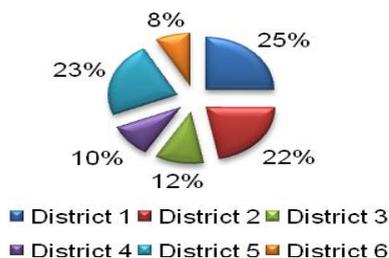

The frequency of Vrancea earthquakes with magnitude over 6 on Richter scale is estimated so: (Wenzel et al.: 2002)

- If  $M_w \geq 6.5$ , 10 years
- If  $M_w \geq 7.0$ , 25 years
- If  $M_w \geq 7.4$ , 50 years

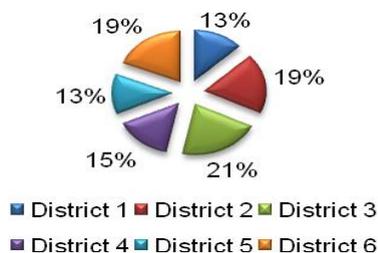

If we consider that an earthquake over 7 occurs every 25 years, the annual probability of occurrence is estimated to 4%.

#### *Vulnerability module*

Within this module we propose to notice the extent of an earthquake whose intensity is greater than 7. This requires an assessment of Bucharest housing stock. In 2011 in Bucharest were recorded 113863 buildings mainly concentrated in 3 of the 6 districts, as follows: District 1, District 4 and District 2 together comprising 70% of total buildings in Bucharest.

**Figure 2:** The structure of Bucharest buildings portfolio

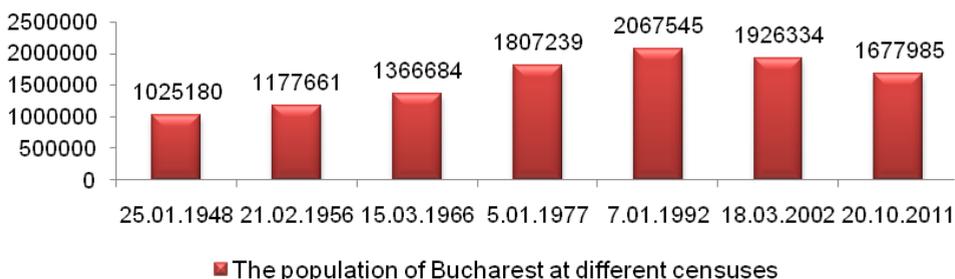

**Figure 3:** Distribution by district of Bucharest conventional dwellings in 2011

Source: Authors' processing based on data provided by [www.insse.ro](http://www.insse.ro)

For a detailed image we considered relevant to assess the number of conventional dwellings, a total of 803794 in 2011. These are evenly distributed in the 6 districts of the capital. Even if the lowest number of buildings can be noticed in District 3 here we can find the greatest number of dwellings, 170205. 98.4% of the total number of conventional dwellings from Bucharest is private property, 1.4% state property and 0.2% private group property.

Also, to observe an earthquake's impact, in addition to housing stock, we should take into account the population exposed to such an event:

**Figure 4:** The population of Bucharest at various censuses

Source: Authors' processing based on data provided by [www.insse.com](http://www.insse.com)

Considering the fact that in comparison with 1977 the population decrease was around 7% we expect in case that an earthquake with the same intensity occurs to face similar consequences in terms of number of people affected. Using Holt Winters forecasting method the next value for the Bucharest population is 1.429.636 people. It is also useful to notice the share of casualties in the total population recorded in Bucharest after the 1977 earthquake. There were registered 1424 deaths and 7598 casualties. By reporting to the total population we obtain the value 0.5%. If a similar event occurs at present this share will be greater, respectively 0.54%. This increase is explained by the decrease of the population, tendency that seems to continue in the future.

We first have to do some clarification on structure of Bucharest housing stock. Thus, 60% of the buildings have been built before 1977, the remaining 40% after 1977. (Lungu, 2002:12)

We use average values for the area where the dwelling is situated, finishing work and surface. The average surface of living rooms in Bucharest is 21.1 square metre (sqm)/room and considering the structure of dwellings depending on the number of rooms we obtain a average surface of a dwelling of 50 sqm.

**Table 2:** The structure of housing stock depending on the number of rooms

	Share in total
1 room	15.5%
2 rooms	40.7%
3 rooms	32.9%
4 rooms	9.2%
5 rooms and more	1.7%

Source: Authors' processing based on data provided by [www.insse.ro](http://www.insse.ro)

To determine an average market value we consider the two moments of the construction year: before and after 1977, so we get:

**Table 3:** Determination of market value taking into account the year of construction

Year of construction	Market value	Market value of a 50 sqm dwelling
Before 1977	1250 Euro/sqm	62.500 Euro
After 1977	1600 Euro/sqm	80.000 Euro

Source: Authors' processing

Average market value of Bucharest housing stock =  $60\% * 803.794 * 62.500 + 40\% * 803.794 * 80.000 = 55.8$  billion Euro.

The average replacement value is 875 Euro/sqm in case of an average level of finishing works, so for the same 50 sqm dwelling results a replacement value of 43.750 Euro.

Once determined this value we can notice that in case of a compulsory insurance policy the amount received as compensation is insufficient to bring the dwelling to the situations before the event. The next step is to determine real value. This value results by applying the remaining value coefficient to the replacement value.

**Table 4:** Determination of real value taking into account the year of construction

Year of construction	Remaining value coefficient	Replacement value	Real value of a 50 sqm dwelling
Before 1977	55%	43.750 Euro	24.063 Euro
After 1977	76%		33.250 Euro

Source: Authors' processing

Real value of Bucharest Housing stock =  $60\% * 803.794 * 24.063 + 40\% * 803.794 * 33.250 = 22.3$  billion Euro

Level of potential damages in Bucharest in case of a Vrancea earthquake with a 8 intensity:

**Table 5:** Damages distribution depending on the degree of destruction

Damages	Share in the total number of dwellings	Destruction degree
D0-no damage	11%	0%
D1-slight damage	22.7%	0%-30%
D2-moderate damage	28.5%	30%-60%
D3-heavy damage	23.6%	60%-80%
D4-very heavy damage	12.1%	80%-100%
D5-destruction	2.1%	100%

Source: Authors' processing (Trendafiloski et al.,2008:13)

Average potential damages=22.3 billion Euro \* (11% \* 0% + 22.7% \* 15% + 28.5% \* 45% + 23.6% \* 70% + 12.1% \* 90% + 2.1% \* 100%)= 10.2 billion Euro

To determine the level of potential insured losses we have to know the insurance coverage in Bucharest:

**Table 6:** Insurance coverage of dwellings in Bucharest

	Bucharest
Number of optional insurance policies	377.976
Number of compulsory insurance policies	129.411
Total insurance policies	517.687
Number of dwellings	792.391
Insurance coverage of dwellings	64%
By optional insurance	47.7%
By compulsory insurance	16.3%

Source: Authors' processing based on [www.csa-isc.ro/MediaCentre/](http://www.csa-isc.ro/MediaCentre/)Press Release

Total amount insured through compulsory policies= 2.588.220.000 Euro

Total amount insured through optional policies = 60% \* 377.976 \* 24.063 + 40% \* 377.976 \* 33.250= 10.484.222.693 Euro

Total amount insured= 13 billion. Euro

Mean Damage Ratio=10.2 billion Euro/13 billion Euro\*100=78.46%

*Financial losses module*

Based on data considered above we can determine the Average Annual Loss:

$AAAL = \sum p_i \cdot L_i$ , where  $p_i$  is the annual probability of occurrence and  $L_i$ , the loss generated by the event  $i$ .

$AAAL = 4\% \cdot 10.2 \text{ billion Euro} = 408 \text{ million Euro}$

## 5. Conclusions

Cat models development should become a priority for insurers especially nowadays when cat risks are considered a real problem. Due to high compensations payable in a short period of time, an objective risk assessment is essential for the insurance company for its financial situation in order not to be affected.

In this study we used three different measurements: market value, replacement value and real value. Insurers recommend using the real value, or sometimes the

replacement value when an insurance policy is bought but never the market value because it is questionable. Therefore, although insurers would receive higher premiums because of higher amount insured this fact wouldn't imply also compensations over the damage value. In addition, potential insured persons often are not willing to pay high amounts of money in order to ensure their dwellings. Given the fact an insurance established at market value would avert potential clients more, a compulsory insurance of dwellings is considered to be in fact a "compromise". In our vision the main coordinates of public-private partnership are the compulsory insurance of buildings with an insured amount chosen by the policyholder and taking as reference the real value of buildings but also subsidizing insurance premiums for those people who can't afford it. In addition alternative risk transfer solutions should be considered for natural catastrophe: earthquakes or floods.

# ECONOMIC AND FINANCIAL INSTABILITY PERIODS INDUCED THROUGH THE BANKING SYSTEM

**Ionita Rodica-Oana**

*Academy of Economic Studies, Bucharest, Romania*

*ionitarodica.oana@yahoo.com; ionita\_oana2005@yahoo.com*

**Abstract:** This paper is an empirical study which analyzes the influence of banking system to the economic and financial environment. At the basis of this research there are two subjective definitions of economic instability periods (CII) and of financial instability periods (FII) and two composite indexes called EWI (Economic Warning Index) and FWI (Financial Warning Index) defined in a prior research. The countries included in the study are Czech Republic, Hungary and Romania. There is both a quantitative and qualitative approach. Using econometrics techniques as OLS regressions, Fixed effects and Fixed dummy effects there were identified significant banking indicators in explaining economic and financial instability periods. Then, I compose a banking index which captures the costs occurred to the banking system and I assess its performance in explaining the economic and financial instability indexes through in the sample and out of the sample techniques. This research aim to observe the influence of the banking sector evolution to the incidence of economic and financial instability periods and give us a warning regardless any negative trends in the macroeconomic or financial activity, affecting the national or the global situation. Using model simulations on historical data, the model performance was assessed upon in the sample and out of sample estimation techniques. The evaluation results suggest that banking indicators give us a warning signal of the negative trend of economic and financial environment.

**Keywords:** *economic instability, financial instability, leading indicators, banking system.*

**JEL classification:** *G01*

## 1. Introduction

The recent economic and financial crises have had a significant impact on the world economy. It revealed the need of continuous improvement in identifying, measuring and predicting vulnerabilities of the economy as a whole. A key lesson drawn from the past experience was that we have to take into consideration the interconnections between economic, financial and banking system.

Current crises offered a great lesson that the surveillance for crises prevention must be more rigorous and with a better incorporation of financial sector. After its onset it was highlighted the requirement to take care about cross-border spillovers, macro-financial linkages within and across countries and broader systemic risks for the global economy.<sup>3</sup>

---

<sup>3</sup> Kato,T.(2010), "Early Warning Systems and Their Role in Surveillance", Deputy Managing Director, International Monetary Fund

Because it is not possible to predict the exact point in time at which the crisis sets in, the purpose of this paper is to identify possible vulnerabilities induced through banking system and to treat them in order to mitigate the costs of the economy. I defined a set of eighteen potential leading indicators from banking/financial sector, in the period 2000 - 2012. It was composed a balance panel with seven hundred and eighty observations. At the basis of my decision to choose a continuous model was the fact that it motivates policy makers in steering policy continuously. Using econometrics techniques there were identified significant banking indicators in explaining economic and financial instability periods. Then, it was composed a banking index which captures the costs occurred to the banking system. Its performance in explaining the economic and financial instability indexes it was assessed through in the sample and out of the sample techniques. The research result reveals the importance of the banking system indicators in explaining economic and financial instability periods. A better incorporation of those indicators in supervisory tools of decision factors would help in mitigating economy costs occurred in such difficulty periods.

This paper is organized as follows. Second section presents us literature review of economic, financial and banking indexes created to identify the vulnerabilities and to treat them in order to avoid large scale damages. Those researches aim to obtain a complete picture of the evolution of concerns to improve measuring, predicting and managing the vulnerabilities to the economic system. It is also highlighted the current precarious context. Third section presents the construction of the panel data, through selection of the countries, selection of potential leading indicators and of the research period. There are also presented the transformations of the variables, in order to obtain comparable results. Fourth section presents us the composition of the model, followed by econometrics techniques of estimation as OLS, Fixed effects and Fixed dummy effects applied for the panel and econometrics techniques used to assess its performance in term of in-the-sample and out-of-sample fit. Fifth section shows the results, presenting the estimations and their interpretations. Last section concludes about the utility of this model in actual environment and summarizes the main ideas. Econometric code in R language and detailed description consisting in five appendixes is available at request.

## **2. Literature review**

The interest of researchers in early warning was visible even in the 1979 years with Paul Krugman's and Bilson models for explaining currency crises. Paul Krugman in his paper "A Model of Balance of Payments" presents the situations when balance of payments problems transforms into balance of payments crises<sup>4</sup>. Paul Krugman believes that only an analysis of international size could give a warning regarding the amplitude of the current crises. He identifies three generations of currency crises, from which the third one tries to answer at two questions: should the economies with large currency debt avoid currency depreciation and what is the role of capital mobility. In first edition of his book "The Return of Depression Economics", Paul Krugman associated crises with bacteria that once were severe epidemics, but

---

<sup>4</sup> Krugman, P. (1979), "A Model of Balance-of-Payments Crises", *Journal of Money, Credit and Banking* 11(3), pp. 311–325

considered defeated by the modern medicine. Surprisingly those bacteria revived in a stronger form, resistant to all antibiotics. His conclusion is that the entire economy is “a surprisingly dangerous place”.<sup>5</sup>

Those things happen in a context in which Ben Bernanke (2004) and Robert Lucas (2003), among other economists, declared few years ago that even the economy will occasionally suffer any recoil, the era of great depressions is already gone. The economic cycle was considered an outdated notion. The economist states that we have to learn from all economic and financial crises, because anyway those are very hard to predict. Graciela Kaminsky, Saul Lizondo and Carmen Reinhart in their paper “Leading Indicators of Currency Crises” compose an early warning system in predictive purpose for currency crises. The authors use as leading indicators a broad variety of variables: external sector, financial sector, real sector, public finances, institutional and structural variables, political variables and “contagion effects”, whose behavior is studied. They compose an index of exchange market pressure with the significant indicators. When this index is above its mean by more than three standard deviations it is considered as crises.<sup>6</sup>

Lucia Alessi and Carsten Detken (using signaling approach developed by Kaminsky, Lizondo and Reinhart used to predict foreign exchange and banking crises) composed early warning indicators for costly asset price boom/ bust cycles. They highlight 3 gaps identified on “leaning against the wind”. They identify high-cost boom which is a boom followed by three years of real GDP growth lower with at least 3 percentage points than the potential growth and low-cost boom. In 1989 it was a HCB, in 2000 only 60% of the first wave has been found, and they also identified a new wave in 2007. The conclusions of the paper highlights that financial variables are preferred to real variables in predicting costly asset price booms.

Rose and Spiegel analyzes the occurrence and effects of a crisis using a Multiple Indicator Multiple Cause (introduced by Goldberger 1972), focusing on national variables, but ignoring cross country “contagion” effects. They analyze a continuous variable, taking care only on the cross-country incidence, and ignoring the time-series effects, fact which failed the results because they take care on national variables. The analysis of Stephen G. Cecchetti, Marion Kohler and Christian Upper based on 40 systemic banking crises reveal that current financial crises is composed from a broad range of economic factors and they identify systemic banking crises tendency to create negative output effects.<sup>7</sup>

The paper’s dataset “This Time is Different: A Panoramic View of Eight Centuries of Financial Crises” includes African, Asian, European, Latin American countries, North America and Oceania, in 1800-2006 period and use variables as debts, prices, exchange rates, government finances, trade, GDP and capital flows and construct a composite index of financial instability that is multidimensional. The conclusion is that “financial crises are more a way of life affecting all” and that serial default is a widespread phenomenon across emerging markets and several advanced economies. If prior to World War II, serial banking crises in advanced economies were most common, as other emerging markets developed their financial sector,

---

<sup>5</sup> Krugman, P. (2000), “The Return of Depression Economics”

<sup>6</sup> Kaminsky, G., S. Lizondo and C. Reinhart (1998), “Leading Indicators of Currency Crises” <http://ideas.repec.org/p/prs/pra/mprapa/6981.html>

<sup>7</sup> Cecchetti, S.G., M. Kohler and C. Upper (2009), “Financial Crises and Economic activity”, NBER Working Paper Series

they became part to the “serial banking crises”. Also, they identified a pattern in the incidence of IMF programs. Another important fact is that private debts increase prior to a banking crisis and that banking crises precede or coincide with sovereign debt crises. Debt continues to rise after default as arrears accumulate and GDP contracts. The authors identified that short term debts become public after the crises occurs. Their analysis confirms that financial crises emanate from the financial centers with transmission through interest rate shocks, commodity prices collapses, capital flows and shocks to investor confidence. An extremely valuable conclusion is that tranquil period of 2003-2007 proves once that each lull is followed by a new wave of defaults.<sup>8</sup>

Another paper of Carmen M. Reinhart and Kenneth S. Rogoff is focused on banking crises and highlights that crises are more severe for the financial centers like UK, USA and France. They analyze for the first time in the literature the role of “housing prices” and find similarities of behavior of frequency and duration of banking crises between developed and middle-income countries.<sup>9</sup>

### 3. Data set

I construct a balanced panel of three countries over 2000 – 2012 at annually frequency, obtained from World Bank and containing a number of seven hundred and eighty observations. I choose to perform the analysis for Czech, Hungary and Romania because according to Eurostat Database and World Bank analysis those countries registered comparable level of variables as GDP per person, unemployment rate, public debt, budget balance and other economic or financial indicators. Because the number of observations is the same for all countries, the panel is balanced. I chose to use annually percentage changes (%) data in order to avoid the limitation of available indicators with predictability power of the model. Using monthly or quarterly data the explanatory power of the model could be reduce by omitting important potential leading indicators which are not available in monthly frequency.

At the basis of this research there are two subjective definitions of economic instability periods (CII) and of financial instability periods (FII) and two composite indexes called EWI (Economic Warning Index) and FWI (Financial Warning Index) defined in a prior research. Economic Warning Index (EWI) represents a weighted cost of economic instability periods. Financial Warning Index (FWI) represents a weighted cost of financial instability periods. On the other side there was identified a set of potential leading indicators belonging to banking sector. Those eighteen indicators were selected based on their significance and on their relevance related to crises symptoms. My selection of indicators was influenced by availability of data and frequency of observations. During the research a problem in estimating the crisis monitoring indicators was the lack of timely and appropriate data, which avoid a complex analysis based on more variables and more years.

The entire list of potential leading indicators was obtained from World Bank database in the idea of having consistency of the methodology used for calculation of this

---

<sup>8</sup> Reinhart, C.M. and K.S. Rogoff(2008), “This Time is Different: A Panoramic view of eight Centuries of Financial Crises”, NBER Working Paper

<sup>9</sup> Reinhart, C.M. and K.S. Rogoff (2008), “Banking crises: An equal opportunity menace”, Working paper 14587

indicator. According to World Bank, the definitions of indicators which compound the panel are as follows<sup>10</sup>.

Bank capital to assets represents the ratio of bank capital and reserves to total assets.

Bank nonperforming loans to total gross loans represent the value of nonperforming loans divided by the total value of the loan portfolio. The loan amount recorded as nonperforming should be the gross value of the loan as recorded on the balance sheet, not just the amount that is overdue.

Claims on central government include loans to central government institutions net of deposits.

Claims on other sectors of the domestic economy include gross credit from the financial system to households, nonprofit institutions serving households, nonfinancial corporations, state and local governments, and social security funds.

Deposit interest rate is the rate paid by commercial or similar banks for demand, time, or savings deposits. The terms and conditions attached to these rates differ by country, however, limiting their comparability.

Domestic credit provided by the banking sector includes all credit to various sectors on a gross basis, with the exception of credit to the central government, which is net. The banking sector includes monetary authorities and deposit money banks, as well as other banking institutions where data are available (including institutions that do not accept transferable deposits but do incur such liabilities as time and savings deposits).

Foreign direct investments are the net inflows of investment to acquire a lasting management interest in an enterprise operating in an economy other than that of the investor.

Interest rate spread is the interest rate charged by banks on loans to private sector customers minus the interest rate paid by commercial or similar banks for demand, time, or savings deposits

Lending rate is the bank rate that usually meets the short- and medium-term financing needs of the private sector and it is normally differentiated according to creditworthiness of borrowers and objectives of financing.

Listed domestic companies are the domestically incorporated companies listed on the country's stock exchanges at the end of the year, without including investment companies, mutual funds, or other collective investment vehicles.

Market capitalization (also known as market value) is the share price times the number of shares outstanding.

Money and quasi money comprise the sum of currency outside banks, demand deposits other than those of the central government, and the time, savings, and foreign currency deposits of resident sectors other than the central government. This definition is frequently called M2. The change in the money supply is measured as the difference in end-of-year totals relative to the level of M2 in the preceding year.

Portfolio equity includes net inflows from equity securities other than those recorded as direct investment and including shares, stocks, depository receipts, and direct purchases of shares in local stock markets by foreign investors.

Real interest rate is the lending interest rate adjusted for inflation as measured by the GDP deflator.

---

<sup>10</sup> World Bank, 2013, <http://data.worldbank.org/indicator>

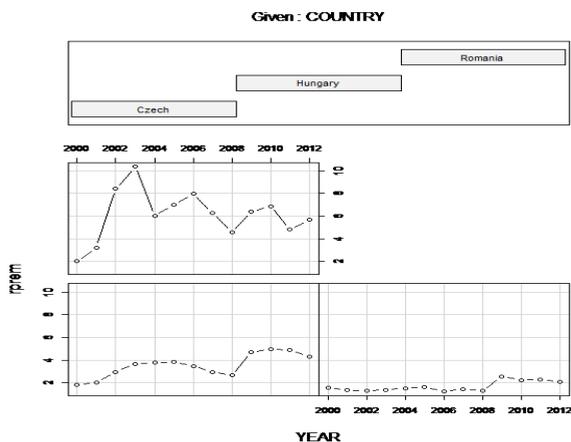

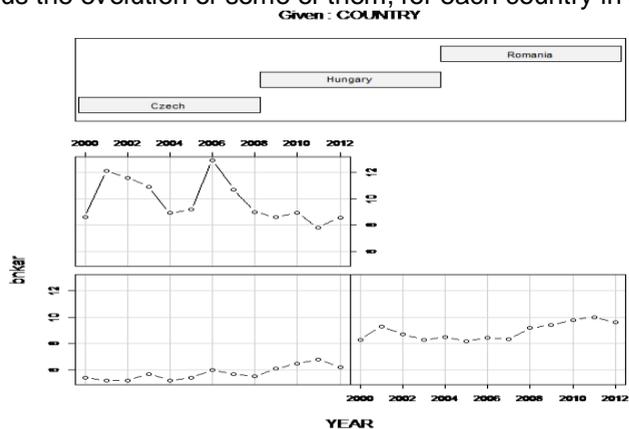

Risk premium on lending is the interest rate charged by banks on loans to private sector customers minus the "risk free" treasury bill interest rate at which short-term government securities are issued or traded in the market.

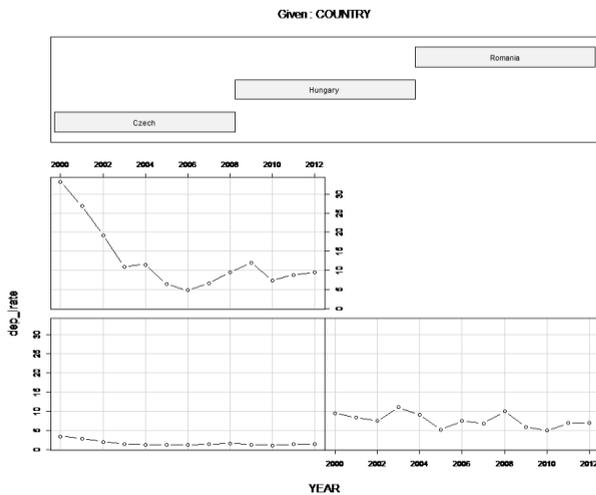

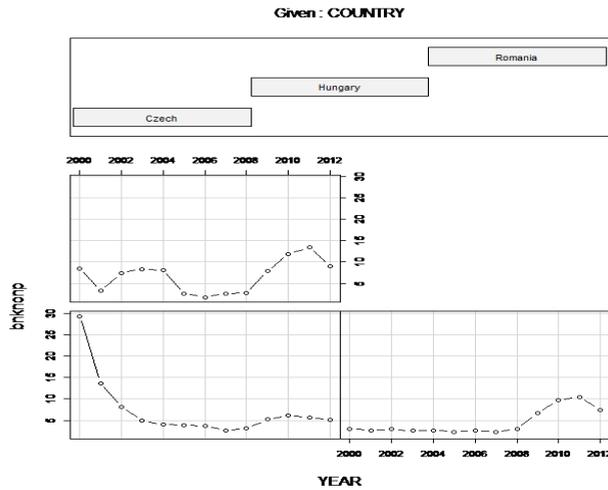

S&P Global Equity Indices measure the U.S. dollar price change in the stock markets covered by the S&P/IFCI and S&P/Frontier BMI country indices.

Stocks traded refer to the total value of shares traded during the period. This indicator complements the market capitalization ratio by showing whether market size is matched by trading.

Turnover ratio is the total value of shares traded during the period divided by the average market capitalization for the period.

The above indicators were collected for Czech, Hungary and Romania because despite the difference which appears for each country and for time to time, those countries registered a similar level of data. In the period 2000 – 2012, according to the data those variables registered evolutions (either positive or negative) from 15% to 37,705%, indicating instability periods. Using annually percentage changes assure us that the variable are standardised and there are no outliers in the dataset. To justify the choice of potential leading indicators, the following four graphs present us the evolution of some of them, for each country in the analyzed period.

## 4. Model

### 4.1 Composition

At the basis of this research there are two subjective definitions of economic instability periods (CII) and of financial instability periods (FII) and two composite indexes called EWI (Economic Warning Index) and FWI (Financial Warning Index) defined as follows in a prior research <sup>11</sup>.

CII was composed by applying weighted schemes to monthly industrial production growth, unemployment rate growth and external trade growth. In this equation a growth of unemployment rate represents a cost for the economy, so it enters with positive sign in composition of CII. Because first difference of external trade is negative, it also represents a cost for the economy. Industrial production growth

<sup>11</sup> Rodica – Oana Ionita, 2013 - “Early Warning Indicators of economic and financial instability indexes” published at FIBA – International Finance and Banking Conference

enters in the equation with negative sign, because it adds value for the economic activity.

FII is composed by applying weighted schemes to an interbank benchmark index specific to each country and to a capital market index. For the interbank reference index I used PRIBOR for Czech Republic, BUBOR for Hungary and ROBOR for Romania. For capital market I used BUX for Czech Republic, PSE for Hungary and BET for Romania.

$$CII = \frac{(unr - ext - indp)}{FII = ABS\left(\frac{PRIBOR / BUBOR / ROBOR + BUX / PSE / BET}{2}\right)}$$

$$EWI = 0.006 * ecsi + 0.0111 * mmir + 0.0148 * cpri + 0.0049 * rtt + 0.0186 * hicp + 0.0319 * stockmc + 0.0124 * ir3m + 0.3697 * exchr\_gr + confin * 0.0032 + ind\_k * 0.5 + ln\_fres * 0.0275$$

$$FWI = 0.02 * ecsi + 0.0234 * mmir + 0.019 * cpri + 0.0139 * rtt + 0.043 * hicp + 0.5 * stockmc + 0.0607 * ir3m + 0.0147 * exchr\_gr + confin * 0.1614 + ind\_k * 0.1344 + ln\_fres * 0.0096$$

For those indicators it was tested in prior research the heterogeneity across countries and years and it was revealed that the countries and year of the research are comparable, registering small differences.

On the other side, there are eighteen potential leading indicators belonging to banking system. Those eighteen indicators were selected based on their significance and on their relevance related to crises symptoms.

## 4.2 Methodology

This article purpose is to investigate which of the banking indicators are significant in explaining periods of economic instability quantified through CII, periods of financial instability quantified through FII, economic warning index (EWI) and financial warning index (FWI).

One of the methods used for estimating the unknown parameters in the two linear regression models was OLS. Because OLS regression does not consider heterogeneity across countries and time I continue the analysis with fixed effects and fixed dummy effects. In the following analysis I considered also the heterogeneity across countries and across years. I estimated fixed dummy effects because the simplest approach to model heterogeneity is to assume that each country has its own specific intercept (dummy). Each component of the factor variable is absorbing the effects particular to each country. I also performed a Fixed effects estimation. In panel data analysis, the term fixed effects estimator (also known as the within estimator) is used to refer to an estimator for the coefficients in the regression model. If we assume fixed effects, we impose time independent effects for each entity that are possibly correlated with the regressors.

In Table 1 are available the results of the three different of estimations for the four indexes.

**Table 1:** Estimation results

Index/ Adjusted R <sup>2</sup>	OLS	Fixed effects	Fixed dummy effects
CII	48.53%	38.03%	97.41%
FII	57.35%	37.53%	91.00%
EWI	89.80%	42.87%	99.97%
FWI	70.51%	42.91%	98.69%

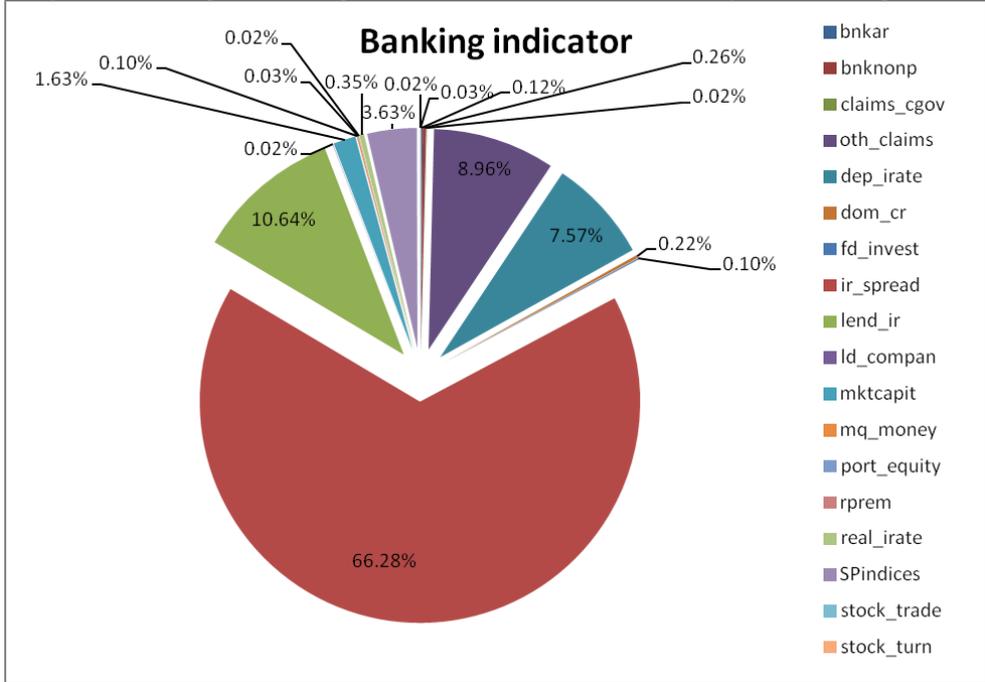

Comparing the results it is visible that fixed effects estimation has the lower explanatory power of the indexes, it explain the economic and financial warning index only in proportion of 42.87%, respective 42.91%. OLS estimation increase the explanatory power of the model explaining the economic instability period in proportion of 48.53%, financial instability period in proportion of 57.35%, economic warning index in proportion of 89.80% and financial warning index in proportion of 70.51%.

By including a dummy in the model, fixed dummy effects estimation fits better the model. According to the estimation, banking indicators explain over 90% of the economic and financial instability periods and indexes.

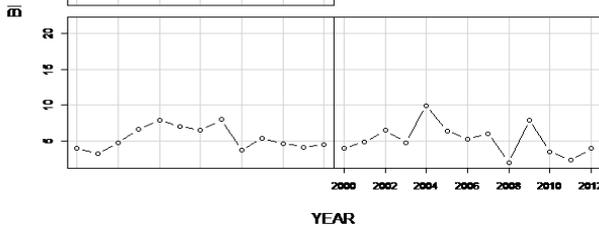

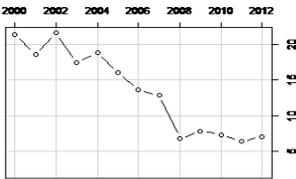

In order to identify vulnerabilities of the economic and financial environment, I composed a banking index that is multidimensional with significant variables estimated using Fixed Dummy Effects. This index represents the cost of the banking system. Higher values of the index indicate higher costs suffered by the banking system and also a cost for the whole economic environment. The significant variables were weighted according to their p-value significance. As smaller was the p-value, as important was that variable in explaining the Early Warning Index, illustrated in Graph 5. In Graph 6 it is presented the evolution of the Banking Index (BI). According to the Graph 6 its is visible that the index behave better for Romania, than for the other countries included in the study. I made this affirmation because the index captures Romania's ascending cost of banking starting with 2008 and up to the middle of 2009 and the new cost occurred starting with 2011 and up to the present.

Graph 5: Banking index weights

Graph 6: Banking Index

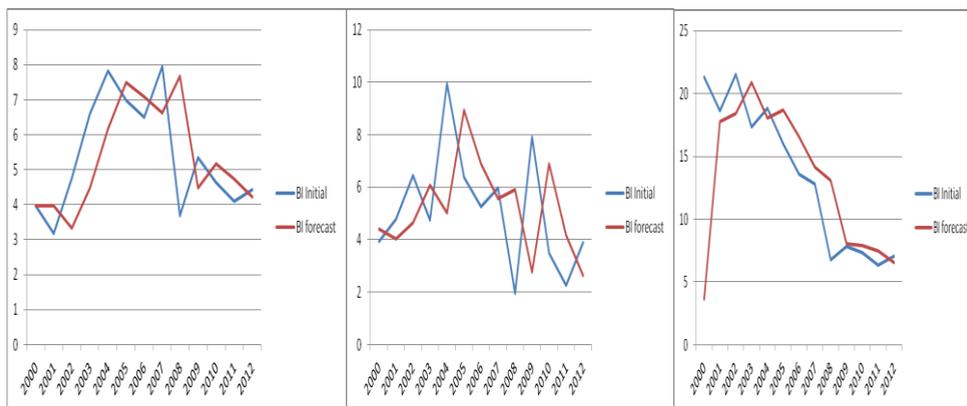

Given : COUNTRY

### 4.3 Performance

As follows I used econometric techniques to assess in the sample and out of sample performance of the model. Based on in the sample estimation, Graph 7 – 9 captures the comparison between the observed and the forecast values registered by the Banking Index. It is visible the comparability of the two series (from left to right: Czech, Hungary, Romania) with small differences which may appear from calculation of collected data.

### 5. Results

At the basis of this research there are two subjective definitions of economic instability periods (CII) and of financial instability periods (FII) and two composite indexes called EWI (Economic Warning Index) and FWI (Financial Warning Index) defined in a prior research. Because it is not possible to predict the exact point in time at which the crisis sets in, the purpose of this paper is to identify possible vulnerabilities induced through banking system and to treat them in order to mitigate the costs of the economy. I defined a set of eighteen potential leading indicators from banking/financial sector, in the period 2000 - 2012. The countries included in the study are Czech Republic, Hungary and Romania.

Using econometrics techniques as OLS regressions, Fixed effects and Fixed dummy effects there were identified significant banking indicators in explaining economic and financial instability periods. Comparing the results of the estimations, fixed effects estimation has the lower explanatory power of the indexes, it explain the economic and financial warning index only in proportion of 42.87%, respective 42.91%. OLS estimation increase the explanatory power of the model explaining the economic instability period in proportion of 48.53%, financial instability period in proportion of 57.35%, economic warning index in proportion of 89.80% and financial warning index in proportion of 70.51%. Fixed dummy effects estimation fits better the model, explaining over 90% of the economic and financial instability periods and indexes

According to the analysis, there are some significant variables which are very important in explaining the occurrence of an economic and financial instability periods, giving important signals to policy makers in order to limit potential damages

which can appear. In the future, a special attention should be granted to permanently monitoring potential leading indicators, reacting to the signals received and include those indicators in the policy measures undertaken, in order to cover all the areas of the economy and to protect against potential risks.

I, then composed a banking index which captures the costs occurred to the banking system and I assess its performance in explaining the economic and financial instability indexes through in the sample and out of the sample techniques. Using model simulations on historical data, the model performance was assessed upon in the sample and out of sample estimation techniques, suggesting that the observed and forecasted values follow the same trend, with small differences. The evaluation results suggest that banking indicators give us a warning signal of the negative trend of economic and financial environment.

## **6. Conclusions**

In this research I composed a banking index which captures the costs suffered by the banking system, based on a panel including Czech, Hungary and Romania over the period 2000 – 2012 at annually frequency. I use eighteen potential leading indicators representing country specific variables. Using econometric techniques I identified which of those indicators are significant in explaining the instability periods of economic and financial environment. Then I assess the model performance in terms of in the sample and out of sample forecast. At the basis of my decision to choose a continuous model was the fact that it motivates policy makers in steering policy continuously and the fact that there is no need to decide between yes/ no value of crisis.

Summarizing, banking indicators have a higher explanatory power in explaining the evolution of economic and financial instability periods, explaining more than 90% from the indexes which capture the cost incurred at the economic and financial environment. After observing the influence of the banking sector to the incidence of economic and financial instability periods, I composed a banking index which captures the cost suffered by the banking system. As higher is the level of this indicator, as higher there are the costs registered.

Concluding, I state that this index fits well Romania's behavior then for the other countries included in the study, fact which is perfectly right because the countries have terms and conditions attached which differ by country, however, limiting their comparability.

A limitation of the model consist in data availability an also in the fact that it is hard to find a model which fits to all the countries included in the panel, because even if those countries are comparable, they have different regulations which affect their behavior in the current context.

# THE INFLUENCE OF CORPORATE SPECIFIC FACTORS UPON FINANCING DECISIONS

**Lăcătuș Viorel-Dorin, Văidean Viorela-Ligia, Cuceu Ionuț-Constantin**

*Department of Finance, Faculty of Economics and Business Administration, "Babeș-Bolyai" University Cluj-Napoca, Romania*

*viorel\_lacatus@yahoo.com*

*viorela.vaidean@econ.ubbcluj.ro*

*ionut.cuceu@econ.ubbcluj.ro*

**Abstract:** *The purpose of this paper is to analyze the existing theories for the capital structure of a corporation and to determine the factors that influence the financing decisions of Romanian corporations. The gearing ratios vary a lot among Romanian corporations pointing out the fact that the internal specific factors are the ones with a greater impact upon their capital structure, and not the external factors. Our empiric research evaluates the determining factors for the debt ratio (total debt/total assets) of some Romanian corporations, focusing on its explanatory variables by including them within simple and multiple econometric models. The panel data indicators computed for the companies in the Cluj area listed on the Bucharest Stock Exchange were evaluated with the OLS and FEM techniques. The results have been interpreted, pointing out that company size and asset turnover seem to have a positive influence upon the debt ratio of selected companies, while profitability and liquidity seem to influence the debt ratio of selected companies negatively.*

**Keywords:** capital structure, debt ratio, theories of capital structure, determinants of capital structure, empirical data.

**JEL classification:** G32.

## 1. Introduction

The capital structure of a company represents the way that company finances its assets through some combination of equity and debt, of own and borrowed funds. Basically, capital structure policies involve a trade-off between risk and return. Besley and Brigham (2011) argue that „using more debt raises the riskiness of the firm’s earnings stream, but a higher proportion of debt generally leads to a higher expected rate of return. A higher risk associated with greater debt tends to lower the stock’s price. Therefore, the optimal capital structure of a company is utmostly considered to be the one that strikes a balance between risk and return to achieve the ultimate goal of maximizing the price of the stock.”

Generally, capital structure decisions are considered to be influenced by six primary factors:

- the *firm’s business risk* - the greater the firm’s business risk, the lower the account of debt that is optimal.
- the *firm’s tax position*. A major reason for using debt is that interest is tax deductible, which lowers the effective cost of debt.
- the *financial flexibility*, i.e. the ability to raise capital on reasonable terms under adverse conditions.
- the *managerial attitude* (conservatism or aggressiveness) with regard to borrowing. Some managers are more aggressive than others, hence some firms

- are more inclined to use debt in an effort to boost profits.
- the *growth rate*. Firms that are in the growth stage of their cycle typically finance that growth through debt, borrowing money to grow faster. The conflict that arises with this method is that the revenues of growth firms are typically unstable and unproven. As such, a high debt load is usually not appropriate. More stable and mature firms typically need less debt to finance growth, as its revenues are stable and proven.
- the *market conditions* can also have a significant impact on a company's capital-structure condition.

These six points widely discussed by the specialised literature on the field largely determine the target capital structure of a company, but operating conditions can cause the actual capital structure to vary from the target at any given time.

## 2. Literature Review

The optimal capital structure of an entity has raised major debates in the last tens of years, and as a result there exist numerous capital structure theories, ranging from the works of Modigliani and Miller (1958) to the trade-off theory of Kraus and Litzenberger (1973) and pecking order theory of Myers and Majluf (1984) and furthermore towards the agency theory and the market timing theory.

Among a great variety of foreign specialists, some Romanian authors have also investigated these theories in detail, such as Mihalca G and Antal R (2009) that have analysed the trade-off and pecking order hypotheses on the Romanian market empirically, on a sample of non-financial Romanian firms, listed on the Bucharest Stock Exchange (BSE) from 2005 to 2007. Using a panel data analysis, they found that the pecking order theory could be successfully applied to the Romanian market, as the Romanian profitable firms with a high proportion of tangible assets have a lower debt ratio.

Several determinants of the capital structure of a corporation among manufacturing companies listed on BSE have been analysed by Vătavu S.(2012), her findings establishing size as the main financial indicator with significant impact on the capital structure of companies operating in the manufacturing industry.

The specialized literature classifies the determinants of the capital structure of a corporation into two large categories: *external factors*, reflecting the macroeconomic conditions specific to every country (such as economic growth, inflation, interest rate etc) and *internal factors*, specific to each and every corporation, such as the size of the company, its assets' tangibility, its profitability and liquidity, the assets' turnover, its investment opportunities and others.

## 3. Methodology and Data

Our paper investigates the influence of corporate specific factors upon the financing decision of thirteen companies performing in the Cluj-Napoca area and listed on the BSE, acting within different fields of activity. The capital structure of these economic entities has been studied as a function of different internal factors.

The dependent variable is the debt ratio of these companies, i.e. the leverage, traditionally computed as the ratio between total debt and total assets. We have used their book values, directly from the companies' annual financial statements. Furthermore, the first independent variable is the profitability of the company, computed as total operating income divided by total assets. According to the diverse existing theories, we may expect either a positive or a negative correlation. Secondly,

the size of the company was considered as an independent variable, measured as a natural logarithm of the company's total assets. We expect a positive correlation. Then, we have considered asset tangibility as another independent variable, computed as the ration between tangible fixed assets and total assets, and further expecting either a positive or a negative correlation. The fourth explanatory variable is the liquidity of the company, determined as the ratio of cash and current accounts to total assets and the fifth explanatory variable of this study is the assets' turnover, computed as total sales divided by total assets.

Our study focuses on the econometrical modelling of the debt ratio of Romanian companies through simple and multiple regressions, using panel data. The study uses a data basis constructed with the help of BSE data for companies listed during the 2009-2011 time period, comprising 39 observations for each independent variable and for the dependent variable as well. The authors have restricted the research area upon the listed companies of Cluj county. These panel data were processed using the Gnu Regression, Econometrics and Time-series Library (Gretl) software, using both the Ordinary Least Squares (OLS) and Fixed Effects Model (FEM) techniques.

Firstly, we obtained several simple linear econometric models, of the form:

$$y_t = a + bx_t + \varepsilon_t,$$

where:

$y_t$  = the debt ratio of companies <sup>not</sup> DebtRatio;

$x_t$  = several independent variables;

$\varepsilon_t$  = residual variable

The independent explanatory variables used in this study are the ones mentioned above: the profitability of the company, its size, asset tangibility, liquidity and asset turnover.

Furthermore, the linear multiple econometric model is considered to be of the following shape:

$$y_t = a + bx_{1t} + cx_{2t} + dx_{3t} + ex_{4t} + fx_{5t} + \varepsilon_t,$$

where:

$y_t$  = the debt ratio of companies <sup>not</sup> DebtRatio;

$x_{1t}$  = the profitability of company  $i$  at time  $t$ ,  $x_{1t}$  <sup>not</sup> Profitability;

$x_{2t}$  = the size of the company,  $x_{2t}$  <sup>not</sup> CompanySize ;

$x_{3t}$  = the assets' tangibility,  $x_{3t}$  <sup>not</sup> AssetTangibility.

$x_{4t}$  = the liquidity of the company,  $x_{4t}$  <sup>no</sup> Liquidity

$x_{5t}$  = the assets' turnover,  $x_{5t}$  <sup>not</sup> AssetTurnover;

From an econometric point of view, the existence of individual effects imposes the choice for an estimation method that would produce non-shifted results. Where there are individual effects and they are correlated with the independent variables, the OLS estimation produces shifted and inconsistent results, which we didn't quite agree with. Under these circumstances, it would be recommended to use an estimation method that takes into account the presence of individual effects and that produces non-shifted results, such as the FEM.

#### 4. Simple regressions – results and interpretations

At first, the following simple models were considered for estimation using linear regressions on the panel data for the analysed companies:

Model no 1:  $y_{it} = a_i + bx_{1it} + \varepsilon_{it}$ ,  $x_1$ - the profitability of the company

- Model no 2:  $y_{it} = a_i + bx_{2it} + \varepsilon_{it}$ ,  $x_2$ - the size of the company  
 Model no 3:  $y_{it} = a_i + bx_{3it} + \varepsilon_{it}$ ,  $x_3$ - the assets' tangibility  
 Model no 4:  $y_{it} = a_i + bx_{4it} + \varepsilon_{it}$ ,  $x_4$ - the liquidity of the company  
 Model no 5:  $y_{it} = a_i + bx_{5it} + \varepsilon_{it}$ ,  $x_5$ - the assets' turnover

Source: Authors' processing in Gretl

Note: Within parentheses there are the p-values, and \*\*\* designates the 1% significant coefficients, \*\* designates the 5% significant coefficients while \* designates the 10% significant coefficients.

After estimating the models' coefficients, the following simple regressions were obtained with the FEM technique:

Model no 1	$DebtRatio_{it} = 0.355655 - 0.156546 Profitability_{it}$
Model no 2	$DebtRatio_{it} = 2.44432 - 0.121395 CompanySize_{it}$
Model no 3	$DebtRatio_{it} = 0.577847 - 0.288945 AssetTangibility_{it}$
Model no 4	$DebtRatio_{it} = 0.348803 + 0.319186 Liquidity_{it}$
Model no 5	$DebtRatio_{it} = 0.316152 + 0.137296 AssetTurnover_{it}$

The above presented regressions may be interpreted as follows:

Model no 1: For a one unit increase of  $Profitability_{it}$ , the  $DebtRatio_{it}$  will decrease, on average, with 0.156546 units.

Model no 2: For a one unit increase of  $CompanySize_{it}$ ,  $DebtRatio_{it}$  will decrease, on average, with 0.121395 units.

Model no 3: For a one unit increase of  $AssetTangibility_{it}$ , the  $DebtRatio_{it}$  will decrease, on average, with 0.288945 units.

Model no 4: For a one unit increase of  $Liquidity_{it}$ , the  $DebtRatio_{it}$  will increase, on average, with 0.319186 units.

Model no 5: For a one unit increase of  $AssetTurnover_{it}$ , the  $DebtRatio_{it}$  will increase, on average, with 0.137296 units.

Table 1 compares the  $R^2$  and the adjusted  $R^2$  of these models. The negative values for the adjusted  $R^2$  might point out towards some useless regressors in the model.

We may notice that the adjusted  $R^2$  reaches the maximum value of **0.963896** for model no 2. We may further say that  $x_{2it}$  representing the size of the company would have the highest explanatory power and model no 2 is the most representative among the other studied models. Still, by taking into account the p-values, the only significant coefficient is that of liquidity with OLS, in model no 4.

## 5. Multiple regressions – results and interpretations

Furthermore, we have considered multiple regression models, for the  $DebtRatio$  as the dependent variable and the above mentioned independent variables, on turns. We have estimated the coefficients of these models and we have compared the values obtained for the adjusted  $R^2$ . The model having the maximum adjusted  $R^2$  points out the fact that the independent variable used for that regression has the highest explanatory power. To follow, it will be considered for another series of multiple models, together with another independent variable, and so on. Knowing that an adjusted  $R^2$  that increases as we add more independent variables in the model points out that the explanatory power of the regression increases, we have obtained the models presented in Table 2.

The below presented results point out the fact that size and asset turnover seem to determine the debt ratio of companies, according to model no 8. For model no 9, asset turnover was found significant for the leverage of the analysed companies. Nevertheless, model no 10, the last and most complex model, suggests that profitability, liquidity and asset turnover are significant for the Cluj listed companies.

Summing up, the relationships between the explanatory variables and the DebtRatio as a dependent variable for the Cluj area companies listed on the BSE, we may conclude that the following relationships were validated:

- a positive relationship between company size and its debt ratio;
- a positive relationship between asset turnover and the debt ratio;
- a negative relationship between profitability and debt;
- a negative relationship between liquidity and debt.

## 5. Conclusions

These estimations reveal the dependence degree between the debt ratio of the studied companies and certain explanatory variables. Company size, asset turnover, liquidity and profitability were found important for the debt ratio of selected companies. The higher the size of the company and its assets' turnover, the more borrowed capital companies use. On the other hand, the higher the liquidity and profitability of these companies, the less borrowed capital they need in order to finance their business.

Because of data inaccessibility, this study was carried out on a reduced number of companies and time periods so the size of the sample is a limitation of this research. Still, as new data become available, this would become a direction for our future research.

All in all, when it comes to financing decisions, after analyzing a number of factors, a company establishes its target capital structure, the one it believes to be optimal, which is then used as a guide for raising funds in the future. Besley and Brigham (2011) consider that „the target might change over time as conditions vary, but at any given moment the firm's management has a specific capital structure in mind, and individual financing decisions should be consistent with this target. If the actual proportion of debt is below the target level, new funds will probably be raised by issuing debt, whereas if the proportion of debt is above the target, stock will probably be sold to bring the firm back in line with the target debt/assets ratio". All in all, the debt ratio presents a particular importance for each company, regardless of its activity field.

# THE ROLE OF SAVINGS RATE IN DEEPENING MACROECONOMIC IMBALANCES IN CHINA

**Șarlea Mihaela, Manța Ștefan George, Văidean Viorela Ligia**

*„Babeș-Bolyai” University, Faculty of Economics and Business Administration, Cluj-Napoca, Romania*

*viorela.vaidean@econ.ubbcluj.ro*

**Abstract:** *It is well known that China is a growing power and its impressive economic indicators have been the subject of numerous studies along the years. China's impressive economic growth in the years 2000 based on one hand by an expansionary monetary policy, on other hand by promoting export growth had also brought into discussion another factor: that of the high savings rate. This article brings into light China's high savings rate -household, corporate and governmental- each with its role played in the entire equation of China's growth. There have been a lot of studies concentrating on this relationship between savings rate and economic growth. It appears that, in the case of China there is a positive relationship between high savings and high economic growth at least on the short run. This is due to the national savings rate which contributed to current account surplus that facilitated outflow and inflow of capital. Domestic investments and foreign growth had contributed to rapid economic growth despite the low level of consumption. If we add here the low demand for imported goods and the growth of households saving rate in the last year we have an image of deep macroeconomic imbalances. Furthermore, if we add to this analysis the idea of an external saving rate that proved to grow quicker than the world capacity to absorb this flows we have a vivid image of an empire as „rich country, poor population”. This high savings rate in the long run will deepen macroeconomic imbalances. As a spiral this would have to accelerate reforms in the field of pensions, healthcare, social security. On top they would have to encourage the development of the banking system in order to create an image of a powerful country also in the long run. With these internal reforms the savings rate for households will encourage consumption and a normal level of savings, for corporations it will boost investments and for government it will lead to a balance account closer to reality and better use of the incomes.*

**Keywords:** savings rate, current account, monetary policy, macroeconomic imbalances.

**JEL classification:** E21, F32, H62, J11

## 1. Backgrounds

In 1957 Friedman created the permanent income hypothesis in which he stated that a rational consumer will save only when their current income is higher than anticipated future permanent income. China is one of the Nations with a rapid economic growth rate, but at the same time it has one of the highest rates of saving. And that's highly due to the high rate of household saving.

Conventional perception is that saving contributes to an increase in investment and GDP growth in the short term, as demonstrated by several authors over time such

as DeGregorio, Jappelli and Pagano (1994). The basic idea was induced by Lewis (1995) - a sustained increase in the rate of savings will lead to an acceleration of economic growth. Carroll, Overland and Weil (2000) concluded that "if utility is partially dependent of the way in which consumption is assimilated by a habit stock determined by a past habit then a standard economic growth model can cause increase in consumption rate". There are also several studies that show an interdependent relationship between these two variables, like an increase in economic growth will lead to higher savings rate and vice-versa. Carroll and Weil in 1994 proved this relationship between OECD countries, the exception was a study realized by Baharumshah in 2003 for Asian countries - an econometric study between 1960-1997 for North Korea, Thailand, Malaysia, Singapore. The only country that proved the original causality relationship was Singapore.

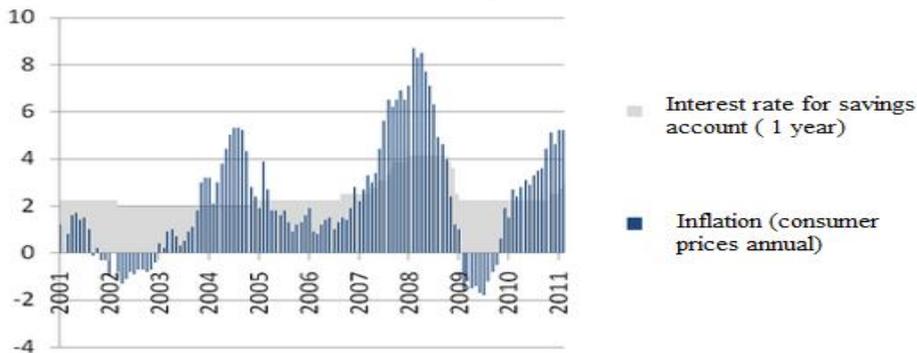

## **2. The savings rate in China – facts and figures**

It is well known that a country like China has a high level of savings rate and determined not only by the household savings, but also corporate and governmental. In regards to the rate of household saving, there have been many reasons over the years listed as the explanation of the high rate of growth. The population in China were taught to save over the years. One of the main reasons might be due to the regime and their caution. There might also be considered pollution-related problems, an underdeveloped social system, and high rates of poverty, limited medical insurance and low access to the healthcare system. The efforts of the authorities to reduce the savings rate will prove unsuccessful if prior to these, a more advanced social, healthcare system will not be created.

So, there are three main elements in sustaining China's high level of savings rate: education, pension system and health. The pension system needs reform. The demographic policy adopted in late 1970s "one child per family" resulted in strengthening the idea of self-sustaining after retirement. In this context, a study conducted by Modigliani and Cao (2004) demonstrated that households saved around 5% of income before 1978. In contradiction with the elderly, people at middle age rely upon revenue growth to achieve a target saving rate. In 2010, another study by Charmon and Prasad, showed that populations at middle age in China, in contrast with other states save less compared to young or old population. This demographic policy would lead to a decrease in household saving rate due to the fact that by 2050 there will be an increase in the elderly population.

Apart of these demographic and social factors, we might add the lack of competition in regards to the bank services offered to the population. Figure 1 shows the evolution of inflation and the interest rate for 1 year saving deposits between 2001 and 2011:

**Figure 1.** Evolution of interest rate (saving deposits) and inflation 2001-2011

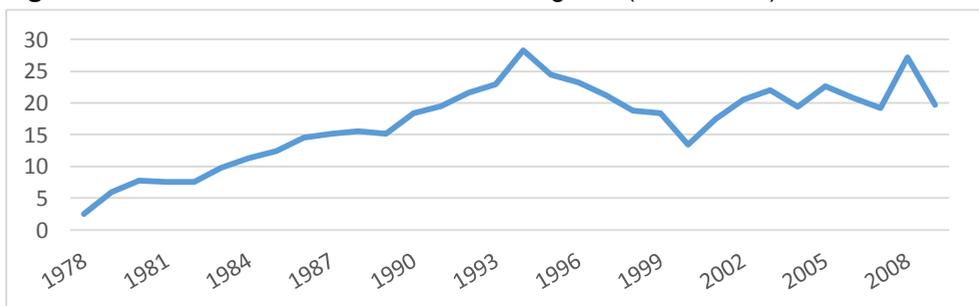

Source: People Bank of China, National Bureau of Statistics

Due to the increase of inflation between 2007 and 2008 and again in 2010-2011, the household savings rate decreased. It was also the objective of the government that tried to increase consumption in order to boost the economy. Although the overall countries savings rate increased from 37,3% to 52,4% between 2002 and 2008, in the last decade the percentage of the household savings rate decreased by 10%. These statics however showed that the population saved less at banks, and the international banking liquidity crisis highly also contributed.

There were a lot of reforms during the years that we consider important in determining the level of saving. Between 1950 and 1978, all the houses were given by the authorities at affordable prices. Between 1982 and 1985, a program of privatization of public houses was lunched, that proved to be a failure due to the lack of financial incentives to sustain the credits. In 1991, Shanghai developed a public system to finance the cost of buying a house which granted fund to the real-estate developers in order to build new houses. The most important reform was in 1998 when the state adopted a new Directive in order to increase the number of households that lead due a real " housing bubble".

**Figure 2:** Evolution of overall household saving rate (1978- 2009) %

Source: Authors' calculation after Federal Reserve Bank of Saint Louis, 2012

We can compare this percentage with the state reforms. When the state was responsible with household granting, the savings rate was only 2.5%. At the beginning of 1990 it was 20 and 25%. The more important raise was registered between 1994 and 2008. 2008 marked the year of the fiscal package stimulus

implemented by the government as a response to the financial crisis. As a result, a large number of people gained access to credits in order to acquire a house.

In regards to corporate savings, an important factor is the tendency of firms to retain earnings. According to data from Worldscope, more than half of China's listed companies in the industries have not paid any dividend over the past decade. In comparison, in countries like India, Singapore, Korea, Japan the percentage was around 30%. In 2008, only, the profit reported by Chinese listed companies was of only 36 percent of the total profits recorder by all companies. The same authors argued that the high rate of corporate saving is due to the high rate of State-owned companies because of the fact that leadership and corporate savings are a key element in achieving the current account surplus. The rate of payment of dividends, which reflects the percentage of earnings paid out as a dividend to shareholders decreased by 10% since 2001. Due to the role played by these gains, increase corporate savings withheld are closely linked with the growth of corporate profits. Their earnings were around 30% per year, from 2000 onwards, the wage growth rate of 15% per annum. One of the explanations for this increase in profits could be caused by a surplus of rural labor capital factor that increases wages and outlasted wages increase and boost profits. The assumptions regarding the causes of earnings were retained. Here we mention as possible causes, few dividends paid by Chinese firms. And as explanation of why most net gains have been retained by these companies - namely underdeveloped financial system and poor corporate governance, low access to credits of small companies that could lead to a decrease in wages that brings low productivity and low profits. Other reason might be the entry barriers that limit the development of services in which labor is very important. We also have to consider the fixed exchange rate and the interest rate. There are other economists that say that this exchange rate leads to an increase in household savings and other that state that it is a confusing role between the exchange rate and current account because China's exchange rate fluctuated along the years and renminbi is stronger than other currencies from emerging countries(Chinn and Wei, 2009).

Sources of disposable income and governmental savings (million Yuan) are, according to Central Bank of China value added in production (1), labor compensation (2), net taxes on production (3), net income from production (4), net current transfers (5), disposable income (6), consumption (7). We calculated the total net income as  $(1) + (3) + (4) + (5) - (2)$  and savings as  $Savings (6) - (7)$

The percentage of Government saving rate has fluctuated quite a lot, at a level below the 4.4% between 1992 and 1999, reaching a minimum of 2.6% in 1999 to a level of 10.8% in 2007. Disposable incomes of the Government, composed mainly of Government production, property income, taxes on production, income from taxes and social security income without compensation on the labor increased from 1608.9 billion Yuan in 1999 to 6308.4 billion Yuan in 2007. The increase in revenue from taxes on production contributed most to the increase in government revenues during this period. This was mainly due to the increase of investment in that country as a result of cheap labor and aid offered by the authorities to increase the use of the labor cooperatives in the country. It also led to an increase in the number of branches created by multinational companies in the country. It also lead to an increase in net taxes to 65% in government incomes. The main foundation was the 1994 fiscal reform. Thus, from a low level of net income as a percentage of GDP at the beginning of the 1990's, effective system of tax collection, along with a growth of approximately

10% per year growth led to an increase in Government revenues from 1999 to 2007. The second largest contributor to government revenues are net current transfers. According to the data provided by the Central Bank, the Government has shown a consistent increase in revenue, and an increase in government savings. All of these contributed to China's image of "rich country, poor population". However, although we note a striking change in relation to the revenue collected by the Government and as a result an increase in the rate of accumulation, tax collection percentage remains low compared with other economies such as Japan, the US and Germany (Yang et al., 2011).

It is obvious that the aggressive growth policy has facilitated the increase in saving. And monetary policy, which is supposed to have a decisive role and a strong impact on long-term interest rates and economic activity in general will affect corporations largely through the establishment of future revenues and dividends paid. It therefore directly affects savings rate of corporations. Monetary policy by determining the interest rates on deposits will directly affect the population and their saving rate. It led to the increase in government revenue.

There were a lot of voices during the years that talked about the effects of high rates of savings in the long run. Under the terms of 50% savings rate, consumption was sacrificed. Keynes said that "consumption-to repeat the obvious-is the goal and the ultimate objective of all economic activities". The high saving rate has allowed the Government to adopt policies of rapid growth. Unlike other developing States with high volume of imports the promotion of exports (partly due to the high level of savings) it allowed the development of several industries and also the creation of preconditions for technological development. There are voices, such as the Economist (2008) in which the economist Lardy highlighted the fact that the level of savings helped save the banking system, blamed for the large number of non-performing loans. Furthermore, it argued that the revenue brought in by households savings has helped to sustain the banking system by boosting savings deposits.

A lot of economists have expressed concern over this increase in current account surplus from China. They warn that it grows more than the world's capacity to absorb. Meanwhile these flows are likely to become even more dangerous in the context of all the austerity measures adopted by several countries that made the aggregate demand to decline. This has left many countries under the threat of „liquidity trap” in which the Chinese trade surplus could be interpreted as a policy of so-called "beggar-thy-neighbor". This exports the unemployment from China as a country in the period of economic boom to countries with already high levels of unemployment and low rate of GDP growth.

Among the most notable and obvious developments of Chinese economy there were impressive growth rates on both saving and exports, thus the current account surplus. These indicators have had an upward trajectory, especially after China's accession into the World Trade Organization (WTO). And this impressive accumulation of capital, including during the crisis have resulted in an increase of foreign reserves, almost 3 times higher than those of Japan, the second place in the world in this perspective. It is obvious that with WTO, China's business climate has become more attractive, and the profitability of firms has increased. However, due to the institutional rules that were meant to facilitate the promotion of exports, a large part of these gains have been saved in the corporate sector or collected by the Government, which has led to higher savings rate. This, along with low consumption,

low demand for imported goods and the growth of households' saving rate has resulted in deepening macroeconomic imbalances.

Furthermore, these imbalances are a real danger, particularly for an economy like that of China. Low consumption rate as a percentage of GDP implies that the rapid economic growth of China in recent years has been encouraged by domestic investments and foreign growth. And this practice by supporting increased growth and trying to avoid external shock and limiting unprofitable investments will become more and more difficult in light of the current economic crisis and the turbulence generated by the euro zone crisis. Moreover, due to massive foreign reserves in dollars or bonds denominated in euros, China is subject to major risks in case the euro and the dollar depreciates (Sheng and Liugang, 2011).

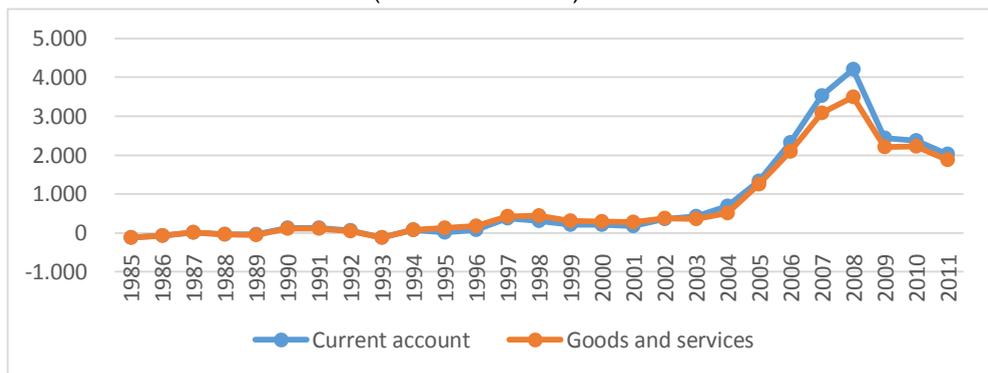

### 3. The external account balance of China – the present situation

The balance of payments includes payments and revenues made by a country that reflects all stock flows across the border of a country with the rest of the world over a period of time. To analyze China's foreign imbalances we consider this flows as being most representative of the current account, foreign direct investment and foreign currency reserves.

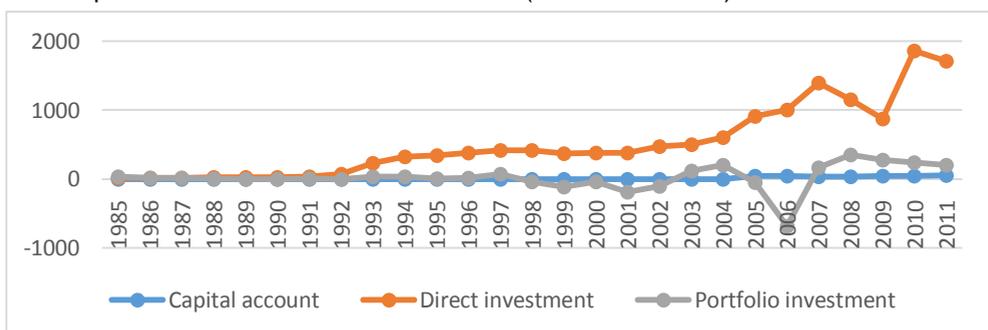

We will analyze the most important trends of China in the external account balance. Thus, we will consider the evolution of the balance of the current account, the capital account and the foreign currency reserves during 1985-2010.

**Figure 3:** International balance of payments of China 1985-2010

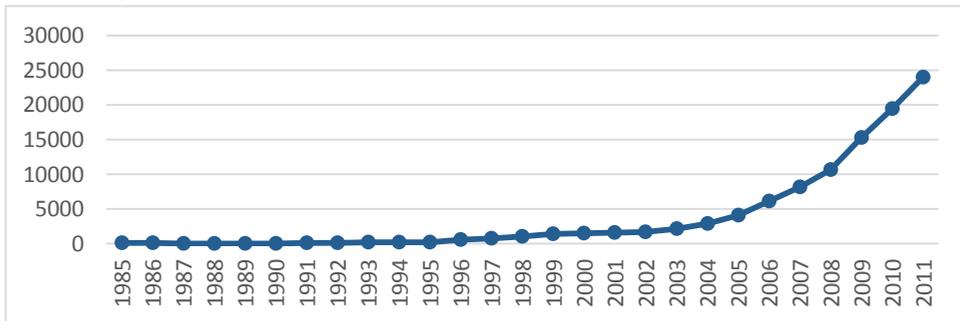

#### 2.1. Current account evolution (100 million USD)

#### 2.2. Capital and financial account evolution (100 million USD)

### 2.3. Foreign reserve evolution ( 100 million USD)

Source: Authors' calculation after State Administration of Foreign Exchange

In regards to trade development, we note that there are undetectable imbalances at the beginning of the 1990, even deficit being recorded in some years. A significant change is noted as from 2001, the surplus grew considerably, especially in the years 2005-2007. On the other hand we have highlighted the development of trade in goods and services. There is a similar, sometimes identical to the developments in the current account surplus.

Although we note an increase in the surplus in the beginning and middle of 1990, we can say that the capital account was more or less balanced even before the entry of China into WTO (2001). After this event, however, the current account recorded a surplus due to the opening of the economy. We also have a large increase in foreign direct investment since the beginning of the 1990. Moreover, China has become the second most attractive country for such investment, after the United States (according to the data supplied by OECD). In the light of the financial crisis in 2008, both foreign direct investment and portfolio investments decreased, but remained at a high level, reaching in 2010 to a surplus of 4% of GDP. All these major surpluses in the current account and the capital account resulted in an explosion of foreign currency reserves. In 2000, China held 10.9 billion dollars in reserves, equivalent to 0.9 percent of GDP. In 2012, according to the US treasury has reached the level of 45% of the GDP in 2011. Much of China's assets are invested in US Government bonds with a slow recovery.

If balance of payments statistics recorded stock flows across the border in exchanges and capital, net foreign assets statistics provide the capital position in the economy's related to financial assets and liabilities. A surplus in the current account is flagged with an increase in net foreign assets, while a deficit of current account brings a drop in net foreign asset position (Yang, 2012).

And as the current account surplus kept growing after 2001, it became increasingly clear that accumulating foreign reserves is directly connected with the fixed exchange rate policy. Thus, it is a continuous expansion of current account surpluses and capital inflows. With all the efforts of the authorities to limit the increase in reserve requirements by trying some of the stresses and strains of withdrawals capital they proved ineffective in light of the fixed exchange regime.

According to data supplied by the same source, SAFE, in 2011, in just 10 years after the onset of the fulminating expansion of China after the year 2000, China has gradually become a major creditor of the whole world. Thus, in these 10 years the position of foreign net assets grew from a borrower's debt of 6.2% of GDP in 2000

to a net lender about 30.5 percent of GDP. And here, a very important role was played by the foreign currency reserves as it reaches even half of GDP. The top 10 countries in this statistics hold together 2/3 of the total foreign exchange reserves in the world. For a country considered one of the major contesters of the role of the dollar on international markets makes an important job in enhancing this role. Through the enormous quantities of dollars bought, China maintains, artificially the price of the dollar high and the price of its own currency, artificially low- thus promoting the dollar as a reference currency. In order to maintain fix exchange rate the Chinese authorities buys every day 1 billion USD from the exchange market (Bergsten, 2010). The same tactic is observed at Hong Kong, Malaysia, Singapore, Taiwan in order to maintain a competitive position versus that of China.

There are different opinions towards the role played by the surpluses and deficits in realizing economic growth. Imbalances are general considered dangerous. And along the time, the developed countries proved this theory.

According to Figure 2, several imbalances are noticeable along the years. We note, for example, in 2005, that developed States registered surplus, while those emerging states registered deficit. From the beginning of 2000 and until 2010, the situation was reversed. If we look at the situation in 2000 up to the years of the crisis, in 2008 we can say that the developed States' deficit was increasing and the emerging States surplus grew even four times since 2000. However, the developed States registered important economic growth. By the year 2008 China's situation had changed, reaching a surplus of 435.9 billion dollars, 15.1 percent of the total surplus recorded by the entire group in transition. In 2008, the U.S. had a surplus almost double than that of China, and three times as high as that of Germany. As China had the largest surplus of emerging countries, emerging group reached half of the surplus recorded in 2008, and developed countries have reduced the deficit four times as compared to 2008.

**Table:** Global current account balance (billion USD)

Country	1995	2000	2005	2008	2010

#### 4. Conclusions

Thus, the most important role that the savings rate will play in creating imbalances in the Chinese economy is the external savings rate. Thus, we analyzed several pathways through which it could achieve a decrease in the short or long term in external savings rate. Even though this rate of accumulation is due to long term causes we believe that in the short term, certain actions may prove successful.

- On the short run:

Considering the fact that the current account surplus is the difference between national investment and national savings, we can say that encouraging private investment can be a solution even though it may not affect national saving rate. If a large portion of those savings would be attracted to the national investment, the result would be a decrease in foreign savings and it will eventually lead to a fall in unemployment, and perhaps even to an increase in the labor productivity.

Encouraging private investment is important, as all short term economic stimulus packages have encouraged domestic investment. A short-term economic policy to encourage public investment from the Government could lead to a fall in unemployment and the rural and urban infrastructure, as example. Other short-term solutions could stimulate private consumption through the granting of tax exemptions for owners of small and medium enterprises to promote investment in new equipment and modernizations. Another way would be to boost household consumption. Because of the reasons listed above in this analysis this could prove difficult due to the consumption habits. However, a solution could be the lowering of fees such as taxes on property or cars or others.

- On the long run:

One of the long-term solutions that could be taken into consideration could be the development of the banking and financial system and to modernize the social security system in order to reduce the rate of saving, which would have a beneficial effect upon encouraging consumption. Carroll (2010) proposes a system of "pay as you go" in order to resolve the problems of the pension scheme. Through it, payments of fees from the active labor force would be used to finance the pensions of current elderly. It would bring a sense of security among people currently employed by creating a secure income in the retirement years and it will lead to a decrease in the rate of saving. Also, we might add here a solid system of insurance in case of loss of employment. There might be introduced a series of limited-term income to encourage finding a new job. Also, we recommend creating a developed and competent social health insurance to cover the cost of daily care problems and some extraordinary costs as well, in order to discourage population to save as to get good health package.

**Abstract.** *For any investor, the economic entity's financial reporting contributes decisively to a decision on maintaining the operational management team, changing it, purchase new shares or sell shares in that company. For this reason we think it is very important that an assessment of the entity's financial performance should be made and build a credit rating model to generate a fair and reasonable picture of it.*

**Keywords:** *performance, rating, bankruptcy*

### 1. Introduction

In evaluating the rating of economic entities, credit banks use their own rating systems. In bank lending, credibility is an essential element of moral and material support without which a credit may not be granted. Thus, customer knowledge is a key aspect which is achieved through a thorough analysis and documentation to evaluate the reality of the patrimonial and financial situation of the entity.

The default risk is an important issue that has been and continues to be in the attention of managers as they are always interested in the smooth running of the production cycle. Also, both investors and lenders study and observe the bankruptcy risk of a company as they are interested in recovering loans and interest.

The essential problem for any stakeholder is "anticipate risk, and minimize its occurrence and control it."<sup>1</sup>

All models of bankruptcy are based on a scoring function which is used to determine whether the company will go bankrupt or will it achieve good results in the next period of analysis.

In recent years, the economy has led tens of thousands of companies in Romania into insolvency, the figure increasing annually, respectively in 2012 a number of 21,692 companies became insolvent compared to 19,894 in 2011 and relating the net turnover of the companies entered into insolvency this is evolving exponentially. In these market conditions, financial performance evaluation of the operational activities and financial activities of the entities has a very important role in the economy of enterprises, both in terms of their own situational awareness and regarding the financial standing of their business partners.

Financial standing targets the quantitative side of the economic entity where the indicators are based solely on financial standing and they form the basis for determining a score, which classifies the economic entity in a particular class of financial performance or a rating class.

The quantitative side of the entity refers to indicators such as liquidity, solvency, profitability, leverage, indicators that send the first signal of danger for any business.

Financial standing is primarily used by banks to analyze creditworthiness of the enterprise asking for a bank loan, these banking institutions then fitting the entity into a performance class from „A to E”, based on a certain score. Regarding the practical part of the paper we used the information presented in the financial statements of SC Tourism Aries SA, with the help of which we then calculated the financial standing indicators used in the rating models, respectively banking models and also models regarding bankruptcy analysis, all of these providing information concerning the financial standing of the economic entity.

## 2. Methods and results

Eating type analysis is based on a series of economic and financial indicators used in financial analysis, indicators considering the financial strength of the company.

Subject of financial analysis is the assessment of the company's financial policy in a prior period and facilitate future decisions. This is based on the financial statements of the company, but also on other sources of information.

Determining a company's rating, together with the rating of underlying securities represent the foundation stone for the approval of a loan, its cost( interest rate), but also the decision to continue financing a company or not, in case of a rating downgrade. The rating system is a unitary system in accordance with Basel II regulations on internal rating system approach.

At the base of rating analysis are three basic principles, namely:

Clear rating responsibilities;

- Strict enforcement of the "four-eyes" principle in the rating process;
- Rating authorisation independent of the account management.
- The credit rating must be sub-divided into three parts, as follows:
- The proposal rating is made by management account or credit analysis;
- Approval by analyzing credit rating;
- Approval rating by those who make decisions for the client.

According to Basel II client rating is unique, that each borrower has a credit rating level which he is assigned after the rating analysis.

To analyze company performance by bank based models (BRD - GSG and Transilvania Bank) and statistical and mathematical models : Altman, Robertson, we built a rating model, based on the following indicators: rotation of current assets, current liquidity ratio, solvency, financial profitability rate and indebtedness.

The results obtained from analysis using our own model can be seen in the following table:

**Table 1: Model of Rating**

	Accomplished 31.12.2008	Accomplished 31.12.2009	Accomplished 31.12.2010	Accomplished 31.12.2011	Accomplished 31.12.2012
<b>1) Current assets rotation</b>					
Turnover	195 677 945	229 415 602	215 805 947	219 754 104	243 626 062

Source: the company's own financial statements

Analyzing the indicators that comprise the model, we have:

- Current assets rotation decreased between 2008-2011, due to the current assets growing faster in this period compared to the net turnover, this increase being given especially by the debts is approximately 80% of current assets. In 2012 Current assets rotation increased by 7.75% on account of the advance of turnover in relation to current assets;
- The current liquidity ratio decreases in 2009 and 2010 compared with the previous year by about 2% and 12.5%, due to the faster increase in current liabilities than current assets, the company obtaining some loans at this time. In 2011 and 2012 the current liquidity ratio increases by about 6% -7%;

- Solvency decreases in 2010 and 2011 because of rising debt levels, followed in 2012 with an increase of 12.29% compared to 2011 due to a lower debt, the long-term debts being zero;
- Return on equity recorded a decrease of 67.51% in 2010 due to lower net income 67.42% mainly because of a lower activity that year. Throughout the whole period growth is achieved only in 2011, an increase of 14.9% due to the net result of the advance;
- Indebtedness has an upward trend in 2010 and 2011, when it grows by 14.84% and 8.53%, followed in 2012 by a decrease by 7.32% due to lower capital bank liabilities.

It is noted that the company recorded a good rating on all years analyzed, but it is decreasing compared with the total score in 2008 and 2009, going from 39 points in 2009 to 34 points in 2011 and 2012. This is due to lower net income, or profit representing only 61.37% in 2012 compared to the level reached in 2009.

Decrease in profit is due to the decrease in business activity, its turnover in 2012 was below the level of 2009 and lower by about 1.5%, and total expenditure growth, especially operational costs, and these increased by 12 % compared to 2009.

To improve the total score of 2012 and reaching that threshold as in 2009, we assumed the following scenario:

- A 15% increase in production in 2012, from 224,870,563 to 258,601,147, leading to an increase in net turnover, income and therefore the recorded net profit will increase by 72.79% .

Based on these assumptions we obtain the following results:

**Table 2:** The following application scenario own

	Accomplished	Accomplished	Accomplished	Accomplished	Accomplished
	31.12.2008	31.12.2009	31.12.2010	31.12.2011	31.12.2012

<b>Mark</b>	<b>Good</b>	<b>Good</b>	<b>Good</b>	<b>Good</b>	<b>Good</b>

Source: the company's own financial statements

Following this scenario we find that the rate of return on equity increased from 4.71% to 17.55% placing the category A.

To increase the company's rating for the financial year 2012 from "Good" to "Very Good" is necessary to increase the rotation of current assets, current assets being at a high level, debts representing 80% of them in 2012.

Compared to 2009 the current assets increased in 2012 by 23.88% and the debt increased by 46.99%, therefore we recommend a tougher trade credit policy, but at the same time to not affect greatly the pace of sales growth.

### 3. Conclusions

To increase the company rating it has to improve its debt collection, but also affecting the least the trade policy in order to increase the net turnover and the net profit, respectively. Another measure that is necessary is to reduce short-term debt especially debt credit institutions, which may be financed through a long-term loan with an interest more convenient, but also because the company has no long-term debt in 2012.

Contracting the long-term loan might help disperse the debts, or a better ratio of current debt in total debt.

According to our rating model we can observe that the company recorded a good rating on all years analyzed, but it is decreasing compared with the total score in 2008 and 2009, going from 39 points in 2009 to 34 points in 2011 and 2012. This is due to lower net income, or profit because it represents only 61.37% in 2012 compared to the level reached in 2009.

Decrease in profit is due to the decrease in business activity, its turnover in 2012 was below the level of 2009 and lower by about 1.5%, and the total expenditure growth, especially operational costs, increased by 12 % compared to 2009.

To increase the company's rating for the financial year 2012 from "Good" to "Very Good" is necessary to increase the rotation of current assets, current assets is at a high level, debts representing 80% of them in 2012.

Compared to 2009 the current assets increased in 2012 by 23.88% and the debt increased by 46.99%, therefore we recommend a tougher trade credit policy, but at the same time to not affect greatly the pace of sales growth.

The analysis of financial performance and risks faced by the company is very important to know in which category of loans is the company framed by banking models, but also to know its risk of failure and to implement effective policies to avoid risk or at least reduce its effect.

# IMPLICATIONS OF THE FINANCIAL SYSTEM ON THE CAPITAL STRUCTURE OF THE ENTERPRISE

**Toderașcu (Sandu) Carmen, Rusu Valentina Diana**

*"Alexandru Ioan Cuza" University, Faculty of Economics and Business Administration, Iași, România*

*Sandu\_carmen@yahoo.com*

*Valentinadiana.ig@gmail.com*

**Abstract:** *This paper aims to identify the types of financing structures of the economy that exist in European Union countries highlighting the features of each structure. For each type of financing system of the economy identified we observe the financial resources available to companies. Depending on these we identify how there are financed the companies in each market, more exactly what capital structure do they have, and moreover what is the optimal capital structure in each case. So, by this analysis, we want to see if the financing system of an economy influences the optimal structure of the companies operating in the capital market from that country. In various stages of development of the financial system, the company financing depends on the general characteristics of the environment in which the enterprise operates. The financing system existing in a country plays an important role on the capital structure of an enterprise from that country because, according to the specific of each country, the enterprises have access to more or fewer financial resources. We also analyze the supply of financial resources within each system, exactly the actual money that businesses can have on those markets and key management decisions on enterprises financing. In this paper we combine the theoretical analysis with the empirical results obtained by the studies realized by European Commission. It is important to keep in mind that the results obtained by the analysis realized in the last years may be influenced by the manifestation of the global financial crisis. An important result of this analyze is that the external environment and the disturbances in the external environment have a significant influence on the financing of businesses operating in a country. This was proved again by the impact of the current financial crisis on the activities of the enterprises on each financial market from European Union.*

**Keywords:** *financing system, capital structure, incipient financial system, economy of financial intermediation, financial crisis*

**JEL Classification:** *G32, O11, P51*

## 1. Introduction

The financing system of an economy represents all economic relations, mechanisms, institutions and instruments by which the necessary financial resources in the national economy are mobilized from the agents that have available capital funds (Boariu, 2003). The financing system existing in a country plays an important role on the capital structure of an enterprise because according to the specific of each country the enterprises have access to more or fewer financial resources.

Listen

Read phonetically

It has been proved countless times that the operation of an enterprise without adequate capital is one of the most common causes of business failure. Besides a sufficient capital, a company must have an adequate capital structure, i.e. an optimal combination of equity and loans. A certain capital structure determines for a particular company an average cost that may decrease or increase depending on the capital structure. Therefore, choosing and obtaining an optimal capital structure is an important issue of enterprise financing.

To choose the optimal capital structure of a company there are analyzed a number of factors which decide on a certain proportion of borrowed capital and equity, and each financing decision will be made in accordance with the capital structure.

In various stages of development of the financial system, the company financing depends on the general characteristics of the environment in which the enterprise operates. Rousseau and Sylla (2003), show that countries with more sophisticated financial systems have more capital available for the enterprises and also have new ways of financing. So, through this paper we want to identify if there are significant differences between the financial structures of the firms in countries that have different financing systems.

## **2. Material and Method**

To conduct the research we will analyze on the one hand the literature in this field, initially highlighting some characteristics of how to determine a company's capital structure, and then we will expand the analysis at macroeconomic level identifying the types of existing financing schemes of the national economies. In addition to the specific literature in the field we will also analyze the study conducted by Flash Eurobarometer no. 271 regarding the firm's access to finance, where we will identify the financial structures of firms in different countries of the European Union based on the existing financing system in these countries. The study was conducted in the period between June and July 2009. This study considered 9.063 firms from the European Union, Croatia, Iceland and Norway.

The sample chosen for the study includes four types of firms: micro-enterprises (with 1 to 9 employees), Small-enterprises (with 10 to 49 employees), medium-enterprises (with 50 to 249 employees) and large enterprises (with 250 employees and more). The survey excluded companies from the following sectors of activity: agriculture, fishery, public administration, financial services, household activities and extra-territorial organizations. The survey was conducted on the basis of a questionnaire that was applied to the companies that were part of the representative sample in the mentioned period.

## **3. Results and Discussions**

In each moment, the company managers are considering a particular capital structure, considered appropriate at that moment, but over time this structure changes as a result of the following factors:

The degree of business risk: The risk is inherent in a business especially if the company uses debt. The acceptance of a certain risk degree for a business implies operation with a high level of indebtedness in that company. In the business risk, uncertainty of the operating revenues has an important place. The enterprises that have an uncertain operating income are likely to face a default, even without having

resorted to debt financing. Thus these firms must finance their activity especially with their own capital.

The influence of taxes on borrowed capital: Companies resort to borrowed capital because the interest paid is a deductible expense and the result is the reduction of the payable tax, which lowers the effective cost of debt financing. If the firm has taxable income, the financing through bond loans will reduce the tax paid by the bondholders. The borrowed capital is not attractive if the firm does not apply the interest deductibility.

The company's ability to obtain capital on reasonable terms, and because of the business flexibility: Obtaining capital on reasonable terms is extremely important, especially when the economic environment is adverse, when economic monetary policy in the economy is restrictive. So, the financial flexibility is the ability to raise capital on reasonable terms if unfavourable circumstances. The treasurer of the firm must be aware that to ensure the stability of the firm's activity it is necessary a constant supply of capital.

When the money supply in the economy is limited, or when firms face difficulties in operating activities, capital providers prefer to lend firms with a stable financial position, strong companies; the firms that do not fall into this category are having important problems in raising the necessary capital to achieve the expected capital structure. So, the future potential availability of funds and the consequences of insufficient funds have a major influence on the optimal capital structure of the firms (Bistriceanu, et. al., 2001).

Another factor exercising influence on the capital structure is the type of assets held by the firm. In the case of a state of insolvency, the cost of this state depends on the types of assets that the company has. If the share of investment in less liquid assets (tangible assets, research and development assets) is higher, the costs of the state of insolvency are higher.

In analyzing the problem of the optimal financial structure there were formulated some theories, such as the classical theory of the capital structure, Modigliani and Miller's theory and the modern theory. All these theories are analyzing the optimal financial structure in relation to the cost of the capital.

Going forward, at the macroeconomic level, we conclude that the main role of the financing system of an economy is insuring the movement of capital to meet the financing requirements of the national economy in terms of enhancer their performance (Emery, 2007).

The financing schemes of the developed countries have registered since the 1980s, important changes as a result of the reforms that have taken place in most countries. Thus, before the 70s the firms in most countries (except U.S. and U.K.) were financing through loans from banks and other specialized financial institutions. About 80% of all firms on the market appealed to financing through bank loans. The financial environment was based on a set of regulations aimed at: the control of the interest rates, quantitative restrictions on the investments of the financial institutions, financial segmentation of the activities and the specialization of financial intermediates, exchange rates and capital movement's control.

Since the 1980s there have been undertaken important reforms, following these reforms has been registered the explosive growth of capital markets, the increased competition and the increased role of financial markets in financing the national economy. In this context, there have occurred changes also in the behaviour of the enterprises regarding the investing and financing activities.

The financial innovations have led to the creation of new financial products that have allowed the diversification of investments and financing arrangements. During the 90s the main source of external financing of the enterprises has been the financial market by issuing shares, bonds and titles of the open market. On the other hand, bank loans, which previously had the highest share in the financing of the enterprises decreased significantly.

The evolution of the financing system of the economy is reflected in a diversification of the financial instruments or assets. This diversification is possible thanks to the specialized operators that ensure the creation, the storage, and the release of these assets and which most often play a key role in carrying out financial transactions, especially the transactions which give birth to these instruments (Brokman, 2007).

The analysis of the evolving process of the financial systems requires both a historical and a comparative approach. From a historical perspective we want to highlight the effective changes that have affected the financial system of each country, as outlined above. While, from the comparative perspective we are interested in the current state of the financial systems in order to highlight their common and specific characteristics.

The firms in countries with market economies can acquire their financing resources by internal financing (self-financing), through which there are provided the necessary resources for the development of the companies from their own results; and by external financing that involves the procurement of the financial resources from the exterior of the firms (loans from banks, leasing, issuance and sale of securities, etc.). An economic agent that could not cover their full costs on their own resources, by internal financing or self-financing is forced to resort to external financing.

The analysis conducted by the U.S. economists John Gurley and Edward Shaw, developed in 1960 in their paper "Money in the Theory of Finance" had as a result two ways of external financing of the economic agents. Direct financing which is characterized by the fact that the economic agents that have available cash are financing directly the economic agents that need financial resources, by buying the securities issued by those on the financial market. This type of financing is done through the capital markets and the open markets. And, indirect financing or "mediated" which is distinguished by the fact that a financial intermediary is interposed between the economic agents that need capital and the economic agents that want to place their surplus cash capital. Intermediaries through which is developed the indirect financing are represented by banks and other licensed financial entities (savings banks, insurance companies, mutual funds, investment, etc.).

Depending on the importance of the degree of intermediation in financing, we can distinguish two types of external financing schemes (Vasile, 2004): financing systems of debt economies, in which the external financing of enterprises is done mainly through loans from banking and non-banking institutions. This financing system highlights a low level of self-financing and weak development of the domestic financial market. And, the second type represented by financing system of market economies, where enterprises' financing is conducted primarily by issuing securities underwritten directly by the owners of capital and through banks.

From the comparative analysis of the financing systems of the enterprises activity in various countries we can say that there are:

- Economies of countries where the financial resources needed to business development are ensured through self-financing, due to the

reduced capacity of financial markets to mobilize financial resources. These are particularly the areas where the financial activity is still heavily dominated by the monetary operations and by the interference of central or commercial banks. Most countries in Africa and some Latin American countries have financial characteristics that enable them to assimilate to this type of financial structure;

- Economies of countries that rely on indebtedness, respective on the monetary resources purchased with loan title from credit organizations. These may be called economies of financial intermediation. They are characterized by a certain diversity of the financial assets. Besides the existence of money there are observed the appearance of various saving and credit instruments. But creating and managing these tools are mainly based on the intervention of financial intermediaries, more or less specialized;

- Economies of the countries where prevail obtaining of monetary resources through capital markets. This economies use a wide range of financial assets that are not only an institutional offer received from financial intermediaries, but also an offer of primary securities issued by non-financial companies and other entities. These characteristic features can be seen in North America, Western Europe, Japan and several countries on the Pacific Coast.

Analyzing these major types of financial structures we can draw the implications that the financial environment characteristics have on the financial management of the company. This analysis shows that each type of financial environment is delimiting the area of financial management of the enterprise, determining the objectives, its means of action and even its problems.

In an incipient financial system, the financial management, for most businesses has concerns about the knowledge of monetary regulations, and also forming and using of a self-financing as high as possible. The external financing proposed by less differentiated intermediaries it is mainly used to cover current activity needs.

In an economy of financial intermediation, the financial management is dominated by the pursuit of the relationships established between enterprises on the one hand, and banks and other credit institutions, on the other side. These reports aimed primarily settlement operations, short and medium term financing and investment operations (Neave, 2009).

In a financial market economy, the financial management is oriented towards the general knowledge of tools and capital market constraints. Even if the company does not have direct access to these markets and depends on the services offered by banks and other credit institutions, it is profoundly influenced by the continuous changing financial instruments and the variables that appear (interest rate, exchange rate) (Dragotă, et. al., 2003).

From those presented above we observe the major role played by the existing financial system in an economy in the way the businesses are financed. Also depending on the existing financial system in an economy we can talk about an increasingly wide range of financial instruments, which among others (support of settlement, placement and risk coverage operations) offers new ways of financing the business activity.

For example, in the economies with an incipient financial system there is a limited range of financial instruments issued by resident enterprises and other units. This

range includes generally the currency and other liquid savings instruments (savings accounts, term deposits). The financial assets in the form of shares, bonds, are poorly diversified, and when they exist on the market they have a limited distribution. Possession of money in the form of bank notes or current account is the dominant financial asset storage.

In the economies of financial intermediation there is enriched the range of savings and placement instruments. However, in the absence of active capital markets, financial products offered to savers and investors allow only a limited diversification. Traditional forms of fundraising promoted by credit institutions are term deposits and the lending offers are the traditional forms of short-term financing. There are credit institutions that are engaged in investment financing but they are usually specialized bodies in providing loans for the purchase of equipment in leasing. There may be universal banks that aim offering short-term loans, together with medium and long term loans.

In the market economies the financial instruments are very diverse. The applicants for capital or the operators involved on the market are engaged in a battle of strong competition to attract those who save or invest. In such a context, financial managers have ample opportunities of choice and initiative for their company. At the same time they are determined to make a more complex selection between the financial products offered, taking into account issues related to cost, efficiency, the duration and risk (Vasile, 2004).

In various stages of development of the financial system the financing of the company depends on the general characteristics of the enterprise operating environment. Thus, in an incipient financial system there are distinguished weak opportunities of external financing. The funds available on the market are reduced and the public administrations and entities require certain restrictions, to partial avoid the private entrepreneurs borrow. The companies must focus on forming and allocation of the self-financing resource which represents the only source of regular funds for most units. Yet the access of the companies to external financing provided by banks or other credit institutions, is a major concern because these resources would provide opportunities for expanding the business.

In an economy of financial intermediation the businesses financing concerns, mainly, their relations with banks and other credit institutions. The financial managers address their major financing requests to credit institutions. These are the main source of external finance, and most often the exclusive source. The financial intermediaries are primarily oriented towards short-term funding requests. But gradually they expand their scope of action to integrate also the long-term credit, especially targeted on investments. However this extension leads to crises in most countries due to a poor assessment of risks related to these term commitments (Neave, 2009). For the financial managers of companies, this development causes a net change of their funding solutions. First, they addressed to banks to finance short term operations, but they must cover their needs for equipment purchase or cash flow from their own resources. In a second step, the diversification of credit offers from the financial intermediaries allows to the firms to negotiate with them the short-term loans, but also the medium and long term ones.

Capital market in these economies plays a secondary role in the mobilization and allocation of necessary funds. Only the most important firms may eventually resort to issue of shares, bonds or short term titles.

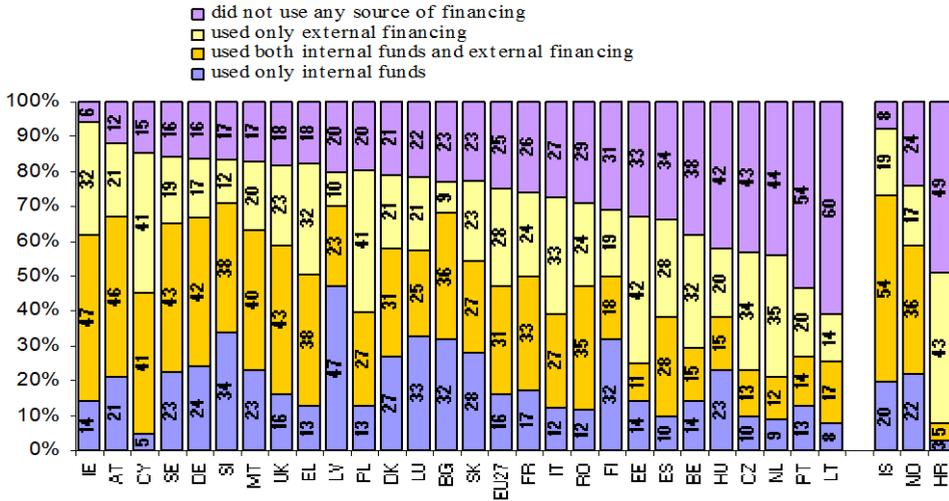

Financial market economies allow business managers to seek funding , placement or hedging solutions which ensures an appropriate response to business needs at the best cost (for financial instruments and hedging), or at the best yield (for the investment instruments). This expansion of choice is due to market development and financial institutions but also to the multiplication of the financial instruments addressing different needs. However, the financial market economies expose the managers of the firms to new financial difficulties. On the one hand, the financial markets suffer from instability phenomena affecting the interest rates, the exchange rates and the financial asset values. The instability of these variables can lead to severe losses and serious disruptions to the financial management of enterprises, being the cause of a worsening of the financial risk. On the other hand, these economies are exercising more severe financial constraint for the enterprises. With wider access to the financing opportunities in capital markets, they are the subject to continual pressure from the purchasers of securities (shares, bonds), which are bringing their contribution to the enterprise resources and because of that are monitoring the progress of the enterprises performance and risk.

After we have analyzed the main types of existing financial systems and business financing arrangements as part of each system, we will highlight below some empiric results obtained by the Flash Eurobarometer to reinforce the results previously obtained by theoretical analysis. More precisely through these empirical analysis we want to identify the financial structure considered optimal by the firms in the member countries of the European Union and see if there are significant differences from one country to another. Especially, given that in the Western countries dominate the financial market economies with developed capital markets, but there are also countries, such as Romania, which have an economy of financial intermediation. So, from the study we observe that a percent of 31 companies which exist on the markets from the European Union countries have used a combination of own funds and external funds to finance their activity. Also, 28% of the analyzed companies used only the external financing in the analyzed period, while 16% of the companies used only the internal funds. Also one quarter of the managers interviewed said they had not used any financing source in the period under review.

The companies from different countries have different financing structures. The optimal financial structure of the enterprise must establish a relationship between debt and equity financing so that financing costs to be as low as they can. This depends on the objectives of growth of the company and on the expected return and the risk level that the company agrees to assume.

Figure 1 presented below shows that the companies in Croatia have used a combination of internal funds and external sources of funding in the lowest proportion in the analyzed period (5%). The enterprises in Lithuania (60%) and Portugal (54%) were the most that have not used any source of funding in the period under review while the fewest enterprises that have not used any source of funding have been met in Iceland (8%) and Ireland (6%). The proportion of respondents who said that their company has used only internal funds in the last six months, ranged from 3% (in Croatia) to 4% (in Cyprus) to 47% in Latvia. In Finland, Bulgaria, Luxembourg and Slovenia, almost one third (32% -34%) of the analyzed companies have used only internal funds. The companies from Croatia and Cyprus were not only among those who did not use internal funds but also among those who used only external financing during the analyzed period (43% and 41%), similar to the situation in Poland and Estonia (41% and 42%).

The companies in Bulgaria, Latvia and Slovenia have used in the lowest proportion only the external financing (with a proportion between 9% and 12%). In Romania we see that 12% of the companies have used only their own funds, 35% have used both internal funds and external financing, and only 24% have used only external financing.

**Figure 1** The financial structure of the enterprises in the European Union, Croatia, Iceland and Norway (using internal and external financing - in%)  
 Source: Flash EuroBarometer, 2009, p. 29

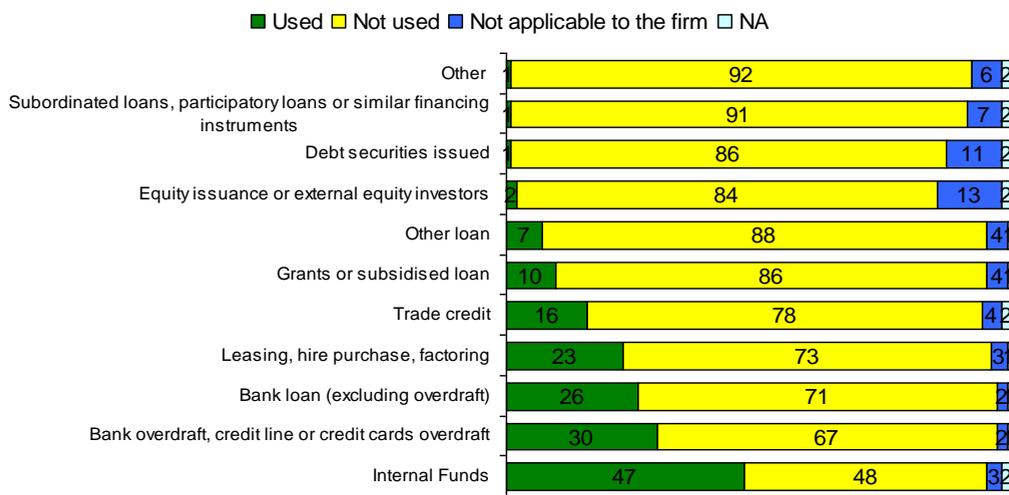

Almost half (47%) of managers in the EU have said that they have used internal funds in the period under review, to finance their operations (as seen from above - some have used only internal funds, while others have used these funds in combination with external financing). In addition to internal funds the companies have also used external sources for financing their operations, totally 58% of companies have used at least one external source of debt financing in the last six months. The most popular source of financing was the bank loans: 30% of the enterprises used bank overdraft facility or line of credit and 26% had received a bank loan. This can be explained by the fact that in the most analyzed countries we have an economy of financial intermediation, where the banks are the main financial intermediaries.

Business debts may also be covered from public resources or resources from a friend or family member: 10% of respondents mentioned that they applied to grants or subsidized bank loans and 7% mentioned "other sources".

Approximately one quarter (23%) of respondents said that leasing, factoring, hire purchase were one of the source of financing used and 16% said they had used trade credit as a source of short term financing. Very few enterprises (1%) have issued debt securities during the period under review, but 11% of managers have found this type of financing as irrelevant to them. The issuance of securities or foreign investment capital was mentioned by 2% of managers as one of the sources of external financing that was used during the research period. More than one-tenth

(13%) of managers have found this type of financing relevant when they were asked to explain the financial structure of their business.

The types of financing sources used by enterprises in the period under review are presented in detail in the figure 2 observed below:

**Figure 2** Using internal and external sources of funding by European Union companies in the analyzed period

Source: Flash EuroBarometer, 2009, p. 30

When we interpret these results we have to be aware by the fact that the study was realized in a period when the current financial crisis is manifested all over the world. So, these sources of financing preferred by the firms may not be the same in a normal period when uncertainty and risk are lower on the markets.

### 3. Conclusions

The financing decision of an economic agent involves choosing the most effective combination of financing sources for the businesses from all existing financing sources. As an Irish proverb says "It is a fool the one who does not take the money that is offered to him." The financing decision of an enterprise implies the most efficient use by the company of the money which is provided, of the funds offered by various financial or non-financial institutions.

Through this study we have presented the existing types of financing of the economy schemes, but also how the companies operate in these systems. We have analyzed the supply of financial resources within each system, exactly the actual money that businesses can have on those markets and key management decisions on enterprises financing.

Analyzing the data obtained by survey conducted by Flash Eurobarometer we have noticed that most businesses prefer financial resources that came from the banks. Banking institutions are considered the main intermediaries in both debt economies and in the capital market-based economies. In the European Union countries we can not speak of the third type of economy, incipient financial economy, because even the developing countries have already implemented an economic system based on

debt financing. Also, note that even in the most developed economies, where the capital markets play an important role and we can talk about a variety of financial instruments, the companies still use the resource provided by banks, because only a small part of the enterprises have access to capital markets and innovative financial instruments.

The most important conclusion that emerges from this paper relates to that: the financing system of the national economy plays an important role on determining the optimal capital structure of the firms. This is evidenced by the fact that the external environment and the disturbances in the external environment have a significant influence on the financing of businesses. This was proved again by the current financial crisis impact on the activities of the enterprises on the market.

**Abstract:** *Risks management means identifying them, assessing, quantifying and strategy to counter them, and finding solutions to some levers to diminish or even eliminate the possibility of developing or their consequences. Hung everywhere, risk is associated with uncertain situations and opportunities. The consequences of risk can result in adverse or positive effects related to the activity of the insurance undertaking or of the reinsurance undertaking. The risk has a pronounced randomly character, and its presence in the field of insurance undertakings and reinsurance. This can be explained by the fact that the risks are taken by these companies and have direct effects on their financial results during the period of validity of the contractual relations. The results of risk effects have an impact on the results of activity of insurance companies. The financial impact of a negative event, exceed the sum of the individual loss, leading in some cases to bankruptcy. The financial impact is due to the positive opportunities, which have not made an appearance, and the first event to transform into income. An important role is the responsibility of the information system, providing solutions based on scenarios, by electronic data processing, consider all types of consequences of a hazard and allow insurance companies and reinsurance, on the other hand, to calculate all the possible consequences of a given event and the ultimate financial impact on them, and finally, to make decisions to base decisions for various insurance products and reinsurance. People insurance records for each situation. In practice the scenario method is only used to make specific estimates for different scenarios depending on the circumstances, which has a certain probability of realization, for the favorable; for the neutral and negative and gives solutions for each individual, taking into account certain criteria. For example, we will present a life insurance in several poses.*

**Keywords:** *risk; general risk; country risk; contractual risks; default risk.*

**JEL classification:** *G22.*

### 1. INTRODUCTION

Insurance and reinsurance companies are operating in all mandatory and optional insurance and pursue profit and loss relief.

The aim of the insurance and reinsurance companies, is par excellence, human and physical risk taking in exchange for receipt of premiums from policyholders and respectively to reassure and when the event occurs unwanted material or human, the insurance company, proceed according to the contract, to pay damages the insured amounts.

The risk is hanging everywhere and is associated not only uncertain situations and opportunities.

The consequences of risk may materialize, either negative or positive effects related activities of the insurance company or reinsurance company.

As a result, the risk is highly random, but a greater proportion made its presence in the insurance and reinsurance companies, because the risks are taken by these companies through insurance contracts and reinsurance contracts when they arise, have direct effects on their financial results only within the validity period of the contractual relationship with the insured, individuals and corporates.

The results of risk effects, positive or negative, impact on the output of insurance and reinsurance companies.

The negative financial impact of an event can exceed the amount of individual losses, leading in some cases to the bankruptcy of insurance and reinsurance companies.

The positive financial impact of an event is due to favorable opportunities, situations where during the validity of the insurance or reinsurance undertaking has not made an appearance event.

Into the activities of insurance and reinsurance companies, "an important role is played by the information system, which is based on electronic data processing takes into account, on the one hand, all the consequences of a hazard and allow insurance companies and companies reinsurance, on the other hand, to calculate all the possible consequences of a given event and the final financial impact on the insurance or reinsurance companies, make decisions, and to base decisions for various insurance and reinsurance products. "Companies need to have relevant information at the appropriate time. Information becomes available thanks to technology arising from Web.

## **2. EXPOSURES TO THE RISK**

For insurance and reinsurance companies is not enough just to identify risks.

A group is important and prioritize risks according to their influence on the insurance and reinsurance companies.

This risk group according to their importance enable insurance and reinsurance companies:

- to make a forecast risks in insurance and reinsurance companies,
- to identify solutions to quantify the impact of risk on them,
- to apply solutions to measure the risk
- to apply the measurement risk solutions to the identified risks
- to find solutions that may reduce the risk of the impact
- to find internal solutions that could reduce the risk of uncertainty on insurance and reinsurance companies
- identification and determination of the direct costs of damage, occurred from the phenomenon
  
- identification and determination of indirect costs of damage, as an occurrence of the undesirable phenomenon
- to provide financial resources for monitoring and forecasting risk financing
- to provide financial resources for control and risk financing.

In practice, risk estimation accuracy depends on:

- the amount of information available to the risk manager
- the quality of information available to the risk manager
- the methods;

- the statistical techniques that can be used
- the ability risk manager
- the subjectivity manager
- the risk control programs
- the risk retention programs
- taking into account all the possible consequences in case of a given event;
- the final impact on the occurrence of a given event the insurance company
- the risk control techniques
- the risk financing techniques.

The risk estimation is based on the design of methods for measuring the importance of risk for insurance companies and their application for the identified risks.

Literature presents two main risk categories: pure risks and speculative risks.

The pure risks are defined as risks that implies a probability of loss unaccompanied by any chance of winning.

The speculative risks are defined as risks that can result from either a loss or a gain. The financial impact of the negative consequences of risk, leading to strong adverse effects on financial planning insurance company, sometimes difficult to absorb and may in some cases lead to bankruptcy.

The exposure characteristics are: the risk frequency is called also the probability of the event in a time and known risk severity consequences.

Exposure characteristics can be measured, knowing facts and information about these risks.

Literature and empirical research make some clarifications in this sense that:

- in the case of pure risk: loss frequency or number of losses in a given period and the size of losses.
- In speculative risks: the frequency of positive and negative outputs and the size of these outputs.

If the risk manager has a huge number of information, we use risk assessment techniques based on the calculus of probability and statistics. To estimate the severity of the exposure, in practice and in the literature are used two concepts:

- maximum possible damage
- probable maximum damage.

Maximum possible damage is the maximum total amount of damage that can occur in a particular place on a particular good and can be estimated even in the absence of adverse event, as a result, is used as limit value.

Maximum damage is the value of the damage they consider the risk manager and will not exceed the maximum possible damage.

In the event that there is insufficient information and data for statistical techniques may be used in less rigorous methods based on the use of a probability scale expression.

By Elaine M. Hall's theory, the probability scale is as follows:

- Very unlikely, in the situation where the probability of the event is below 10%, is less likely, that the event does not occur over the life of the subject of insurance;
- Unlikely, is when the probability of the event is between 10% and 40%, is barely possible that the event does not occur over the life of the subject of insurance,
- Is probably where the probability of occurrence is between 40% and 80%; it is possible that the event occur over the life of the subject of insurance;

- Most likely is the situation where the probability of the event of 80%, it is likely that the event will occur over the life of the subject of insurance.

In practice for risk diagnosis is used:

- The risk matrix
- The risk map.

The risk matrix shows four risk categories as follows:

- Class I represents risks with low frequency and low severity
- Class II are risks with low frequency and high severity,
- Class III are risks with high frequency, low severity
- Class IV represents risks high frequency, high severity category respectively risks with low frequency and low severity, the use technical risk retention.

For class II, respectively risks with low frequency and high severity should be provided.

For class III, respectively risks with high frequency, low severity are recommended control techniques, to be combined with restraint.

For class IV, respectively risks with high frequency, high severity are recommended control techniques, to be combined with restraint.

Risk Map is a tool for diagnosis and risk analysis in business insurance and reinsurance companies.

The achievement of such maps requires:

- To identify risks relating to insurance companies:
- The best estimation of the probability of each event
- The best estimation of losses resulted from each event
- The best estimation of the probability of the events with high probability of occurrence but with little impact on the insurance company
- The combined use of techniques of control and risk financing;
- The control techniques to prevent risks;
- The creation and retention of techniques risk
- The calculation taking into account all the possible consequences if the event
- The calculation taking into account the final impact on the insurance companies for the event.

"The identification and the risk assessment should be made on several levels. First on the overall level of their insurance company and then at all levels of organizational structures. "

" The reinsurance acts only by means of ensuring that allows reducing the share of risks exceeding the possibility of inclusion of insurers, reducing liability insurance business." Because: "reinsurance is a complement to the business of insurance and the receipt path failure risk."

### **3. THE SCENARIO METHOD**

Over time, large volume of personal insurance operations, and data processing and information required computerization of their individual so to be managed separately and the funds and the final results to be highlighted separately from other categories and types of insurance. The security of a person records the status of each insured. Based on these records is known amount of earned premiums to a point, any amounts redeemed, reduced insurance company loans, etc..

In practice, the scenario method is only used to make point estimates. for different scenarios depending on the situation, which has a certain probability of realization,

the state of positive, neutral and to the unfavorable and gives solutions for each individual subject to certain criteria.

These criteria will follow:

- The market size
- The turnover size;
- The unit selling price;
- The turnover;
- The variable operating costs
- The operating variable costs for exploitation;
- The size of the fixed costs of financial
- The brut profit
- The taxes;
- The net profit.

For example, we will present a life insurance for the same person in three phases.

Option 1. Life insurance for 20 years with capitalization.

Estimated solution for Valentin Popescu:

- Date of birth 20.05.1980
- Married with two children,
- Engineer
- Medical history - no
- Risk of occupational disease - no,

Life insurance capitalization benefits:

- guaranteed technical interest of 3.5% per year for the duration of the contract,
- At the end of the profit is shared with customers at the rate of 85%
- Since the third year, the police can be buy
- in case of illness and hospitalization each, day of hospitalization, from the third day, it compensates £ 150 per day.
- If surgical intervention he is payed, as it is also the convalescence, from the third day after the surgical intervation.

Option 2: Life insurance for 20 years with capitalization and no protection. Estimative solution for Valentin Popescu:

- Date of birth 20.05.1980;
- Married with two children;
- Engineer;
- Medical history – not;
- Risk of occupational disease – no.

Annual prima 1200 lei, 100 lei premium per month.

Does the sum assured in case of natural death of 24,000 lei. In case of accidental death £ 48,000. In case of total disability due to accident 72,000.

Variant III. Life Insurance for 20 years with protective caps. Estimated solution for Valentin Popescu:

- Date of birth 20.05.1980;
- Married with two children;
- Engineer 4. medical history – not;
- Risk of occupational disease - no,

First Annual: 1.200 lei, 100 lei monthly premium\.

At the end of the insurance contract, if the insured does not receive guaranteed interest and special reserve. The first month is 100 lei per month, the annual

premium is £ 1,200, of which £ 800 goes on capitalization per year and £ 400 for protection. Protection money if not used by the insured in a year are lost. Protection in case of illness and surgery £ 4,800 per year, and the sum insured is £ 19,200. Therefore, using the scenarios method, the insurance company representative shall simulation provided several potential solutions and estimating the probability of risk, life insurance benefits estimated for each scenario and its impact on insurance and reinsurance company.

#### **4. CONCLUSIONS**

The simulation, as well as risk analysis technique is used to study the behavior of random variables and variables depending on the performance will be decided by the acceptance or rejection.

This technique involves the automatic generation risk analysis, computer, a large number of values of input variables of the system, after previously held:

- Identifying input variables
- Identify random variables
- Identify output variables,

Based on the electronic prelucration, it can be achieved:

- The analysis of simulation results,
- The interpretation of simulation results
- The decision to accept or reject the decision.

Using electronic engineering, risk analysis includes:

- identifying sources of risk;
- Reducing uncertainty
- subject to a decision maker risk that would endanger the viability of the company
- decision to accept or reject the conclusion of insurance;
- construction of future scenarios, plans and projections
- estimating the probability of each scenario
- identify risks relating to insurance companies;
- best estimate of the probability of each event;
- accurately estimate the likelihood of various consequences;
- assessment of the possible consequences of the decision;
- decision helps the decision maker to compare alternatives in terms of the degree of risk and choose the most attractive of them;
- decide whether the risk is acceptable or not.

"If the insurance people know some data about each family regarding the profession (job), work, number of those who have incomes, their age etc, is very helpful in dealing with the activity of the end insurance because according to these elements can indicate the insurance product that best suits the particular situation of each person in that family".

The information system by processing data and information through specialized simulation software, makes it possible to multiple solutions to the same problem for finding the final optimal solution.

**Abstract.** *During the early “liquidity phase” of the financial crisis that began in 2007, many banks – despite adequate capital levels – still experienced difficulties because they did not manage their liquidity in a prudent manner. The crisis drove home the importance of liquidity to the proper functioning of financial markets and the banking sector. Prior to the crisis, asset markets were buoyant and funding was readily available at low cost. The rapid reversal in market conditions illustrated how quickly liquidity can evaporate, and that illiquidity can last for an extended period of time. The banking system came under severe stress, which necessitated central bank action to support both the functioning of money markets and, in some cases, individual institutions. Most transactions or financial commitments have implications for a bank liquidity. Transactions are particularly vulnerable to liquidity problems at a specific institution. Therefore, one can deduce the importance of the correct calculation and liquidity indicator, not only for the bank concerned, but especially for NBR uses that bank risk management tool. That is why the authors took into consideration a sample of banks in Romania to show to what extent the banking crisis has influenced the development banks. The objective of this paper is to provide a global perspective of the liquidity risk from a banking societies’ viewpoint. Our paper belongs to the technical studies that analyze the concrete way in measuring the liquidity risk at the level of the banking societies from Romania. The study is structured on chapters that present the theoretical background in liquidity risk management, also, the paper contains a study cases part, which presents the actual stage and the challenges of the measuring the liquidity risk. The difficulties experienced by banks were due to lapses in basic principles of liquidity risk management. In response, as the foundation of its liquidity framework, the Basel Committee in 2008 published Principles for Sound Liquidity Risk Management and Supervision (“Sound Principles”).*

**Keywords:** *liquidity, risk assets, volatile equity*

**JEL classification:** G21

## **1. Generally Introduction**

Banks need liquidity to offset expected and unexpected balance sheet fluctuations and to provide the necessary funds for development. Liquidity is the ability of banks to effectively deal with the withdrawal of deposits and other debts due and to cover additional borrowing, loan and investment portfolio. A bank has adequate liquidity potential when it is able to obtain the necessary funds (by increasing debt, securitization and sale of assets) immediately and at a reasonable cost. Price liquidity depends on market conditions and the market perception of the level of risk of the debtor institution.

Other distinguished professors believe that banks need liquidity of each bank depends on the situation expressed sheet.

To assess the state of liquidity, particular importance is how to classify bank assets and liabilities.

One of the most prestigious institution which supervisory banking risks - Bank for International Settlements (BIS) - issued by the Committee of the Basel Banking Supervision (the Committee) a set of principles that should underpin bank liquidity management organizations.

Liquidity risk is the probability that the bank will not be able to meet payments to customers due to diverting the proportion of long-term loans and short term loans and bank liabilities Gap structure.

Liquidity risk is considered a major risk, but it is subject to meanings such as extreme liquidity, "safety cushion" or the ability to raise capital at a normal cost.

Extreme liquidity situation involves the failure of banks and manifested by massive withdrawals of funds or credit lines customary closing other institutions, which generates a brutal liquidity crisis.

Liquidity risk refers to the situation where not seem sufficient liquid assets available to meet unexpected needs. In this case, liquidity is rather a "safety cushion" to deal with difficulties.

Also, liquidity risk expresses the event of difficulties, temporary or important to have access to sources of funding to meet the needs. In this case, liquidity shows bank's ability to raise capital at a "reasonable cost" at all times. This ability depends on two factors disjunction: market liquidity and liquidity institution. Market liquidity directly affects the ability to increase the capital of banks. Liquidity of banks is characterized by developments projected financing needs.

Liquidity risk management involves anticipating needs liquid amount to the bank, in conjunction with providing the necessary resources to meet these needs. But maintenance is costly investments in liquid form for the bank and for this reason it is necessary to achieve a more accurate cash flow.

## **2. Analysis method and resulting liquidity in banks**

Bank liquidity problems overlap covering the minimum reserve requirements used by the central bank to conduct monetary policy in light of economic developments conjecture. Thus, we considered a sample of banks in Romania to highlight the state of liquidity and liquidity risk during this period.

### **2.1. Bank liquidity analysis using financial ratios**

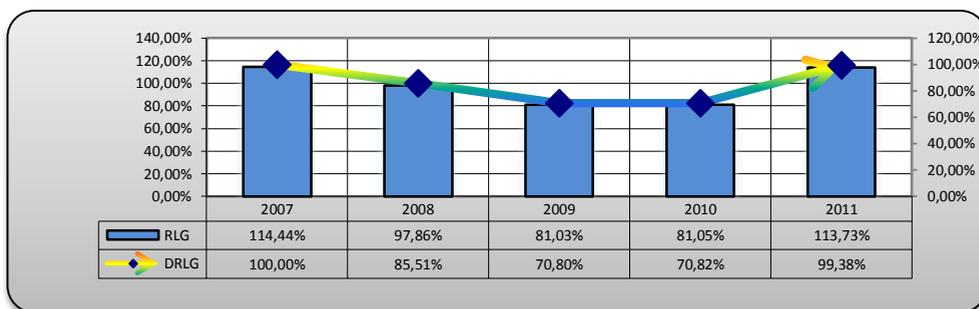

Banking system liquidity indicators, provided for central bank rules and calculated for Romanian banks are: overall liquidity, immediate liquidity, ratio of own funds and

resources permanent deposit coverage ratio, ratio of liquid assets; rate volatile assets, liquidity indicator.

*Ratio of liquid assets (RLG)* reflect the available capacity (deposits with the central bank, cash and cash equivalents, deposits with banks and other assets - AL) of the bank to cover its current liabilities (resources attracted in sight - DCR). General liquidity takes the form of general liquidity ratio as follows:

$$RLG = AL/DCR$$

It is estimated that the bank has a favorable liquidity when liquidity ratio is between 2 and 2.5. In the opinion of other specialists general liquidity ratio should be above 1.5. In the literature Anglo-American view that general liquidity ratio must be at least.

**Figure 1:** General liquidity ratio evolution in Romanian banks  
Source: The banks' own financial statements

In the analyzed banks of the indicator value analysis shows that overall, liquidity ratio recorded during the entire period analyzed values are below the threshold of 1.5. The highest value of liquidity occurred in the years 2007 and 2011 (1.14 and 1.13), but still well below the limit of 1.5. General liquidity developments over the reporting period is unfavorable, so that in the years 2009 and 2010 to reach a level of 81% of the indicator (0.81). In 2011 the situation improved reaching up to 1.13, but in these conditions, the indicator remains below 1.5.

*Immediate liquidity (RLE)* measures the degree to which liquid assets covering payments due in the short term. Immediate liquidity is calculated as a percentage ratio between liquid assets (cash, current account with the central bank and other central banks, short-term investments-TR) and accounts payable (at sight of customers, short-term loans-DCR), that:

$$RLE = TR / DCR$$

**Figure 2:** Immediate liquidity ratio evolution in Romania banks

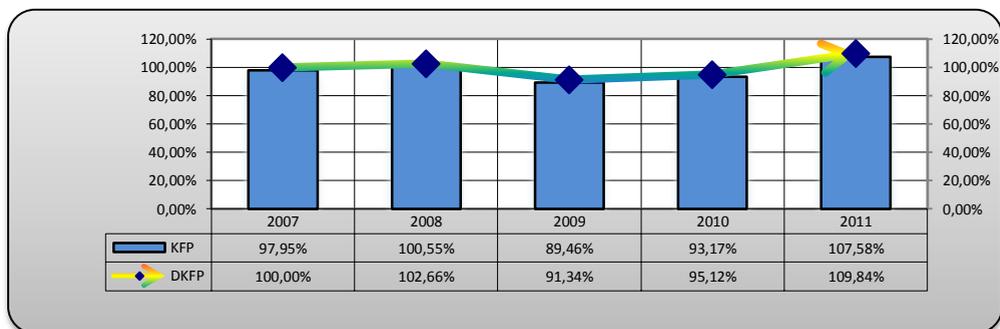

Source: The banks' own financial statements

Liquidity is favorable if it approaches 100%. According to other experts, the optimal level of the indicator is 20%, but financial security is still range between 50% and 100%.

As you can see immediate liquidity in case analyzed banks is maintained with continued entire period analyzed (2007-2011), the range safety. Although immediate liquidity following a downward trend, it remains at a good level. The highest value was recorded in 2007 (91.67%), and then decrease to 61.64% in 2009. From 2007 it began to grow, reaching in 2011 to record the value de73.03%.

*Ratio of own funds and permanent resources (KFP)* is determined as a percentage ratio between long-term bank resources (FTL) and Mon-term assets (ATL):

$$KFP = FTL / ATL * 100$$

**Figure 3:** Ratio of own funds and permanent resources evolution in Romania banks

Source: The banks' own financial statements

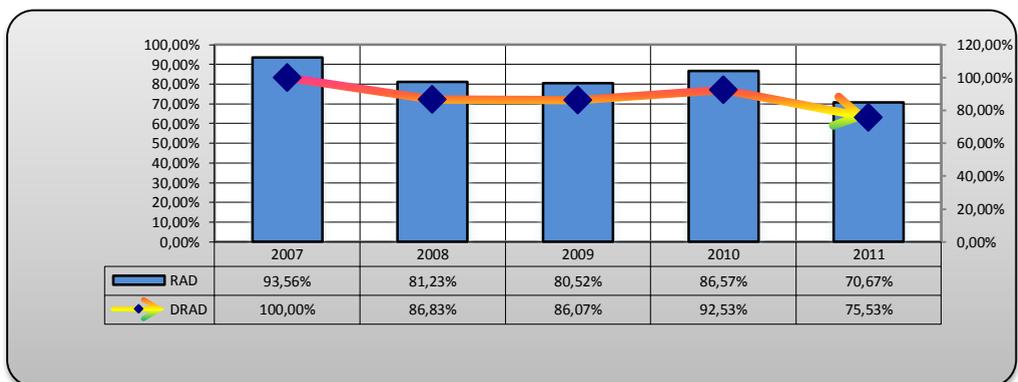

Minimum ratio between long-term bank resources and long-term assets should be at 60%. Analyzing the values of this indicator can be seen that this value is above 60% throughout the period analyzed. The lowest value was recorded in 2008 (89.48%) and the highest was recorded in 2011 (107.56%). Regarding its evolution we see that the trend is sensitive constant DRB Significant indicator values do not fluctuate so in 2008 compared to 2007 it grew by only 3% in 2009 and then decrease

to the value of 89.46% and increase continued until 2010 when record value of 107.58%.

*Deposit coverage ratio (RAD)* is calculated as a ratio of total loans (CRA) and total deposits from customers (DA):

$$RAD = CRA / DA$$

The unit value of this ratio expresses a normal situation. A low rate and would be a nil excess liquidity and reduced profits. An over-unit rate would involve increased risks causing loss liquidation of assets, the need to cover the reimbursement of depositors.

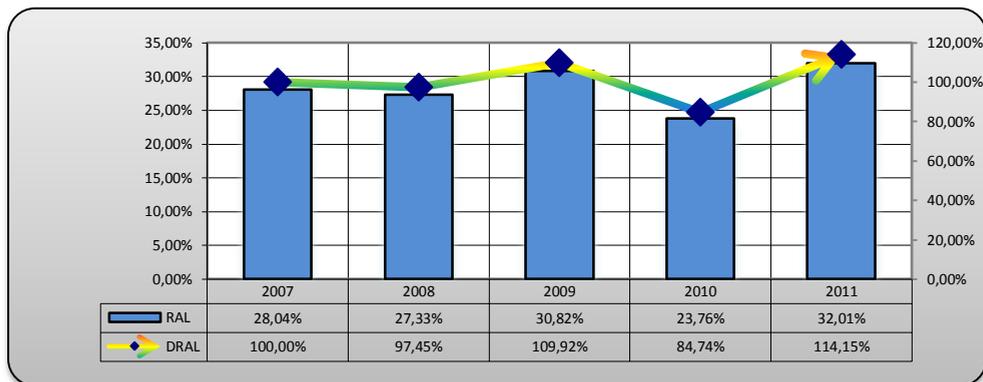

**Figure 4:** Deposit coverage ratio evolution in Romania banks  
Source: The banks' own financial statements

It can be seen that during the period analyzed indicator is below 1, which means that there was an excess of liquidity that means the volume of loans was less than the deposits. The fact that this report is one subunit shows that profit was diminished by the fact that, while in the case of bank loans has benefited from interest and fees related, in terms of bank deposits has to pay depositors interest on deposits. The highest value was recorded in 2007, when its value reached 93.56% and the lowest in 2009 when the indicator equaled 80.52%. Trend during the period under review, overall, is a descendent from 93.56% in 2007 and reached 70.67% in 2011.

*Ratio of liquid assets (RAL)* Ratio of liquid assets (RAL) is determined as the ratio of unemployed availability and marketable securities on the one hand (AL) and total bank assets (TA), ie:

$$RAL = AL / TA$$

This rate illustrates the dimensional size of liquid assets and liquid easily. An over-unit rate is favorable.

**Figure 5:** Ratio of liquid assets evolution in Romanian banks  
Source: The banks' own financial statements

As you can see the indicator values are well below the considered normal. During the analyzed period the indicator value is somewhere at an average of 25%. Trend during the period considered is oscillating, so that the indicator is rising until 2009, followed by a decrease in 2010 and increase in 2011. The lowest value recorded in 2010, and the highest value that has indicator is 2011.

*The share of liquid assets in total volatile resources (RRV) is determined as a ratio of volatile resources (RV) and liquid assets (LA), ie:*

$$RRV = RV / LA$$

Volatile resources include deposits and other resources, which by their nature are short lived or downward changes unexpectedly and untimely. By natural or resources involves employing volatile liquidity. A nil rate is beneficial for bank management.

**Figure 6:** The share of liquid assets in total volatile resources evolution in Romanian Banks

Source: The banks' own financial statements

If the indicator analyzed banks are at a normal value only in 2007 (96.95%) and 2009 (88.47%). In the remainder of the indicator value is above that considered normal when reaching the maximum in 2009 stands at 122.04%. As you can see the indicator increases until 2009, and then to follow a downward trend until 2011.

*Liquidity indicator (RLI)* is calculated as the ratio between actual liquidity (LE) and liquidity necessary (LN):

$$RLI = LE / LN$$

Actual liquidity is determined by summing, for each band, balance sheet assets and liabilities received and shown off balance. Necessary liquidity is determined by summing, for each band, the obligations and commitments data sheet and off-balance sheet highlighted.

Bands commitments received and given commitments are as follows: Under one month; between one and three months Three to six months Six to twelve months. NBR rules provide that if a record surplus of liquidity in any of the bands maturity above, except for the last lane, it will add to the actual liquidity for the next maturity band.

Necessary liquidity destinations are: Setting reserve requirements, loan customer requests, customer requests for withdrawal of funds; Making interbank settlements, payment of other obligations of the bank (payment of dividends, taxes and so on). The main sources of liquidity (effective) are: Cash, Cash, demand deposits with the central bank or correspondent banks, Deposits, Loans from other banks or from the central bank.

**Figure 7:** Liquidity indicator evolution in Romanian banks

Source: The banks' own financial statements

Trend indicator, as can be seen from the chart above, is downward throughout the period analyzed. The only year in which there was excess liquidity was in 2007, when the indicator stood around 1.03, while the remainder of the indicator was positioned

below 1, indicating a lack of liquidity. The lowest value was recorded in 2010 (0.81), the maintaining and 2011.

## 2.2. General liquidity analysis using Eviews program

With EViews program we analyzed the relationship between general liquidity and volume current liabilities and liquid assets available for the period 2007-2011, the banks analyzed. The use EViews program we obtained the following result:

Dependent Variable: R\_GENERAL\_LIQUIDITY

Method: Least Squares

Date: 06/12/12 Time: 16:27

Sample: 2007 2011

Included observations: 5

Variable	Coefficient	Std. Error	t-Statistic	Prob.
C	1.091043	0.055651	19.60515	0.0026
Current_debts	-2.08E-10	2.68E-11	-7.751538	0.0162
Liquid_assets_available	1.90E-10	2.60E-11	7.298575	0.0183

R-squared	0.968132	Mean dependent var	0.976220
Adjusted R-squared	0.936264	S.D. dependent var	0.165249
S.E. of regression	0.041719	Akaike info criterion	-3.232025
Sum squared resid	0.003481	Schwarz criterion	-3.466362
Log likelihood	11.08006	F-statistic	30.37966
Durbin-Watson stat	2.609296	Prob(F-statistic)	0.031868

Source: The banks' own financial statements

It is noted that the t-test probability is below 5% In this case, the probability is less than relevant to that work, the null hypothesis is rejected and the coefficient is considered statistically significant. As a result, we can say that the evolution of general liquidity is influenced by the amount of current liabilities and liquid assets available.

Through F test is intended to measure the independent variables explain the dependent variable evolution. F test of the null hypothesis is that all regression coefficients are null. Whichever probabilities are two possibilities:

- "P" is the lower level of relevance in this case the null hypothesis is rejected, ie at least one of the regression coefficients is DRB Significant;
- "p" is superior levels of relevance, then the null hypothesis is accepted, that all the regression coefficients are significant.

F test results indicate a probability that is less than relevance (0.031) so that the null hypothesis is rejected, which means that at least one of the coefficients is significant. R<sup>2</sup> indicator, shows if new estimated regression is well specified. A regression is well specified if the value of this indicator is as near 1. If regression of overall liquidity, debt and liquid assets available, the value of this ratio is quite close to the value 1, so we can say that regression is well estimated. In other words, 96% of the total variance is due to the general liquidity available liquid assets and current liabilities. Wats Durbin statistic (DW) testing serial correlation of errors. If the value of DW is situated around 2, the errors are not correlated. Regarding the case treated me, the

value of DW stands at around 2, there is likelihood that errors are correlated to some extent.

### 3. Conclusions

Because banking risks are a source of extraordinary expenses, their proper management for revenue stabilization time acts as a shock absorber. If the bank risk management and overall management system is effective, then the bank will be successful. It is important for a bank to manage risks, as this enables them to predict to some extent the event risk and take the time necessary decisions to reduce the risk of potential adverse consequences.

Risk is considered to be one of the organic components of bank affairs. In the current economic environment, it is increasingly felt increasing banking competition, it is noted challenges faced by institutions in this field in the approach to business with a higher risk, but generates a substantial income. Some bankers may accept risk (including expected losses) as long as they can identify and manage uncertainty (unexpected loss). In terms of dynamic and volatile markets, the difference between the two types of losses fade, if not disappear.

# IS ADEQUATE THE METHOD OF LOAN LOSS PROVISIONING? – EVIDENCE FROM ROMANIA

**Chitan Gheorghe**

Academy of Economic Study, Faculty of Finance, Bucharest, Romania  
chitangheorghe@yahoo.com

**Abstract:** *The importance of banking system within the financial system requires a special attention in order to secure its stability. Thus, with the occurrence of the financial crisis, in the context of integration of the financial system and creation of unique financial market, became more stringent the need for the existence of specific tools to prevent financial crises and to guarantee the continuity of normal economic activity. In this category are the macro-prudential supervision tools whose role is to reduce the ability of banks to damage the economy by taking on excess risk. Among them is registered the dynamic provisions intended to be used for enhancing bank soundness and to help mitigate part of the pro-cyclicality of the banking system. The current study addresses the methodology for establishing specific provisions for credit risk at the level of the Romanian banking system, highlighting the direct implications over the credit institutions, and indirect implications over the economy as a whole. The study presents as well the possible course of actions in order to remedy the weaknesses in the recognition of loan losses. Thus, while listing the specialty literature, study presents the regulatory framework applicable to loan loss provisioning, underlining the weaknesses of the static provisioning model and the need to look forward to the dynamic model along with the accounting methodology. In this regard it was considered the worsening of a loan portfolio in macroeconomic context and a hypothetical comparative study between the static and dynamic model has been realized. The results of the study revealed that the current provisioning model has a procycle character without considering the influence of macroeconomic factors over the future worsening of the loan portfolio without allowing recognition of future loan losses due to failure to identify future risks generating events and their credible assessment. Therefore it is required the need to establish reserves during the economic growth periods to cover losses from loans in order to prevent disruption of the banking activity and to limit the risk of insolvency. To achieve this goal it is necessary that all the parties involved, namely the banks, the regulatory authority and accounting organizations, to realize the importance of loan loss provisioning and act accordingly.*

**Keywords:** *loan loss provisioning, static provisioning, dynamic provisioning, macro-prudential tool, procyclicality*

**JEL classification:** G21, G28

## 1. Introduction

The occurrence and manifestation of financial crisis has surprised unprepared the banking system generating negative effects on the stability of the entire financial system and the economy as a whole. One of the weaknesses was the lack of capital and liquidity reserves to be used during the decline phase of the economic cycle in order to limit its negative effects. To prevent and reduce the negative effects of financial crises, respectively to limit losses, liquidity constraints and possibly a credit

crunch, the Basel Committee on Banking Supervision (BCBS) is promoting stronger provisioning practices and establish the set-up of capital buffers and liquidity resources by the credit institutions (BCBS, Basel III: a global Regulatory Framework for Banks and banking systems more resilient, 2011). The capital reserves refers to a capital conservation buffer of 2.5%, comprised of Common Equity Tier 1, is established above the regulatory minimum capital requirement, and a countercyclical capital buffer designed for the periods when excessive credit growth is associated with construction of the systemic risk (Borio, Furfine and Lowe, 2001). As regards the liquidity risk the Committee developed the Liquidity Coverage Ratio in order to provide liquidity for at least one month and the Net Stable Funding Ratio for a time horizon of one year.

The purpose of this article is to analyse in the Romanian banking system, the necessity for application of the dynamic provisioning method for the credit losses, highlighting potential factors influencing the credit risk.

The remaining of the paper is organized as follows. Section 2 deals with Regulatory framework applicable to provisioning for loan losses. Section 3 deals with deterioration of loan portfolio in macroeconomic context. Section 4 deals with the effects of dynamic provisioning model application. Section 5 concludes.

## **2. Regulatory framework for loan loss provisions**

The importance of specific provisions for credit risk or impairment adjustments states in the scope of their own set up, namely in creating a reserve used to cover expected loan losses while own funds serves to absorb unexpected losses. Thus to determine these provisions this requirement must be met. Moreover the specific provisions for credit risk are considered to determine some prudential indicators used as a base for assessment of soundness of credit institutions (the solvency ratio, large exposures, establishing the total amount to be deducted from own funds to determine their total level).

The relationship between accounting and prudential norms should not be underestimated. The differences in assessment methodologies may affect the values of various elements impacting on risk management. There is a fairly broad consensus that more forward-looking provisioning could help to bring accounting valuations closer into line with economic valuations and could eliminate a source of artificial pro-cyclicality (Borio, 2003).

According to NBR Regulation no.16/2012 in the Romanian banking system are used two methods of adjustment: prudential and impairment adjustments. Positive difference between the total prudential adjustments value and the total impairment adjustments is allocated as a prudential filter for determining the own funds and prudential bank indicators.

The prudential provisions are recorded in extra-balance accounts while the impairment adjustments are recorded in balance sheet accounts. Prudential adjustments are determined by applying the provisioning coefficient on gross exposure adjusted with value of collateral accepted as decreased risk factor. Provisioning coefficients are different on classification categories according to perceived risk. Classification of loans are made in five categories (standard, observation, substandard, doubtful and loss) based on debt service, financial performance and judicial proceedings. In assessing financial performance are considered both quantitative indicators (return on assets, return on equity, etc.) and qualitative (ability of manager, business, etc.). Under the framework of global

monitoring of the banks activity on the procedure set out in the Regulation (EC) No.1606/2002, starting with January 1, 2012 (NBR Order no.9/2010), the banking regulatory authority in Romania adopted the International Financial Reporting Standards (IFRS). With the adoption of IFRS, besides determining the prudential adjustments are determined also the impairment adjustments, both individually, for significant exposures which records impairments and collectively, for significant exposures which do not record impairments on one hand and insignificant exposures on the other hand. For impairment recognition must be applied IAS39 according to which *"A financial asset or group of financial assets is depreciated if there are objective evidences of impairment as a result of one or more events that occurred after the initial recognition of the asset and respective generating losses events have an impact that can reliable estimate the future cash flows "*. Among the indices for loan impairment may be mentioned: significant deterioration of the financial situation, the probability for opening the bankruptcy procedure or similar protection procedure, infringement of contractual terms, significant decreases in estimated cash flows for a portfolio of loans.

This modality to admit the credit losses allow to a bank to consider only past events and current conditions. The effects of future credit loss events cannot be considered. Thus, this recognition modality is perceived to have caused delay in the recognition of credit losses, the BCBS promoting and supporting the International Accounting Standards Board for change in the accounting standards towards an expected loss including use of information more forward-looking (BCBS, 2011) (IAS 39 will be replaced by IFRS 9 with annual applicability beginning on or after 1 January 2015 - IFRS).

This involves changes in the modality of determining the expected credit losses, including improvement of internal rating based approach for credit risk implemented by Basel II. Thus a credit institution would consider quantitative and qualitative factors that are specific to the borrower, including the entity's current evaluation of the borrower's creditworthiness. It will also consider general economic conditions and an evaluation of both in the present time and in future periods of the economic cycle. In the Greek banking system Dimitrios, Angelos and Vasilios (2012) find that non-performing loans can be explained mainly by macroeconomic variables (GDP, unemployment, interest rates, public debt) and management quality.

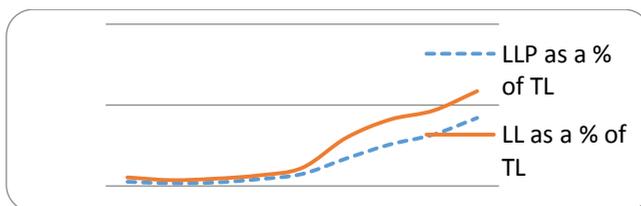

Raducanescu and Dima (2011), after the time of recognition of loss based on the economic cycle are considered two types of model for provisioning: static provisioning models and dynamic provisioning models. In case of static provisioning model, the provisions are determined considering the expected losses (regularly on yearly bases) on a certain moment in time. Dynamic provisioning is a statistical method for loan loss provisioning which uses historical data about estimate level of lending and average ratio of expected losses according to economical cycle phases (Raducanescu & Dima). Also states that applicability of static model to Romanian banking system is moreover motivated by determination of the capital requirements on a short term horizon.

### **3. The deterioration of loan portfolio in context macroeconomic**

Within the specialty literature, the cycle character of banking activity is address in many studies (Drehmann, Borio and Tsatsaronis, 2011, Borio, 2012, Borio, Disyatat and Juselius, 2013). Asea and Blomberg (1998) showed that banks change their lending standards, from tightness to laxity, systematically over the cycle. Majnoni

and Laeven (2002), found that many banks tend to delay provisioning for bad loans until too late, when cyclical downturns have already set in, possibly magnifying the impact of the economic cycle on banks' income and capital.

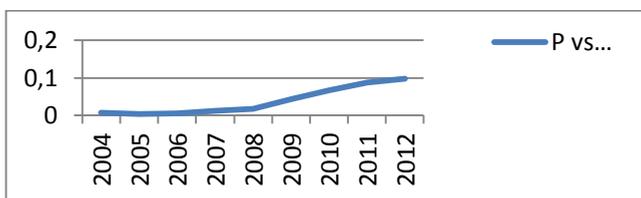

To understand and argue how the modality of provisioning for credit losses within the Romanian banking system may have a pro-cyclic character, we take the approach of deterioration of credit portfolio relative to GDP. Using the consolidated data to the Romanian banking system from the NBR website, figure 1 shows the loan loss provisions (LLP) and the loan loss (LL), both scaled by total loans, between 2004 and 2012.

**Figure 1:** Loan loss provisions versus loan loss ratios

Source: own processing

It is to be observed that provisions are lower than loans loss. Until the end of 2008 , under economic growth premises, we have a similar trend for both elements. Starting to 2009 under the financial crisis premises and due to economic decline (according to NBR data, real GDP decrease from 7.3 in 2008 to -6.6 in 2009, reaching 1.1 at the end of 2012), both loans classified as “losses” and related provisions recording a rapid increase. Until 2010 the growing rhythm of the credits classified as “loss” was more dynamic than the related provisions. After 2010 the related provisions knew a more rapid increase. The ascending trend of provisioning for losses and degree of their coverage on credits classified as “loss” showed that their level has been under evaluated.

**Figure 2:** Loan loss provisions on operating income and operating expenses ratio

Source: own processing

Figure 2 illustrates the importance of provision expenses relative to bank return on system level, an inverse relationship being observed between earnings and provisions in a recession (beginning with 2009).

Similar to Bikker and Metzmakers (2005) is observed that provisioning is substantially higher when GDP growth is lower, reflecting increased riskiness of the credit portfolio when the business cycle turns downwards. The findings are consistent with the call for the implementation of a dynamic provisioning system, similar to other authors. Thus Bouvatier and Lepeti (2008, 2012) found that loan loss provisions made in order to cover expected loan losses amplify credit fluctuations,

in contrast to forward-looking provisioning system which do not affect credit fluctuations.

#### **4. Effects of applying the dynamic provisioning model**

The dynamic provisions are a macro-prudential tool for enhancing bank soundness, with an anti-cycle character that allows to establish provisions higher during the economic growth periods and to use them in order to cover the losses within the economic decline phases. The strongly pro-cyclical nature of bank lending in Spain has led to the implementation of dynamic provisioning system in 2000 (Fernandez de Lis et al., 2001). The working of the Spain dynamic provisioning model and its theoretical mechanism is presented by Saurina (2009<sub>a</sub>, 2009<sub>b</sub>).

The current study does not present in details how to determine provisions for credit losses using the dynamic provisioning method due to lack of data, this being one of the reasons for inapplicability at the level of the Romanian banking system, so a simplified model is presented in exchange showing the influence of implementation of this method over the prudential situation of a credit institution (Table no.1).

The construction of the model is made for a period of three years based on the following hypothesis: the total value of credits to adjusted value of the gross profit and equity remains constant on the entire period; exposure on credits is expressed in lei and in the first two years is framed under prudential classification category "in observation" which provisioning coefficient is 0.02, and in the third year is framed under category "substandard", which provisioning coefficient is 0.05; total value of credits is equal to total value of assets; the provisions determined based on dynamic model are fiscal deductible; the risk level of the portfolio at the end of three years period is 21.33%; to determine solvency are used level I own funds (Tier I), considering that they meet the requirements for recognition.

Is to be noted that the total level of credit risk provisioning at the end of the third year is the same for both models: static and dynamic. Even so the static model does not allows recognition of future credit losses due to lack of identification of risks generating events and its credible assessment. This allows during economic growth recording of some comfortable prudential indicators and allocation of the profits as dividend to shareholders or amplification of lending activity. Instead estimating losses based on some macroeconomic indicators the dynamic provisioning model allows setting up provisions reserves by allocating current earnings in order to cover the future losses.

Thus, as noted from the recorded value of the solvency ratio at the end of the third year, banks that does not establish during the economic growth period reserves to cover future credits losses, records disruption of business activity and are more exposed to the risk of insolvency.

**Table no. 1: Provisioning models**

	Static model			Dynamic model		
	Year1	Year2	Year3	Year1	Year2	Year3
<b>Assets</b>						
Total loans to the value adjusted	1500	1500	1500	1500	1500	1500
Stock of prudential adjustments	75	75	300	75	75	300
Stock of impairment adjustments	30	35	320	30	35	320
Stock of statistical provisions				140	285	0
Total loans to the net value	1470	1465	1180	1330	1180	1180
<b>Income Statement</b>						
Gross profit	150	150	150	150	150	150
Expense provisions	30	5	285	170	150	0
Deductible expenses of prudential filters	45	40	0	0	0	0
Taxable profit	75	105	0	0	0	150
Tax (16%)	12	16.8	0	0	0	24
Net profit	108	128.2	-135	-20	0	126
<b>Shareholders' Equity</b>						
Equity	150	150	150	150	150	150
Net profit	108	128.2	-135	-20	0	126
Total own funds	258	278.2	15	130	150	276
Prudential filters	45	40	0	0	0	0
Total adjusted own funds (Tier I)	213	238.2	15	130	150	276
<b>Equity to Asset</b>	14.49	16.26	1.27	9.77	12.71	23.39
Solvency: Equity to Assets $\geq$ 4%	Solvent	Solvent	Insolvent	Solvent	Solvent	Solvent

Source – own processing

Notes: Total loans to the value adjusted represent gross exposure reduced by related guarantees. Prudential adjustments are determinate according NBR Regulation no.16/2012. Impairment adjustments are those identified as probable and estimable. Statistical provisions are those taken under the dynamic provisioning model.

#### 4. CONCLUSIONS

Given the direct influence of provisions for credit losses over the profit, and indirectly over the capital of a credit institution, the methodology for establishing them is rather important. The current study presents in the Romanian banking system the regulatory framework for establishing specific credit risk provisions and the effects of its application on the prudential situation of credit institutions. The study highlights that the current model used, respectively the static model, is permissible in recognition of future losses, with a pro-cyclical character with a negatively influence on the financial stability of banks. To address this issue it is necessary the early identification of risks to the loan portfolio quality and the early recognition of losses. Consequently it is required the need for changing the accounting methodology and risk recognition by using information that is more forward-looking in order to avoid oscillations in activity and disturbances in the financial statements. This will allow the capture of asset quality deterioration and better asset quality assessments and supervisory reporting. More accurate identification of the factors and their influence on the loan portfolio remains an open issue and will continuing to be the subject of the future researchs.

# THE IMPACT OF FINANCIAL LIBERALIZATION ON ROMANIAN BANKING SYSTEM EFFICIENCY

**Ciupac-Ulici Maria-Lenuța, Beju Daniela-Georgeta**

<sup>1</sup> Department of Economic Sciences, Faculty of Financial Banking Management, Commercial Academy Foundation, Satu Mare, Romania

<sup>2</sup> Department of Finance, Faculty of Economic Sciences and Business Administration, Babes-Bolyai University, Cluj Napoca, Romania

[ulici\\_maria@yahoo.com](mailto:ulici_maria@yahoo.com)

[daniela.beju@econ.ubbcluj.ro](mailto:daniela.beju@econ.ubbcluj.ro)

**Abstract:** *In the last three decades, many emerging countries have moved away from a system of restrictive monetary and financial controls to a more liberalized financial sector. The restrictive imposed policies were expected to contribute to industrialization of the economy and to the stability of the banking sector. However, financial liberalization had big costs on the banking system's competitiveness and efficiency. Financial liberalization has a different impact on banking markets. Thus, there is no size that fits all policies concerning banking liberalization process. For highly efficient banks, competition is improving their efficiency standard, while less efficient banks can't compete with foreign banks and further are decreasing in efficiency or are driven out of the market. Overall, the average efficiency of domestic banking markets should be an important variable in deciding to open up their banking market. Banks that are operating close to the frontier, in general are improving their efficiency following financial liberalization process. Banks that are operating in a further distance can't manage to compete with foreign market entrants, so, they are losing from liberalization process. In this article we propose to measure the impact of financial liberalization process on Romanian banking system. We used the panel regression to study the informational efficiency of three Romanian banks during 2004 - 2012. The dependent variable of the model was the price of stock bank, and the independent variables were the financial indicators (return on equity, return on assets, net profit margin). In the second regression we introduce a dummy variable for crisis period. Our results show that the financial indicators choose do not affect the efficiency of Romanian bank, but the crisis had a negative impact on them. International context, credit risk, the implementation of Basel III and reducing exposures in the absence of investment alternatives remains key challenges to the Romanian banking system in future.*

## 1.Introduction

One of the most important decisions taken by national authorities during the last three decades was the liberalization of financial systems. This process was developed in many emerging market economies from Europe, Latin America, Asia and Africa. The financial deregulation aimed, essentially, to sustain the economic growth, through the smooth progress of financial development.

The measure of financial liberalization were meant to eradicate financial restrictions, by making the central bank more responsible in implementation of monetary policy, restructuring and privatization of financial institutions, eradication of credit control, liberalization of interest rate, removal the obstacle on capital flows, elimination of barriers on competition among financial players, and liberalization of equity markets. Financial liberalization has a positive impact on financial development, according to the finding of several research studies. Financial deregulation leads to better financial evolutions by improved risk sharing between the domestic and foreign intermediaries (Henry 2000a). Better risk sharing can reduce the cost of capital tempting additional investment and growing the level of investment (Henry 2000b, Bekaert and Harvey, 2000), but can also conduce to investments in riskier higher expected return projects (Bekaert, Harvey and Lundblad, 2005). So, financial liberalization is associated with financial flexibility – the efficiency in which capital can be reallocated and supervised.

Improved financial intermediation is frequently associated with a higher economic growth. There are a large literature suggesting that financial development contributes to economic growth, by decreasing the investment costs and pooling capital more efficiently (Lucas, 2005; King and Levine, 1993; Beck, Levine and Loayza, 2000), although a few studies indicate the contrary (Devereux and Smith, 1994).

In many economies, the banking system is the most important component of financial sector, having an essential role in promoting of the economic growth. This is the reason for why the financial deregulation process referred in a large extends to the banking system liberalization. The banking reforms consist in the abolition of the credit control, liberalization of interest rate, privatization of state-owned banks and elimination of barriers in capital flows. The liberalization in banking system seek to improve the efficiency of the banks, to acquire a better allocation of credits, to encourage savings and, consequently, to achieve a higher economic growth.

Difficult economic context has influenced the Romanian banking system, both in the savings, and lending. The biggest challenge for banks was credit risk, given that non-performing loans have increased and are expected to increase further due to financial crisis.

In the context of unpredictable economy and volatile financial markets, the Romanian banking system is facing one of its toughest tests. In addition, the financial position of many banks became more difficult, some of them being forced to absorb significant losses in sovereign debt crisis. Now banks have to regain the confidence of markets and the public, to absorb new regulatory requirements, reduce costs, focus on core activities and increase lending, while ensuring a balance between risk and reward.

In this paper we analyze the impact of financial liberalization on Romanian banking system efficiency. The paper is structured as follows. In section 2 we reviewed the prior literature on the impact of financial liberalization on banking system. Section 3 presents the empirical methodology we have applied to measure the impact of financial liberalization on banking system. In section 4 we showed the results of our empirical investigation and discussed it. Section 5 comprises the most important conclusions of our analysis.

## 2.Literature review

The theory of financial liberalization process is based on McKinnon (1973) and Shaw (1973) works, which is focused on the economic benefits of liberalization.

Denizer, Dinc and Tarimcilar (2000) examine the bank efficiency in pre and post-financial liberalization period in the Turkey during 1970-1994. Their empirical results show that financial liberalization reforms were followed by a decline in bank efficiency.

Bonaccorsi di Patti and Hardy (2005) analyzed the impact of banking system reform on the productivity and cost productivity in Pakistan and on the efficiency of groups of banks (state-owned, foreign, private domestic and privatized). Their result show that the first wave of liberalization in 1991-1992 generates a higher profitability due to the increase in revenues more than the costs, but during 1998-2002 profitability recorded a decline due to a negative contribution from business conditions that more than offset an increase in profit productivity after the second wave of reforms. Efficiency by groups of banks recorded various levels: state owned banks are least efficient, the privatized banks improved their efficiency immediately after their privatization, and the new private domestic banks are among the most efficient and sometimes out-performed the foreign banks. As a result, banking liberalization led to a higher banking performance, especially between 1993 and 1997. A similar research is the empirical study of Abbas (2010) who analyzes the impact of financial liberalization and deregulation on the bank performance in Pakistan, finding that the banks efficiency has improved during 1990-2006. Regarding the group banks' efficiency the more efficient are foreign banks, followed by private banks, nationalized commercial banks and privatized banks.

Studying the relationship between financial liberalization and bank performance in India between 1991 and 2001, Koeva (2003) find that industry concentration, profitability and bank spreads in bank industry have decrease during the period of liberalization. Ghosh, Harding and Phani (2008) examined the impact of foreign banks entry liberalization on agency costs in India, finding that the gains of private banks were almost double than those of national banks after liberalization. They also find a significant relationship between firm-specific abnormal returns and factors usually associated with a bank's potential for takeover. They conclude that the expected gains from the reduction of agency costs represent one reason of the valuation gains associated with banking liberalization.

Williams and Nguyen (2005) examine the impact of financial liberalization on banking performance in South East Asia during 1990-2003. Their findings indicate that bank privatization reform increases bank efficiency performance more than other types of liberalization reforms. Hermes and Nhung (2008) study the impact of financial liberalization on bank efficiency in ten emerging countries from Latin America and Asia during 1991-2000, finding that financial liberalization has a positive impact on bank efficiency.

Maudos and Solis (2011) analyzed the evolution of banking competition in Mexico between 1993-2005, a period characterized by deregulation, liberalization and consolidation of banking system. They found a diminishing in competitive rivalry in the deposit market and a boost in the loan market. The banking reform increased the risk aversion of banks, causing a discouragement to finance private activities which were more profitable, preferring to finance only the less risky which low return. They

conclude, however, that the banking liberalization has certainly revealed consequences.

Adjei and Chakravarty (2012) studied the impact of banking liberalization in Ghana, characterized by the entry of foreign banks, on the cost efficiency of banks. They find that there is an obvious difference in efficiency scores within and between groups by type of ownership, but foreign ownership is not the determining factor. Foreign owned banks existing before liberalization have, on average, performed better in comparison with those that entry after liberalization, but there is a significant difference in efficiency within banks under comparable ownership type.

Parlour, Stanton and Walden (2012) analyze the financial development, intraeconomy capital flows, the size of the banking system, the value of intermediation, expected market returns and the risk of bank collapse. Their empirical result suggests that market's dividend yield is associated to its financial flexibility and capital flows has an important role in explaining expected returns and the risk of bank collapse.

### 3.Methodology

In order to investigate the impact of financial liberalization on Romanian banking system efficiency, we estimate the following panel regressions:

$$p_{it} = c_1 + c_2 * ROE_{it} + c_3 * ROA_{it} + c_4 * MARJ_{it} + \varepsilon_{it} \quad (1)$$

$$p_{it} = c_1 + c_2 * ROE_{it} + c_3 * ROA_{it} + c_4 * MARJ_{it} + c_5 * DUM_t + \varepsilon_{it} \quad (8)$$

where:

$p_{it}$  – represents the price of stock bank  $i$  at time  $t$ ,

$ROE_{it}$  – represents the return on equity ratio of stock bank  $i$  at time  $t$ ,

$ROA_{it}$  – represents the return on assets ratio of stock bank  $i$  at time  $t$ ,

$MARJ_{it}$  – represents the net profit margin ratio of stock bank  $i$  at time  $t$ ,

$DUM_t$  – represents the dummy variable, which takes the value of zero for the period before global financial crisis, respectively one for the period that includes the actual crisis.

We introduce the dummy variable in order to see if the current financial crisis has an impact on Romanian banks efficiency.

### 4.Data and empirical results

#### 4.1.Analyzed data

The analyzed data are quarterly and includes the period Q2 2004 – Q4 2012. We have four banks listed on Bucharest Stock Exchange: Commercial Carpatica Bank (2004), Romanian Bank for Development (2001), Erste Bank (2008) and Transilvania Bank (1997).

In 2012, the Romanian banking system has 365.9 billion RON assets. BCR remained the largest bank in Romania, as asset portfolio. This financial institution held last year, a market share of 19.3%, with assets of 70.6 billion lei. In second place is situated BRD, which approached the threshold of 13% in four years of crisis losing about one percentage point in the share market. Bank had trouble, so ended 2012

with a loss of 332 million lei, after the first years of the crisis was the most profitable. Transilvania Bank holds the third position, thus strengthening its market status, achieving notable growth rate of assets from one year to another, without profit to compromise, which in 2012 grew 40%. During the crisis proved to be the most dynamic large bank, gaining two percentage points in market share during 2009 – 2012 (table 1).

**Table 1: Romanian banks**

Bank	Ticker	Assets (billion. RON)	Share market in 2012 (%)
Romanian Commercial Bank	BCR	70.6	19.3%
Romanian Bank for Development	BRD	47.9	13.1%
Transilvania Bank	TLV	29.3	8%
Commercial Carpatica Bank	BCC	4.7	1.2%

We choose to analyze the banking system efficiency by using the daily closing values of three Romanian banks: Commercial Carpatica Bank - BCC, Romanian Bank for Development – BRD, and Transilvania Bank – TLV. All closing values are expressed in national currency.

The financial indicators (return on equity, return on assets and net profit margin) are also quarterly and are calculated for each bank. In table 2, we can see the descriptive statistics of the analyzed variables.

## 4.2. Empirical results

Aggregate annual results of Romanian banking system show that the analyzed period was a difficult one for banks. Romanian banking market was characterized by an increase in household deposits and lending activity slow. It is surprising to see that financial indicators did not affect the evolution of bank stocks (table 3).

**Table 3: Empirical results without dummy variable**

	(1)	(2)	(3)	(4)	(5)	(6)	(7)
C	0.0123 (0.4619)	0.0070 (0.2798)	0.0126 (0.4778)	0.0113 (0.4261)	0.0073 (0.2951)	0.0074 (0.2962)	0.0117 (0.4430)

Notes: White *t*-statistics are in parentheses. \*, \*\*, \*\*\* indicate statistical significance at 10%, 5% and 1% levels.

Romanian banks experienced an economic slowdown following the current crisis, most implementing comprehensive structural reforms in an effort to reduce debt. Restrictive fiscal policies, tightening credit standards and reduced degree of indebtedness, as appropriate and immediate measures to mitigate the risks associated recession have had a negative contribution to banks evolution. Our results from table 4 confirm the idea said above: the value of dummy variable is negative and significant at 1 percent, respectively 5 percent.

## 5. Conclusions

The major objectives of financial liberalization process were to improve the performance of banking system, respectively to make it more competent and efficient. However, the analyzed banking system continues to play an important role as a resource mobiliser. It remains the principal source of resources for households, small and medium enterprises. Also, it caters the large industries and provides many other financial services.

The Romanian banking system was not enough liberalized, so it was affected by the global financial crisis. There were deepened losses in the banking system; it reached an average of 53 million in 2012, as a result of raising the cost of credit risk, which exceeded the operating profit in some cases. Ratio of the gross customer loans and deposits in the banking system was deteriorated, it rise to 120.12% at the end of 2012, indicating ensuring the necessary liquidity from banks mother. National Bank of Romania scored some changes in the monetary policy rate during 2008 - 2012, when the interest rate was decreased to 5.25% from 10.25% as it was in early.

International context, credit risk, the implementation of Basel III and reducing exposures in the absence of investment alternatives remains key challenges to the Romanian banking system in future.

# THE NEED TO REFORM THE BANKING SYSTEM – A PREMISE FOR THE IMPLEMENTATION OF THE BASEL III ACCORD

**Cosma Daniela**

University of Oradea – Faculty of Economic Sciences  
cosma\_danieladan@yahoo.ro

**Abstract:** *The application of banking reform measures represents a real challenge for banks in this post-crisis period also leading to the rapid implementation of the Basel III Accord. The causes of financial-economic crisis must be identified and dealt with, one of the difficulties the banks face being that to quantify and take risks. The banking system was characterized by weaknesses in the recent global financial crisis. These weaknesses were related to: too much leverage in the banking; not enough high quality capital to absorb losses and an excessive credit growth based on underwriting standards and under-pricing of liquidity. It is felt the need to move from "deregulation" to an accurate banking regulation process, based on an appropriate mix of macroeconomic policies, that is to the ensurance of a balance between the policies meant to stimulate the demand and those policies which can stimulate the demand. The problem of banking regulation is also taking into account the reactions of the business world which emphasizes the fact that an exaggerated regulating process which supresses innovation would be a major risk.*

*Many of the changes in the banking system are inspired by the final draft of the G-20 reunion, that of developed countries, in November 2008, a draft considering the economic re-launch and reform. Basel III considers the reform of the banking system by measures whose cover area is much larger and they refer to both the micro-prudential framework and to the macro-prudential one. The application of all the measures established by Basel III Accord is expected to end by 2019, with different effects in the main segments of banking business: retail, corporate and investment banking. The impact of Basel III implementation in the banking system of the USA is almost similar to that of Europe's, with slight differences regarding the capital and the reduction of mortgage rights, which play a more important role in the USA, the latter having another starting economic point than Europe.*

**Key words:** *banking reforms; macro-economic perspective; monetary policy; bank corporate governance; countercyclical capital, credit crunch, bank leverage.*

**JEL Code:** G01, G21

## 1. Introduction

After the 2000s, the international financial market has evolved stronger and stronger, an evolution many considered to be one leading to an unrealistic economic growth; starting from the American contagion (Badea, Socol, et al. 2010, 192), determined by the "subprime" loans, with a high risk of not being reimbursed by the debtors and expanding on the European economy. Banking institutions were free to find their own strategies for loans and to establish the assumed levels of risk. Also, (Badea, Socol, et al. 2010, 192), the investment funds transferred mortgage loan packages to investors, which, in combination with derivatives have created a chain reaction, leading to the impossibility for the debtors to pay off their loans. The overvaluation

of real estate properties, concomitantly with the failure to pay the loans have led to the creation of inefficient bank guarantees. The losses have been felt both by investors as well as by banks, thus influencing the international financial-banking relations, a fact which has led to the generalization of the crisis at the global level. The clients' lack of trust in the banking system has been felt especially in the contracting of much less loans, these becoming more expensive, and the liquidities of banking institutions less and less.

What happened in 1929-1933, represents, also, a lesson of the banking crisis which has not been learnt too well. In that time, too, just like in the case of the current crisis (since the end of 2007), the banks went bankrupt and the credits slowed down. The crisis expanded in most of the economies of the Western countries and the state became the refuge for the banking system.

All these problems have led to a reform of the banking sector. If in 1933, the reform (Mășu și and Gheorghe 2009, 208) meant the devaluation of dollar, economic and social aids, the launch of new projects and works, the self-limitation of agricultural production, that is a series of measures attempting an economic re-launch, we can say that in the present history is repeating and that these crises have a common point the **"credit crunch"** effect, that is the rarefaction of loans. This effect is often associated with the liquidity crisis (Mășu și and Gheorghe 2009, 209), a reason making us to analyse certain banking regulations and norms, like those of Basel Accords.

## **2. Opinions and orientations in reforming the banking system**

If Basel I Accord, in 1988-1995, by the measures proposed managed to introduce increments of own funds in the banking institutions and by these to improve the economic-financial situation, Basel II, which comes little before the crisis break out (at the end of 2007) contains also recommendations both for governments and for central banks. The recommendations are related both to prudential policies (protection of deponents, measures for the banking institutions in difficulty, the setting up of an appropriate minimum capital of own funds that the banks must comply with), as well as the need to adjust the drawbacks noticed in the banking system, due to failures to appropriately manage the risk, when attempting to ensure a real banking transparency and discipline (Stiglitz 2010, 202).

There are different opinions belonging to economists and business people regarding then banking regulation activity and the way in which this activity should be carried out. No matter it is about "ten construction sites" of the reform (Mășu și and Gheorghe 2009, 222), mentioned by C. Chavagneux in an article; about "nine propositions to end up the crisis" belonging to Lordon F (Lordon 2008, 169); or about "twelve recommendations for the reform application" belonging to Pastre O. and Sylvestre J.M. (Pastre and Sylvestre 2008, 216-218), all have the role to bring a new financial architecture and to build a new banking system.

The sites of the reform could start in Lordon F.'s opinion with "desecuritization" activities, noticing that a part of the disaster made by the crisis has been due to the transformation of debts into bonds, currently being necessary a reverse operation, that of limiting the bonds in a loan portfolio.

The "leverage" is also a risk generator, leading to financial speculations. A reverse operation would be necessary, that of "debt deleveraging" (Lordon 2008, 174-175), by charging some very high percentages of material cover up, in a proportion of 80-90%, with own funds, which would lead to the decrease of such operations.

The anti-speculation monetary policy is part of the activity of Central European Bank, and as Maucour O. (Maucour 2009, 191-205) stated in an article on Basel II, The Basel Committee must propose certain provisions referring to the rating agencies, credit derivatives and the securitization operations that should be added to the Basel II Accord; in this way, there will be prudential rules meant to bring stability to the banking system. Each country's central bank, together with the central banks part of the Basel Committee must set up a minimum level of own funds for the banking institutions. These are propositions by which this Basel II Accord will be updated, changed and completed; many of these changes will be agreed upon and subsequently applied through the Basel III Accord.

Even the problems regarding the change of accounting norms have the role of representing the basis for the reformation of the banking system, because during crisis, together with the decrease of the value of assets, the firms can give up the "real value" of these and adjust the account value in accordance with the market decrease, as it could be seen at the end of 2008. These accounting norms must better reflect the economic value.

A largely debated problem was that of regulating the "tax havens". If the objective of these areas called tax havens was to increase evasion by exiting the fiscally regulated areas and the recording of the trade in the so-called "offshore" financial areas, from now on the regulation of all the financial operators is becoming necessary, which compares tax havens with some "black holes", which should not exist and their disappearance should rebuild the international banking system (Mășu, Buneci and Gheorghe 2009, 225).

The causes of the current economic-financial crisis should be identified and dealt with, one of the difficulties of banks being that of quantifying and taking risks.

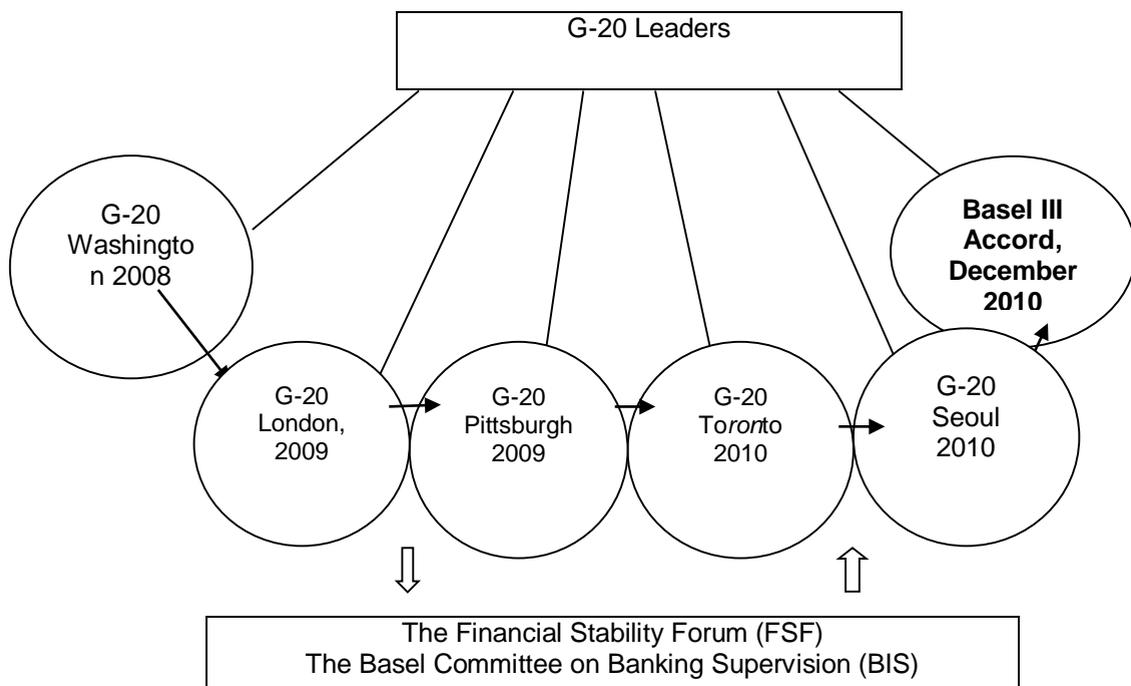

In order to exit the crisis, "*the world economy cannot work continuously with only one engine*" (Rădulescu 2012, 36), that is the American one, from which the crisis started for it expanded worldwide and, in time, it has been noticed that this way of working created economic imbalances. "*Europe, with a much more balanced commerce (from the point of view of deficit/surplus) was playing the role of moderator between the American and Asian flows*" (Rădulescu 2012, 36). That is why there is this stringent need to get to "deregulation" towards a fair banking regulation, based on an appropriate mix of macroeconomic policies, that is towards the ensurance of a balance between the policies meant to stimulate demand and those policies which can stimulate supply.

There is, also, the problem of banking regulation taking into consideration the so-called "exaggerated reactions" of the business world which emphasize the fact that a major risk would be to exaggeratedly regulate thus killing off innovation.

In Stiglitz's opinion, deregulation would have taken place "*when the dangers of excessively taking risks increased, due to the new financial products*" (Stiglitz 2010, 157). These new financial innovations must help correctly manage the banking risks and not amplify the risk. The bankers should not avoid the rigour of regulations, they must ensure the banking transparency, give up those "innovating" products presenting a high risk for the bank to the detriment of its clients.

### 3. The effects of G20 reunion on the creation of Basel III Accord

There have been several precursory stages to the setting of Basel III Accord which were the result of the numerous meetings of the G20 Group. The new elements brought into discussion by the group of the 20 member states (at Washington, London, Pittsburgh, Toronto, Seoul) had in view the implementation of new banking regulations and Basel III Accord represented their finality.

**Figure 0. Basel: the creation of Basel III Accord**

Source: (Constantinescu, 6), <http://www.paneuropa.ro/doc/CRDIV.pdf>

Many of the changes in the banking system are inspired by the final document of the G-20 meeting, of developed countries, in November 2008, a document targeting the economic re-launch and reform based on several directions (Mășu și and Gheorghe 2009, 234):

- **the integrity of financial markets** – can be done by assembling all important banks and by creating "supervision colleges";
- **the reformation of some financial institutions** – such as IMF and the World Bank, thus contributing to the financial stability, to the re-launch of loan activity to the emerging countries;
- **exigency and control** – which requires a better banking supervision, carefulness and control in appropriately managing the risks;
- **support for helping the world economy** – to exit the crisis and economic re-launch.

At the G20 Summit in London in April 2009, the debate was centred on problems regarding the harshening of the reforming rules of the financial sector and it was

forecasted that all the members present at this meeting should progressively adopt the regulation framework and the Basel Committee on Banking Supervision and the national authorities develop and agree on a new global framework of these financial institutions which should solve the problems regarding a much stronger, better quality liquidity, as a short-term cover (Financiarul, 25 June 2010). The G20 Group considered that the new Basel III Accord should be finalized by 2011, in this way it could be implemented much sooner.

In September 2009, at Pittsburgh, the G20 Group laid down a report regarding the promotional actions of the financial regulations established, according to which global standards should be implemented constantly so that they ensure *"a permitted and authorized level to fragment the markets, to protect and umpire the rules"* (BIS, 2010). In their opinion, progress can be achieved only with the help of the Decision Group of the trans-border banks, of the Basel Committee on Banking Supervision and of the World Bank, which establish recommendations for authorities on the problem of crisis management and decision making processes.

In 2009, too, the Basel Committee on Banking Supervision published two consultative documents, in December, with the title ***"The Resistance Consolidation of the Banking Sector"*** a document the press and the Internet wrote about, using as a title "Basel III" and a second document: ***"International Framework for Liquidity Risk Measurement, Standards and Monitoring"***. These are part of the activity of the Basel Committee, yet they are just projects not representing a legal framework for a new accord. The news brought by this accord will have a major impact on the banking sector, on the loan offer and on the economic growth problems (Financial News 16 April 2010).

All these meetings continued with those from Seoul and Toronto, in 2010, had as final objective the materialization of this accord, in the same time establishing solutions for the recent economic crisis.

An appropriate solution to exit the crisis came from the G-20 leaders, who had agreed within the International Monetary System to create a Programme for the improvement of the destabilization effects of capital flows, yet together with global liquidity management measures, in order to prevent the shocks.

The introduction of the Basel III Accord is due to several reasons (Nucu 2011, 58) easy to understand:

- **the disastrous effect of banking crises**, noticed by losses of economic productions with approximately 60% of GDP, in the period before the crisis;
- **the frequency banking crises precede one another with** (since 1985 to present there have been over 30 banking crises in the Basel Committee member states);
- **the benefits brought by the Basel III Accord** which must overcome the cost of implementing this accord, based on the reason that a solid banking system leads to a sustainable development and it has long-term positive effects.

#### **4. Micro and macro-prudential measures at the banking system level**

As compared to the other two Basel accords, Basel III targets the reforming of the banking system through measures whose cover area is much larger and which refer both to the micro-prudential framework as well as to the macro-prudential framework.

The immediate objective of these regulations is to limit the risk of new financial-banking crises, which, implicitly, lead to system crises and the need to use a macro-prudential approach based on supervision rules. In order to realize the importance of these rules, we have used a comparison between the macro and micro-prudential perspective:

<b>Macro-prudential Perspective</b>	<b>Micro-prudential Perspective</b>	
<b>Immediate objectives</b>	Limiting the financial crises so that they do not become systemic	Limiting the difficulties of banking institutions at the individual level
<b>Final objectives</b>	Avoiding the costs regarding the GDP	Protecting both the consumers (investors or deponents) and the banks
<b>Characterization of risk</b>	Considered being dependent on a collective behaviour (endogenous)	Considered being independent from the individual behaviour (exogenous)
<b>Correlation of banking institutions</b>	Important	Not important
<b>Carrying out prudential control</b>	In terms of risk: from the top down	In terms of each banking institution's own risk: from the bottom up

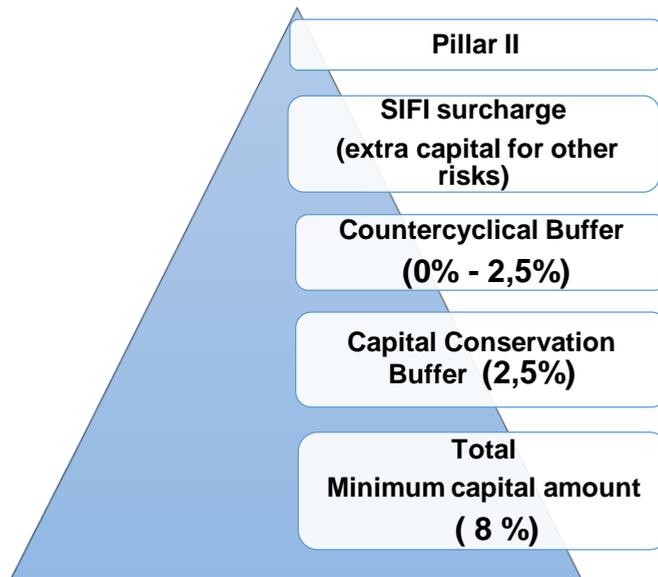

**Table 1:** The comparison of macro and micro-prudential perspectives at the level of banking institutions

Source: processed after (Borio 2011, 159)

At the **micro-prudential** level there is the need for measures stipulating a consolidation of the quality of banking capital, mainly following own capitals (capital reserves, the reported financial result), the minimal requirements of level I own funds (own funds and hybrid instruments), and the reconfiguration of some eligibility criteria for the instruments necessary to determine level I own funds. Due to the problems emphasized by the current crisis, there is the need for an increase in the exigencies to cover the risks, a limitation of the leverage effect (as an additional measure to the capital requirements) and not in the least the setting up of some liquidity standards, both on short term (30 days) in order to cope with the liquidity crises and on long-term (1 year) for an as solid as possible profile of structural liquidity (Nucu 2011, 59). The **macro-prudential** perspective (RNB Report, 2011, 124) presents anti-cyclic measures:

- the introduction of an anti-cyclic capital damper having the role of banking protection against systemic risks associated to the non-sustainable increase of the credit and of a fix capital preservation damper in order to cover the losses if the bank has financial problems;

- the calculation of the leverage effect in order to limit the level of debt of the banking system during periods of economic boom;
- measures for the systemically important banks, oriented towards the reduction of their bankruptcy probability and impact; the establishment of equal competition conditions they have in view reducing the competitive advantage that these banks have in the area of funding; the reduction of the cost owed to the public sector intervention. Also, they have in view supplementary requirements to diminish the losses, yet, also supplementary capital fees for “capital surcharges” banks.

Graph 1: Topping up further

Source: (Constantinescu, 17), <http://www.paneuropa.ro/doc/CRDIV.pdf>

Carrying into effect these measures depends on the transition period available to meet the requests. If the period of time is short, banks prefer narrowing their loan offer in order to raise faster the level of capital and to change the structure of assets. If the implementation takes place gradually, in a longer period of time, this impact can diminish and banks can find other ways: profit capitalization, share issue, change in the structure of liabilities, etc. Although the period of transition for the implementation of these measures is either shorter or longer, the consolidation of the financial system is carried out.

## 5. Conclusions

We could say that the compliance with the terms of Basel III implementation is important for the consolidation of the banking system and the responsibility of this implementation lies not only on the regulating bodies specialized in this implementation, but also on the specialists on problems of risk management, at the level of banks. Also, banking audit has an important role in reviewing and disciplining the efforts to apply these regulations. The application of these measures represents

a serious challenge for banks in this post-crisis period and state uncertainty. The economic growth is quite weak and the sovereign debts have emphasized the fragility of the financial-banking sector.

The application of all the measures established in the Basel III Accord is expected to be over by 2019, with different effects on the main banking business segments: retail, corporate and investment banking. The retail activity and that of corporate banking especially affected by those provisions of Basel III Accord regarding the capital and liquidity superior requirements and the investment banking activity suffers changes at the level of capital markets. The market of OTC derivatives will be affected by the fact that the banks must have a superior level of capital in order to be able to cover, apart from the other risks, the credit risk of the counterparty and the market risk.

The impact of implementing Basel III in the banking sector in the USA is almost similar to that of Europe's; there might be slight differences regarding the capital and the deduction of mortgage rights, which play a more important role in the USA, having another economic starting point than in Europe.

Regarding the regulations proposed by Basel III Accord, they have a more reduced impact at the level of our country. This is due to the fact that the banks are capitalized well enough, this capital being made up of level I own funds which own 80% of total own funds afferent to the banking system, at the end of 2011; capital hybrid instruments are almost missing and the aggregate leverage effect shows a value of 6% (which is according to the requirements), therefore the new norms will be seriously felt at the level of Romanian banking system. The challenge (Nucu 2011, p.68) for the Romanian banking system knows other directions, too, such as: the design, quality of data and the complexity of reporting. Also, an as efficient as possible banking corporate governance and which corresponds to the business model and risk profile is more than opportune for the implementation of the Basel III Accord. Regarding the liquidity standards, The Romanian National Bank stated that liquidity supervision in the case of branches should be the authority's task in the host member state and these standards should be applied both at the individual level and at the consolidated level.

## FINANCIAL DEVELOPMENT, INSTITUTIONS AND ECONOMIC POLICY – PANEL DATA EVIDENCE

**Filippidis Ioannis**

*Aristotle University of Thessaloniki, Department of Economics, 541 24,  
Thessaloniki, Greece  
filioan@yahoo.com*

**Abstract:** *In recent years significant researches have been done to identify what are the determinants of financial development. With regard to this outline, the main objective is to investigate the effect of economic, political and social dimension of institutional quality, as well as the effect of political and macroeconomic factors on financial development. More specifically, the present work aims to contribute to the relevant literature in the following ways: i) in the econometric front, we employ dynamic panel techniques, that allow for heterogeneity among variables, avoiding the known problems of traditional techniques. More specifically, we employ the “system GMM” estimator controlling for endogeneity among variables; ii) we disentangle into economic, political and social institutional quality in order to quantify the effect of institutions on financial development and check the robustness of our results; iii) in the same logic, we decompose our measure of financial openness into equity- and loan-related foreign assets and liabilities in order to assess whether the hoarding of risky vs. riskless assets or the accumulation of equity vs. debt liabilities affect the development of domestic financial institutions; and iv) to control for a potential bias among variables, we include a large set of information, which covers all the spectrum of possible effects on finance, giving emphasis on political factors and government policies. Our main finding from the regression analyses is a robust empirical relationship from institutions to financial development, a result consistent with most empirical studies. Also, we find a stronger effect from economic institutions to banking sector development and from political institutions to stock market development. Regarding the trade and finance link, we find that openness has a much stronger association with bank-based finance than with stock market development. As for financial openness, equity-related assets and liabilities have a more robust impact on financial development. Finally, government policy in terms of less government size and less interest rate controls have a significant effect on the banking sector rather on the stock market sector.*

**Keywords:** Financial development, institutions, trade openness, financial liberalisation, panel data analysis.

**JEL classification:** G29, F19, K49.

### 1. Introduction

In recent years significant researches have been done to identify the question: what are the determinants of financial development? The main findings from this literature can be summarized as follows. First, the degree of a country’s openness, such as capital account openness (Chinn and Ito, 2002; Demirguc-Kunt and Detragiache, 1998) and trade openness (Rajan and Zingales, 2003; Beck et. al., 2001, 2003), helps the development of the financial sector. Second, a country’s institutions, formed by

a country's legal origin (La Porta et al, 1997, 1998; Beck et al 2000, 2003; Djankov et al 2007) or by a country's geography and initial endowment (Acemoglu, Johnson, and Robinson, 2001), affects both creditor rights and private credit, and the extent of creditor rights protection has an independent effect on financial sector development. Third, political economy factors, where the government's position as arbitrator of financial contracts, potential borrower and regulator of the financial system, impacts on the functioning of the financial market (La Porta et al, 1999, 2002; Andrianova et. al., 2008). Finally, macroeconomic factors, such as the level of inflation, impact on financial sector development (Boyd et al, 2001).

Based on these results, our main objective is to investigate the economic, political and social dimension of institutional quality, as well as the effect of political and macroeconomic factors. More specifically: i) we employ the "system GMM" estimator developed by Arellano and Bover (1995), and Blundell and Bond (1998), controlling for endogeneity among variables; ii) we disentangle into economic, political and social institutional quality in order to quantify the effect of institutions on financial development; iii) in the same logic, we decompose our measure of financial openness into equity- and loan-related foreign assets and liabilities in order to assess whether the hoarding of risky vs. riskless assets or the accumulation of equity vs. debt liabilities affect the development of domestic financial institutions; iv) we include a large set of information, which covers all the spectrum of possible effects on finance, giving emphasis on political factors and government policies; and v) in order to investigate the whole impact of institutional changes on financial development, our data consists of 44 countries, for the period 1988-2007.

## 2. Methodology

To assess the relationship between institutions and financial development, the following model is estimated:  $y_{it} = \alpha y_{i,t-1} + \beta x_{i,t-1} + \gamma z_{i,t-1} + \eta_i + \varphi_t + u_{it}$ , where  $y_{it}$  is financial development,  $x_{it}$  is institutions,  $z_{it}$  is a vector of controlling variables including trade openness (TO), financial openness (FO), inflation (INFL), gdp growth (GDP), government size (GOV) and interest rate controls (RATE).  $\gamma$  is a parameter vector.  $\eta$  is an unobserved country-specific time-invariant effect and can be regarded as capturing the combined effect of all omitted variables.  $\varphi_t$  is the time effect.  $u_{it}$  is the transitory disturbance term. The subscripts i and t represent country and time period, respectively.

Arellano and Bond (1991) propose the first-differenced GMM estimator for dynamic panel data models which uses all lagged values of  $y$ ,  $x$  and  $z$  as instruments for  $\Delta y_{i,t-1}$ ,  $\Delta x_{i,t-1}$  and  $\Delta z_{i,t-1}$  in the first-difference equation above. The Arellano-Bover/Blundell-Bond estimator augments Arellano-Bond by making an additional assumption, that first differences of instrument variables are uncorrelated with the fixed effects. This allows the introduction of more instruments, improving efficiency. It builds a system of two equations - the original equation as well as the transformed one - and is known as System GMM. In other words, a "system GMM" estimator enables the lagged first-differences of the series ( $y_{it}$ ,  $x_{it}$ ,  $z_{it}$ ) dated t-1 to be used as instruments for the untransformed equations in levels. Based on the combination of first-difference equations with suitably lagged levels as instruments, and levels equations with suitably lagged first-differences as instruments, the system GMM estimator generally produces more efficient estimates by improving precision and reducing the finite sample bias (Baltagi, 2008).

### 3. Results

In Table 1, we present the results for the stock market. Overall financial openness index (namely FO) is decomposed into equity-related (foreign direct investment and portfolio equity, namely EQUITY) and loan-related (financial derivatives and debt, namely LOAN) assets and liabilities. As expected, financial openness is highly associated with stock market development in all specifications. The coefficients of FO, EQUITY and LOAN for the stock market are 0.076422, 0.2020214 and 0.1019987, respectively. It is noticeable that the impact of EQUITY is greater than of political regime (note that lower values of POL indicating a higher degree of democracy), which at best reaches -0.1672581 (column 3) and of gdp growth (0.0151378, column 2). The other variables, even though they are of the correct sign at most cases, are not statistically significant. In sum, political institutions, financial openness (particularly risky assets and liabilities) and economic performance (measured by gdp growth) are the main determinants of stock market sector development.

Regressions use 'System GMM' based on the xtabond2 command developed by Roodman (2006) for use with STATA. Robust standard errors are reported in brackets. \*\*\*, \*\*, and \* denote significance at the 1%, 5%, and 10% level, respectively. Arellano-Bond test for serial correlation and Hansen test for over-identifying restrictions report p-value.

A different logic prevails in the banking sector (Table 2). Economic institutions are statistically significant in all cases. The coefficients of 0.0588339, 0.0571176 and 0.0658521 indicate the significant role and magnitude of economic institutions in the context of the banking sector development. Even though the banking sector is affected by a wide spectrum of variables, since trade, inflation, government size and interest rate controls are statistically important (note that higher values of RATE and GOV indicating a higher degree of interest rate liberalization and a lower degree of government intervention, respectively), economic institutions seem to have the greater effect. In sum, the results demonstrate that the banking sector is more responsive in changes in economic institutions (rather than in changes in political institutions), trade and macroeconomic policies (inflation), as well as in political choices (government intervention and interest rate controls). Finally, the impact of the lagged value of the dependent variable is significant in all cases, emphasizing the dynamic view of financial development.

### **Conclusions**

In this paper we construct the new data set on institutions and policies indices for 44 economies from 1988 to 2007. We go beyond the identification of the effects of an overall institutional index and try to provide a more comprehensive assessment of the financial development-institutions-policy links by asking which dimension of institutions (economic, political, social) matter vis-à-vis financial development and whether the effects of institutions and policies differ when the dependent variable differ (stock market or banking sector development).

Our main finding from the regression analyses is a robust empirical relationship from institutions to financial development, a result consistent with most empirical studies. Also, we find a stronger effect from economic institutions to banking sector development and from political institutions to stock market development. Regarding the trade and finance link, we find that openness has a much stronger association with bank-based finance than with stock market development. As for financial openness, equity-related assets and liabilities have a more robust impact on financial development. Finally, government policy in terms of less government intervention and interest rate liberalization have a significant effect on the banking sector rather on the stock market sector.

*alex1avram@gmail.com*

**Abstract:** *The recent global financial and economic crisis has revealed some weaknesses in the regulation and supervision of the financial system and its architecture, especially in the treatment of systemic risks and vulnerabilities, and also the financial implications and downsides of the globalization process. The global nature of financial crisis has highlighted the fact that, although integrated financial markets may offer a number of significant benefits, risks involved are worthy of taking into consideration. In order to ensure the financial stability of the highly integrated global landscape is needed the reform of the financial system architecture, both nationally and internationally.*

**Keywords:** *financial markets, banks, supervision, regulation, financial crises*

**Jel Classification:** *E02, E44, E59, E61, E65*

## **Introduction**

In order to have an efficient answer to the current economic and financial crisis, it is important to understand where and how the crisis started. Although the crisis started as a financial one and later turned into an economic one that influences every aspect of our daily life, we believe that an important part of the answer given to the crisis must address the financial sector thru better regulations and supervision for and from the financial sector triangle: government, financial institutions and corporations. In our paper, using a descriptive methodology based on survey and data interpretation, we are trying to see the factors and the catalysts of the current economic and financial crisis and the figure out a series of improvements that are necessary for an efficient and sound financial system.

## **1. Characteristics of the global financial crisis**

The disruptions relate to the developments in the U.S. mortgage market and, for a better understanding of the transformations suffered, one should make a brief foray into history. Thus, after the 30's crisis, based on the "New Deal" program of the Roosevelt administration, a public body-the Federal National Mortgage Association (Fannie Mae) – was created. Its objective was to increase the volume of loans and mortgages, for stimulating the economy by all the positive effects that the development of the construction sector may have on it. Fannie Mae took over from the initial lenders the default and liquidity risk, which it could manage much better than the first line distributors credits, as it had a portfolio of mortgages much more

diverse and more widespread at the national level than the usual banking institutions. This body could borrow funds itself on longer term than banks, which was likely to reduce the liquidity risk.

This institution exclusively received for discount operations mortgage securities, subject to certain rules. Currently, these rules constitute the referential for defining the so-called *prime loans*, which are actually mortgages of rank one (prime mortgages). At the end of the 60s, the loans contracted by that body in order to refinance its mortgage securities discount operations have come to constitute a significant part of the U.S. government debt. Therefore, in order to relieve the state of the activity of that institution, the Johnson administration reorganized the U.S. mortgage market by creating a new body - the Government National Mortgage Association (Ginnie Mae) - responsible for managing the state guaranteed mortgages, under the scheme for veterans and other social assisted persons.

In 1970, Ginnie Mae began issuing bonds collateralized by mortgage debt, which enabled the transfer of risk of default to the subscribers of such titles and relieve the federal budget of a substantial part of the debt incurred for financing of public programs for the construction of housing. In technical terms, the operation consists of grouping similar mortgages and the issuance, on this basis, of securities (bonds) collateralized by the assets of the issuer. These titles were placed on the capital markets, and their redemption at maturity is done directly from the owners. Also, in 1970, a new body was established, the Federal National Mortgage Corporation (Freddie Mac), to issue securities based on classical mortgage loans, but also to create a competitor to Fannie Mae, which was to be privatized.

## **2. Securitization and the rating agencies**

In time, these institutions were able to mobilize significant capital for mortgage refinancing, their main operations aiming at acquiring and holding assets in prime mortgages, as well as the transformation of mortgage loans in a variety of debt securities collateralized by mortgages. The general name of this operation is securitization, a technique that transforms less liquid financial assets into negotiable securities such as bonds.

Rating agencies, which assess the credit risk related to the transferred assets, had the role to protect the holders of securities and to supervise the administration of the issuers. This risk embodies the risk of nonpayment, late payment, interest payment, etc. If it is considered that a risk is too big for the investors to be interested, there are some techniques used in order to increase the solvability. Entities with unfavorable ratings, through the process of securitization, can refinance at interest rates available for higher ratings. At these kinds of interest rates, they would not have access without this technique. Securitization also provides the opportunity for own funds to be invested in profitable activities, besides the fact that it enables the removal of loans from the balance sheet,

Subject to securitization there can be used mortgages, credit cards, consumer loans, claims on customers, loans to finance investment projects, etc. Securities collateralized by mortgage debt, known generically as "Asset Backed Securities", (ABS), are those securities which are issued based both on packages of residential mortgages and commercial mortgages, but more of them are based on residential mortgages. Mortgages from three sources: a single creditor, multiple creditors, as well as Fannie Mae or Freddie Mac portfolios in the U.S represent the base for most mortgage backed securities (MBS). (Cerna, 2008).

Mortgage securities based on mortgage loans from one lender are usually issued through swap transactions in which the lender changes the package of mortgages for MBS. Mortgage securities backed by multiple creditors allow some creditors to pack mortgages in exchange for the receipt of mortgage securities representing a proportionate part of a larger package. These may include the following titles: mortgage pass-through securities, collateralized mortgage obligation and stripped mortgage-backed securities. Most of the mortgage securities created were mortgage pass-through securities often named mortgage-backed securities (MBS), or participation certificates (PCs). The mortgage pass-through securities represent direct ownership rights on a package of mortgages. They can be wrapped again to create a guarantee for more complex mortgage securities known as collateralized mortgage obligations (CMO). A characteristic of the third category of mortgage securities, stripped mortgage-backed securities (SMBS), is that the cash flow collected on the mortgage base divides into two parts. The channel for the amounts received on the account of the repayment of mortgage loans is the Principal Only securities, while the entire interest paid is allocated to Interest Only securities. Generally, mortgage securities tend to provide coupon rates higher than the treasury securities issued by the U.S. Government. In part, this is because the interest rates charged for mortgages are higher than the interest rates offered by the U.S. government. At the same time, however, the higher interest rates of the mortgage securities also reflect the level of investment risk raised by the uncertainty due to the advance repayments. In the U.S., the GNMA, FNMC and FNMA guarantee these mortgage securities. The mortgage pass-through securities issued and/or guaranteed by the organizations listed above are the most numerous (AAA credit rating).

This structure of the market, based organizations supported by the state, proved to be very profitable, and therefore attracted other financial institutions as well. Thus, if in 2003 the semi-completed 76% of the total issuance of debt securities backed by mortgages and other assets of the issuer, the remaining 24% representing the large financial corporation is on Wall Street, in mid-2006, the share of the semi-public bodies decreased to 43%, while the share of private securities increased to 57% of the total. The major private issuers of this type of securities were the well-known U.S. investment banks (Wells Fargo, Lehman Brothers, Bear Stearns, JP Morgan, Goldman Sachs, and Bank of America) but also the big companies specialized in providing high-risk loans. Parallel with this rapid and radical transformation of the market, there was a change in lending standards in the U.S. following the deregulation process. In this liberal framework, while Fannie Mae and Freddie Mac have continued to provide almost exclusively prime loans, the private corporations have increased their market share, mainly through the securitization of mortgages with high risk and of the so called "Alt-A loans" granted to solvent, but less reliable debtors than the first class customers.

**Table 1:** The increase in the issuance volume of debt securities backed by mortgages (USD billion)

TYPE	2004	Percent	2006	(January- June)	Percent
Prime	57.7	52	67.2		26
With high risk (subprime)	37.4	34	114.3		44

Alt-A	15.8	14	76.5	30
Total	110.8	100	258	100

Source: Goolsbee, 2007:27

However, this increase in the quantity of securities backed by doubtful mortgages created a problem, because the main purchasers of such securities were institutional investors with a limited exposure to the holding of such securities. Consequently, only a small proportion of claims with high risk could be sold to institutional investors in search of higher yields.

To address this issue there was adopted a strategy of dividing risks in more categories or "tranches" with separate administration, thus determining a widening of the market for mortgage debts with high risk. From a technical point of view, this operation consists in dividing the portfolio of claims into two parts: one characterized by a low risk level and, one with high-risk level. To this end, firms on Wall Street have opted for a new financial instrument, created in 1987 by the financial investment firm, Drexel Burnham Lambert, called collateralized debt obligations (CDO).

To understand the operation of risk division, let us assume the existence of a specific portfolio of mortgages with high risk, divided into three classes of risk, with a CDOs issue. At maturity, the issuer redeems (repays) with priority securities of the tranche with the lowest risk (the senior tranche), which contains very secure and safe loans, but which usually carry low interest. After the titles in this tranche have been redeemed, there are withdrawn the titles in the intermediate tranche, with a higher risk, but also a higher yield (the mezzanine tranche). Finally, the titles in the third installment are redeemed only if the titles of the two previous installments have been fully redeemed. Because the titles of the latter class are the first affected by any possible loss in that portfolio of mortgages, they are not listed at the stock exchange, but, given their high risk, they carry the highest yield. In this way approximately 80% of high risk claims are sold to institutional investors, while the rest are sold to hedge funds, to specialized compartments in speculative operations of the firms on Wall Street and other investors attracted by high potential earnings that were provided by such transactions (Bordo, 2007).

An essential difference between CDOs and other mortgage derivatives on one hand, and securities listed at stock exchanges and futures contracts on the other hand, is that the former are not traded on stock exchanges, but on over-the-counter markets (OTC). On these markets, transactions are carried out directly between customers and dealers, unlike the stock market where sale or purchase orders are intermediated, as for the data about the volume of transactions and prices, these are not published officially. The price formation method has no transparency. It should also be noted that there does not exist a supervisory authority for OTC markets, that allows the identification of large or vulnerable exposures, nor do lenders of last resort exist, in order to provide the liquidity needed in special situations.

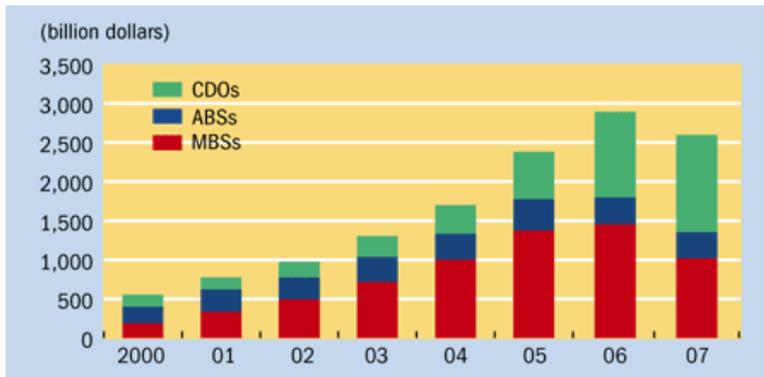

Figure 1 Issuance of structured credit instruments in the U.S.A and Europe  
 Source: Author

Therefore, investors who sought to obtain high profits have ignored the degree of risk involved by such securities. Until the spring of 2007, some top managers of financial companies have begun to concern about debt securities secured by subprime mortgages. However, given the still low interest rates and the high liquidity, the demand for structured credit products with AAA ratings and higher than normal yields, has continued to increase until mid-2007. The demand for real estate in the U.S. has increased considerably in the recent years, which led to a considerable increase in prices, which could be said that have almost doubled and even more from 1997 to 2006-2007.

Price evolution together with the exponential growth of prices after 2000 put the U.S. housing prices in a speculative bubble, the increase being determined by expectations regarding future price increases, rather than by economic foundations. The explanation lies in the fact that the homes were purchased for their future anticipated price level, price that could offset the initial yield offered. On the other hand, this increase was driven by the increased volume of mortgages granted, by the eased access to these credits and by the development of the construction sector in the period of economic prosperity.

In 2005-2006 interest rates began to rise and housing prices to decline moderately in many U.S. regions. As a result, outstanding loans rose as the initial terms have expired and variable interest rates rose. The inability of borrowers to honor the installments of maturing mortgages resulted in the mass start of the sale of properties by property holders and credit institutions. The market was flooded of houses from liquidation of mortgages, while new houses were not sold so well either, which led to a further decrease in the value of homes. Selling these houses below their market value (and obviously the price of acquisition or accepted value of collateral) has increased the default rate of loans and the incapacity to recover the total claims by credit institutions (Bordo, 2007).

The mortgage market crisis actually began when investors with very large debts, such as hedge funds have tried to adjust their exposure or, to exit the losing positions, which made the high-risk mortgage backed securities' market to become illiquid. In this way, in August 2007, when hedge funds had to pay the premiums required by their brokers, had found them stuck on unfavorable positions. The situation has worsened even further, because with the termination of transactions,

there were no market prices any more, to serve as benchmarks, or other means to determine the value of the securities contained in various tranches of risk.

### 3. Vulnerabilities highlighted by the global financial crisis

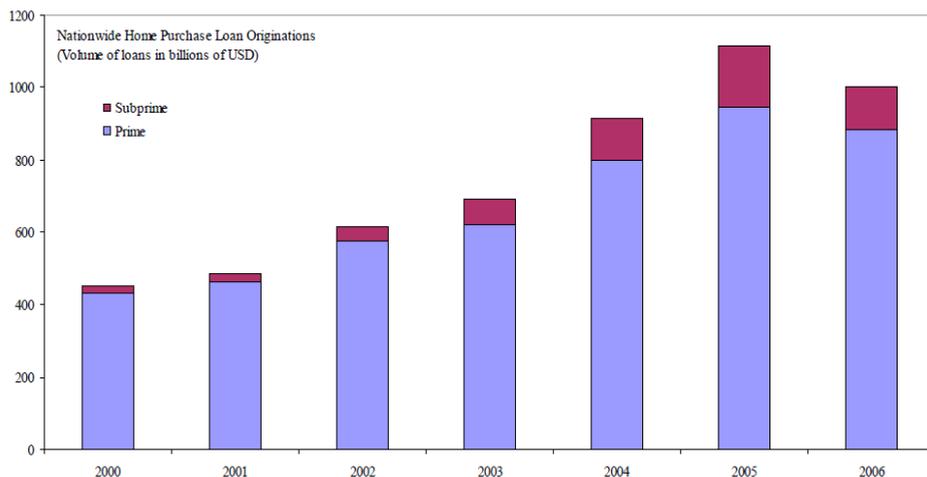

The recent financial crisis, that has stuck the world economy in 2007 and still persists to this day, is a remarkable mix of factors, that have been seen before in a serious of smaller scale financial crisis:

- a) asset prices that have increased to become unsustainable;
- b) credit booms that have increased the debt to new levels unseen before;
- c) the accumulation of systemic risk in the lending process;
- d) the inability of the supervision and regulation to contain the wide spread effects of the crisis.

However, the recent crisis had turned up with new factors that gave it the global magnitude that we are still seeing today:

- e) the widespread use of toxic assets;
  - f) the interconnectivity among the global financial markets;
  - g) the central role that the housing sector played in this crisis, with all its implications.
- Some authors, (Claessens et al 2010) consider that the catalyst of the crisis was the US overloaded housing and mortgage markets, with its increased securitization, and the increasing share of subprime loans within the lending activity between 2000 - 2006

(Figure 3)

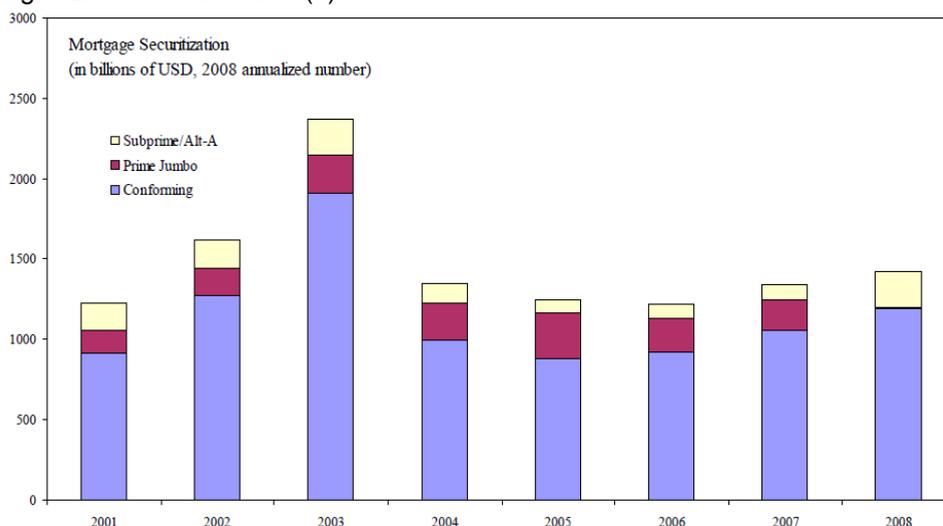

**Figure 3:** Prime and subprime loans

Sources: HMDA, IMF staff estimates.

The subprime loan crisis has affected the entire U.S. financial system and a good part of the international financial markets. The increase in mortgage arrears can be explained, to a large extent, by how smooth and even fraudulent the granting of loans on this market was, together with a key role in creating a framework for easy development and emergence of the crisis played by the process of financial innovation (Figure 4).

Today, the supervisory authorities reassess their financial system supervision framework. Although the wave of reforms in financial system supervision architecture began about 10-15 years ago, in the light of the current crisis, reform of financial system surveillance appears to be imminent. Thus it can be argued that the need for reform stems from the fact that the main objective of monitoring the financial system, found in limiting financial institutions' exposure to risk, is hampered by the esoteric nature of the instruments offered by financial institutions and, on the other hand, the probability of radical change in the degree of exposure. Due to the rapid changes in the risk exposure profile of institutions, the effectiveness of traditional methods of supervision and prudential regulation is significantly reduced. Therefore, the need to reform the process was one of the themes currently discussed by international organizations and forums (1) .

**Figure 4:** Mortgage securitization  
Source: IMF staff estimates

TUAC (2) argues that, in light of current events, there is a need for both increased regulation and supervision of financial markets in order to adapt to the needs of the real economy. Regulatory process should aim to promote responsibility among institutions and markets as well as social protection objectives.

The need for change is felt to provide better coverage through regulation and supervision of international financial markets and to ensure better cooperation between institutions, nationally and internationally, for the early detection of risky behaviors of participants in the national and international financial market. Furthermore, the new framework should address the global financial system's weaknesses that have led to, or have intensified the crisis:

- Unsustainable growth model;
- Accelerating the process of financial innovation that gave rise to an uncontrolled structured finance industry; the risks were not spread out, but concealed, the pace of innovation in this area went beyond the companies' ability to assess risks in derivatives, and the ability of supervisors and regulators to monitor;

- Institutional arbitrage between jurisdictions and financial institutions, which helped to blur the border between the regulated and shadow banking system, allowing financial groups to practice a double accounting, using off-balance sheet transactions, also encouraging irresponsible risk-taking, and investment strategies based on the leverage;
- Prevalence of shareholder value over market integrity and long term interests;
- Poor quality assessment of loans that were transferred to other entities through the process of securitization;
- Lack of supervision of systemic risk - although the increase in indebtedness and the underestimation of credit risk have been identified before the crisis, their magnitude and implications for systemic risk was underestimated. There has also been found a failure in determining the connections between regulated and unregulated market participants;
- Weaknesses in the rating agencies - has seen a very high trust in rating agencies, failure in the models and methodologies used by them, and conflicts of interest in the rating process;
- Procyclical tendencies, fed by the existing regulatory framework and accounting procedures;
- Weaknesses in risk management practices, techniques and models using historical data based on short periods, unsuitable for estimating the likelihood and size distribution of potential losses from credit risk through structured products. More high compensation encouraged excessive risk-taking, without prior analysis of long-term risks;
- Weaknesses in the framework of disseminating information about the risks involved, thus undermining public confidence;
- Inadequate procedures for solving the problems of ailing institutions;
- Lack of transparency in OTC markets.

It is considered essential that regulatory and standardization bodies put efforts to achieve a prudential regulatory framework designed to protect the stability of financial institutions. Feeble regulation and supervision, such as those relating to the underwriting standards in the U.S. mortgage market have aggravated the current crisis, making it essential to strengthen prudential regulation and provision by the individual national regulatory authorities of a first line of defense in preventing imbalances in the financial system. (G-20, 2009)

## **Conclusions**

In our opinion, the consequence of the shown disruptions was that hedge funds stopped their transactions, while the CDO market and the credit related derivatives have virtually ceased to exist. As a result, issuers of CDOs could not place their titles and ceased to issue new ones. Without partners on the secondary market, many initiators of mortgages with high risk have not been able to sell their claims, which put them in a critical situation, given that most of these initial creditors are weakly capitalized, unregulated financial corporations.

Regarding the banks financing the initial lenders, they have ceased their support, which made the latter unable to meet payment obligations related to the stock of mortgage loans granted. Their reaction was ceasing the granting new loans, regardless of their degree of risk, and some of the initiators of mortgages, threatened

by bankruptcy, made requests to postpone the triggering of this procedure - facility provided by U.S. law.

Finally, potential buyers and homeowners could not get mortgages any more, which has put them in the situation of not being able to pay for construction work performed. In turn, constructors, which previously have loans to build homes for sale, could not sell their homes and therefore could, not repay loans, etc.

We consider that all these phenomena have resulted in a strong contraction of demand in the construction of housing, with all the series of negative implications for the economic growth. The fact that those hedge funds and other investors did not buy high-risk mortgage debt any more, has shown that not all these claims were longer considered secure forms of investment, and therefore, buyers of cash receipts (debt securities issued by companies with high solvency) have ceased to buy those titles. Accordingly, securities prices have dropped and their issuers have not been able to procure the necessary funds for the repayment of mortgages and other types of loans they have contracted from big banks and financial corporations. In this way, when the credit resources were exhausted, in the financial system appeared a new request for additional loans.

Hedge funds and other risk seeking investors have also played an important role in the spreading of the crisis' consequences worldwide. Indeed, when the CDO prices fell and investors could not exit the losing positions any more, they began to sell other assets, in particular high yield securities such as shares of companies from countries with emerging market economy, in order to get high enough profits to enable them to cover losses. As a result, the prices of shares have fallen at all stock exchanges in the world and, emerging countries currencies' have depreciated more than was the case in the light of the fundamental economic variables (Cerna, 2008). Taking into account the consequences of these developments, beyond the losses of the U.S. economy, spectacular bankruptcies, causing millions of unemployed and affecting all sectors, another more serious problem appears, namely the repercussions of the U.S. crisis on international financial markets and world economies. The propagation of the crisis effects appears as an unquestioned reality, through a simple fact that, currently, we can no longer speak of an isolated financial crisis in the U.S., but rather of a global financial crisis, which through the implications on the real economy, has become a generalized economic crisis.

## THE FRAMEWORK RESULTING FROM THE BASEL III REGULATIONS

**Motocu M. Marius**

*The Department of Finance and Accounting Computer Science, Faculty of Economic Sciences, "Bogdan-Voda" University, Cluj-Napoca, Romania  
mmotocu@gmail.com*

**Abstract:** *The banking sector is under prudential regulations set internationally by the Basel Committee, in order to ensure its strength, stability and mitigate competitive inequities. Its founding principle is based on a minimum solvency ratio introduced in 1988 in the form of the Cooke ratio, resulting in a harmonization of the rules of banking supervision governing the level of own funds.*

*Basel II was introduced after the various financial crises of the 1990s (the Mexican crisis of 1994, the Asian crisis, and the Brazilian and Argentinean crisis). Despite a series of reforms, Basel II has quickly shown its limitations with the 2007 crisis that has strongly impacted the financial markets and the world economy generally. In this context, the Basel Committee has developed within Basel III a number of requirements which aim at strengthening the resilience of the banking institutions and financial system. These adjustments will be applied to the three pillars already in place and relate to capital, liquidity and systemic risks.*

*The new Basel provisions relating to the calculation of the numerator of the solvency ratio are declined according to the triptych: strengthening the quality of prudential eligible own funds instruments, increase of the statutory deductions provided by Basel II, and higher minimum thresholds of solvency ratios. Furthermore, a limitation of the lever, calculated from the balance sheet and elements of off-balance sheet based on non-weighted by the risks, will be introduced.*

*The Basel III criteria entering into force between 2013 and 2018 constitute one of the major challenges to which the banking sector will face. The real impact of the Basel III reform will depend on the attitude of the banks that will have to change in their strategy, their cost structure and policy of remuneration of the shareholders. A reform which will have therefore an impact on the world economy ensuring as estimated by Governors and supervisors, stability and long term economic performance. This paper will present the main adjustments proposed by the Basel Committee.*

**Keywords:** *capital requirements; liquidity coverage ratio; leverage ratio.*

**JEL classification:** *G21; G32.*

### Introduction

The new architecture of European financial regulation confirms the need to stem the systemic spread of financial risks by increasing the prudential ratios. The immediate cost of these requirements is offset by the lower occurrence of major crises. The additional costs induced by a strengthening of the liabilities of the banks' capital requirements is not necessarily a strong negative impact on the cost of intermediation.

The recommendations of the Basel Committee, echoed by the G20 countries, modify capital requirements from the Basel II regulations in a logical macro-prudential. The new standards aim on the one hand, to mitigate the procyclicality of previous framework by introducing more flexibility in prudential targets. This is to avoid the liquidation of assets and the sudden restriction credit crisis. They fold, on the other hand, on a narrower equity, less open to hybrid products.

## **1. Equity Capital Strengthening**

There are two ways to avoid a liquidation precipitated asset: either raise own funds in the event of blow, or allow a temporary decline in the prudential ratio. As appropriate to maintain a certain level of own funds at any time, they must be more abundant outside periods of crisis. However the regulatory prudential ratios of own funds were not a real constraint when the crisis because many banks had much higher ratios. The Basel Committee has decided to raise the level of capital called hard (common equity Tier One) strengthening the same time, the quality of capital that constitute and adding a cushion (conservation buffer) additional 2.5% in which banks can draw in case of difficulties. In other words, the target capital is set at 7%, but banks may deviate temporarily in a margin of 2.5%. However some voices, especially in financial circles to consider that these new restrictions will affect the cost of credit and ultimately dampen growth. Others, in contrast, emphasize the incomplete nature of the reforms.

### **1.1. Pillar 1 and Capital Requirements**

The crisis has shown that the risk-weighted capital ratios sometimes give a false idea of the General solidity of banks and it happens the rules of weighting to underestimate the actual risks. Finally, in order to remedy to this problem and to support the requirement of own funds against the risk, Basel III has developed a leverage ratio which should help contain the build-up of systemic risk in the event of rapid development of leverage.

#### **1.1.1. Improvement of Equity Capital Quality and Level**

- *Improvement of equity quality and coherence*

Basel III is intended to improve the quality of equity capital of banking institutions to strengthen their ability to absorb losses (BCBS, 2011). Equity capital is divided into next 3 categories as shows Figure 1. *Tier 1* is decomposed itself into two categories, the Core Tier One (solid core) and Tier One. Core Tier 1 (commonly referred to as Common equity or solid equity) corresponds to the narrower base of equity capital (including capital and reserves). Tier 1 (or basic equity capital) includes capital, reserves and certain hybrid securities (subordinated debts). The new regulation is more restrictive and many hybrid securities should be removed (and integrated in Tier 2) from Tier 1. *Tier 2* (which includes the entire complementary equity capital) was harmonized and incorporates hybrid titles which are not included in Tier 1. *Tier 3*, according equity capital belonging to Tier 3 will be removed from regulatory capital. It is currently used to cover market risks (BCBS, 2011).

- *Equity capital amount increase*

The financial crisis has underlined the need for the banking sector to have a larger volume of equity capital, mainly with reference to Level 1. Basel regulations currently require a minimum Core Tier 1 of 2%, which will be increased to 4.5% by Basel III. Minimum Tier 1 equity ratio has increased from 4% to 6% by Basel III.

Equity capital – Basel III	
Tier 1	<b>Core Tier 1 (Common Equity)</b>
	Capital, retained earnings Gains and losses directly recognized in equity Minority interests when the branch is a bank and according to a cap Treasury shares, intangible assets, goodwill Shareholdings in financial and insurance companies Insufficient provisions in relation to the expected loss Gains or losses from cash flow Miscellaneous
	<b>Lower Tier 1</b>
	Equity instruments able to absorb losses, satisfying certain conditions Instruments of the same nature held in other financial institutions (banks, insurance)
Tier 2	Subordinated loans which have a period of at least five years and which meet certain conditions Instruments of the same nature held in other financial institutions (banks, insurance)

**Figure 1:** Composition of regulatory capital under Basel III

Source: Author based on Moss Adams LLP (2012)

Two additional buffers were introduced to absorb losses during periods of crisis. *Capital conservation buffer:* 2.5%, consisting of Core Tier 1 items. This buffer is designed to ensure that banks can maintain a minimum capital level during an economic recession. *Countercyclical buffer:* 0 – 2.5%. This buffer is introduced at the request of the national regulatory authority to deal with sectorial risks during a period of strong growth of credit. This variable ratio is a function of macroeconomic variables and must consist of Tier 1 capital.

Application of the additional buffer will be communicated to banks with 12 months before entering in force, and its reduction will be applied immediately in order not to penalize credit granting.

A buffer for systemic risk is considered for banks identified as systemic. The level remains to be defined.

**Table 1:** Changes in capital ratios under Basel III

Capital requirement in 2019			
	Core Tier 1 after deduction	Total Tier 1	Total equity capital
Minimum	4.50%	6.00%	8.00%
Conservation buffer (Cb)	2.50%		
Minimum (incl. Cb)	7.00%		
Countercyclical buffer	0 – 2.50%	8.50%	10,50%
Systemic risk buffer	To be defined		

Source: Author based on Moss Adams LLP (2012)

The minimum 8% solvency ratio has increased to 10.5%, including the protection buffer. It corresponds to the sum of Tier 1 and Tier 2 that can be concluded from Table 1 as above.

The Basel Committee has adopted a series of reforms that will strengthen the equity requirements for *counterparty risk*, *market risk*, *systemic risk* and *securitization operations*.

### 1.1.2. Review and strengthening of securitization measures

Securitizations and re-securitizations are also affected by the Basel III reform. In fact, capital requirements will be higher for re-securitization positions with a weight multiplied by 3-4 and a stronger requirement for liquidity positions. On the other hand, it will implement the alignment of capital requirements for securitization positions with a flat-rate charge to reduce regulatory arbitrage between banking and trading portfolios (Lessambo, 2012). Finally, the Committee strengthens the requirements in relation to the information disclosed.

### 1.1.3. A better management of counterparty risk

A review of counterparty risk measurement is initiated with a default exposure calculated by the model of *Effective Expected Positive Exposure* (EEPE). To determine the capital requirement for counterparty risk, the banks must use the highest value of the two models:

- The model of the portfolio level based on the EEPE calculated from current market data.
- The model of the portfolio level based on the EEPE calculated from a stress scenario.

In addition, the Basel Committee has shown the rules of counterparty risk management taking into account the *Wrong Way Risk*, that is, the risk that the exposure to a counterparty to be adversely correlated with its credit quality or, in other words, that the exposure to grow while counterparty credit quality deteriorates. The consideration of the wrong way risk adverse will be translated in an additional capital requirement.

In addition, the market value of the counterparty risk will now be taken into account by *Credit Value Adjustment* (CVA). More specifically, CVA measures the difference between the risk free value of a credit portfolio and the *value at risk* of the same portfolio, i.e. integrating default counterparty risk (AFME, 2012). Capital requirements in relation to CVA will be used to offset potential losses from *marking to market* (MtM) related to the counterparty's default or its credit quality deterioration. CVA takes into account the variability of credit and market spreads (CF, 2010).

$$CVA = \sum_t^T NPV_t Pft - \sum_{t=1}^T \frac{Flows_t Pft}{(1+r+\beta)^t}$$

Where we denote: T = *Maturity*; NPV<sub>t</sub> Pft = *Net Present Value of the portfolio*; Flows = *Flows at date t of the portfolio*; β = *Risk premium*.

Finally, the Committee recommends the use of clearing houses for derivatives to reduce counterparty risk.

#### **1.1.4. Strengthening the measurement of market risk**

The Basel Committee has also introduced a series of reforms for the measurement of market risk in response to the financial crisis of 2007. The 2007 crisis has shown an underestimation of the risk measured by VaR models in times of high volatility. An additional capital requirement associated with a measure of VaR in *crisis conditions* (*Stressed VaR* - sVaR) is necessary to correct VaR pro-cyclicality (BCBS, 2011). Criteria laid down by the Basel Committee for the calculation of Stressed VaR, sVaR, are the following:

- Stressed VaR must be calculated on a weekly basis;
- The confidence level is 99%;
- Minimum detention horizon is 10 working days;
- The observation period shall correspond to a period of significant financial stress in the bank's portfolio.

Basel Committee recommends a VaR calibrated according to shock history for a period of one year in relation to the important losses of 2007/2008.

In terms of impact, Stressed VaR is about 3 times the current VaR. Moreover, an additional „incremental” requirement for specific rate risk for vanilla credit derivatives in the trading portfolio is introduced under the name of Incremental Risk Charge (IRC). This corresponds to an additional risk of default and ratings' migration. IRC is calculated by default scenarios for the bank's trading portfolio, taking into account the historical default probabilities.

Similarly, an additional ”incremental” requirement for specific rate risk of exotic credit derivatives in the correlation based trading portfolio (synthetic CDO and hedging CDS) is introduced essentially under the term of CRM (Comprehensive Risk Measure). CRM aims at measuring default and migration risk (the same methodology as for the calculation of IRC), and the diffusion of CDS spreads and correlation basis, with the possibility of a lower limit ensuring a minimum capital requirement.

#### **1.1.5. Systemic risk consideration**

The Basel Committee includes systemic risk in the center of Basel III project to draw conclusions from the consequences of the bankruptcy of Lehmann Brother on the financial system. In fact, excessive interdependence of systemic banking institutions has equally passed shocks in the financial system and the economy. The Financial Stability Board has published a list of 29 credit institutions deemed “too big to fail”, i.e. too big so that their collapse not to lead automatically to the collapse of the financial system.

European institutions that are part of the list, will need to reinforce their equity capital by 2019 in terms of systemic risk due to the risks that their size or complexity not to press on the international financial system if they would get into difficulties. They will have to allocate a Tier 1 capital ranging from 1% to 2.5% of their assets weighted to the risk they pose to the entire system according to:

- Their size,
- Their interdependence with other institutions,
- The international nature of the institution,

- Their complexity and difficulty of the other institutions to be their substitute in the event of a collapse.

The exact level of this excess requirement will be set in 2014. It will be implemented gradually, starting in 2016, and will be completed in 2019. Among the capital requirements for these 29 financial institutions, the Committee introduces more equity capital requirements to mitigate risks arising from the exposures of major international financial institutions:

- Increased capital requirements for exposures to other players in the financial sector.
- Application of liquidity requirements that penalize excessive recourse to short-term interbank financing to cover assets with long-term maturity. (See the section on the liquidity requirement).
- Increased capital requirements for exposures related to the trading portfolio, derivatives and securitizations, and off-balance sheet exposures.

Finally, the Committee encourages the use of central counterparties for OTC derivative transactions.

### 1.1.6. Leverage ratio

The Basel Committee has introduced a new indicator to reduce the leverage in the banking sector and to cover the modeling risk. Indeed, the crisis has highlighted that many banks have accumulated excessive leverage, while showing solid capital ratios. In times of crisis, these leverage effects have increased the pressures of asset price decrease and have destabilized the financial system. The value of the ratio corresponds to the average monthly leverage ratio per quarter. The minimum requirement of the ratio is 3% of core equity capital (T1). BCBS (2011) will test this minimum Tier 1 leverage ratio of 3% during the parallel run period from 1 January 2013 to 1 January 2017.

$$I_{EL} = \frac{C}{V_{Bt} + Sd_{CDS} + E_B}$$

Where the inputs of this ratio are:  $I_{EL}$  = Leverage ratio;  $C$  = Capital;  $V_{Bt}$  = Total balance sheet before tax;  $Sd_{CDS}$  = CDS balance;  $E_B$  = other off-balance components (To be defined).

## 1.2. Pillar 2 about Risk management and monitoring

The new requirements are structured around the following points: addressing governance and risk management at the level of the institution; taking into account the risk related to off-balance sheet exposures and securitizations; risk concentration management; incentives for better risk management and long-term yields; robust compensation practices; valorization practices; resilience tests; accounting standards applicable to financial instruments; corporate governance; prudential boards and the use of monitoring tools for liquidity control (see below).

## 1.3. Pillar 3 and Market discipline

To enhance market discipline, the Basel Committee also requires improved communication in relation to the trading portfolio and, in particular, in relation to the

perimeter of the complex products, securitization products and the direct responsibility of the off-balance sheet vehicles. The information provided on equity capital will be strengthened. Thus, the Committee introduces a breakdown of assets by economic and geographic sector, as well as an internal rating and allocation system for equity capital impacted by various risks. All equity capital items should be the subject of a statement accompanied by a detailed approach of the accounts published. Eventually the banks will be required to disclose certain remuneration elements and in particular the link between performance and risk-taking by financial institutions.

## **2. Introduction of liquidity management supervisory standards and measures**

The financial crisis has demonstrated the critical role of liquidity in the financial system and the difficulties faced by banks in maintaining their liquidity despite an adequate level of equity capital.

The objective of the Basel Committee is *to introduce harmonized global standards for liquidity* and to ensure that banks have sufficient liquidity to deal with a sudden hypothetical liquidity shock. To this end, the Basel Committee has introduced *two ratios*, the first related to liquidity in the short run, the *Liquidity Coverage Ratio (LCR)*, and the second related to liquidity in the long run, the *Net Stable Funding Ratio (NSFR)*. These two ratios are accompanied by the implementation of monitoring tools which will help supervisors in controlling and maintaining liquidity.

### **2.1. The short term ratio Liquidity Coverage Ratio (up to a month)**

“The Committee has developed the LCR to promote the short-term resilience of the liquidity risk profile of banks by ensuring that they have sufficient HQLA (high-quality liquid assets) to survive a significant stress scenario lasting 30 calendar days” (BCBS, 2013).

$$\frac{\text{High – quality liquid assets}}{\text{Total net cash outflows over the next 30 calendar days}} \geq 100\%$$

The LCR, as above (BCBS, 2010), builds on traditional liquidity “coverage ratio” methodologies used internally by banks to assess exposure to contingent liquidity events. The total net cash outflows for the scenario are to be calculated for 30 calendar days into the future (BCBS, 2010). The standard requires that the value of the ratio be no lower than 100% (i.e. the stock of high-quality liquid assets should at least equal total net cash outflows). This ratio will come into force on January 1, 2015. It is based on the 2007 global financial crisis scenario, including the assumptions of institution’s credit rating downgrading, the partial withdrawal of deposits, the loss of blank interbank funding, significant increase in reductions for financing based on securities.

## 2.2. The long term ratio Net Stable Funding Ratio (up to a year)

$$\frac{\text{Resources for a period greater than one year}}{\text{Required stable funding for a period greater than one year}} \geq 100\%$$

The NSFR is defined as the amount of available amount of stable funding to the amount of required stable funding (BCBS, 2010). Net Stable Funding Ratio (NSFR) is designed, as above ratio (BCBS, 2010), to rectify funding asymmetries and to provide the long-term resources necessary to deal with a liquidity crisis for a one-year period. This ratio will be introduced on January 1, 2018.

### 2.3. Introduction of monitoring tools

The implementation of this ratio is accompanied by the monitoring tools designed to provide a global view on liquidity risk. Thus, a series of five ratios will help create a larger homogeneity of prudential supervision within the liquidity scheme. These metrics capture specific information related to a bank's cash flows, balance sheet structure, available unencumbered collateral and certain market indicators (BCBS, 2010). The lack of liquidity of a bank proves that many long-term assets were funded by borrowing in the short term. More this asymmetry of deadlines is important, most profits are high, and more exposure and refinancing challenges are felt. Also, this phenomenon has failed to lead some actors into a sort of chasm of "illiquidity", potentially leading to insolvency and thus to the bankruptcy. Finally, this flag is designed to communicate the differences between the inputs and outputs contract of liquidity of the balance sheet and off-balance sheet per deadlines.

#### 2.3.1. Contractual maturity mismatch

According to the Basel III framework "the contractual maturity mismatch profile identifies the gaps between the contractual inflows and outflows of liquidity for defined time bands. These maturity gaps indicate how much liquidity a bank would potentially need to raise in each of these time bands if all outflows occurred at the earliest possible date. This metric provides insight into the extent to which the bank relies on maturity transformation under its current contracts" (BCBS, 2010).

#### 2.3.2. Concentration of funding

This ratio is designed to identify interbank funding sources of such importance that the withdrawals could cause liquidity problems. It goes, therefore, in the direction of funding resources' diversification recommended in the Committee's *Sound Principles* (BCBS, 2010).

$$\frac{\text{Funding liabilities sourced from each significant counterparty}}{\text{The bank's balance sheet total}}$$

Significant counterparty means a single counterparty or a group of related counterparties, representing more than 1% of the total balance sheet of the bank (BCBS, 2010).

*Funding liabilities sourced from each significant product/instrument*  
*The bank's balance sheet total*

A “significant product/instrument” means an instrument/product or a group of instruments/products whose total amount is more than 1% of the total balance sheet of the bank. A currency is regarded as “significant” if the total amount of liabilities in that currency is at least 5% of the total liabilities of the bank. The two ratios mentioned above must be reported separately for the following timeframes: less than 1 month; 1-3 months; 3-6 months; 6-12 months; more than 12 months. Finally, banks must make available the list of assets and liabilities stock by significant currency.

### **2.3.3. Available unencumbered assets**

Banks are required to report the amount, type and location of available unencumbered assets that can be mobilized as titles on secondary markets and/or eligible as collateral within the central bank’s permanent facilities. In addition to providing the total amounts available, a bank should report these items (that could serve as collateral for secured borrowing in secondary markets at prearranged or current haircuts at reasonable costs) categorized by significant currency. “A currency is considered “significant” if the aggregate stock of available unencumbered collateral denominated in that currency amounts 5% or more of the associated total amount of available unencumbered collateral (for secondary markets and/or central banks)” (BCBS, 2010).

### **2.3.4. LCR by significant currency**

Regulatory requirements for the short-term liquidity ratio (LCR) are in a single currency, but for liquidity monitoring this ratio must be monitored in each of the major currencies, to better monitor the possible asymmetries of currencies. LCR in currency means (=) reserves of high quality liquid assets in every significant currency / Total net cash outflows\* in each significant currency over a 30-day period (where\*: *after deducting the cost of foreign exchange risk hedging*). A currency is “significant” if total liabilities denominated in the currency in question represent at least 5% of the total liabilities of the bank.

### **2.3.5. Market-related monitoring tools**

The last item in the category of monitoring tools is *market data*. “High frequency market data with little or no time lag can be used as early warning indicators in monitoring potential liquidity difficulties at banks” (BCBS, 2010). The supervisory authority has proposed three levels of information for monitoring and detecting any liquidity problems:

- Market related information (share price, debt markets, currency markets, commodities markets, ratios related to specific tools)
- Financial sector related information (coefficient, stock and bond markets for the financial sector in general and for some of its segments)

- Bank-specific information (the price of its shares, CDSs, the prices negotiated in the money market, the situation of renewals and pricing of its financing with various maturities, price/performance ratio of its obligations and/or subordinated debt on the secondary market).

### 3. In conclusion

Basel III reform is structured around a series of regulatory adjustments and increased capital requirements that we have quickly reviewed in this paper. We can already see that these adjustments will be costly for banks' equity capital and will certainly alter the structure of banks and business lines. These adjustments will be accompanied also by the development of information systems designed to meet regulatory requirements. Finally, the deadline for implementation of Basel III in 2019, the increased capital requirements to channel risk, the uncertainty related to reform implementation in most financial institutions are all elements that we could question and whose effectiveness we are already challenging.

**Abstract:** *In this study we tested the existence of long memory in the return series for major Central Eastern European and Balkans stock markets, using the following statistical methods: Hurst Exponent, GPH method, Andrews and Guggenberger method, Reisen method, Willinger, Taqqu and Teverovsky method and ARFIMA model. The results obtained are mixed. The Hurst Exponent showed the existence of long memory in all indices, except PX. After applying the GPH method, the results showed that BET, ATHEX, SOFIX and CROBEX have a predictable behavior. The ARFIMA model results support the existence of long memory for BUX, SAX and BELEX. The predictable behavior of index returns may suggest that the CEE and Balkans stock markets are not weak form efficient.*

**Keywords:** *emerging markets, long memory, market efficiency, ARFIMA model*

**JEL Classification:** *C14, C58, G14*

## 1. Introduction

The efficient market hypothesis has major implications for the capital markets, investors behavior and trading strategies. According to Fama (1965) the random walk hypothesis implies that price changes do not have memory, which means that the past cannot be used to predict the future. For this reason, is essential to identify the presence of long memory in index returns, which is manifested through the existence of correlations for high lags. In a case of a shock on the capital market, it will not be assimilated quickly in the course and will pass a longer period of time to reach the equilibrium, which will lead to a higher risk on the market.

In the case that the return series have a long memory, it means that the returns are not independent. In this conditions, the efficient market hypothesis in weak-form is not valid, the return series do not follow a random walk process. The indices have a predictable behavior, which can offer the investors the opportunity to predict the future evolution of index courses using past information for the market and to obtain abnormal profits.

There is a large literature regarding the existence of long memory on the capital markets. A number of studies are carried out for the emerging markets of Central and Eastern Europe. Necula C. and Radu A. (2012) conducted a survey in which

they took into consideration the capital markets from Romania, Hungary, the Czech Republic, Poland, Bulgaria, Slovenia, Slovakia and Croatia. Using non-parametric methods (R/S statistic and GPH method) and ARFIMA-FIGARCH models, the authors concluded that all markets surveyed present long memory in returns, except Slovakia. In another study made by Festic M. et al. (2012) for the Hungarian and Croatian capital markets are used Lo's (1991) modified rescaled range (R/S) test and the wavelet ordinary least squares (WOLS) estimator of Jensen (1999). The R/S test results indicated the possible presence of long memory in Croatia, while there is no evidence against the null hypothesis of long memory in Hungary. The WOLS estimator showed the existence of long memory for CROBEX, while on the other hand, there is no long memory for BUX. However, it is found that there is long memory for some stocks in its composition. Moreover, Kasman S. et al (2009) has tested the existence of long memory for Czech Republic, Hungary, Poland and Slovakia using a semi-parametric method of Geweke Porter Hudak and the parametric method of Sowell. They concluded that all the capital markets analyzed present long memory, except Poland. There are also studies for both long memory in returns and volatility. Kasman A. and Torun E. (2007) examined the existence of long memory for the Turkish capital market during 1988-2007. They used ARFIMA, GARCH, IGARCH, FIGARCH and ARFIMA-FIGARCH models. In order to test the existence of dual long memory, the authors estimated ARFIMA-FIGARCH models, both for normal distributions, and for Student distributions. Long memory coefficients are significant, both for mean and variance, thus showing the presence of dual long memory for Turkish capital market. They found that the models performance that used Student distribution is superior to those models that used normal distribution. Another research for Turkey was conducted by Korkmaz T. et al (2009), taking into account the period 1988-2008. Using the ICSS method proposed by Inclan and Tiao (1994), they identified four structural breaks. The ARFIMA-FIGARCH models signaled the existence of long memory in volatility. Dajcman S. (2012) investigates the long range dependence for eight capital markets in Europe. Unlike other studies, in order to detect the long memory, the author use a dynamic approach. In this sense, the author uses a rolling window method to show that the long memory parameter is variable in time. The results have pointed out that the increase of the long memory parameter coincided with the major financial market disruptions which characterized the capital markets during the period October 1999 – April 2011.

Other studies were developed for Asian capital markets. Maheshchandra J.P. (2012) has analyzed the Indian capital market using daily returns of BSE and NSE during 2008-2011. In order to detect the existence of long memory in volatility are estimated several models: ARMA-GARCH, ARMA-IGARCH, ARMA-FIGARCH. The results highlighted the presence of long memory in the conditional variance. Tan S.H. et al (2009) has analyzed the Malaysian capital market during 1985-2009, taking into account both growth and recession periods, finding the existence of long memory and the possibility of forecasts the courses, especially before the crisis of 1997. Gabjinova et al. (2008) has analyzed two indices: KOSPI1 (Korea 1995-2002) and KOSDAQ1 (Korea, 1997-2004) and six exchange rates EURO, GBP(UK), JPY (Japonia), SGD (Singapore), CHF (Suedia) and AUD (Australia). The possible existence of long memory has been investigated using DTA method (Detrended Fluctuation Analysis) and some models: AR(1), GARCH(1,1) and FIGARCH. As a result, it is concluded that there is insignificant long memory in returns and only the volatility is characterized by long memory.

Further, there are studies for stock markets in Africa. Onour I. (2010) has realized a study for Tunisia, Egypt and Morocco during the period 2002-2006. Using the GPH method and ARFIMA model, it was concluded that this capital markets have short memory. Following the results of FIGARCH model, it was found that the shocks are not likely to persist for long periods on the markets. Boubaker A. and Makram B. (2012) explore the presence of long memory for capital markets in North Africa (Morocco, Egypt and Tunisia), finding that the return distributions can be modeled more adequate through the alpha distribution than by normal distribution. As a result of ARFIMA and FIGARCH models estimations, it was concluded that there is long memory both in returns and volatility.

The South American capital markets have been studied by Assaf A. and Cavalcante J. (2005) which used Lo's (1991) modified rescaled range (R/S) test, V/S statistic proposed by Giraitis et al. (2003), Robinson method and FIGARCH model and signaled the presence of long memory in volatility and a low evidence in returns.

Also, there are studies for groups of emerging and developed countries. Bhattacharya S. N. and Bhattacharya M. (2012) have studied the long memory for ten emerging markets (Hungary, China, Brazil, Chile, Malaysia, Korea, Russia, Mexico, India and Taiwan) during 2005-2011, using the following methods: Hurst-Mandelbrot's Classical R/S statistic, Lo's statistic, GPH method and GPH method modified by Robinson (1995) applied both for absolute and squared returns. The conclusions were that there is a long memory for all countries surveyed, with the exception of Malaysia (the existence of long memory was rejected by Lo's statistical method and by the Robinson method for  $T^{0.65}$ ). Bentes S. and Mendes da Cruz (2009) have analyzed the G7 capital markets from 1999 to 2009. The results have shown the existence of long memory in volatility in Germany, Italy and France, while in Japan it appears to be the least visible and most low intensity. Consider thin trading that characterizes the emerging capital markets, Limam I. (2003) examine the presence of long memory for fourteen capital markets (United Kingdom, Japan, USA, Brazil, India, Mexico and the eight Arab countries) with different degrees of development. By using the GPH and MLE methods and ARFIMA model, the author has detected the existence of short memory for developed capital markets, while the long memory is associated with emerging markets.

The objective of this study is to examine the existence of long memory in returns for nine indices in CEE and the Balkans emerging stock markets: BET (Romania), BUX (Hungary), SAX (Slovakia), PX (Czech Republic), PFTS (Ukraine), BELEX (Serbia), SOFIX (Bulgaria), ATHEX (Greece) and CROBEX (Croatia). The existence of long memory for emerging markets implies that the future evolution of indices is predictable and will influence the investors behavior on these markets. This study comes to rich the financial literature in the field of long memory. Previous studies have focused on the EU emerging markets, but there are quite a few studies that include the Balkans capital markets. Also, in order to check the existence of long memory in return series, this study uses the method proposed by Willinger, Taqu and Teverovski (1999), that has not been used previously in other research carried out for Balkan markets. The paper is organized as follows. Section 2 presents the empirical methods and models used to identify long memory in return series. Section 3 outlines the characteristics of the sample analyzed. Section 4 provides a synthesis of the results obtained. Section 5 concludes.

## 2. Methodology

The statistical methods used in this study for the detection of long memory are: Hurst Exponent estimated by R/S statistics, Hurst Exponent determined by the method proposed by Willinger, Taqqu and Teverovski (1999), Geweke Porter Hudak (1983) method, Andrews and Guggenberger (2003) method, Reisen method (1994) and ARFIMA (1980, 1981) models. Furthermore, will be presented briefly these methods. The Hurst Exponent is determined through the classical R/S analysis, which because of its simplicity is the most popular method used to detect long memory. Let  $X(t)$  be the course of a stock market index at time  $t$  and  $R_t$  the logarithmic return, determined by the equation:

$$R_t = \ln\left(\frac{X_{t+1}}{X_t}\right) \quad (1)$$

The R/S statistic is the range of partial sums of deviations of time series of its mean, rescaled by its standard deviation. It is take into consideration a sample of continuously compounded returns  $\{R_1, R_2, \dots, R_\tau\}$  and let  $\bar{R}_\tau$  denote the sample mean  $\frac{1}{\tau} \sum_{t=1}^{\tau} R_t$ , where  $\tau$  is the period of time considered. The R/S statistic is given by:

$$(R/S)_\tau = \frac{1}{s_\tau} \left[ \max_{t=1}^{\tau} \sum (R_t - \bar{R}_\tau) - \min_{t=1}^{\tau} \sum (R_t - \bar{R}_\tau) \right] \quad (2)$$

where  $s_\tau$  represents the usual standard deviation estimator. Hurst (1951) has shown that the rescaled range, R/S, for many records in time is described by the following equation  $(R/S)_\tau = (\tau/2)^H$  (Cajueiro, D.; Tabak, B., 2004).

Willinger, Taqqu and Teverovsky (1999) proposed a new R/S analysis in determining the long memory, which involves the use of equally weighted returns. It is recommended to use EW series over blocks of size 10 and 20. The authors consider the analysis proposed by Lo accept too easily the null hypothesis of no long-range dependence in the time series. In order to remove the "extra" short-range dependence and isolating hibriden „pure" long-range dependence effects, the authors proposed partitioning of time series into non-overlapping blocks of size  $m$ , e.g.  $m = 10, 20, 50$ , and „shuffle" the observations within each block, so that is a random permutation of the time indices. The effect of such a shuffling experiment is to destroy any particular structure of the autocorrelation function below lag  $m$ , but to leave the high lags essentially unchanged (Willinger, Taqqu, Teverovsky, 1999). In order to estimate the parameter of fractional integration  $d$ , can be used both parametric and semi-parametric methods. In this study the parameter  $d$  is estimated by the Geweke and Porter Hudak (GPH 1983), which is a semi-parametric method. The GPH method is based upon the estimation of the spectral density function, as follows:

$$\ln[I(\lambda_j)] = c - d \ln[4 \sin^2(\lambda_j/2)] + \eta_j, \quad \forall j = 1, \dots, n \quad (3)$$

where:  $\lambda_j = 2\pi j/T$  ( $j = 1, \dots, T-1$ ) represents the harmonic frequencies and

$$I(\lambda_j) = (1/2\pi T) \left| \sum_{t=1}^T e^{i\lambda_j t} (x_t - \bar{x}) \right|^2 \quad (4)$$

is the periodogram  $x_t$  at these frequencies. Considering the number of observations used in the estimation of the regression is:  $n = g(T) = T^\lambda$ , where  $0 < \lambda < 1$  (Kasman, S. et al., 2009). In order to improve the method proposed by Geweke Porter and Hudak (1983), Andrews and Guggenberger (2003) proposed a simple biased-reduced log-periodogram regression estimator,  $\hat{d}_r$ , of a long parameter,  $d$ , that eliminates the first and higher order biases of the GPH (1983) estimator. The bias reduced estimator is the same as the GPH estimator, except that uses additional regressors in the pseudo-regression model that yields the GPH estimator. The reduction in bias is obtained using assumptions on the spectrum only in the neighborhood of the zero frequency. In order to define the biased reduced estimator  $\hat{d}_r$ , it is consider a semiparametric model for a stationary Gaussian long-memory time series  $Y_t; t = 1, \dots, n$  and the spectral density of the time series is given by  $f(\lambda) = |\lambda|^{-2d} g(\lambda)$  (5), where  $d$  is a long-memory parameter,  $g(\cdot)$  is an even function on  $[-\pi, \pi]$  that is continuous at zero with  $0 < g(0) < \infty$  and  $f(\lambda)$  is an integrable over  $(-\pi, \pi)$ . The authors use the regressor  $X_j$ , as in Robinson (1995a). Because the parameter  $d$ , proposed by Geweke and Porter-Hudak (1983) was criticized due to its finite-sample bias, Andrews and Guggenberger (2003) proposed a new bias-reduced log-periodogram estimator  $\hat{d}_r$  of the long-memory parameter  $d$ . The estimator  $\hat{d}_r$  is defined to be the least squares (LS) estimator of the coefficient on  $-2 \log \lambda_j$ , and  $\lambda_j^2, \lambda_j^4, \dots, \lambda_j^{2r}$ , for  $j = 1, \dots, m$ , where  $r$  is a (fixed) nonnegative integer. The authors take  $m$ , such that  $m \rightarrow \infty$  and  $m/n \rightarrow 0$  as  $n \rightarrow \infty$ . When  $r$  is 0, corresponds to the GPH estimator,  $\hat{d}_{GPH}$ . The bias-reduced log-periodogram estimator  $\hat{d}_r$  is defined by:

$$\hat{d}_r = (X^{*'} M_Q X^*)^{-1} X^{*'} M_Q \log I \quad (6),$$

$$\text{where } M_Q = I_m - Q^* (Q^{*'} Q^*)^{-1} Q^{*'}, \quad X^* = X - 1_m \bar{X}, \quad Q^* = Q - 1_m \bar{Q}' \quad (7)$$

represents the deviation from column mean regressor vector  $X^*$ , and matrix  $Q^*$ ,  $\log I, X, Q_k$  denote column  $m$ -vectors whose  $j$ th elements are  $\log I_j, X_j, Q_{k,j}$  and  $Q_{k,j} = \lambda_j^k$ , for  $j = 1, \dots, m$  and  $k = 1, 2, \dots$ ,  $Q$  denote the  $m \times r$  matrix whose  $k$ th column is  $Q_{2k}$  for  $k = 1, \dots, r$  and  $1_m$  denote a column  $m$  vector of ones and  $\bar{X} = \frac{1}{m} X' 1_m, \bar{Q} = \frac{1}{m} Q' 1_m$ . Andrews and Guggenberger recommend the use of

$r = 1, r = 2$  in order to get better results for the biased-reduced log-periodogram estimator,  $\hat{d}_r$ , of a long-memory parameter  $d$  (Andrews and Guggenberger, 2003).

Another method used in this study is that proposed by Reisen (1994). Compared to the method proposed by Geweke Porter and Hudak (1983), there is a replacement of the periodogram function by its smoothing version based on the Parzen lag window. The truncation point in the Parzen lag window is denoted by  $m = T^\beta$ , for  $0 < \beta < 1$  (Reisen, et al., 2006).

Taking into account the studies made by Granger and Joyeaux (1980) and Hosking (1981), an ARFIMA process  $(p, d, q)$  can be expressed as follows:

$$(1 - L)^d \phi(L)x_t = \theta(L)\varepsilon_t, \quad \varepsilon_t \sim iid(0, \sigma_\varepsilon^2) \quad (8)$$

where  $\phi(L); \theta(L)$  are the autoregressive and moving average polynomials of order  $p$  and  $q$ ,  $L$  is lag operator. When parameter  $d$  takes value between  $(-0.5; 0.5)$  the process is stationary and invertible. For  $-0.5 < d < 0$  the series have long-range negative dependence or anti-persistence. For  $0 < d < 0.5$ , the series have long memory, the autocorrelations are positive and decay slowly at a hyperbolic rate. For  $d > 0.5$ , the series is covariance non-stationary, but mean-reverting. If  $|d| > 1$ , the series does not revert to its mean (Kasman, S. et al., 2009).

### 3. Data

In this study, the sample consists daily returns of the nine stock indices for the CEE and the Balkans countries: Romania (BET), Hungary (BUX), Slovakia (SAX), Czech Republic (PX), Ukraine (PFTS), Serbia (BELEX), Bulgaria (SOFIX), Greece (ATHEX), Croatia (CROBEX), during January 2005-November 2012. The daily

logarithmic returns were determined using the following equation:  $r_t = \frac{I_t}{I_{t-1}}$  where

$r_t$  - index return at time  $t$ ,  $I_t, I_{t-1}$  - represents the index prices at time  $t$  and  $t - 1$

. The statistical properties of the indices are provided in Table 1.

Table 1: Descriptive statistics

Notes: ADF represents Augmented Dickey Fuller (1979) unit root test,  $H_0$ : the series has a unit-root,  $H_1$ : the series is stationary; the lag length was chosen

according to the Schwarz Information Criterion. The critical values for the test with constant are those of MacKinnon (1991): 3.43 (1%), 2.9 (5%), 2.57 (10%), \*\*\*denotes significance at 1%.

The mean returns are positive for Romania, Hungary, Czech Republic and Ukraine. In the case of Slovakia, the mean return is negative. The Balkans capital markets registered negative mean returns, except Croatia. All the capital markets manifested a high volatility, in particular Serbia, which registered the highest standard deviation from the mean returns. The skewness coefficients are negative for Romania, Hungary, Slovakia, Ukraine and Bulgaria, which reflects that there is a tail of the returns distribution to the right, compared to the normal distribution, this because of positive extreme values. Similar results for BET index were obtained by Lazar D. et al. (2009). In the case of Czech Republic, Serbia, Greece and Croatia the skewness coefficients are positive, indicating a greater probability of growth, than decline. The results are in accordance with those obtained by Festic et al. (2012) for Hungary. All kurtosis coefficients register values higher than three, meaning that the returns distribution is more sharp than the normal distribution, indicating leptokurtosis. The results of the Jarque Bera test indicate that the normality hypothesis is rejected for all the markets. The results of the ADF test show that all of the return series are stationary. This characteristics are similar to those obtained by Kasman et al. (2009) for Hungary, Czech Republic and Slovakia.

#### 4. Empirical results

In order to detect the long range dependence the Hurst Exponent, GPH method, Andrews and Guggenberger method, Reisen method, Willinger, Taquq and Teverovski method and ARFIMA model are used. The estimation results are presented in the tables below.

**Table 2:** Tests for long term persistence using the Hurst Exponent and Reisen method

Index	Hurst Exponent-R/S Statistics	Hurst Exponent-R/S with EW returns	Hurst Exponent-R/S with shuffled returns	Reisen Method $\hat{d}$

Notes:() standard deviation in parenthesis; EW-equally weighted \*\*\*,\*\*, \* Significant at 1%, 5%, 10% level, respectively.

The Hurst Exponent estimated by R/S analysis, registered values higher than 0.5, indicating the presence of long memory for all the capital markets, except Czech Republic. The return series present long term dependencies and have a predictable behavior. For Czech Republic, the Hurst Exponent is less than 0.5, showing an anti-persistent behavior. In the case of R/S analysis with equally weighted returns, all Hurst Exponents have values higher than 0.5, indicating the existence of long memory for all indices. Also, it has been calculated a Hurst Exponent using the R/S analysis with shuffled returns. In the table above, it can be seen that all indices register values between 0.5 and 1, which indicate a persistent long-term dependence. The results of Reisen method detect the existence of long memory for all indices, except SOFIX.

Notes: The number in parenthesis are the SE, are realized GPH estimates for  $T^{1/2}$  \*\*\*,\*\*, \* Significant at 1%, 5%, 10% level, respectively

The results of GPH method indicate that the fractional differencing parameter estimated values are between 0 and 0.5, which means that BET, SOFIX, ATHEX and CROBEX exhibit long memory. For BELEX, the fractional differencing parameter  $d$  is less than 0, showing an anti-persistent behavior. The results of Andrews and Guggenberger test indicate that the value of long-memory parameter estimated with  $r=1$ , is statistically significant only for SOFIX and CROBEX. For  $r=2$ , the Andrews

and Guggenberger test found presence of long memory only for BET Index. Similar results were obtained by Hiremath,G.and Kamaiah, B. (2011) for Chile and Brazil.

Notes: \*\*\*,\*\*,\* Significant at 1%, 5%, 10% level, respectively; Q() – Ljung Box statistics

In the table above, it can be seen that the value of the parameter d is significant at a confidence level of 1%

for all indices. For all indices, except PX, the parameter  $d$  takes values between  $0 < d < 0.5$ , implying that the series have long memory, autocorrelations are positive and hyperbolic decline toward zero. Long memory refers to the fact that stock prices have a predictable behavior, showing that these capital markets are not weak-form efficient. Similar results in financial literature were obtained by Kasman and Torun (2007) for another emerging market, Turkey. So, ARFIMA models can be used by investors to predict returns and thus have the possibility of obtaining abnormal earnings. For PX, the estimated value of parameter  $d$  is higher than 0.5, which means that the process is mean-reverting, since there is no long term impact of the innovation variance on the process future values.

Source: (authors' calculations)

Notes: IV – innovation variance; EW – returns equally weighted; \*\*\*, \*\*, \* Significant at 1%, 5%, 10% level, respectively.

According to the results presented in Table 5, when EW series over blocks of size 10 are used, the Hurst Exponents record values higher than 0.5 for BET, SAX, PFTS, SOFIX, ATHEX and CROBEX, indicating a long term dependence in return series. On the other hand, in the case of BUX, PX and BELEX, the return series are anti persistent, which means that the performances from the past will change in the future. Similar results are obtained for blocks of 20 observations, except for the PFTS Index, in which case we obtain a Hurst Exponent <0.5.

## 5. Conclusions

Analyzing the existence of long memory in return series for nine indices from Central Eastern European (Romania, Hungary, Slovakia, Czech Republic, Ukraine) and Balkan emerging markets (Serbia, Bulgaria, Greece, Croatia) we have found mixed results depending on the statistical methods that are used. The Hurst Exponent estimated by classical R/S analysis, indicates the presence of long memory for all indices, except PX. According with the results obtained by GPH method, the return series for BET, ATHEX, SOFIX and CROBEX exhibits long memory, while the return

series for BELEX Index is anti-persistent. The results of Andrews and Guggenberger test are similar to those obtained by GPH method in the case of BET, SOFIX and CROBEX. Using Reisen method, we have found that SOFIX exhibits short memory. The results provided by Willinger, Taqqu and Teverovsky method, indicate a long range dependence for BET, SAX, PFTS, SOFIX, ATHEX and CROBEX. According with ARFIMA model estimates, all indices, except PX, have a predictable behavior, the investors can obtain abnormal profits, suggesting that these capital markets are not weak-form efficient.

As direction of future research is recommended the analysis of long memory in volatility of these indices, the detection of the structural breaks and the estimation of GARCH models for modeling volatility. It also should be investigated the causes that lead to the appearance of various degrees of predictability of returns and volatility and their impact on the construction of portfolios and trading strategies of investors.

## COMPARATIVE ANALYSIS OF THE BANK'S CAPITAL ADEQUACY ACCORDING TO THE BASEL AGREEMENT

**Tesu Ramona**

*Faculty of Economics Science and Business Administration, Babes-Bolyai University of Cluj-Napoca, Romania*  
[ramotesu@yahoo.com](mailto:ramotesu@yahoo.com)

**Abstract:** *The present article has as a research field the theoretical, methodological and practical aspects of the capital bank adequacy mechanism, according to Basel Agreement. In this paper we intend to present the advanced approaches of measurement and the minimum requirements regarding the bank capital. The objectives of the research theme, presented in this paper, are oriented mainly towards: presenting the principles and rules which governance the bank capital adequacy mechanism; calculation and comparison of the bank capital adequacy indicators. An objective that we consider needs to be mentioned is the reflection of the modifications which will affect the bank environment in the next years, as a result of adopting the new General Frame of Bank Supervision. Even though the actual stage of research is advanced, in the Romanian and foreign literature, which dedicates a lot of theoretical and empiric studies of the bank capital adequacy mechanism, in this moment, the international crises pointed out the purpose and the implications of the credit institutions within the financial system. In our paper we will use a theoretical and a practical research. The theoretical research describes the laws, rules of application in the banking field in our country. In the practical research we will use as a research method, the quality-comparative analyses, by presenting details regarding the bank capital adequacy indicators. Within the study methodology, we will use the available channels in order to structure in an useful way the research by: description, explanation, exemplification, simulation, comparative. Within the approached channels we mention: reading, analyzing information, research on specialty sites, discussions in the professional groups, discussions with the top managers of the bank, explanation, induction and deduction, conclusion and supporting our own opinion. Among the complicated, difficult, urgent problems of the European integration, within globalization and change, in the foreground we have the state of the economy, the economic problems, situation of the banking system. In Romania there is now a modern and competitive banking system, which provides circulation of the economy and domestic supplies banking products and services in accordance with trends in the European banking sector. In this way, the action line, I did a comparative study determining capital requirements under Basel 1, Basel 2, the standardized approaches, credit risk determined. Capitalization of Romanian bank's remain comfortable, providing good conditions for meeting additional capital requirements Basel III. In what concerns the capital adequacy management, the leading structures of a credit institution need to establish strategies and effective policies in order to maintain, on a continuous base, a level, a correct structure of their own funds, proper for covering the risks that the credit institution is exposed to. We conclude that a bank needs to increase its own funds, which is achieved by several methods decided by management. Presentation of concrete cases in approaching the bank's capital adequacy represent the personal work which completes the study concerning the purpose of back-up accounting in the banking system, adequate correlation of the risks and capitals.*

## **1. Generally Introduction**

The present article aims to reflect that the current global financial turmoil continues to pose a threat to the effectiveness of the Accord Basel rules which are aimed at achieving global financial stability. This study presents the common problems of the credit institutions, introducing theoretical aspects and also practical aspects of applying a model and of interpreting risk situations, considering the attempts of alignment of the Romanian banking system to the requests of the European Union, materialized in the stipulations of Basel Accord. Considering the scientific research methodology, the following issues were set: introduction, motivation, importance and scientific research methodology, objectives, development of the article, estimated scientific results. In the introduction is being argued the research theme, the necessity and the importance of it. In the present economic-financial context, the fluid character which often brings major differences of opinion. The motivation of choosing the research theme is formulated and further the used research methodology is being presented. In the scientific research methodology, there are presented the scientific research areas, the field and the objectives of the scientific research, and also its structure. The present research is based on a deductive approach - strictly qualitative. For analyzing all the data I used the following research methods: comparative method, document analysis, external observation. I choose this subject for scientific reasons and realistic reasons. I consider that Romania's chances, on the road to the European integration in globalization, firstly depend on its own performance, the quality of management at all levels. Romania's efficient integration within the above mentioned context cannot be achieved otherwise than through a performance superior to that already existing. The necessary performance can be achieved only with an advanced, new, modern management, with good results of own funds in the banking system. The objectives of this study are determining capital requirements under Basel Accord I, Basel Accord II, Basel Accord III the standardized approaches, credit risk and interpretation of this evolution in the banking system. Imposing minimum capital adequacy regulations is one way of fostering stability in the global banking system.

## **2. Literature review**

Even though the stage of research in this field is advanced, in both Romanian and foreign literature, which dedicate a lot of theoretical and empiric studies to bank's capital adequacy mechanism, in this moment the international crises pointed out the purpose and implications of credit institutions in the financial field. We want, in the allocated space, based on those already presented, to refer to the „capital adequacy in the banking system”. Referring to the literature in the field, a very useful starting for our research is the series of papers developed under BIS (Bank for International Settlements).The BIS carries out research and analysis to contribute to the understanding of issues of core interest to the central bank community, to assist the

organisation of meetings of Governors and other central bank officials and to provide analytical support to the activities of the various Basel-based committees. The BIS also comments on global economic and financial developments and identifies issues that are of common interest to central banks. The research agenda of the BIS is focused on key areas of interest to central banks, such as monetary and financial stability, monetary policy and exchange rates, financial institutions and infrastructure, financial markets, central bank governance, and legal issues. The National Bank of Romania offers to its users, information's regarding the determining capital requirements under Basel Accord I, Basel Accord II, Basel Accord III the standardized approaches, credit risk, through the Reports of Financial Stability and the Annual Reports. I have been used due to their importance, new character and desire to be largely and deeper known and especially used in the scientific research and in the practical activity.

### **3. Research design and methodology**

Considering the scientific research methodology, the following issues were set: introduction, motivation, importance and scientific research methodology, objectives, development of the article, estimated scientific results. In the introduction is being argued the research theme, the necessity and the importance of it. The motivation of choosing the research theme is formulated and further the used research methodology is being presented. In the scientific research methodology, there are presented the scientific research areas, the field and the objectives of the scientific research, and also its structure. The present research is based on a deductive approach - strictly qualitative. For analyzing all the data I used the following research methods: comparative method, document analysis, external observation. I choose this subject for scientific reasons and realistic reasons. I consider that Romania's chances, on the road to the European integration in globalization, firstly depend on its own performance, the quality of management at all levels. Imposing minimum capital adequacy regulations is one way of fostering stability in the global banking system. Romania's efficient integration within the above mentioned context cannot be achieved otherwise than through a performance superior to that already existing. The necessary performance can be achieved only with an advanced, new, modern management, with good results of determining capital requirements under Basel I, Basel II, Basel III the standardized approaches, credit risk determined in the banking system. I consider that bank's capital levels should be regulated to enhance global financial stability.

The objectives of this study are presentation of concrete cases in approaching the capital bank's adequacy represent the personal work which complets the study concerning the purpose of back-up accounting in the banking system, adequate correlation of the risks and capitals, evolution of the capital requirements and interpretation of this evolution of in the banking system. For analysis of national or international data, we used comparative longitudinal research method (showing the evolution of bank's capital adequacy according to Basel I, Basel II and Basel III).

## **4. Results and discussions**

### **4.1. Capital requirements under Basel Accord III**

Basel Accord III is a comprehensive set of reform measures, developed by the Basel Committee on Banking Supervision, to strengthen the regulation, supervision and risk management of the banking sector. The reforms target:

-Bank-level, or micro-prudential, regulation, which will help raise the resilience of individual banking institutions to periods of stress.

-Macro-prudential, system wide risks that can build up across the banking sector as well as the pro-cyclical amplification of these risks over time.

These two approaches to supervision are complementary as greater resilience at the individual bank level reduces the risk of system wide shocks.

Micro-prudential regulatory measures CRD IV are the following three:

a) Strengthening the regulatory capital requirements to increase capacity to absorb further losses under / cessation of business by:

- Removing inconsistencies in the definition of capital
- Identifying eligible items comprising the capital and their relative level of risks taken by credit institutions by establishing the responsibility of shareholders to increased capital requirements, namely:
  - Increase the minimum equity requirement (common shares, share premium, retained earnings and reserves) from 2% to 4.5%
  - Increasing the Minimum Tier 1 (equity and hybrid instruments) from 4% to 6%.
  - Although total capital requirement of 8% stayed structure is unchanged in meaning:
  - Increase the share of equity (or shareholders effort to total own funds) and, respectively,
  - Decrease weight Tier 2 (subordinated debt) to those of level 1 - 100% as it is now at 33%.

b) The introduction of new prudential ratios

c) Establishment of capital buffers. In the first period (until 2016) the change in the structure of total of own funds by increasing equity. From 2016 until 2019 occurs progressively establishing the damper fixed capital conservation to be achieved as presented in equity elements (based on effort shareholders).

d) Recognition diminished role of central counterparty credit risk by reducing capital requirements for exposures to such entities

e) Increased capital requirements for OTC transactions settled through a central counterparty

f) Maintain current level of positive discrimination SME sector (75% risk weight for SMEs to 100% risk weight to corporates) as a stimulus for its development

g) Remuneration

h) Corporate Governance.

These measures aim to:

-improve the banking sector's ability to absorb shocks arising from financial and economic stress, whatever the source

- improve risk management and governance

- strengthen banks' transparency and disclosures.

#### 4.2. The evolution of own funds in the X-Bank

a) In order to determine minimum capital requirements for credit risk under Basel III, according application standard approach we leave the X-Bank balance of 2011, highlighted the beginning case study. X-Bank's own funds at 31 December 2010 and 31 December 2011, broken down into their components and is as follows:

**Table no.1:** X-Bank's Own Funds at 31 December 2010 and 31 December calculated according to Basel Accord III

<b>Own funds - in RON -</b>	<b>31 December 2010</b>	<b>31 December 2011</b>
Subscribed and paid up share capital	2.352.000	2.837.000
Share premium	-	2.000
Eligible Reserves *	848.000	580.000
Intangible assets	75.000	110.000
50 % of the shares and other equity securities held in other credit and financial institutions in excess of 10% of their share capital	84.000	36.000
50% of holdings in insurance companies, reinsurance companies	-	-
Own shares redeemed	-	-
<b>Total Tier I</b>	<b>3.359.000</b>	<b>3.565.000</b>
Revaluation reserve	50.000	48.000
Subordinated loans	247.000	123.000
50% of the shares and other equity securities held in other credit and financial institutions in excess of 10% of their share capital	-84.000	-36.000
50% of holdings in insurance companies, reinsurance companies	-	-
<b>Total Tier II</b>	<b>213.000</b>	<b>135.000</b>
<b>Total equity</b>	<b>3.572.000</b>	<b>3.700.000</b>

(Source: author based on archive of The National Bank of Romania)

b) Such X-Bank assets will have the following degrees of risk:

**Table no. 2:** The Weighted Assets of the X-Bank calculated according to Basel III

1. 2. Cash, deposits with central banks <b>APRCASH</b> = CASH*0% = 5000.000*0% = 0 u.m. <b>APRDBC</b> = DBC*0% = 2.218.000*0% = 0 u.m
3. Bills and other bills eligible for refinancing with central banks (government bonds) <b>APREPA</b> = EPA*0% = 8.410.000*0% = 0 u.m.
4. Claims on credit institutions (maturity of up to 3 months) <b>APRCIC</b> = CIC*20% = 994.000*20% = 198.800
5. Claims on customers

<p><b>APRCC = CC*100% + CC*75% + CC*35%, so:</b>  CC loans to companies – 100%,  To individual-consumer loans - 75%,  To individual-guarantees property - 35%</p> <p>(Credit-provision) x risk weight =  0.000.000*100%+5.000.000*75%+7.101.000*35% = 10.000.000</p>
<p>6. Bonds and other fixed income securities (municipal)  <b>APROA = OA*20% = 915.000*20% = 183.000</b></p>
<p>7. Shares and other variable income securities (the company)  <b>APRAAV= AAV*100% = 221.000*100% = 221.000</b></p>
<p>8. Participating credit institutions - are not in stock X-Bank</p>
<p>9. Parties associated companies, f which:  - Parts in credit institutions (with residual maturity greater than 3 months)  <b>APRPIC = PIC*50% = 195.000*50% = 97.500</b></p>
<p>10. Intangibles' Assets  <b>APRIN = IND*0% + INN*100% = 110.000*0% = 0</b>, where:  IND is deducted from the own funds  INN is no deducted from own funds</p>
<p>11. Tangible Assets  <b>APRIC = IC*100% = 434.000*100% = 434.000</b></p>
<p>12. Unsubscribed and paid up share capital  <b>APRCSN = CSN*0% = 0</b></p>
<p>13. Other Assets  <b>APRAA = AA*100% = 93.000*100% = 93.000</b></p>
<p>14. Prepaid expenses and accrued income  <b>APRCVAV= CAV*100%=494.000*100%=494.000</b></p>

(Source: author based on archive of The National Bank of Romania))

c) Total credit risk-weighted assets = 0 u.m.+ 0 u.m.+ 0 u.m.+ 0 u.m.+ 22.101.000 u.m. +183.000 u.m.+221.000 u.m.+195.000 u.m.+0 u.m. +434.000 u.m +0 u.m +93.000 u.m +247.000 u.m. = 23.474.000 u.m.

d) Solvency ratio must be at least 12% so

e)  $12\% * \text{Average risk own funds} \leftrightarrow \leq 12\% * 23474000 \text{ um} = 2,816,880 \text{ u.m.} \leq 3,700,000 \text{ u.m.}$

The solvency ratio has the value:  $\text{Own funds} / \text{Total credit risk-weighted assets} * 100 = 3.700.000 / 23.474.000 * 100 = 15,76\%$

**Table no. 3:** Comparative Analysis of Capital Requirements under Basel I, Basel II, Basel III - (the Years of references 2011)

Capital requirements Basel I Basel II Basel III	Basel I	Basel II	Basel III
Capital requirements for credit risk, counterparty credit risk, the risk of dilution and incomplete transactions	2.471.980	3.088.875	3.294.800
Capital requirements for position risk, foreign exchange risk and commodities risk	132.000	132.500	133.000

Capital requirements for operational risk	1.444.050	1.447.050	1.500.000
<b>Total requirements of capital</b>	<b>4.048.030</b>	<b>4.668.425</b>	<b>4.927.800</b>

(Source: author based on archive of The National Bank of Romania)

Analysis comparative of capital requirements calculated under the three agreements Basel reflect the fact that:

Capital requirement under Basel I < capital requirement under Basel II < capital requirement under Basel III.

Thus the need for capitalization of banks is increasingly bet on increasing. We will need to adopt new models asset management, balance sheet size will be bet on the determinate of all funds that the bank may increase (liabilities) and total assets will be adjusted to equal the liabilities available. Also we believe that the bank will be necessary to grow up tier one level from 2% to 7% in 2019. Another important element is to avoid future bottlenecks to request bank to possible growth and create liquid assets from various sources, such as the exchange of bills or other debt instruments. Although total capital requirement of 8% stayed structure is unchanged in meaning: increase the share capital (shareholders effort to total own funds) and, respectively, lower weight Tier 2 (subordinated debt) to of the level 1 to 100% as it is now at 33%. It should be noted that along with measures surveillance and efforts to increase the share capital to shareholders, a contribution to maintaining a high level of solvency ratio had substantial stock of government securities existing bank balance, characterized by a low risk and high liquidity, with a direct impact on capital requirements. However the presence of excess of these elements can adversely affect operational efficiency as a result of debt levels attached to the existence of a much smaller share of loans to the real sector. The completion of these requirements solicit eligible participants more capital.

## 5. In conclusion

Since the recent crisis, stress testing and reverse testing have become integral tools in managements of banks'. Liquidity management and compliance is central to Basel Accord III. It is placing new demands on financial institutions as well as providing new opportunities. Accepting a higher risk level by credit institutions means strengthening the level of own funds, even over the level stipulated by the bank. Capital adequacy is prominent feature in the management of any risks encountered by the credit institution. The credit institutions should manage the inherent risks. The very efficient management of risk it is essential for the success on long term of any bank. We want to mention and express our opinion that the methods and techniques of managing risk, calculation of capital need permanent revision and adaptation to the changes that take place on the financial market the appearance of Basel Accord III, which are absolutely necessary in the actual economic and financial context. Implementing Basel III is a significant challenge for any bank. The key issues are deciding how best to implement a solution that allows them to comply, how to streamline their systems and processes for improved operational effectiveness and how to reduce their capital requirements.

# A MACROPRUDENTIAL SUPERVISION MODEL. EMPIRICAL EVIDENCE FROM THE CENTRAL AND EASTERN EUROPEAN BANKING SYSTEM

**Trenca Ioan, Balogh Peter, Mutu Simona**

*Finance Department, Faculty of Economics and Business Administration, Babes-Bolyai University, Cluj-Napoca, Romania*

*ioan.trenca@econ.ubbcluj.ro*

*petibalogh@yahoo.com*

*simona.mutu@ubbcluj.ro*

**Abstract:** *One of the positive effects of the financial crises is the increasing concern of the supervisors regarding the financial system's stability. There is a need to strengthen the links between different financial components of the financial system and the macroeconomic environment. Banking systems that have an adequate capitalization and liquidity level may face easier economic and financial shocks. The purpose of this empirical study is to identify the main determinants of the banking system's stability and soundness in the Central and Eastern Europe countries. We assess the impact of different macroeconomic variables on the quality of capital and liquidity conditions and examine the behaviour of these financial stability indicators, by analyzing a sample of 10 banking systems during 2000-2011. The availability of banking capital signals the banking system's resiliency to shocks. Capital adequacy ratio is the main indicator used to assess the banking fragility. One of the causes of the 2008-2009 financial crisis was the lack of liquidity in the banking system which led to the collapse of several banking institutions and macroeconomic imbalances. Given the importance of liquidity for the banking system, we propose several models in order to determine the macroeconomic variables that have a significant influence on the liquid reserves to total assets ratio. We found evidence that GDP growth, inflation, domestic credit to private sector, as well as the money and quasi money aggregate indicator have significant impact on the banking stability. The empirical regression confirms the high level of interdependence of the real sector with the financial-banking sector. Also, they prove the necessity for an effective macro prudential supervision at country level which enables the supervisory authorities to have an adequate control over the macro prudential indicators and to take appropriate decisions at the right time.*

**Key words:** *banking supervision; macro prudential monitoring; risk; bank liquidity; bank capital adequacy, financial stability*

**JEL classification:** *E44; G01; G32*

## 1. Introduction

In the recent years, the banking sector has experienced various crises at national, regional or international level. One of the positive effects of these crises is the increasing concern of the supervisors regarding the financial system stability. The onset of a financial crisis has always been difficult to predict, but there are some signals that indicate financial vulnerabilities in the banking system. These enable policy formulation and implementation of tools for the prevention and mitigation of financial imbalances.

Schou-Zibell, Albert and Song (2010) have highlighted the need to strengthen the links between different financial components of the financial system. Excessive risk-taking combined with weak prudential supervisory framework and reckless monetary policies are considered the major roots of the financial crisis. If risks are well managed, the banking institutions can lead to prosperity, but if we consider the macro level of all banks from the system, we must take into account the overwhelming role of central banks and regulators.

The identification by supervisors of properly risk managed banks turned to be a difficult task. Prudential supervision should not be focused only on individual banks. It should have a macro prudential perspective that examines the risk distribution within the financial system in time and also the negative externalities.

The purpose of this empirical study is to identify the main determinants of the banking stability and soundness in the Central and Eastern Europe (CEE) banking systems. We assess the impact of different macroeconomic variables on the quality of capital and liquidity conditions and examine the behaviour of these financial stability indicators, by analyzing a sample of 10 banking systems during 2000-2011. The methodology is based on the empirical work of Schou-Zibell, Albert and Song (2010), which developed a supervisory framework for monitoring and examining the macro financial soundness.

This paper is organized as follows. Section 2 summarizes the literature review. Section 3 describes the data. Section 4 details the methodology. Section 5 presents the empirical findings. Finally, Section 6 concludes.

## **2. Literature Review**

A great amount of studies in the literature demonstrated that certain developments in macroeconomic indicators may be associated with banking crises. To name a few, the decline of GDP, excessively high real interest rates and high inflation rate may significantly increase the probability of developing a systemic banking crisis.

Shocks or negative externalities from trade imbalances can also stimulate the occurrence of banking problems. Gavin and Hausmann (1998), Morris et al. (1990), as well as a report from IMF (1993) highlight that adverse shocks in trading activity have a significant impact on the banking systems of Argentina, Chile, Colombia and Uruguay. They show that in some cases substantial decline of commercial activity precedes a banking crisis (Norway, Finland and Spain). However this claim has not been verified for Japan or Sweden. Demirguc-Kunt and Detragiache (1998) haven't found evidence of negative externalities from trade to banking stability.

The evolution of domestic credit to the private sector (as % in GDP) may be an early warning signal of problems in the banking system. A sharp increase of the domestic credit leads to financial vulnerability especially in situations of credit quality deterioration and risks incensement. Evans et al. (2000) shows that a sharp increase in lending capacity of banks is an indication of a poor credit rating and therefore of poor credit quality. However there is a significant number of studies that found that a too optimistic credit expansion could lead to a financial crisis (Kaminsky and Reinhart, 1999; Gavin and Hausmann, 1998).

In different studies was found that the ratio of money and quasi money (M2) to total reserves (international reserves, gold and currencies under the control of monetary authorities) has a significant influence on banking sector vulnerability. Banking system problems may be related to sudden withdrawals of capital. Demirguc-Kunt and Detragiache (1998), as well as Calvo (1996) show that this indicator is a good

predictor of a country's vulnerability to balance of payments crises, which could affect the whole banking systems.

### 3. Data Analysis

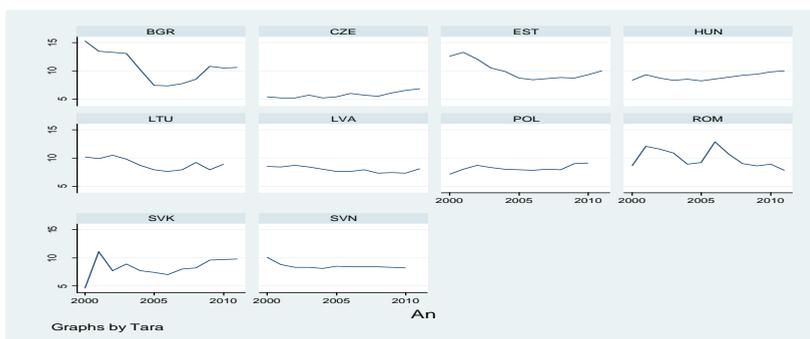

The data is representative for ten CEE banking systems: Bulgaria, Czech Republic, Estonia, Hungary, Latvia, Lithuania, Poland, Romania, Slovakia and Slovenia. The analysis covers the period 2000-2011. Table 1 presents the variables used. They can be grouped into the following categories: financial stability indicators, macroeconomic indicators, monetary indicators and market indices.

**Table 1:** Variables used in the study

Indicator	Symbol	Type	Source
Bank capital to assets ratio (%)	CAPA	Financial Stability Indicator	WDI
Bank liquid reserves to bank assets ratio (%)	LIQU	Financial Stability Indicator	WDI
Bank nonperforming loans to total gross loans (%)	NPER	Financial Stability Indicator	WDI
Inflation, GDP deflator (annual %)	GDPD	Macroeconomic	WDI
GDP growth (annual %)	GDPG	Macroeconomic	WDI
Money and quasi money (M2) to total reserves ratio	MQM	Monetary	WDI
Domestic credit to private sector (% of GDP)	PRVT	Macroeconomic	WDI
Trade (% of GDP)	TRD	Macroeconomic	WDI
Real interest rate (%)	RINR	Market	WDI

The historical evolution of the bank capital to total assets ratio in each country is illustrated in Figure 1. During 2010-2011 the highest capitalization ratios of banks were registered in Bulgaria (from 2000 to 2004 and from 2009 to 2011) and Romania (2005-2008). The smallest capitalization ratio was recorded in the Czech Republic (from 2001 to 2011). In Bulgaria the maximum capitalization rate was reached in 2000 (15.30%). In Romania the maximum capitalization ratio was reached in 2006 when it was 12.90%. The bank capital to total assets ratio register an average rate of 8.72% over the entire period analyzed. This shows a good level of capitalization of the banking system in Eastern and Central Europe. The minimum value is recorded by Slovakia in 2000 (4.6%) and the maximum value is recorded by Bulgaria in 2000 (15.3%).

During 2005 - 2008 there is a reduction of the capital to total assets ratio, which can be explained by an increase in financial intermediation through less conventional sources. After the 2007-2008 crises, banks have started to pay attention again to capitalization. The level of this rate increased after 2008 in all countries, except Romania, where the ratio decreased from 10.70% in 2007 to 7.80% in 2011.

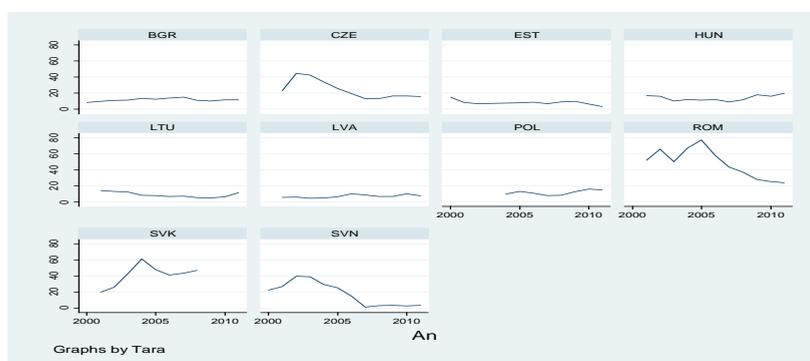

**Figure 1:** The evolution of bank capital to total assets ratio

Source: authors' processing

Regarding the bank liquid reserves to total assets ratio during the period 2000-2011, the highest values of these rates were recorded in Romania (in 10 of the 12 years analyzed) and the minimum values were recorded in Latvia during 2001-2005 (between 4.3% and 6.24%) and Slovenia in the period 2007-2010 (the rate lies between 1.12% and 2.32%). Over the entire period analyzed, Romania registered the highest average value of this indicator (47%), followed by Slovakia (41%).

Analyzing the annual evolution of the indicator, the maximum value of the bank liquid reserves to bank assets ratio was recorded in 2005 in Romania (77.21%) and minimum in Slovenia in 2007 (1.12%). The average value of this indicator is 18.38%. Interesting evolutions are recorded in Romania and Slovenia that register the extremes of these values. In Romania, the liquid bank reserves to total assets ratio increased from 51.49% in 2001 to 77.21% in 2005 and gradually decreased to 23.63% in 2011. In Slovenia, the liquid reserves to total assets ratio decreased from 39.68% in 2002 to 25.07% in 2005 and then fall sharply to 3.08% in 2011 (Figure 2).

#### 4. Empirical Methodology

The empirical analysis regarding the impact of macroeconomic indicators on the financial stability of the banking system is made using the panel regression technique, through the least squares method. The panel regression model allows determining the macroeconomic variables that underlie movements in the financial

stability of the banking system. Panel regression models are estimated for two major macro prudential indicators: the capital adequacy to total assets ration and the liquid reserves to total assets ratio.

The panel consists of 10 cross-sections corresponding to Central and Eastern European banking systems and 12 years from 2000 to 2011. To capture the specific characteristics of each analyzed banking system were introduced individual fixed effects for each cross-section. They take into account the particularities of each country's banking system that are constant over time. In order to detect the existence of fixed effects we applied the F test. Its null hypothesis states that the dummy variables associated with the sections are equal to 0 ( $H_0: \mu_1 = \dots = \mu_{n-1} = 0$ ). The null hypothesis is rejected. Thus, the test result indicates the existence of fixed effects.

The use of fixed effects regression allows us to control for omitted macroeconomic variables that differ among countries but are constant over time. An underlying assumption in such models is that the model error does not display autocorrelation (Schou-Zibell, et al., 2010). Panel regressions are often used with fixed effects to allow the possibility of the dependent variable to interact between countries regardless of the explanatory variables included in the regression (Demirgüç-Kunt and Detragiache 1998).

In the present research, the panel regression model with fixed effects takes the following form:

$$IMacroP_{it} = \alpha_0 + \alpha_1 MacroI_{it} + \alpha_2 X_{it} + \theta_i + \varepsilon_{it} \quad (1)$$

where  $IMacroP_{it}$  represents the macro prudential indicators (the bank capital to total assets ratio and the bank liquid reserves to total assets ratio), categorized as financial stability indicators (FSI) of the  $i$  banking system at time  $t$ .  $\alpha$  is the constant of the regression equation.  $MacroI_{it}$  represents the  $i^{th}$  country-specific macroeconomic indicators at time  $t$ ,  $X_{it}$  is a set of control variables for the banking system  $i$  at time  $t$ ,  $\theta_i$  is the fixed effect for the banking system  $i$  and  $\varepsilon_{it}$  is the error term.

## 5. Empirical Results

### 5.1. Determinants of Capital to Total Assets Ratio

The availability of banking capital signals the banking system's resiliency to shocks. Capital adequacy ratio is the main indicator used to assess the banking fragility. In analyzing the determinants of the capital to total assets ratio we start from a basic regression that includes as explanatory variables the GDP growth, the inflation rate and the domestic credit to the private sector as percentage in GDP. In the second model we add the nonperforming loans ratio, which is expected to exert a negative influence on bank capital to total assets ratio. Finally, we account for the international trade activity of the countries analyzed in the third model, introducing it as a control variable (Table 2).

**Table 2:** Determinants of bank capital to assets ratio

Source: authors' calculation

The determinants of the capital to total assets ratio for the analyzed banking systems are shown in the table above. Analyzing Student t statistic, we observe that several variables are significant in explaining the dependent variable. The share of the private domestic credit to GDP has a significant negative impact on the rate of bank capital to total assets in all of the three regression models. By introducing the nonperforming loans ratio in the model the intensity of the relationship between the private domestic credit in GDP ratio and the ratio of bank capital increases (Model 2). This means that an increase in bad loans, especially in the private credit sector, may possibly damage the quantity and quality of the bank capital. Thus, adding to the basic equation the nonperforming loans ratio and an increase of 1% in the domestic credit to private sector (as share in GDP), determine the capital to total assets ratio to decrease by 0.036%. Introducing in the regression model the percentage of international trade in GDP as explanatory variable, the impact of the private domestic credit ratio is higher, resulting a decrease of 0,046% of the capital to total assets ratio (Model 3).

These three regression models highlight that in countries where an important part of the credit is allocated to private domestic sector there is a greater possibility of deteriorating the quality and the quantity of bank capital. A sudden increase in the domestic credit to private sector as percentage in GDP ratio can create problems in the banking sector. This can cause financial vulnerabilities and the erosion of bank capital.

By introducing trade activity as a control variable, a rise in the GDP growth significantly influences the capital to total assets ratio in a negative manner. Thus, in the third model an increase by 1% in the GDP growth reduces the ratio of capital to total assets by 0.063%. A possible explanation for this finding is that if the GDP growth rate increases, banks use a higher proportion of their capital to finance loans and implicitly economic growth rate increases. On the other hand in case of a decreasing GDP, banks are increasing their capital in order to prevent some possible financial imbalances caused by the economic downturn.

An absolutely normal result that justifies the robustness of the regressions is revealed in the positive relationship between the capital to assets ratio and the trade activity. Thus, an increase in import and export activity of a country can improve the bank capital. On the other side, possible shocks on a country's trade activity can lead to deterioration of the bank capital. The regressions did not revealed significant influences of the nonperforming loans ratio and the inflation rate on bank capital to assets ratio.

## 5.2. Determinants of Bank Liquid Reserves to Total Assets Ratio

One of the 2008-2009 financial crisis causes was the lack of liquidity in the banking system which led to the collapse of several banking institutions and macroeconomic imbalances. Given the importance of liquidity for the banking system, we propose several models in order to determine the macroeconomic variables that have a significant influence on the liquid reserves to total assets ratio (Table 3). We propose this liquidity proxy as dependent variable, because it includes the most liquid reserves of banking systems such as: bank holdings in national currency and the bank deposits at central banks. The bank assets considered include claims against other governments, non-public enterprises, private sector and other banking institutions.

**Table 3:** Determinants of bank liquid reserves to bank assets ratio

Source: authors' calculation

In order to identify the determinants of bank liquid reserves we start from a basic regression that includes as independent variables the inflation and GDP growth rate. Inflation is introduced as explanatory variable because it is an indicator of a vulnerable macroeconomic environment. We found a direct significant relationship between liquid reserves of the banking system and inflation. The sign of this relationship is as expected because the inflation reduces the value of bank guarantees (Evans et al., 2000). However a decrease in the inflation rate has the effect of reducing the nominal income of banks, affecting their liquidity.

In Table 3 (Model 4) it could be seen that, by including in the regression model more macroeconomic variables, the impact of inflation on liquidity ratio increases, from 0.469% to 0.682%. After introducing in the regression the ratio of nonperforming loans to total gross loans and the real interest rate, the GDP growth becomes significant (Model 2). As expected, the GDP growth rate influences in a positive manner the liquid reserves to total assets ratio.

The real interest rate has a positive significant impact on the liquidity. The sign of this relationship is as expected. Under conditions of low liquidity in the market the real interest rates increases (Stracci, 2005). Those who observe the liquidity deficit are expecting greater returns, which anyway are eroded by high intermediation costs in terms of poor liquidity. Generally, in such cases, central banks intervene by injecting liquidity to reduce the real interest rate and to improve market liquidity.

Banking systems may be vulnerable in the presence of sudden outflows of capital, especially in countries with fixed exchange regime (Demirguc-Kunt and Detragiache, 1998). To check this hypothesis in Central and Eastern European banking systems we include as explanatory variable a monetary indicator, the share of the money and quasi money aggregate indicator (M2) in total reserves. We found a strong negative relationship between the liquid reserves in total assets ratio and the M2 in total reserves ratio. A 1% increase in the money supply to total international reserves ratio determines a decrease with 8.45% of the liquid reserves to total assets ratio.

## 6. In Conclusion

The empirical study confirms the interdependency between the economic sector and the banking sector. Business cycle captured by GDP growth evolution has a significant influence on the capital to total assets ratio and on the liquidities to total reserves ratio. During economic booms bank capital erosion occurs due to increased bank assets during those periods, but there is an increase of bank liquid reserves. On the other hand, higher inflation increases bank reserve liquid. Bank capital to total assets ratio is negatively influenced by the evolution of the domestic credit to the private sector (as percentage in GDP) and positively influenced by the development of a country's international trade activity. However, an increase of the real interest rate determines the liquid reserves to total assets ratio to increase. Also, the increasing of the share of the monetary aggregate M2 in the total international reserves determines the significant decreasing of the liquid reserves to total assets ratio. Even if in Romania were registered good levels of capital adequacy and bank liquidity indicators, we consider that high attention is needed in the administration of the bank capital and liquidity, because of the high fluctuations observed in our analysis. As a final conclusion, we consider that there is a real need for an effective macro prudential supervision at country level which enables the supervisory authorities to have an adequate control of macro prudential indicators depending on the macroeconomic evolutions and to take appropriate decisions, at the right time, on the appropriate macro prudential policy in order to avoid financial crises.

**Abstract:** Nowadays, a more and more overwhelming role comes to global performance considering the intense competition at every market level. The competition law governs any conducted activity, thus the weakest, without the capacity of adaptability being removed from the competition, also economic, social and environmental changes which, at a global level, led to changing the way of thinking and conducting the global economic activities. At present, performance plays a fundamental role in the survival of the entities found in a permanent adaptation to the market demands by implementing new and successful management strategies. These strategies must cope with the elements specific to contemporary economy, meaning a competitive, unstable and turbulent environment and, under these circumstances, viability of economic agents cannot be achieved without talking about performance. Modern economic entities must cope with the demands of the new global economy, such as global economic crises, economic liberalization, high growing pace of competition, so that they can achieve the predetermined objectives, having the maximum of effects with the minimum of effort, but at the same time one should not neglect the social and environmental factors, directly or indirectly involved in conducting the activity. In the conditions of an environment which denotes less stability, the entities must be capable of making strategical decisions necessary for maintaining a balance and for being able to address and implement strategies for future, strategies which allow maintaining the organisation healthcare unaltered. Thus, we cannot bring into discussion the competitiveness of an entity in the conditions of a turbulent, fluctuating and especially competitive environment without talking about performance. This scientific approach has started from the premise that any economic entity has the goal of getting performance in conducting the activity. Thus, we have tried to get inside the problems of defining the concept of performance, starting from its beginnings until present, following the path taken by this concept from defining it according to a series of criteria such as: profitability, productivity, flexibility, adaptability, growth, to defining it as the level of achieving the organizational objectives; to assessing it according to productivity and efficacy of the economic entity; to its contemporary approach as the creation of value. Moreover, we are trying the defining of performance according to efficiency, efficacy and economies. As a result, being performant means combining all three variables, their combination reflecting the level of performance of an entity.

**Keywords:** performance, efficiency, economies, efficacy, yield.

**JEL classification:** M41

## 1. Introduction

At present, when competition for each market share has become more and more severe, performance plays a fundamental role in the survival of under in a continuous adaptation to market requirements by implementing new and performing management strategies. These strategies must cope with the elements specific to contemporary economy, defined by a competitive, unstable and turbulent environment, and under these circumstances, the viability of economic agents cannot be achieved without referring to performance.

The term of *performance* has been defined repeatedly and at different times in the social evolution and it is in a continuous development, without having reached an agreement, because there is a numerous series of factors which influence performance directly or indirectly, such as the activities performed by the entity, the interests and the objectives of each economic entity.

The term of *performance* has a Latin origin, where the verb *performare* had the meaning of finalizing a predetermined activity. Nowadays, the significance of performance comes from the English language, from the verb *to perform*, which signifies the regular accomplishment of a thing that requires ability or a certain skill. The noun *performance* denotes the manner of achieving the objectives predetermined by an entity.

## 2. Research methodology

In order to achieve all the objectives referring to the scientific research, this particular research is based on certain methods of the scientific inquiry, methods which will be outlined further on. Thus, throughout this scientific approach, we used the method of theoretical study and analysis in order to extrapolate the research level regarding performance from the beginnings to present days. Furthermore, we used the comparative method for approaching theoretical aspects, aspects which are better emphasized with the help of this method by gathering them and then comparing them. The observation method is also used throughout this scientific approach, first appealing to its non-participating character, by exposing researchers' various opinions, and then to its participating character, by drawing some conclusions related to the presented approaches.

Regarding the research techniques and procedures which we used throughout this scientific approach, we considered the following: the study of specialised bibliography, using various bibliographic sources, such as regulations, articles and special books, statistical sources, gathering and then processing data, presenting theoretical aspects by using graphics-figures. The research this approach is based on is a fundamental one, which aims at the study of the performance concept, a characterization of this concept being based on certain criteria. Actually, this research pursues finding the answers to some questions, such as: -what does performance represent? – how can we classify performance? - what was the evolution of the notion of performance in time?, the research being done by studying special bibliography( books, articles) and carrying out a temporal analysis of the performance concept.

### 3. History of the performance concept

One of the major discussions in the contemporary market strategy refers to the decisive factors of the company's performances. Teachers from various fields focused on explaining the company performance and on identifying the sources of different levels of inter-firms performance. (McGahan and Porter 1997) . Nicoleta Barbuta-Misu (2008) states the fact that performance in a modern company may be defined as a state of competitiveness achieved through a high level of efficiency and productivity, having the goal of assuring a durable position on the market.

Nadia si Cătălin Albu (2005) consider the concept of performance as not being easy to define, because it is an ambiguous and integrative concept. Performance means success, competitiveness, achievement, action, constant effort, it is optimizing the present and protecting the future. Performance is created by a company through environmental reporting, following the way of creating value.

According to Alazard and Separi (1998) , performance leads to a global vision of interdependencies between internal and external parameters, quantitative and qualitative, technical and human, physical and financial ones of management.

The concept of performance is analyzed in time, being directly influenced by the evaluation criteria of it, thus we can find the following periods:

1. *Between 1957-1979*, a period when the evaluation of performance does not know a convergence, this one being defined on the basis of a *range of evaluation criteria*, such as: profitability, productivity, creativity, flexibility, adaptability, growth, development, market penetration, planning, quality of staff;
2. *Between 1981-1994*, a period when performance is defined as being a standard of the level of *achieving the organisational, strategic objectives*; thus, it is considered that an activity is successful if it achieves the goals. Under these circumstances, performance depends on the multiple established goals and objectives;
3. *Between 1995-2000*, when performance is defined according to *productivity and efficiency of the economic entity*, thus, by means of productivity, the results achieved at the involved means being reported, and by means of efficiency, the results achieved at the predicted results;
4. *From 2000 until present*, when performance is defined according to *value creation*. The success in a company activity lies in its capacity to identify the sources of value creation and to exploit them properly. The value is judged both from the products point of view and from the organization as a whole.

Throughout these periods, a gradual transition is made starting from the economic performance to the organizational and social one and then to the global one. Performance evolved altogether with society development, being in a permanent adjustment to the social and environmental conditions of the period to which the performance reference is made.

Lulia Jianu (2007) in the book *Evaluarea, prezentarea si analiza performantei întreprinderii*, makes a detailed presentation about the notion of performance, throughout its evolution, out of which we have considered relevant the views of the following authors:

- *Georgopoulos and Tannenbaum* (1957) consider it as being the equivalent of organizational efficiency, which represents the degree with which an organization, as social system and keeping in mind some limited resources and means, achieves

its goals without an excessive effort from its members. The criteria used for assessing performance are: productivity, flexibility, interorganizational tensions;

- *Yachtman and Seashore (1967)* define performance as being the company capacity to exploit the environment so as to achieve rare and essential resources to its function;

- *Price (1968)* considers that performance is synonymous with organizational effectiveness, and it uses the following as criteria of evaluating performance: productivity, conformity, institutionalizing;

- *Labrousse (1971)* characterizes company performance, during this period, as being a chain of attributes specific to it: a company capable of coping with foreign competition, a well-run company which manages to quantify its productive effort at minimum costs, a company capable of exploiting a niche and establishing an important enlargement;

- *Moh (1972)* identifies as criteria of evaluating performance: productivity, flexibility, adaptability;

- *Gibson (1973)* uses the following criteria in assessing performance: productivity, efficiency, satisfaction, flexibility, development, survival;

- *Harrison (1974)* defines performance as the final outcome of evaluating the effort;

- *Shashua and Goldschmidt (1974)* are the first researchers who managed to define the concept of financial performance, according to the following criteria: profit margin, share profitability, capital profitability, rate of operating capital, rate of activity. These criteria simply represent indicators for measuring profitability and financial position, indicating the enterprise performance;

- *Klein (1976)* sustains that performance is a subjective and relative notion, mentioning six indicators which highlight the company performance: growth of the added value, return on engaged capitals, growth of fixed assets, changes in the workforce, covering the operating needs from the working capital, appointed liability compared with self-financing capacity;

- *Dubois (1979)* does not define performance, but he assesses it using five rating indicators: growth, profitability, productivity, liability, solvency;

- *Bourguignon (1995)* defines performance as being determined by achieving the organizational objectives;

- *Burlaud and Langlois (1999)* considers that performance is not bad or good in itself. It is the same performance which can be evaluated as good if the objective is modest, or as bad if the objective is ambitious;

- *Cohen (1995)* makes a comparison between performance and efficiency and he sustains that performance assessment consists in comparing a monetary indicator showing the outcome of the company and a monetary indicator related to the employed means;

- *Lorino (1995)* considers that performance for an enterprise means everything that contributes to the improvement of the value-cost couple and not only what contributes to the cost decrease or to the value increase;

- *Porter (1986)* believes that the company performance depends on the ability to create value for its clients;

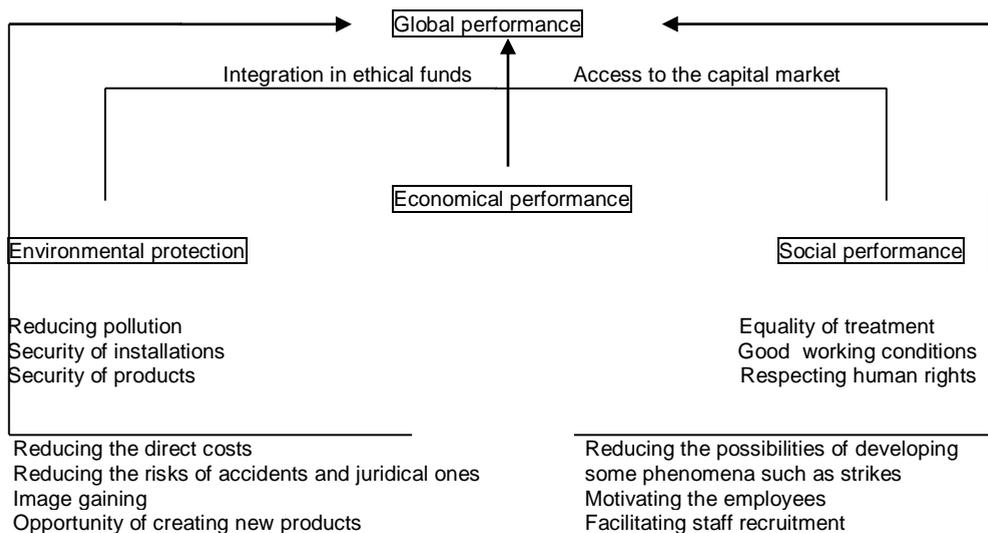

- *Marmuse (2000)* defines performance as being the one which allows maintaining a distance from the competition on a long term by being very motivated (based on the rewarding systems) applying to all members of the organisation;

- *Waterman (1995)* assimilates performance to the concept of excellence, which

is based on four factors: the organization efficiency, social identity, achieving the objectives, the reputation of the organizations.

Continuous performance is the ultimate goal which is intended to be achieved by any organization, because only by attaining it can growth and a further progress develop. This represents the most important quantifying key of an entity's success. At present, the goal is to achieve a global performance which is determined and conditioned by a mixture of internal and external parameters, technical and human, qualitative and quantitative ones. Global performance is a summation of the socio-economical performances with the ones of the environmental protection.

Reynaud (2003) manages to present global performance schematically by using the Figure 1:

**Figure 1** - Global performance of the entity  
Source – Reynaud , 2003

According to this figure, in order to achieve global performance all growing criteria of environmental performance must be monitored and carried out, as well as the economical one and last but not least the social one, among these criteria being noticed: reducing direct costs, image gaining, motivating the employees, increasing the profitability.

Based on the foregoing, on the definitions and characterizations made to performance over the years, we can conclude that performance represents the degree in which an entity comes to achieving both the internal and external environment, by an optimal combination between efficacy, economies and efficiency. Regardless the field we relate ourselves to, you cannot be a winner without knowing the purpose and the means, without tracing out a way to follow and the resources you need in order to develop the process in which you are involved, without being prepared and motivated to succeed. Without a proper management of an activity we cannot discuss about performance and a successful system.

#### 4. Performance defined using the 3E : efficiency, efficacy and economies, as forms of manifestation

Professor Mihai Ristea (2002) thinks that the following three concepts can be associated with performance: efficiency, economies and efficacy. This approach to performance was named by the professor as being the equation of the 3Es, and mathematically, it could be represented as follows:

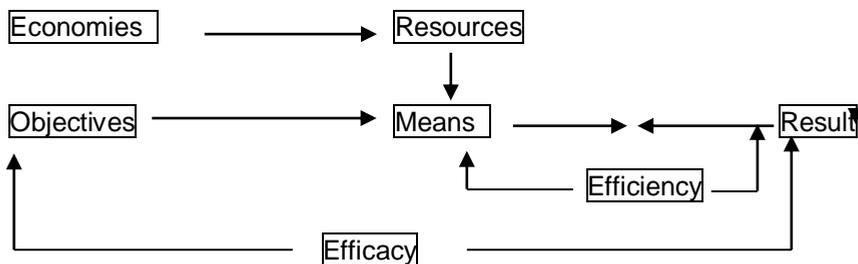

$$PERFORMANCE = EFFICIENCY + EFFICACY + ECONOMIES$$

It can be noticed the fact that an entity is successful when it is efficient, effective and economical. Therefore, to be successful means combining all three variables, the combination of which reflect the performance level of an entity.

*Efficiency* consists in either using a quantity given by resources, aimed at the highest level of the achieved results, or reducing the quantity of the used resources with the aim of achieving a predetermined result.

*Economies* consists in providing the means, the necessary resources to performing an activity at the minimum cost.

*Efficacy* is determined by achieving or exceeding the predetermined results to the actual results made throughout the development of the activity. This represents the ability of the enterprise to meet and even exceed the expectations of users of the accounting information (shareholders/associates, clients, suppliers, employees, government) at the same time with reaching the predetermined organizational objectives. An entity reaches efficacy when it manages to improve the way of using all sources which are available and necessary to the development of the activity, performing as well as possible the needs and the requirements of the external partners of the organization. Schematically, the relation between efficiency, efficacy, economies can be synthesized using the Figure 2:

**Figure 2** – Articulation of efficiency-efficacy-economies

Source- Jianu, 2007

It must be stated the fact that the correlation of the 3 Es leads to performance achievement only if this performance is long-lasting, having the target of achieving the strategic objectives.

Performance is a state of competitiveness of an enterprise, reached by a level of efficacy and efficiency which ensures a sustainable presence on the market, as those presented by Niculescu and Lavalette (1999) .

The notion of *efficiency* has known, throughout its history, more approaches in the professional literature . Some authors consider that an activity is efficient when the goal is achieved with the least effort. In this situation it is important to establish the level of correlation between the achieved results and the established objective, from which the activity developed becomes efficient.

As a general approach, efficiency is defined as the direct or indirect report between the useful achieved effects and the effort made:

$$Efficiency = \frac{Effect \text{ or } Effort}{Effort} \quad \frac{Effort}{Effect}$$

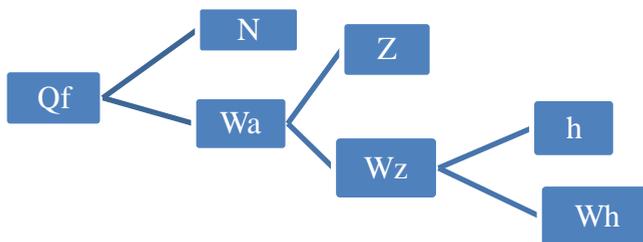

According to some researchers, a temporal character was assigned to this report, efficiency being defined as the maximum effect obtained at a certain level of expenses, in the shortest time.

Efficiency is found in many forms, depending on the activity which is carried out and the results which are obtained, thus being outlined the following forms of efficiency:

- *Productivity* – when determining the efficiency of using human resources ;
- *Profitability* – case when the capacity of making profit is assessed ;
- *Efficiency* – the decisive factor being the efficiency of using assets .

*The efficiency of using human resources* can be expressed by a series of rates designed by reporting the results obtained when using human resources. These results can be expressed by producing manufactured goods , by the exercise production, turnover, value added; while human resources used can be expressed by the average number of staff, total consumption of days-man or hours-man.

The influence of labour productivity on the production of manufactured goods is shown in the Figure 3:

**Figure 3** – The influence of labour productivity on the production of manufactured goods

Source – Camelia Burja, 2009

Profitability is a form of economic efficiency which highlights the financial results of an enterprise. It summarizes the quality of the conducted activities at every stage, at all levels; it synthesizes the productivity of factors of production consumption, the performance of all developed activities. Maximizing profitability is the aim of any capital holder, the goal of the entire activity taking place in a market economy. Profitability provides resources for both developing the respective economic activities and for increasing personal and public consumption.

Burja C. (2009) considers that the yield determined by the efficiency of using fixed assets expresses the report between the useful economic effect synthesized by a series of summary indicators ( goods production, turnover, value added , profit) and the value of fixed assets provided by the economic agents.

When you want to analyze the economic-financial performance of an entity it is used a series of indicators which transpose the achieved results on one hand and, on the other hand, the efforts made to have results with the purpose of achieving an analysis of the efficiency of the whole developed activity.

To summarize the above, we can say that performance represents a state of continuous competitiveness of the enterprise reached by a level of efficacy, economies and productivity (efficiency) which can guarantee a stable position on the market, position which must be improved permanently, considering the intense competition of our days.

As a result, efficacy represents a quantification of what is done, efficiency represents an indicator of how it is done and economies is a measure of the minimum cost of providing the sources for developing the activity; and the primary aim is reaching the objectives, simultaneously with providing the growth of maximum possible value.

The growth of value is found under different forms and this growth of value is presented as such to the users of accounting information such as shareholders, suppliers, clients, employees, banks. The higher the growth of value is at the organization level, the more resources it has in order to be able to reinvest them in the competitive struggle on a long term.

## **5. Conclusions and suggestions**

Regarding this scientific step, we can conclude that we have approached a complex theme, contemporary to global economy, and that is the performance of the economic entities, treated from the view of the evolution of defining this concept, of the way of approaching it, of the different forms of its manifestation.

The aim of this approach is to clarify the notion of performance. We can conclude from this approach that performance must not be regarded only from the economic and financial point of view, but it is necessary to include the aspects related to the environmental and social factors as well. We cannot discuss about performance without taking into account these two essential factors in current market conditions. Nowadays, the economic entities are under permanent pressure, thus we have higher and higher demands from shareholders, from employees, from clients, from suppliers and in order to be able to cope with all these requirements in optimal conditions, the entity must adapt to all these demands, this being the only way to discuss about global performance. This approach has attempted to present a synthesis of the concept of performance, the evolution of it in time, a definition of this concept using efficiency, efficacy, economies.

# AN ANALYSIS OF THE PERCEPTION OF CHARTERED ACCOUNTANT TRAINEES REGARDING ACCESS TO THE ACCOUNTING PROFESSION AND PROFESSIONAL TRAINING NEEDS

**Bunea Ștefan, Săcărin Marian, Gîrbină Maria Mădălina**

*Department of Accounting and Economic and Financial Analysis, Faculty of Accounting and Management Information Systems, Academy of Economic Studies, Bucharest, Romania*

[stefanbunea@cig.ase.ro](mailto:stefanbunea@cig.ase.ro)

[sacarinm@gmail.com](mailto:sacarinm@gmail.com)

[mgirbina@cig.ase.ro](mailto:mgirbina@cig.ase.ro)

**Abstract:** *In Romania, the certification of the quality of chartered accountant is accomplished by CECCAR<sup>(i)</sup>. It is conditioned by the completion of the period of initial training. A part of this period is provided by the universities, while the other part is provided by CECCAR through the national 3-year internship programme. The objective of our survey was to analyse the way in which chartered accountant trainees perceive the access to the accounting profession, their own limitations in terms of competences, the need for professional training, and the benefits ensured by the professional training within CECCAR. Being a member of IFAC<sup>(ii)</sup>, CECCAR has implemented the requirements of the international education standards. The results of the survey confirm that due to differences in their educational backgrounds trainees perceived certain barriers preventing their access to the accounting profession. They also considered that the training of chartered accountants should be provided by CECCAR rather than by the universities. The self-assessed competence level of trainees in fields such as accounting, taxation, or IT was appreciated as at least good, while the competences regarding organizations and businesses, international financial reporting, corporate governance, and financial markets were appreciated as modest. The need for professional training is assessed by trainees considering the immediate practice and not the expectations regarding future career development or future evolutions of accounting practices. The trainees in our survey do not consider necessary any investment in competences that they cannot use immediately at the level required by small and medium-sized businesses they work for. This implicates that results should be interpreted with caution and other factors (such as long term trends and expectations) should be considered in establishing the educational needs of future accountants.*

## 1. Introduction

In Romania, the professional training required in order to acquire the title of chartered accountant starts at the university level but continues with the internship programme provided by CECCAR.

Both graduates of the faculties in this field as well as graduates from other fields of economics have access to the accounting profession, provided they pass the

internship access examination. The requirements for the access to the accounting profession are defined by CECCAR taking into account the knowledge and competences provided by the universities for the graduates of the faculties in this field, but also the requirements of the international education standards (IES 1 "Entry requirements to professional accounting education programmes" and IES 2 "Content of professional accounting education programmes"), as well as the recommendations of the Ministry of Public Finance, the Ministry of Justice, and those of the business environment.

Over the past few years, the access to the accounting profession has been facilitated by the protocols concluded by CECCAR with the accounting Master's programmes provided by many of the universities in Romania. In order to access the internship programme without an entrance examination, it is necessary as the curriculum of the Master's programme in question to comprise at least 5 of the 7 disciplines for which one needs to take an exam in order to access the internship programme, and for the applicant to pass the examinations with a mark of 7 (out of 10) or above.

The CECCAR trainees come from different generations and have been educated at different universities. That is why it is very likely that they may perceive the access to the accounting profession in different ways. Irrespective of the way of access, the trainees meet to a reasonable degree the minimal requirements imposed by CECCAR. However, entry into the profession is perceived as being easy by some of the trainees and as difficult by others. The expectations in terms of the professional acquisitions within the internship programme also differ. The personal needs in terms of professional training may differ significantly, depending on the perspectives offered by the labour market, on the current activity of the trainees, on their predisposition to intellectual effort, and the individual's own standards regarding personal education and development.

## **2. Literature review**

In Romania, the scientific preoccupations regarding accounting education have been around for only a few years. These most often involve either the analysis of the coherence of the universities' curriculums with IFAC's international Education standards, or the analysis of the degree to which universities prepare graduates for the needs of the labour market.

Investigating whether the education of the young graduates ensured by the Romanian universities is adequate or not, in terms of the curriculum, to the employers' requirements, Diaconu P. et al. (2011) points out that the curriculums of the Romanian universities in the field of economics, although adequate in terms of theoretical knowledge, ought to be adjusted taking into account the needs of practice, especially in terms of the development of the personal skills which are very important in a competitive selection process: communication, initiative, motivation, honesty, capacity for analysis and synthesis, organization, etc.

Muțiu A. and Tiron A. (2009) conducted an evaluation of the stage of the curriculum provided by the Romanian universities regarding the disciplines which contribute to the development of the leadership abilities of graduates. Their conclusion was that Romanian universities provide the starting point for leadership development and prove that the degree of cohesion with the IES provisions has grown rapidly.

Albu et al. (2011) analysed the hybridization process of the accounting jobs in Romania during the period 2007-2009. The competences regarding the IFRS were

relatively unimportant to hybrid accountants in the first two years, but they gain a certain degree of relevance by 2009. From the analysis of the company websites, the requirements for IFRS knowledge occur mostly in the case of the branches of certain foreign entities. The authors identify a series of institutional, technical, and global factors, which determine an evolution toward the hybridization of the tasks that accountants have. They also analyse if the implementation of the IFRS is associated with any changes in the skills required by the employers or if they lead to the hybridization of the accountants' tasks.

The image and the role of professional accountants depend on certain stereotypes. In this context, there have been conducted studies with regard to appreciating whether the universities train specialists that correspond to the existing stereotypes of the accountant or if the universities take on an active role in the betterment of the image of professional accountants in society, in agreement with the tendencies followed by the profession (Albu et al., 2012).

It is the aim of the present survey to expand the area of investigation in terms of accounting education so as to include the manner in which future chartered accountants perceive the access to the accounting profession and the postgraduate professional trainees.

### **3. Research methodology**

The main objective of our survey was to analyse the way in which chartered accountant trainees perceive the entry into the profession, the professional requirements that need to be met in order for one to acquire the title of chartered accountant, and CECCAR's role in satisfying these needs through the internship programme.

In order to achieve this objective, we have tried to find out the following:

- Which are the fields of competence relevant to the access to the profession and which are either not represented or just poorly represented in the initial training stage (undergraduate/Master's level)?
- Which are the fields of competence which the trainees perceived as barriers hindering entry into the profession?
- Who should provide the training of the future chartered accountants (the universities or rather CECCAR)?
- How was the practical experience acquired?
- How do the trainees appreciate the level of competence in the various fields defined in the IES 2 standard issued by the IFAC?
- What are one's own professional training needs?
- Do the competences of a chartered accountant exceed the needs of the small and medium-size enterprise practices? Etc.

For this purpose we have put together a questionnaire with 19 questions, of which 15 are closed and 4 are open.

The questionnaire was distributed to a number of 200 trainees included in CECCAR's collective internship programme (either direct, during the technical training courses, or by e-mail). The questionnaire targeted trainees who passed the examination for access to the internship programme, who are enrolled with CECCAR's territorial branches (other than the Bucharest Branch and the Ilfov Branch), and who work in small and medium-sized enterprises (SMEs), but also in small offices (SMPs). The responses came from the following branches: Argeş, Gorj,

Mehedinți, Bihor, Satu Mare, Tîrgu Mureș, Arad, Timișoara, Vrancea, Bacău, Ialomița, and Constanța.

146 responses were received (response rate 73%), of which 18 were cancelled because they were incomplete. Consequently, the sample is made up of 128 respondents, of which 29 are men (22.65%) and 99 – women (77.35%). The structure by years of internship: 34.38% first year, 21.88% second year, 43.73% third year. The structure by age: 33.59% between 20 and 30 years of age; 39.06% between 30 and 40; 27.34% over 40.

60.93% of the respondents are graduates of a faculty of accounting or other departments in this field. 56.81% of the first year trainees have not graduated from a faculty/department in this field, while 71.42% of the second year trainees hold a degree in this speciality.

#### **4. Survey results**

A little more than half of the respondents consider that the accumulation of specialty knowledge and professional experience needed to obtain the professional qualifications in the field of accounting should be provided as part of the internship programme provided by CECCAR (58.59%) rather than by the universities (41.41%). These expectations regarding CECCAR's educational programme are more evident in the case of first year trainees (61.36%) and drop slightly in the case of second year (60.71%) and third year (55.36%) trainees.

Most of the respondents who are third year trainees and fall into the 20-30 years of age group consider that training in the field of accounting should be accomplished at the university (72.73%) rather than by the internship programme provided by CECCAR, while the trainees who fall into the age group of over 40 years are of the other opinion (78.57%).

This perception is determined by the fact that, over the past few years, the universities (especially those in the larger university centres) brought the curriculums of their faculties/departments in this field closer to the requirements for access to the profession. Access to the profession is perceived as being easier by the young trainees than it is by those who are part of the last age group. At the same time, the young trainees perceive the added value ensured by the completion of the internship programme provided by CECCAR less strongly than do those in the last age group. The concluding of protocols between CECCAR and the Master's programmes of many universities with a view to facilitating access to the internship programme without the need of an examination is appreciated very favourably by the trainees. These protocols involve the development, as part of the curriculum of the accredited Master's programmes, of the nucleus of competences that are absolutely necessary for access to the profession (at least 5 of the 7 disciplines required for the internship access examination need to be comprised by the curriculum, and the examinations need to be passed with a mark of 7 out of 10 or above).

The faculty one has graduated from does not seem to be a relevant factor in the perception of the trainees with regard to who should provide the professional knowledge and competences necessary for access to the profession (i.e., CECCAR versus the universities). 58.97% of the graduates of the faculties in this field and 58% of those who do not hold a degree in accounting opined that it is CECCAR that should ensure the achievement of the requirements for access to the profession. This situation is explained by the fact that, irrespective of the initial training, the

examination for access to the internship programme with a view to acquiring the title of chartered accountant allows the selection of candidates with a reasonable and comparable level of knowledge, in accordance with the CECCAR requirements. These requirements involve the acquisition of knowledge and competences ensured by the faculties/departments in this field. These requirements are covered by the graduates of faculties other than the faculties in this field through individual effort, practical experience, and the support provided by CECCAR in the training of the candidates for the access examination.

The respondents consider that the larger part of their specialty knowledge and competences are the result of the professional experience acquired with the aid of the employers and of a favourable work environment (56.82% of the first year trainees and 60.71% of the second and third year trainees, respectively).

The percentage of those who consider that the current professional level is rather a result of the internship programme provided by CECCAR increases from one internship year to the next (9.09% of the first year trainees, 17.85% of the second year trainees, and 25% of the third year trainees). This evolution confirms an increase in the awareness of the existence of the added value ensured by CECCAR's educational programme as one advances inside this programme. However, the respondents tend to assign importance especially to the knowledge and competences used in the professional activity and they consequently attribute the greater part of their professional acquisitions either to specialty practice or to individual effort.

A reverse evolution in comparison to the one mentioned above is noted in terms of attributing the current professional level to the universities. It is the first year trainees who consider that a large part of the professional acquisitions were ensured by the universities (34.09%). The percentage drops as the trainees progress in their attending the internship programme provided by CECCAR and the respondents accumulate relevant practical experience (21.43% of the second year trainees and 14.29% of the third year trainees).

An analysis by age groups confirms the opinions collected according to internship years. The young specialists (age group 20-30) attribute their current professional level to the universities (44.19%). The same proportion (44.19%) of respondents in this age group attributes the professional level to enterprise practice. This situation is explained by the fact that 51.16% of the respondents comprised in this age category are graduates of a faculty in this field, the rest being graduates from faculties in other fields (48.84%).

The education programme provided by CECCAR is more appreciated by the respondents who fall into the latter age groups (by 18% of the ones aged 30-40 and 25.71% of those aged over 40) than it is by the ones of the first age group (11.63% of the ones aged 20-30).

This perception is justified by the respondents either by the fact that the internship programme covers a series of competences insufficiently represented in the initial training period, or by the fact that the programme ensures the development of new competences, and especially the maintenance of the existing knowledge and competences, in a context where enterprise practice favours the loss of a large part of this knowledge and of these competences, as a result of the limitations imposed by the job requirements (most of the respondents work as employees with SMEs or SMPs and so do not use except part of the competences ensured by the access to the profession and, subsequently, by the internship programme).

The respondents were asked to appreciate how they acquired the practical experience that they have. Regardless of the internship year and age group, the perception of the respondents is that the role of the employer and the existence of a favourable work environment, on the one hand, and also the existence of mentors, on the other hand, are the essential factors in the acquisition of relevant practical experience (from 70.45% in the case of first year trainees to 83.33% in the case of third year trainees). It is the first year trainees who insisted that their practical experience was the result of their individual effort, in a situation where no one was willing to provide any help in this sense (29.55%). In terms of age group, it is the especially those in the first group (26.19%) and those in the last group (28.57%) who have the same perception.

This perception is much weaker among the third year trainees (16.67%), but also among those aged 30-40 (14.29%).

Given the differences that still exist among the curriculums of the faculties in this field but also given the differences in the manner of the approach of the content elements of the disciplines involved in the access examination for the acquisition of the title of chartered accountant organized by CECCAR, we have tried to identify those competence domains which were either not represented or just poorly represented in the curriculums and in the content elements during the initial education (undergraduate and/or Master's level, as the case may be).

**Table 1:** The domains not represented or poorly represented in the curriculums during the initial education period (undergraduate and/or Master's level).

Competence domains: a) Financial Accounting compliant with the European directives; IFRS; c) Management Accounting; d) Performance Management; e) Consolidated Accounts; f) Audit; g) Evaluation; h) Forensic Accounting; i) Law; j) Professional Ethics.			
Total respondents	Year I	Year II	Year III
b)89.84%	b)81.82%	b)100.00%	b)91.07%
e)66.41%	e)70.45%	j)82.14%	j)62.50%
j) 62.50%	h)61.36%	e)78.57%	e)57.14%
h)52.34%	f)56.82%	i)67.86%	h)48.21%
i)47.66%	j)50.00%	h)46.43%	i)44.64%
f)36.72%	i)38.64%	c)42.86%	c)39.29%
c)35.94%	g)29.55%	j)17.86%	f)30.36%
g)23.44%	c)27.27%	g)17.86%	g)21.43%
d)15.63%	d)25.00%	d)7.14%	d)12.5%
a)5.47%	a) 6.82%	a) 7.14%	a) 3.57%

Let us arrange in descending order the competence domains not represented or poorly represented in the course of the initial education, taking into account the opinions of all of the respondents: IFRS, Consolidated Accounts, Accounting Ethics and Doctrine, and Forensic Accounting. At the opposite end of the scale are domains such as Management Accounting, Evaluation, Performance Management, and Financial Accounting compliant with the European directives.

Because 39.07% of the respondents are not graduates of a faculty in this field, we have tried to check if the general order is also validated in the case of the group made up of the respondents who have a university degree in this field. The conclusion is that the order is confirmed in the case of 3 of the 4 disciplines (the opinion regarding Forensic Accounting was not validated). At present, most faculties/departments in this field have included in their undergraduate or Master's curriculums the discipline of Forensic Accounting.

The requirements of the examination for access to the internship with a view to acquiring the title of chartered accountant must be formulated taking into account the knowledge and competences ensured by the initial (i.e. undergraduate) education process. Despite all this, the respondents perceive the existence of certain barriers hindering access to the profession.

The evaluation of the knowledge and competences taken into account in order to define the minimal requirements for the access examination involves the curriculums of the faculties in this field from the large university centres, especially those of the Academy of Economic Studies, Bucharest. Although there is a certain degree of convergence among the universities' curriculums, the de facto convergence is much weaker.

In descending order, the perception of the respondents regarding the existence of barriers hindering access to the profession involves the following competence domains: IFRS (86,71%), Consolidated Accounts (72,65%), Law (39,06%), the Taxation (34,37%), Audit (31,25%), Professional Ethics and Doctrine (30,46%), Forensic Accounting (29,68%), Management Accounting and Performance Management (13,28%), Evaluation (12,5%), and Financial Accounting compliant with the European directives (10,93%).

The perception of the existence of these barriers is the consequence of several factors:

- the trainees belong to different generations and were educated at different schools (for instance, those who enter the profession after several years after they've completed their undergraduate studies perceive more acutely the existence of certain barriers, as a result of the fact that they need to cover a significant part of the requirements through individual effort;
- those who graduated from universities other than the Academy of Economic Studies, Bucharest, perceive the existence of certain barriers in terms of the requirements connected with IFRS and Consolidated Accounts);

At the Bucharest Academy of Economic Studies' Faculty of Accounting and Management Information Systems, the undergraduate curriculum includes three disciplines which are meant to develop competences for the understanding and application of IFRS (Financial Accounting compliant with IFRS, Consolidated Accounting, and Accounting Policies and Choices).

The Faculty of Economics and Business Management of the Babeş-Bolyai University of Cluj-Napoca does not comprise in its undergraduate curriculum the disciplines dedicated to the study of IFRS. Elements specific to IFRS and consolidated accounting are developed as part of the disciplines of Financial Accounting and Advanced Accounting. The discipline Taxation is missing from the curriculum, although elements of the general theory regarding the fiscal system are dealt with as part of the discipline Public Finances. The competences in terms of professional ethics and deontology are covered by the disciplines Accounting Deontology and Business Ethics.

The Accounting and Management Information Systems Department of the Faculty of Economic and Administrative Sciences, Alexandru Ioan Cuza University, Iași, does not have in its curriculum the disciplines dedicated to the study of IFRS. Elements regarding consolidated accounting are developed as part of the Master's programmes. Certain elements regarding IFRS are developed by the teaching staff in the context of the teaching of the discipline of Financial Accounting (in compliance with the European directives), as part of some comparative analyses of accounting policies, without being explicitly present in the syllabuses. Detailed knowledge regarding fiscal legislation is developed as part of the discipline Enterprise Fiscal Operations Accounting. The disciplines Forensic Accounting and Accounting Ethics and Doctrine are not included in the undergraduate curriculum but rather in the Master's level curriculums.

At the specialization Accounting and Management Information Systems within the Faculty of Economics and Business Administration of the West University of Timișoara, the discipline Consolidated Accounting, although optional, is selected by most of the students. The disciplines dedicated to the study of IFRS are developed as part of the Master's programmes. Elements regarding the understanding and application of IFRS are developed, by the choice of the teaching staff, as part of the discipline Financial Accounting. The discipline Forensic Accounting is mandatory. The study of Ethics and Deontology of the Accounting Profession is not included in the undergraduate curriculum, but is developed as part of the Master's programmes. The candidates must update, most often through their own efforts, the legislation right up to the date of the access examination (for instance, fiscal legislation undergoes changes at the turn of each year, and they are included in the new approved subjects, which are, however, not covered by the initial (i.e. undergraduate) education;

Having the respondents meet the minimal requirements for access to the profession demanded by CECCAR, we have tried to check in what manner they appreciate that they possess reasonable knowledge, taking into account the list of competence domains provided by IES 2. Consequently, we asked the respondents to appreciate on a 1-5 scale the level of knowledge in the fields stipulated by IFAC for the complementing of the competences necessary for acquiring the title of chartered accountant.

The competence domain where most of the respondents appreciate themselves as having a level that's at least "good" is Accounting and Financial Reporting for Businesses (Ministry of Public Finance Order no. 3055/2009 with the subsequent amendments) (level 4). In fields such as Taxation, Management information Systems, CECCAR's Professional Standards, Human Resources, and Management Accounting, the level is satisfactory. However, of the total respondents, 43.75% appreciate themselves as having a level that's at least "good" in the case of Taxation, 41.40% in the case of Management Information Systems, and 32.81% in the case of CECCAR's Professional Standards. Much fewer are those who appreciate that they have a competence level that's at least "good" in the case of Management Accounting (26.15% of the total) and Human Resources (7.81%).

We note that, for this set of competences, the percentage of those who have a level greater than 3 increases from one internship year to the next, which means that CECCAR's educational programme, doubled by the practical experience, contributes to the betterment of the respondents' perception with regard to their own competences.

The competences in the case of which the respondents appreciate themselves as having at least a reasonable level are the ones used in their current activity, most of these respondents being employed in small and medium-sized entities or small accounting offices (SMPs). With regard to Human Resources competences, it could be a misperception, because the respondents confine this competence domain to keeping the employee register and to calculating their salaries and social contributions and related taxes.

Public Institutions Accounting and Bank Accounting are fields which a year ago were not included in the set of minimal requirements formulated by CECCAR for the internship access examination with a view to acquiring the title of chartered accountant. At the moment, these requirements are limited, although most of the faculties in this field have included these disciplines among the mandatory disciplines in their undergraduate curriculums. This is the main cause that explains the very poor self-assessment level in these two domains. Only 7 of the respondents work in a public institution and only 4 in a credit institution.

Most of the respondents accuse the fact that neither in the initial education period nor within the educational programme provided by CECCAR is enough attention paid to the development of knowledge and especially competences regarding organizations and businesses, business administration, and the accountant's role in a business. Certain respondents considered that the interdisciplinary approach is lacking. Many of the respondents do not understand why they should invest in the development of competences in domains such as international finance, financial markets, enterprise finance, given the fact that the outlook does not justify such an effort (these domains are considered as being relevant to professionals who work in large organizations, strongly integrated in the financial system and connected to international trade).

Corporate governance is perceived as a theoretical discipline par excellence, useful in the development of management culture rather than having consequences in terms of the operation of organizations and risk management. The place and role of the professional accountant in corporate governance is a topic in connection with which most of the respondents are unable to express themselves. This field is developed by most universities as part of their Master's programmes. Elements of corporate governance are the object of presentations as part of management, finance, and audit courses.

These competences regarding organizations and businesses are not included in the trainees' training programme but are part of CECCAR's national continuing professional development programme. Each year, chartered accountants must attend, as part of this programme, at least 40 hours of continuing professional training.

## **5. Conclusions**

The results of the survey confirm that a large percentage of the trainees perceive certain barriers to the access to the accounting profession due to differences in their educational background and consider that the training of the specialist accountants should be provided rather by CECCAR than by the universities. The access to the profession is perceived as being easier by the young trainees than by those who are part of the last age group. This could be explained by differences in motivation but also in higher support offered by universities in the case of younger trainees. At the same time, the young trainees perceive the added value ensured by the completion

of the internship programme provided by CECCAR less strongly than do those in the last age group. The disciplines most often indicated for not passing the access examination were, in this order: Law, The Fiscal System, Forensic Accounting, Accounting, Evaluation, Audit, and the Ethics and Doctrine of the Accounting Profession. These opinions are coherent with the ones shown by the respondents with regard to the perception of the existence of barriers to the access exam.

The self assessed competence level in fields such as accounting, the fiscal system, and IT was appreciated as at least "good" while the competences regarding organizations and businesses, IFRS, corporate governance, and financial markets was appreciated as deficient. The need for professional training was assessed based on the immediate practice and not on the expectations regarding career development or future evolutions in accounting practice. The trainees do not consider necessary any investment in competences that they cannot use immediately and at the level required by small and medium-sized businesses. Most of the respondents consider that the level of professional knowledge and competences acquired by chartered accountants in Romania as a result of passing the skills examination organized by CECCAR is superior to the competences required by the practical activity in a small or medium-sized enterprise (57.81%). Only 35.39% consider that these competences are adequate to the needs of small and medium-sized enterprises.. This implicates that results should be interpreted with caution and other factors (such as long term trends and expectations) should be considered in establishing the educational needs of future accountants.

The main limitation of our research is the fact that we have not considered the Bucharest-Ilfov region trainees. We intend to conduct a separate study for these trainees as we expect some of them to hold more complex and demanding jobs. In addition, most of them are graduates of ASE Bucharest and it is likely that their perception on these issues be different.

We intend to obtain additional information and relevant conclusions using superior statistical tools. We want to expand the field of research on the elements of competence perceived as having the greatest contribution to enhancing the usefulness of professional accountants.

## THE RELEVANCE OF ACCOUNTING INFORMATION GENERATED BY THE APPLICATION OF IAS 29 RELATED TO SHAREHOLDERS CAPITAL

Bunget Ovidiu, Dumitrescu Alin, Deliu Delia

*West University of Timișoara, Faculty of Economics and Business Administration*

**Abstract:** *The current economic environment evolves under globalization circumstances, and it stands for the markets' globalization trend. Under these circumstances, information has a primordial role. The content of the transmitted information has changed significantly. As part of the economic information, the accounting information evolved as well and its whole circuit has been continuously modernized in the rhythm of the global changes. Thus, it had to adapt to the swing of capital markets worldwide and to aim toward a unique international accounting language, for the taste and understanding of its users.*

*Historically, Romanian accounting records have been heavily influenced by the use of information for tax compliance purposes.*

*The primary function of financial/accounting details collection and recording process has been seen by many Romanian entities and management/staff within the entities (both State and private) as being for taxation compliance and taxation reporting purposes. As a result of this, the reported information has tended to reflect a "form over substance" disclosure, that is, greater importance is placed on having particular documents or recording something in a specific way, rather than in "accurately" reflecting the financial position of the enterprise at a point in time or indicating whether the results for the period are an appropriate representation of what has occurred.*

*Romanian accounting laws and regulations are not as such at fault, with the regulations providing for and encouraging treatments that are consistent in many ways with international accounting principles. Issues have however arisen on how laws and regulations are applied and have tended to reflect the background and outlook of Romanian accountants.*

*Up to 31 December 2003, Romania was considered to be a hyperinflationary economy, under the criteria of IAS 29 "Financial reporting in hyperinflationary economies". For Romanian statutory reporting, IAS 29 was not applied. In looking at financial statements where there are significant non-monetary items, users should keep this in mind and consider if there have been any revaluation of tangible and intangible assets and on what basis.*

*The objective of IAS 29 is to establish specific standards for entities reporting in the currency of a hyperinflationary economy, so that the financial information provided is meaningful. Our empirical analysis encompasses a hyperinflationary economy covering a wide variety of hyperinflationary conditions.*

**Keywords:** *hyperinflation, IAS 29, monetary items, accounting information*

## **I. Introduction**

Starting with the financial year that ended at 31<sup>st</sup> of December 2012, the economical entities quoted on the Bucharest Stock Exchange were obliged to present their annual financial statements in accordance with the International Financial Reporting Standards (IFRS), in the way they were approved by the European Union, the legal requirement being stipulated by the Ordinance no. 881/2012 issued by the Finance Ministry and by the Ordinance no. 1286/2012 issued by the Finance Ministry for approving the Accounting Regulations in accordance with the International Accounting Standards, applicable for the companies holding stock exchange quotations.

Romanian entities are not on their first experience concerning the application of IFRS. Another precedent already exists – applying the Ordinance no. 94/2012 issued by the Finance Ministry for approving the Accounting Regulations harmonized with the 4<sup>th</sup> Directive of the European Economic Communities and with the International Accounting Standards, between 2001 and 2005, when the Romanian National Referential has been substituted for the one prescribed by OMFP no. 94/2012, by taking into consideration carrying out two out of three criteria regarding the turnover, total assets and number of employees.

The applying marked the beginning of a new stage in the life of the Romanian professional accountants through the new born challenges, although it was done in a „traditional” way, just like in the sketches of the Romanian writer Caragiale – „ok to get it revised, but without changing anything”. The adhering to the European Union meant also a step „aside” for the Romanian accounting, by giving up on the OMFP no. 94/2001 and applying accounting regulations in accordance with the European Directives; still, it is true that the substantial deviation that was already existing at the beginning of 2000 has disappeared.

The partial applying of the International Accounting Standards has had as a consequence the not applying of IAS 29, although, till the end of the financial year 2003, the Romanian accounting was characterized by hyperinflation. On 31<sup>st</sup> December 2012, this datum has changed – IFRS are being integrally applied, but the economic reality is different – almost 10 years had passed since Romania got out of the hyperinflation area.

## **II. Literature review / previous research**

Our study case’s premise starts from the economic reality of applying the IFRS starting with 31<sup>st</sup> of December 2012 and from the already existing materials in the specialty literature.

Since this debate is a new one – applying IFRS (and, in consequence, IAS 29) in Romania by the entities quoted on the capital market at 31<sup>st</sup> December 2012, we have not found any Romanian specialty literature that would have approached this subject until now. Also, the International specialty literature that approached this matter is extremely reduced.

Still, we can emphasize Higson's point of view<sup>12</sup> concerning IAS 29. Empirical evidence is presented on the efficacy of procedures summarised in IAS 29: Financial Reporting in Hyperinflationary Economies for estimating the loss in purchasing power from holding monetary items during hyperinflationary periods. His empirical analysis encompasses 32 hyperinflationary economies covering a wide variety of hyperinflationary conditions and spanning a period of more than 80 years. While the estimation procedures summarised in IAS 29 perform poorly under all the hyperinflationary conditions encompassed by our sample, they are especially poor when the rate of inflation accelerates towards the end of a relatively short hyperinflationary period. For these latter economies, the best estimate of the actual purchasing power loss is typically only a small fraction of the figure obtained under the IAS 29 procedures. For hyperinflations of longer duration, the IAS 29 procedures return estimated purchasing power losses that are typically around 10% larger than our best estimate of the actual losses. Higson also derives and empirically tests a general class of 'two point' estimation formulae that make more efficient use of the sparse information set on which the IAS 29 estimation procedures are based.

The results obtained from this procedure are encouraging and suggest it is possible to obtain reliable estimates of purchasing power losses using only sparse information sets provided realistic assumptions are made about the way monetary holdings respond to variations in the purchasing power of the currency.

### III. Research methodology

According to IAS 29 and IAS, the financial statements of an entity that reports in the currency of a hyperinflationary economy should be stated in terms of the measuring unit current at the balance sheet date; therefore, the non-monetary items should be restated by applying a general price index at the acquired or contribution date. The Standard states the fact that an economy is being considered hyperinflationary when, among other factors, the cumulative inflation rate over three years approaches, or exceeds, 100%.

In order to observe the application of IAS 29 stipulations by the Romanian entities that are quoted on the Bucharest Stock Exchange, we have selected a sample of five companies: Biofarm SA, Boromir Prod SA, Compa SA, Electroputere SA and Farmaceutica Remedia SA. The reason we chose these five is because they are the first five companies that published their preliminary financial statements at 31st December 2012 on the Bucharest Stock Exchange website, [www.bvb.ro](http://www.bvb.ro).

### IV. Research results

The continuous decrease of inflation and other factors connected to the characteristics of the Romanian economical environment, indicates that the economy, which had its functional currency adopted by the entities quoted on the Bucharest Stock Exchange, ceased to be under hyperinflation starting with 1<sup>st</sup>

<sup>12</sup> Higson, A., Shinozawa, Y., & Tippet, M. (2007). *IAS 29 and the cost of holding money under hyperinflationary conditions*. *Accounting and Business Research*, 37(2), 97-99,101-107,111,113-114,119-121. Retrieved from <http://search.proquest.com/docview/198109635?accountid=8107>

January 2004. This way, the amounts stated in the monetary unit at 31<sup>st</sup> December 2003 are treated as a basis for the valuation in the financial statements.

In the context of applying professional judgment, only three categories remain in the scope of inflating valuations: property, plant and equipment, share capital and reserves at 31<sup>st</sup> December 2003. Given that subsequent laws (from 31<sup>st</sup> December 2003 onwards) prescribed the revaluation of property, plant and equipment at fair market value, the application of revaluation by inflating becomes redundant.

*What happened to the value of the share capital?* It was more than often increased with revaluation surpluses before 31<sup>st</sup> December 2002, for the purpose of keeping a fair view on the financing sources. These revaluations under the prescriptions of IAS 29, must be written off from the value of the share capital, reclassifying them as retained earnings. The problem is that under Law no. 82 / 1991, accounting documents must be kept for ten years, thus giving rise to a high risk of being unable to perform the restatements, in the absence of proper documentation.

The accounting treatment for *inflating the share capital* is:

<b>118</b>	<b>=</b>	<b>1028</b>
<b>Retained earnings from the first time adoption of IAS 29</b>		<b>Adjustments to share capital</b>

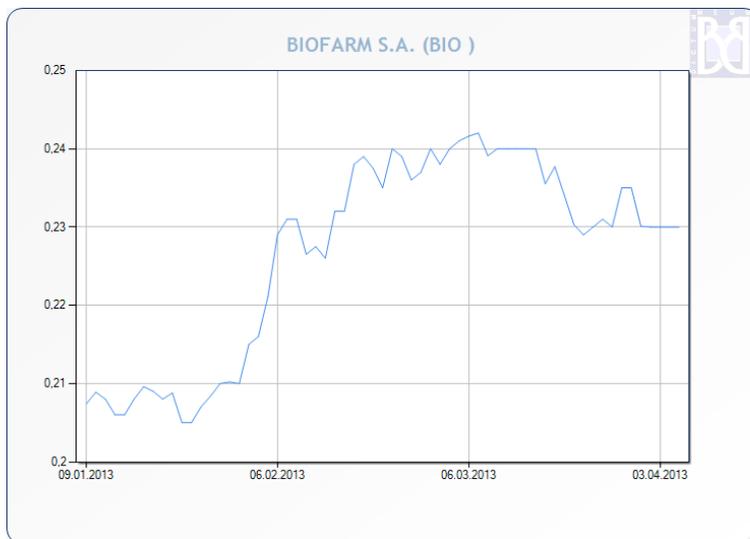

The effect is that the share capital is increased with the inflation differences, which in turn express nominal value loss of the currency. These differences are subsequently covered by the same extra capital resulting from the inflation. This way, the operation is reversed and at this point we question the motivation of performing the restatement in the first place.

There is a distinct possibility that a shareholder requests to withdraw from the capital structure of the entity, between the moment of submitting the financial statements, which contain the inflated capital, and the actual moment of covering the retained loss from the restatement. In this situation, *which is the valuation used to assess the shareholder's equity?* Based on the adjustment made on the presumption of hyperinflation, the valuation should be the inflated amount (which, as a parenthesis, can exceed the total value of share capital in existence before the inflation). An early conclusion can be drawn from here that the inflation of share capital can lead to the presentation of redundant information and to the representation of the capital structure in a manner far from being true and fair.

From our sample of five entities, we have found that three of them did not perform a share capital inflation: Farmaceutica Remedia SA, Compa SA and Electroputere SA. The remaining two, Biofarm SA and Boromir Prod SA presented, in their preliminary financial statements as at 31<sup>st</sup> December 2012, adjustments to share capital resulting from inflation, as follows:

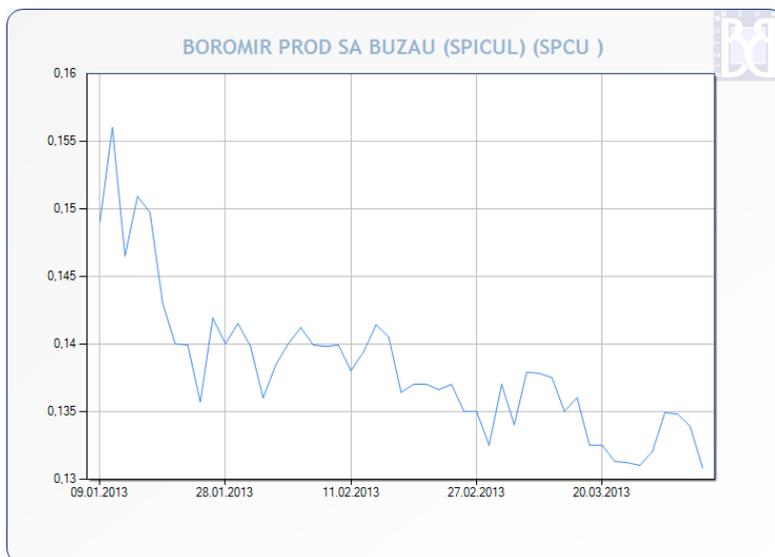

- i) Biofarm SA had a share capital of RON 109,486,150 as at 31<sup>st</sup> December 2012, and adjustments amounting to RON 24,983,008 representing adjustments to share capital based on the rate of inflation.
- ii) Boromir Prod SA had a share capital of RON 23,306,374 as at 31<sup>st</sup> December 2012, and adjustments amounting to RON 34,396,893 representing adjustments to share capital based on the rate of inflation.

In order to be able to draw a conclusion regarding the relevance of inflating the share capital as per IAS 29, we have followed the fluctuation of the exchange rate from the date of the preliminary financial statements at 31<sup>st</sup> December 2012, until 15<sup>th</sup> February 2013, as per the graphics below:

**Graphic no. 1** – Fluctuation of the exchange rate from the date of the preliminary financial statements

Source: <http://www.bvb.ro/ListedCompanies/EmitGrafic.aspx?s=BIO>

**Graphic no. 2** – Fluctuation of the exchange rate from the date of the preliminary financial statements

Source: <http://www.bvb.ro/ListedCompanies/EmitGrafic.aspx?s=SPCU>

It can be observed that a significant value resulting from the restatement of the share capital did not impact in large fluctuations in respect of the stock exchange rate.

## V. Conclusions

The conclusion of this paper is that the very relevance of the accounting information is questioned in the matter of inflating share capital as per IAS 29, along with the utility of such information.

There are also important costs with updating the share capital value with the National Office of the Commerce Registry and with the re-actualization, which is in fact supported by the going concern principle, meaning that the shareholders have provided financing sources which can be considered as being stated in real and not nominal currency terms.

The very same reporting framework indicates, in IAS 1, paragraph 23:

*In the extremely rare circumstance that the leadership concludes that comply with a requirement set out in a standard or interpretation, leading to confusion as to conflict with the objective of financial statements established in the Conceptual Framework, but the regulatory framework will ban fail to implement this requirement, the entity must reduce as far as practicable those aspects of performance that perceived as causing confusion by revealing the following information:*

- a. *The title of the Standard Interpretation or concerned, the nature of the invitation, as well as why management has concluded that compliance with the same confuse so that would conflict with the objective of the financial statements set out in the Framework;*
- b. *for each year presented, adjustments to each item of financial statements that management has concluded that it would take to achieve the true picture.*

In conclusion, some entities' management did not choose to consider the effects of hyperinflation on the share capital, because this aspect is, in their opinion, an accounting adjustment which does not reflect the legal nature of the capital holdings and which can give rise to confusion among the shareholders, as to the differences in share capital which would result in comparison to the statutory financial statements.

## **SOME DISCLOSURE ASPECTS REGARDING CONSOLIDATED FINANCIAL STATEMENTS**

**Cîrstea Andreea, Baltariu Alexandra-Carmen**

*Faculty of Economic Science and Business Administration, Babeş-Bolyai University, Cluj-Napoca, Romania*

*andreseverin@yahoo.com*

*baltariu\_alexandra@yahoo.com*

**Abstract:** *The purpose of this article is to analyze the current state of consolidated reporting practice harmonization concerning the choice of presenting the income statement, the changes in equity, the methods used for presenting the cash flow statement, the extant methods for evaluating and reporting goodwill, the extant methods in which jointly controlled entities are accounted in the consolidated financial statements, or the choice for recognizing investments in subsidiaries, jointly controlled entities and associates in the separate statements of the parent company. In order to achieve our goal we selected the first 10 groups, in order of their capitalization value, that were listed on each of the following capital markets: London Stock Exchange, NYSE Euronext (Paris Stock Exchange) and Deutsche Börse (Frankfurt Stock Exchange) and we analyzed, in a qualitative and in a quantitative manner, for a period of six years starting with 2007, their consolidated financial statements with the design to establish exactly which of the aspects stated in the International Financial Reporting Standards were being used for the items presented above. In order to complete the empirical research part of the paper that addresses from a comparative perspective the evaluation of the degree of material harmony between the reporting practices of groups listed on the three stock exchanges above-mentioned, we used statistical and mathematical methods represented by the I Index first described by Van der Tas. Taking into account the fact that since 2005 all listed companies on the European stock exchanges were required to adopt the international accounting standards for their consolidated financial disclosures, the degree of material harmony was studied only in reference to those requirements that presented two methods or possibilities of disclosure. Our findings suggest that the groups analyzed present a high degree of material harmonization with respect to the reporting practices considered, especially in the last three years.*

**Keywords:** *consolidated financial statements; disclosure; IAS/IFRS; accounting harmonization.*

**JEL classification:** M41

### **1. Introduction**

The preparation and presentation of consolidated financial statements has become, over time, a mandatory requirement for all group companies worldwide. This practice was first seen in USA and then was taken over by groups of companies in Europe. Nowadays, in Europe, listed groups should prepare a set of consolidated financial statements based on IFRS. This is required by EU Regulation no.1606/ 2002, which states that “member states are required to take appropriate measures to ensure compliance with international accounting standards” (EC, 2002). The obligation of listed groups to prepare consolidated financial statements based on IFRS, since

2005, comes as a first step, but also as a support for the efforts of regulators to implement a single set of international accounting standards accepted and used globally.

This paper brings into focus the analysis of some aspects which can give us a clearer picture of the presentation of information in the consolidated financial statements of listed companies in 3 stock exchanges with great impact on the European capital market, namely London Stock Exchange, NYSE Euronext and Deutsche Börse Group. The reason behind our choice of selecting the sampled data is described in the case study presented in third section of the paper.

First, we select the prior research findings, namely the literature review regarding the central theme of the article. Then, this research continues as follows: in the second section we present a brief description of the international accounting regulations concerning consolidated financial statements. In the third part, the empirical analysis of the disclosure of consolidated financial statements of listed groups is detailed in order to shape an idea about some important aspects for which IFRSs offer a choice. In the fourth part we expose our conclusions based on the findings in the case-study.

## **2. Literature Review**

We consider that two streams of literature are relevant to our study: studies on the accounting harmonization process and studies investigating the consolidated financial statements and their disclosure according to the international or national regulations.

International accounting harmonization and convergence represent one of the most debated issues both in research literature and in practice. Harmonization scope allows making comparisons of international financial accounts easier, faster and cheaper (Carlson, 1997). Thus, in order to provide more transparent and comparative information, the accounting standards setters join their forces for issuing a single set of standards applicable to all entities around the world. The process of harmonization and convergence plays an important role for the accounting systems and was in the attention of researchers since early '80s. The prior studies having as central theme the measure of accounting harmonization can be grouped in two main categories: studies that measure the formal harmonization (de jure harmonization) and studies that measure material harmonization (de facto harmonization). The first category includes studies that quantify the degree of compatibility between the international accounting standards, IAS/IFRS and national accounting standards. In this case, the literature include, among others, the studies of Tay and Parker (1990), Rahman et al. (1996), Aisbitt (2002), Garrido et al. (2002), Fontes et al. (2005), Ding et al. (2007). The second category consists of research papers aimed at analyzing the degree to which the provisions contained in international accounting standards IAS/IFRS are actually implemented in the practice, or in the preparation of financial statements. In this category we can mention the following studies: Canibano and Mora (2000), Parker and Morris (2001), Rahman et al. (2002), Delvaile et al. (2005), Aisbitt (2006), Baltariu and Cirstea (2012).

Regarding the design and the presentation of consolidated financial statements, we found analyzed in the research literature four main theories, that have an impact on the disclosure of information in consolidated financial statements (Abad et al., 2000

Baluch et al., 2010: 1-12; Grossi and Gardini, 2012: 1-28; Müller, 2010: 56-63). All these research studies brought an added value to the topic of consolidated financial statements reporting.

### **3. International Referential for Consolidated Financial Statements**

From the very beginning, the IASB has played an important role and had a substantial contribution to the international accounting harmonization process. The main objective of the regulatory body is to develop a single set of high quality, understandable, enforceable and globally accepted financial reporting standards based upon clearly articulated principles. There have been issued until now a number of 41 IASs and 13 IFRSs applicable to profit-oriented entities. Since 2001, almost 120 countries have required or permitted the use of IFRSs for their companies listed on the stock markets pioneering the way towards a global accounting harmonization. This trend of using a single set of accounting standards for reporting brings us to mind the following question “Can all accountants worldwide speak the same language?” (Rezaee et. al, 2010). Actually, the regulatory body committed to reduce the differences concerning the preparation and presentation of the financial statements, doing this because the financial reporting plays a key role in decision making. So, in other words, the financial statements are the main vehicle of information available for all users (Muniain, 2003). The financial statements are considered a key accountability tool for different users. Increasing relevance of financial statements is due to the existence of evidence of limited financial resources whose use must take into account social needs, the interest of stakeholders, the citizen rights, the quality and efficiency of the public services (Nistor and Stefanescu, 2012). The International standards underlying the preparation and presentation of consolidated financial statements are now: IFRS 10, 11 and 12. These were issued in 2011 and are applicable from 1 January 2013, actually replacing IAS 27, 28 and 31 which until 2013 were the basis for the preparation and presentation of consolidated financial statements of listed groups. Below we will briefly present the objective of each standard that was the basis of the preparation and presentation of consolidated financial statements of groups subject to our empirical study, namely IAS 27, 28 and 31.

Thus, IAS 27 has the twin objectives of setting standards to be applied: in the preparation and presentation of consolidated financial statements for a group of entities under the control of a parent; and in accounting for investments in subsidiaries, jointly controlled entities, and associates when an entity elects, or is required by local regulations, to present separate (non-consolidated) financial statements. IAS 27 Consolidated and Separate Financial Statements outlines when an entity must consolidate another entity, how to account for a change in ownership interest, how to prepare separate financial statements, and related disclosures. Consolidation is based on the concept of “control” and changes in ownership interests while control is maintained are accounted for as transactions between owners as owners in equity. (IAS 27.1)

IAS 28 Investments in Associates outlines the accounting for investments in associates. An associate is an entity over which an investor has significant influence, being the power to participate in the financial and operating policy decisions of the investee (but not control or joint control), and investments in associates are, with limited exceptions, required to be accounted for using the equity method. IAS 28

applies to all investments in which an investor has significant influence but not control or joint control except for investments held by a venture capital organization, mutual fund, unit trust, and similar entity that are designated under IAS 39 to be reported at fair value with fair value changes recognized in profit or loss (IAS 28.1).

IAS 31 Interests in Joint Ventures sets out the accounting for an entity's interests in various forms of joint ventures: jointly controlled operations, jointly controlled assets, and jointly controlled entities. The standard permits jointly controlled entities to be accounted for using either the equity method or by proportionate consolidation. IAS 31 applies to accounting for all interests in joint ventures and the reporting of joint venture assets, liabilities, income, and expenses in the financial statements of venture owners and investors, regardless of the structures or forms under which the joint venture activities take place, except for investments held by a venture capital organization, mutual fund, unit trust, and similar entity that (by election or requirement) are accounted for as under IAS 39 at fair value with fair value changes recognized in profit or loss (IAS 31.1).

## **4. Empirical Analysis – Case Study**

### **4.1. Description of Study-Sample**

As we can see in table 1, the groups included in our study were selected from the largest European capital markets, London Stock Exchange, Paris Stock Exchange and Frankfurt Stock Exchange, respectively. According to the European Federation of Stock Exchanges – FESE – taking into consideration the criteria of trade value and of turnover value, in January 2013, London Stock Exchange, NYSE Euronext and Deutsche Börse Group (Frankfurt Stock Exchange) were the largest stock exchanges in the European capital market (European Equity Market Report, 2013). From NYSE Euronext we selected Paris Stock Exchange as we considered it having the largest size and capitalization values. Afterwards, from each stock exchange we selected the first ten groups of companies included in the trading indexes FTSE100 (London Stock Exchange), NYSE Euronext100 (Paris Stock Exchange) and DAX30 (Frankfurt Stock Exchange) and considered them in order of their capitalization value. From the sample we excluded the groups which operate in the financial sector. Table 1 presents the remaining sample of groups included in our analysis. In order to extract the necessary information for our study, we consulted the documents containing the consolidated financial statements of the groups and the parent company individual financial statements (in most of the cases). The area of documents studied was comprised of the Annual Reports, the Reference Documents and the Financial Reports which were published on the groups' websites. All the groups considered were obliged to comply with the international financial reporting standards regarding their consolidated disclosures. The period analyzed included six years, namely: 2007, 2008, 2009, 2010, 2011 and 2012.

**Table 1: Study Sample**

No.	Company Name		
	<i>London Stock Exchange</i>	<i>Paris Stock Exchange</i>	<i>Frankfurt Stock Exchange</i>
1.	Vodafone Group plc.	Sanofi	SAP AG
2.	BP Plc.	Total	Siemens AG
3.	GlaxoSmithKline Plc.	L'Oréal	Bayer AG
4.	British American Tobacco Plc.	LVMH Moët Hennessy-Louis Vuitton	Basf SE
5.	Royal Dutch Shell Plc.	GDF Suez	Daimler AG
6.	SABMiller Plc.	Danone	BMW Group
7.	Diageo Plc.	EADS N.V.	Deutsche Telekom AG
8.	Rio Tinto Plc.	Schneider Electric	E.ON SE
9.	BHP Billiton Plc.	Air Liquide	The Linde Group
10.	AstraZeneca Plc.	EDF Electricité De France	Volkswagen AG

#### 4.2. Research Methodology and Results

This article approaches the theme of material (de facto) accounting harmonization within consolidated financial disclosures from an international perspective. De facto accounting harmonization is studied with respect to several elements and methods which will be presented in short in the next paragraph. The elements which we selected for analysis refer to disclosure requirements which are mandatory but present two possible methods of application. The choice of the method to be used in order to fulfil the disclosure requirement belongs to the entities. These methods regard the presentation of consolidated financial statements; the practices with respect to evaluation and reporting of goodwill and of joint ventures, more specifically of jointly controlled entities, known also as joint arrangements from IFRS 12 Disclosure of Interests in Other Entities (issued by the IASB in May 2011); and the evaluation and reporting of investments in subsidiaries, joint ventures and associates in the parent company individual financial statements. As we mentioned above, our analysis comprises several elements which are synthesized as follows:

- Element number 1 (E1): the disclosure requirement regarding the presentation of results of operations, as stated in IAS 1 Presentation of Financial Statements, which currently allows groups the choice of disclosure of either *a single, continuous statement* (method 1), or two separate statements – *an income statement* and *a statement of comprehensive income* (method 2).
- Element number 2 (E2): in the case of presenting the results in two separate statements, the disclosure of other comprehensive income can be done either in *a statement of comprehensive income* (method 1), or *in a statement of recognized income and expense directly in equity* (method 2).
- Element number 3 (E3): the disclosure requirement regarding changes in equity, which is stated in IAS 1. In this case we observed that some groups preferred to disclose the information regarding the changes that had occurred in equity in a separate statement – *the statement of changes in*

*equity* (method 1) – while other groups chose to disclose this information only in the *Notes to Consolidated Financial Statements* (method 2).

- Element number 4 (E4): as stated in IAS 7 Statement of Cash Flows, this statement may be drafted by using either *the direct method* (method 1), which shows each major class of gross cash receipts and gross cash payments, or *the indirect method* (method 2), which adjusts accrual basis net profit or loss for the effects of non-cash transactions.
- Element number 5 (E5): regarding the practice concerning the evaluation and reporting of goodwill, IFRS 3 Business Combinations allows the choice between *the full goodwill approach* (method 1) and *the purchase goodwill approach* (method 2). In the case of full goodwill approach, the total amount of goodwill (the parent company share, as well as the minority interests incumbent value) is taken into consideration and evaluated and the initial recognition is done based on the price paid by the acquiring company for purchasing the net assets of the acquire. Under the purchase approach, goodwill is presented as being equal to the amount (price) paid by the acquiring entity, considered at fair value, minus the fair value of the net assets of the acquired.
- Element number 6 (E6): with respect to interests in jointly controlled entities, the groups have a choice between: *the proportionate consolidation method* (method 1), whereby the group's proportionate interest in the assets, liabilities, revenues and expenses of jointly controlled entities are recognized within each applicable line item of the financial statements; or *the equity accounting method* (method 2), which involves recording the investment initially at cost to the group, including any goodwill on acquisition and adjusting in subsequent periods the carrying amount of the investment as to reflect the group's share of the jointly controlled entity' post-acquisition profit or losses and its share of post-acquisition comprehensive income.
- Element number 7 (E7): refers to the parent company individual financial statements in which the investments in subsidiaries, jointly controlled entities and associates are allowed to be recognized either *at fair value* (method 1), as stated in IFRS 3, or *at cost* (method 2), as stated in IAS 27 Consolidated and Separate Financial Statements.

The research methodology of the present paper includes both qualitative and quantitative research methods. Among the qualitative research methods the analysis of documents, the analysis of consolidated financial statements of groups included in the study-sample, the comparative and the interpretative methods are distinguished. As to the quantitative research methods, in order to complete the empirical research part of the paper that addresses from a comparative perspective the evaluation of the degree of material harmony between the reporting practices of groups listed on three stock exchanges, namely London Stock Exchange, Paris Stock Exchange and Frankfurt Stock Exchange, we used statistical and mathematical methods represented by the *I Index* first described by Van der Tas, 1988: 165-168. The *I Index* is a measurement method of financial reporting practice harmonization at an international level, which focuses on “the degree to which the companies in one country apply the same or only a limited number of alternative accounting methods, compared to the companies in another country” (Van der Tas, 1988: 165). Taking into account the fact that since 2005 all listed companies on the European stock exchanges were required to adopt the international accounting

standards for their consolidated financial disclosures (EC Regulation no. 1606/2002), the degree of material harmony was studied only in reference to those requirements that presented two methods or possibilities of disclosure. The I Index does not take into account multiple reporting and since our study encompasses groups of companies listed on three different stock exchanges, we considered the I Index developed for the case of more than two countries, namely the I Index with correction factor. The formula of the I Index with correction factor is as follows:

$$I^x = \left( \sum_{i=1}^n (f_i^1 x f_i^2 x \dots x f_i^m) \right)^{1/(m-1)} \quad (1)$$

Where:

$f_i$  = relative frequency of method  $i$  in country  $m$ ;  $m$  = number of countries;  $n$  = number of alternative accounting methods.

The values of I index can fluctuate between 0 (no harmony) and 1 (all companies from all countries included in the analysis are using the same reporting practice).

The results of the analysis are presented in table 2, table 3 and table 4. Tables 2 and 3 contain the results of analysis of the consolidated financial statements of groups included in the study-sample separated in two periods of time each comprising three years, 2007-2009 and 2010-2012 respectively. On each row of the two tables is presented the absolute number of groups which selected one of the two methods in order to disclose the elements that we described in the previous paragraph. The absolute number of groups is presented for each stock exchange and for each year separately. Table 4 presents on each of its rows the calculated value of the I Index with correction factor, namely the degree of material harmony extant between all groups included in this study regarding each of the reporting practices that we described above.

## 5. Conclusions and Limits of the Study

Based on the results obtained in the analysis, which were presented in the previous section in tables 2, 3 and 4, we can synthesize certain conclusions regarding the

degree of material harmony of reporting practices taken into consideration for the consolidated disclosures of the groups included in the sample. First of all, we can remark that with few exceptions, the degree of material harmonization was constant for each element taken into consideration throughout the period analyzed. The first exception regards the accrual of the value of the degree of material harmony for the first analyzed element, the disclosure requirement of results of operations. Since 2007 until 2012 the values of I Index with correction factor increased as we can see in table 4. We consider this change due to the fact that a revised form of IAS 1 was issued in September 2007, its requirements starting to be effective for annual periods beginning on, or after the 1<sup>st</sup> of January 2009. IAS 1 currently allows groups the choice of disclosure of either a single, continuous statement of comprehensive income, or two separate statements – an income statement and a statement of comprehensive income. After the revision of the standard more groups harmonized their practice of presentation of the income and comprehensive income. Another exception refers to the second element included in our analysis, the presentation of group results in two separate statements, the disclosure of other comprehensive income being done either in a statement of comprehensive income, or in a statement of recognized income and expense directly in equity. The first two values of I Index, for 2007 and 2008, are 1, this being due to the fact that all the groups analyzed which presented 2 separate income statements, were using for comprehensive income disclosure the statement of recognized income and expense directly in equity. Starting 2009, in the consolidated financial statements of some of the groups analyzed the disclosure of this item was done through the statement of comprehensive income. Thus, the value of I Index changed to 0,51. In 2011 and 2012, we can remark that the values of I Index increased again, this time due to the fact that a lot more of the groups disclosed their comprehensive income in the statement of comprehensive income. This can be considered another of the consequences of the revision of IAS 1. With respect to the third element of our analysis, we observe a constant increase in the values of the I Index with correction factor. An explanation of this increasing trend is the choice of groups to start presenting the disclosures regarding changes in equity directly in the statement of changes in equity, and only more detailed information in the Notes to Consolidated Financial Statements. With regard to the other four elements of our analysis we can remark that the values of the I Index with correction factor are almost constant throughout the entire period analyzed, with a larger number of groups showing preference for the indirect method of presenting the statement of cash-flow, the purchase goodwill approach, or for using the equity accounting method for the evaluation and presentation of investments in jointly controlled entities. The fact that in 2008 a review of IFRS 3 and IAS 27 took place, the full goodwill approach being thus introduced as a method of goodwill disclosure, did not have a great effect on the material harmony of goodwill disclosure practice within the groups analyzed, only two of them making use of the new method since 2010. Also, we can observe that the I Index's values for the seventh element analyzed are 1 starting 2007 until 2012, all the groups which presented the parent company individual financial statements in their annual reports preferring to evaluate the investments in subsidiaries, jointly controlled entities and associates at cost.

Our paper makes a contribution to the extant literature on material harmonization of the consolidated financial reporting practice by examining the current state of de facto harmonization regarding several reporting practices in the consolidated

financial statements of 30 groups listed on three different stock exchanges. Our findings suggest that the groups analyzed present a high degree of material harmonization with respect to the reporting practices considered, especially in the last three years, 2010, 2011 and 2012. The limitations of our research – the small number of groups sampled, the use of a single quantitative method for the analysis – do not allow us to draw any general conclusions with respect to the degree of material harmony extant between all the listed groups on the respective capital markets. These limitations, however, are being considered as challenges that can be addressed in our future research.

## BUSINESS MODELS FOR TAX AND TRANSFER PRICING PURPOSES

**Corlaci Alexandra**

*<sup>1</sup>Accounting and Audit Department, Faculty of Economics and Business Administration, Babes-Bolyai University, Cluj-Napoca, Romania*  
[alexandracorlaci@yahoo.com](mailto:alexandracorlaci@yahoo.com)

**Abstract:** *In order to remain competitive, the multinational enterprises (MNEs) are forced by the globalization phenomenon (which manifestation has become more and more stringent) to analyze continuously their effectiveness. In this respect, the structure of the business represents an element which might have an important impact for the enterprises overall results. This is why, in the last decades, the MNEs granted special attention to business structures and put significant efforts in business restructurings, where the case, with the scope to keep the efficiency and to remain on the market. Generally, the operational business restructuring process follows one of the business model globally developed, namely manufacturer or sales business models. Thus, according to the functions performed, assets used and risks assumed, the entities within the group are labeled into limited risk units (such as toll manufacturer or commission agent), medium risk (contract manufacturer, commissionaire, stripped distributor) or high risk units (fully fledged manufacturer, fully fledged distributor). Notwithstanding the above, there should be emphasized that the operational business restructuring has to be undertaken with maximal care, as it might have important fiscal impact. Having this regard, the purpose of the present investigation is to provide, from a tax and transfer pricing point of view, a systematic and structured analysis of the generally characteristics of business models (manufacturer and sales business models) used by multinational enterprises in the process of business reorganization, with the scope to increase their performance and the sustainable competitive advantages. Thus, by using the fundamental (theoretical) and qualitative research type, this paper is aiming to present the most important characteristics of each business model (general overview of each model, the principal risk assumed, the usual transfer pricing method used for the remuneration of intra-group transactions). The principal investigation techniques (research methods) used were the literature review and the analysis of international regulation in the taxation field. The present paper follows the positive research perspective.*

**Key words:** *business restructuring, business model, manufacturer models, sales models, transfer pricing*

### Introduction

In the present globalised economy, the international companies (regardless of products or sectors) face the pressure of increasing competition. Thus, they are bound to examine on a continuous basis the effectiveness of their business structures and to adjust their activity to these changing circumstances. As a consequence, the business restructurings undertaken by multinational enterprises have been a widespread phenomenon in recent decades because the globally competition forces them to maximize synergies and increase related efficiencies.

The need for an international company to change / to restructure its activity is generally underlay by both internal and external factors, such us: increasing demand in certain territory, changing customer demand, proximity to the sale market, various cost related factors (transportation cost, labor cost, energy cost, raw materials cost), savings from economies of scale, the need to increase the productivity by decreasing the costs, the need for specialization, centralization of functions etc.

Due to the development of global business models, the reorganization operations affecting an entity's industrial, commercial and supply chain processes has become increasingly common in the last years while taking various forms. These kind of industrial and commercial restructurings have complex and (often) significant consequences for international tax purposes, although tax considerations by themselves are generally not the principal driver for the reorganization.

From a transfer pricing point of view, the business reorganizations are defined as "cross-border redeployment by a multinational enterprise of its functions, assets and/or risks" (OECD Report – Transfer Pricing aspects on Business Restructurings). This paper is aiming to describe, from a tax and transfer pricing point of view, the general characteristics of the business models used in present times by multinational enterprises. We choose to analyze this subject as we consider this is a hot topic in the present globalised economy, due to the fact that business reorganizations might have a dramatic impact on the allocation of the taxable profits of a multinational enterprise among the countries in which it activates.

### **Research methodology**

The purpose of the present investigation is to describe, from a tax and transfer pricing point of view, the general characteristics of the business models used by multinational enterprises. In this paper, the fundamental research type was applied and the deductive research method was used (meaning that general conclusions were extracted based on available data).

One of the investigation techniques used was the literature research. We analyzed the international scientific literature on accounting and taxation topics, starting from older papers (Hirshleifer, 1956 & 1957; Dean; 1955 and Cook; 1955) to newest ones (Johnson, Christensen & Kagermann, 2008; Bakker, 2009). The papers observed were found in the following databases: SpringerLink, Jstor, Emerald and ScienceDirect. As a research key, we tried to found papers discussing about "business restructuring", "business reorganization", "transfer pricing impact in case of business restructuring" etc.

Another investigation technique used was the analysis of international regulations in taxation filed (OECD reports or discussion papers on Transfer Pricing topic: Transfer Pricing Guidelines for multinational enterprises and tax administration; Transfer Pricing aspects of business restructurings chapter IX of the Transfer Pricing Guidelines), with the scope to find out how the specialized international institution estimates the impact of business restructuring for tax and transfer pricing purposes. Moreover, we applied the comparison investigation technique, by using as comparison criteria: the assets used, the risks assumed, the function performed, the profitability (evidently, the profitability is growing up simultaneously with the functions and risks undertaken). According to the functions performed and risks assumed, the entities are labeled into limited risk units (such as toll manufacturer or commission agent), medium risk (contract manufacturer, commissionaire, stripped distributor) or high risk units (fully fledged manufacturer, fully fledged distributor). Further on in this

paper, the most important characteristics of each of the above types are presented by comparison with the other types.

### **Literature review**

The resource allocation and transfer pricing problem are topics with a long debate in the accounting, management science and economics literature.

According to the study conducted by Ho (2008), the international transfer pricing is a multidisciplinary research area involving aspects of accounting, marketing, behavioral sciences, business policy, international business, economics, finance, legal sciences, taxation. On the other hand, Sikka & Willmott (2010) consider that transfer pricing is at the intersection debates regarding: the MNE accounting, the social responsibility and the states right to tax.

The earliest studies on the transfer pricing issue were realized by Hirshleifer (1956 & 1957), Dean (1955) and Cook (1955) who provided the first reasons and were between the first sustainers of the later developed *decentralization theory*. For example, Dean wrote: "...the modern integrated multiple product firm functions best if it is made into a miniature of the competitive free enterprise system". Chang & Hong (2000), adepts of the decentralization theory as well, defines the business groups as "a gathering of formally independent firms under the single common administrative and financial control". According to Golub & McAfee (2011), the modern corporation is a semi-autonomous aggregation of business units that run transactions both between them and with entities outside the group.

There are a lot of studies suggesting that business groups provide efficient forms of governance in certain circumstances by showing that companies affiliated to groups tend to exhibit higher profitability than independent companies in the same countries (Ghemawat & Khanna, 1998; Khanna & Palepu, 1999; Chan & Choi, 1998). This approach relied on the *resource-based theory*, who emphasizes the role of both intangible and tangible resources as the ultimate source of competitive advantage and performance (Barney, 1986; Wernerfelt, 1984). Certain researchers (Pahalad & Hamel, 1990; Kogut & Zander, 1992; Teece, Pisano & Shuen, 1997) consider that intangible resources like brand or technology shared among group entities are particularly important sources of sustainable competitive advantage. This approach leads to the conclusion that a group possessing more intangible resources would exhibit higher performance.

In our times, in order to increase their performance, companies are faced to reorganize their activity by operating various restructurings which may involve cross-border transfers of valuable intangibles. Business model innovation (restructuring) is seen as material to obtaining profit and "focuses on aspects such as creating new markets, developing go-to-market initiative and innovation thereof, competitive disruption or competitive positioning and developing new value propositions" (Debruyne & Schoovaerts, 2006). According to Johnson, Christensen & Kagermann (2008), the elements of a succesul business model are: customer value proposition, key resources (resource based theory), key processes (diversification theory) and profit formula. They also consider that restructuring generally requires more effort than anticipated.

From a tax perspective, a business model's cost base and revenue potential are the most relevant aspects. In the value chain of getting the products to market, all business models have a certain organization of assets used, risks assumed and functions performed, that trigger the company's overall success (Bakker, 2009).

For tax and transfer pricing purposes, the fact that a multinational group entity is labeled as manufacturer, distributor or services provider has immediate effect of attaching consequences to the taxation of that company (Bakker, 2009).

### Business models for tax and transfer pricing purposes

Generally, a business model reorganization consist of “stripping out intangible assets, functions and risks which were normally integrated in local operations and transferring them to more specialized and centralized regional or global entities within the group” (OECD, 2010).

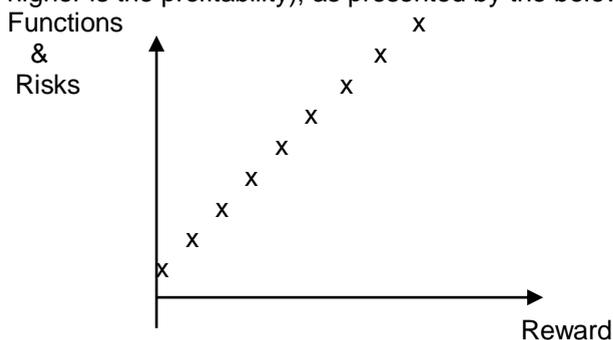

Thus, since the mid-90’s, business restructurings have usually involved the centralization of intangible assets and of risks with the potential profits that might be derived by them. The most used forms of business restructurings were represented by the following processes:

- Conversion of a full – fledged distributor into a limited risks distributor or a commissionaires for a related party operating as a principal;
- Conversion of a full – fledged manufacturer into a contract manufacturer or a toll manufacturer for a related party operating as a principal;
- Transfer of intangible property (IP) rights to a central entity within the group. (OECD, 2010).

Notwithstanding the above, there are also business restructurings which involve the allocation of more intangibles and more risks to operational units (manufacturers and distributors). Moreover, there are business restructurings consisting of the rationalization, specialization or de – specialization of operations, such as: research and development, manufacturing processes, manufacturing sites, distribution activities, marketing services etc.

However, independently of the business restructuring forms and reasons, there are certain typical transfers that might arise when such restructurings are put in place, as follows: transfer of tangible assets, transfer of intangible assets and transfer of activities (ongoing concern). Another feature common to all business restructurings is the fact that such a process always involves the reallocation of profits among the entities within the group, either immediately after the restructuring or over certain years.

Typically, the profitability of an entity depends on the functions performed and risk assumed (meaning that the higher are functions performed and risk assumed, the higher is the profitability), as presented by the below figure:

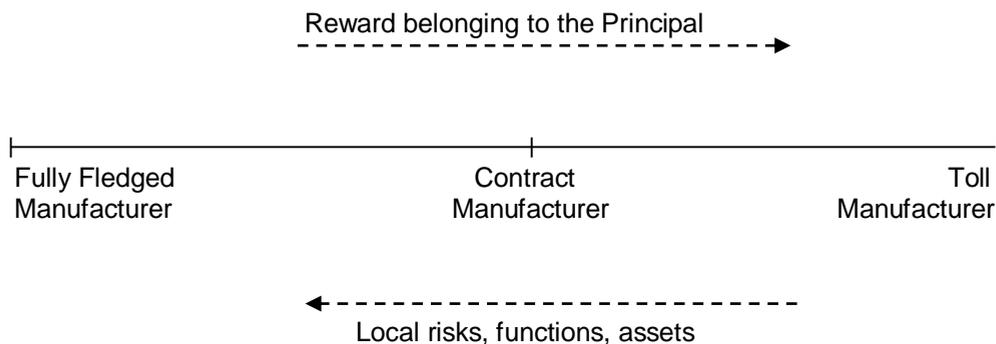

**Figure1.** Relation profitability – risks & functions

Source: realized by authors

In the bellow paragraphs there will be presented the most important characteristics, (from a tax and transfer pricing perspective) of manufacturer and sales business models

A. Manufacturer models

Manufacturing is the process of transformation from raw materials into finished goods. As presented in the chart below, manufacturing is generally performed in one of three risk/function models recognized for transfer pricing purposes: toll manufacturing, contract manufacturing and fully fledged manufacturing.

**Figure 2:** Manufacturer models

Source: realized by authors

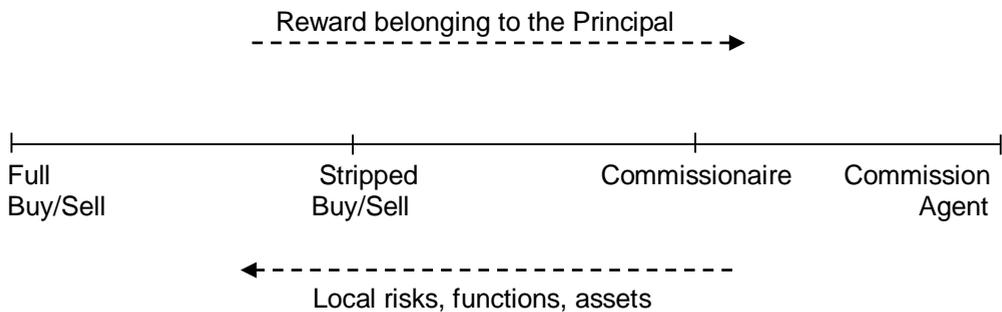

A toll manufacturer is actually a service provider which activity generally consists of processing raw materials following the specification and clearly instruction of the principal. The toll manufacturer does not become the owner of the raw-materials, work-in-progress or goods manufactured; it has no responsibility for production scheduling, procurement of raw material, quality control, distribution, logistic or revenues collections (Adams & Graham, 1999). Thus, such an entity assumes neither inventory risk and usually owns no valuable intangible (just routine manufacturing/processing skills). The transfer prices used for remunerating the operations performed by a toll manufacturer can be determined by using the cost-plus method or the transactional net margin method (assuming that the comparable uncontrolled price method – CUP, cannot be used).

A contract manufacturer generally provide manufacturing functions based on a written agreement, becomes the owner of the raw materials and the finished products and is responsible for processing the raw materials (quality control). The contract manufacturer bears the inventory risk, and generally bears more risks and responsibilities than a toll manufacturer, however, the procurement decisions, production scheduling and logistics remain with the principal. Also, the contract manufacturer does not hold valuable intangibles. As in case of a toll manufacturer, the transfer prices used for remunerate a contract manufacturer might be determined by applying the cost-plus method or the transactional net margin method (assuming that the comparable uncontrolled price method – CUP, cannot be used).

A fully fledged manufacturer typically assumes all the relevant functions related to the production process (sourcing and purchasing raw materials, finding clients, R&D - use of intangibles, production schedule, quality control, logistics) and also the associated risks (inventory risk, market risk, warranty risk etc). If the fully fledged manufacturer and the distributor with which it transacts use valuable intangible, the most appropriate method to be used for determining the transfer prices is the profit split method.

### B. Sales models

The sales or distribution represent the process by which a product/service is passed through the business system to the end-consumer. As in the manufacturer case, there are different types of distributors (depending on functions performed, risks assumed and assets used), as presented in the chart below:

**Figure 3:** Sales models  
Source: realized by authors

A commission agent is an intermediary that arranges the sales of products to customer on behalf and on the name of the principal, while the latter is the goods' owner and generally signs the sales contracts (no inventory risk for the commission agent). The remuneration for activity performed by the commission agent is typically based on the cost-plus method (assuming that the CUP method cannot be used), or a commission (percentage) on the sales.

A commissionaire is similar with the commission agent, with the difference that it sells the goods on behalf of the principal but in its name. The commissionaire does not become the owner of the goods and does not bear any inventory risk. The transfer prices used for remunerate a commissionaire might be determined by applying the resale-price method or the transactional net margin method (assuming that the comparable uncontrolled price method – CUP, cannot be used).

A stripped buy/sell distributor is similar to fully fledged distributor, with the difference that the former is stripped of certain functions and risks. The stripped buy/sell distributor become the owner of the goods sold (immediately prior to the sale to the client) and thus bears certain limited inventory risks. Also, the distributor acts in its account and in its name. As in case of a commissionaire, the transfer prices used for remunerate a stripped buy/sell distributor might be determined by applying the

resale-price method or the transactional net margin method (assuming that the comparable uncontrolled price method – CUP, cannot be used).

A fully fledged distributor is acting more autonomously than a stripped distributor; the activity performed is decentralized, with little or no central control or consistency.

#### Other transfer pricing aspects relevant for business restructurings

In order for a business restructuring to be in compliance with the transfer pricing rules, then, these rules have to be respected both by the restructuring itself and by the post restructuring transactions as well.

The arm's length principle (which is the international standard that OECD member countries have agreed should be used for establishing transfer prices for tax purposes) treats the entities within a group as separate units rather than inseparable parts of a single business. Consequently, for transfer pricing purposes, it is not enough that a restructuring process makes operational and commercial sense for the group as a whole, but the process should be arm's length at the level of each individual entity (taxpayer).

#### **Conclusions**

As a consequence of the globalized economy, the pressure of competition and the need for increasing the efficiency are important drivers for business restructurings. Generally, a business reorganization consist of "stripping out" intangible assets, functions and risks which were normally integrated in local operations and transferring them to more specialized and centralized regional or global entities within the group. The industrial and commercial restructurings have complex and (often) significant consequences for international tax purposes due to the major impact they have on the allocation of the taxable profits of a multinational enterprise among the countries in which it activates.

By using the fundamental research type, the literature review and comparison as investigation techniques, this paper was aiming to present, from a transfer pricing point of view, the general characteristics of business models used in present times. More exactly, the paper presented the general features of manufacturer business models (fully fledged manufacturer, contract manufacturer, toll manufacturer) and sales business models (fully fledged distributor, stripped distributor, commissionaire, commission agent).

**Abstract:** *In the scientific literature, accounting harmonization is a top topic because it helps to increase the comparability of financial statements. Also in Romania in the last 10 years became a topic that is very often debated. The harmonization is trying to reduce differences of financial reporting statements between countries or, in the other words, it is trying to bring to a common denominator of existing rules when appear conflicts of comparability between them. The purpose of this paper is to measure the harmonisation between national and international regulation for a significant element of financial position statement, such as noncurrent assets. This paper provides an empirical research of information that must be presented by entities which apply national accounting standards or international ones when financial statements are prepared, trying to measure the harmonization between the two referential. Thus, in trying to determine the harmonisation, we use the Jaccard coefficient in order to provide an overview of the degree of harmonization of accounting practice. When measuring the degree of comparability of Romanian accounting regulations with International Accounting Standards we analyzed noncurrent assets and impairment of assets using the Jaccard coefficient for accounting treatments and we calculated an average of similarities between the two regulations. Further, the results suggest that there is an average level of harmonization for the accounting treatment of noncurrent assets and for determining the impairment of the assets, the methods are the same. The study contributes to the development of accounting literature about the harmonisation between national regulation and international standards regarding the noncurrent assets and impairment of the assets, which together with the other elements define the activity of the business. In addition, the study provides an analysis of how the regulations treats noncurrent assets, during the life of the asset, namely: the recognition phase, the evaluation and the depreciation.*

**Keywords:** *Noncurrent assets, national and international regulations, accounting harmonisation measurement.*

## **1. Introduction**

International Financial Reporting Standards including International Accounting Standards (IAS) cover all aspects and regulations issued by the IASB regarding accounting standards. Companies in the European Union publicly traded are required to prepare financial statements in accordance with IFRS since 2005. IAS / IFRS are a set of principles and guidelines to approach accounting, with the stated purpose of providing information about the financial position and performance of the enterprise. This information will be useful to a broad group of users in making economic decisions.

OMPF 3055/2009 is a guide to the application of accounting regulations with European Directives. All entities in Romania must use these standards for conducting and preparing financial statements. As IAS / IFRS, these regulations provide information about the position and financial performance, and cash flows for the year ended, information that is useful to financial statements users.

In this respect, in Romania has made remarkable steps which led to considerable legislative progress by switching to the application of international accounting standards and accounting harmonization with the rules contained in the regulations in Europe. Thus, in our country since 1 January 2007, according to OMFP 1121/2006, companies that are listed on a regulated market are required to apply for financial statements IAS/IFRS referential. Entities which operate on a regulated market may choose to apply this referential, but there is no obligation to do so.

After introduction, the second section aims to present an overview of noncurrent assets and impairment of assets using the relevant literature. The third section provides the methodology research that we used for this paper. Also, this section includes the main elements chosen to be analyzed in the regulations. The next section is a case study, where we explained the similarities and differences between national regulation and international standards. The last section presents the conclusions regarding the accounting harmonization of both standards and some suggestions for further researches.

## **2. Literature review**

Information is considered a key element that helps to economic prediction for the entity, prediction that could not be made without relevant information. In making decisions, disclosure of information is essential and their absence leads to negative effects (Edmiston, 2011). The literature shows that reporting can be accomplished by establishing a common point between international standards and policies adopted by entities in practice (Kueppers and Sullivan, 2010).

In terms of tangible assets, Manea and Stefan (2009) analyses the criteria that must be met when recognize an asset as a tangible one and addresses the importance of recognizing for the first time a tangible asset. The conclusion of the research highlights the need of experience and professionalism of the company's management in order to avoid recognition of an asset in an improperly.

The domain of intangible assets is studied by Tiron Tudor and Dragu (2010), in researching the impact of international accounting standards on accounting practices harmonization with European Union. In the article, is a case study on the reporting of intangible assets, exposing differences arising, if any, on the financial statements of different companies that apply the same methods of recognition. The

research objective is to demonstrate trends of harmonization of EU member countries following the adoption of financial reporting standards.

Pozzoli et al (2011), based on an empirical study that analyzes the accounting treatment of intangible assets in the financial statements, assessing 90 listed companies in Italy between 2007-2009 which have reported financial statements in accordance with IAS / IFRS. The research focuses on the one hand, the presentation of intangible assets in the financial statements and on the other hand, the entity's ability to invest in the future in order to make a profit and be competitive in the market. The method used by the three authors is the application of ratios, such as: intangible assets and total assets held by the entity, impairment of intangible assets related to intangible assets.

Barth and Clinch (1998) demonstrated through the conducted researches that may result from the revaluation of assets both, increases and decreases, resulting relevant values. However, due to the nature of the asset, growth could affect the value of the relevant asset.

According to Pozzoli et al (2011) Impairment of assets (IAS36) is applied at least once per year and the entities apply impairment before preparing financial statements.

To determine the degree of harmonization of national accounting with IAS / IFRS, Ding et al (2007) have measured differences using two indicators:

- absence – highlighted item is covered only by the IAS / IFRS;
- divergence – identify an element which is defined in national regulations and IAS / IFRS, but have different accounting treatment.

Qu and Guohua (2010) identified relevant studies conducted on the harmonization of measurement methods using the Euclidean Distance, Jaccard coefficient and Spearman. In this respect a relevant example is the case study conducted by Fontes et al (2005), which measures the degree of harmonization of national standards from Portugal with IAS / IFRS, using financial statements entered between 1977 and 2003, first of all using Euclidean distance, followed later by the Jaccard coefficient and the Spearman method.

Also, Jaccard coefficient had been applied in Romanian literature by Mustata (2008), measuring the level of harmonization between national and international regulations, using computational tools such as Euclidean distance and Jaccard coefficient. The study revealed a degree of conformity between national regulations with the international standards and in the period 1973-2007 has been a significant increase. Thus, Jaccard coefficient was used for the case of intangible assets which are regulated in international accounting standard and national regulations (Dragu, 2010). Strouhal & co (2011) exemplifies the use Jaccard coefficient by measuring the degree of harmonization between national regulations of the countries: Romania, Estonia, Latvia, Czech Republic with International Accounting Standards.

### **3. Methodology research**

In this paper, determining the similarities and differences for the information on tangible assets, intangible assets and impairment of assets that must be disclosed, both for those who use national regulations and for those who use International Financial Reporting Standards for preparing financial statements, is done through the application Jaccard coefficient. The choice of this coefficient is due to the use in

the accounting literature a series of articles describing this factor, exemplified by measuring the degree of harmonization between national and international regulations, using the Jaccard coefficient. In our research, we try to measure the harmonization between OMFP 3055/2009 with IAS 16 "Property, plant and equipment", IAS 36 "Impairment of Assets" and IAS 38 "Intangible Assets". In this respect, by transposing the coefficients in the field of accounting, to determine the compatibility of the Romanian accounting regulation and IAS, the formula for calculating Jaccard coefficient is:

$$S_{ij} = a / (a + b + c)$$

and

$$D_{ij} = (b + c) / (a + b + c),$$

- $S_{ij}$  – the degree of similarity between the two sets of accounting regulations analyzed;
- $D_{ij}$  – the degree of differences between the two sets of accounting regulations analysed;
- $a$  – the number of elements which take the value "1" in both sets of regulations;
- $b$  - the number of elements which take the value "0" in both sets of regulations;
- $c$  - the number of elements which take the value "1" in set of rules "i" and the "0" set "j".

Each element analyzed and found in sets of accounting, whether national or international, is symbolized by the figure "1". For items that are not treated in any accounting regulations we allocated the number "0". For each set of accounting regulations, we selected items that they treat. Thus, we classified standards based on three criteria, namely: recognition, measurement and impairment. Then we divided each criterion according to which elements are characterized, then assigning the number "1" when both standards are dealing with the subject or a "0" if do not treat the selected item, it is insufficient mentioned or is not explained.

The criteria were chosen from international accounting standards and national regulations. Furthermore, we analyzed the assets using the recognition, measurement and depreciation for each criterion to establish the common points and the different treatment of the two regulations. Therefore, we determined for each particular criterion chosen the similarities ( $S_{ij}$ ) and the differences ( $D_{ij}$ ) between those two regulations. Thus, we determined the final values of selected regulations, in other words, the degree of similarities between national regulations (OMFP 3055/2009) and International Accounting Standards (IAS 16, IAS 36 and IAS38).

The checklist of the investigated elements were chosen because these represents the important steps when dealing with an asset. The study provides an analysis of how the regulations treats noncurrent assets, during the life of the asset, namely: the recognition phase, the evaluation and the depreciation.

The elements taken into consideration for each standard are:

- Intangible assets – *recognition*: formation expenses, development costs, patents, licenses, trademarks, brands, goodwill, customers lists; *evaluation – initial measurement*: acquisition cost, production cost; – *subsequent measurement*: book value, revalued value and residual value; *impairment – determination method*:

impairment tests, depreciation – *depreciation methods*: straight – line method; digressive method, accelerate method and units of production method.

■ Impairment of assets – *indicators of impairment – external sources*: market value, negative changes – *internal sources*: different changes, negative results; – *recognition*: book value is bigger than the recoverable value, recognize in the profit or losses of the period; – *evaluation*: recoverable value.

Thus, for tangible assets are followed seventeen elements, which are described or not in national regulation or in international standard. Also, for the intangible assets are verified sixteen items and for the impairment of assets are eight elements. Those elements were chosen from both regulations and checked if the element is explained or treated in standards.

#### **4. Comparative study on the accounting treatment of tangible and intangible assets in the national and international regulations**

##### **4.1. IAS 16 “Property, plant and equipment”**

Accounting treatment of the tangible assets such as property, plants and equipments which these receives in terms of national regulations (OMPF 3055/2009) and from the point of view of international accounting standards (IAS 16) are the following:

- International standards recognize the following as tangible assets: land, land improvements, buildings, installations, means of transport, technological equipment, offices equipment. An item that appears only in national legislation covers advances and tangible assets in progress which are shown separately in the category of tangible assets. Thus, under this criterion have a similarity of 75% and a degree difference of 25%.
- Initial evaluation is recognized in both sets of standards is carried at acquisition cost, production cost and fair value, in this case having a degree of similarity of 100%. Subsequent measurement is done using accounting value and the revalued value and is treated by both sets of accounting. International Accounting Standards recognizes the concept of residual value as the estimated amount after deducting the estimated costs of disposal, if the asset were already of the age and condition expected at the end of its life. For this criterion, the similarity is 67% and the difference is 33%. Thus, in terms of tangible asset valuation, the similarities between the two regulations are 85% and the difference is 15%, the only criterion differently treated by IAS 16 is the residual value.
- To determine impairment are applied tests but are recognized only by International Accounting Standards. Depreciation method is used for both sets of regulations. National regulations mentions four methods of determining depreciation and international standards find only 3 methods. Average recorded for impairment of assets is 67% similarity and 33% differentiation.

After calculating the Jaccard coefficient on the conformity of national legislation with international regarding tangible assets, we obtained a figure of 76.47% for similarities and the diversity is recorded at a rate of 23.53%.

## **4.2. IAS 38 "Intangible assets"**

From the point of view of the recognition of intangible assets note that there are differences between international standards and national regulation on expenses and customer lists. OMPF 3055/2009 clearly specifies that customer lists are not considered intangible assets. In terms of formation expenses, IAS 38 considers that it not fulfilled the criterion to be considered intangible assets, which are recognized directly as an expense in the income statement.

Initial measurement can be done at acquisition cost or production cost, terminology accepted and explained by both sets of standards. Regarding further evaluation there are some differences on the residual value. IAS 38 defines residual value, "the value of an intangible asset associated with finite useful life is zero, with the following exceptions: if there is a commitment by a third party to purchase the asset at the end of its life or when there is an active market for that intangible assets: residual value can be determined by reference to the same market and it is likely that such a market will exist at the end of the asset "(IAS 38), while the 3055 OMPF defines residual value as the fair value of good ("whether the financial statements are prepared in accordance with national regulations for the first time, the acquisition cost or production cost of an asset cannot be determined without undue expense or delay, the residual value at the beginning of the financial year may be treated as cost of acquisition or production, provisions disclosed in the notes "(OMFP 3055/2009 art. 67, paragraph 2)).

Depreciation, the component of the way in which is determined the impairment of intangible assets and is recognized and accepted by both regulations, but only international standards takes into consideration the impairment testing as another method of calculating impairment.

In terms of intangibles, national regulations against international standards, average exposed the issue, we note that the similarity of operations is in the proportion of 68.75%, and the differences between the two regulations are 31.25%.

## **4.3. IAS 36 "Impairment of Assets"**

The recognition impairment of the statements shown in the above, at the rate of 100%, according to international standards.

Indications of impairment are taken in both reglementations from internal sources: physical wear or moral changes: unproductive asset, restructuring plans, planning before the estimated date prior to disposal, the economy weaker than expected and the external: market value, changes with an adverse effect on the entity. Thus, for each source have assigned the value "1", that is, the similarity between the two measures is 100%.

Therefore, entities that prepare financial statements using accounting information from the national standards for impairment are the same as those who is using international standards for reporting financial statements.

## **5. Conclusions and Scope for Future Research**

In conclusion, accounting harmonization aims to improve comparability of financial information. International harmonization of accounting rules and practices seek to define the scope and content which can be determined, starting with normalization of accounting. The financial statements of a company have to provide information

on the position and financial performance, and cash flows. Usefulness of these documents is reflected in the economic decisions taken by users of information which they are intended. Also, financial statements offer managers a view of the entity, information which is used for set tangible objective. Furthermore, financial statement has to be transparent and correctly done, to provide an overview for the activity of the entity, these elements underpinning the development of strategies and objectives.

Regarding harmonization of national regulations with international accounting standards, we can say that the similarity of accounting treatment of noncurrent assets and the impairment of assets into the two standards is achieved in a proportion of 80%.

Future researches can focus on analyzing the information required to be disclosed regarding the noncurrent assets and the impairment of assets of the entities that are publicly traded and preparers of financial statements in accordance with International Accounting Standards.

*scrisan@kpmg.com*

**Abstract:** *Asset revaluation can trigger different signals to investors depending upon company type, asset intensity and category and investors' expectations. In the same time, motivations behind asset revaluation decisions are diverse, being influenced by management incentives, credit covenants, faithful representation and various other reasons. In many cases the revaluation decision is imposed upon the company by auditors or the need to reduce information asymmetry. In Romania, one of the main decision drivers is the Fiscal Code, due to buildings taxation provisions. For companies that revalue their fixed assets for taxation purposes only (which is the case for most small companies in Romania), the primary concern is to reduce the fiscal impact – the preferred scenario in this case is most likely to be the one that reduces tax expenses. Our research aims to provide a full picture of the motivations behind the revaluation decision and point to the manipulation instruments made available to companies by the allowed alternatives in what regards (1) which assets to be revalued and (2) how to recalculate book values. By means of a case study we identify the options available to a revaluating company and show how each one can impact the financial statements and financial ratios, thus influencing financial statement users' perception. Our analysis is limited to fixed assets revaluation, as these are the ones revaluated by most Romanian companies. The comparative analysis shows that the decision to not revalue certain assets categories can lead to serious distortions of the faithful image. Financial ratios can be significantly impacted by the type of assets revalued, depending upon the revaluation direction (upward or downward) and the revaluation differences. In upward revaluation leverage ratios and solvency can improve, leading to a better position in relation to credit covenants. Equity is also positively affected. Alternatively, a decrease of assets' value will be reflected in a negative manner upon these indicators, which might be a serious reason for a company to not revalue, thus not preserving the true and fair value of assets in the financial statements. Companies can choose between two alternatives of recalculating book values and depreciation. The option taken can also influence the company's financial position. Our study shows that impact over profitability is lower and that profit tax is not affected in a significant manner even if an influence can be identified.*

**Keywords:** *assets' revaluation, fair value, financial statements, motivations*

**JEL Classification:** *M49*

## **1. Introduction**

The motives behind companies' asset revaluation decision are diverse but are usually motivated by two main reasons: constraint or various other incentives. Constraint is usually due to specific financial reporting standards and / or national norms. In USA, the national accounting standards (US GAAP) do not allow upward revaluations while companies reporting under the International Financial Reporting

Standards (IFRS) can choose between the historical cost model and the fair value model. In Romania, Fiscal Code provisions include a buildings' taxation scheme that is directly correlated to their gross book value and revaluation frequency. Higher time spans between revaluations can lead to higher taxations quotas. Large and /or listed companies are audited and auditors will seek insurance that assets are reflected at fair value in the financial statements, imposing the companies to revalue their assets. Besides constraint one of the various motives can be investor's reaction to revaluation but there are other reasons too. Depending upon motivations behind the revaluation decision companies might revalue only some of their assets. The approach to valuation in itself and then to the accounting treatment will influence equity and the asset-related financial indicators of the revaluating company. The purpose of our research is to highlight the diverse motivations behind the assets' revaluation decision and to illustrate by means of a case study the manner in which the decision of which assets are to be revaluated, the valuation approach and the accounting treatment can influence relevant financial indicators. We believe that this analysis and its findings are useful to all parties involved (company, valuers and financial statement users), giving them insight to the particularities of the process, the sensitive spots and the degree to which financial statements can be manipulated. The article unfolds as follows: first, we present the research methodology used. Second, we make a literature review that summarises the literature's findings regarding motives and incentives behind revaluation decision and investor's reactions to revaluation. Third, by means of a case study, we present the impact over the company's financial statements following assets revaluation, considering several alternatives and highlighting the sensitive areas. Conclusions are presented in the end and we point to further research possibilities.

## **2. Research Methodology**

Our research is based on both literature review and case study. Literature review has involved a qualitative and quantitative analysis that led to a clustering of the revaluation motivations researched. We have relied during our literature review process on content analysis and comparative analysis. Our content analysis is orientated to the meaning of the studied documents. Comparative analysis was used in order to emphasis resemblances and differences between the articles studied and synthesize conclusions. We have also relied on interpretative analysis in order to compare conclusions with the status of Romanian companies' incentives behind revaluation decision. For the case study we have used mostly comparative, critical and interpretative analysis. The calculations made represent the quantitative aspect of our analysis. Comparative analysis is made for the interpretation of the effect of different alternatives chosen. In the end, critique and interpretative analysis is used to highlight the impact of decisions made during the process.

## **3. Literature Review**

The companies' financial statements information has a great deal of influence over the investor's actions (Gaeremynck and Veugelers, 1999). Financial statements users are primarily concerned with their relevance and credibility. While credibility is considered by some authors as a lesson fast learned, relevance, especially where fair value is involved, can be difficult (Kadous et. al, 2012). Studies made over a period of four decades show asset revaluation can have an influence over the companies' value and that fair value is a significant indicator for investors. Sharpe

and Walker (1975) found that stock prices increase for companies with upward revaluations while Standish and Ung (1982) considered that following revaluations companies' value only increases when stock owners have positive expectations. Revaluation and stock price are found to be directly related by Jaggi and Tsui (2001) while Bart and Clinch (1998) consider that revaluation of financial and tangible assets is correlated to market quotations while fixed assets revaluation is considered relevant only depending upon company type and when is made every three years or less. Kadous et. al (2012) find that the relevance of financial situation is influenced by the perception of users regarding the fair value estimation. So, in general, studies show that revaluation is generally considered to be relevant by investors but they perceive this revaluation in various ways, depending upon company, assets' intensity, approach of fair value measurement, geographical area etc. and is usually correlated with investors' expectations.

Reviewing academic researches made upon the subject of asset revaluation motivations we have found that there is a leading positivist stream of research based on empirical studies. We have analysed a number of eighteen studies made during the last 20 years on various geographical areas, mostly Great Britain and its influence areas, where revaluation was allowed before IFRS. The main motivations and incentives identified by these studies are:

- Better access to financing
- True and fair image of the company
- Signals for investors
- The intensity of assets
- The need to reduce information asymmetry
- Low liquidity
- Management opportunism
- Political costs (for large companies)

Many studies consider that better access to financing is a serious incentive behind asset revaluation decision and that asset revaluation can be a solution for companies at risk of violating financial covenants or with cash flow difficulties (Whittered and Chan, 1992; Brown, Izan and Loh, 1992; Easton et. al, 1993; Cotter and Zimmer, 1995; Black et. al, 1998; Gaeremynck and Veugelers, 1999; Jaggi and Tsui, 2001). During the last years though, there is research that takes the opposite view, finding that better credit leverage is no longer a motive for revaluation (Senga and Sub, 2010) and that this motivation's strength varies from a country to another (Barlev, 2007). A fair company value is considered to be better supported if companies include revaluation reserves in their book values (Easton et. al, 1993) and some companies revalue assets in order to signal the fair value of assets to investors (Jaggi and Tsui, 2001). Easton et. al (1993) consider that the level of revaluation reserves is a significant explanatory variable for the stock price of companies with important changes of debt-to-equity indicator but not for other companies. Revaluation of fixed assets is considered to be more reliable (Lynn and Peasnell, 2000) and is positively associated with the magnitude and intensity of assets and negatively with liquidity. Management opportunism is considered to be a motive for the decision of assets revaluation decision as this is considered a way to manipulate earnings (Black et. al, 1998; Quagli and Avalone, 2010). The need to reduce information asymmetry between management and shareholders' and other information users is also identified as a motivation (Quagli and Avalone, 2010).

These studies also point to several motives that lead companies to the decision to not revalue: high revaluation costs, conservative positions of internationally listed companies (Pierra, 2007), credibility issues (Gaeremynck and Veugelers, 1999, Lin and Peasnel, 2003, Cotter, 1999), a high quantity of assets, especially equipment and machinery (Easton et al, 1993), enough internal financing resources (Whittered and Chan 1992). Results are not always consistent from a study to another and there are limitations due to sampling and methods used and also due to the fact that the economic and legal environment of each country is also a relevant variable (Barlev et. al, 2007). We subscribe to Barlev's opinion that revaluation motivations are largely depending upon the specific legal and economic environment of each country. Without basing this conclusion on a study, but analysing Romania's regulation and practices, we believe that for Romanian companies the main revaluation motives are (1) Fiscal Code stipulations, (2) the need of correlation between the net book values and mortgage values estimated for company's assets that secure loans, (3) the need to reflect the fair value of assets in the financial statements (especially for listed companies or under the auditor's pressure) and (4) the need for equity improvement. Other motivations, as earnings management or reduction of information asymmetry might be also relevant but do not prevail.

#### **4. Case study**

We have used a case study to illustrate the possible impact over financial statements of various alternatives available when a company decides to revalue. Our aim is to identify the manner in which each option available to the company in this process can impact the financial statements and financial ratios, thus influencing financial statement users' perception. The case study will allow us a quantitative assessment of this impact, even if limited to the actual situation of the subject. Our analysis is limited to fixed assets revaluation, as these are the ones revaluated by most Romanian companies.

We have considered a company (hereinafter the "Company") with a relevant fixed assets intensity and also complex activity (production and trade). The Company owns land, buildings and equipment. Last revaluation made three years ago had as main purpose buildings' taxation and the Company only registered the values for the accounting group of Buildings (212). Our Company is currently in position to revalue its assets at the end of the financial year. This case study analyses the whole process, presenting first the current situation and revaluation decisions taken by the company as well as revaluation effects. We have then taken into consideration all alternative scenarios available for the company in order to do a comparative analysis of the financial impact (accounting and fiscal). The decision areas identified were: (1) to revalue or not the assets; (2) in case of a positive revaluation decision, which category of assets is to be revaluated; (3) for assets that get depreciated, which of the accounting treatment alternative allowed (for gross book value and depreciation calculation) should be considered.

Due to taxation issues the Company considers to revalue buildings at year end. The fixed assets structure before the yearend possible revaluation is presented in Table 1:

**Table 1 – Structure and weight of fixed assets**

<b>Structure and weight of fixed assets</b>	
Weight of tangible fixed assets in total fixed assets	99.65%
Weight of tangible fixed assets in total assets	40.80%
Tangible fixed assets distribution:	
- Land	0.59%
- Buildings	74.40%
- Equipment	25.01%

Source: Author's projection based on Company data

Tangible fixed assets represent over 40% of total assets, therefore an important weight. The land was never revalued which is an indication that the financial statements might not reflect a fair value for land. Land and constructions owned by the company compose a real estate property, made of three buildings and land with a 1,625 square meters area. The new valuation is made based on the income approach as the property is the type that generates revenues and this approach was considered relevant. In the end, the appraiser had to allocate the value between land and buildings, as the income approach lead to the value of the overall property. For value allocation the appraiser has deduced the market value estimated for land from the total value estimated for the property and the result was allocated to buildings. The resulted values are presented in Table 2. An analysis of the valuation report shows that the appraiser has chosen the upper value level for land, which has led to a smaller value allocated for buildings (motivated by taxation reasons).

**Table 2 – Valuation results and value allocation**

<b>Value allocation following revaluation</b>	
<b>Description</b>	<b>Fair Value (Lei)</b>
Total property of which	2,768,211
- Buildings	1,375,651
- Land	1,392,560

Source: Company valuation report

Revaluation differences are presented in Table 3.

**Table 3 – Revaluation differences**

<b>Revaluation results</b>					
	Yearend gross book value	Yearend depreciation	Yearend net book value	Estimated fair value	Revaluation differences
	Lei	Lei	Lei	Lei	Lei
Land	6,022	-	6,022	1,392,560	1,386,538
Buildings	807,724	65,680	742,044	1,375,651	633,607
<b>TOTAL</b>	<b>813,746</b>	<b>65,680</b>	<b>748,066</b>	<b>2,768,211</b>	<b>2,020,145</b>

Source: the Author

The Company decided to register only the revalued value of buildings and not the land. With regard to recalculation of gross book values and depreciation, OMFP 3055/2009 (in accordance with IAS 16 provisions) allows two alternative treatments:

- depreciation is calculated proportionally with the change within the asset value, the revalued value being the new net book value – coded by us as Treatment A
- depreciation is eliminated from the gross book value of the asset and the net book value is restated at the revalued value of the asset – coded by us as Treatment B

The Company decided for treatment B. The estimated fair value is the new book value (which equals the net book value) and depreciation becomes null.

**Table 4 – Book values recalculation**

<b>Recalculation of book values and depreciation - Treatment B</b>				
Recalculated gross book value	Yearend depreciation	Recalculated net book value	Yearly depreciation	Previous year depreciation
<b>Lei</b>	Lei	Lei	Lei	Lei
<b>1,375,651</b>	<b>0</b>	<b>1,375,651</b>	<b>30,570</b>	<b>17,822</b>

Source: the Author

*Alternative scenarios to be considered:*

At year end, the Company could choose between the following alternatives, which we have coded below:

- NO-REV - to make no revaluation
- B-REV - to evaluate only the buildings and recalculate book values and depreciation in accordance to one of the previously presented possibilities:
  - o B-REV\_A - accounting treatment A
  - o B-REV\_B - accounting treatment B (the chosen option)
- L&B-REV - to reevaluate both land and buildings and recalculate book values and depreciation for buildings in accordance to one of the previously presented possibilities:
  - o L&B-REV\_A - accounting treatment A
  - o L&B-REV\_B - accounting treatment B
- To reevaluate all fixed assets (including machinery and equipment) and choose one of the two accounting treatment alternatives (A or B).

Our case study considers the first five alternatives and the impact of each. The land fair value and revaluation differences were presented in Table 3. In Table 5 we present the recalculation of book values for alternative treatment A.

**Table 5 – Alternative recalculation of book values**

Recalculation of book values and depreciation – Scenario B-REV_A				
Recalculated gross book value	Yearend depreciation	Recalculated net book value	Yearly depreciation	Previous year depreciation
Lei	Lei	Lei	Lei	Lei
<b>1,497,413</b>	<b>121,762</b>	<b>1,375,651</b>	<b>33,276</b>	<b>17,822</b>

Source: the Author

The effects of the various alternatives are presented below.

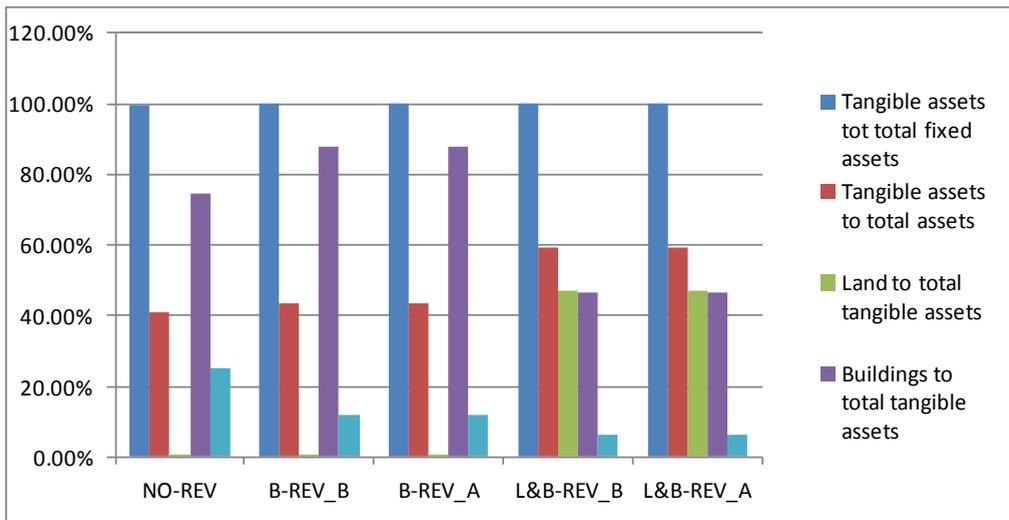

1. *Local taxes*: according to the Fiscal Code in force at the respective date, buildings' tax (applied to gross book value) is of 0.9% if a revaluation took place at least three years before or 5% if no revaluations were made. Table 6 illustrates the fiscal impact, showing an important increase with tax expenses for the no revaluation alternative. The smaller expense occurs for the alternative chosen by the Company (as this returns the smaller gross book value). The Company also registers an expense with valuation services which has to be considered. Land revaluation alternatives are not presented as land taxation is not related to land book values.

**Table 6 – Fiscal impact**

Buildings' tax expense modification				
Description	Previous year tax	Scenario		
		NO-REV	B-REV_A	B-REV_B
Tax quota	0.90%	5%	0.90%	0.90%
Tax on buildings (Lei)	7,270	40,386	13,477	12,381
<b>Yearly variation</b>		<b>556%</b>	<b>185%</b>	<b>170%</b>
Revaluation cost			3,000	3,000
Total expenses (Lei)	7,270	40,386	16,477	15,381
<b>Yearly variation</b>		<b>556%</b>	<b>227%</b>	<b>212%</b>

Source: the Author

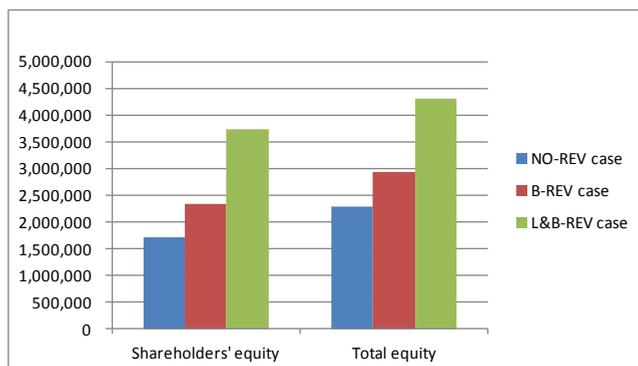

2. *Assets structure*: the fixed assets' structure will vary greatly (see Figure 1) depending upon the chosen scenario. While the weight of tangible fixed assets in total fixed assets does not exchange dramatically, their weight in total assets increases from 40% (the No-Rev case) to 59% (if the Company decides to register the land at fair value too). The fixed assets structure is significantly modified if the Company chooses to register the revaluated value of land, the land weight increasing from 1% to 47% in total tangible assets. It can be easily observed that before revaluation the financial statements do not reflect the true and fair value of assets and that the Company's option of not registering the newly estimated fair value for land leads to an unfaithful representation of the Company's worth.

**Figure 1** – Structure and weight of fixed assets

Source: the Author

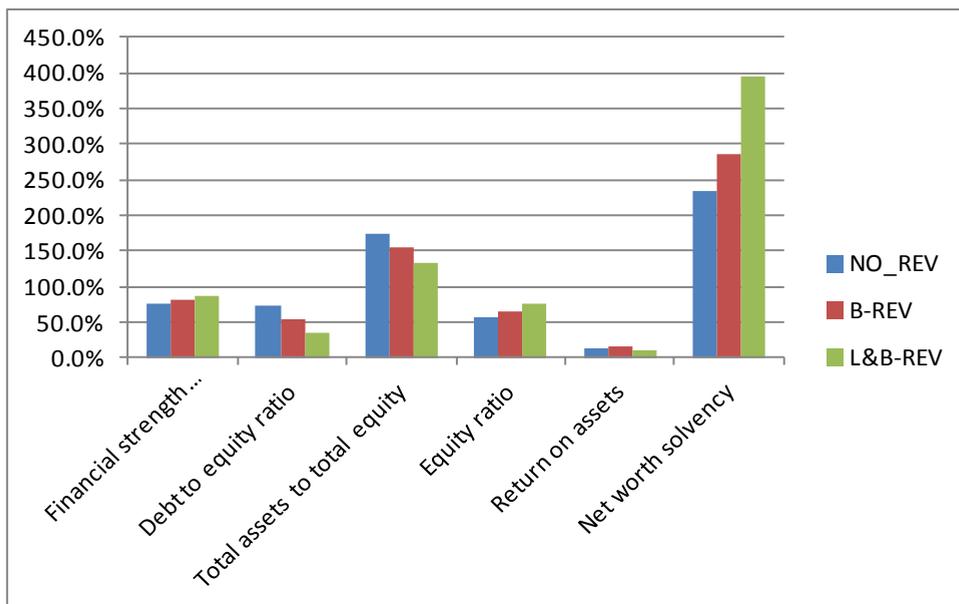

3. *Equity*: The increase of revaluation reserves leads to an increase in shareholders' equity and total equity. In this case, also, the highest increase (by 88%) takes place if the Company decides to register the estimated fair value for land too. Figure 2 presents the variation for three alternatives, as revaluation differences are the same regardless of the accounting treatment alternative chosen.

**Figure 2** – Equity variation

Source: the Author

4. *Financial ratios*: we have also analysed the impact upon the Company's several financial ratios for the 5 alternative scenarios presented. Modifications are obvious for financial leverage and solvability but overall, all financial indicators improve, especially if the new land value is also registered. From the analysed ratios, those that increase are financial strength ratios (illustrated here by shareholders' equity to total equity), equity ratio and net worth solvency. Leverage ratios as debt to equity and total assets to equity decrease, which enables the Company to have a better position in relation to credit covenants. Return on assets remains at a low level.

**Figure 3** – Financial ratios variations

Source: the Author

5. *Fiscal effects*: for fiscal effects we have pursued first the effect upon buildings' tax (presented in table 6). Company profit will be also affected by depreciation expense but only at accounting level, as supplementary depreciation is not a deductible expense. We have assumed that for the following year the Company will maintain the same level of revenues and expenses and analysed the effect over the accounting profit and profit tax generated by the depreciation and buildings' tax expenses for the five scenarios presented

**Table 7** – Comparative profit and loss situation

<b>Profit and loss</b>				
	Year end		Following year	
<i>'Lei</i>	<b>B-REV_A</b>	<b>B-REV_B</b>	<b>B-REV_A</b>	<b>B-REV_B</b>
Turnover	4,450,607	4,450,607	4,450,607	4,450,607
Operational revenues	4,477,668	4,477,668	4,477,668	4,477,668
Total operational expenses of which	3,783,293	3,783,293	3,801,766	3,805,761
- taxes	23,016	23,016	28,127	29,223
- depreciation	97,308	97,308	110,670	113,569
Operational margin	694,375	694,375	675,902	671,907
% operational margin	16%	16%	15%	15%
Financial margin	(48,781)	(48,781)	(48,781)	(48,781)

<b>Gross profit</b>	<b>645,594</b>	<b>645,594</b>	<b>627,121</b>	<b>623,126</b>
<b>Profit tax</b>	<b>105,601</b>	<b>105,601</b>	<b>105,034</b>	<b>104,859</b>
<b>Net result</b>	<b>539,993</b>	<b>539,993</b>	<b>522,086</b>	<b>518,267</b>

Source: The Author

Effects over gross profit are due to an increase of expenses with buildings' tax and depreciation. On the whole we have a small variation of the operational margin and effects upon profit tax are even smaller, as shown in Table 8 below:

Table 8 – Profit and profit tax variation

<b>Profit and profit tax variation</b>				
	<b>Year end</b>		<b>Following year</b>	
Lei	<b>B-REV_B</b>	<b>B-REV_A</b>	<b>B-REV_B</b>	<b>B-REV_A</b>
Operational result	694,375	694,375	675,902	671,907
<i>Yearly variation</i>			<i>-2.66%</i>	<i>-3.24%</i>
Gross profit	645,594	645,594	627,121	623,126
<i>Yearly variation</i>			<i>-2.86%</i>	<i>-3.48%</i>
Profit tax	105,601	105,601	105,034	104,859
<i>Yearly variation</i>			<i>-0.54%</i>	<i>-0.70%</i>

## 5. Conclusions

The literature review on the matter of motivations behind asset revaluation decisions and markets reaction to revaluation enables us to believe that there are cases where asset revaluation can bring significant changes in the company's financial statements and influence financial statement users' perception. Motivations behind revaluation decisions are diverse, stretching from the need to reflect the true and fair value of assets and reduce information asymmetry to the companies' need to improve equity and financial ratios demanded by credit covenants. For Romanian companies an important driver behind the revaluation decision is the buildings' taxation system.

The case study presented allows us to better understand the manner in which management's decisions can influence the financial statements structure after revaluation, offering insight to the particularities of the process, the sensitive spots and the degree to which financial statements can be manipulated. The company's management has at hand several options (to revalue or not, to revalue only some assets' categories and to recalculate book values) and each has an influence upon balance sheet elements and several financial ratios. Thus, depending upon incentives, management can be in a position to manipulate assets' revaluation to a certain degree which would serve their purpose better.

For Romanian companies that revalue their fixed assets for taxation purposes only (the case for most small companies in Romania), the primary concern is to reduce the fiscal impact – the preferred scenario in this case is most likely to be the one that reduces tax expenses. As land is not taxed at the registered value, companies are

not obliged to revalue the land unless they have other motivations (faithful representation, financial ratios improvement). The decision of not revaluing the land may lead to a distorted image of the assets' worth respectively of the financial statements. The comparative analysis shows that revaluation can have a strong impact over balance sheet elements as equity and asset related ratios, as leverage and solvency while profit and profit tax do not vary in a significant way. Depending upon the revaluation direction (upwards or downwards) and management's decisions regarding subsequent accounting treatment these ratios can improve the company's position in relation to credit covenants or the opposite. Therefore financial statements users have to be cautious in interpreting information following revaluation processes and ask for more details.

The analysis made is limited to the actual situation of the subject company considered and also to the ratios and balance sheet elements analysed. Many other research areas are possible, like a study made on Romanian revaluing companies in order to understand revaluation motivation drivers or preferred decisions following revaluations.

**Abstract:** Forestry plays a significant role in both our country's and global economy. Any entity, in the present case, forest entity, must operate under specific legislation and its own status. In this respect, the conduct of activities within the entities should be based on appropriate national and/or international legislation that represents the base line in linking the entities' interests with the objective requirements of economy. Thus, in establishing a legal framework to correspond to activity development of each type of society, a variety of regulations have been drafted along with repealing or modifying others. Currently, economic legislation comprises a wide range of regulations which are projected on the ways in which activity is developed within the forest entities and not only. Regulations in force, besides highlighting the forest entities' interests, also include all precautions in the conduct of forestry activities in ungrounded ways and the emergence of some adverse events.

**Keywords:** forest entities, legal framework, legal status of operation

**JEL classification:** M40 – M: Business Administration and Business Economics; Marketing; Accounting, M40: General.

### 1. Introduction

Although economic activity is that performing production tools, consumer goods, works, services and even the social structure in which men live, all related actions shall comply with certain laws in force at the time. On the other hand, in the future there will survive only those people who will manage to accomplish additional needs based on a legal ground, using most effectively the resources included in the economic circuit and reducing, as far as possible, the consumption of limited resources to achieve the effects resulting from an economic and social action useful to a society. Thus, even in the field of forestry, whatever the choice, this implies both a gain and a waiver and streamlining economic activity requires the efficient meet of the needs in a continuous growing and diversifying with the limited resources available. "The chapters" they have started to interfere in are: management, conservation and restoration of forests, without neglecting the possibilities of intersecting national or global forest interests with local

populations' interests. The starting point in the orientation towards these directions has been considered the hypothesis that a healthy forest can not mean anything but a healthy society. Therefore, any simple or complex human activity, repeatable or unrepeatable complies with one or more specific laws.

## **2. Methodology and motivation research**

The scientific actions taken in developing this paper, are reinforced with scientific arguments based on the information gathered from literature, from regulations, various documents, international databases and other sources deemed relevant to the theme of research, using research methods as documentation, comparison, analysis, synthesis, methods of mediated collection of data found in presentation and dissemination documents, reports, studies, summaries, methods specific to positivism employment in terms of epistemological positioning. It is worth mentioning the fact that it is difficult to address all the issues related to research theme, limitations due to certain barriers encountered during the research such as practical documentation difficulties encountered in some national forest entities or in other states. The motivation for studying this matter is determined by several factors, including: the observation that society as a whole needs a "healthy" forest system in all aspects - economic, legal, etc., idea generalized in most countries, elements of personal, cultural nature, etc. In seeking to clarify the motivation elements, it may be mentioned that the problems that Romanian economy is currently facing start from the share of the entire national economy, continue with the problem of forest profitability, the problem of legal framework which is sometimes incoherent, establishing the forestry operation regime and the forest entities status, as well as incorporating sustainable development in forestry and regional and global development strategies.

## **3. Forest entities' legal status of operation**

Performing an activity in a field of activity or another, requires full knowledge of the legislation in force, the regulations on every undertaken action, knowing the legal framework for establishing the entities having a significant contribution. The legal framework of forest entities operation is a complex concept comprising three basic components: the system of laws to which the forest entity in question relates, the legal framework by which home market is correlated with external markets, and all the institutions responsible for establishing the framework in which the entity may conduct its activity. In Romania, in accordance with existing legislation, the following legal forms can be chosen, each with its own features, advantages and disadvantages: PFA, AF, RA, OC or SC, but the legal form that can be identified with forest entities in our country, up to present, is the autonomous type.

If we analyze the entities type situation by legal status registered in the Trade Register in Romania during the period prior to the infiltration of economical- financial crisis in global economy, so before 2006, the situation may be presented schematically as follows:

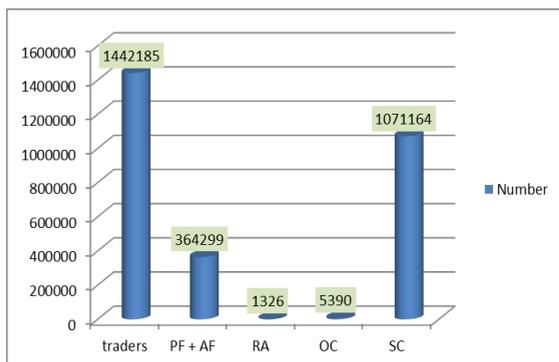

Figure 1. Fragmentation of the number of entities registered with the Trade Register in Romania between 1990-2006.

Figure 2. The shares held by different entities registered with the Trade Register in Romania between 1990-2006 in the total number.

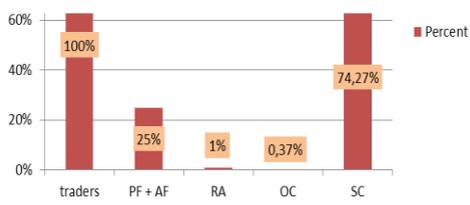

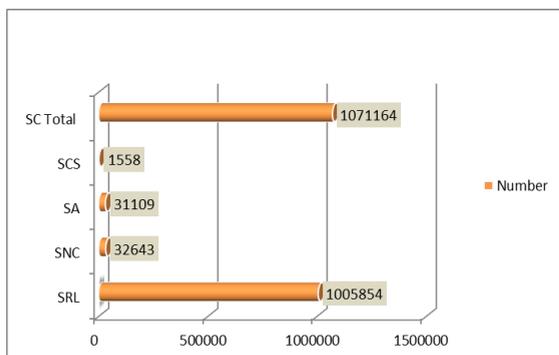

Figure 3. Segmentation of the number of trading companies registered with the Trade Register in Romania between 1990-2006, on constituent parts.

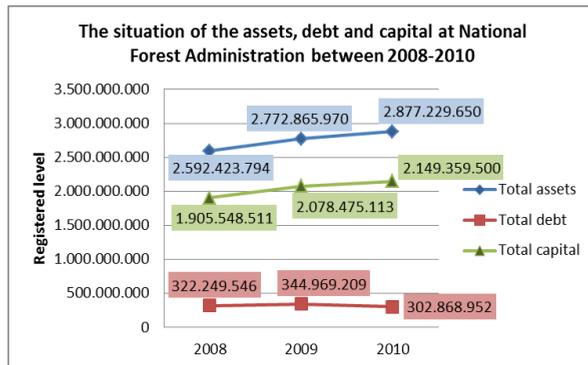

The source for figures. 1.- 3.: processing data "Statistical Summary - Operations in the Central Trading Register", drafted by the National Trade Register Office, Bucharest, data taken from the Process of setting up business in Romania, Radu Vasilica accessed on <http://steconomice.uoradea.ro/anale/volume/2006/management-si-marketing/40.pdf>, 07.12.2011.

From the above figures, we can see that entities registered with the Trade Register (CR) in Romania prior to the installation of economical-financial crisis, with the largest share are the trading companies, the most of them being the SRL, while at the first sight, the number of autonomous administrations has no significant importance and no outstanding contribution among all the entities in Romania. Nevertheless, the autonomous administrations in Romania have a special importance due to the size of the heritage that they own/manage.

Trying to analyze the situation of entities between 2006 - 2010, we can see that in time, the situation evolution is not regular but rather a sinusoidal evolution, meaning that since 2008 - the year when the global financial and economic crisis started, in Romania, the number of trading companies has dropped because of two aspects: exclusion of some companies due to their inability to withstand market conditions during the difficult period of crisis and then due to investors' lack of confidence in Romanian economy that would have determined other companies

registered at CR; this is the reason why we considered as more relevant the analysis of the number of entities by legal categories in consecutive and similar periods of time in terms of national/international/global economic and financial conditions. Continuing this analysis for forest entities, it may be noted that although their number does not have the same irregular fluctuations, problems that manifest in this area are still sensitive and significant, requiring constant research to find relevant solutions in different situations. Specifically, in an attempt to synthesize and study the size of forest heritage managed by National Forest Administration as a whole and, turning our attention only on the assets, debt and capital, the situation could be outlined as follows:

**Figure 4.** The situation of assets, debt and capital at NFA between 2008 - 2010  
Source: processing the data from the financial statements of the National Forest Administration for the three financial years

From the data in the figure above, it appears that behind the figures recorded there is the extremely complex task of the National Forest Administration (NFA) to manage assets effectively and sustainably, to monitor and analyze the situation of debt exigibility, so that from both economical and especially social point of view, the overall situation of the heritage managed by the NFA to be improved, benefited and increased. Therefore, although from Figure 1. and Figure 2., it initially seems that we can draw only the idea that autonomous administrations are few in number or percentage of total entities in Romania, this can be completed by the observation that, in what the heritage owned or managed by autonomous administrations is concerned, the situation is not so simple, but they, by cumulation record high values of significant heritage categories such as assets, debt and total capital.

Thus, directing our attention towards the specific of forest entities, it is worth mentioning some aspects related to current organization of the Department of Forests. In this regard, we note that after December 2000, according to the organizational structure provided by the previous Government, the Forest Department was transferred from the former Ministry of Water, Forests and Environmental Protection (MWFEP) to the Ministry of Agriculture, Food and Forestry (MAFF) by Governmental Decision no. 12/4.01.2001 on the structure and organization of the Ministry of Agriculture, Food and Forestry and also on its functioning method. Subsequently, following another Governmental Decision, the Ministry of Agriculture, Food and Forestry has been transformed into the Ministry of

Agriculture, Forestry and Rural Development (MAFRD), involving then other organizational changes.

Taking forest entities' legal status of operation into account, it may be noticed that in Romania they employ their activity in relation to respecting the specific of autonomous administrations according to Law no.15/1990, with subsequent amendments and completions including issues on the treatment of economic entities, owned by the state and exercising the role/function as autonomous administrations or trading companies. According to the legislative act mentioned, in our country autonomous administrations are organized and work in various areas of strategic branches of national economy set by government. These autonomous administrations are formed and operate, perform the tasks/roles for which they were established, based on economic management, so that they have the responsibility to manage all the goods/material resources and/or money, operating on financial autonomy principle or basis, having the possibility to be set up by government decision for those of national importance, or by decisions adopted by the county councils or by municipal bodies from the state administration, in case of local interest, from the branches and areas outlined by the government.

The same law provides that when establishing an autonomous administration, the business, assets, name and head office will also be established, enabling the foundation in this structure of other subunits needed for achieving the business object. The entry of real estate owned by autonomous administration, owned by third parties by official transfer of ownership, or conclusion of agreements/transactions for situations that need to be solved in a trial by the courts of law or of some litigations having a value size of more than 10 million lei is made with the approval of the competent ministry.

Specifically, in MAFRD, according to Governmental Decision no. 229/2009 on reorganization of the National Forest Administration – Romsilva and approval of the organization and operation regulations, forest management will be the responsibility of National Forest Administration, currently consisting of a number of 41 Forestry Departments plus research-development Resort for fur animal breeding in Târgu-Mureş. National Forest Administration - Romsilva is autonomous administration of national interest under state authority, by the central public authority responsible for forestry and application of national strategy in the field of forestry being its business object, acting to preserve, protect and develop forests – management of game, of fish in mountain waters and superior capitalization of other forest products. In the structure of the National Forest Administration there are territorial units without legal personality - forestry departments and research-development Resort for fur animal breeding in Târgu-Mureş - and units with legal personality such as: F.R.M.P.I. Bucharest (Forest Research and Management Planning Institute), etc. National Forest Administration is dependent on self financing and should cover all its expenses from income, including those from investment, afforestation etc. Romanian forest fund is about 27% of the country with a total area of 6.5 million ha, of which 3.4 million ha is public property, and from the area of 6.3 million ha covered with forest, only 3, 3 million ha is public property. Forest area is 0.27 ha/capita, a figure located below the average of European continent of 0.30 ha/capita.

On the other hand, Law no.15/1990 stipulates that an autonomous administration develops annually the three financial basic elements: the income and expenditure budget, the balance sheet, profit and loss account, plus other components of financial statements and even other financial overviews if this is the case, drawn up

according to the forms or models specified by the Ministry of Finance. It is worth mentioning that the balance sheet and profit and loss account of the autonomous administration are handed to the Ministry of Finance, or, where appropriate, to local financial departments in the jurisdiction of which the headquarter in question is situated, in order to be endorsed. Talking about the same financial items, it may be reminded that the balance sheet and the profit and loss account of the autonomous administration established on a national scale/level should be drawn up, displayed and published in the Official Gazette of Romania, Part III, issues which the autonomous administrations of local importance are not exempt from, noting that in this case their publication and printing will be done/found in the local press. Also, to find funds that provide financing potential losses/deficits or their covering, the autonomous administrations can "enjoy" the grants provided from the state budget or local budgets as subsidies, if the funds anticipated/provided in these budgets offer the solution, or can turn to loans/bank credits. An issue that can not be overlooked by the autonomous administrations in receiving state subsidies is that they must be used exclusively in meeting the purposes they were given/granted, without any deviation in this regard.

Throughout the legislative act, references to receipts and payments operations carried out by the autonomous administrations can be found, establishing the management board, the obligations of its members, term of office, etc. It should be noted that annually, in the first month of a new financial year, the management board give notice to the related ministry or regional/local territorial administration of a synthesis run by that administration during the previous year and an estimating report about the activities that are expected to be conducted in the current financial year. This report submitted by the NFA is laborious, including detailed references on all significant aspects of the administration related to the previous year or the current one.

On the other hand, in Romania, a special case is that of private forest districts which, up to this moment are either subordinated to Local Councils or belonging to monasteries. Thus, forest districts subordinated to Local Councils, as a legal form, are still autonomous administrations which manage the public forest fund given to that local community and monasteries forest heritage, in most cases, is given to be managed by some forest districts subordinated to the National Forest Administration or by other private forest districts subordinated by the Local Councils, and in few cases, monasteries have established a private forest district. Although the establishment of these private districts is relatively recent, it appears that most specialists in forestry and environment, technicians, officials of the Romanian Government, research centers, NGOs, as is the case Ecopolis Center for Sustainable Policies (<http://www.universulpadurii.ro/index.php?article&sid = 27097>, accessed on 27.04.2012), concluded that the situation did not follow the course desired by those who decided upon this procedure, but just the opposite, illegal deforestation is more extended in recent private forest districts, even if at national level, by now there is no percentage or value level of illegal deforestation on the Romanian territory, there are only approximate percentage situations carried out in the county or region where there was a correlation between forest area and deforestation made both in private forest districts and in the forest districts subordinated to the National Forest Administration. For this reason, at present, as shown in the studies of Ecopolis Center for Sustainable Policies, many practitioners who have in sight the concept of sustainable development, consider as a basic

necessity a rethinking of forest regime, especially organizational and less likely as a legal form. A possible solution would be picturing a way to organize the forest districts subordinated to the National Forest Administration in regions (as is the case with universities in Romania to achieve the requirements and provisions of Law No. 1 of 2011 - National Education Law, No. 1 of 2011, published in Official Gazette, Part I, no. 18 of 10 January 2011 - which renders the essential even in the content of the principles on which the national education system is based on, according to art. 118 of the law) and the search for solutions to assimilate private current forest districts, so that the most effective strategies as long-term effects can be better planned, implemented and then reviewed in an area with many implications in social life as the field of forestry, all based on the idea that "many hands make light work and the effect still increases".

Trying to synthesize the legal organization of forest entities in other states, to achieve a spatial analysis of these entities, we can notice that there are many similarities between the treatment of forest entities in our country and those of other EU countries, USA, etc.

For example, in Germany, the State Forestry Administration is subordinated to the Ministry of Food, Agriculture and Forestry and has one administration for each province/region. For example, in Bavaria region the Administration is responsible for all aspects of forest in Bavaria. Such an administration conducts a dialog with the landowners, citizens and social groups of interest to determine interests and appropriate solutions for sustainable development policies of the forestry sector; somewhat similar to the forests given to be managed by the National Forest Administration or by other private forests districts subordinated to Local Councils from our country. Wood industry in Bavaria region involves a work force of 156.000 people, and the number of employees in the timber trade can be calculated according to the statistics of Federal Employment Agency, estimated at 10.000 employees. As happened in our country, the global economic crisis has affected the forestry sector and wood inclusive, which have not remained immune, resulting in less number of employees in this area with more than 10.000 people since 2006.

In Finland, the forest fund is owned by the state and managed by the Finnish National Forest Administration, otherwise, similar situation to the Romanian forest fund. In this state, forests owned by families and individuals are transmitted from generation to generation by inheritance, reason for which the Finns generally use the term of "forest family". Finnish state owns 34% of forest land, private industry owns 8% and other bodies 5%. Basically, state forests are located in the north of Finland, and 45% of them are under strict protection. Usually, the Finnish lumber stations are small and the number of lumber stations larger than 2ha is about 440.000, while the number of those over 20 ha is 26.000. The share of the lumber stations of over 100 hectares is only 9%. The number of forest owners in this country reaches 900.000, representing about one fifth of the population. About half of the lumber stations were acquired by inheritance and a private forest changes its owners, on average, every 23 years. The forest sector in Finland generates about 5.5% of Finnish GDP – while in our country agriculture, forestry and fishing all together barely manage to be about this value - and a fifth of Finland's export revenues are derived from forest industries. In the U.S., in 1905, the Forest Service was founded, which is an Agriculture Department agency that manages public lands consisting of national forests and

grasslands, the federal agency having four levels of organization:

a) Ranger District. There are more than 600 Ranger districts, each district with a staff of 10 to 100 people. Districts vary in size from 50.000 acres (20.000 hectares), to more than 1 million acres (400.000 hectares). It should be noted that in Romania, in forestry practice, there can be also found the term of district which corresponds to the surface covered by a ranger, respectively to the forest funds which are the responsibility of the subordinated foresters.

b) National Forest Administration, which is found in 44 states to manage a number of 155 national forests and 20 grasslands. Each such forest is composed of several Ranger Districts and the person responsible for a national forest is called the forest supervisor – somewhat the counterpart of the Ranger in our country. This level coordinates activities between districts, allocates the budget and provides technical support for each district.

c) Region: There are 9 regions, numbered 1 to 10, with the provision that Region 7 was eliminated some years ago. Regions are usually large geographical areas, including even more states and the person responsible is called regional forester – somehow the counterpart of the regional forester = Ranger from us, but there is no similarity in terms of covered area.

d) At national level, this is known as the Washington Office. The person who oversees the entire Forest Service is called chief, being a federal employee working with the President Administration to develop a budget to submit it to the Congress, during the Congress also providing information on what was done and even monitoring the activities of the Agency.

If you consider the "forest system" in Canada, Forest Service is a department of the Canadian Government to shape the natural resource contributions to the overall country economy, in society and on the environment. During more than a century, the Forest Service has conducted research on the health of forests in Canada with the purpose to ensure that forest sector needs are met, and also the satisfaction of economic, social and/or cultural needs of the future generations are not compromised. Forest lands in Canada, other wooded lands and other lands with trees stretch for about half the country's lands, reaching an area of nearly 400 million hectares. Canadian Forest Service works with the provinces and the territories to ensure that the nation's resources are managed sustainably and in a way that optimizes benefits for all. Forest industry in Canada has approximately 600.000 people and the Canadian forest products range from raw materials, logs, lumber, structural panels, softwood, cellulose and paper to an increasing series of bioproducts including mushrooms, plant extracts, resins. Canada is the third supplier of forest products in the world after Germany and the United States of America. One thing worth noticed is the unquestionable importance that the Canadian state allocates both to research in general and research within the field of forestry, chapter in which the Romanian state is still lacking both in research in general and the situation of research activity in forestry, although the scientific literature frequently reminds of the hypothesis/principle that a nation cannot evolve/progress economically, socially, etc. without being based on well-founded and developed research.

If the spatial analysis of the organization and functioning of forest entities will be spread over several countries, continents, it will be seen that can be identified both similarities and specific features of each area, features that will leave a significant mark on the efficiency of forest activity in each country. Overall, however, it appears

that following the review of the functioning and organization of forest entities of the states above, we may conclude:

Table no. 1. Identifying common and differentiated elements of organization and functioning of forest entities in the analyzed countries

Analyzed country <ul style="list-style-type: none"> <li>• Romania;</li> <li>• Germany</li> <li>• Finland;</li> <li>• U.S.A.;</li> <li>• Canada.</li> </ul>	Common elements
	a common element of all countries is the basic principle of legal functioning and organization, plus the management element: the forest
	Differentiated elements
	one of the elements that differentiates the analyzed countries is the area an organization form lies on, respectively the forest fund area managed by it.

Source: synthesis by the author after studying the organization and legal functioning of forest entities of the analyzed in the text above.

In an attempt to outline the above issues relating to "Legal treatments in forest resource management", there have been found similarities and differences even regarding the definition of "forest" – component part of the forest fund with the land meant for afforestation, ponds, etc.. In the world, the forest is currently defined as "an area of more than 0.5 ha covered by trees of more than 5m in height and consistency of at least 0.1 or trees which are able to reach these limits in normal circumstances" (after World Forest Resource Assessment, 2005 of IUFRO, 2005). In Romania, according to the Forest Code are considered forests "the lands with an area of at least 0.25 ha, covered with trees, which provides a consistency of at least 0.1; trees must reach a minimum height of 5m at maturity, in normal growing season conditions. " Another aspect found during research is that the European Union has defined a community strategy to include the issue of environment in economic policy using different instruments as the market mechanism, Member States reporting annually to EU Commission economic policies developed in this respect (Peter Condrea, Ionel Bostan, 2008).

#### 4. Conclusions and research perspectives

Therefore, it may be stated that all rules governing the rights and obligations of forest entities will involve outlining all specific legal attributes of these economic units which will reflect the effects on the performed activity and on performance resulting from undertaken activity. Thus, all involved in one way or another in the activity of Romanian forest entities should make every effort, ability, means they have or they can draw to achieve the goals that were established at the time of their establishment, the more so as there is the example of other states that have managed to own an effective and sustainable 'forest system'. Tributary to what has been mentioned, the great Romanian forester, Dracea Marin, said that "Forests are primarily earth peace, agriculture shield and good work guarantee of that time and, as such, one of the reasons for the existence of the Romanian people". The integrity of the forest system is given by all flows of information, money, raw materials etc. existing between the forests cultivation system, exploitation, industrialization and final consumers, integrity that will only be maintained through a close relationship of these components. Regarding the organization of state economic entities in the forest filed as autonomous administrations and not as trading companies, they are

given, among others, the possibility to receive grants from the state budget or local budgets in case of deadlock situations, within the funds limit provided in their budgets and which may be used only to overcome the moments for which they were received, as also required in art. 9 of Law No. 15/1990. On the other hand, some differences between the autonomous administrations, trading companies and public institutions could be: non-profit organization, do not produce any benefit; public revenues consist of taxes and fees plus other income set by law, while those of autonomous administrations and trading companies come from performed work, rendered services and other activities, documents related to conducting business are differentiated according to the specific of each type of entity, existing some general similarities regarding the information carriers, what in future could determine a basis for the development of a research paper on the advantages and disadvantages of the entities of autonomous administration type that could be considered or placed in the sphere of some "pearls of the economy" or by the "black holes" of the economy.

# NEW CORPORATE REPORTING TRENDS. ANALYSIS ON THE EVOLUTION OF INTEGRATED REPORTING

**Dragu Ioana, Tudor-Tiron Adriana**

*Accounting and audit department, Faculty of Economics and Business Administration, Babes-Bolyai University, Cluj- Napoca, Romania*

*ioanadragu@yahoo.com*

*adriana.tudor.tiron@gmail.com*

**Abstract:** *The objective of this paper is to present the new corporate reporting trends of the 21<sup>st</sup> century. Integrated reporting has been launched through a common initiative of the International Integrated Reporting Committee and global accounting organizations. However, the history of integrated reports starts before the initiative of the IIRC, and goes back in time when large corporations began to disclose sustainability and corporate social responsibility information. Further on, we claim that the initial sustainability and CSR reports that were issued separate along with the financial annual report represent the predecessors of the current integrated reports. The paper consists of a literature review analysis on the evolution of integrated reporting, from the first stage of international non-financial initiatives, up to the current state of a single integrated annual report. In order to understand the background of integrated reporting we analyze the most relevant research papers on corporate reporting, focusing on the international organizations' perspective on non-financial reporting, in general, and integrated reporting, in particular. Based on the literature overview, we subtracted the essential information for setting the framework of the integrated reporting evolution. The findings suggest that we can delimitate three main stages in the evolution of integrated reports, namely: the non-financial reporting initiatives, the sustainability era, and the revolution of integrated reporting. We illustrate these results by presenting each relevant point in the history of integrated reporting on a time scale axis, developed with the purpose of defining the road to integrated reporting at theoretical, empirical, and practical levels. We consider the current investigation as relevant for future studies concerning integrated reports, as this is a new area of research still in its infancy. The originality of the research derives from the novelty of integrated reporting, and the aim to explain its origin, which is important to know if we want to understand the present and the future of corporate reporting.*

**Keywords:** non-financial information, sustainability and social responsibility, integrated reporting.

**JEL classification:** M41, M14.

## 1. Introduction

The paper presents the stages of integrated reporting evolution: international non-financial reporting initiatives, sustainability and CSR era, and finally the emergence of integrated reports.

On the background of 21st century challenges of globalization, pollution, resource scarcity, and other negative effects that affect current and future generations, some of the most prominent professional organizations – Federation of European

Accountants, European Financial Reporting Advisory Group, Sustainability Accounting Standards Board, Climate Disclosure Standards Board, International Integrated Reporting Committee, Federation of European Accountants - have decided to take action and replied by implementing non-financial reporting initiatives.

The measures undertaken by international organizations generated a period of 20 years when corporations continuously improved their reporting strategies for non-financial information disclosure. Therefore, corporate non-financial reporting has developed from predominately single-issue reports that were mostly environmentally focused, to multi-issue reports or sustainability reports. Currently, this trend towards multi-issue reporting goes further towards *integrated reporting*, which means sustainability reporting integrated within the financial or annual report. This could be one of the major topics in the debate on the future of sustainability reporting.

In order to provide a deep understanding of the concept of integrated reporting we have gathered various definitions, opinions and facts upon the concept of integrated reporting.

## **2. Literature review**

### **2.1. Non-financial reporting practices**

Non-financial reporting had a remarkable evolution in time, both on regulation side and in practice.

In 2008, KPMG was conducting a study on the corporate reporting trends followed by the top 250 companies of the Fortune 500 and top 100 companies from 16 countries. They found that 77% of the sample companies implemented GRI guidelines while more than 80% issued sustainability reports (KPMG, 2008). In only one year, this number grew to approximately 1.400 corporations that according to Eccles & Saltzman (2011) published non-financial information. The scholars also mention that during the period 2008- 2010, the promoters and early adopter of non-financial reporting enlarged by 29%.

The financial crisis has changed the perspective upon the world economy, so that many called for a sustainable approach to rebalance the economy. In 2010, the UN Global Compact Leaders' Summit militated for sustainability and non-financial reporting (UN Global Compact-Accenture, 2010).

### **2.2. Setting up regulations for non-financial reporting**

If until now we discussed the implications of the corporate reporting practice, the following mentions refer to the initiatives in the form of regulations for non-financial information.

One of the most prominent regulations was entered by France that created a framework for sustainability reporting within its Nouvelles Regulations Economiques. The United States issued the Sarbanes–Oxley Act in 2002 enforcing, among others, environmental information disclosure. Denmark prepared a set of rules for sustainability reporting that are included in the Danish Financial Statements Act, while Sweden adopted mandatory sustainability reporting for public companies.

On the European scale, we note the European Commission and business community initiative that have built the European Alliance for Corporate Social

Responsibility in 2006, an organization that acts as promoter for corporate social responsibility and social-environmental integration.

In addition, TMX Group, NYSE Euronext, BM & FBOVESPA, Bourse de Luxembourg promote sustainability reporting. Further on, Johannesburg Stock Exchange mandates non-financial reporting and Bursa Malaysia has a series of corporate social responsibility requirements. If in Singapore public companies have to apply sustainability reporting on a voluntary basis, Shanghai stock exchanges introduced mandatory environmental disclosure.

### **2.3. Early literature on integrated reporting and non-financial information**

We argue that non-financial information is as much valuable as the financial one.

From the investors' perspective, the value of the extra financial information is beginning to increase in importance. This statement is supported by Clements & Brown (2012) who claim that ESG integration in long term strategy financial plans determines shareholder value. Radley (2012) mentions that nowadays decision making processes are influenced by socially responsible investors and socially responsible investment analysts. This perspective outlines the relevance of non-financial performance in the analysis of financial and extra-financial information. In testing the non-financial impacts, investors and analysts consider the following information: governance, natural resources, social and community, capital (human, intellectual). In addition, the Moody's and Standard & Poor rating agencies favor sustainability reporting practices, developing ratings and indices on sustainability for measuring sustainability.

After a considerable overview on the actual need of the non-financial information (sustainability, corporate social responsibility reporting), we start a discussion on integrated reporting and its connection to sustainability. Mentioned for the first time by White (2005) in his study on corporations' reports, *integrated reporting* has known a continuous evolution as scholars and academics, as well as international organizations, became interested in research that implies the sphere of integrated reports. A study on ASX 50 listed organizations from Australia reveal six criteria for measuring the level of IR (ACCA, 2011: 13): mission and strategy, management approach, performance tracking, risk management, stakeholder engagement, format public reporting. Maroun and Solomon (2012) discuss mandatory integrated reporting for 10 South African corporations, aiming to find if mandatory requirements influence the level of IR disclosure. Eccles et al. (2010) explains how corporations can adopt integrated reporting practices. Integrated reporting can be described as a mixture of integrated thinking, stewardship for manufactured, human, intellectual, natural and social capital, strategic objectives and value creation, long term vision, transparency and trust, flexibility, avoiding complex and extended reports, and implementing technologies and innovation (Farrar, 2011), disclosure of forward-looking information, assurance on the quality of this type of information, annual presentation, positive aspects and challenges, holistic and integrated view on financial and sustainability elements, performance areas as subject for reporting integration, assurance on material sustainability or non-financial issues (Rossouw, 2011).

Eccles et al. (2010) defines integrated reporting as the process of ESG integration into the annual report of the companies. Deloitte Touche Toohmatsu Limited (Deloitte, 2011) understand integrated report as a means of presenting the story of the organization, that falls in the responsibility of the CFO and should contain

sustainability elements (Ernst & Young, 2011). The International Integrated Reporting Committee- IIRC, sets integrated reporting at the intersection between strategy, financial performance, governance, and social, environmental, and economic pillars (Robinson and Tinker, 1998), so that stakeholders can have a complete picture of the organizations financial and non-financial performance (Deloitte, 2011).

Nowadays, corporations practice integrated reporting, though there is no framework for the components of an integrated reports nor available standards or regulations. Loska (2010) considers that integrated reporting will lead to new standards in the area of non-financial reporting, although international organizations still have to face a series of challenges, in particular: stakeholder engagement and effective communication, connection between financial and non-financial information, establishing the IFRS perspective upon integrated reporting, and finally, the definition of sustainability. However, the IIRC is committed to develop a framework for integrated reports and has already issued a series of principles and content elements that should suit any proper integrated report. They are implementing a pilot program that surveys the adoption of integrated reporting. Up to now, more than 75 organizations have joined the IIRC pilot program. All of these early adopters issued integrated reports during the period 2009-2012. The main determinants of integrated reporting have been: engagement with shareholders, a strong commitment to sustainability cause, developing a “sustainable strategy” (Eccles & Saltzman, 2011: 58), and the perspective of social responsibility investors (Radley, 2012).

### **3. Methodology**

We engage in a systematic literature review analysis with the purpose of identifying the most relevant stages of the evolution of integrated reporting. Therefore, we set up our framework based on the overview of corporate non-financial reporting, sustainability, and CSR literature, as well as previous empirical studies in the field of IR. We build our case mainly on the background sustainability literature, as integrated reporting is in its early development stage. Organizations that adopt integrated reporting cannot rely on reporting standards or an agreed set of guidelines. Thus, in this particular situation, practice precedes theory and the subjects that follow on IR can contribute to the development of mandatory or voluntary requirements in the field.

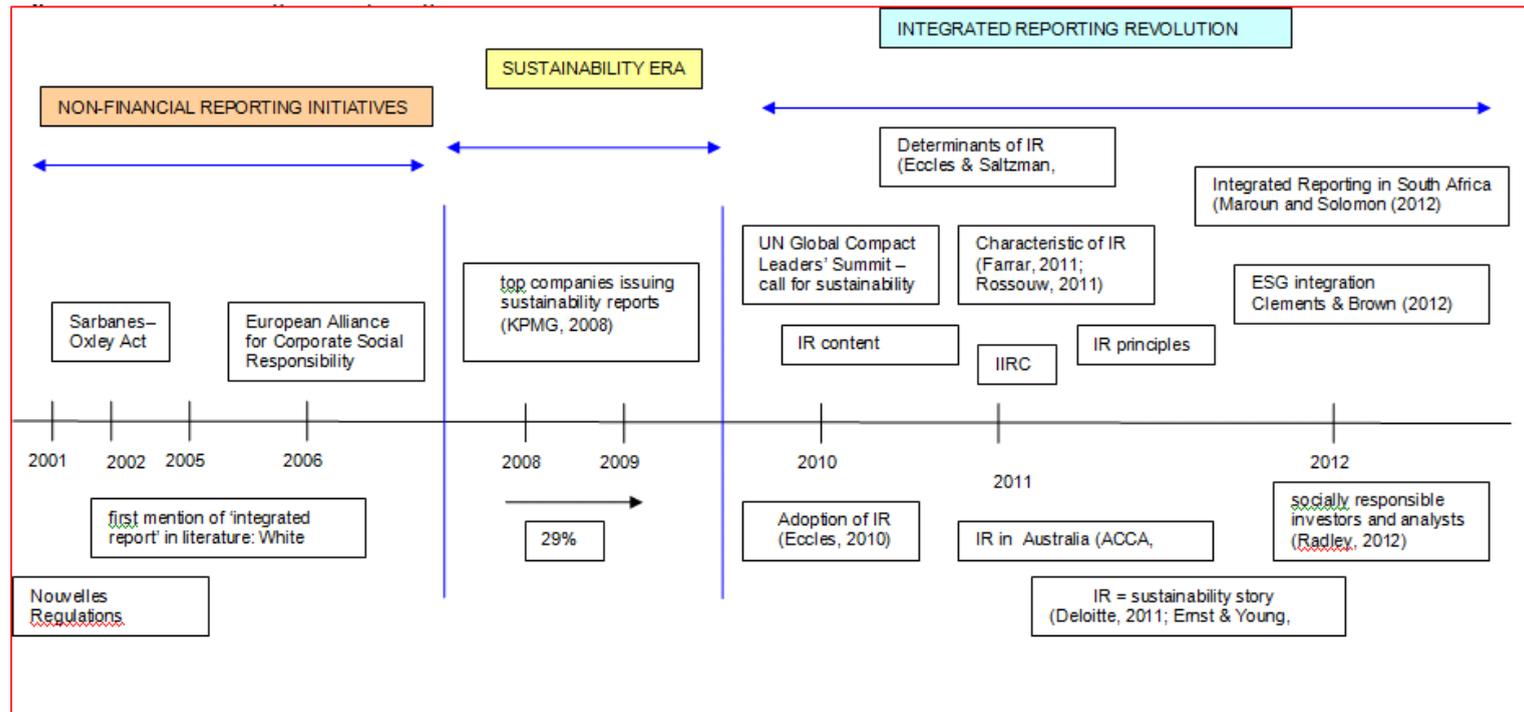

### **4. Findings**

The analysis on integrated reporting (Figure1.) revealed the existence of three stages in corporate reporting literature: (1) *non-financial reporting initiatives*; (2) *sustainability era*; (3) *integrated reporting revolution*. Therefore, the period 2001-2006 has been subject for various non-financial reporting regulations issued at both national and international level. As a consequence, companies were beginning to report on sustainability facts in 2007 and the number of sustainability/social responsibility reports continued to increase a year later. Early literature on integrated reporting debuted in 2010, in a period when world events were changing the perspective on extra-financial information. In 2011, the IIRC issued its first *Exposure Draft* on integrated reporting, mentioning the *content elements* and *principles* for integrated reports. During 2010- 2012, scholars and academics

developed theoretical and empirical studies in the field of integrated reporting. Their research involved mainly the subjects of IR determinants, adoption, and characteristics. More specific studies concentrate on the stage of integrated reporting with respect to a certain country (e.g. South Africa – with mandatory IR or Australia – IR on a voluntary basis). Others approach the process of ESG – environmental, sustainability, and governance- integration or the role of non-financial information in the decision making process when socially responsible investors and analysis are involved.

Finally, we agree that the evolution of integrated reporting shows in fact the *road to integrated reporting*, from early regulation initiatives, to sustainability implementation, and in the end, the single report containing both financial and non-financial information.

**Figure 1: The Road to Integrated Reporting**

Source: authors' compilation

## 5. Conclusions

The current research was meant to present the stages of integrated reporting evolution. Reviewing the most relevant literature in the field of non-financial reporting, sustainability/corporate social responsibility, and integrated reporting, we identified three main coordinates for IR: the international non-financial reporting initiatives, the sustainability era, and the IR revolution. In addition, the paper brings a deeper understanding upon the process of integrated reporting adoption, providing in the same time evidence on how this new reporting trend emerged both in theory and practice. The paper outlines research developed by scholars and academics as well as surveys and studies conducted by international organizations. The background literature in the area of integrated reporting suggests that organizations practices have preceded theory, as corporations have started to apply IR in the absence of standards and regulations. However, a common framework is necessary for the future development of integrated reporting. Therefore, the emergence of integrated reporting trend is limited by the gap between practice and regulation. From a regulatory perspective, the debate on voluntary versus mandatory integrated reporting remains an open question for the international corporate reporting environment. Some countries and stock exchanges already adopted mandatory integrated reporting, while other states and organizations militate for voluntary IR requirements. Voluntary or mandatory, we argue that integrated reporting should be assisted by a new set of global corporate reporting standards that would improve the IR practice and lead ahead the evolution of IR. We conclude by adding that is essential to know the history of integrated reporting, in order to understand the current reporting practices, and to be able to forecast future evolutions of corporate reporting.

[marginean.radu23@yahoo.com](mailto:marginean.radu23@yahoo.com)

**Abstract:** *This study, theoretically and practically, presents the accounting system for forestry special purpose funds in Romania. In addition, the main problems Romanian forestry faces nowadays are highlighted in the content, given the legislative changes expected in the near future. Accounting treatments specific to Romanian forestry regarding special funds, namely the conservation and regeneration fund, the accessibility fund, the environmental fund and the improvement fund are governed in the current law, mainly by the Forestry Code in Romania - Law 46/2008 supplemented by other specialized works used within the National Forest Directorate in Romania. Among the specific forestry regulations, special purpose funds are an area of interest in the current economic crisis being presented under several aspects: establishing the Fund, its utility and calculation method, its recording into accounting, or its specific tax implications. The main objective of this paper is to provide both a framework for analysis and presentation of the problems faced by forestry activity in Romania, and the accounting treatments specific to forestry activities, by illustrating the main entries made through financial and accounting documents. Given that we fully realize the environment's importance in our lives, we understand the very close relationship between the forestry business' enactment, its financing and its supervision. Special funds are the basis for financing forestry projects. Their study covers a gap in the specialized literature, providing specialists, practitioners and other stakeholders a framework. In the current economic and political context, the forestry problems, environmental issues in general are perceived to be more stringent. The solutions identified as a firm response to the existing problems are therefore of major importance, of which, in this study, we have identified and proposed several solutions. Practical examples have as grounds real data extracted from invoices, and the accounting items correspond to the National Forest Directorate.*

**Keywords:** *accounting, environmental issues, forestry, forestry funds, special purpose funds.*

## 1. Introduction

The study's main objective is to identify and present many current concerns regarding forestry activities in Romania, and to present the accounting treatments specific to special funds in forestry with practical examples.

The paper presents the regulation and operation of funds specific to forestry under the Romanian accounting legislation and the current issues of the forest system. However, in terms of funds and from an accounting point of view, the adjustment of Romsilva National Forest Directorate in Romania to the rules of the Minister of Public

Finance Order no. 3055/2009 with subsequent amendments and additions in force on that date is described in detail. We believe that special funds intended for financing various forestry activities in Romania are not investigated sufficiently in the specialized literature. Underfunding is a common problem in conditions of economic crisis, like the one we are going through now, and without a clearly identified horizon, we can as a first matter study and review *the existing funding sources, in our case the special forestry funds*.

Therefore, we consider appropriate to approach the subject, as the forest sector issues are current in 2013, and the examples in this study may be useful to specialists.

## **2. Research methodology**

The method used in our research is mainly based on descriptive analysis and on the dynamic comparison method, in order to highlight the specific problems the forestry sector faces and the accounting treatments specific to forestry in Romania.

The data used in this paper comes mainly from legal sources regulating forestry activities in Romania (Forestry Code), in conjunction with OMPF 3055/2009, which currently regulates accounting in Romania, completed by economy and accounting specialized works, applied in forestry. However, for the examples in Chapter 4, accounting data from the central forestry unit in the country was used, namely the National Forest Directorate (NFD), thus emphasizing specifically the processing and recording of financial-accounting information in forestry.

## **3. Aspects of the current problems of the Romanian forestry sector**

In Romanian forestry, there currently are a number of factors negatively influencing standing crops, of which we can mention:

1. Excessive exploitation of standing crops, increasing in the last 6 years;
2. Low concern for providing an adequate legal framework for the Romanian forest sector issues;
3. Insufficient concern for artificial regeneration of forests, limiting logging and creating forest belts;
4. Reviewing and adapting the funding sources to the current needs for the forestry sector;

According to the representative of Romsilva National Forest Directorate, Chief Engineer Dr. Adam Crăciunescu, 2012 was a good year for forestry, concluded in terms of profitability under the specific indicators. However, according to the estimates, 2013 will be a year of reforms in the Romanian forestry. The current concern for reforming administration appears in the context of the area administered by the overhead is decreasing. In the future, about 40,000 ha will be returned to former owners, which will certainly lead to a considerable decrease of turnover. The stated objective for 2013 is that of "increasing management efficiency, improving technical works and providing optimal conditions for the young trees to carry out their functions" (Adam Crăciunescu, 2012, page 3). The same author points out other flaws in the Romanian forestry, such as organizing a forest guard, the forest development activities or implementation of the "due diligence" European regulation on placing the wood on the market. The resources of Romsilva NFD, at this time, as many other branches of the national economy are currently underfunded, Chief Engineer Dr. Adam Crăciunescu stating that *"investment activity is a priority [...] own resources are far from sufficient, as well as the public ones. This is why the own*

*development resource is intended primarily to provide modern productive equipment for all our activities. We need to continually improve the level of mechanization of forest works, starting with those of forest nursery culture, land and soil preparation, planting new trees and caring for the young forest, wood exploitation, transport and manufacture”* (Adam Crăciunescu, 2012, page 4).

Another forestry problem is the national system’s need for forest belts. Academician Victor Giurgiu emphasizes the issue of financing forestry, calling it “feeble and uncertain funding”, which, although it is provided by the Forestry Code law through special funds, is “formal” (Victor Giurgiu, 2012, page 14).

The importance of forests for the Romanian culture and civilization is known and recognized on the local realm. Thus, within the popular Romanian consciousness, there existed the expression “the forest, the Romanian’s brother”, expressed by the great national poet Mihai Eminescu in the poem *Doina*. Unfortunately, the Romanian forest is currently suffering because of legislation inability to stop the phenomena such as illegal logging and other loopholes. On medium and long term, deforestation “represents disasters caused by indifference and recklessness with serious effects over time and space on the natural environment, society and economy. Deforestation’s consequences are severe: landslides, soil desertification, climate destabilization (global warming, green-house effect), extinction of many species, showing serious and severe conditions (storms, hurricanes), etc.” (Dacina Crina Petrescu, 2009, page 180).

According to the Statistical Yearbook of Romania (2012, pages 446-447), Romania’s total forest in 2011 is of 6.519 million hectares. A first negative statistical particular sign, designed to raise questions is the decline of forests’ artificial regenerations, from 15,533 hectares in 2006 to 11,499 hectares in 2011, 25.97% less. As a negative effect, corroborated to the previous observations, the surface covered with felling in our country in 2011 amounts to a total of 107,690 hectares, compared to 86,167 hectares in 2006, increasing by 24.97% over 2006. In addition, the total volume of wood exploited by forestry traders in 2011 is 16,204,000 cubic meters, compared to 11.739 million cubic meters in 2006, 38% more.

As forests are an important long-term factor in balancing the Romanian natural ecosystem, noting the significant increase in timber harvesting between 2006 and 2011 (38%), the decrease of artificial regenerations by 26%, and the increase of the area covered with felling by 25 %, we can conclude that the ecosystem in Romania will seriously suffer over time. Viable solutions to existing problems can be found only if the technical, financing and legal sources are identified in order to protect this great national wealth of Romania, which is the forest.

#### **4. Accounting treatments on forest funds**

In this section of the paper, we shall theoretically and practically present the funds specific to forestry. In forestry, by law, there are four types of special funds: *the conservation and regeneration fund, the accessibility fund, the environmental and the improvement fund.*

##### **4.1. The conservation and regeneration fund**

Under Article 33 of the Forestry Code (Law 46/2008, art. 33, paragraph 1), the forests conservation and regeneration fund is established mandatory by the forest fund administrator of public property or by the forest owners. This fund, being part of the fiscal reserve system, interest bearing, tax-free and tax deductible is at the

administrator's disposal and in his account or in the forestry provider's charge. To elucidate the legal operation framework, we shall recall the formation sources of the fund, its utility and the specific accounting records with a practical example.

*The formation sources* of the fund, according to the Manual of accounting policies and application procedures consistent with OMPF 3055/2009 (2012) are:

1. "revenue from cashing the value of lands permanently removed from the standing crop;
2. revenue from cashing the value of growth losses caused by the trees logging before the exploitability age established by forest planning;
3. revenue from compensation for damages caused to the forest;
4. revenue from the payments determined by the favourable effects stemming from the protective functions of forests;
5. revenue from the sale of standing timber from the primary and accidental I products (15% - 25%)".

The above statement can be filled with art. 33, paragraph (2) of the Forestry Code, according to which, the conservation and regeneration fund of forests is formed also of "15-25% from the value of timber authorized for logging. This is derived from primary and accidental I products, calculated at the average price of a meter cube of standing timber/foot. For the State owned forests, the Romsilva National Forest Directorate establishes the annual percentage rate. For the other forms of forest ownership, the annual percentage rate shall be established, where appropriate, by the forest districts referred to in Article 10, paragraph (2). This amount is transferred by buyers/holders of operating licenses, directly in the forest administrator's account or in the one of the forest service provider" (*Forestry Code*, art. 33, paragraph 2, letter F of Law 46/2008).

**Also, article 123 of the Forestry Code provides that "the average price of a cubic meter of standing timber/foot is determined annually by order of the head of the central public authority responsible for forestry" (Law no. 46/2008 - Forestry Code).**

*The utility of the forests conservation and regeneration fund* is chiefly aimed at the forest conservation and regeneration in many ways that can be found in the forestry activity, among which we mention (*Manualul de politici contabile si proceduri de aplicare a Planului de conturi 3055/2009*, 2012; page 139, *Forestry Code - Law 48/2008, article 33, paragraph 3*):

- "regeneration of areas covered with felling;
- forestation of bare lands recorded in forest management or of those taken for forestation;
- reinstalling forest on lands temporarily occupied from the standing crop;
- carrying out relief and care works of natural regeneration and of the existing young crops;
- performing works in the forest genetic resources included in the National Catalogue of forest reproductive materials;
- covering the costs of restoring forests damaged by natural disasters;
- carrying out care works for young trees, as well as clearing and cleaning works;
- land purchasing, according to the methodology for determining the equivalent value of lands and the calculation of monetary obligations".

**The calculation method of the conservation and regeneration fund is provided in the same Forestry Code Law. According to the formula below (article 33 paragraph (2) letter f of Law 46/2008, for a 25%), a percentage between 15% and 25% may be applied:**

$$\text{Conservation fund} = \frac{T_v * A_p * 25}{125}$$

Where  $T_v$ = Timber value,  $A_p$ = Average price

After determining the values of the conservation and regeneration fund, we proceed to bookkeeping it from formation to consumption. The main accounting records to that effect, are presented in Table 1.

**Table 1:** Bookkeeping the conservation and regeneration fund

Type	Operation	Correspondent accounts according to the NFD Chart of Accounts, compliant with the OMPF 3055/2009
Formation of the conservation fund	Counter value of 15 - 25% of the meters of primary and accidental I products; operating permit (NFD/others)	65845=47211 (4622=47212)
	Counter value of land permanently removed from the standing crop, public property	65841=47211
	Increase losses	65842=47211
	50% of the rent for temporary occupation of land	65842=47211
	compensation for forest damage	65843=47211
	Counter value of conservation fund for the wood corresponding to the private property (according to contract)	65846/4622= 47212
Fund consumption	forestation and regeneration	47211=74161
	Special protection functions	47211=74162
	expenditure on forest disasters	47211=74163
	land purchases, care works, recesses, cleaning	47211=74164 47211=74166
	forest management, private property	47212=4622

Source: *Manualul de politici contabile si proceduri de aplicare a Planului de conturi 3055/2009*, 2012, page 140.

Example 1: Based on the invoice 1911/28.11.2012, the retention of the conservation and restoration fund is determined and recorded. It contains the following information:

- VAT reverse charge,
- Standing timber/foot P.1125 MICOAIA, GROSS VOLUME – 262 CM, BARK – 21 CM, NET VOLUME – 241 CM, 179.79 lei/cm, total amount 43,329.39 lei;
- Standing timber/foot P.1161 PR BATRANEI, GROSS VOLUME – 104 CM, BARK – 10 CM, NET VOLUME – 94 CM, 183,71 lei/cm, total 17268.74 lei;
- Standing timber P.1099 RUNCULEU, GROSS VOLUME – 38 CM, BARK – 2 CM, NET VOLUME – 36 CM, price 140,80 lei/cm, total 5068,80 lei;

The conservation and restoration fund is calculated in percentage to the collected amount of the invoice representing the primary + accidental I products:

Invoice no. 1911/28.11.2012 recording 404 cm wood on key accounts, results from the following calculation:

$$Cf = \frac{Tv * Ap * 25}{125} = Cf = \frac{404mc * 85lei * 25}{125} = 6.868 lei$$

Where,

*Cf= Conservation fund*

*Tv= Timber value*

*Ap= Average price (Set by law at 85 lei)*

Accounting records:

Formation of the conservation and restoration fund:

65845	=	
47211		6,868 lei
<i>"15%-25% of the proceeds realized from the sales of meters"</i>		<i>"Income from the forest regeneration fund managed by the NFD"</i>

Fund transfer to the National Forest Directorate (monthly):

	=	4812
6,868 lei		5121
<i>"Settlements from other operations"</i>		<i>"Bank accounts"</i>
47211		
=		
4812		6,868 lei
<i>"Income from the forest regeneration fund managed by the NFD"</i>		
<i>"Settlements from other operations"</i>		

## 4.2. The accessibility fund

The accessibility fund is the second of the four special funds operated in forestry. This fund is constituted in accordance with Law 56/2010 regarding the access to national standing crop. It is provided in article 4, paragraph 1, and its declared destination is the support of forest road construction and interventions to existing roads for their maintenance. The main works intended to be financed from the Fund are reconstruction, consolidation, rehabilitation, alteration and extension works (Law 56/2010, article 1).

The accessibility fund consists of the following resource (Law 56/2010, article 5):

- "(a) up to 10% of the timber sold and collected as provided by law, from the primary and accidental I products (percentage established by order of the head of the central public authority responsible for forestry)
- (b) the amount due to the administrator of the public property forestry fund, determined according to article 42 paragraph (1) letter b) of Law no. 46/2008 on Forestry Code, as amended and supplemented.

The forest accessibility fund is an interest-bearing fund.

The fund's remaining available amounts at the end of the calendar year shall be carried forward to the next year with the same destination".

Given the description of the fund, its utility is shown in article 6 (Law 56/2010, article 6):

- "designing the works of forest road construction;
- designing of intervention investments for existent forest roads;
- executing the construction works of new forest roads;
- executing the intervention-investment works for existent forest roads";

**Table 2:** Bookkeeping the accessibility fund

Operation	Correspondent accounts according to the NFD Chart of Accounts, compliant with the OMPF 3055/2009
Up to 10% of the meters of sold and collected primary and accidental I products	58711 = 475851
50% of the rent of temporary forest	65872 = 475851 475851 = 4812
For other properties	4622 = 475852

Source: *Manualul de politici contabile si proceduri de aplicare a Planului de conturi 3055/2009*, 2012, page 141.

Example 2: Based on the invoice 3546/22.08.2012, the retention of the accessibility fund is determined and recorded. The calculation of the accessibility fund is made by applying 10% to the collected invoice amount representing "primary" and "accidental I" products.

It contains the following information:

- VAT reverse charge;

- The wood derived from primary and accidental I products, 37 cm, 148 lei/cm, total 5,476 lei;
- The wood derived from secondary and accidental II products, 26 cm, 112 lei/cm, total 2,912 lei;

$$Af = \frac{Pv * 10}{110} = \frac{5476 * 10}{110} = 498 \text{ lei}$$

Where,

Af= Accessibility fund

Pv= Production value

Accounting records:

	658711	
=		475851
		498 lei
	<i>"Expenditure on extra-budgetary fund - 10%"</i>	<i>"Income from the accessibility fund"</i>

#### 4.3. The environmental fund

The environmental fund is one of the most important financial tools provided to support the environment. Thus, the environmental fund is provided by the GEO no. 15/2010, contained in Law 167/14.07.2010, being replaced at that time by the GEO 196/2005 on environmental fund.

Under current legislation, the environmental fund has the following *sources of formation* (Law no. 167/14.07.2010, article 7):

- *"a 2% contribution of the proceeds from the sale of wood and/or wood materials obtained by the administrator or by the owner of the forest, except firewood, ornamental trees and shrubs, Christmas trees, wicker and seedlings;*
- *a 3% contribution of the amount charged annually for managing hunting, paid by hunting fund managers [...]*
- *the law also provides for a 3% contribution of the revenues from the sale of ferrous and nonferrous metal scrap, including goods destined for dismantling, obtained by the scrap generator, namely the owner of the dismantling goods, natural or legal person. The amounts are paid as they are earned by the traders engaged in collecting and/or recovering waste, which are bound to transfer them to the Environmental Fund".*

**Table 3:** Bookkeeping the environmental fund

Operation	Correspondent accounts according to the NFD Chart of Accounts, compliant with the OMPF 3055/2009
Fund formation of 2% timber	658921= 44781 NFD (4622 = 44782 others)
Fund formation of 3% hunting fund charge	65892=4478
Fund formation of the invoice of waste iron arising from cassation:	4111= 708 ( reverse charge Art.160 Fiscal Code) 5121 = 4111 (97%) 4728 = 4111 (3%) 6358 = 4728

Source: Adapted from *Manualul de politici contabile si proceduri de aplicare a Planului de conturi 3055/2009*, 2012, page 141.

#### 4.4. The improvement fund

The improvement fund is the last of the four special funds. It is regulated by the Order 2353/2012 of the Minister of Environment and Forests, published in the Official Gazette of Romania no. 422/25.06.2012 for approval of the "Methodological norms for the formation and the use of the land improvement fund for forestry purposes". On this Order's entry into force, the old law, the Order of the Ministry of Agriculture, Forests, Waters and Environment no. 499/2003 was repealed.

By law, the sources of the fund are (Order of the Ministry of Environment and Forests 2353/2012, art. 1):

- "a) the fee for lands' permanent removal from the standing crop referred to in art. 41 paragraph (1). a) of Law no. 46/2008 - Forestry Code, as amended and supplemented;
- b) interest charged under the law, for the cash availability, and for the deposits made up of revenues earned from carrying out activities referred to in letter a)".

However, legislation mentions the fund's destination. Thus, this fund ensures (Order of the Ministry of Environment and Forests 2353/2012, art. 4):

"a) funding the research, design and execution of the works stipulated in the development, improvement and enhancement projects through forestation of degraded lands established in improvement areas;

b) the financing of technical and economic studies preparation and documentation for achieving protective forest belts;

c) the funding of land forestation for categories achievement of The Protective Forest Belts National System;

d) compensation for the income loss corresponding to the actual area occupied by forest belts, stipulated in art.101 paragraph (1) of Law no. 46/2008, with subsequent amendments".

From an accounting perspective, the improvement fund is recorded as follows:

**Table 4:** Bookkeeping the improvement fund

Operation	Correspondent accounts according to the NFD Chart of Accounts, compliant with the OMPF 3055/2009	Simultaneous bookkeeping
Counter-value of forestations on degraded land from the improvement fund	23113 = 404 TVA	/
Collection of the improvement fund from the ministry	5121 = 4722	2311=404
Works payment from the improvement fund	404=5121	404=4812 paid by the NFD
Performance guarantee	404=167	/
Consumption from the improvement fund	4722=23113	/
Budgetary allocation for ecological restoration	47511=23112	/
Extra-bookkeeping of improved lands, on the date of the final acceptance, including VAT, from own sources or from the budget	4722=23113	Final receipt on achieving the state of sturdy wood, about 10 years

## 5. Conclusions

The Romanian forestry special funds, governed by relevant government structures and coordinated by Romsilva National Forest Directorate, prove to be of interest to economists, as *they represent the key to a balance* between man and nature in social terms and between the forestry industry and the health ecosystem through economy. Seen as funding sources for urgent and current forestry projects, the four special funds can really achieve their purpose *when adapting the funds based on the forestry needs* in order to answer the Romanian social needs.

We want to emphasize the difference between a general matter of economics and a matter of environment. If a general matter of economics can have immediate effects that are obvious, discernible, verifiable, and in some cases an effective post-effect response, the matters of environment generally occur on medium or long periods, and the lack of concern for their effective and sustainable resolution can have disastrous and irreversible consequences for man.

## **IFRS IN THE SMALL AND MEDIUM-SIZED ENTITIES.DIFICULTIES AND OPPORTUNITIES OF THE IFRS FOR SMES**

**Moț Ioana**

*Accounting Department, Faculty of Economics and Business Administration, West University of Timișoara, România;*

*oana\_yoana@yahoo.com*

*Doctoral programme - Accounting*

*Scientific coordinator – Prof. Univ. Dr. Mateș Dorel*

**Abstract:** *Over the years, the accounting have to meet a series of transformations and adaptations to the new trend by globalization, harmonisation and integration, trying to unfold transformations carried out at European and international level. In the same way and SMEs have undergone a series of changes, moreover SMEs shall draw up financial statements often use only owner-managers or use only tax authorities or other government authorities. Financial statements elaborated only for these purposes are not necessarily financial statements general purpose.*

*IASB (International Accounting Standard Board) has developed and published a separate standard devised to apply financial statements with general purpose and other financial reporting of the small and medium-sized entities (SMEs), entities private and public entities without liability, called IFRS for SMEs (The International Financial Reporting Standard for Small and Medium-sized entities).*

*The International Financial Reporting Standard for SMEs has become an issue of wide interest and for Romania. Through the contents OMPF 3055/2009 is a harmonisation with European Directives and International Standards, fundamental purpose being upgrade the comparability of financial statements of the economic entity.*

*In an effort to reduce the workload of SMEs has been provided the fact that IFRS for SMEs should be reviewed every three years and may be implemented by any entity, whether adopted or not full set of IFRS.*

*We believe that IFRS for SMEs is different than the full set of IFRS, due simplification, which allows flexibility provisions and showing accounting required information for this class of entities, but in applying the standard simplified scheme for SMEs has revealed a series of opportunities and challenges. IFRS for SMEs allows a particular accounting policies on recognition and measurement principles, offers greater flexibility in developing their accounting rules than provisions of full IFRSs.*

*Having regard to theoretical concepts discussed above, we carry out a case study, which shows the comparable presentation by applying of financial statements OMPF 3055/2009 and IFRS for SMEs in reporting financial assistance in Romania.*

*According to studies, rules used in the preparation and presentation of financial statements present a yawning abyss regarding accounting standards and those applying them in practice, due to the existence of multiple accounting regulations, confusing and permanently changing.*

*Through this article it soughts to point out the accounting rules used by entities in Romania, in financial statements presentation.*

**Keywords:** *financial statements, standard, SMEs, IFRS for SMEs, harmonisation, performance*

### **1. Introduction**

The International Financial Reporting Standards, known as IFRS abridged, having its origin in English - International Financial Reporting Standards, shall be carried as a set of standards "based on principles" as laid down general rules, but shall require and specific accounting treatments. These are issued by the International Accounting Standards Board (IASB) in order to apply financial statements and other financial reporting entity's directed to profit, providing information regarding the position, performance and cash flows of the entity, appropriate to users in decision-making process (International Financial Reporting Standards – IFRS, Part A – Conceptual framework and provisions, 2011).

IFRS-s shall lay down the rules for the recognition, assessment, presentation and description which deals with transactions, events and conditions that are important in the financial statements with general purpose. IRFS is based on the general framework conceptually, which deals with the concepts which outlines the information given in the financial statements with general purpose. The aim being to facilitate Frame formulation and logically consistent IFRS-sized. It also provides a basis for using reasoning in solving professional accounting.

### **2. The jump SMEs to IFRS**

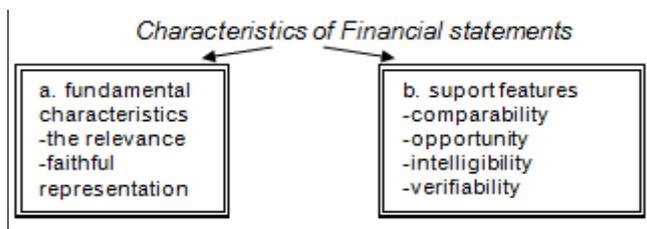

The Council for International Financial Reporting Standards Board (IASB) has published at the time of the year 2006 the project for the preparation of Financial Reporting Standards for SMEs, which was published in Romania, in 2009, by CECCAR with permission and review the Review Committee IASCF.

This standard has been developed and published by IASB having as foreground presentation by SMEs financial situations of general purpose, since SMEs shall draw up accounts only for noncommercial owners or only for noncommercial tax authorities or other governmental authorities (International Financial Reporting Standards (IFRS) for Small and Medium-sized Entities, 2009).

IFRS for SMEs is designed for use by small and medium-sized entities, falling within the following categories:

- a. do not have public accountability
- b. public financial situations general purpose for external users.

The fundamental objective of SMEs is to provide information regarding the position, performance and cash flows of the entity (Feleagă N. and Feleagă L., 2005), and giving the qualitative characteristics of financial statements, as can be seen in the figure below.

**Figure no. 1:** Characteristics of financial statements

Source: own processing

Unlike the full set of IFRSs and other national accounting standards, IFRS for SMEs is much shorter constituting a single standard in its own right, which was carried out in accordance with the requirements and the needs of SMEs which represents a percentage of 95% by number entities existing at the global level.

Full IFRS completely shows more accounting treatments, while IFRS for SMEs provides for a single treatment, that is the easiest, and it also allow the choice of a certain accounting policies on the principles of providing and assessment offering greater flexibility in the development of their own accounting rules.

Practically speaking, the IFRS for SMEs is seen as an accounting framework for entities which have no size and nor the resources required to use the full set of IFRSs.

### 3. Challenges and opportunities in applying IFRS for SMEs

In applying the standard simplified for SMEs have resulted in a series of opportunities and challenges, taking into account both financial statements and accounting policies (Caloian Florentin, 2012):

#### A. Financial statements

OMFP 3055/2009	IFRS for SMEs
<p>The legal entities who satisfy 2 criteria of the 3 listed:</p> <ul style="list-style-type: none"> <li>- Total assets ≤ 3,650,000 euro</li> <li>- Net turnover ≤ 7,300,000 euro</li> <li>- Number of employees ≤ 50</li> </ul> <p>You must submit financial statements which may include the following:</p> <ul style="list-style-type: none"> <li>- Statement of financial position</li> <li>- Profit and loss account</li> <li>- Statement changes its own capital</li> <li>- Statement cash flows</li> <li>- Explanatory notes</li> </ul> <p>The legal entities which on the date of financial statements not exceeds 2 criteria of 3 herein above, shall simplified financial statements such as the following:</p> <ul style="list-style-type: none"> <li>- Short balance sheet</li> <li>- Profit and loss account</li> <li>- Simplified notes</li> </ul> <p>* You can present the statement of changes own capital and/or statement cash flow.</p>	<p>A complete set of financial statements should include:</p> <ul style="list-style-type: none"> <li>- Statement of financial position</li> <li>- A single statement of income for the reporting period covering all the income items and expenditure which are recognized during the period</li> <li>- A statement of changes in capital</li> <li>- A statement of cash flows</li> <li>- Accounting policies and other explanatory information</li> </ul> <p>There is no format for the statement of financial position. But in the balance sheet are provided as follows:</p> <p>A. assets:</p> <ul style="list-style-type: none"> <li>- Cash and cash equivalents</li> <li>- Trade and other receivables</li> <li>- Financial assets</li> <li>- stocks</li> <li>- Tangible and intangible</li> <li>- Investment property</li> <li>- biological assets</li> <li>- Investments in associates and joint ventures</li> <li>- Deferred tax payable</li> <li>- Deferred tax assets</li> </ul> <p>B. equity and duty:</p>

<p><i>Declaration of Conformity</i> Entities must disclose in the financial statements notes that they have not been drawn up in accordance with Accounting Law 82/1991, republished and provisions of OMPF 3055/2009.</p> <p><i>Deviation from regulations</i> Annual financial statements must give a true and fair view of the assets, of liabilities, financial position, profit or loss of the entity. If application of the regulations is not sufficient to ensure an accurate picture of entity, it should present additional information in the notes.</p> <p><i>Comparative information</i> An entity must provide comparative information for one year for the amounts presented in financial statements.</p> <p><i>Materiality threshold and aggregation</i> Balance sheet and profit and loss account of elements are preceded by</p>	<ul style="list-style-type: none"> <li>- trade payables and other nature</li> <li>- Financial liabilities</li> <li>- exigible tax debts</li> <li>- Deferred tax liabilities</li> <li>- provisions</li> <li>- Equity attributable to owners of the parent</li> <li>- Controlling interests</li> </ul> <p>Other items presented in the statement of comprehensive income, such as:</p> <ul style="list-style-type: none"> <li>- income</li> <li>- The cost of financing</li> <li>- Share of profit or loss of associates</li> <li>- Tax expenses</li> <li>- Profit or loss</li> </ul> <p>Cash flow statement shows the cash flows generated and used during a specified period. The Explanatory Notes shall provide additional information of financial statements.</p> <p><i>Conformity with the IFRS for SMEs</i> An entity is accordance with IFRS for SMEs will make a recall explicit and without reservation in respect of compliance in notes.</p> <p><i>Deviation from standard</i> In extremely rare cases, when management concludes that ensure conformity IFRS for SMEs should be misleading and would be in conflict with the objective of financial statements of SMEs, the entity will drift away from that requirement, except situations where the regulation prohibits such deviation.</p> <p><i>Comparative information</i> An entity will present comparative information on previous accounting periods for the amounts shown in financial statements.</p> <p><i>Materiality threshold and the aggregation</i> An entity shall present separately each class significant of similar items.</p>
--	---

Arabic numerals, with the presentation of details in notes.	
---	--

B. Accounting policies

OMFP 3055/2009	IFRS for SMEs
<p><i>Definition accounting policy</i> Definition accounting policy is consistent with the definition of IFRS-SME. The method of depreciation is considered accounting policy.</p> <p><i>Selection of accounting policies</i> Directive IV EEC does not contain strict rules in this respect, except that when transactions are significant in accordance with certain criteria and internal judgment of the entity who classified this must be treated separately</p> <p><i>Accounting treatment of changes of policy</i> Policy changes may be caused by: -initiative of entity -decision of an authority A voluntary change in accounting policy can also be determined by: -changing entity exceptional situation or economic conditions in which they operate -to need to obtain more relevant and credible information.</p> <p><i>Error correction periods prior</i> Errors are periods prior restated retrospectively. Restatement of comparative information balance sheet and profit and loss account is expressly prohibited. Insignificant errors can be attributed to the profit and loss account.</p>	<p><i>Definition accounting policy</i> Accounting policies are the principles, the bottoms, like conventions, rules and practices applied by an entity which prepares and presents financial statements.</p> <p><i>Selection of accounting policies and other guidance hierarchy</i> To select an accounts when IFRS-SMEs does not treat specifically a transaction, an event or a condition, management will be with a view to applying sources: -requirements and guidelines IFRS - SMEs for similar things -definitions, recognition criteria and a basis for the assessment of assets, liabilities, income and expenditure -general principles.</p> <p><i>Accounting treatment of changes in policy</i> Changing an accounting policy is booked as follows: -an entity must account for a change an accounting policies resulting from a change of IFRS-SMEs -when an entity has chosen to apply IAS 39 - Financial instruments: recognition and measurement, inseed of the requirements IFRS-SMEs for financial instruments -other changes in accounting policies are accounted retrospectively.</p> <p><i>Error correction periods prior</i> Significant errors in previous periods are corrected retrospectively, except situations when the determination of error is impossible.</p>

When correcting the error causes a loss carried forward, it must be covered before any distributions.

#### 4. Case Study

Having regard to theoretical concepts discussed above, we will carry out a case study, which shows comparability of preparation and presentation of financial statements by applying OMPF 3055/2009 and the IFRS for SMEs, financial reporting entity in Romania.

##### A. Applying OMPF 3055/2009

Case study has been carried out at SC Radiant Glass SRL, has as their main activity and trimming processing flat glass.

The entity shall draw up balance sheet and profit and loss account and explanatory notes, submitted in accordance with Accounting Law no.82/1991 reissued and with the regulations in accordance with Directive IV EEC, approved by OMPF 3055/2009. In table no. 1 shows the main elements of the financial statements ([www.mfinante.ro](http://www.mfinante.ro)):

**Table no.1:** Financial statements according OMFP 3055/2009

<b>Balance sheet elements (RON)</b>	<b>31.12.2010</b>	<b>31.12.2011</b>
<b>Fixed assets-total</b>	<b>30575</b>	<b>30575</b>
<b>Current assets-total, of which:</b>	<b>936937</b>	<b>947252</b>
Stocks	689538	764561
Claims	137955	162660

-loss	0	1005

Source: own processing

Financial statements of the above is the source of the basic information to carry out the analysis financial. They are formal reports on the state and financial performance of entity in presenting an image of financial position and its profitability at the end of a period of the current financial year.

### **B.Application of IFRS for SMEs - Presentation of Financial Statements**

Case study has been carried out on the example BEAUTY DENT SRL, which is providing services in the field of dental technique.

Since its establishment till now the company has diversified and expanded the range of products and services. The Laboratory with European standards and has a team of experienced technicians who are able to please the most exacting demands, using materials and tools of-the-art and supplies disposable.

On the basis accounting entity shall draw up the balance sheet and profit and loss account and the rest of the reports, which are presented in accordance with Accounting Law no.82/1991 reissued and with International Accounting Standards. Taking into consideration that in the *IAS 1 - Presentation of financial statements* is not given any form of balance sheet and profit and loss account, the entity can create their own format so that the information presented fulfills all accounting information requirements.

In table no. 2 shows the main elements of financial statements ([www.mfinante.ro](http://www.mfinante.ro)):

**Table no.2:** Financial statements according IAS 1:

<b>Balance sheet elements (RON)</b>	<b>31.12.2010</b>	<b>31.12.2011</b>	<b>Variation (%)</b>

Source: own processing

By balance sheet is should be noted that the entity complies with International Accounting Standards and Regulations Directive -IV- EEC, with respect to the allocation of assets and liabilities. The profit and loss account is reflected the company performance and presents a distinct structure of the financial statements by processing and systematization all revenue and expenditure recorded in current financial year.

International Accounting Standards leave a large freedom of thought accounting officer, in such a way that professional reasoning decisions the best, for the financial statements present a true and fair view of business performance.

## **5. Conclusions**

In the case of Romania accounting reform in the field has been influenced by the perimeter of European and international developments in the area. The tendency was, to provide a framework for the elaboration and presentation of comparable financial statements both with European Accounting Directives and with IFRS. This approach is wants to contribute to improving the comparability of financial statements of entity in Romania. So IASB has carried out a specific simplified standard for small and medium sized entities (IFRS for SMEs), coming in their support in carrying out and presenting financial statements general purpose.

In our country has not been imposed a bill to determine this standard, but by OMFP 3055/2009 has occurs the harmonization of national rules with EU directives and international standards, with a view to presenting annual financial statements.

Information to be provided by annual financial statements on the basis of analysis financial. Financial statements must be drawn up in such a way as to provide information about the position and financial performance, as well as the accurate entity. Each of the component of the financial statements shows different information about same transactions and events carried out by economic entity during the course of a financial year. Therefore, each financial situation analyzed separately is unable to provide an overall picture of the entity by analyzed.

Accounting system IAS/IFRS applied to certain operators in Romania since 2000 and there is an intended to gradually generalize these international standards, so that they can be applied and in the smallest entity. However, it is an unwieldy system, with more than one accounting records, calculations more complicated and different results from accounting system governed by legislation presented, so that there is a certain inertia, to the disadvantage of applying IAS/IFRS.

Some experts consider that many of the companies, by a number of different accounting tricks have concluded the year with profit, in order to be able to access bank loans. These entities will collapse as soon as the implementation of the standards. Such a situation will create additional problems entities preserve, because they will have to apply new accounting standards at a time when that will be affected by competition in the common market predatory european. The only chance to overcome such difficulties is that all economic agents to record profit real up to application of the new accounting system, since, in the case where the profit is artificially created by application of the new standards, the companies are likely to become bankrupt.

In the markets with a competitive level on the rise, the application allows an entities IFRS relate to other similar entities at world level and to enable investors and other users looking to compare company performance with competitors on a global level.

**Abstract:** *This paper offers a preliminary analysis regarding the convergence of European stock markets. The sample consists of all 27 countries of European Union split in seven sub-groups related to income level, euro adoption and development level. The patterns analysed through this article are an important indication of expected convergence in EU stock markets. This study analyses the evolution and the trend of market capitalization and stocks traded and their correlation with some important determinants, namely inflation, capital formation, enrolment years, trade, FDI, government debt. Results show a negative correlation between initial level of market capitalisation and its growth rate and also of initial level of stocks traded and its growth rate. These results could be a sign of absolute convergence. Further research in this area is needed to see if there exists conditional convergence when heterogeneity among individuals is controlled for.*

**Keywords:** market capitalization, stocks traded, convergence, stock markets, EU

**JEL classification:** G15, G30

## 1. Introduction

By this study, we offer a preliminary analysis of patterns of the stock markets in European countries. We base our analysis on 27 EU countries which are split in sub-groups based on their income-level and Euro adoption. We have 7 sub-groups of countries: high income, upper middle income, euro and non-euro countries, developed, developing and emerging countries. The convergence model is usually applied for economic growth but, recently has been applied to stock markets as well (Narayan et al., 2011).

The introduction of a global capital market, if technologies are the same, would speed up the convergence for domestic product but would slow down the convergence for personal income according to Barro and Sala-i-Martin (1992). Still, some authors (Allen et al., 2006; Soto, 2003) suggest that countries which receive greater private capital flows have also grown faster due to the development of financial structure in response to the real economy.

Convergence in European Union has been the centre of many analyses for many researchers, which have divided in several areas like: monetary convergence (Orlowski, 2005, Mylonidis and Kollias, 2010), convergence on macroeconomic variables (Brada et al., 2005) and recently in convergence of stock markets (Narayan et al., 2011). The studies present Germany and France with the higher degree of convergence in euro zone (Mylonidis and Kollias, 2010) and Czech Republic as the best to obtain price stability (Orlowski, 2005) from the emerging countries. Still, Mylonidis and Kollias (2010) report that the process of convergence is still on-going.

In theory, European Monetary Union is considered a good example of convergence because it led to a single currency, a single central bank, and a single monetary policy (Narayan et al., 2011). Still there are more realistic researcher (Kim et al., 2005) which consider that effectiveness of different economic convergence criteria associated with European Monetary Union differs across member states. Also, Mylonidis and Kollias (2010) support that the introduction of the euro optimizes European economic integration and follows convergence process that is taken place from over two decades (Kim et al., 2005).

In this context we consider that an in-depth analysis of market capitalization and stock traded in the process of convergence in European stock markets is of greater importance. Not many studies have analysed the patterns of these indicators on European stock market in the context of convergence or have treated the relationship between market capitalization and stocks traded and different variables. This paper tries to address this gap and investigate possible channels through which EU countries could converge completely.

The patterns which are analysed through this article are an important indication regarding the expected convergence within European stock markets.

The objective of this paper is to offer a preliminary view on the relationship between variables, by calculus and graphical representation.

The paper is organized as follow: section 2 provides a brief view on literature review on convergence hypothesis and stock markets convergence, section 3 describes the data, section 4 presents the relationship between stock market indicators and growth of stock markets and section 5 concludes.

## **2. Theoretical literature review**

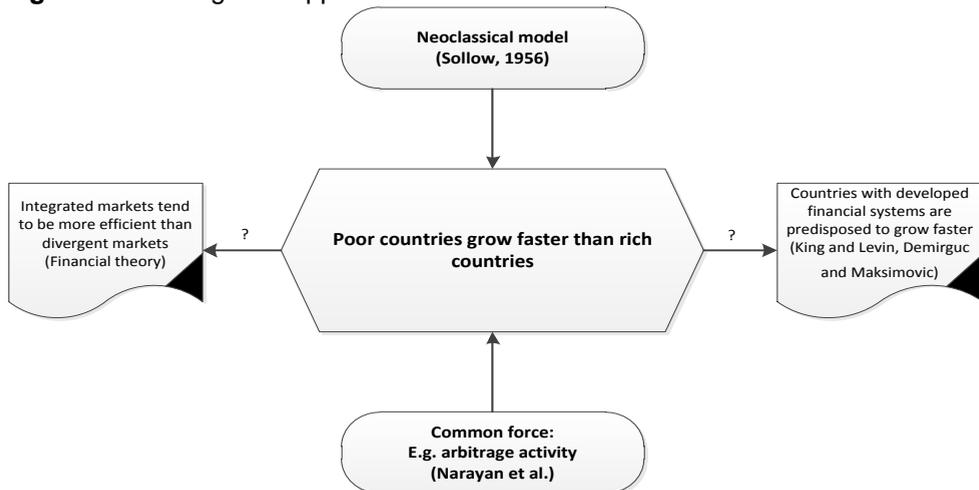

Convergence hypothesis is usually applied to economic growth and has been inspired by Baumol (1986). This theory regard specially if low growth countries converge to high economic growth and the speed of convergence (see Barro, 1991; Barro and Sala-i-Martin, 1992).

Specifically, Barro and Sala-i-Martin (1992) are asking if poor countries or regions tend to grow faster than rich ones, and what are the forces that could lead to convergence over time particularly in the levels of per capita income and product. Narayan et al. (2011) also support that there is a common force that make a market converge to another market such as arbitrage activity, that bring markets together. Barro and Sala-i-Martin (1992) study the convergence across the 48 contiguous U.S. states. They exploit data on personal income since 1840 and on gross domestic product (of each state) since 1963. This involves keeping constant school enrolment rates and ratio of government consumption to GDP. The empirical results for the U.S. states indicate that the speed of convergence for output is only slightly faster than that for personal income.

Neoclassical growth models, such as Sollow (1956), Cass (1965) and Koopmans (1965) describe this as the pattern where a country's per capita growth rates tends to be inversely related to its starting level of income per person. Providing that countries have similar preferences and technology, poor countries tend to grow faster than rich countries. So, there is a force that encourages convergence in levels of per capita income across countries (Barro, 1991). Barro (1991)'s results support the convergence hypothesis in a study of 98 countries between 1960-1985. So, for a given quantity of human capital, a poor country will grow faster than a rich country.

But King and Levine (1993 a), b)), Demirguc and Maksimovic (1996) argue that countries which have better developed financial systems, especially efficient banks and stock markets, are predisposed to grow faster because they provide access to much funds necessary to constrained economic enterprises. Financial theory considers that integrated markets tend to be relatively more efficient than divergent markets (see Narayan et al., 2011). Convergence also involves that markets are integrated. Thus level of financial development of countries seems to be a central factor underlying conditional convergence, according to past studies results (Fung, 2009).

**Figure 1.** Convergence approaches

Source: Accomplished by author following Solow (1956), Narayan et al.(2010), King and Levine (1993), Demirguc and Maksimovic (1996).

Convergence can be absolute and conditional. Absolute convergence of financial markets is taking place when countries share the same fundamental characteristics regarding financial markets. The only difference across countries is its initial level of financial market development (Narayan et al., 2011).

The conditional convergence takes place when financial markets across countries differ in terms of factors relating to the performance of their financial markets.

Recently, this theory has been applied to financial markets see, inter alia: Brada et al. (2005), Su et al. (2010), Orlowski (2005), Elyasiani et al. (2007), Narayan et al. (2011), Fung (2009) and Mylonidis and Kollias (2010).

The reasons for applying the theory of convergence on financial markets are based on the literature on stock market interdependence and portfolio diversification according to Narayan et al. (2011).

Narayan et al. (2011) focus their research on convergence of stock market for 120 countries covering the period 1985-2008. Convergence of stock markets is proxied by stocks traded and market capitalization. Dataset used is a balanced panel with an annual time component. Due to the large number of countries, they used 11 different panels based on the following criteria: high income, middle income, low

income, OECD, CSI and developing countries. Their analysis is carried also at a regional level. The main finding is that, based on the conditional convergence model, convergence of market capitalization and stocks traded is found for 4 panels. These are high and low income panels, the OECD panel, and the Sub-Saharan African panel. The speed of convergence is high, in most of the cases it is depicted between 20% and 30%.

Mylonidis and Kollias (2010) carry a research work on convergence on European stock markets in the first euro-decade. These are the major stock markets namely Germany, France, Spain and Italy, the largest and most developed markets in the euro area (Kim et al., 2005). The dominant position of Germany within the euro zone seems to be (re)affirmed by tests conducted herein. These criteria included convergence in long term interest rates, inflation rates, as well as, in the fiscal position of prospective eurozone members. The study examines the time-varying long-run relationship in the post-euro era using daily data from January 4, 1999 to July 23, 2009, transformed in logarithms. In general, the empirical results suggest that although some convergence has been taking place over time, it is still in the process of being achieved.

The differences between these studies is that Narayan et al., (2011) take into consideration 120 countries from the worldwide and Mylonidis and Kollias, (2010) study four European stock markets. Still, the results are somehow similar, Narayan et al. (2011) show a high degree in convergence in high income countries while Mylonidis and Kollias (2010) remark that the most developed countries are having the highest degree of convergence.

Monetary convergence, especially in European countries represent another research part of the convergence literature. In this context, Orlowski (2005) develops a monetary policy framework necessary in implementation of monetary convergence in Eurozone for EU accession countries. This is based on direct inflation targeting. This model is possible only for countries with developed financial markets (Mishkin, 2000), excluded for smaller accession states. So, countries which are subject of this study are: Poland, Hungary and Czech Republic, the larger accession countries which have adopted DIT policies. The analysis implies that the monetary convergence begins with flexible inflation targeting and concludes with a full-fledged euroization using ordinary least squares (OLS). The theoretical framework suggests adopting flexible DIT policies for monetary convergence to the eurozone. Czech Republic seems to be the best performer within the examined group to obtain price stability.

Another study that completes the research on European stock market is Brada J.C. et al. (2005) who estimate the convergence of macroeconomic variables using the rolling cointegration between financial and real macroeconomic aggregates of the European Union (EU). They examine three groups of countries: benchmarks of EU performance, recently members of EU and first round candidates. The sample period for the recent EU members generally covers the 1980-2001 period while for the rest of the countries the data begin in early 1990s and run through 2000 or 2001. For all estimations are used monthly data. The results show there is no systematic difference in the cointegration pattern of the EU members who joined in the 1990s and those who joined in the earlier expansion of the EU. The countries that recently joined the EU exhibit time-varying cointegration with the reference countries over much of the 1980-2000 sample period.

Other authors which have studied convergence across different variables or institution in stock markets are: Elyasiani et al. (2007), Fung (2009), Choong et al. (2010), Chordia et al. (2005) and Kumar (2010). Elyasiani et al. (2007) results` support the existence of convergence across different financial institution. They examine risk and return linkages in US commercial banks, securities firms and life insurance companies between 1991 and 2001. The main finding is that large financial institutions exhibit much larger volatility spillovers than smaller institutions. The results also confirm the presence of a higher level of convergence between banks and brokerages and tighter link in risk among large financial institutions. Also, Fung (2009) tests for convergence in financial development and economic growth by incorporating the interaction between the real and financial sectors into an otherwise traditional test for convergence. The sample consists in 57 countries running from 1967-2001. Results support the existence of conditional convergence among countries in economic growth and financial development, but only for high and middle income subsamples. Choong et al. (2010) focus on the role of stock markets as a channel through which foreign capital flows could promote growth. The findings reveal that FDI exhibits a positive impact on growth, while both foreign debt and portfolio investment have a negative impact on growth in all sample countries. However, results indicate that stock markets might be a significant channel through which capital flows affect economic growth. The sample is formed of 51 countries with different growth experiences (32 developing and 19 developed) and contains various categories of foreign capital flows from 1988 to 2002. Chordia et al. (2005) study individual actions following how market converge to efficiency based on the data of large NYSE firms. They indicate that efficiency does not happen immediately. But Kumar N. (2010) uses the growth model in order to capture the trends and patterns of market capital, domestic saving, GDP growth in Indian context. He also investigates the relationship between market capitalization, saving and GDP growth over the last three decades or so. Time series data for the study is considered for the period 1983-2007. The results indicate further growth of market capitalization and positive association between macro indicators. It supports the hypothesis that Indian stock market is emerging and has opportunity to attract investors from overseas.

### **3. Data description**

The sample consists of all 27 countries from European Union. We have classified these countries by their level of development, income level and euro adoption. These allowed us to disaggregate the data into seven panels: high income and middle income, developed, emerging and developed countries, euro and non-euro countries. The country classification based on their income level is defined by World Development Bank and country classification based on their level of development is made according with Dow Jones Indexes classification. This classification begins with analysts' examination of countries based on three broad categories of metrics for each country: Market & Regulatory Structure, Trading Environment, and Operational Efficiency. Euro area delimitation is taken from Eurostat.

**Table 1.** Country classification

Income level		Development			Euro area	
<i>High income</i>	<i>Middle income</i>	<i>Developed</i>	<i>Emerging</i>	<i>Developing/ Frontier</i>	<i>Euro</i>	<i>Non-euro</i>
Austria	Bulgaria	Austria	Czech	Bulgaria	Austria	Bulgaria

The data is represented by two market indicators namely market capitalization and stocks traded and by various macroeconomic variables and national accounts data with annual frequency. In our determination we use the following explanatory variables: inflation, capital formation, primary and secondary enrolment years, interest rate spread, domestic credit provided by the banking sector, domestic credit provided by the private sector, trade (exports plus imports), foreign direct investment and government debt. All these variables are in percentage of GDP form. The choice of the variables is based on the theoretical reasons we found in the literature.

**Table 2.** Variables

Description	Definition	Source
<b>Inflation</b>	- annually standard deviation calculated of consumer index price.	Eurostat
<b>Capital formation</b>	- gross domestic fixed investment - in literature capital formation is generally associated to economic and also have positive effect on market capitalization by facilitating faster rate of growth (see Kumar, 2010).	World Bank
<b>Primary and secondary enrollment years</b>	- the number of years of full-time equivalent duration in primary and secondary education in the school system	World Bank
<b>Interest rate spread</b>	- the interest rate charged by banks on loans to private sector customers minus the interest rate paid by	World Bank

Description	Definition	Source
	commercial or similar banks for demand, time, or savings deposits.	
<b>Domestic credit provided by the private sector</b>	- credits allocated to the private sector	World Bank
<b>Domestic credit provided by the banking sector</b>	- includes all credit to various sectors on a gross basis, with the exception of credit to the central government, which is net.	World Bank
<b>Trade is the sum of exports and imports of goods and services measured as a share of gross domestic product.</b>	- is the sum of exports and imports of goods and services measured as a share of gross domestic product.	World Bank
<b>Government debt</b>	- is the entire stock of direct government fixed-term contractual obligations to others outstanding on a particular date. It includes domestic and foreign liabilities such as currency and money deposits, securities other than shares, and loans	World Bank
<b>Foreign direct investment</b>	- are the net inflows of investment to acquire a lasting management interest (10 percent or more of voting stock) in an enterprise operating in an economy other than that of the investor. It is the sum of equity capital, reinvestment of earnings, other long-term capital, and short-term capital as shown in the balance of payments.	World Bank

Source: Accomplished by author based on World Bank definitions

The credits allocated to the private sector are considered a measure of financial development in Fung (2009) study about convergence of financial development and economic growth. Credits allocated to the private sector are credits issued by both depository and non-depository institutions, which excludes those allocated to the public sector because those allocated to the private sector normally yield higher returns and are more likely to reflect fluctuations in the level of intermediated finance (Xu, 2000).

Narayan et al. (2011) use similar variables with us except government debt. At this stage we carry just a descriptive analysis and depict some correlations of these variables with the market capitalisation.

Stock markets indicators are market capitalization of listed companies and stocks traded. These measures were used by Narayan et al. (2011) and Choong et al. (2010) who have taken them as percentages in GDP.

The market capitalization measures market size as the ratio of market capitalization to GDP, and stocks traded measure stock market liquidity. Total stock value traded measures market liquidity and is defined as the product of share price and the number of shares traded. As an indicator of stock market development, it not only reflects stock market liquidity, but also its interaction with market size. For this reason, Choong et al. (2010) consider that trading value may be considered a better indicator of stock market growth than market capitalization ratio alone. Also, trading value complements market capitalization because a market may be large, but have little trading. Taken together, market capitalization and trading value provide more information about a nation's stock market than using only a single indicator (Choong et al., 2010)

Market capitalization is considered the biggest macro indicator for doing a country analysis which is defined as the value of listed shares divided by GDP and it is a measure of the size of stock markets relative to the economy (Kumar, 2010). The author, however, states that market capitalization is not an universal indicator of predicting economic performance but has a positive effect of financial development on economic growth (Kumar, 2010).

#### 4. Common patterns of stock market convergence in EU

Table 3a contains some descriptive statistics namely mean, standard deviation, coefficient of variation, skewness and kurtosis for market capitalization. The results are reported for seven panels namely high income, middle income, developed, emerging, developing, euro and non-euro countries. We notice that the mean is highest in developed countries followed by high income countries and the lowest is for developing countries. A comparative analysis of the mean reveals that the mean of market capitalization in developed countries is 88 times the mean for developing countries and 11 times the mean for emerging countries. Also, the mean for high income countries is 48 times the mean of middle income countries. Still, euro and non-euro panels seem to have similar means. The coefficient of variation suggests that volatility is highest for high income countries. Narayan et al. (2011) report a contrary situation for their panel of 120 countries. Regarding the level of development we find the highest volatility for developed countries which also have the highest mean. Skewness reports for all panels an asymmetrical distribution with most values concentrated on left of the mean, with extreme values to the right. Kurtosis show for all panels a leptokurtic distribution sharper than a normal distribution with values concentrated around the mean.

**Table 3.** Descriptive statistics of market capitalization<sup>13</sup> (mil.\$) during 2001-2011

Panels	Mean	Std. Deviation	Coeff. variation	Skewness	Kurtosis
<b>High Income</b>	41900000	70800000	1.69	2.51	9.47
<b>Middle income</b>	859000	1030000	1.20	1.84	5.76
<b>Developed</b>	63000000	80100000	1.27	1.92	6.43
<b>Emerging</b>	5660000	5180000	0.92	1.59	4.57
<b>Developing</b>	713000	811000	1.14	2.45	9.15
<b>Euro</b>	36000000	53900000	1.50	1.94	6.49
<b>Non-euro</b>	35600000	85000000	2.39	2.84	9.88

Source: Own author's computations based on data

Next we consider the same summary statistic for stocks traded (see table 4). The mean results here show similar results with those of market capitalization. The highest mean is for high income countries and developed countries. Euro group presents comparable results with non-euro group similar with market capitalization. In terms of volatility of stocks traded high income countries experience the highest

<sup>13</sup> Market capitalization (also known as market value) is the share price times the number of shares outstanding. Listed domestic companies are the domestically incorporated companies listed on the country's stock exchanges at the end of the year

volatility. In fact, developed countries have the highest volatility and emerging countries have the lowest volatility in developments panels. Non-euro countries also supports the highest volatility. Skewness and kurtosis values suggest similar interpretations with those from market capitalization.

**Table 4.** Descriptive statistics of stocks traded<sup>14</sup> (mil.\$) during 2001-2011

<b>Panels</b>	<b>Mean</b>	<b>Std. Deviation</b>	<b>Coeff. variation</b>	<b>skewness</b>	<b>kurtosis</b>
<b>High Income</b>	53300000	111000000	2.08	4.27	29.90
<b>Middle income</b>	108000	167000	1.55	2.44	9.19
<b>Developed</b>	81100000	129000000	1.60	3.54	21.71
<b>Emerging</b>	2990000	2460000	0.82	1.11	3.43
<b>Developing</b>	92800	137000	1.48	2.70	11.36
<b>Euro</b>	44200000	4600000	1.69	2.07	7.03
<b>Non-euro</b>	47400000	141000000	2.98	4.47	26.41

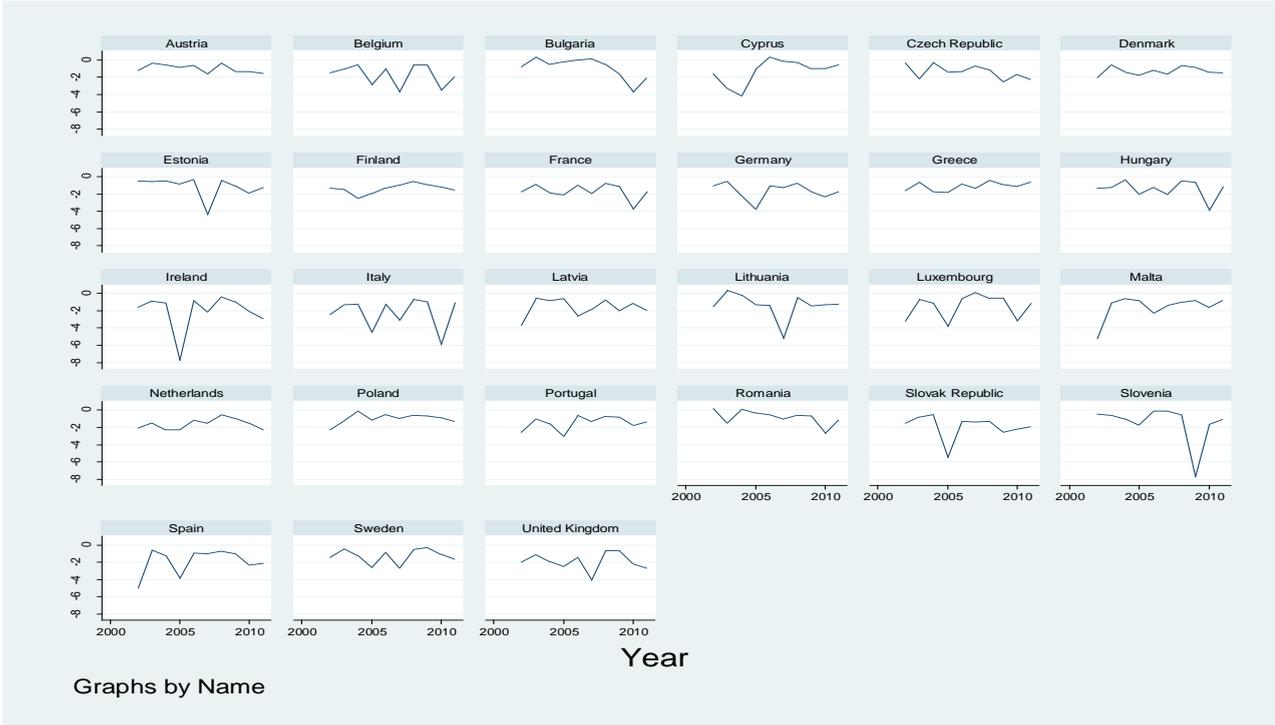

Source: Own author's computations based on data

The evolution of market capitalization growth rate between 2001-2011 can be followed in figure 2. It can be seen a decrease in the majority of the cases between 2008-2009 which was followed by a recovery starting with 2010. Interesting pattern records Poland which hasn't followed the evolution of the others countries and hasn't registered a slowdown during financial crisis. Poland even doubled the number of listed companies from 2008 to 2011 and its turnover value has started to increase recently. Overall stocks traded depicts the same trend as market capitalization. Several countries began to recover starting with the year 2011 including Germany, Italy, Finland, Austria and Poland.

In this analysis we could follow and test the convergence hypothesis which states that economies with lower initial levels of market capitalization per capita will tend to grow faster than the others (Solow, 1956). This type of convergence is named conditional convergence.

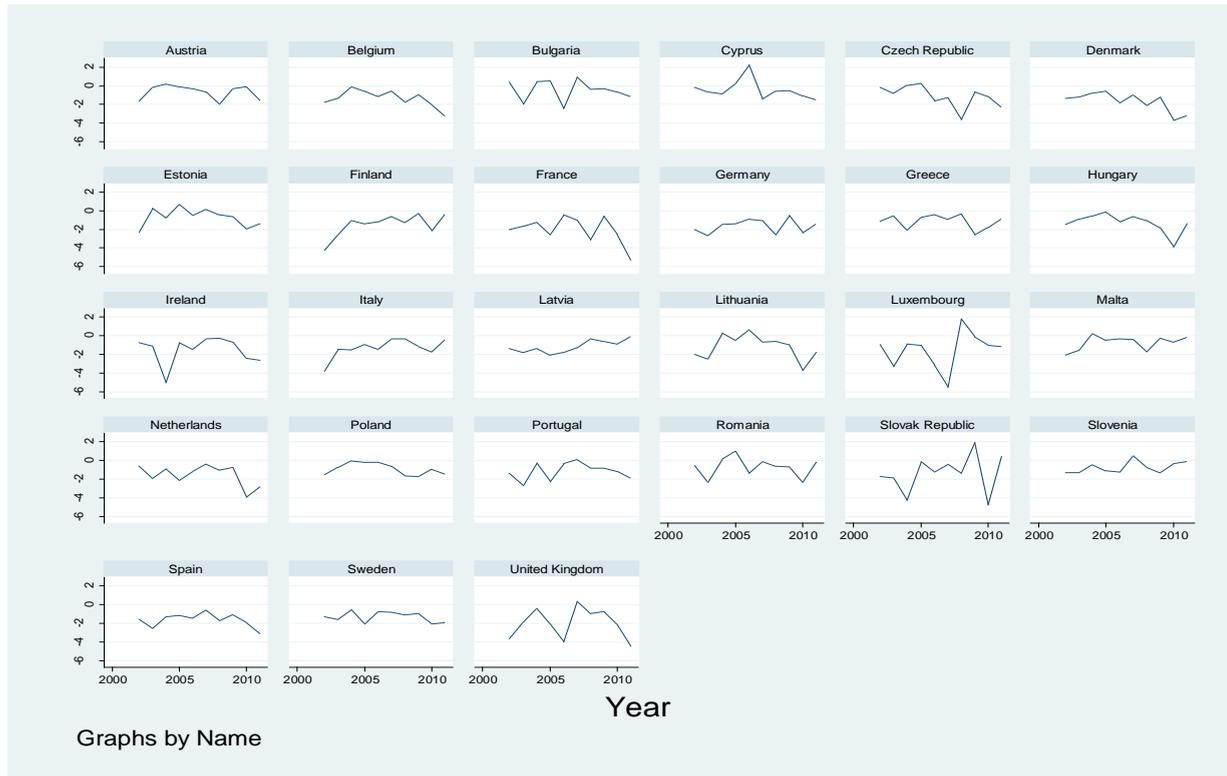

<sup>14</sup> Stocks traded refer to the total value of shares traded during the period.

Figure 2: Market capitalization growth rate (log) during 2001-2011

Source: Author's calculations based on World Bank Data

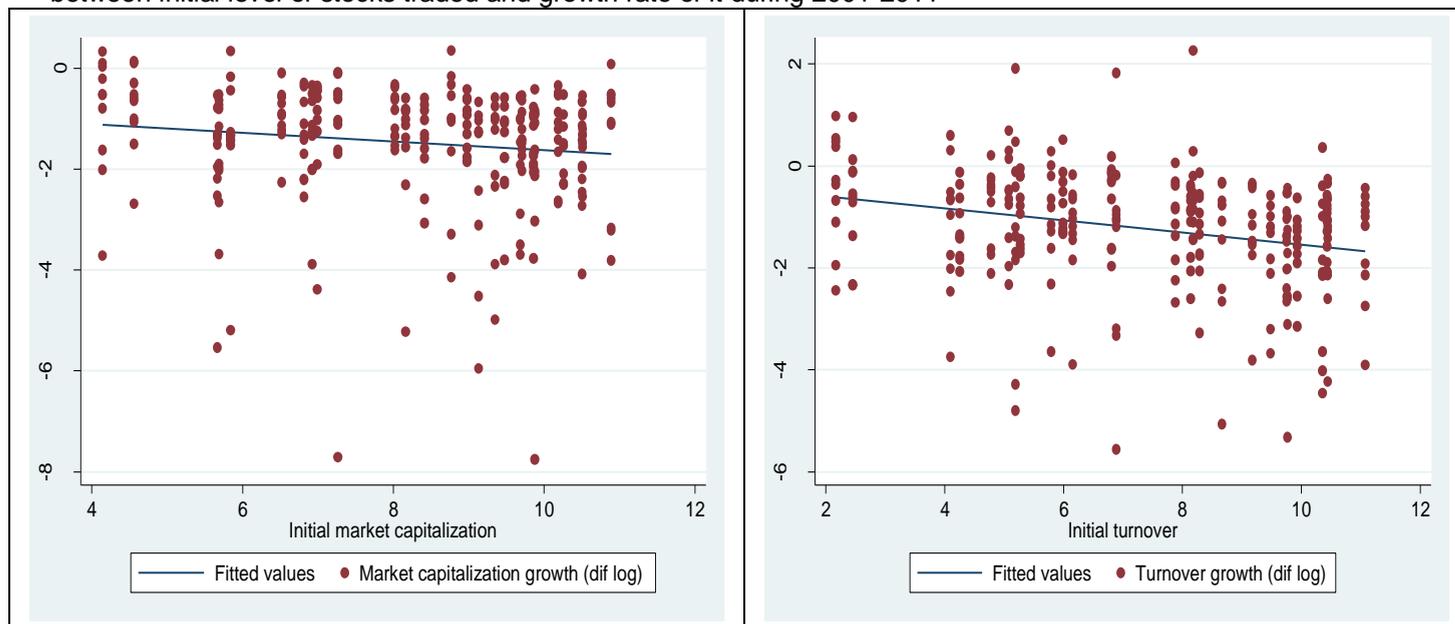

**Figure 3: Stocks traded growth rate (log) during 2001-2011**

Source: Author's calculations based on World Bank Data

In the next figure we represent a negative relationship between the growth rate of market capitalization and turnover and the initial level of market capitalization and stocks traded per capita. Based on these results we can confirm that the convergence hypothesis seems to verify in these countries. These results show that the countries with the lowest level of market capitalization or stocks traded per capita tend to grow faster than the countries with the highest values.

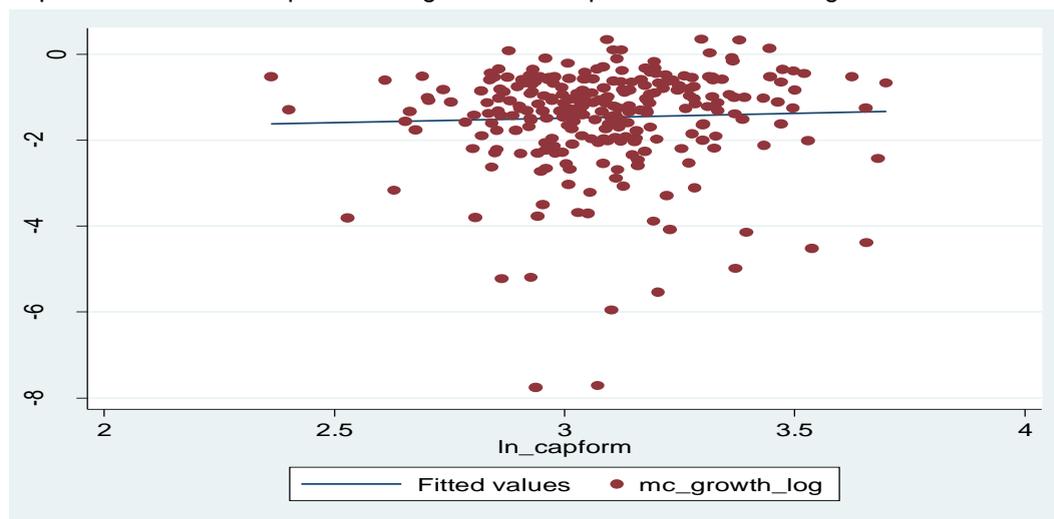

**Figure 4:** Correlation between the initial level of market capitalization and growth rate of market capitalization and correlation between initial level of stocks traded and growth rate of it during 2001-2011

Source: Author's calculations based on World Bank Data

## Relationship between macroeconomic variables and market capitalization/stock trade growth

**Figure 5.** Relationship between market capitalization growth and capital formation during 2001-2011

Source: Author's calculations based on World Bank and ICRG Data

In the above figure we represent a linear relationship between capital formation and market capitalization growth. We observe a positive correlation between market capitalization and capital formation during the considered period. The higher is the level of capital formation, the lowest is market capitalization in these countries. The same results are available for stock traded.

In this paper we intended to do a preliminary analysis for determinants of market capitalization and stocks traded. The theoretical literature offers us enough reasons to believe that these determinants could enhance market capitalization and stocks traded. For the 27 European countries, we checked as initial steps only the convergence hypothesis. At this stage we only looked at the correlations. For further research, we intend to employ dynamic panel methodology. An OLS estimation has been carried. A positive correlation was noticed between market capitalization growth and interest rate, government debt, trade, private credit. Also, were observed negative correlations with primary and secondary years. Still, no significant results were depicted when OLS estimation was carried. Since OLS is a biased and inconsistent estimator for our case (Barro and Sala-i-Martin, 1992) because the lagged values of variables we intend to use are endogenous and the lagged dependent variable will be correlated with the composed error term (Narayan et al., 2011), we intend in a future work to improve the methodology by controlling for differences between the countries and including dynamics for market capitalisation variable.

## **5. Conclusions**

In this paper we presented a pattern of the EU countries regarding their stock market determinants such as market capitalization and stock traded. When splitting the countries in sub-groups, we noticed that the indicators records larger values in developed and high income countries from developing and middle income countries. Still, countries from euro area present similar results with countries from non-euro area.

We depicted a negative correlation between initial level of market capitalisation and its growth rate and also of initial level of stocks traded and its growth rate. By depicting these results, we can state that in these countries there is a sign of absolute convergence. Further work is needed in the area to test for conditional convergence by using appropriate estimators that would control for heterogeneity among countries and endogeneity. As policy recommendation, the countries with low initial of market capitalisation and low initial value of stocks traded should enhance their market capitalisation by new financing opportunities offered by stocks for the firms, due to low transaction costs. As absolute convergence could be depicted in terms of deterministic calculus, gaps could be reduced between European countries (between middle income and developed for example) if for the middle and low income countries market capitalisation and value of stocks traded would increase.

The study of these patterns has revealed interesting findings. Expected relationships between market capitalization/stocks traded and market growth were confirmed by the results.

## THE COMMUNICATION PROCESS OF THE FINANCIAL REPORTING

**Nicolaescu Cristina, Moț Ioana**

*Faculty of Economics, Aurel Vlaicu University of Arad, Romania*

*Faculty of Economics and Business Administration, West University of Timișoara, Romania;*

*cristina\_nc2@yahoo.com; oana\_yoana@yahoo.com;*

**Abstract:** *An information has value through the financial reporting. Such are taken into account factors such as: the nature of the event referred to financial reporting, the adequacy of the presentation, the credibility and integrity of information, readability necessary to allow some conclusions on a reasonable impact on the financial statements, the investors risk profile and processing skills recovery opportunities. Communication is not an end in itself. Its existence can not be conceived outside support a general policy orientated goals undertaken by the organization. In this situation, organization and communication should be viewed as complementary tools and not as independent techniques.*

*In the communication process, it must be designed in such a way as to contribute to the objectives of the entity. Communication is managed in accordance with the overall strategic plan of the specific activity of that entity.*

*The financial communication tools are: accounting information and financial information. We can say that for accounting and its environment is interested accounting information and for financial analysis is interested financial information conducted with the help of financial indicators.*

*In determining values for financial reporting information, should be considered category of users whom it is addressed as well as the purpose for which the information is used.*

*Entering barriers to effective communication, due to lack of a common reference system or a difference in experience between the entity and its external environment leads to failure.*

*This article aims to answer the question to what extent the current contents of financial reports for these factors and provide useful information to users.*

*To demonstrate the communication within an entity will present research conducted for 4 business entity of 4 different counties*

*Communication is not an end in itself. Its existence can not be conceived outside support a general policy orientated goals undertaken by the organization. In this situation, organization and communication should be viewed as complementary tools and not as independent techniques.*

*The conclusion is that the way in which financial information is transmitted by the annual financial statements depends not only on the quantity or quality of the information but also on the way we effectively communicate with all that it involves.*

**Keywords:** *communication; financial reporting; entity; accounting regulations; informations; financial statements.*

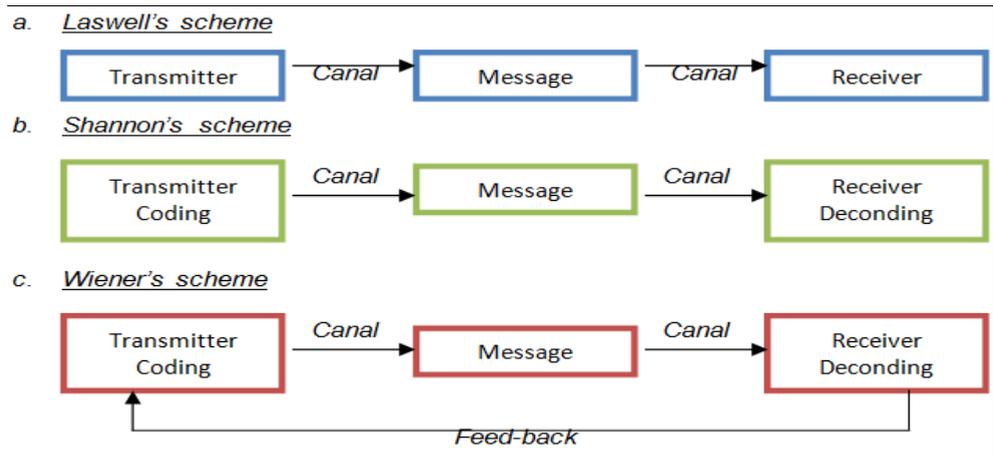

**JEL classification:** *M 41*

## 1. Introduction

Communication is defined - by most specialists - as a set of actions that share the transmission of information in the form of messages, signs, news or written texts, etc. between transmitter and receiver by means of a channel. This term is related to our existence as human beings, then as a society, because human beings and communication are interdependent.

Along the existence, mankind has progressed by improving the communication.

(Figure no. 1)

**Figure no. 1 – The communication progress**

**Source:** own processing

In other words, the individual civilization endows it with a technique to increase the strength and activity significantly, while its fundamental nature has changed.

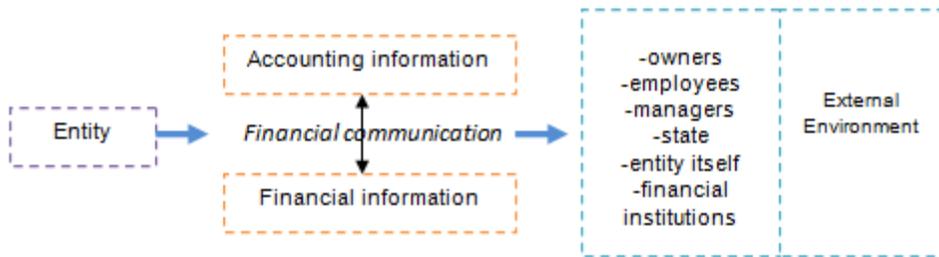

## 2. Methodology of financial communication

Entity-level communication is achieved by providing accounting and financial information through financial statements and financial and economic analysis, so that the external environment of the entity to be satisfied.

According to the statements of the above we can draw the following financial communication:

- ✓ Provision accounting and financial information
- ✓ Sources of information provision through financial statements and economical and financial indicators
- ✓ The destination information is the external environment of the entity.

Is drawn through communication link between the entity and the external environment. (figure no. 2) Entering barriers to effective communication, due to lack of a common reference system or a difference in experience between the entity and its external environment leads to failure.

**Figure no.2 - Graphical representation of entity-level communication**

**Source:** processing after Dorina Lezeu, Eduard Florea, 2004

### 3.Communication of financial reporting at international and nationally level

Financial statements of an entity represent the most important means by which accounting information is made available to decision makers.

Structure of financial statements is the following:

Annual financial statements	Simplified financial statements
<ul style="list-style-type: none"> <li>• Balance sheet</li> <li>• Profit and Loss Account</li> <li>• Statement of changes in equity</li> <li>• Statement of Cash Flows</li> <li>• Explanatory notes</li> </ul>	<ul style="list-style-type: none"> <li>• Simplified Balance sheet</li> <li>• Simplified Profit and Loss Account</li> <li>• Explanatory notes</li> </ul>

At international level the financial statements are different from country to country. Thus U.E. decided to implement Financial Reporting Standards (IFRS) in accordance with EC Regulation no.1606/2002 of the European Parliament and of the Council, aiming to increase transparency, improving the financial accounting communication and comparability of financial statements information and other financial reports.

IFRSs address the requirements from international level of developed and emerging economies to have a common set of accounting rules addressed to all those who work in business.

As it is shown in the IASB (International Accounting Standards Board), users use the information in the The financial communication, leading to economic decisions:

- a. deciding when to buy, hold or sell
- b. Assess management administration
- c. assess the entity's ability to meet salaries
- d Assess guarantees for loans made
- e. Determine entity profit and dividends

f. regulate the entity etc.

In Romania, the main law that governs currently the accounting and financial reporting environment comprises Accounting Law 82/1991, republished and Ministry of Finance Order 3055/2009 (OMPF 3055/2009).

Accounting Law indicates accounting framework provisions on Romanian entities and OMPF 3055/2009 refers to financial reporting and related accounting provisions, in accordance with European directives (Directive to IV for individual financial statements and VII to Directive for consolidated financial statements).

#### **4. Case study**

The entity's financial communication is achieved most of the times through financial statements. A basis of these reports we can see the approach of a business entity from one financial year to another.

To demonstrate the communication within an entity will present research conducted for 4 business entity of 4 different counties, currently incapacitated for liquidity, according to BDI (Bulletin of insolvency proceedings) no. 4720-4817 of 18.03.2013. The study refers to the period 2008-2011, having as a real data information provided by the Ministry of Finance of Romania.

Referred business entity are:

- a. ALACOM IMPEX SRL, based in Deva, with the activity - retail of footwear and leather goods in specialized stores, founded in 2003.
- b. GENERATIV CONSTRUCT SRL, in Timisoara, with activity - other specialized construction, established in 2007.
- c. INTER EDIL GEO SRL, from Arad, as predominant activity - construction of residential and non-residential buildings, taking into being in 2001.
- d. MAGNOLIA 91 SRL, based in Oradea, with the activity of underway - Renting and operating of own or leased real estate, date of establishment 1991.

To reflect the situation of insolvency of companies, we drawn up Figure. 3 – financial data and indicators.

**Figure no. 3 – Financial data and indicators**

**Source:** own processing

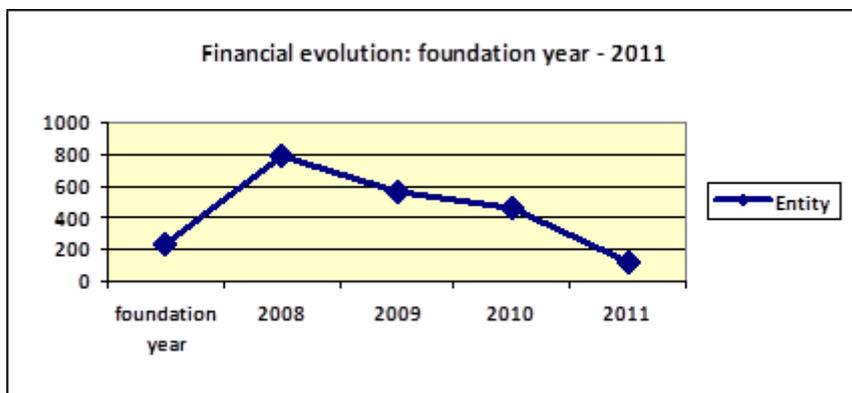

According to existing data in the balance sheets and profit and loss statement of entities results these:

- Commercial entity climax was reached in 2008 where each of the four entity has recorded positive value increasing as against the previous years.
- The year 2009 was the beginning situation of uncertainty on business continuity.
- From the data provided in the above documents are observed insufficient information provided.
- Those entity have reached a disability cash, due to the low level of communication to the financial statements of managerial level, as well as

management focusing on enrichment desire, and less on activity in a relatively constant rate, leading to continuity trust future activity.

- The balance sheet is not sufficient the entities communicating financial data, simplifying the it provides indicators of financial statements. You must put a higher value on the balance.

The evolution of entities can be represented graphically as follows:

**Chart no. 1 – Financial evolution of the entities**

**Source:** own processing

It is noted that the evolution of the four business entity has decreased from year to year, falling in the category of entities with an unhealthy position on the Romanian market.

Given all those elements we believe that the four economic entities do not understand the importance and role of financial communication, which has led to their position in the list of entities failing.

## 5. Conclusions

At the level of communication stays elements such as: transmitter, receiver and message so that the information passed is correctly perceived through the channel. Currently we can say that the communication accounting (financial) is not used correctly perceived within entity, because year by year, an increasing number of entity enters in the inability to continue operations.

One reason for this approach is the lack of generating communication of information through the monthly financial statements, quarterly or annually by the entity.

Objective of financial statements is to provide information about the financial position, performance and cash flows of the entity that are required at managerial decision making.

As a corollary, we can say that the presence of financial statements contributes to the enrichment information for users but also to strengthen accounting as a privileged source of information because it is the basis to any strategic and financial analysis.

In conclusion, communication must occupy a leading position in the expansion and continuation of any entity.

# THE BEHAVIOUR OF ROMANIAN ACCOUNTANTS FROM TIMIS COUNTY: CREATIVE OR NON-CREATIVE

**Schmidt Anca, Megan Ovidiu**

*The Department for Accounting and Auditing, Faculty of Economics and Business Administration, West University of Timisoara, Timisoara, Romania*

*ancaschmidt@yahoo.com*

*ovidiu.megan@feaa.uvt.ro*

**Abstract:** *Creativity and innovation are two very trendy concepts for the current period which is characterized by a very difficult economic context. The creativity and the innovation usually stimulate the competitiveness of economic organizations. But what about creativity in the field of accounting? Are the accountants creative? Is creativity benefit for the quality of accounting information? The aim of our study is to review study the accounting literature and practical experience of Timis county organizations in order to create a picture of Timis county accountants' behaviour. For the achievement of the proposed objectives the authors based their opinion on a research study by questionnaire realized at Timis county level.*

**Keywords:** Financial accounting, creative accounting, management accounting, IFRS

**JEL classification:** M41

## 1. Introduction

Globalization has become the main theme for conferences and seminars debates in the international economic community. It is a key phenomenon of 21 century, affecting about every aspect of our lives, including even economic behaviours and in accounting area. Globalization, which characterizes the economic world, led to the necessity of understanding and comparison of the financial statements of different corporations and also to present the fair view of businesses rather other interests like public interest in taxation.

Romanian accounting developed remarkably in the last twenty tree years, as shown by the flow of accounting literature in this field. This development is mainly the result of EU accession as well as of harmonizing and subsequently converging national, European and international accounting standards.

The globalization increased for sure the competitively of multinational companies and asked for creativity and innovation for all area of activities.

Accounting has always been considered the main language and very tool of business. It has always concerned itself with determining how a business is doing and what the bottom line is. But over the last twenty years, the field of accounting has been changing dramatically in response to such explosive trends as the computer revolution, increased national and international regulations, and frequent tax law changes all over the world, the globalization of business, and the on-going growth through green fields expansions or mergers and acquisitions followed nowadays by downsizing and restructuring of corporations facing economic difficulties. In this increasingly complex and competitive business environment,

accounting skills are very much in demand and accounting has become a dynamic career for many young people.

The accountants have a very important role to prepare, report, and control the financial position and the financial results of all companies who act within the world-wide economy.

This period brings a decrease of world economy, the most affected countries being the poorest one.

Taking into consideration this economic context we try to find out which the behaviour of accountants is and which the evolution in this field is. We know very well that the decrees of economies stimulate companies and individuals to become more and more innovative, more and more creative. By this paper we try to find out if the behaviour of Romanian accountants follows the trend and they become creative.

## **2. Theoretical background**

At international level different accounting patterns of behaviour can be identified which are the outcomes of many years of development influenced by factors such as cultural values, legal systems (even tax regulations), political orientations, and economic development. The challenge now is to adapt what has served well in the past to the new global imperatives of transparency and credibility of accounting in order to facilitate efficient flows of capital to the world's financial markets.

Nowadays creativity is essential to problem solving and requires productivity, unconventionality, and the capacity to build on preceding innovation. Creativity is essential to problem solving of a company and represent a previous step to innovation. Creativity requires unconventionality and the capacity of an economic entity to build on preceding innovation.

At international level an important issue is represented by the professional accountancy work and how much creativity needs. In order to answer to this challenge we have to see before the diverse field of activity where an accountant could work.

Most of accountants seem to be involved in financial accounting, a significant part of them work in taxation and finally a smaller part of accountants are involved in audit and managerial accounting.

Usually financial accounting activities seem to require for more creativity than does taxation and auditing. Speaking about managerial accounting work, this activity require an intermediate level of creativity. Hood and Koberg examined few years ago the relationship among public accounting firm culture and accountants' measured creativity. By this survey they found no relationship between accountants' measured creativity and firm culture, job satisfaction, or turnover intention.

The international literature has infrequently investigated the nature and consequences of creativity in accounting work. Speaking about the accountant's creativity the humanistic psychologist Abraham Maslow (1998) argues that accountants have the smallest vocabulary of any profession, lack creativity, fear change.

*Other important issue is related to the level of creative accounting within Romanian companies from Timis County. It is a tabu subject but creativity for accountants means to try to full fill the financial objectives with the help of accounting standards flexibility.*

Anyway creativity has a bad name within the accounting industry for obvious reasons. Although, apparently, accounting seems to be a straightforward mechanical process which does not involve creativity and imagination, essentially, we can notice that most of the companies use a correction of the result and an adjustment of the statement of account, therefore, being able to elude the existing judicial and accounting rules.

Subject of Creative Accounting is normally portrayed maligned and negative act. Creative accounting brings to mind the various huge scandals of yesteryear that took down mighty firms. Creative accounting referring to accounting practices that may follow the letter of standard accounting practices, but it deviate sometime from the spirit of those rules.

Creative accounting, as is known in Europe, or earnings management, as is known in United States, is defined by different ways:

- For Schipper "creative accounting" can be equated with disclosure management, in the sense of a purposeful intervention in the financial reporting process;

- Creative accounting, in Turillo and Teller's opinion represents "an instrument of improving annual accounts, a prop and a result of financial and fiscal engineering", while Trotman (1993) argues that this concept "allows the display of a new favorable image of the results and the statement of account".

- For Merchant and Rockness creative accounting means any action on the part of management which affects reported income and which provides no true economic advantage to the organization and may in.

- Naser said "creative accounting may be defined as: the process of manipulating accounting figures by taking advantage of the loopholes in accounting rules and the choices of measurement and disclosure practices in them to transform financial statements from what they should be, to what preparers would prefer to see reported and the process by which transactions are structured so as to produce the required accounting results rather than reporting transactions in a neutral and consistent way" Park argues that creativity contributes to success in professional accounting. Usually individuals who are seeking to be successful in the diverse world of accounting must be able to use creative problem-solving skills in a consultative process. But this situation is also available also for accountants?

Along Europe the incidence of creative accounting is particularly strong in the United Kingdom compared with the countries of continental Europe such as France, Germany, Spain or Romania where the Roman law tradition applies and accounting rules do not allow the flexibility that enables accountants to make choices that favour them.

In USA the common law tradition is applied as in the UK, but the high risk and cost of litigation have led the accounting profession to formulate agreed, highly detailed procedures that can be justified in court. By contrast, litigation risk is much lower in the UK.

### **3. Research methodology and results**

The object of the current article refers to the presentation of the conceptual delimitations regarding creativity and its application into accounting area by a detailed description of theoretical framework proposed by some authors, as well as the brief review of the literature written on the topic in the last 30 years.

Also, we can see how the specific literature regarding the aspects concerning the magical land of creativity we have decided to shortly review the main aspects approached at the European level regarding the role in the field of accounting.

In order to achieve this aim, we analyzed approximately 10 academic articles available in three scientific databases.

Our approach regarding the exploratory research includes three stages:

The first consists in finding the information about creativity and creative accounting in the databases.

The second stage consisted in grouping them on the most frequently approached themes.

The third stage consisted in a survey on 31 big companies from Timis County regarding the creativity and creative accounting within accountants.

In our research, we have used the deductive method concluding some remarks based on the already existing theories, the type of research used being the fundamental one. The utility of such a research contributes to the assurance of the premises for the development of future research.

Regarding the employees involvement in the field of accounting the majority of Timis county companies involve their employees in different financial accounting and reporting activities. On the other hand taxation seem to be not so important for this companies looking at the percentage of employees involved in this field of accounting. This could be a wrong conclusion if we take into account the real situation. The majority of big companies from Timis County use external services in order to cover taxation needs.

Managerial accounting seems to have an increasing role for this period characterized by financial crisis. Mainly the multinational companies are trying to develop the controlling activities and the number of people who are working in this field.

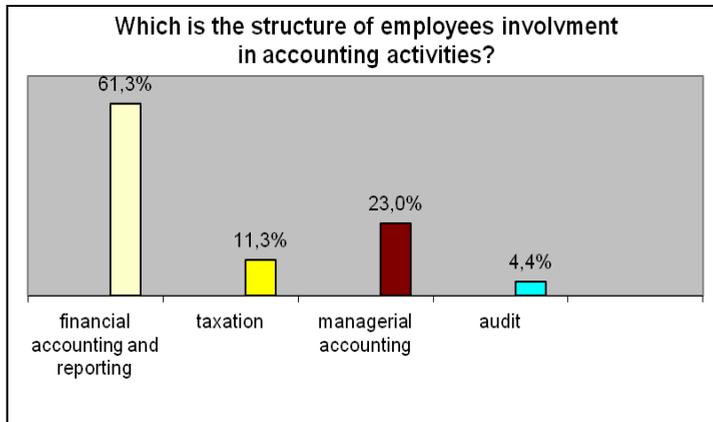

Figure 1 The structure of employees involvement in different accounting activities

For each category of accountants, as graduate of a business university degree, the creativity is quite important in order to catch different kind of accounting study cases.

But the level of creativity for these 4 categories of accountants seems to be very different. Thereby for the professionals involved in financial accounting and financial reporting the level of creativity is very important.

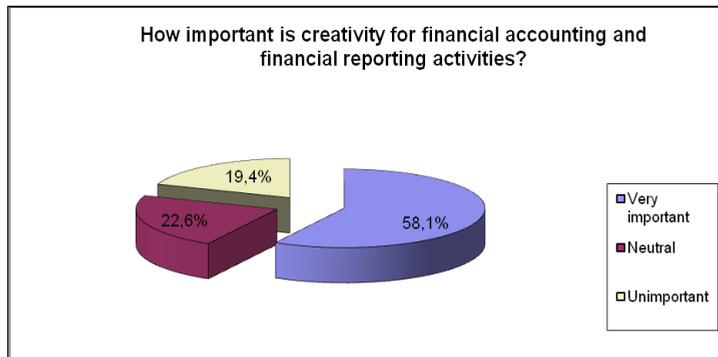

Figure 2 The importance of creativity for financial accounting and financial reporting

The results are very obvious negative in case of controllers and professionals in taxation (less than 15%). The big majority of these categories are considering the creativity is not so important in their activity.

Controllers work is fully dedicated to internal use of the information for controlling different business processes and for management decision making. Therefore, creativity might be required only for the information structure and content presented in order to help the internal users to better understand the facts. The accuracy of information is the key characteristic of their task and the information provided is asked by the business itself giving no much room for interpretations.

For auditors, the creativity seems to be at least as important as for the professionals involved in financial accounting and financial reporting. Almost 61% say creativity and logical is very important for auditors in order to discover creative fraud attempts. Fraudulent financial reporting has become an important concern for the audit profession (especially that the constant audit failures from the past two decades have decreased the public trust in the audit profession) and jumping in the client shoes in order to understand the potential information manipulation became a must. Therefore, creativity of the client has to be mirrored by creativity of the auditor. By thoroughly understanding the client's stakeholders' interests and the interests of the entity itself and identifying the conflict between these parties the auditor can identify the potential areas for creativity.

However, even if this seems to be the natural and much needed development of the audit profession there is a different trend noticed within the audit profession. While the auditors recognize in the answers provided that the creativity is important, instead of applying it in the audit missions performed, they revert to the basic audit procedures that used to be efficient and effective in the early years of audit – substantive tests of details procedures. This trend was borne also by the big failures that proved to be very costly to the audit companies that performed the audit of the respective companies. While the courts that analyzed the audit work performed concluded that the auditors' analysis was subjective and biased, they fined the audit companies with huge amounts. Thus, in order to be able to prove in any court that

the auditor complied with its obligation, they removed from the audit procedures most of the analytical procedures that might be interpreted as biased or subjective. If this trend will continue, the auditors will become document checkers and the probability of risk of failure will increase.

#### **4. Discussions and conclusions**

Our research study is an exploratory investigation of some interrelated questions exploring the accountants and their creativity.

Speaking about the accountant's creativity the humanistic psychologist Abraham Maslow (1998) argues that accountants have the smallest vocabulary of any profession, lack creativity, fear change.

But this is an international approach and we can not say that this approach is available also for Romania of nowadays. The accountant's behavior in each country should deal with social norms. As well the cultural characteristics of a country can generate important differences between accountant's decisions/behaviors.

For the Timis county we can see that the creativity is a characteristic of a big part of accountants community, mainly for professional involve in preparation of financial statements. That creativity should be discover by auditors and should be limited by detailed implementing rules.

As well our research is limited by several design and measurement choices. We measured creativity among professional accountants in a single county. The generalizability of our results from county to country level is untested. Similarly, our samples of accountants are nonrandom, which further limits the generalizability of our results.

**Abstract:** *This paper aims to point out the contribution of professional accountants to the sustainable development of organization and the way they generate sustainable organizational success through their direct involvement in creating organizational culture. Professional accountants can be considered value creators in organizations because of their commitment in developing and implementing strategies, policies, plans, structures and governance measures which set the framework for the creation of added value. The ethics and values of conduct in organizations are supported by professional accountants through their behavior and the actions they carry out. Thus, the quality of professional judgment becomes a differentiating factor for accounting professionals.*

**Keywords:** organizational culture, ethical values, ethical behavior, accounting professionals.

**JEL classification:** M41, M49.

## 1. Introduction

In international literature, organizational culture has been interpreted in different ways by many researchers famous in this field.

Authors such Thomas J. Peters and Robert H. Waterman in "In Search of Excellence", which became a best-selling success, defined organizational culture as "a dominant and coherent set of values shared by the organization's members, induced by symbolic means." The two authors have contributed to spreading the concept of organizational culture, demonstrating through concrete cases there is a close link between large corporations' dimensions of organizational culture and their performances.

Author Antonio Strati (1992) stated: "Organizational culture is a set of symbols, beliefs and behavior patterns learned, produced and recreated by people who devote their energy and life's work to an organization. It is expressed in the design and organization of work, the events created by this culture and into the services the organization produces. "

American researcher Edgar Schein (2010) defines culture of economic groups as "a pattern of basic assumptions shared by the group in solving the problems of external adaptation and internal integration, that have worked well enough to be considered valid and, therefore, good to be shared with other new members as the correct way to perceive, understand and feel in relation to those problems."

According to the author Geert Hofstede (1996), organizational culture can be defined as "a collective mental programming that distinguishes the members of an

*organization of the members of other organizations."*

French author Maurice Thevenet (2010), in a recent paper, considers that there is a culture specific to each enterprise, "*consisting of ways to meet current situations occurring in the professional life*" and proposes a description of the organizational culture, looking at it as an essential resource of organizations, which must be taken into account by their management.

In a practical study, author Samuel Certo (2002) defines organizational culture as "*a set of common values and beliefs that the members of the organization have on the operation and existence of their organization.*"

According to some American authors, organizational culture "*involves rituals, symbols and stories associated with categories of people, offering an insight into their beliefs and values, the things that are important to them and the reasons behind those choices.*"( Dygert and Jacobs, 2006)

Also, the term organizational culture has been debated as well in the specialized literature in our country by many authors concerned with this field of interest.

Thus the author Alexander Puiu (2007), in "Management - analysis and comparative studies", defines organizational culture as "*a structured set of material and spiritual results of the organization, which integrates a system of values and beliefs that is systematically cultivated and transmitted among its members and outside the unit.*" This view is different because it highlights both the spiritual and material elements that make up the culture of an organization.

Romanian authors Ovidiu Nicolescu and Ion Verboncu (2008) defined organizational culture as "*a set of values, beliefs, aspirations, expectations and behaviors shaped over time in each organization prevailing therein and conditioning directly and indirectly its functionality and performance.*"

In the perspective of Romanian authors Tatiana Gavrila and Viorel Lefter (2002), organizational culture reflects "*managers' thinking, ethical standards, types of behavior, management policies adopted, traditions, attitudes and specific events that have marked the evolution of the firm*".

Authors Eugen Burdus and Gheorghita Căprărescu (1999) stated that organizational culture is "*an assembly of artificial products, core values and concepts, modes of thinking and behavior patterns that are generally accepted in an organization as common basis for action*".

Organizational culture "*is represented by the beliefs of an organization's employees expressed through a system of attitudes, behaviors, empathies, expectations, aspirations and values of performers and managers, outlined during its development, determining in a considerable manner its functionality and performance while having an impact on the satisfaction of its members*".( Ciochină, 2004).

Analyzing the definitions given by great researchers, both in the international as well as in the national literature, our opinion is that the term organizational culture reflects a set of principles, strategies, ethical and behavioral values implemented within an organization in order to increase its economic and financial performances.

The characteristics of organizational culture were identified by several researchers depending on the approach of the term organizational culture as follows:

- Authors Peters and Waterman identified eight characteristics as common features among companies with superior results. These included: *unity of action and decision making; openness to customer; assuring quality and reliability; atmosphere that encourages creative thinking and innovation;*

*respect and focus on the contribution of each employee; maintaining the basic philosophy of the company; performing in domains and business related to organizational management; maintaining the number of senior management positions at a minimum; decentralization and centralization of certain functions.*

- Author Gary Johns (1997), in one of his works of reference, pointed out synthetically the following features of organizational culture:
  1. Culture is a *true lifestyle* for members. Organizational culture becomes evident only when it is compared to that of other organizations or is subject to change;
  2. Culture tends to *be stable over time* because it involves assumptions, values and core beliefs.

Unlike the characteristics identified by the previous researchers, other features of organizational culture have been identified such as:

- organizational culture comprises an integrated model of human behavior: values, ethical standards, symbols, beliefs, aspirations accepted by most of the employees;
- these components are formed over time and become more powerful;
- the behavior pattern is characteristic and dominant and is stable over time;
- organizational culture characterizes all members of an organization or most of them;
- organizational culture plays an important role in integrating employees and adaptation to the external environment of the organization;
- organizational culture takes into consideration the material results and expresses itself through the products and services the company offers.

Factors that may influence organizational culture are business environment, leadership, management practices and the interaction process, both formally and informally, and they should be taken into account in any analysis, especially when change is needed in the organization. As stated by Schein (1991), culture operates with a default set of beliefs that can not be changed unless they are brought to the surface and analyzed.

Organizational culture influences the expectations of individuals that are part of an organization, defines the type of persons who will fit into the organization and affects how people interact with each other both in the internal and external environment. Regulations imposed by organizational culture determine what is desirable or undesirable, the appropriate or inappropriate behavior in an organization, and their lack affects the optimal function of organization.

## **2. Interrelation organizational culture – ethical values**

Organizational culture includes values, attitudes, beliefs and behavioral norms that consider the ethical component transmitted by the founders or senior managers and adopted by all employees of an organization, provided that they meet their expectations. Once these expectations are adopted they translate into behaviors and attitudes expected both within the company and in relation to the external environment. Behaviors, attitudes are formed over time, based on the rules of conduct established by codes of conduct, but also on plans, company objectives, job descriptions, and reward and punishment system. Ethical behavior is a prerequisite to obtain high performance and competitive advantage in business environment.

An important place is held by managerial ethics, which determines the behavior and actions of managers within organizations and the manner in which decisions affect individuals and social groups.

Romanian managers should be aware that the starting point in determining ethical behavior is the organizational culture, by the mean of which information about the desired ethical climate are transmitted. Companies that are characterized by positive and strong ethical climate set clear expectations from their members, thus creating preconditions for increased performance.

Decision of one person can influence the trajectory of an entire organization. Contemporary organizations illustrates how managers, in their run for success and following own interest, have decreased the company's values, if not the total disappearance of their business because of unethical decisions. The Corporation's Savior became its gravedigger. And it was not a matter of competence!

In the organizational context, business ethics plays a fundamental role in promoting or undermining the image of the corporation. Ethics means a set of standards used to assess the correctness or unfairness of a person's relationships with others in terms of truth and justice.

Professional ethics also plays a dual role: an ethical reflection applied to a particular field of work (profession) or the rules established by a professional group to ensure the practices of each of his members, gathered in a code, including the code of ethics of the profession. Broadening of the meaning of the word „code” led to the inclusion in it of rules set by organizations outside professional ones, such as governments. This raises the question of the relationship between "public" and "private", between professionals and non-professionals. Professional accountants are subject to the strictest ethical standards.

The ethical decision is a process meant to explore all aspects of choosing between several possible actions, depending on the organization's recognized moral values, and then to weigh those options and recommend a course of action.

Distinctive features of this method of ethical assessment of an organization are:

- procedural methods, thus more objective; procedures are generally designed so as to be assimilated relatively easily and not requiring any special ethical-philosophical knowledge;
- actions applied to resolve ethical issues that have great social, economic and political importance - through its impact on people and the financial interests involved (acceptance of new technologies, the development of ethical codes, the adoption of public policies and so on.);
- a complex framework, that must be organized by professionals and involves a large number of persons: well-structured groups of evaluation, different decision methods, techniques to achieve consensus, standards for reporting results etc.
- scientific competence when the problems assessed are not collected from the public agenda, but the work of various organizations (the consequences of the use of genetically modified organisms, the probabilities of those consequences, which are the stakeholders and so on).

Professional accountants play a central role in the organization's operating system. In today's economic, complex and fast evolving business environment, the financial position will be the champion of change. In this environment, the key will be the ability to deliver correct professional judgment on multidimensional subjects.

Central attributes of professional judgment, technical excellence and ethics should be protected and promoted further on - and this is why we need to increase the number of accounting professionals for our economies. They will be more than technically proficient.

The attributes possessed by accountants facilitates entrepreneurship, helps managers create added value and manage risk. They are specialists in building partnerships and communicate effectively. In other words they are the ones who add value to the business.

Within organizations, professional accountants may have different roles as creators, mediators, custodians and rapporteurs of sustainable value in terms of both performance and compliance:

- as creators of value, professional accountants have a role in the development and implementation of strategies, policies, plans, structures and governance measures that provide the framework for sustainable value creation.
- as mediators of value, accounting professionals have a role in informing and guiding decision-making process and implementing strategies to create sustainable value.
- as preservers of value, professional accountants provide protection for the strategies of sustainable value creation against strategic, operational and financial risks and ensure compliance with regulations, standards and best practices.
- as rapporteurs of value, accounting professionals are providing transparent information that give lasting value to stakeholders.

### 3. Conclusions

Organizational culture reflects a set of principles, strategies, ethical and behavioral implemented values within an organization in order to increase its financial and economic performance. Factors that may influence organizational culture are business environment, leadership, management practices and the interaction process, both formally and informally, and they should be taken into account in any analysis, especially when change is needed in the organization.

Professional accountants play a central role in the organization's system of operation and development. Attributes possessed by accountants facilitate entrepreneurship and help managers create value and manage risk. They are specialists in building partnerships and effective communication. In other words they are the ones who add value to the organization fully.

**Abstract:** *The auditing of the financial statements is a certification service intended to offer the users more credibility regarding the quality of accounting information. This is the reason why the present study selected all the Cluj county entities that, according to the public information, between 2005-2012 were subject to financial audit in order to estimate, at this level, the influence of foreign investments in the financing structure. The information provided by the financial statements of these audited entities (with or without foreign participation in share capital) was analyzed for the calculation of the relevant indicators to determine the evolution of the equity financing, the recourse to external financing funds, the ratio of external funds and equity funds used for financing and the assessment of the efficiency of foreign capital invested at the level of these entities. In order to meet this objective, we considered the information from the financial statements of the concerned entities, published between 2008-2011. For the relevance of the study, we eliminated the audited entities that did not have financial statements published in all of the four financial years for various reasons (dissolution, liquidation, merger, or temporary suspension of activity) or had negative working capital. The financial statement information was analyzed in view of the calculation for each audited entity of the rate of financial autonomy, the debt ratio, the debt to equity ratio and of the rotation speed of equity. The audited entities were classified into 2 major categories: audited entities with a foreign participation in share capital and audited entities with the whole share capital financed by equity funds. We applied the simple average method at the level of the both audited entities categories for each of the four analyzed indicators. Furthermore, we performed an analysis from the static and dynamic point of view of the results. The conclusions that we reached are relevant for the emphasis of one of the two categories of audited entities for one or the other financing methods, for a specific proportion of the financing forms and for the assessment of the management of shareholders' capital in the analyzed time span.*

**Keywords:** audited entities; financial statement; foreign investments; equity funds.

**JEL classification:** M41, M42

## **1. Introduction and Literature Review**

The financial statements of the audited entities offer the users more credibility. The auditors play an important part in offering a guarantee in what concerns the reliability and accuracy of the information in the financial statements of the audited companies. (Boța-Avram, 2012) The financial audit is in fact a certification service that results in a report in which the auditor expresses an opinion concerning the compliance of the significant aspects of the financial statements with the general accepted principles of accounting (Loebbecke, 2010). Financial auditing brings many benefits, among which we mention, considering the relevance for the present study, the following: the increase of trust of the users in the accounting information Ghiță, 2008), the increase of trust in the company, the detection and prevention of significant alteration of information in the financial statements (Oprean, 2007). There are also reviews in the literature according to which the auditor's role in society is that of validating the truth and fairness of the financial statements (Dart, 2011). Therefore, the activity performed by auditors is placed by investors in a special position of public trust (Martens and McEnroe, 1992). Another clue as to enhance confidence in the activity performed by auditors is the process by which auditors has selected, retained and compensated. In addition, the literature accomplishes two goals: identification of the problem of audit independence as an outcome of vesting the authority to make an auditor-related decisions with corporate boards of directors, and proposing a structure to allow shareholders to direct path for deciding on choice and auditor compensation (Rashad, 2002). Therefore, in order to accomplish this study were selected only the audited entities because their financial statements indicate a high level of credibility, based on these considerations.

## **2. Research Methodology**

The entities that between 2005-2012 were subject to statutory audit according to the provisions of the OMFP 3055/2009 represent the basis of the present study. According to these provisions, the audit of the financial statements is mandatory in the case of entities that at the drafting date exceed the limits of two of the three following size criteria:

- total assets 3.650.000 Euro;
- net turnover 7.300.000 Euro;
- average number of employees during the financial year 50.

We took into account in an exhaustive manner all the audited entities during this period across the Cluj county (304 entities). We analyzed information regarding these entities for the financial years 2008-2011 in what concerns:

- the incidence of foreign investments on the financial status
- the level and evolution of assets, of equity funds, of debts and turnover;
- the level of financial dependence and management of the controlled resources

In order to meet the objective of this study and to guarantee the relevance of the results, we eliminated from the study 102 audited entities that did not publish between 2008-2011 any information through the financial statements. This was due to the changes that appeared in the structure of the social capital and/or the activities (mergers, dissolutions, liquidations, insolvencies, temporary suspension of activity). Also, 29 other entities were not taken into consideration due to their negative values of their equity funds. Consequently, out to the total 304 entities that were subject to the statutory audit across Cluj county between 2005-2012, we included 173 audited entities in our research. Therefore, our study is exhaustive in what concerns all the

entities audited in this period in the Cluj county and that published in all the 4 years (2008-2011) their financial statements and had positive values of their equity funds. In view of the analysis of the evolution in the temporary interval of 4 years of the relation between foreign investments in the audited entities on one hand and the financial dependence rate, namely the management of the controlled resources on the other hand, we used some indicators relevant in this respect:

- Rate of financial autonomy ( $R_{FA}$ ) to emphasize the evolution of the financing of the audited entities activity from equity funds (Bătrâncea, 2008);
- Debt ratio ( $D_R$ ) in order to see how the audited entities' assets are financed on the basis of debts to third parties;
- Debt to Equity Ratio ( $D_{ER}$ ) to emphasize to what extent the resources of audited entities resources were purchased with foreign capital;
- Rotation speed of equity ( $R_{SE}$ ) to show management efficiency in what concerns the shareholders' capital in the analyzed time span (Greuning, 2005).

The above-mentioned indicators were calculated for each audited entity. These were divided into two categories: entities with foreign participation in share capital and entities without foreign participation in share capital. In view of the interpretation of the results, we applied the simple average method on the values of the indicators in each of the two categories, according to the involvement/non-involvement of foreign investments.

### 3. Results and Discussions

Out of the 173 entities audited in the present study (positive value of equity funds and published financial statements for the financial years 2008-2011), 26 had foreign participation in share capital (foreign investments), and 147 audited entities didn't have foreign participation in share capital.

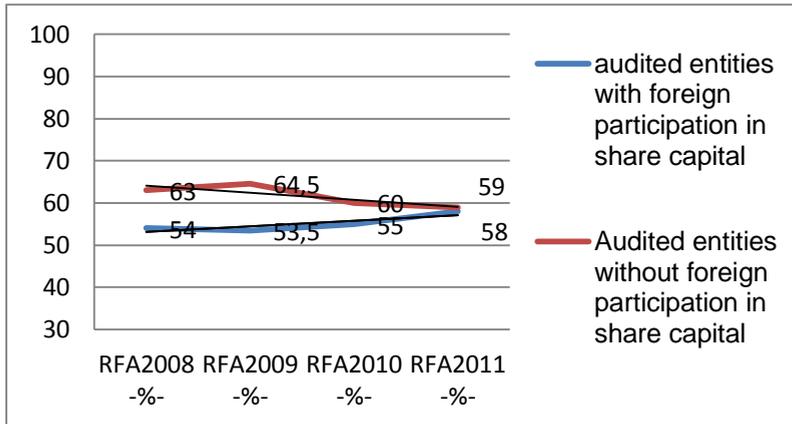

In the beginning, the study analyzed the extent to which the audited entities finance their activity out of equity funds, showed by the rate of financial autonomy ( $R_{FA}$ ). From a dynamic standpoint, the increase of this value is highly appreciated, and the financial security interval is [30%, 100%] (Achim, 2009). The results of the study show the following evolution on the long term of the rate of financial autonomy for the two categories of audited entities:

**Table 1:** The evolution of the rate of financial autonomy for the audited entities in relation with the foreign participation in share capital

Foreign participation in share capital	Rate of Financial Autonomy (RFA)			
	RFA2008 -%	RFA2009 -%	RFA2010 -%	RF2011 -%
YES	54	53.5	55	58
NO	63	64.5	60	59

Source: Statistical processing performed by the authors

We notice that both categories of audited entities are situated inside the safety interval, almost in its center. This shows that the audited entities finance their activity mainly from equity funds (Self-financing). During the economic-financial crisis, the audited entities were not confronted with difficulties in facing the payment necessities and attracting external financing resources would not be mandatory.

**Figure 1:** The evolution of rate of financial autonomy for audited entities  
 Source: Statistical processing performed by the authors

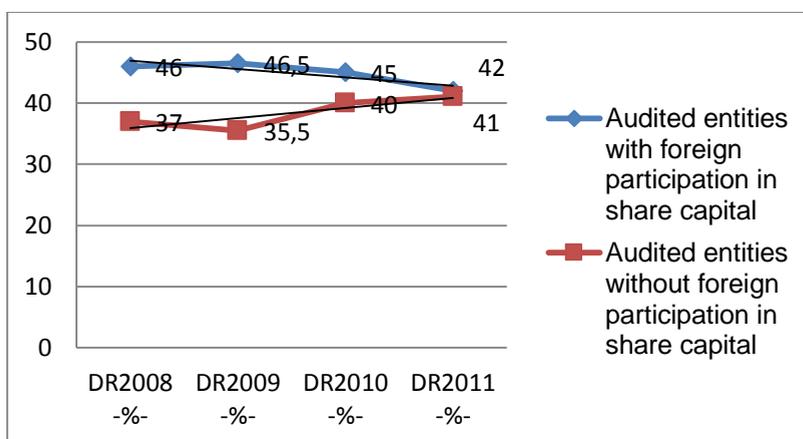

Taking into account the dynamic aspects regarding the evolution of the rate of financial autonomy, according to figure 1, we can notice that the audited entities without foreign participation in share capital show values superior than the other category of entities, which means that these tend to finance their activity especially of equity funds (increase of share capital, undistributed profit) and recourse less to external financing sources in comparison to the audited entities with foreign participation in share capital. The opposite trends set by the two categories of entities are worth mentioning. The audited entities without foreign participation show a decrease in the preference for the financing from equity funds (drawback), whereas the audited entities with foreign participation in share capital tend to choose the financing mainly from equity funds (Advantage). Regardless of the financing options, at the 2011 level the percentages of the financing options are the same. In the case of both types of audited entities, these tend towards the percentage of 58-59%, namely at the middle of the safety interval (reach the optimal value). The stabilization of the rate of financial autonomy for the audited entities from Cluj county at the optimal value at the 2011 level means adequate contribution of equity funds to the development of activity and the convergence of corporate governance politics towards an external adequate indebtedness (even optimal). Moreover, we studied the evolution of the (Debt Ratio) ( $RPF_A$ ) to show the extent to which the assets of the entity are financed by the total indebtedness (on the short and long term). In the specialized literature, the opinions tend to show a preference for an ascending trend and the maintenance of the indicator in the safety level [0%, 30%].

**Table 2:** Debt Ratio evolution for the audited entities - the foreign participation

Foreign participation in share capital	Debt Ratio (DR)			
	DR2008 -%-	DR2009 -%-	DR2010 -%-	DR2011 -%-
YES	46	46.5	45	42
NO	37	35.5	40	41

Source: Statistical processing performed by the authors

Both categories of audited entities show values that slightly exceed the limit of the safety interval, thus the assets are excessively financed on the basis of long and short term debts towards third parties. This aspect can be considered to be unfavorable if we refer only to the extent to which this indicator for audited entities complies or not with the limit of the safety interval. However, if we analyze the debt ratio evolution from a dynamic point of view during the financial years 2008-2011 we obtain the following information according to figure 2:

**Figure 2:** The evolution of Debt Ratio for audited entities

Source: Statistical processing performed by the authors

The audited entities with foreign participation in share capital show an ascending trend during the four financial years and had a decrease of 8.7%. Therefore we noticed the trend of decreasing the excessive financing on the basis of third parties debts (advantage) and consequently the increase of the financing based on equity funds. In the case of audited entities without foreign participation in share capital, we noticed an opposite trend (unfavorable evolution). Although the percentage of financing on the basis of third parties debts is situated over the safety limit, we noticed an ascending trend between 2008-2011 in what concerns the preference for the insurance of the financing from this source (10.81% increase). In what concerns the evaluation of the type of financing of the audited entities activity it is important to determine the extent to which the economic resources of the company are procured from foreign capital. In the case of the debt to equity ratio (DER) we consider that a descending evolution of the indicator is favorable. The upper accepted limit considered to be reasonable in the case of this indicator is 200%. The total amount of debt must be twice bigger than the value of equity funds of the entity

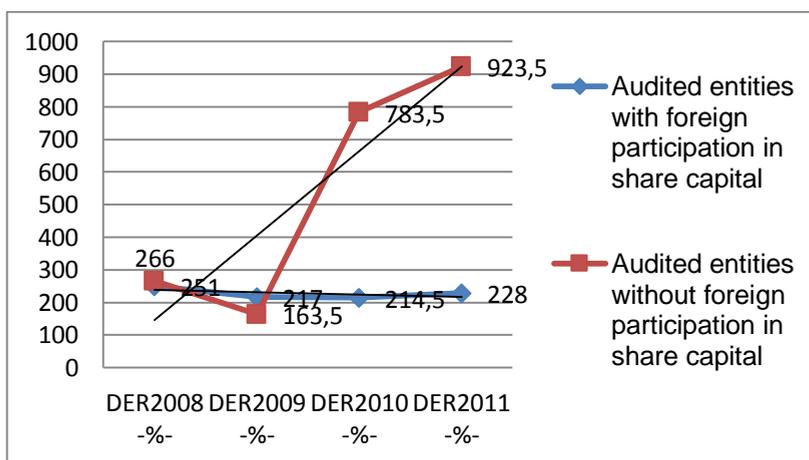

so that it will not affect the capacity to support long term debt. The debt to equity ratio for the audited entities show between 2008-2011 values that exceed the maximum acceptable limit that guaranteed security in what concerns the reimbursement capacity of long term debts.

**Table 3:** Debt to Equity Ratio Evolution for the audited entities in relation with the foreign participation in share capital

Foreign participation in share capital	Debt to Equity Ratio (DER)			
	DER2008 -%-	DER2009 -%-	DER2010 -%-	DER2011 -%-
YES	251	217	214.5	228
NO	266	163.5	783.5	923.5

Source: Statistical processing performed by the authors

Even though the audited entities with foreign participation in share capital show indicator values that exceed the maximum safety limit, these can be considered minor (an average of 13.81%). This is an oversized value of the third parties debts (external resources) as compared to the debts towards shareholders (internal resources). Whereas in the case of this audited entities categories we can say that the exceeding of the safety limit is reasonable, we cannot say the same thing on the audited entities without foreign participation in the share capital. In this case, the exceeding of the maximum acceptable limit, during the four financial years is an average of 167.06%. At the level of all audited entities in Cluj county that published financial statements between 2008-2011 and had positive equity funds, the shareholders are not very involved from a financial point of view in the progress of activities; they avoid assuming risks deriving from the equity funds investments and they prefer the alternative of attracting external resources for financing. To have a complete overview on these aspects we need to present the evolution on the long term of the debt to equity ratio, according to figure 3:

**Figure 3:** The evolution of Debt to Equity Ratio for audited entities

Source: Statistical processing performed by the authors

Although they only slightly exceeded the maximum value acceptable for the debt to equity ratio (unfavorable aspect), the audited entities with foreign participation in share capital show a descending evolution trend of this indicator (favorable aspect). Consequently, we noticed an increase in the funding of business out of equity funds, rather than external financing (Bank credits, commercial credits).

We cannot say the same thing regarding the audited entities without foreign participation in share capital, where the debt to equity ratio tends towards an exponential ascending trend (unfavorable aspect).

Consequently, the equity financing of shareholders decreases and the long term debt financing increases, through financial, commercial, fiscal and wage debt.

The risk represents the decreased capacity of the audited entities from this category to support long term debt. The efficiency of using the shareholder's capital (the number of rotations performed) to obtain a certain turnover is measured with the rotation speed of equity indicator. An increase in the rotation speed of equity reveals an increase of the management efficiency in the administration of shareholders' capitals.

**Table 4:** Rotation Speed of Equity evolution for the audited entities in relation with the foreign participation in share capital

Foreign participation in share capital	Rotation Speed of Equity (RSE)			
	RSE2008 -%	RSE2009 -%	RSE2010 -%	RSE2011 -%
YES	7.5	5	6.5	4.5
NO	2	2	2	6

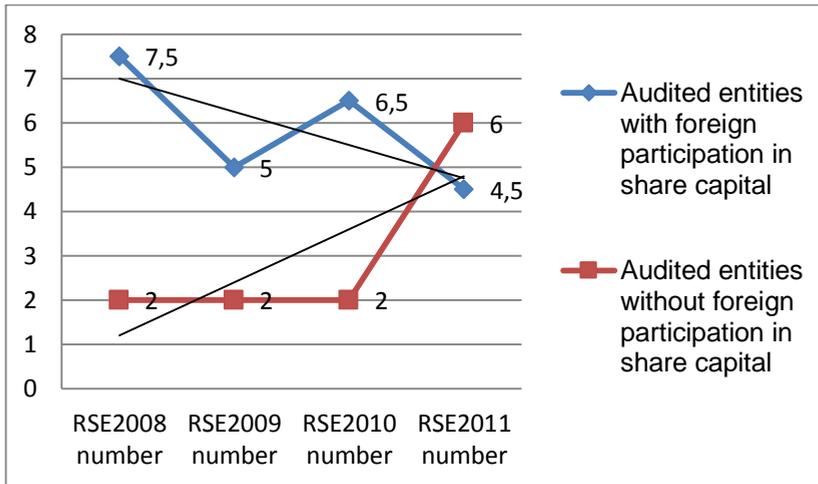

Source: Statistical processing performed by the authors

The audited entities with foreign participation in share capital show superior efficiency levels in what concerns the use of shareholders capitals, as compared to audited entities without foreign participation in share capital. Apparently, the foreign investment involvement entails the high efficiency of the activity.

To have a complete overview on the capital use efficiency it is important to perform a dynamic analysis of the rotation speed of equity for the financial years 2008-2011, according to figure 4.

Although high values of the indicator were registered and consequently a high efficiency, the audited entities with foreign participation in share capital points out a decrease on the long term of this level of performance, the trend is a descending one.

In the financial year 2011, the rotation speed of equity shows a decrease in relative sizes as compared to the financial year 2008 with 40%, the efficiency level became inferior to the audited entities without foreign participation in share capital.

**Figure 4:** The evolution of Rotation Speed of Equity for audited entities  
Source: Statistical processing performed by the authors

On the other hand, the latter ones show an ascending trend of the evolution of management efficiency in the administration of shareholders' capital, the level of the rotation speed of equity indicator showing increases in the analyzed time span with 200%.

These entities reach the 2011 year level to be more efficient as compared to the audited entities with foreign participation in share capital.

We consider useful for getting an overview and some relevant information on the results of the research, the centralization of information presented above. Therefore, it can be achieved the following synthesis on the results of the study, which includes the analyzed aspects as well as the results obtained for the two categories of audited entities, as it results from table no. 5:

**Table 5:** Financing sources and the shareholders' capitals use efficiency for the audited entities

Analyzed aspects for 2008-2011 for audited entities during 2005-2012	Audited entities typology							
	Audited entities with foreign participation in share capital				Audited entities without foreign participation in share capital			
	Static		Dynamic		Static		Dynamic	
	Medium level achieved	Optimal level	Achieved trend	Optimal trend	Medium level achieved	Optimal level	Achieved trend	Optimal trend
Equity financing	55%	[30%, 100%]	Asc	Asc	62%	[30%, 100%]	Desc	Asc
External resources involved in financing	45%	[0%, 30%]	Desc	Desc	38%	[0%, 30%]	Asc	Desc
Extent-resources procured from foreign capital	228%	<200%	Desc	Desc	534%	<200%	Asc	Desc
Efficiency of invested capitals used	5.9	-	Desc	Asc	3	-	Asc	Asc

Source: Statistical processing performed by the authors

As shown in the previous table, the audited entities with foreign participation in the share capital or those which have the share capital of local origin, achieve different levels of performance concerning the indicators taken into consideration.

#### 4. Conclusions

The two categories of audited entities that we analyzed in the present study show different evolutions (according to the involvement of foreign investments) regarding the dynamics of the main financing type, the extent to which the audited entities resources were procured out of foreign capital or the management efficiency of the administration of shareholders' capitals.

Our study shows that audited entities with foreign participation in share capital show an adequate proportion of equity capital with a positive, ascending evolution during time.

The dependence on external resources is too high, but it is important that the trend is a descending one in this case. The slightly high but reasonable proportion between the total debt and the equity capitals show a moderate risk in what concerns the choice of external or internal financing.

The audited entities without foreign participation show a reduction of the trend of resorting to external financing, preferring equity financing. In this way, the business, as well as the external capital dependency risk is reduced.

The financial involvement degree of entity shareholders is quite high. The shareholders' own resources are more efficiently used than in the case of the other audited entities categories.

On the other hand, in the case of audited entities without foreign participation in share capital, although they finance their activities to an adequate extent from their own funds, the contribution of shareholders in the business process shows a descending, negative evolution. The dependence on external financing is quite high; moreover, it shows growing tendencies in the future.

Moreover, the percentage of these external financing is much higher than the level of financial involvement of shareholders in the management of the audited entities.

Consequently, the audited entities prefer the external resources, an increasing trend (possibly indebtedness, assuming high risks) that subsequently they do not use efficiently enough given the fact that they show rotation speeds of equity more reduced than in the case of the other categories of audited entities.

In conclusion, the most stable audited entities from the financing resources point of view and the efficiency of their use, the most stable are the audited entities with foreign participation in the capital. In the case of these, the most well funded assumption is the one of continuing the activity without any prospect of reducing it.

After analyzing some credible information, of some audited financial statements, it can be found in the Romanian entities with foreign participation in the share capital, a more effective use of shareholder's capital, given that these businesses are self-financed to a lesser extent compared to the entities which have registered exclusively local capital. The management option in the field of financing is predominantly oriented towards the effective use of external resources, with the ultimate in reducing the risk of investments through a lower implication of the shareholder's capital in financing.

**Abstract:** *The study is based on public information provided by the National Trade Register Office regarding all audited entities within the county of Cluj. In accordance with the legal provisions, the audited entities must notify, in case they meet the legal requirements, if they contract financial audit jobs. The processed information refers to the connection of the management's nature and the source of the capital for these entities with the frequency of the changes occurred in the structure of the entity and/or of the social capital. Operations of such nature, considered for the period 2005-2012, refer on one side to absorption mergers, dissolutions without liquidation followed by merger, partial divisions and transfer of the audited entity's headquarters in other counties (positive operations) and on the other side to operations of liquidation, insolvency, dissolution followed by liquidation, temporary suspension of activity for a maximum period of 3 years (negative operations). Positive operations are considered by authors to have as an impact the optimization of the indicators of financial position and/or performance, and the negative operations as those unlikely to meet the principle of activity continuity. The study aims to determine whether there is a correlation between a certain type of corporate governance on one side and the frequency of the two categories of changes in the structure of the activity and/or of the social capital. Conclusions are relevant for at least two reasons: the study is exhaustive, there have been taken into consideration all the audited entities in the county of Cluj and, moreover, the analyzed period is very expansive (the last seven financial years). On the other hand, from the previous studies it appears that within audited entities there is a higher preponderance of foreign management in comparison with a more moderate foreign investment. Relevant in this respect are the findings regarding the nature of the changes in the structure of the activity and/or of the social capital within the audited entities where there is an overlap between the foreign governance and the foreign investment.*

**Keywords:** corporate governance; audited entities; restructuring operations; foreign investment; social capital.

## 1. Introduction and Literature Review

Regardless of an entity's size or its field of activity, the management is of utmost importance in determining the manner in which an entity can use the available resources as efficiently as possible in order to achieve the intended results and to make optimal decisions in this respect. Ensuring an effective corporate governance is a relatively new aim on the list of objectives regarding international economic convergence, also as the manner in which the audit can contribute to achieving this goal. This is a topic of great interest and debate between the two academics and

practitioners or specialists (Boța-Avram, 2012). The general objectives of the audit include verifying and subsequently ensuring that within financial statements there are no assets, liabilities, or equity which do not exist or do not belong to the entity and that the accounting principles have been respected when preparing the financial statements (Oprean, 2007). Other authors' opinions regarding audit's objectives come to support the promotion of the idea of regularity, sincerity and the true and fair view of financial statements, having as field of application everything that has a key role in determining the results and establishing the financial statements (Ghiță, 2009). These aspects are complemented by the fact that financial audit is independent of management and the Board of Directors, being performed by professional accountants in order to increase the usefulness and credibility of financial and accounting information (Florea, 2011). Therefore, the users of the information provided by financial statements rely on the financial auditors' objectivity and integrity, and also on the responsibility that comes with the profession of financial auditor (Crăciun, 2002). Corporate governance includes an additional level of responsibility: external audit, which along with internal audit are considered the pillars of corporate governance (Ghiță, 2008). For effective management of any organization, corporate governance must have an adequate level of information system which gives the relevant information in order to facilitate the decision making process (Topor, 2011). A significant role is assigned to the financial auditor which contributes in providing some reasonable guarantees for investors concerning the efficiency with which management manages the economic and financial situation (Fraser and Pong, 2009). The financial auditor must provide a reasonable assurance level on the true and fair view of the financial statements and on the fact that the company's practices and accounting policies are verified and certified (Sikka et al., 2009). On the other hand, the literature consists of general information regarding the nature and sequence of foreign or local management within Romanian entities. There is a relatively low statistically fundamented amount of information concerning the business conducted in Romania, run by foreign managers, and even less, related to a comparison between foreign and local managers' efficiency. Since the relevance of the information drawn from this kind of study is subjected to considering the entities that have a significant impact on national economy, and whose financial statements present credibility (are audited), we considered appropriate to conduct the study starting from the entities subjected to external financial audit.

## **2. Methodology**

The study is based on information submitted in September 2012 by the National Trade Register Office. They include the situation of all entities with private capital from the county of Cluj in the period 2005-2012. The data collected, processed and used in this study refers to the nature of management (foreign or local), the local or foreign participation at the social capital, the field of activity of every audited entity, and it also reveals if there were any changes in the structure of the activity and/or social capital within every one of these entities in the analyzed period. This public information was strengthened in order to analyze the effectiveness of foreign management in comparison with local management for all audited entities in the county of Cluj, based on the changes in the structure and/or social capital developed

during the last 8 years. A high frequency of such operations can have different meanings:

- positive (the operations aim to optimize the indicators of financial position and/or performance as a result of the activity subsequently developed by these entities): absorption mergers from the absorbent entity's perspective, dissolutions without liquidation followed by merger from the absorbed entity's perspective, partial divisions and transfers of the audited entity's headquarters in other counties.
- negative (the operations meet or are unlikely to meet the principle of activity continuity): liquidations, insolvencies, dissolutions followed by liquidation, temporary suspension of activity for periods up to 3 years.

Entities with foreign management were considered those entities which in the analyzed period had chosen individuals with foreign citizenship and/or legal entities associated with individuals with foreign citizenship to fulfill certain attributions, as administrators, chairman of the Board of Directors or member of the Board of Directors. The inclusion in the study in an exhaustive manner of all audited entities (in accordance with the records of the National Trade Register Office) and their monitoring for a sufficiently long period of time (8 years) confers relevance and rigor to the information drawn from the analysis of data processing.

The interdisciplinary nature of the study confers relevance to the research results. Interdisciplinarity emerges from notions related to general economy (approach of the local and foreign investments), accounting (notions related to audited entities, changes in the structure of the activity and/or social capital) and management (correlation of such data with the type of corporate governance: foreign or local). The study has significant practical implications for it reveals the dynamics of audited entities' evolution by reference to the frequency of changes in the structure of the activity and/or social capital (of positive or negative nature). This way, one could shape an overall image on the stability of the audited entities' activity, and on the perspective of activity continuity and future evolution of the audit market.

### 3. Results and Discussions

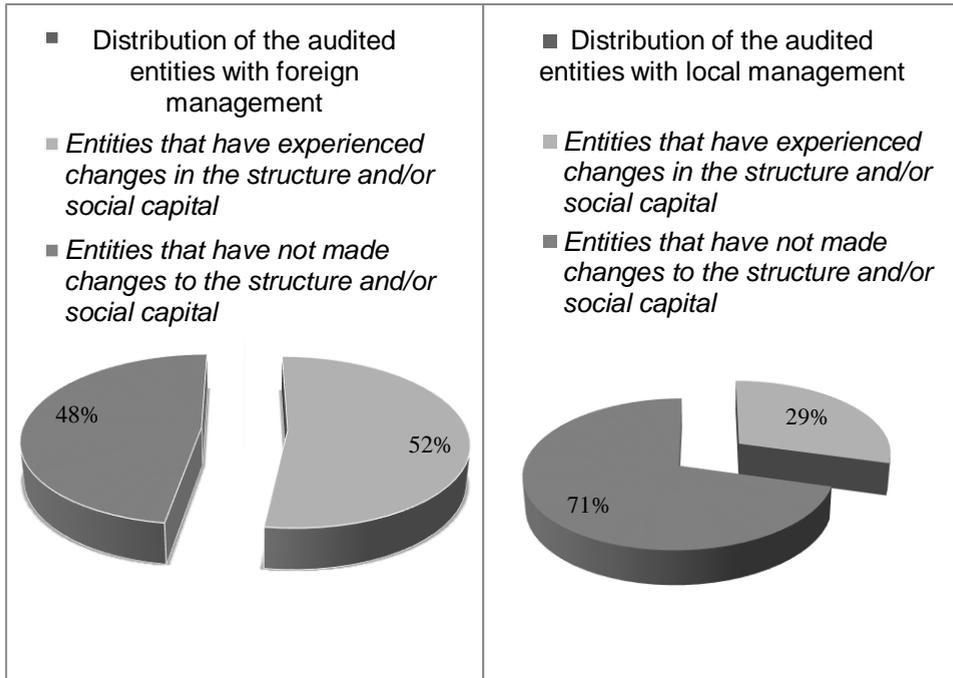

Foreign management can be identified in a significant number of audited entities in the county of Cluj (28.29%), and the percentage of audited entities which have experienced changes in the structure and/or the social capital exceeds one third (35.85%) of the entities subjected to financial audit activities in the period under consideration.

**Table1:** Distribution of audited entities correlated with the nature of management and changes in the structure and/ or the social capital

Explications	Foreign management	Local management	Total
Audited entities which have experienced changes to the structure and/or social capital	45	64	109
Audited entities which have not experienced changes in the structure and/or social capital	41	154	195
Total number of audited entities	86	218	304

Source: Statistical processing performed by the authors

The percentage of audited entities which have experienced changes is lower in the case of audited entities with foreign management (41.28%) than those with local management (58.71%). The same report of inferiority is maintained in the case of audited entities which have not registered modifications, having foreign management (21.02%) compared to those with local management from the same category (78.97%). Because the percentage of entities with foreign management is lower within the total of audited entities, it shows significance the assessment of the changes occurred in the structure and/or social capital, using the nature of management as the main criteria.

**Figure 1:** Distribution of audited entities according to the nature of management  
Source: Statistical processing performed by the authors

The audited entities with foreign management experienced changes in proportion of 52%, while a lower percentage of 48% did not experience any changes in the structure and/or social capital according to figure 1. Regarding audited entities with local management the situation is different, as the percentage of those which experienced changes is lower than 29% in comparison with the percentage of entities which did not register any changes. Therefore, audited entities with foreign management present a tendency with 79% higher than those with local management towards changes in structure and/or management. This result reveals the fact that audited entities with foreign management manifest superior dynamics in terms of adapting to economic conditions: they either experience changes which improve the financial position and performance, or these changes aim to reduce the losses of capital invested in distressed activities by terminating or reducing the activity. In

order to deepen the study and to obtain information regarding the nature of these changes, one has made a correlation of the obtained information with:

- foreign or local participation to the social capital;
- the specific field of activity of every audited entity: production, services or commerce;
- the existence or absence for every situation (in the analyzed period) of certain changes to the structure and/or social capital, and also the nature of these changes.

### 3.1. The Structuring of Audited Entities With Foreign Management

If, for the period under consideration, we approach the audited entities with foreign management in more detail according to the size of foreign investment to the social capital, the field of activity (production, services, commerce) and the nature of change operations in the structure of the activity and/or social capital, we obtain the following distribution:

**Table 2:** Distribution of audited entities with foreign management

Type of management		Foreign management													
		With foreign participation to the social capital							Without foreign participation to the social capital						
Structure of social capital		With foreign participation to the social capital							Without foreign participation to the social capital						
Field of activity		Prod		Serv		Com		Total	Prod		Serv		Com		Total
Number of entities		Yes	No	Yes	No	Yes	No		Yes	No	Yes	No	Yes	No	
		6	12	12	9	0	4	43	1	6	26	7	0	3	43
Type of change	Insolvency	2	-	2	-	0	-	4	1	-	0	-	0	-	1
	Liquidation	0	-	1	-	0	-	1	0	-	0	-	0	-	0
	Absorption merger	0	-	1	-	0	-	1	0	-	0	-	0	-	0
	Partial division	0	-	0	-	0	-	0	0	-	0	-	0	-	0
	Dissolution without liquidation-merger	0	-	1	-	0	-	1	0	-	25	-	0	-	25
	Dissolution followed by liquidation	1	-	3	-	0	-	4	0	-	0	-	0	-	0
	Temporary suspension of activity	0	-	0	-	0	-	0	0	-	0	-	0	-	0
	Transfer of headquarters	3	-	4	-	0	-	7	0	-	1	-	0	-	1
	Total changes	6	-	12	-	0	-	18	1	0	26	-	0	-	27

Source: Statistical processing performed by the authors

The audited entities with foreign management experienced changes in proportion of 41.28% in the period 2005-2012. Correlated with the existence of foreign investment, one can identify the following situations:

a) Audited entities with foreign participation to the social capital

The entities from the service sector experience a higher frequency of changes in structure and/or social capital. Thus, from the total number of entities with foreign management and foreign participation to the social capital which have registered changes, 66.67% are entities with activities belonging to the service sector (percentage of 3.95% from the total of audited entities included in the study). The percentage of entities from the service sector which experience changes in structure and/or social capital of positive nature is of 50% (absorption mergers, dissolutions without liquidation followed by merger, partial divisions and transfers of the audited entity's headquarters in other counties).

The commerce sector is the most stable in terms of changes in structure or activity of the entities included in the study.

b) Audited entities without foreign participation to the social capital

The audited entities from the service sector gather a percentage of 96.3% from the total of changes in the activity's structure experienced by the entities with foreign management and without foreign participation to the social capital (percentage of 8.55% from the total of audited entities included in the study). All these entities have exclusively recorded in the analyzed period operations considered to be of positive nature. Regardless of the structure of the social capital, the audited entities from the commerce sector did not experience any operation of insolvency, liquidation, merger, dissolution, suspension of activity or transfer of headquarters in the analyzed period.

The incidence of insolvencies within the audited entities with foreign management is of 5.81%, being higher in the case of those with foreign participation to the social capital (9.3%) in comparison with those which do not record foreign participation to the social capital (2.33%). In contrast, one can notice within the latter category a high frequency of dissolutions based on the absorption performed by the absorbing entity as a result of the process of absorption merger (92.59%). On the other hand, within the entities with foreign management and foreign participation to the social capital, there is a higher frequency of dissolutions followed by liquidation (22.22%) and of transfers of headquarters in other counties (38.89%) by reference to the overall changes in the entities' structure and social capital.

The systematization of these operations of positive nature (absorption merger, dissolutions without liquidation followed by merger, partial divisions and transfers of headquarters) and of negative nature (liquidations, insolvencies, suspensions of activity), depending on the estimated impact that it would have on audited entities, it provides a centralized image of their frequency in the period 2005-2012.

### **3.2. The Structuring of Audited Entities With Local Management**

The audited entities with local management, both those with and without foreign participation manifest a higher tendency to experience changes in the structure and/or social capital (58.72%) in comparison with the entities with foreign management (41.28%). The detailed results of the study are highlighted in the following summary:

**Table 3:** Distribution of audited entities with local management

Type of management		Local management													
Structure of social capital		With foreign participation to the social capital						Without foreign participation to the social capital							
Field of activity		Prod		Serv		Com		Total	Prod		Serv		Com		Total
Number of entities		Yes	No	Yes	No	Yes	No		Yes	No	Yes	No	Yes	No	
		0	2	2	7	0	0	11	6	34	49	97	7	14	207
Type of change	Insolvency	0	-	0	-	0	-	0	4	-	2	-	1	-	7
	Liquidation	0	-	0	-	0	-	0	0	-	2	-	0	-	2
	Absorption merger	0	-	0	-	0	-	0	0	-	0	-	0	-	0
	Partial division	0	-	0	-	0	-	0	0	-	2	-	0	-	2
	Dissolution without liquidation -merger	0	-	1	-	0	-	1	1	-	24	-	1	-	26
	Dissolution followed by liquidation	0	-	1	-	0	-	1	1	-	7	-	4	-	12
	Temporary suspension of activity	0	-	0	-	0	-	0	0	-	4	-	1	-	5
	Transfer of headquarter.	0	-	0	-	0	-	0	0	-	8	-	0	-	8
	<i>Total changes</i>	0	-	2	-	0	-	2	6	-	49	-	7	-	62

Source: Statistical processing performed by the authors

a) Audited entities with foreign participation at the social capital

The audited entities with local management and foreign participation experience the lowest percent of changes, namely 0.66% from the total of entities included in the study. Similar to the previous situations, these changes in the structure and/or social capital are registered in the period 2005-2012 by the audited entities from the service sector. The proportion of positive and negative changes is equal, each one quantifying a rate of 50% from the total of changes related to these entities' activities. Therefore, in terms of frequency regarding changes in the structure and/or social capital, the audited entities with local management and foreign participation to the social capital are the most stable, especially those from the commerce and production sectors which did not experience any kind of change during the eight years under consideration.

b) Audited entities without foreign participation to the social capital

The audited entities with local management and without foreign participation to the social capital experience the highest frequency of changes in the structure and/or social capital, namely 96.88% from the total of audited entities with local management and 20.40% from the total of audited entities included in the study. If we observe the results of the study for this type of entities taking into consideration their field of activity, it appears that the highest frequency of changes was recorded

in the service sector (79.03%), and the sectors of production and commerce have showed a greater stability in terms of changes (about 10% each).

This detail reveals that such entities which register a high frequency of changes, they either encountered significant difficulties from the perspective of business continuity, or they reorganized themselves in order to improve their activity, action imposed by the difficult economic and financial conditions. In order to highlight the trend, it is relevant to analyze the type of change experienced in the period under consideration by every audited entity with local management and without foreign participation to the social capital. In this situation (audited entities with foreign management and without foreign participation to the social capital), the changes of positive nature (absorption mergers, dissolutions without liquidation followed by merger, partial divisions and transfers of the audited entity's headquarters in other counties) have registered a high frequency (58.06%).

The frequency of insolvencies in the period of time 2005-2012 within the audited entities with local management is of 3.21%, lower than the frequency of insolvencies within the audited entities with foreign management. One can observe within these entities both a necessity and also a high ability of reorganization, emphasized by the high frequency of positive operations, of changes in the structure and/or social capital in general, and also of the dissolutions without liquidation followed by merger in particular (these entities represent 42.19% from the total of changes registered within this sub-category, respectively 12.56% from the total of entities with local management and without foreign participation to the social capital).

### **3.3. The Typology of Corporate Governance Decisions**

The centralization and correlation of the study's parameters (nature of management, foreign investment, field of activity - production, services, commerce - and also the preponderant typology of changes in the entity's structure and/or the social capital) facilitates the process of relatively emphasizing the manner in which corporate governance has reacted in the period 2005-2012 concerning the management of the analyzed entities, namely:

- defensive managerial decisions, of adaptation to the difficult economic and financial conditions sustained by a high frequency (for a certain type of management and field of activity) of the following operations: merger, liquidation, insolvency, dissolution, suspension of activity and transfer of headquarters to another location;

- offensive managerial decisions to increase the audited entities' performance, emphasized by the high frequency of the operations of positive change in the structure and/or social capital: absorption mergers, partial divisions, dissolution without liquidation followed by merger, transfer of the entity's social headquarters to another location;

- neutral management policies, of maintaining the audited entities' stability, highlighted by a relatively small number of decisions aiming operations of change in the structure and/or social capital previously mentioned;

- a relatively low incidence of insolvencies;

**Table 4:** The typology of corporate governance decisions of the audited entities in the light of changes in the structure and/or social capital

Parameters	Foreign management						Local management					
	With foreign participation to the social capital			Without foreign participation to the social capital			With foreign participation to the social capital			Without foreign participation to the social capital		
	Production	Services	Commerce	Production	Services	Commerce	Production	Services	Commerce	Production	Services	Commerce
Defensive decisions, ability to adapt to difficult conditions (high frequency of operations)		x			x			x			x	
Offensive decisions, to increase the performance (high frequency of positive operations)		x			x			x			x	
Neutral managerial policies which aim the activity's stability (relatively low frequency of operations)			x			x	x		x			
The relatively low incidence of insolvencies			x		x	x	x	x	x			

Source: Statistical processing performed by the authors

#### 4. Conclusions

After analyzing the previously centralized data, one can draw some estimations regarding the audited entities' tendency concerning their activity, based on the corporate governance decisions. The audited entities belonging to the production sector experience the lowest frequency of operations such as those previously mentioned, except the audited entities with local management and without foreign participation to the social capital. Thus, regardless of the management's nature and the existence or absence of foreign investment, the audited entities from the service sector had the higher dynamics in terms of management decisions regarding operations which aim to change the structure of the activity and/or the social capital:

- in this sector, there are both defensive decisions (high frequency of all operations) and offensive decisions (higher frequency of the operations considered of positive nature);

- from this point of view, the aggregate evolution of these entities' performance can be mixed: performance increase for some entities, but also decrease for others;

- starting from these premises, the corporate governance decisions aim either to diminish losses and come with efficiency measures, or to increase the

performance indicators and less likely to constantly maintain the financial and economic parameters that measure performance;

-insolvency has a lower incidence than the production sector and higher than the commerce sector.

In general, audited entities from the commerce sector have a relatively low frequency of changes in the structure of activity and/or social capital. It is significant that insolvency has the lower incidence within this field of activity. The decisions to increase the performance through the high frequency of positive operations are specific to the service sector, these being adopted equally by the foreign or local management, regardless of the nature of participation to the social capital. The largest number of insolvencies is reflected within the audited entities with local management and without foreign participation to the social capital.

## 1. Introduction

Sampling is widely used in market research, scientific analysis, market analysis, opinion polls and not least in the financial statement audit. We wonder what is actually sampling and how did it appear?

At first, audit included testing and verifying all elements of a class of transactions or account balance, over the entire audited period. The owners of these companies were interested in discovering major fraud and mistakes in financial statements.

The invention of computers and database servers resulted in developing markets. It became impossible for auditors to check and test all data units from the populations. Globalization has encouraged the apparition of multinational companies, creating the possibility for all companies to buy raw materials from different continents, to use cheaper labor and sale their products to global markets.

Companies become more and more complex, so the number of users of financial statements increased also. Not only associates were interested in the correct presentation of the financial statements, but also creditors seeking to recover money, potential investors, employees, customers, suppliers, the public, government (figure 1, figure 2).

Since the late nineteenth century, sampling is used for checking the accounting postings (Moyer, 1951).

The Englishman Lawrence R. Dicksee, (Dicksee, 1907), was the first that raised the issue of an effective audit. In 1907, he stated that a full audit practice or a balance sheet audit depends to some extent on the internal controls of the entity audited. This idea was reinforced by American researcher Montgomery, a decade later.

In 1917 the Federal Reserve Bulletin prints a set of audit procedures that mention the sampling method, referring to the selection of "some inventory items".

AICPA, American Institute of Certified Public Accountants, published in 1929 a set of auditing standards called "Verification of Financial Statements", which emphasizes that the existence of effective internal controls justify the performance of fewer other audit procedures. Same institute, in 1956, established a committee aimed to study the problem in audit sampling, the Committee highlighting the need for extension of the new audit technique.

In the book "Statistical Auditing" (Roberts, 1978) the author explains the theory of sampling, stating that the error identified in a population should be smaller than the tolerable error.

The first standard studying the method appeared in America in 1981 and was called "Audit Sampling". This standard was completed by Amendment 111 in 2002. IAASB issued in 1997 a standard with the same name.

According to the Explanatory Dictionary of Romanian Language in 2002, the verb "to sample" has three meanings: 1. compare the sample with a standard, 2. choose persons to be statistically representative for a survey, 3. taking samples (1) at predetermined intervals (<fr. échantillonner). Sampling becomes "the action to sample".

Descriptive statistics studied sampling, which is a basic concept of this science, along with statistical population, statistical unit and sample.

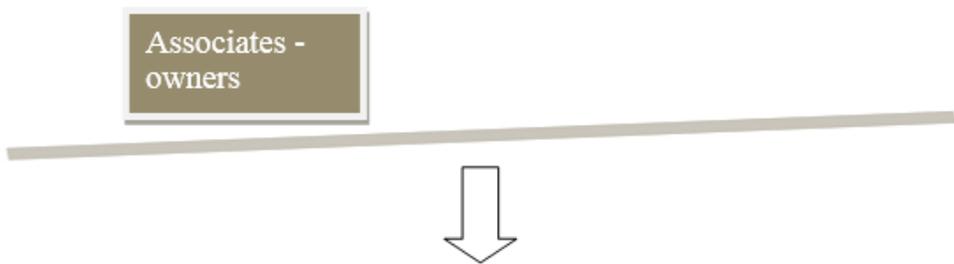

Statistical population represents a set of simple or complex elements, which have one or more essential common characteristics, characteristics attributable to the elements and to the whole population. (Florea at al., 1985)

Statistical unit is the component element of the statistical population, on which it will be performed direct observation. Statistical unit is the original carrier of information

or the logical subject of statistical information. Due to the variety of aspects in which may be presented the statistical unit, it comprises a precise definition, which excludes the possibility of different interpretation by observers and so any error that may prejudice the investigation value. (Buiga, 2003)

The sample is a subset of a statistical population, constituted based on well established criteria. (Buiga, 2003)

Audit sampling involves, according to International Standard on Auditing 530, Audit Sampling, performing audit procedures to less than 100% of the component items of a class of transactions or account balance.

## 2. Case Study

The preparation of European countries for integration into the European Union imposed the harmonization of national accounting and financial statements with those used in EU countries and the adoption of international accounting standards in this area. Once national accounting standards began to be harmonized with international legislation, it became mandatory the harmonization of national and international audit standards.

Economic globalization and complexity of capital markets has made possible not only the harmonization of international accounting standards with the national ones, but also the convergence of international accounting and auditing standards with the American regulations.

This process of harmonization and convergence is achieved in stages. The first step involves providing a legal framework that will comprise the new accounting and auditing regulations. The second step is to ensure gradual implementation of the new legislation on various categories of economic agents until the application of these regulations in the whole economy is achieved.

International Standard on Auditing 530 "Audit Sampling" was prepared by the International Auditing and Assurance Standards Board in 1997. In the United States, Auditing Standards Board issued Statement on Auditing Standards number 39 in 1981, a statement on auditing standards studying the audit sample.

International and American standard setters are aware of the need for uniform audit standards in a globalized market. This questions the ISAs convergence with U.S. regulations. Our intention is to study the degree of convergence of international standards with U.S. standards referring to audit sampling, using Jaccard coefficients.

First subject analysis the recognized sampling methods. The two regulations recognize both the non-statistical and statistical method of sampling, statistical method assuming statistical selection and availability of special programs, non-statistical method involving the use of professional judgment.

We have considered the way audit sample was selected and what factors influence sampling, both standards indicating the importance of population characteristics, objectives and audit risk selection. In selecting a proper sample all the population's elements should have an equal chance of being chosen.

Under both international and American regulations misstatements identified in the selected sample could refer to tolerable errors, anomalies or material misstatements. Tolerable errors are errors that projected to the entire population do not affect the accuracy and fair view of the financial statements. Anomalies should be carefully assessed, yielding conclusive evidence that they are not representative for the entire population. For material misstatements, adjustments must be proposed to the financial statements.

The last topic studied is the case sampling is appropriate. International and U.S. auditing standards emphasizes that the two cases for which sampling is appropriate are tests of details and controls.

Fontes is the first researcher to use Jaccard coefficients as a means of measuring the degree of formal harmonization, in his book *Measuring Convergence of National Accounting Standards with International Financial Reporting Standards* in 2005. The Jaccard coefficient measures the degree of convergence of international auditing standards (ISA 530) and U.S. auditing standards (SAS 39).

The similarity degree indicates the degree to which the two standards are similar for issues considered and is calculated according to the formula:

$$S_{ij} = \frac{a}{a+b+c}$$

The degree of dissimilitude is the difference between maximum similarity (1) and similarity identified, highlighting the differences between the two regulations.

$$D_{ij}=1-S_{ij}$$

Following the calculations from table 1 it can be observed that the two regulations have a maximum degree of similarity (100%), the degree of dissimilitude is zero. The study shows that both standards agree on application of statistical and non-statistical sampling in auditing, that sampling is appropriate for tests of details and controls, the factors affecting audit sampling being audit risk, audit objectives and population's characteristics.

### 3. Conclusions

Audit sampling involves the application of audit procedures to less than 100% of items within an account balance or class of transactions. Nowadays the technique is indispensable, the economic entities operating with sophisticated computer systems and large amounts of data.

International Standard on Auditing 530 and Statement on Auditing Standard 39 are the two main international and American normalized referentials, referring to audit sampling. The two standards are studied using Jaccard indicators in terms of the degree of similarity and dissimilarity concerning different issues. The Jaccard coefficient measures the degree of convergence of international auditing standards (ISA 530) and U.S. auditing standards (SAS 39).

International auditing standards and American auditing standards, study the sampling problem, both regulations presenting common points with regard to accepted sampling techniques, factors influencing the audit sample, treatment of identified misstatements and the circumstances in which sampling is appropriate. The study shows that both standards agree on application of statistical and non-statistical sampling in auditing, that sampling is appropriate for tests of details and controls, the factors affecting audit sampling being audit risk, audit objectives and population's characteristics.

**Table 1:** The similarity degree between International and American standards regarding audit sampling

Topics	ISA 530	SAS 39	Computation of Jaccard coefficient	
			$S_{ij} = \frac{a}{a+b+c}$	$D_{ij} = 1 - S_{ij}$
<b>1. Sampling methods</b>				
1.1 Statistical sampling	1	1	$S_{ij1} = 1$	$D_{ij1} = 0$
1.2 Non-statistical sampling	1	1		
<b>2. The factors that influence audit sampling</b>				
2.1 Population's characteristics	1	1	$S_{ij2} = 1$	$D_{ij2} = 0$
2.2 All the elements from a population have equal chances to be selected	1	1		
2.3 Audit objectives	1	1

**Abstract:** *The environment in which the accounting and auditing firms operate is changing. The economic, technological and financial contexts directly affect their business. In addition, the customers have become more fastidious in terms of the nature, the speed and the precision of the required services. All these developments force the firms to improve their organization by incorporating appropriate performance measurement systems. The objective of this paper is to examine how the organizational performance it is perceived in accounting and auditing firms. In this sense, we checked the perspectives of the balanced scorecard model in a Big Four office and in a small office. The sample consists of 10 Romanian auditors. Eight of auditors are working in one of the Big Four. To achieve this study, were selected only managers. The other two auditors operate in a small office, they being, at the same time, also associates. The sample is homogeneous in terms of the training, the sector of activity and experience. To enable an objective analysis of results, the name of the offices will not be made public. The results showed that in the Big Four office all four perspectives of the balanced scorecard model are checked, while in the small office the number of perspectives is lower, because learning is informal and not materialized. On this perspective, the Big Four office, periodically analyzes the results and try to identify the causes that led to differences in the objectives set. Possible causes that were invoked: overloading of the auditor, additional works, not included in the letter of assignment and the lack of competence of the auditor. Regarding the internal perspective, each office has its own mode, but obviously the Big Four office has human, logistics and financial resources more important, that enabling it to keep its reputation in the market. Instead, the financial goals are the same for both offices analyzed: profitability increasing.*

**JEL Classification:** G 34, M14, M42

## 1. Introduction

Accounting and audit firms must face permanent development challenges such as the evolution of the economic context, characterized by the competition increasing, instability and globalization, as well as the change of the benefits requested by customers, in terms of nature, speed and accuracy. In such a situation, aspects like strategy and performance measurement becomes extremely important. A performance-oriented strategy means a management with technical and operational rationality centered on customer. The performance of an accounting and auditing firm should be seen as a result of a causal process, relative to a chosen context

based on strategy (Lebas, 1995) or, in other words, as an achievement of organizational objectives (Bourguignon, 1996). It is measured not only by optimal use of production tools, but also through the ability to create and provide services to customers. In addition, operational information must be supplemented by information of a strategic nature, which allows taking into consideration the environmental trends, the weaknesses and the strengths of the office (Carassus, 2006).

Therefore, in order to ensure the sustainability and to benefit from potential opportunities in terms of new customers and services, accounting and auditing firms are forced to acquire a flexible structure, to change their behaviors and to integrate new skills (Bailly-Masson, 2000). In this context, it is worth reflecting on how to track performance in the domain of accounting and auditing services.

The objective of this paper is to examine how it is perceived the organizational performance in accounting and auditing offices. To achieve this objective, were realized semi-directive interviews with Romanian auditors who are working in two offices of different sizes. They were interviewed about the size and performance measurement tools. For this purpose, we used the balanced scorecard model of Kaplan & Norton (1992).

The rest of the paper is organized as follows: the first section provides information about the multidimensional nature of organizational performance, the second section summarizes the literature on organizational performance, the next section presents the study of how it is perceived the organizational performance in Romania; the paper concludes with conclusions and future research directions.

## **2. A Multidimensional Conceptualization of Organizational Performance**

In contemporary society there is a real cult for performance. This concept is used almost systematically in an implicit and explicit manner. However, its content varies from one specialist to another. In other words, performance is a social construction that takes many meanings as the number of individuals or groups who use it (Allouche & Laroche, 2005; Boudabbous, 2011). In relation to stakeholder theory (Freeman, 1884), performance can be interpreted according to the different actors that make up the stakes or interests in such entity (Gilbert & Charpentier, 2004). For some people, accounting and financial dimension is predominant, while others are interested in consumer-product dimension, socio-political dimension or employee dimension (Le Louarn & Wils, 2001).

The diversity of the performance indicators used in the literature show that the performance is covering concepts whose meaning is often contextual and leads to numerous interpretations (Allouche et al., 2003). On the same line, Chrétien et al. (2005) warns that the performance contains a set of complementary and sometimes contradictory parameters, which does not have the same importance, even if the economic dimension remains dominant. As a result, the performance appears as a compromise rather composed of optimized results than of maximized results, the firm's perennially being the horizon line to which converge the eyes of the stakeholders (Montebello, 1976).

According to Venkatraman & Ramanujam (1986), the organizational performance includes besides the financial performance, measured by indicators such as profitability, sales, market value and operational performance. For the latter the measurement indicators used are: the social image of the organization, the marketing effectiveness, the novelty and the quality of the products etc.

Raad (2004) considers the organizational performance a multidimensional and complex concept, not limited to financial results, for its evaluation being necessary the reference to numerous organizational results, both internal and external. Also, Bourguignon (2000) defines the performance as the achievement of the organizational objectives, whatever the nature and the variety of the objectives.

She designates, in the same time, a result, an interpretation of that result (success or failure) and an action that generated it (Bourguignon, 2000). Furthermore, the performance is an evolving concept, because the factors that can contribute to the success of an organization in a process of innovation may become incompatible with the factors required by a development phase (Boudabbous, 2011). In addition, some combinations of human, technical, organizational and financial factors prove effective in a given context and less effective in others (Carrière & Barrett, 2005).

Researchers warn on the need to clarify and validate the definition of performance (Becker & Gerhart 1996; Rogers & Wright 1998), because an inadequate definition often raises problems of evaluation. Practitioners seem to use the term of organizational performance to describe a wide range of measures (Heffernan & Flood 2000). Theorists, also, have proposed various conceptual frameworks for measuring the organizational performances. Of these, the most commonly invoked are the organizational effectiveness model of Morin et al. (1994) and the balanced scorecard of Kaplan & Norton (1992).

The organizational efficiency model of Morin et al. (1994) is a court that makes a person or a group of persons on an organization, particularly on the activities, outputs, outcomes or on the impact he expects from it. The model makers have identified four dimensions of the organizational performance, defined by criteria and indicators. These are: the organization's sustainability (the systemic dimension), the economic efficiency (the economic dimension), the value of the human resources (the social dimension) and the legitimacy of the organization to the external groups (the political dimension). According to these three authors, the performance criteria must be specific and organizational characteristics. Choosing the measurement indicators raises some problems. The balanced scorecard of Kaplan & Norton (1992) is a balanced mix of both external indicators and internal indicators, with regard at processes, innovation, education and growth. They associate outcome indicators, which are the effect of efforts previously employed with indicators which allow the increasing of the future performance. They also combine objective and subjective indicators contributing to the performance achievement.

### **3.Literature Review on Organizational Performance**

The literature on organizational performance is extremely rich. But most recent research is concerned with the communication of the organizational performance. Thus, some studies have examined trends in communicating the organizational performance. In principle, it is accepted that transparency in communicating the organizational performance is essential for the proper functioning of the capital markets, jobs, goods and services (Aerts et al., 2007). The financial scandals of the last decades have shown that, when reduced reliability of the information provided by the firm, the loss of the value beyond the shareholders affects other stakeholders (Cormier et al., 2009). Furthermore, an incomplete communication prevents the adoption of corrective action by the various parties involved and can accelerate the destruction of the enterprise value. For this reason, the regulations from some

countries have included clauses that would guarantee that the performance disclosure of the firms is credible, transparent and ethical.

Other studies have considered the developments in modern communication means and pursued the measuring of organizational performance communication on the internet. Ubiquity of the internet has pushed firms to reconsider their reporting strategies to take advantage of the flexibility that the internet offers them in terms of presentation and content of the Annual Reports (Ajinkya et al., 2005). In addition, on the internet can be provided much more information than through traditional means, even outside the reports (Cormier et al., 2009), which makes the relationship between firm's management and partners to be more direct, more dynamic and interactive (Hodge et al., 2004).

There are also studies that were interested in the validity and the interest of the measurement of the determinants factors of organizational performance communication. Thus, Cormier et al. (2009) showed that managers take into account the interests of certain parties involved, such as shareholders, in establishing communication strategies of the organizational performance. Beyond the information needs of shareholders, the managers' decision to communicate certain information about performance is likely to be influenced by the compromise between reporting direct costs and benefits of such communications (Scott, 1994). The analysis of the relationship between costs and benefits of the communication of the organizational performance does not take into account, however, explicitly, the differences between companies in terms of corporate governance mechanisms. However, it is likely that a company's governance structure still affects the organizational performance communication.

The analysis of the determinants factors of the organizational performance communication is based on the literature about the balanced scorecard (Kaplan & Norton, 1996; Marston & Pole, 2004, Ittner & Larcker, 1998). Choosing the variables in different studies is based on the premise that there is an association between the organizational performance communications, on the one hand and the considerations of financial markets, the corporate governance mechanisms and the firms' exposure to the economic environment, on the other hand. The indebtedness, the available cash flows, the beta systematic risk, the concentration of capital degree, the board independence, the firm size, or the number of employees are just some of the variables used to identify the determinants of organizational performance communication.

Finally, there are studies dealing with relevance of the information communications regarding the organizational performance for firms' earnings assessing. Because shareholders assume the residual financial risk and they are not involved in current operations, they are most interested in communication policies and practices of the firm. Based on these communications, shareholders appreciate the value of the firm and decide the retention or the sale of shares. Previous studies suggest that investors appreciate the value of a firm, based on the financial and non-financial performance (Banker et al. 2000).

#### **4. Methodological Aspects: Sample Selection and Results**

##### *Sample Selection*

The sample consists of 10 Romanian auditors. Eight of auditors are working in one of the Big Four. In that office there is a hierarchy of employees in several degrees, depending on the operational responsibilities and activities. To achieve this study,

were selected only managers. The other two auditors operate in a small office, they being, at the same time, also associates. The sample is homogeneous in terms of the training, the sector of activity and experience. To enable an objective analysis of results, the name of the offices will not be made public.

*The Model Presentation*

In this study, we used the balanced scorecard model of Kaplan & Norton (1992). This represents "a management system that can channel the energies, skills and knowledge specific to individuals throughout an organization, in order to achieve long term strategic goals" (Kaplan & Norton, 1996).

In contrast to traditional systems performance assessment, the balanced scorecard model is based on four distinct perspectives (Kaplan & Norton, 1992):

- learning and growth: the focus is on active individuals, in organization, and on infrastructure. An appropriate investment in these areas is critical to ensuring long-term success;
- internal perspective: the focus is on the performance of the essential internal processes, which are the engine of the organization. Improving these processes is considered an indication of future financial success of the company;
- customers: to transform the processes improving into financial success, companies must ensure customer satisfaction: this approach allows the company to remain focused on the needs and customer satisfaction;
- financial perspective: this perspective provides measurement results that the company provides to its shareholders;
- the four perspectives pursued simultaneously offers a nuanced view on current and future business performance.

*Data Collection*

The prospects of the balanced scorecard model (Kaplan & Norton, 1992) have been verified in the context of the survey. In this regard, have been realized semi-directive interviews of approximately 45 minutes, with the 10 auditors from the sample.

*Data Analysis and Interpretation of the Results Obtained*

The information noted during the interview and the documents provided by the respondents were analyzed in terms of content. To describe the instruments operating in the offices was made an analysis grid. The results obtained are as follows:

<b>Issues pursued on four perspectives</b>	<b>Results</b>
Learning and growth: actions that promote continuous improvement	In Big Four office, the learning is formalized. Periodically are reviewed the results and checked if the quantitative and qualitative objectives have been achieved. They identify the causes that generate differences. If there is a technical incompetence of the auditor's, the office may establish a training program for it. In the small office, however, the learning is in an informal way and not materialized.
Internal perspective: the processes by which the office express its	In Big Four office is implemented an information system on customers, in solving a case, involving multiple people. There are informatic tools that allow

priorities to promote customers	smooth functioning of the process. In the small office, was a workspace that enables to respond quickly to customers. In addition, efforts are made to always dispose of all appropriate documentation of the office's needs.
Customers: strategic actions applied to satisfy customers	In the Big Four office the policy is that in order to maintain and develop its portfolio of customers, the auditors should be very careful about the quality of services. This quality is measured by customer satisfaction, customer age, ability to attract new customers, loss of customers, etc. In the small office, the customer perspective translates into: direct contact with clients, ability to listen and understand customer needs, good reputation and customer satisfaction in terms of response time and quality of the provided services.
The financial perspective: the extent to which the organization of the office allowed financial goals achievement	In Big Four office, there are settled quarterly financial targets to achieve a good financial return. These are checked monthly. The small office referred to both files and entity profitability.

### 5. Conclusions and future research directions

To meet the economic, technological and financial challenges, the accounting and auditing firms, as well as other entities from the service sector, can improve their organization by incorporating some appropriate performance measurement systems. In literature there are many models developed for performance measurement. Choosing the appropriate model depends, however, on the entity's objectives.

This paper examines how it is perceived the organizational performance in accounting and auditing firms. In this sense, we checked the balanced scorecard model perspectives (Kaplan & Norton, 1992) in a Big Four office and in a small office. The results showed that in the Big Four office, all the four perspectives of the balanced scorecard model (Kaplan & Norton, 1992) are checked. In the small office the number of perspectives is lower, because the learning is an informal way and not materialized. On this perspective, the Big Four office, periodically analyzes the results and try to identify the causes that led to differences in the objectives set. Possible causes that were invoked: overloading of the auditor, additional works, not included in the letter of assignment and the lack of competence of the auditor. Regarding the internal perspective, each office has its own mode, but obviously the Big Four office has human, logistics and financial resources more important, that enabling it to keep its reputation in the market. Instead, the financial goals are the same for both offices analyzed: profitability increasing.

There are still many paths of research in this area. Thus, the sample could be extended to employees in several offices and might attempt a quantitative validation of the model. In addition, we can try an extension of the model by adding additional axis like the strategic vision or the external groups' legitimacy.

**Abstract:** *This exploratory study of the internal audit in the public sector in function, points out the need for the involvement of public sector entities, showing that in its role has traditionally focused mainly on evaluating internal control and not on the process of risk management and corporate governance. The objective of this study is to analyze the role of the internal auditing in risk management in public institutions from Bihor County. The method chosen is the research is based on questionnaire and the analysis of the institutions has been divided into two categories, so that, when the sample was taken in consideration, the likelihood that local public institutions of Bihor County have organized the public internal audit activity. Based on responses from 49 entities from public sector, the result of the study show us that the public internal auditors know they can play an important role in the risk management, but there is a number of other activities which must be conducted within the organization. So, they tend to understand the concept of risk management and risk management process, where it is carried out, and of the role they can play in improving and activity, however, issues of disposable incomes allocated to activity, and enough personnel specializing in the field, as well as a lack of interest of management to increase the efficiency and profit of the public internal audit activity, are issues that impede performance and risk management.*

**Keywords:** Auditing, Public entities, Internal Auditing;

**JEL classification:** M40, M42

## **1. Introduction and motivation of the study**

Internal audit provide constant review and appraisal of the systems and procedures introduced by the management with the intention to enable the management to control and utilise their resources properly and effectively (Mu'azu Saidu Badara and Siti Zabedah Saidin, 2012:404). In recent years, enterprise risk management has received a wider attention (Beasley, Clune & Hermanson, 2006) and become an agenda in both public and private sectors (Wood, 2009). Economic recession Romania is facing at the moment generates imbalance in public entities, progress in limiting public resources, low quality of service, the multiplication of risks and uncertainties, as well as the lack of performance. All these reasons take us to the study of the internal audit in the public sector, because the public entities have to change the traditional role of the audit (Deloitte, 2011), from evaluating internal control to the process of risk management and corporate governance.

It used to be that internal auditing in the public sector served as a simple administrative procedure comprised mainly of checking accuracy of transactions, pre-payment verification and control, counting assets and reporting on past events to various types of management, but in recent times, governments moving toward higher levels of transparency must demonstrate accountability in the use of public money and efficiency in the delivery of services. Larger and more complex operations demand greater competency and professionalism from internal auditors to minimize and manage risk (Deloitte, 2011).

In Belgium, Sarens G. et al (2010) makes an analysis that provides an in-depth analysis of risk management and internal control practices within Belgian social security public institutions (sspi). The findings show that: risk management and internal control are not highly developed; internal control is more developed than risk management; and risk management concepts like risk identification and evaluation are part of internal control, rather than internal control being part of risk management. Also concluded the fact that the traditional internal control philosophy (focusing on conformance) is more wide-spread than the recent risk management philosophy (focusing on performance) could be a reason why the performance requirements of the SSPI are not met.

With respect to internal audit's involvement in the identification and assessment of risks in the local public sector and public institutions, Ernst& Young (2008) has achieved a relevant study on a sample of 400 local authorities and 125 public institutions. The study was based on the questionnaire which was sent to these entities and had questions about the governance of the public sector, the trends of organizations with regard to the risks and identify significant areas, the stage of implementation of internal control. The answers about the responsibilities of the internal audit were the following:

**Table 1 The activities of the internal audit function in the public sector entities and public global institutions.**

Types of activities	Public institutions		Local public sector	
	Systematically %	Often %	Systematically %	Often %
Evaluation of internal control	47	32	20	44
Testing the effectiveness of procedures	40	30	17	44
Risk identification	32	16	6	27
The audit of the financial statements	26	42	15	43
Audit of information systems	25	38	8	22
Audit of subordinate entities	13	31	41	38
Formulating procedures	5	26	25	43

Types of activities	Public institutions		Local public sector	
	Systematically %	Often %	Systematically %	Often %
Evaluation of public policies	-	6	21	36
The consistency of internal control	-	21	6	26

Source: Ernst & Young (2008)

The survey shows that the identification and assessment of weak points in terms of risks is subject to regular internal audit assignments in a percentage of 32% in public institutions and local entities, 6% in the public sector. Also testing the effectiveness of auditing procedures, information systems, and financial information are rarely subject to public internal audit missions, and missions with an indirect internal audit (writing manuals of procedures, internal consistency checks) are often subject to choice. The assessment of the internal control and audit of subordinated entities about the systematic and common responsibilities of the internal audit in most of public entities (79%, 64%, 42%, 79%), demonstrates that the internal audit assignments are still traditional.

Another poll conducted by Deloitte (2009) shows improper risk management in the public sector. The survey was conducted in 200 government departments in 28 States, according to officials, 48 percent of the public believes that the world of risk management is one of many challenges met by the financial departments of public entities.

The implementation of relatively recent internal audit in the public sector in Romania and financial resources will decline in economic conditions, leading to the premise to conduct an empirical study to identify to what extent public audit, there are participating, improves and helps to smooth risk management in public entities in Romania.

Therefore, regarding the previous researches (Rudasingwa Justin, 2006; Mu'azu Saidu Badara and Siti Zabedah Saidin, 2012) we proposed as objective the analysis of the role of internal audit in risk management of the local public institutions in Bihor County.

The analysis was conducted in order to obtain information regarding:

- The internal auditor's role in risk management (Anuntaakalukul A., 2010);
- The activities undertaken with regard to risk management and the internal audit risk management (IIA, 2011);
- The role of public audit on the identification and assessment of risks (Ahmad N. et al, 2009);
- Internal audit skills to cope with the development of risk management (Matthew Leitch, 2004);
- Lack of motivation activities relating to internal audit and risk management (IIA, 2011).

We believe that all replies to questionnaires being released, would help us to form an opinion on the role of internal audit in public institutions and risk management, and to determine the reasons for these processes are not carried out.

The study undertaken focused on public institutions that operate locally and use of public financial resources. Local government institutions are taken into account in our analysis are those in the Bihor County, the County Council and town councils of municipalities, towns and communes, that the law derives income and use budgetary appropriations.

## **2. Research methodology**

The objective of our study is to analyze the role of the internal auditing in risk management in public institutions, at local level. As the current research, there has been a positive-type research, and in doing so (Ionaşcu I., 2003:76) the positive approach in accounting assumes that any theoretical formulation cannot be valid unless it is verified empirically, by confronting the hypothesis with the facts.

The method chosen in the research is based on questionnaire, and Francois de Singly (1998:21) states that the survey-based questionnaire serves the explanatory data, and as a form of research we opted for the statistical survey.

## **3. The construction and presentation of sample review**

The analysis of the institutions has been divided into two categories, so that, when the sample was taken in consideration, the likelihood that local public institutions of Bihor County have organized the public internal audit activity.

From the analysis of the sites linked to the Mayor's and the Board of Auditors 'Bihor report on 2010, we found that public internal audit activity at the level of municipalities is not organized in the form of individual departments, it unfolds as an outsourced. So, using a single questionnaire for both categories of institutions that do not provide relevant answers and would have hindered the process of gathering information, which we consider relevant to their classification depending on the organization of public internal audit division.

As a result, the sample is comprised of two categories of institutions:

- class I, consisting of the County Council and town councils of municipalities in Bihor: Oradea, Beiuş, Salonta and Marghita; and the mayoralties of cities in Bihor County, namely: Aleşd, Nucet, Săcueni, Stei, Valea lui Mihai and Vaşcău; a total of 11 entities;

- class II, consisting of the municipalities of the 91 municipalities found in the County. The data are recorded and reported by the Directorate General of public finances Bihor, and the sample chose a representative geographical distribution. For the two categories of institutions we have realized 2 questionnaire containing questions relevant to the work of risk management in the context of public internal audit division and the respondents are internal auditors of public employees in selected public institutions (where there is organized the public internal audit office) and unemployed people in the management of institutions (where the public external audit service is outsourced). The questionnaires were sent electronically and listed.

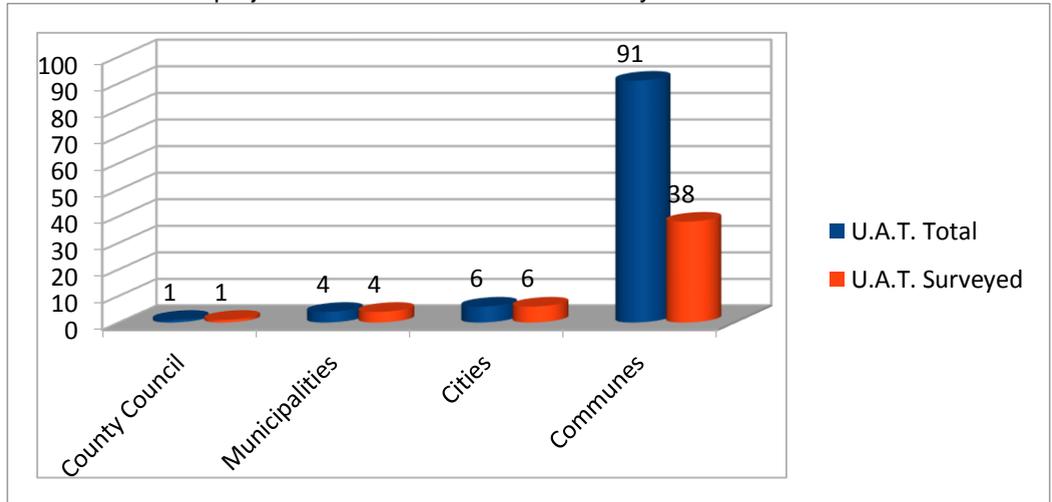

As a result of the questionnaire, we obtained a total number of 49 responses, representing a response rate of 48.03 %. By clicking on the two distribution categories, the response rate for the first category is 100%, and for category II the response rate is of 41.75 %.The non-response rate is higher than that of the responses and we think the reasons are the lack of system of public internal audit, including outsourced, or negative perceptions, distrust, on opinion polls.

## **4. Analysis of the collected data**

The sample size is 102 territorial and administrative units and their distribution are presented as evidenced by the following graph:

**Graph 1.** Distribution of administrative territorial units

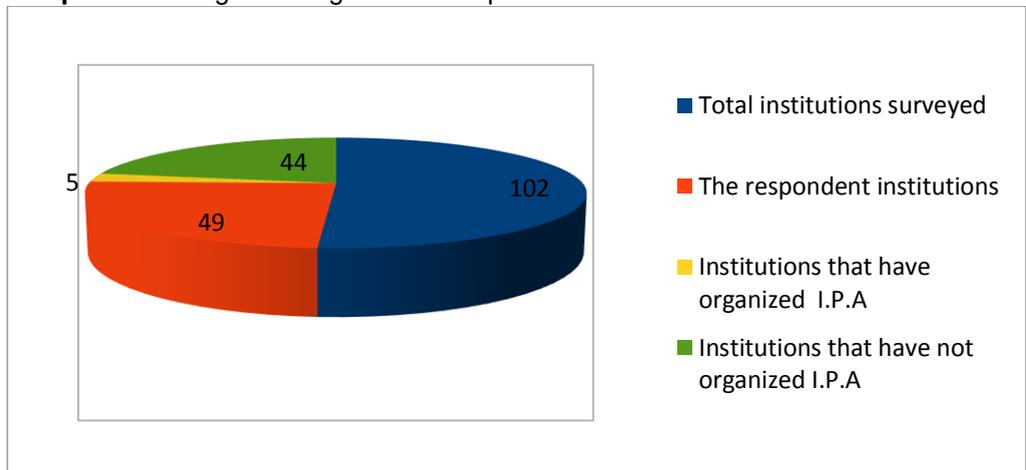

Source: projection made by the author

Source: projection made by the author

From the point of view of the internal audit division, common question for both categories of respondents, of total institutions surveyed 10.2% declare that organized public internal audit and its activities that include the control, the control environment, risk assessment and monitoring. The rest of 89.79% institutions performing public internal audit as outsourced service.

**Graph. 2** The degree of organization of public internal audit

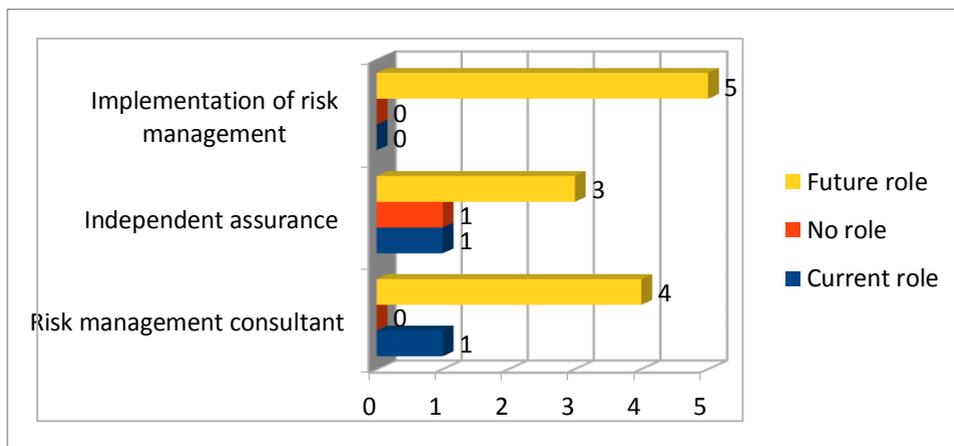

Source: projection made by the author

For the first category of respondents, the questions were focused on the role of internal audit in public in current business practices and activities for the process of risk management, counseling and support granted by the audit reports on the implementation of the process improvement and performance increase.

As a result of the questionnaire, all 5 of the first entity category indicated that the internal audit activity, the public has had responsibility for implementing risk management, reflecting an active role in the learning process of the management to respond to existing risks (80%) and for the identification and assessment of risks (80%). However, only 66.6% offering independent on the process of risk management, and on the advisory role, it seems that the public internal auditors tend to understand well enough to see the risk management implementation process.

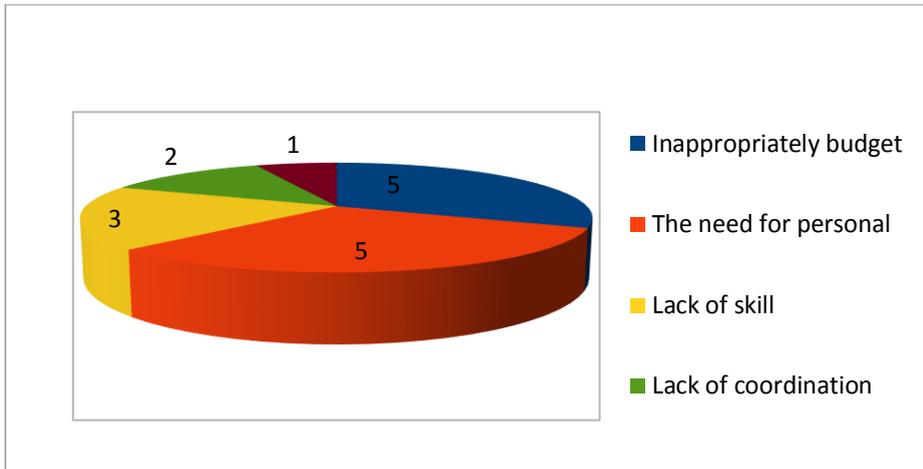

**Graph. 3** Description of the role of public internal audit risk management

Source: projection made by the author

Among the shortcomings identified in the analysis, they could identify the sufficient revenue or funds available and the specialist personnel. In all entities, public internal audit work was carried out with 1-2 auditors, which according to the questionnaire applied requires knowledge of the practices and techniques of management of risk management. The problem of the lack of personnel in the field of public internal audit at the national level is reflected in the local plan generated by the current economic situation of our country and blocking positions in the public domain as well.

**Graph 4.** Problems encountered by the public internal auditors:

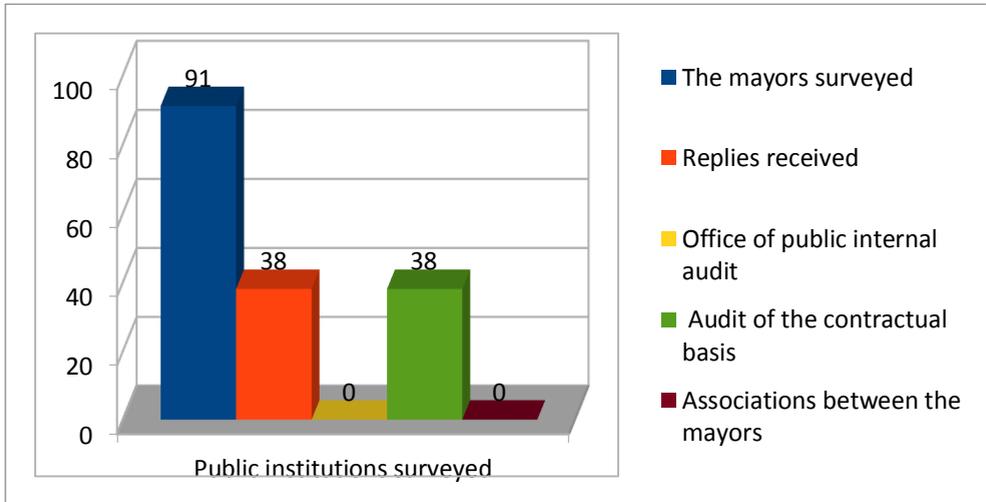

Source: projection made by the author

As for the second category of entities considered for the analysis undertaken, out of 91 from mayoralties in records, we achieved a number of 38 replies. The response rate is of 41.75% and respondents are persons or institutions in the Finance Department, so the answers can be considered relevant to the analysis.

The municipalities surveyed all declared that the work of the public internal audit in the form of outsourced service, or under contractual form. Excluding non-response rate, an increase in the level of activity of internal audit in public administration, in one form or another, and as the regulations require, the local public entities which have not set up their own internal audit department or have not been in cooperation to ensure that the internal audit activity it may be provided by the internal auditors qualified individuals on the basis of contracts for the provision of services, in accordance with the provisions of the law of 2002 on the audit of 672/public, republished in 2011.

At the same time, however, it can be seen that public institutions were not considered appropriate to amend the article 24 in the law 273/2006 on local public finances on the formalization of possibility of association of local public institutions, for the organization and conduct of internal audit, through the county structures with legal personality of associative structures of local public administration authorities, recognised as being of public utility or development associations established in accordance with the law of intercommunity, existed at the level of the institutions surveyed no association of its kind.

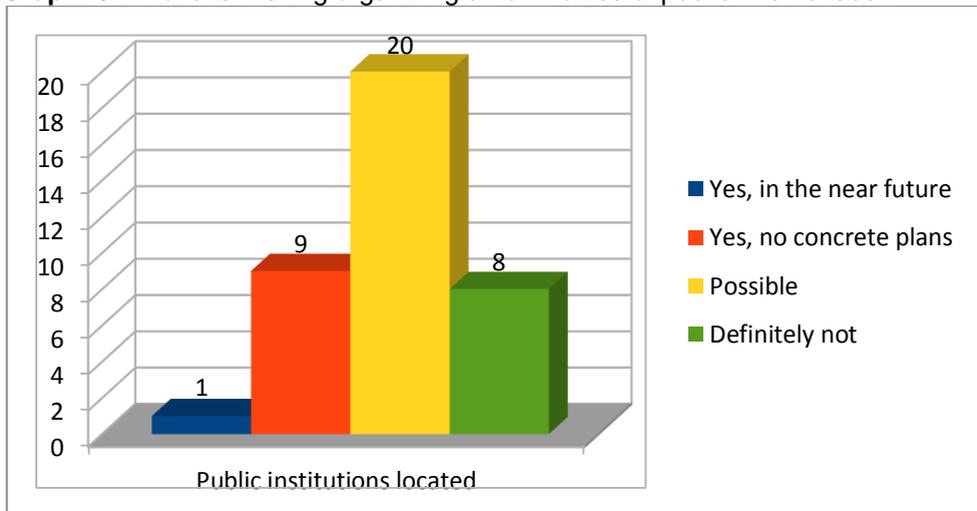

**Graph. 5** Form of organisation of public internal audit

Source: projection made by the author

With regard to the organization of a future office of public internal audit, only one institution has expressed the willingness to hold a certain office, while only possible 52.63% consider this opportunity, arguing the lack of staff and a budget.

**Graph. 6** Institutions wishing organizing an own office of public internal audit

Source: projection made by the author

Taking into consideration the risk management, over 13% of the analysed institutions argue that it is in an advanced stage of development, 37% are in the process of implementing or has been recently adopted, and the rest do not carry out activities specific to the risk management process.

Of the interviewed institutions, in 60% of cases, the liability risk management belongs to a risk officer and the remainder belongs to a person who has other duties.

## Conclusions

We examine the role of internal auditing in risk management in the public sector from the local entities of Bihor county and we find that the activities of the public sector, as well as in the private sector are becoming increasingly more complex due to the news that appear and the risks they face. Organizations providing risk management increasing attention, but implementing an effective risk management requires time and knowledge.

We also document that the public internal auditors know they can play an important role in the management of risk, but there is a number of other activities which must be conducted within the organization. So, they tend to understand the concept of risk management and risk management process, where it is carried out, and of the role they can play in improving and activity, however, issues of disposable incomes allocated to activity, and enough personnel specializing in the field, as well as a lack of interest of management to increase the efficiency and profit of the public internal audit activity, are issues that impede performance and risk management.

The limitation of the paper concerns the analysis of a single county, and the rate of respondents. For future research we should validate our findings by extending the review in other counties of Romania. Likewise, future research should look at the possibility of inserting institutions that use internal audit from private sector, making a comparison between the two sectors.

## CHALLENGES OF FINANCIAL AUDIT - THE IMPACT OF INTRODUCING UNIQUE REGULATION OF FINANCIAL MARKETS IN ROMANIA

**Pepi Mitică, Nicolae Traian Cristin**

*Department of Finance and Accounting , Faculty of Economic Sciences, University "OVIDIUS", Constantza, Romania*

*e-mail:pepi.mitica@gmail.com*

*e-mail: [traian.nicolae.profesor@gmail.com](mailto:traian.nicolae.profesor@gmail.com)*

**Abstract:** *The theme of our research is related to the new type of relationship between financial audits (statutory) and unique regulation of financial markets in Romania. The Romanian authorities have decided as from 2013 regulation of financial markets, capital market, insurance market and private pensions market to achieve by a single entity, this situation will also lead to a number of challenges in the relationship between the auditor and the new regulatory regime. The main elements of our study are: the relationship between the audit committee and regulatory authority; quality of financial reporting for financial market entities. The auditor plays an important role in financial markets because it certifies the financial statements in accordance with European Union practice . It is also interesting to note potential interference that can occur in single regulation between compliance audit and financial stability and return on investment between performance audit and financial markets. In this case, financial regulation can coexist with compliance audit. EU legislation recommends that the auditor discuss with the audit committee the quality and acceptability of the financial reporting process. This recommendation is what should constitute a possible consensus to be highly unlikely between audit committees would align auditors in financial reporting disputes with management financial entities. In this regard, auditors should identify the factors we consider important in determining the quality of financial reporting. .We conducted this research in an effort to identify the possible divergence between the type of regulations that can emit single regulatory authority and the audit process. New regulator will operate on two levels, issue general regulations apply to all three categories of financial markets, capital market, insurance market and private pensions market, but in the same time and in greater extent will issue specific regulations of each market in part. We want to identify the extent to which audit the entities in these markets will be influenced by these changes. Interest is our largest to determine whether the audit can identify any changes in the new regulatory requirements on quality of financial statements. Our research results show the high importance of the audit committee in ensuring the high quality of financial reporting in the financial markets and seeks to identify potential points of conflict between audit conservatism and unique market regulation.*

**JEL:** *M42, M48, N20*

## **Introduction**

The achievement of this research is the result of the emergence of a regulatory entity for financial markets in the institutional landscape of Romania. This entity will regulate the capital market, insurance market and private pensions market, while money market will remain under the authority of the central bank. Under these conditions new elements occur that redefine the relationship between financial (statutory) audit and regulatory policies of public authorities in the field. Auditors play a crucial role in the functioning of capital markets by serving as independent agents that scrutinize firms' financial statements on behalf of shareholders, creditors and other accounting users. In the European Union, they attest that companies, in preparing their financial reports, conform to international financial reporting standards (IFRS) as specified by the International Accounting Standards Board (IASB). It is a well-accepted notion that auditing reduces the information risk in accounting reports, thereby improving investors' investment decision (Arens et al. 2006). Overall, the demand for and the supply of auditing determine the equilibrium auditor conservatism and audit quality. Companies with high business risk induce auditor conservatism, while companies with low business risk induce auditor aggressiveness. This finding contributes to the literature by linking auditor conservatism to client characteristics and therefore identifying the determinants of auditor conservatism in a capital market setting. We also provide a theoretical explanation for the positive relation between firm business risk and conservatism that has been documented. If auditor conservatism is in force, a greater client pressure on auditors improves audit quality, but if auditor aggressiveness is in force, a greater client pressure on auditors impairs audit quality. Client pressure on auditors can take the form of potential client businesses for the auditor, such as nonaudit services and repeat audit engagements (Kornish and Levine 2004). This result is contrary to the popular belief that client pressure on auditors is always bad. We find that client pressure is desirable when the auditor is conservative. The nature of investment efficiency depends on the auditor's attestation.

### **1. Literature review**

Research has documented that there is a positive association between the effectiveness and knowledge of the audit committee and the quality of financial reporting (e.g., Stickney, C., Weil, R., Schipper, K., Francis, J., (2010). They found that more active and independent audit committees were associated with a decreased incidence of financial statement fraud while in a study evaluating a 10 year span of documented incidents of financial fraud. That the financial expertise of audit committee members had little association with the frequency of fraud, work by Watts, R., (2003) suggests that greater financial expertise of audit committee members may lead to a more effective relationship with external auditors. For example, Nocera, J., (2005) found that audit committee members with more knowledge in auditing were more likely to express support for external auditors in reporting disputes with management. This implies that audit committees with financially astute members will be more likely to help auditors in their struggle to maintain their independence from the pressures imposed by management. However, Gibbins et al. (2001) found audit partners' modal response to the importance of audit committees in resolving financial reporting disputes with the client management was

"low." One possible rationale for this finding is outlined in a study by Cohen et al. (2000) who found that experienced external auditors believe that the lack of financial expertise of audit committee members negates the effectiveness of the committee. The effectiveness of audit committees and their ability to help auditors in their quest to maintain true independence may also be somewhat hampered by the strong influence of management. Our recommendations are to invoking new concepts and requirements that may be subject to uncertainty and ambiguity, potentially inhibiting their impact. If there is a lack of consensus on what constitutes financial reporting "quality" then it would be difficult for external auditors to evaluate this attribute and to enlist the support of audit committees in a reporting dispute with management. Although the Ramsay Report (2001) does not discuss the issue of financial reporting quality in the same manner as the BRC, it is imperative for companies in their ability to raise capital from external sources to have a similar understanding of the attributes that constitutes financial reporting quality as that found in primary global markets.

## **2.Financial regulators versus financial auditor independence**

*The tasks of the regulatory model shall include the following:*

(1)undertaking measures aimed at ensuring regular operation of the financial market;(2) undertaking measures aimed at development of financial market and its competitiveness;(3)undertaking educational and information measures related to financial market operation;(4) participation in the drafting of legal acts related to financial market supervision;(5)creation the opportunities for amicable and conciliatory settlement of disputes which may arise between financial market actors, in particular disputes resulting from contractual relations between entities covered by FSA supervision and recipients of services provided by those entities;(6) carrying out other activities provided for by acts of law.The aim of financial market supervision is to ensure regular operation of this market, its stability, security and transparency, confidence in the financial market, as well as to ensure that the interests of market actors are protected.

*Supervision of the financial market:* A stable, competitive and financial system founded on integrity provides the basis for a functioning economy, sustainable employment and secure levels of affluence. The task of supervising the financial markets is therefore a crucially important one in all national economies.

*Integrated supervision:* As an integrated supervisory institution, the FSA, which was founded in 2012, brings together responsibility for supervising all significant providers and functions under one roof. The authority supervises, insurance undertakings, pension companies, corporate provision funds, investment firms and investment service providers, investment funds, financial conglomerates and exchange operating companies. It also monitors activities to ensure that trading in listed securities complies with legal requirements and the principles of fairness and transparency (supervision of the market and stock exchange

*Tiered structure of supervision :* Any efficient and effective supervisory system builds on the work of "upstream" supervisory instances. This is referred to as the tiered structure of supervision. The first tier of monitoring and control is provided by each financial institution's own internal auditing department. The institutions' supervisory boards and auditors form the second tier, which, while appointed by the

individual companies, is composed of independent, third-party experts. The state system of supervision takes over at the third stage.

*Mission:*The primary mission of the institution is to assist through legal, administrative and informational means for the maintenance of stability and transparency on the non-banking financial sector, and to ensure the protection of the consumers of financial services and products.

*Regulatory activity:*The Commission's regulatory activity includes drafting and adoption of regulations and instructions provided for in the legislation, issuance of guidelines and instructions regarding the implementation and interpretation of the codes and laws. The Commission adopts secondary legislative acts concerning laws' implementation in relation to the carrying out of financial supervision. The regulation of the market participants' activity is in conformity with the European legislation, norms and practices.

*Licensing regime:*In its licensing activity the Commission is guided by the principle of impartiality and implementation of a unified approach and criteria with respect to all applicants. The Commission examines the documents that have been attached to the applications for permit issuance or amendment of one that has already been granted in view of their compliance with the regulatory requirements. It is being established whether all the required documents and data have been provided and whether the legal limitations to certain licensing proceedings have been complied with.

*Sanctions:* The relationship between the regulatory body of the capital market - and financial audit can be extended to the single regulatory authority, authority to possess a broad area of responsibility. In this sense, insurance companies and private pension funds can assimilate capital market entities, when acting as investment funds. In this case, financial regulation can coexist with compliance audit. For those synergies to be real we felt that our research must answer the questions on the link between financial auditor independence and audit committee role with financial reporting quality.

### **3. Research methodology**

Thus, we are also interested in how external auditors interpret the recommendations of the BRC as it pertains to financial reporting "quality." To examine how external auditors perceive the effectiveness of the BRC to enhance the quality of the financial reporting process and help maintain auditor independence, we investigate the following research questions. We conducted our research in a study showing the effects of regulation on the single financial authority: functions and responsibilities of the audit committee; quality of financial reporting; communication with the audit committee. The study was conducted on a total of 34 respondents who expressed an opinion on the functions and responsibilities of the audit committee, the quality of financial reporting and the quality of communication with the audit committee.

**Research Question 1:** What do financial auditors consider as important functions and responsibilities of audit committees and what are the resulting implications of these issues for auditor independence?

**Table1: Audit committee elements of influence(n=34)(Research question 1)**

Panel I: Influence elements of audit committee	Mean	s.d.	Freq	%
Influence elements of audit committee				
Ensuring quality of accounting policies and oversight of financial reporting			23	67%
The internal controls of ensuring quality			15	45%
The review of the relationship between the company and external auditors			15	45%
Anticipate financial risks			9	26%
Ensuring the selection/retention of quality, independent auditors			6	19%
The regularly review of the relationship between internal auditors and management			5	14%
High quality, and timely disclosure of financial and other material information to the board, unique markets regulatory, and shareholders			5	14%
Develop a direct, strong, and candid relationship with outside and internal auditors to encourage them to speak freely			4	12%
Other			5	14%
Will audit committee elements of influence change over the next 3 years?				
Yes			20	60%
No			14	40%
Audit committees role in appointment/reappointment of financial auditor <sup>1</sup>	4.55	1.45		
Panel II : Audit committee Effectiveness				
Effectiveness of Audit committees in fulfilling financial reporting responsibilities <sup>2</sup>	4.22	0.91		
The administrative board role in influencing the effectiveness of an Audit committee <sup>3</sup>	4.76	1.68		
The management role in influencing the effectiveness of an audit committee <sup>3</sup>	4.52	1.48		

Reliance placed on audit committee to resolve financial reporting disputes with management <sup>4</sup>	2.81	1.31		
The corporate ownership role in determining the effectiveness of an audit committee <sup>3</sup>	4.89	1.72		
Audit committee influenced by financial analysts' expectations to accept aggressive accounting <sup>1</sup>	3.79	1.38		
Is it important to distinguish between "Form" and "Substance" of Audit committees? Yes No			27 7	80% 20%
Factors that constitute a "good" audit committee				
Independence			15	45%
The expertise in financial literacy			14	43%
Commitment			13	38%
Asks good questions			12	36%
Business knowledge			10	29%
Knowledge of auditing controls			8	24%
Experienced			4	12%
<sup>1</sup> 1=Not influenced at all; 7 = Significantly Influenced				
<sup>2</sup> 1=Not Very Effective; 7 = Very Effective				
<sup>3</sup> 1 =Insignificant Role; 7 = Highly Significant Role				
<sup>4</sup> 1=No Reliance; 7 = High Reliance				
<sup>5</sup> 1=Not Knowledgeable; 7=Highly Knowledgeable				

**Research Question 2:** What are the factors that financial auditors perceive determine financial reporting quality and what role does the audit committee play?

**Table 2: Financial reporting quality (FRQ) (N=34) (Research question 2)**

Panel I: Factors that determine Financial Reporting Quality	Mean	s.d.	Fre q.	%
Clarity of company's financial disclosures <sup>1</sup>	5.57	1.29		
Degree of aggressiveness or conservatism with respect to accounting principles <sup>2</sup>	6.02	1.27		
Other significant management decisions in preparing financial disclosures <sup>2</sup>	5.38	1.21		
Determining factors in financial reporting quality (listed in rank order based on frequency of response)				
Clarity of financial disclosure			16	48%
Degree of aggressiveness and conservatism in accounting principles and estimates			15	43%
Other significant decisions by management in preparing the financial disclosure			5	14%
A comparison to current industry practices			2	5%
Quality of accounting staff			2	5%
Panel II: Audit Committee (AC) and Financial Reporting Quality				
Role ACs currently play in ensuring FRQ <sup>2</sup>	3.43	0.93		
Role ACs should play in ensuring FRQ <sup>2</sup>	5.58	1.15		
AC's effectiveness in reducing likelihood of financial reporting fraud <sup>3</sup>	3.32	1.18		
Do ACs have enough power to confront management?				
Yes			29	85%
No			5	15%
Major challenges today in working with audit committees to ensure sound financial reporting? (listed in rank order based on frequency of response)				

Lack of sufficient financial sophistication on the part of audit committee members			16	48%
Audit committees lack the power or the will to work towards ensuring sound financial reporting			13	38%
Time Constraints			2	7%
Other (e.g. compensation, compensating liabilities)			2	7%
<sup>1</sup> 1=Little Importance; 7 = Extreme Importance				
<sup>2</sup> 1=Insignificant Role; 7 = Highly Significant Role				
<sup>3</sup> 1=Not Very Effective; 7 = Very Effective				

**Research Question 3:** What factors affect the level and quality of communications between the financial auditors and the audit committee?

**Table3:Communications with audit committee (n=34) (Research question 3)**

	Mean	s.d.	Freq.	%
The management influences on the nature, extent, and quality of communication between an outside auditor and the AC <sup>a</sup>	5.06	1.35		
AC factors (characteristics) that will encourage an open and frank communication between an outside auditor and the AC (listed in rank order based on frequency of response)				
Real competency			15	45%
Real independence			8	24%
Private meetings with the Audit Committee			6	19%
Receptive/questioning			6	19%
Frequent meetings/interest			3	10%
Involved in the selection of the auditor			3	10%
Real longevity			2	5%

Other			2	5%
Auditing firm ( auditor) factors (characteristics) that will encourage an open and frank communication between an outside auditor and the AC (listed in rank order based on frequency of response)				
A strong relationship development (openness)			7	21%
Knowledge of client/industry/audit committee			6	17%
Frequent meetings			3	10%
Challenge the audit committee			3	10%
Alter the contract with the financial auditor (longer term, limit liability, rotation, hired by audit committee)			3	10%
Willingness, if necessary, to lose client (with support from the firm)			3	10%
Other			3	10%
<sup>a</sup> 1=Not influenced at all; 7 = Significantly influenced				

## Conclusions

Our research sought to identify the challenges and opportunities raised by a single financial supervisory authority to the independent financial auditor . We conducted on a total of 34 respondents who expressed an opinion on the functions and responsibilities of the audit committee , the quality of financial reporting and the quality of communication with the audit committee .The major functions of an audit committee are to oversee the financial function of the Company. They should have oversight responsibility for systems of internal controls, quality financial reporting and disclosure and financial risk management. Almost half of the respondents (45 percent) also indicated that ensuring quality internal controls and overseeing the audit process, including regularly reviewing the relationship between the company and its external auditors, are important responsibilities of an audit committee. This latter finding suggests that audit committees potentially may evaluate if there is too close of a relationship between management and the auditors that may call to attention a perceived lack of independence on the part of auditors. Surprisingly, despite the emphasis placed by the auditing profession on the potential importance of the interactions between the audit committees and the internal auditors, few auditors (14%) stressed the role of the audit committee in enhancing the effectiveness of the internal audit function.The legislation requires has called for the auditor to discuss with the audit committee the quality and not just the acceptability of the financial reporting process. This recommendation is consensus on what

constitutes “quality,” it will be highly unlikely that audit committees would align with auditors in financial reporting disputes with management. However, the recommendation raises the issue of how “financial reporting quality” is to be defined. In this regard, auditors were asked an open-ended question regarding factors they consider important in determining financial reporting quality. Finally, we asked three questions regarding communications between the external auditor and the audit committee. First, in an open-ended question auditors identified audit committee factors or characteristics that encourage an open and frank communication. The most frequent factors cited were: competency (45 percent); independence (24 percent); private meetings with the audit committee (19 percent); and receptive to auditors questioning financial reporting positions (19 percent). In a second open-ended question we asked participants to identify auditor or audit firm factors that encourage strong communication. There were no overwhelming factors noted. However, those that were cited were: develop a strong relationship with the audit committee (21 percent); knowledge of client/industry/ audit committee (17 percent); frequent meetings (10 percent); challenge the audit committee on financial reporting issues (10 percent); alter the contract with the financial auditor (longer term, limit liability, rotation, hired by audit committee) (10 percent); and willingness to lose a client (10 percent). Therefore, it is possible that the mixed empirical evidence on the economic consequences of the directives of financial authority is due to the use of pooled samples in empirical studies that combine firms with the independence of auditors.

**Abstract:** *This paper presents a new approach in evaluating risks of material misstatements in financial audit using dependency structure matrices (DSM). This perspective allows the identification of significant audit risks and can be used by audit managers to optimise resource allocation by focusing on higher risk areas. DSM matrix is widely used in other areas such as industrial production, design engineering and risk management. This approach is not used in financial audit so far. The financial crisis has diminished the activity of the audit clients and has imposed smaller audit fees. The auditors have to optimize their processes in order to maintain the quality of audit, even to improve it for the same audit remuneration. DSM matrix is a solution for this problem. This article points out have to use DSM matrix in financial audit process in order to optimize the allocation of resources, while maintaining audit quality. Our research aims to improve the risk evaluation stage in the financial audit process using DSM matrix to evaluate higher risk areas. We used the Project DSM Tool for representing significant accounts in the Purchase to pay process for a financial audit. Dependencies between accounts were used for creating a DSM matrix that depicts higher risk areas. Also, for each account, several resource allocation parameters such as costs and number of hours to be used for performing audit procedures on that account (from both audit team and client personnel).*

*Our research suggests that DSM can provide useful information in detecting risk areas in significant classes of transactions identified in a risk based audit and we recommend using DSM matrix in the planning phase of the audit in order to avoid redundancies in the audit execution phase. This is important considering that the European Commission recommends in the Green Paper for Audit to improve the quality of audits following the setbacks to the profession caused by the financial crisis.*

**Keywords:** audit, risk based approach, DSM matrix, optimizing cost, resources' allocation

## 1. Introduction

The audit activity is mainly influence by the time allocated to the audit mission and by the resources optimization. As a fact, when splitting the working time, the audit has to realise their priorities considering the risks that can be associated with financial statements. Disseminating this, Pratt, Jiambalvo, J. (2002) pointed out some elements that are related with the audit team and the performance obtained by it. Their study revealed that resources allocation, the number of tasks that each

audit member has and the time budget are elements that influence overall the audit activity.

Asare, S. Cohen, J., Tompeter, G. (2005) emphasise the importance of audit team qualification, Burke, C. S. & all. (2006) proved that the audit team efficiency is influenced by the managerial personnel resources, by managerial materials and by solving the accounting problems taking into considerations all the risks that are associated with company's financial statements, while Francis, J. R. (2004) demonstrated that information about accounting policies and how they are applied by the audited company is important in the audit examination process. Similar conclusions regarding the performance of audit team were extracted by Scott, T., W., Tiessen, P. (1999) who establishes that the audit activity is influenced by their prior targets. As a fact, depending on the mission type and on the resources allocation, there could be realised a comprehensive process of the audited company, of their accounting policies and of how they apply them.

In the main literature, there is a multiple research upon the risk that could be associated with the audit process, evidence about that being pointed out for example by Ohta, Y. (2009) and Knechel, W. R. (2007) who realises a summary about the business risk audit, its history, evolution, and further perspectives.

In order to reveal the risk encountered in the audit process, there is an important need to detect the areas where the audit should pay higher attention, as there are higher risks associated with it. As a fact, the resources allocation is mainly influenced by identifying the potential risk areas in the audit process. Consequently, a proper tool to realize this type of allocation can be the use of dependency structure matrix tool.

DSM matrix is a tool used generally in order to improve the modelling of the system process. As a fact, it can be used for identify groups, for creating packages or for revealing the regions that have similar characteristics. This aspect can be revealed in the audit process in order to identify the areas where the risks are higher, so important financial distresses could be omitted.

The DSM technique was first developed by Steward D. (1967) in order to optimize the product development processes. Further improvements were brought also by the same author in Steward, D. (1981) when he applied it for design engineering process. The design structure matrix is one of the most important research methodologies through which the dependencies between the variables encountered are revealed. The idea of using this, is to optimize the relationship between the activities pointed out in the matrix and moreover to obtain a perspective about the planning activity as Pieroni, M. (2005) and Manzione, L., Melhado, S. B. (2007) proved out. Smith, R. P. and Eppinger, S. D. (1995) redefined the concept of DSM, while Browning, T. R. (2001) reviewed the implementation of Design structure matrix for decomposition and integration problems and emphasis new directions where this model could be applied.

New innovations to this technique were proposed by Banerjee, A. Carrillo, J. and Paul, A. (2007) who realized an analysed upon the complexity involved in the algorithms used for constructing the DSM matrix.

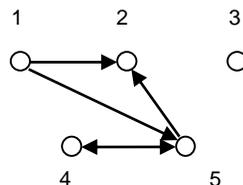

Other innovation were proposed by Mori, T. et al. (1999), in order to developed proper methodology for optimizing the DSM process. As a fact, the partitioning and tearing algorithms were proper developed. Actually, these two ways of quantifying the algorithms from DSM matrix were proposed by Gebala, D.A. and Eppinger, S. D. (1991). The partitioning algorithm is used for reorganizing the ascending sequence

of the items of the matrix for maximising the availability and the amount of the information that the elements analysed had. On the other hand, the tearing algorithm is based on identifying and reorganizing the blocks of elements that are encountered in the matrix. The idea is to check those elements that could become a package, or that have similar characteristics that have to be taken overall into consideration. Regarding the DSM matrix, even though it was proved that it brings important efficiency in reducing the total time allocated to the project, the DSM tool has been rarely applied in economic fields. It was mainly used in engineering studies, like Manzione. L, Melhado, S. B (2007) , Pieroni, M (2005), Murphy, G.C., Notkin D., and Sullivan, K.J. (2001), Müller, H. A., Wong, K. and Tilley S. R. (1994). In order to focus on the perspective of auditors, it is recommended that DSM matrix to be properly applied. As a fact, the time allocated to the audit mission is going to be reduced and moreover a proper resources allocation could be realized. As the financial audit needs additional knowledge to identify the risks associated to audited company, we consider that the DSM tool application can improve sharply the resources allocation. As a fact, the DSM matrix represents the dependencies through which the elements a applying the design structure matrix to system decomposition and integration problems: a review and new directions related, and consequently aspects that are not generally detailed analysed would be encountered in the audit process.

## 2. Research Methodology

We propose an audit approach based on a new methodology to evaluate risks of audit. This new approach refers to uses graph theory to represent accounts in significant classes of transactions identified using risk based approach. The DSM matrix solves this issue. DSM matrix is based on graph theory, like our assumption. A graph is a model that visually describes elements and relationships between them. The components of a graph are: vertices (nodes) and edges. Nodes may or may not have a weight and the edges may or may not have directions and/or costs. Graphs may be represented using adjacency matrix which is a  $n$  by  $n$  matrix ( $n$  = number of vertices in the graph) with elements  $a_{i,j}$  that may be 0 (if there is no edge from  $i$  to  $j$ ) or 1 (if there is an edge between  $i$  and  $j$ ).

Please refer to Figure 1 for graph example and to Table 1 for the adjacency matrix representing it.

**Figure 1:** Graph example  
Source: Authors projection

**Table 1:** Adjacency matrix

	1	2	3	4	5
1	1	1	0	0	1
2	0	1	0	0	0
3	0	0	1	0	0
4	0	0	0	1	1
5	0	1	0	1	1

Source: Authors projection

The authors used the Project DSM Tool to depict the significant accounts in the purchase to pay class of transactions. In a typical audit the main accounts to be considered for this class of transactions are as follows:

- Inventories;
- Property, plant and equipment;
- Advances to suppliers;
- Admin expenses;
- Commercial expenses;
- Production expenses;
- Discounts;
- Accounts payable;
- Cash and bank

Please refer to Figure 2 for the representation of accounts that impact the risk of significant misstatement for the purchase to pay class of transactions.

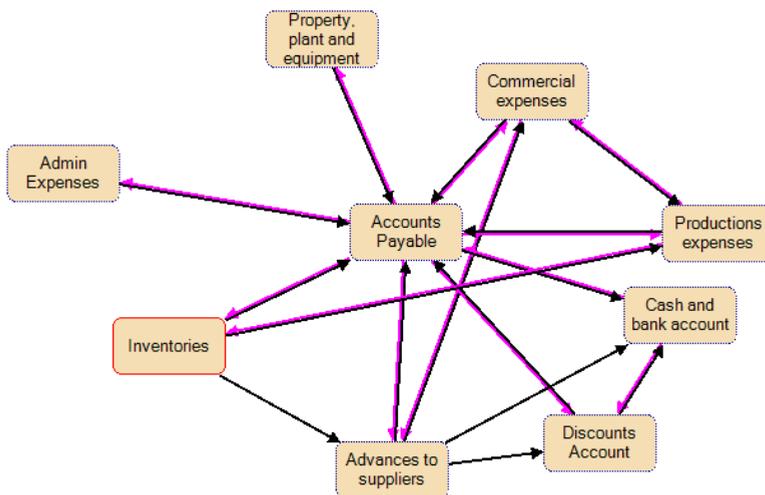

**Figure 2:** Representation of accounts and audit risk  
Source: Author export from Project DSM Tool.

We established the dependencies between significant accounts in the Project DSM Tool based on the following rationale:

- The inventories account relates to Accounts payable, Production expenses and Advances to suppliers accounts;
- The Property, plant and equipment account relates to the Accounts payable account;
- The Advances to suppliers account relates to Accounts payable, Cash and bank, Inventories and Discounts accounts;
- The Admin expenses accounts relates to the Accounts payable account;
- The Commercial expenses account relates to the Accounts payable, Advances to suppliers and production expenses accounts;
- The Production expenses account relates to the Accounts payable, Commercial expenses and Inventories accounts;
- The Discounts account relates to Accounts payable, Cash and bank and Advances to suppliers accounts.
- The Cash and bank account relates to Accounts payable and Discounts accounts;
- The Accounts payable account relates to all accounts above.

Please refer to Figure 3 for the dependencies map, as described above:

**Figure 3:** Accounts dependencies in the Purchase to pay process  
Source: export from Project DSM Tool

Please refer to Figure 4 or the Project DSM Tool menu for defining dependencies between accounts.

Components	Strength
System: RISK AUDIT	
2 Accounts Payable	<input checked="" type="radio"/> Dependent <input type="radio"/> None
3 Discounts Account	<input checked="" type="radio"/> Dependent <input type="radio"/> None
4 Productions expenses	<input type="radio"/> Dependent <input checked="" type="radio"/> None
5 Commercial expenses	<input type="radio"/> Dependent <input checked="" type="radio"/> None
6 Admin Expenses	<input type="radio"/> Dependent <input checked="" type="radio"/> None
7 Advances to suppliers	<input checked="" type="radio"/> Dependent <input type="radio"/> None
8 Property, plant and equipment	<input type="radio"/> Dependent <input checked="" type="radio"/> None
9 Inventories	<input type="radio"/> Dependent <input checked="" type="radio"/> None

**Figure 4:** Defining dependencies for the Cash and bank account

Source: export from Project DSM Tool

For each account we allocated a standard number of hours and cost, considering a typical audit engagement. For instance, for the Cash and bank account, we considered 20 hours for audit team members and an additional 8 hours needed from client personnel (for audit support purposes). Also, a cost of 3000 RON was considered based on hourly rates for audit senior and junior staff.

Please refer to Figure 5 for the defined resources in the Project DSM Tool

ID	Name	Effort (H...)	ID	Name	Total Cost
1	Cash and bank account	28,0	1	Cash and bank account	5000
2	Accounts Payable	48,0	2	Accounts Payable	3000
3	Discounts Account	28,0	3	Discounts Account	3000
4	Productions expenses	68,0	4	Productions expenses	8000
5	Commercial expenses	48,0	5	Commercial expenses	8000
6	Admin Expenses	48,0	6	Admin Expenses	5000
7	Advances to suppliers	48,0	7	Advances to suppliers	5000
8	Property, plant and equipment	48,0	8	Property, plant and equipment	5000
9	Inventories	68,0	9	Inventories	8000

### 3. Results and discussion

Based on the data input above, we obtained the following results in the Project DSM Tool:

- DSM matrix;
- Combined resource allocation assessments;

The DSM matrix shows the areas with potential high risk of material misstatements based on dependencies between account classes as described in the previous section. We noticed four areas with potential higher risk that should be considered when planning the audit procedures. The areas where audit managers should focus their tests are depicted in Figure 6.

#	Task	1	2	3	4	5	6	7	8	9
1	Inventories	●					●		●	
2	Property, plant and equipment		●						●	
3	Advances to suppliers	●		●		●			●	
4	Admin Expenses			●	●				●	
5	Commercial expenses			●		●			●	
6	Productions expenses	●				●	●		●	
7	Discounts Account			●					●	
8	Accounts Payable	●	●	●	●	●	●		●	●
9	Cash and bank account			●				●	●	●

**Figure 6: DSM Matrix**

Source: export from the Project DSM Tool

In the first stage of the analysis, as per the DSM matrix results, auditors should consider for testing the following account pairings:

- Discounts - Accounts payable - Cash and bank account
- Commercial expenses – Production expenses
- Advances to suppliers – Commercial expenses – Discounts – Accounts payable – Cash and bank account
- Admin expenses – Commercial expenses

The Accounts payable should be considered for further testing as it is related to all accounts in the Purchase to pay process.

In the second stage of the analysis, auditors may conclude that two of the areas, Commercial expenses – Production expenses and Admin expenses – Commercial expenses, do not contain risks of material misstatements and should not be further tested.

The combined resource allocation table shows the total allocated resources (audit hours and costs) considering the dependencies described in the previous section and a rework percentage of 10-20% (i.e. up to 20% of the work performed by auditors will have to be re-performed following reviews from the audit managers).

Please refer to Figure 7 for the allocation table as per the Project DSM tool.

Option N...	Score	Action	Complexity	Cost	Effort
Perform	10	Simplify: Admin Expenses depends on Accounts Payable	21,0	8,9	9,8
Perform	10	Simplify: Accounts Payable depends on Admin Expenses	21,0	8,9	9,8
Perform	10	Delay element 6: Admin Expenses	21,0	8,9	9,8
Perform	10	Promote element 6: Admin Expenses	21,0	8,9	9,8
Perform	7	Promote element 9: Inventories	21,0	14,3	13,9
Perform	7	Delay element 2: Accounts Payable	80,2	48,2	52,5
Perform	7	Promote element 2: Accounts Payable	80,2	48,2	52,5
Perform	6	Delay element 3: Discounts Account	21,0	10,7	11,5
Perform	6	Delay element 1: Cash and bank account	21,0	17,9	11,5

**Figure 7: Combined resource allocation**

Source: export from the Project DSM Tool

Based on the output from the Project DSM Tool we observe that the most complex elements are Accounts payable, the same account that we observe from DSM matrix.

From this analysis we observe that the Accounts payable are the most significant element and the risks are concentrated in this area.

This type of analysis can help the management team to choose the most efficient allocation of resource while covering all significant risks of misstatement.

#### **4 Conclusion**

Evaluating audit risk is one of the main challenges in the audit process especially when using a risk based approach. Auditors have to find a balance between the allocated resources and the assurance obtained from performing audit procedures considering the costs. The financial crisis had a significant impact on audit fees, with audit firms constantly having to reduce costs while maintaining audit quality. Even in the Green Paper for Audit the European Commission recommends having high quality financial audits because the sustainability of this profession is doubtful.

The current approach on financial audit must be reconsidered in order to provide creditworthiness for the audit opinion.

Our research aims to improve the risk evaluation stage in the financial audit process using DSM matrix to evaluate higher risk areas. Based on this evaluation audit managers can better allocate resources to cover these areas and thus to optimize the audit process while maintaining audit quality.

As shown in this paper, DSM can provide useful information in detecting risk areas in significant classes of transactions identified in a risk based audit.

We recommend using DSM matrix in the planning phase of the audit in order to avoid redundancies in the audit execution phase.

The main limitation of our research is the lack of real life audit data. In order to obtain real audit data, inside information is needed and the confidentiality principle of audit does not allow auditors to disclose such information.

Our plan is to develop our research by applying DSM matrix to an audit engagement and to compare the results in detecting risk between the classic audit approach and the DSM approach. When the model would be implemented into practice will be able to analyse the gain in audit quality made by this new methodology.

**Abstract:** *Modern economic theories reject the generalization of theories concerning the economic and financial crises. Each financial crisis is unique, a historic accident, generated by specific factors in a certain socio-economic and political set-up. According to these theories, crises cannot be anticipated so as to minimize their negative effects. In spite of the fact that economic and financial crises are not identical and do not produce identical effects, history teaches us that they are strongly correlated with the cyclic nature of economic processes. The current economic recession, which shows in all fields of activity, is determining auditors to make evaluations which are a lot more precise, based on extensive procedures, as long as the presumption of activity continuity into the future is accurate. In this context, internal audit is individualized as an managerial assistance function, which allows a correct perception of the reality of the business as a whole and/or as predefined processes. The purpose of this paper is to create an overall picture of internal audit by collecting data and information from literature and showing the dimensions and the internal audit practices internationally. Therefore, we conducted a research based on the analysis of national and international publications, various articles and studies in the financial press, on the emergence and development of the internal audit function both internationally and nationally. Later we analyzed the position of internal audit in terms of global financial crisis, all these leading to the usage of a comparative study of twelve international companies in order to highlight the specific features of the internal audit function in each organization. Our intention is to emphasize aspects of internal audit departments, relations between them and the management, their role in companies based on studies provided by Protiviti, a global consulting and internal audit services company, having experts specializing in risk, consultancy and transactions.*

**JEL classification:** *M42*

### 1. Introduction

From a territorial, durational and economical and political effects' standpoint, the 1929 crisis, also known as the Great Depression, can be considered, up to this moment in time, the most severe. The Great economic Depression, which started in the United States of America, was preceded by a period of 9 years (between 1920 and 1929) of economic development, which was supported by the increase in circulation of the monetary mass by the Central Bank of America – Federal Reserve (FED), as well as the relaxation of the credit standards and reduction in interest rates.

As a consequence of FED's monetary and financial policy, the population bought stock massively, which registered a constant increase in the Stock Exchange, up until September 1929, when the great Wall Street Crash happened. FED intervened by reducing the monetary mass and by restricting credits, the follow up being a massive bankruptcy in all sectors of the economy: agriculture, industry and banking. National production decreased to half its previous values and the unemployment increased.

The current financial crisis was triggered in the USA in 2007, ten years after the last extended financial crisis from South-East Asia. The first signs of what was to come were experienced in the summer of 2007, when financial institutions started acknowledging that they are dealing with significant losses on sub prime mortgage backed securities (CAFR 2009). The crash of the Federal Housing Administration (USA) is often considered responsible for the generation of the crisis, but the vulnerability of the financial system was caused by complicated contracts and financial operations, subjected to leverage ratios. The USA's monetary policy priced credits at ultra-low rates, thereby encouraging very high leverage ratios and, according to American Professor of Sociology John Bellamy Foster (who wrote extensively on the subjects of financial crisis), a "hypertrophy of the financial sector". A report on the crisis published by the Association of Chartered Certified Accountants identifies as the main factors that generated the crisis the following elements (CAFR, 2009:442):

- The failure of corporate governance
- The failure of institutions to assess and manage the existing links between business risks and the remuneration and incentive systems, which were not at all designed to favor stockholders
- Errors in the process of identifying and managing risk
- The weak influence or even a minimal manifested power of banks' risk management departments
- Weaknesses in the financial reporting systems and regulations.

The relevant economic theories, which established efficiency as an essential instrument of economic growth, are being called to question. Globalization, as a mass phenomenon, combined with the exacerbation of commercial policy the financial markets in order to gain profit by any means necessary, constitute the apotheosis of the economic crisis. The appetite for considerable profits with minima efforts was instilled in generations of managers, who were trained to step up to manage big corporations, and fostered, in the beginning of the 80's, economic policies which permitted the complete deregulation of all economic markets, but especially the banking and stock exchange markets, concomitantly with an unprecedented reduction of the state in the economy (CAFR, 2009:383-446).

As a result of the crisis, it was considered necessary the reports handed in by auditors in the preceding periods were submitted to analysis, which highlighted the fact that, in numerous situations, shortly after an auditor emitted an unqualified opinion regarding the financial statements of a company, they were no longer capable to continue their activities and they collapsed. The attention was focused on auditors who gave the green light on these financial statements, signing their consent that the accounting practices and regulations were kept. In many cases the auditors also provided their clients with other services, besides financial audit, which inevitably raised into question the delicate subject of the auditors' independence. When internal control and internal audit is efficient, the time allocated by the financial

auditor is diminished. This fact means fees reduced for the auditing activity according to Dobre F., Vilsanoiu D., Turlea E. (2012).

One of the reproaches of the audit activity would be precisely the non-compliance with the auditor's independence criteria, necessary for the financial audit to be efficient. The following elements also have a negative impact on the audit activity and can be taken into account in the context of economic crisis:

- Using an audit model which had become obsolete, when considering the complexity of the transaction subjected to said audit
- Not granting due importance to audits based on risk-aware methodologies

According to the International Internal Audit Standard 2110, even though it is not very explicitly mentioned, the internal audit should convey to management and the audit committee from within the company, the results of the efficiency monitoring and evaluation activity, with which the risk management systems functions. The internal auditors will have to check and evaluate the efficiency of the risk management system, which needs to be approached as an integral part of the assurance activities for companies' management. Thus, the internal audit is not responsible for the implementation of the risk response actions, but is responsible for providing management with reports which convey the significant information regarding key risks and their efficient management. Thereby, the internal audit offers insurance as to the efficient functioning of risk management, without being responsible for making any decisions as regards response actions to mitigate the identified negative risks. Therefore, one of the major effects of the crisis is the drastic decrease of the users' confidence in the accuracy and completion of financial statements, financial auditors being the ones to offer a reasonable level of assurance regarding the faithful image reflected by financial statements.

## **2. Case study concerning the analysis of internal audit practices in multinational corporations**

### ***2.1. The objectives of the case study and stating the used material***

The actual case study is based on research conducted by the company Protiviti, which is a global business consulting and internal audit firm, composed of experts specializing in risk, advisory and transaction services. Protiviti has offices in 61 major markets, out of which 33 are in the US and 28 in two Americas, Asia and Europe. The firm also has risk consulting partnerships with firms from Abu Dhabi, Caracas, Dubai, Jakarta, Kuwait and Lima.

The company was founded in 2002, when Robert Half International, reached an employment agreement with Arthur Andersen LLP to hire approximately 800 professionals. These were familiarized with Andersen's internal audit, business and risk consulting practices. The employees were the basis from which Protiviti started. The name of the company was chosen based on a branding study conducted by the founding company. It is an invented term which communicates the key attributes - professionalism and pro activity, as well as independence and integrity. The presence of the three „i” in the word represents „independence”, which is, probably, the most important concept. Beyond the linguistic aspects, the name proved to be unique, becoming a world brand.

Protiviti services respond to challenges related to: managing operational and financial risk, the technology to manage risks and effectiveness; litigations and investigations.

The studies conducted by this company are focused on describing the internal audit activities of several multinational companies. Based on information from these studies, verified with information from the companies' websites, a comparative study of several relevant characteristics related to internal audit was conducted. The first two subchapters of the study familiarize the reader with general information about the organizations, their scopes of activity and describe their internal audit department. The next two subchapters cover aspects related to the setting of objectives for the twelve companies and the manner in which they are to be reached. The last subchapter describes the relationship between the internal audit and the corporate governance of the entities.

The aims of the present study are identifying the main characteristics specific to the internal audit function of multinational corporations, emphasizing the internal audit's role in identifying and managing risk and, also, its relationship with the audit committee.

## 2.2. General description of the companies

**Table 1.** The activity domains of the companies

Financial services	Pharmaceuticals	Energy	Other fields of activity (Electronics, software)
Accenture Commonwealth Bank Deutsche Bank SPB Bank Mandiri	Dentsply Talecris	Enel Shell	Royal Phillips Electronics SAP

Source: Authors' projection based on data collected from each company's website

The entities analyzed within the scope of this project come from various, distinct activity fields, as it can be observed in Table no. 3. Thus, half of these entities are part of the financial sector, namely: Commonwealth Bank, Deutsche Bank, Bank Mandiri are highly developed banking institutions in the area in which they come from;

- *Deutsche Bank*, with their headquarters in Germany, is an investment bank based on a strong private franchise system. A banking leader in Germany and in Europe, Deutsche Bank offers financial services all around the globe and continues to extend its services in Asia, North America and the important world markets.

- *Commonwealth Bank* from Australia is one of the largest companies listed on the Stock exchange, offering complete financial services to its clients. This bank has more than 1.000 branches, 3.500 ATMs and 3.800 postal agencies, having the largest distribution network in the financial services market from Australia. Internationally, the bank has branches in Indonesia, New Zealand, China, Great Britain, USA, Singapore and Japan.

- *Bank Mandiri* is the largest bank in Indonesia. It was formed by the merger of four state banks. In 2008 the bank had approximately 960 subsidiaries, some of

which were in Singapore, Hong Kong, the Cayman Islands, Shanghai and Dilly. Some of the most important branches of the bank are Bank Syariah Mandiri, Mandiri Sekuritas, AXA Mandiri, and Bank Mandiri Europe Ltd. in London.

- *Accenture* (Ireland) offers management consulting, as well as other technology and externalization services, its activities being spread over 52 countries. In the last fiscal year, the company, which is listed on the New York Stock Exchange, had a net turnover of over 21 billion dollars.

**5.1** *Prudential Plc.* (Great Britain) is an international company that offers financial services such as: insurance, pensions, investments and others. Structurally, Prudential PLC, is made up of four entities, namely: Prudential UK, Prudential Corporation Asia, Jackson National Life Insurance Company, and M&G. Prudential PLC has a reputed number of over 21 de millions clients.

**5.1** *SPB* is an insurance specialized company originating in France and which operates in over 11 countries and has more than 822 employees. It was focused mainly on the banking sector, but currently offers not only banking products insurance policies, like insurance policies for banking cards, but also insurance policies for consumer products, such as insurance policies for mobile phones or other technological goods, insurance policies for sport equipment and insurance policies which cover everyday life events (like marriage, retirement).

The two companies from the medical field, DENTSPLY International and Talecris, have their headquarters in the United States of America.

*DENTSPLY* is a dental instruments and equipment producer, present in more than 120 countries. It is predominantly active on the USA and Canadian markets, but it also penetrated the European market (particularly France, Germany, Italy, Switzerland and England). *DENTSPLY* is also present in Central and South America, the Pacific Rim and South Africa. At the same time, the company holds marketing activities in Moscow in order to serve former Soviet Union countries.

*Talecris* worked in partnership with Bayer Pharmaceuticals until 2005 when the two companies separated. *Talecris* commenced its activity with revenues reaching 1 billion dollars, but then the company meant a series of products without having a real organizational structure. Presently, *Talecris* is a global entity which discovers, develops and produces essential treatments for humans whose health is in danger, by offering different therapeutic methods.

*Enel* and *Shell* are two of the energy sector giants, on a worldwide scale, being the main energy suppliers.

*Shell* is a Dutch company with revenues of 278 billion dollars in 2009 and over 101.000 employees in 100 countries from the globe.

*Enel* Italia is the largest energy corporation, and in Europe, Latin and North America is the second in terms of installed capacity, production and sales of electricity and gas. After acquiring Spanish utilities' company Endessa, together with its partner Acciona, *Enel* serves consumers with more than 50 million in power and gas. The company operates a varied array of hydroelectric, thermoelectric, nuclear, geothermal, windmill and solar energy stations.

*SAP* is one of the world's largest suppliers of enterprise software and software-related services, which help accelerate business innovation for its clients. The company has locations in over 120 countries. It was founded in 1972 and presently employs 47.500 specialists, out of which 13.000 work in Waldorf, Germany, where the headquarters of the company are. *SAP* has sales points in over 50 countries

worldwide and is listed at the Stock Exchange in several countries. The company had revenues of 10,7 billion dollars in the previous year.

*Philips* is a company originally from the Netherlands and presently employs over 116.000 in more than 60 countries and in 2009 had sales in value of 23 billion dollars. The company is the world's largest producer of lighting equipment, one of the first three producers of medical equipment and the largest producer of consumer goods in Europe (December 2007).

### 2.3. GENERAL INFORMATION REGARDING THE INTERNAL AUDIT DEPARTMENT

**Table 2. Comparative data referring to audit budget, number of years since the functioning of the internal audit department and the number of internal auditors**

Company	Internal audit Budget	No. of years of functioning for the Internal Audit	Number of internal auditors
<i>Accenture</i>	unknown	9	45
<i>Commonwealth Bank</i>	15 mill \$ US	21	90
<i>Deutsche Bank</i>	15 mil. \$ US	50	400
<i>SPB</i>	< 1 mil. \$ US	2	3
<i>Philips</i>	unknown	>70	75
<i>SAP</i>	1-5 mil. \$	14	34
<i>Shell</i>	> 90 mil. \$	>50	250
<i>DENTSPLY</i>	< 1 mil. \$ US	15	5 (full-time) + 10-15 (guest auditors)
<i>Talecris</i>	1-5 mil. \$ US	3	3 interns + 3-4 in partnership
<i>Bank Mandiri</i>	65,4 mil \$	10	117
<i>Prudential Plc.</i>	£16 mil.	not certain	~ 130
<i>Enel</i>	€ 1 mil.	>10	~ 100

Source: Authors' projection based on data collected from each company's website

The comparative analysis is based on three variables, namely:

- The budget apportioned by the company to the internal audit department
- The number of internal auditors
- Number of years of functioning of the internal audit department

The following aspects can be highlighted:

- In companies which have an internal audit department for more than 50 years, such as: Deutsche Bank, Phillips, Shell, the number of internal auditors within the department as well as the budget is higher.
- There are also entities, for which even though the budget is quite high, as well as the number of internal auditors, not the same can be said about the number of yours the internal audit department is in function. This is the case for Mandiri Bank, for which the internal audit department is in function for 10 years, with an apportioned budget of 65,4 million dollars and with 117 internal auditors.
- The case of a relatively low budget for internal audit, but with a large number of internal auditors, is exemplified by Enel that has approximately 100 internal auditors.

**Table 3. Companies' objectives and the strategies to achieve them**

Analyzed criteria	DENTSPLY	Talecris	SAP	Philips	Shell	Enel
<i>Planned objectives</i>	-the reduction of risk exposure -the development of cost reduction programs	- the surveillance of the financial sector	- internal control, the covering of risk management - to increase the efficiency of control processes - to develop the reputation of internal auditors	- the inclusion of management risk in the audit process -to assure financial reposting conformity	- risk management - internal control	- the creation of an international audit department – to follow the ethics' code
<i>Strategies to achieve objectives</i>	- the use of the program ACL; (the use of technology reduces the auditor's travel expenditure)	- Through the use of ACL program	- through the SAP application	- the implementation of ETR	- the compound effect of auditors working with technology (the basis of this company lies on these two elements) - personnel training	- the ERM model (concentrating on the processes and the risks)

Source: Authors' projection based on data collected from each company's website

### 3. CONCLUSIONS AND SUGGESTIONS

The aim of this paper was to stress some aspects of the internal audit function within international companies, based upon information provided by Protiviti, a global consultancy and internal audit company made of risk, consultancy and transaction experts.

In our research, we took into account several criteria:

- The companies' field of activity
- General data about the audit department (age of the audit department within the organization, its budget, the number of internal auditors)
- The objectives of the internal audit department
- The strategies used to accomplish these objectives
- Corporate governance

The companies that we analyzed have different fields of activity, mainly within the financial sector. Half of the twelve companies in discussion act on the financial market, and the rest belong to the pharmaceutical, energetic, software and electronics fields. The correlation between this analysis' criterion and the other variables was not taken into account mainly because of the lack of a representative sample of firms from the same field of activity that could have highlighted the particularities of belonging to the above-mentioned field. However, there might be cases in which a certain feature is specific to a field of activity.

According to information supplied by Protiviti, companies which grant a high budget to the internal audit function, are the following: Commonwealth Bank, Deutsche Bank, Shell, Mandiri Bank, Prudential Plc.; the budgets vary from 15 to 65,4 million dollars, the highest value of 65,4 million \$ is allocated to the internal audit department of Mandiri Bank.

As a general conclusion, it can be said that the internal audit function differs from one organization to another, because the organizational culture has a major influence. However, for all companies, the attention to risk management, internal control and continuous surveillance can be distinguished as joint interests. These common desiderates can be reached with the use of technology or applications, such as: ACL, PGP, SAP, MAPS, AWARE, CAATs etc., which combined with the knowledge and skills of the auditors, contribute to the increased efficiency and performance of internal audit. The role of internal audit is paramount within a company, as the reports and information that it supplies is the basis for managerial decisions.

Several of the companies in discussion decided to constitute an audit committee or a risk committee in order to accomplish their risk management and internal controlling responsibilities.

# AN EMIPRIC STUDY ON THE ROLE AND UTILITY OF THE FINANCIAL AUDIT IN ROMANIA

**Pop (Grigorescu) Ioana Iuliana, Ivan Oana Raluca, Puțan Alina**

<sup>1</sup> Ph. Candidate, University "1 Decembrie 1918" Alba-Iulia, Faculty of Science, Romania co-tutoring University Lleida, Law and Economics Faculty, Spain

<sup>3</sup>[putan.alina@yahoo.com](mailto:putan.alina@yahoo.com)

**Abstract:** *The present article presents the results on an empiric study on the role and utility of the financial audit in Romania. The statistic population is formed from three groups namely the financial auditors, financial managers of the audited firms and the users of the audited accounting information. The results of the questionnaire have been analysed by the help of Kruskal Wallis Test, which has shown that for every statement the differences between the three groups are significant. Next the results have been interpreted globally. This way has been demonstrated the hypothesis according to which there are differences between perspectives and expectancies between the financial auditors, financial managers of the audited firms and the users of the audited accounting information in Romania regarding the role and utility of the financial audit. At the end of the study we have proposed solutions as to getting closer the expectancies of the three groups concerning the role and utility of the financial audit.*

**Keywords:** *empiric study; the role of the financial audit; the utility of the financial audit; differences of perspectives; differences of expectations.*

**JEL classification:** M 42

## 1. Generally Introduction

At the international level the role of the audit is of great interest and widely debated, in order to clarify the difficulties which come in understanding the social efficacy of the financial audit, as a lack of understanding the objectives, responsibilities or its limits.

The hypothesis from which starts this research is the fact that there are differences of perspectives and expectations between the financial auditors, financial managers of the audited firms and the users of the audited accounting information. We focused on realities of Romania and Spain concerning the role, utility and the independence of the present financial audit.

To demonstrate this hypothesis we have proposed the following objectives of the research: (1) Investigating the role and utility of the financial audit in Romania as seen by the financial auditors, managers of the audited firms and the users of the audited accounting information; (2) Determining the significance of the differences of

perspectives and expectations between the three groups in Romania. (3)Identifying some closing possibilities of the expectations between the three groups.

## 2.The methodology of research

To demonstrate the hypothesis and to touch the objectives of the research we have made an empiric research, a quantitative one.

Firstly we have realised a serious activity of research, regarding the statistic population which will enter in the study. This way we have established the three groups interested in the work of the financial auditor to whom the questionnaire is addressed - financial auditors, financial managers of the audited firms and the users of the audited accounting information. According to the characteristics of the statistic population we have established the competence of the sample for each of the three groups, so that the results to be interpreted at the global level and to have a national relevance.

*Table 1 The structure of the sample*

	QUESTIONNAIRES		
	SENT	RECEIVED	
		Absolute value	Percent
AUDITORS	600	211	35,17%
MANAGERS	504	133	26,39%
USERS	492	157	32,30%
TOTAL	1596	501	31,28%

Source: own processing

The questionnaire is anonymous and contains closed questions, positively formulated. To make the work easier for the person who fills in the form and to be able to quantify the answers we limited the answers to five, on a value scale from 1 to 5, according to Likert Scale, where 1 represents the maximum level of agreement, 5 represents the maximum level of disagreement, 3 represents the neutral value and 2 and 4 intermediate values of agreement and disagreement. Only one single answer is to be given.

The process of sending and receiving the answers has been by e-mail, during February-December 2012. The answers have been centralised by an informatics Excel programme, specially designed for it and interpreted with the help of econometric models Kruskal Wallis and Mann Whitney, which have shown if the differences for each statement of the questionnaire between the three involved categories are significant or not.

Also, the results of the tests have been incorporated inside some tables, which are the basis of the descriptive analyses of the questionnaire results.

## 3.Previous studies

In the last years at the international level have been realised a lot of studies empiric and comparative concerning the financial audit. First of all we have to remind the fact that the European Commission has initiated a large process of consulting among the EU member countries concerning the role of the financial audit, the independence of the auditors, information given by the audit Report, concentrating

the audit market inside Big Four or the problems connected to the corporative governance.

If we talk about the role and the utility of the financial audit there are researchers which state the fact that only if the financial audit hadn't been imposed to the firms as a legal obligation but as a voluntary one it could have been proved how appreciated its role is by the firms and users. Other studies sustain the necessity of the financial audit and its regulations by the professional organisms, considering the protection of the users on the capital markets (Humphrey and others, 2009).

In what concerns the term "audit expectation gap" there are studies which sustain the necessity of educating the public regarding the limits of the financial audit (Fowzia, 2010) and (Porter, 2009).

In the last years have appeared studies which debate the role of the financial audit during the periods of the economic crises. This way are being analysed the characteristics of the audit committees from the firms affected by the crises and of those which haven't been affected (Rahmat and others, 2009), are exposed the challenges and opportunities which crises offers to the financial auditors (Fraser and Pong, 2009), or it is offered a reflection on the actual audit practices, specially referring to auditing new forms of investments and complex financial instruments (Sikka and others, 2009). Also, based on the found information from the managers of some financial institutions, it is analysed the present financial crises from the perspective of the corporative governance (Haspeslagh, 2010). The most recent is the study on the firm PriceWaterhouse Cooper from 2011 which analyses the perception of the investors from England on the role and utility of the financial audit in the context of the actual economic crises.

In Romania we do not have many empiric studies on themes of financial audit. Still lately have appeared some specialty magazines, but generally they are reduced. Some examples might be: "The statistic explore of the audit market having as a purpose the appreciation of the auditor" (Jaba, Robu, 2011) and refers to the connection and direct effect which has on the independence of the auditor the financial performance of the audit firm; "The external auditors and the corporative governance under the impact of the financial crises" (Dobroțeanu and others, 2011) which treat the role of the external audit and of the corporative governance in credibility of the financial report of the firms; "The dynamic of the perceptions regarding the external audit under the impact of the financial crises" (Dobroțeanu and others, 2011) an empiric study about the degradation of the perceptions of a group of students on the problems "audit expectation gap" before starting the financial crises and after its starting; "The importance of the information offered by the financial audit for managers, investors and financial analysts" (Cernea, Ștefănescu, 2012) – an empiric study which refers to determining the degree of appreciation of the information delivered by the audit report by the users.

Years ago this type of study were specific to Anglo-Saxon countries, but today they have extended to all European countries, as they allow touching a better convergence between them. My research has a quite big extending and a very welcomed one in Romania as „at the actual moment, the specialty literature does not know a lot of studies dedicated to this problem and especially to investigating the differences of perceptions regarding the external audit in the specific circumstances of the Romanian environment”.

#### 4.The econometric analyses of the obtained results

Kruskal Wallis Test is a nonparametric test used only when there are more than two independent groups. To analyse the data these have been transformed into ranks. The test has been used to evaluate if the differences at the ranks level are significant or not. The calculations have been made for each statement of the questionnaire. The hypotheses associated to the Kruskal Wallis test are:

$H_1$  - There is NO statistic significant difference between the medians of the analysed groups;

$H_2$  – The Medians of the investigated groups differ significantly.

The hypotheses are accepted or rejected according to the value of the K coefficient associated to the test.

The Formula for Kruskal Wallis Test is the following:

$$K = \frac{12}{N(N+1)} \sum_{j=1}^J N_j \bar{R}_j^2 - 3(N+1) = \frac{12}{N(N+1)} \sum_{j=1}^J \frac{R_j^2}{N_j} - 3(N+1) \quad (1)$$

The first formula is equivalent to the following (2) and is being used when all the ranks  $R_{jk}$  are different and have values between 1 and N.

$$K = (N-1) \frac{\sum_{j=0}^J N_j (\bar{R}_j - \bar{R})^2}{\sum_{i=0}^J \sum_{k=0}^{N_j} (R_{jk} - \bar{R})^2} \quad (2)$$

where,

$j$  = the number of groups

$N_j$  = the number of observations inside each group N =total number of observations

$R_{jk}$  = the number of observation K inside the group j

$\bar{R}_{jk}$  = the average of the ranks of the j group observations

$\bar{R}$  = the average of all ranks and observations

K = the calculated value by Kruskal Wallis Test

The correction of K, given by the formula:

$$1 - \frac{\sum_{j=1}^g (t_j^3 - t_j)}{N^3 - N} \quad \text{where,}$$

g is the number of repeating groups

$t_j$  is the number of repeating in the group j

The theoretical interpretation of Kruskal Wallis Test is based on the table values of the Test  $\chi^2$ , for  $c = j-1$  degrees of liberty and a probability of guarantee of the results of  $\alpha$ . As bigger the sums of the group as higher the value of the test is and has more chances to a significant variation. As the differences of the between the ranks of the groups are smaller, going towards 0, the variation is insignificant.

The critical score for:

$\alpha = 0, 01$  level of trust and  $c = j-1 = 3-1 = 2$  degrees of freedom is 9,210, and for

$\alpha = 0, 05$  level of trust and  $c = j-1 = 3-1 = 2$  degrees of freedom is 5,991.

The result K obtained for every statement of the questionnaire was compared to its value  $\chi^2$  from the Table. When:

$K \leq \chi^2$  we accepted the hypothesis as being null, the differences between groups being insignificant;

$K > \chi^2$  we accepted the hypothesis alternative, the differences between groups being significant.

One of the objectives of this research was determining the significance between the differences of perspectives and expectations which exist between the three groups in Romania. This way, according to the results obtained as applying the Kruskal Wallis Test from the total of 34 questions of the questionnaire referring to the role and utility of the financial audit, for 20 of them the differences between perspectives and expectances have resulted as being significant, for a level of significance of 1% or 5%.

*Table 2 Significant differences according to the results of Kruskal Wallis Test*

### **5.An interpretation of the results, perspectives and expectances on the role of the financial audit in Romania**

Next we will try to relate the statements inside the questionnaire and to underline a series of particularities noticed as a result of the global analyses of the answers. We want for this research to go further from the own meaning of the obtained values as an answer to the established statements inside the questionnaire and to underline new ideas and perspectives on the profession of auditor in Romania.

If we talk about the perspectives that the financial managers and the users of the audited accounting information have on the legal responsibilities of the auditors, we can say that part of them have demonstrated that they do not know the present legal norms.

For example, 15% of the financial managers and 10% of the users of the audited accounting information do not know the fact that doing the audited financial situations is not the responsibility of the financial auditor. ISA 700 which is applied in Romania, in art. 26 specify that this has to be stated in every Audit Report, in the section named "The responsibility of the management for the financial situations" in which the auditor "must include an explanation of the fact that the management is responsible for making the financial situations".

The legal regulations connected to the responsibility of the auditor towards revising entirely of the accounting for the audited firm are not known by 23% of the financial managers and the users of the audited accounting information from Romania.

According to ISA 200 the sufficiency of the evidence „is a measure regarding the quantity of audit evidence. The necessary quantity of audit evidence is affected by the evaluation of the auditor regarding the risk of significance devaluation and also by the quality of some audit evidence". According to ISA 530 this way of work "treats

using by the auditor of statistic and non statistic sampling" which will "give the auditor a reasonable basis to formulate conclusions regarding the whole population".

Another example of not knowing the legal regulations in Romania is the fact that 15% of the users do not know that the auditor has the responsibility of checking if the financial situations express the clear image of the financial economic situation, in agreement to the generally accepted accounting principles.

Regarding the responsibility of the auditor of detecting fraud and irregularities in the audited firm it is noticed a taught not-knowing of the legal regulations, by 48% of the financial managers and 63% of the users. The responsibility of the auditor in front of the fraud is a very controversial theme in the history of the audit.

Not a single control system can eliminate the fraud risk that is why we have to take into consideration that it is impossible to guarantee 100%. From here the low level of trust" In the new international context the statutory auditor's mission is more complicated every day, but it must not be forgotten the fact that the audit is not a panacea... it is not a guarantee against fraud, but a modest "assurance source" (Domnişoru, Briciu, 2012).

We must remember the fact that the responsibility for preventing and detecting the errors and fraud belongs to the management of the firm, with the help of the internal control, and "the fact that annually they call for audit, can be considered a means of detecting, preventing or discouraging it" (Domnişoru, 2011).

Next we will talk about the expectancies that the three groups have on the work of the financial auditor. Not knowing the legal representations determines from the financial auditors and from the users of accounting information non-realistic expectancies which in the specialty literature are called "unreasonable expectation gap". We can say that one of the main functions of the auditors, if not the most important, is the public interest one or the social one. Therefore "the auditor serves the society" (Fermin de Valle, 2007), improving the market efficacy and of the society in general.

As a result of the analyses made with the help of Kruskal Wallis Test of the statements referring to extending the responsibilities of the auditor, have resulted significant differences between the three groups participant in the study. Generally the financial auditors refuse new responsibilities, while the other two groups express the expectancies referring to the information that they would like to find inside the Audit Report. 38% of the auditors do not want to pronounce on the efficacy of the market way of the audited firm, 34% do not want to pronounce on the future evolution of the firm, 23% on the profitability of the firm and 31% on the solvency.

The group of users is the one that asks in a higher percent the extending of the auditors' tasks. 49% want the extending of the auditors' tasks so that to pronounce on the efficacy of the market of the firm, 35% on the future evolution of the firm, 38% on the profitability and 38% on the solvency of the firm.

Concerning the future evolution of the firm ISA 570 in art 7 states that "the auditor cannot foresee this kind of events or future conditions". The auditor can "based on the obtained audit evidence" draw conclusions "if there is a significant incertitude towards events or future conditions that might leave place for doubt regarding the entity ability to continue its activity", but his objective inside the mission is "to get enough and adequate evidence regarding the degree of applying the presumption of continuing the activity by the management" in preparing and presenting the financial situations.

Moreover ISA 570 in art 5 states that "any ratio regarding the future is based on available information at the moment of doing this ratio". The following events "might have results that are not according to the ratios that have been reasonable at a certain moment when they have been expressed". To conclude, 35% of the users of the audited accounting situations and 31% of the managers of the audited firms in Romania declare that there is a feeling of in satisfaction regarding concerning the role and objectives of the audit. 43% of the financial users are aware that there is that feeling, therefore 64% of the auditors think that the users wait "too much" from them.

## **6.Perspectives and expectations on the utility of the financial audit in Romania**

The content of the audit was slowly brought to the light and has confirmed the fact that it represents a social necessity. The audit reports are destined to guarantee the transparency of the accounting situations in front of their users, who use them in taking decisions and condition the efficacy of the decisions adopted by different agents from the business environment and therefore the correct working of the market.

One of the statements of the questionnaire refers to the stakeholders of the audited accounting information, to those who ask for the financial situations of the audited firms, namely: shareholders, clients, financial entities, assurance companies, suppliers, Public Administration, financial analysts and employees.

Though from Kruskal Wallis Test there are differences between the three groups participant in the study, it has not been noticed a strong polarisation of the answers. The centralisation of the answers has demonstrated that the categories of users recognised in Romania are: shareholders, financial entities and financial analysts, and the categories less recognised as users of the audited accounting information are the suppliers and the employees.

The next statements group refers to the perspectives of the three categories interested in the auditor's work on some themes connected with the importance and utility of the financial audit. As a result of the analyses made by the help of Kruskal Wallis Test has resulted a certain polarisation of the answers:

Regarding the statement that the financial situations show the clear image of the firm we notice that 90% of the financial managers express their agreement with this statement while 55% between the auditors and 56% of the users express a moderate agreement.

A strong controversial topic is being produced for the statement that the financial audit brings "an added value" to the audited firm. 83% of the auditors agree to it while the financial auditors do not. From here starts the disagreement for the following statement in which 77% from the auditors think that the cost of the financial audit is justified while only 29% of the financial managers of the firms agree to this statement. When we refer to the statement that "the cost of the financial audit is justified in Romania, we take into consideration the fact that the E.O. 90/2008 in art. 27 will state that the fees must be "adequate for the activity that is to be done". The National Ethic Code of the Professional Counters in Romania inside paragraph 200.8 talks about the threatening of "intimidation". One of the examples from this perspective is the case of a firm "on which there is a lot of pressure to reduce the quantity of work only to reduce in fact the fees". Also, the level of the fee might represent a threat at

the professional competence and prudence. The National Ethic Code of the Professional Accountants in Romania in paragraph 240.1 states the situation in which "a lower fee" can lead to the impossibility of realising a mission "according to the technical and professional applicable standards".

A consequence of these differences of perspectives is also the answers which refer to the fact that the financial audit is realised only in the case in which it represents a legal obligation. About 50% of all three categories agree to this statement.

The following questions get general opinions of the three groups referring to the utility of the financial audit:

Referring to the statement that "the financial audit offers a good protection against fraud" as a result of applying the Kruskal Wallis Test have resulted insignificant differences between the three groups, which have expressed a moderate agreement, with an average value of the answers between 2,56 and 2,64. We can say that the auditor's function against fraud has not been constant, but it has suffered modifications in time and space. Today the role of the auditor is not to detect fraud, even if the nature of his job is to discover it.

What is really important for our case is the fact that one of the most important functions of the internal control is that of "bringing security towards the fact that fraud and irregularities can be discovered in due time, assuring in this way the integrity of the accounting registers".

The auditor when plans the evidence which will do inside the mission considers the following things: what types of mistakes makes, what types of fraud or irregularities can be produced, determining the procedures of internal control that can be prevented or detected, if these procedures are functional inside the firm and evaluating the fact if the procedures of internal control cover all kinds of fraud and irregularities that can be produced. Therefore it can be drawn the conclusion that the financial audit even if it does not look directly fraud and irregularities, offers a good protection against them.

For the statement according to which realising a financial audit mission in general takes longer the perspectives of the auditors, of the financial auditors, of the financial managers and of the users of the information for a significance threshold of 1%. The financial managers see the audit mission in terms of costs. For them it represents the number of hours multiplied to the hour, while for financial auditors the audit mission represents responsibility, a limited period of time in which to organise the work efficiently so that to be able to give a reasonable assurance that the financial situations show a clear image of the firm.

The possibility of raising the legal audit limits for firms would lead to dropping the audit market. In Romania the incomes of the physical persons are quite small, what makes for the small and middle size not to reach so easily the compulsory audit limits. We must not forget that in Romania the audit compulsory limits are higher than in other European countries, so there are audited a lower number of firms.

As a conclusion I think that it is necessary a closing of the positions of the financial auditors with that of the users of the audited accounting information. What is to be seen anyway is the fact that in Romania the positions are not as strong, there is not a strong polarisation of the answers (the average value does not closet o 1 nor by 5, but the majority are between 2 and 4). This thing shows the fact that there are problems and in satisfactions regarding the role and utility of the financial audit, there

is a feeling of in satisfaction from the users, but they are aware of his existence by the financial auditors.

The actual differences of perspectives determine future expectations on the auditors 'work. As global analyses of the answers from the questionnaire we have divided expectations of the users of audited accounting information in two categories: realistic and non-realistic.

## **7.Conclusions**

The study of the financial audit and of the perspectives and expectations which there are about this supposes realising a connection between what the financial audit does and what the users think they should do. The controversial discussions on this theme have lasted for more than 30 years under the name of "audit expectation gap". Realising an empiric study of this kind in Romania represents something new, a step forward in the process of improving the quality of financial information.

The realised research has allowed demonstrating the hypothesis according to which there are differences between expectations and perspectives from the financial auditors, managers of audited firms and the users of audited accounting information regarding the role and the utility of the financial audit.

By the help of Kruskal Wallis Test it has been demonstrated that in 59% of the questionnaire statements referring the role and utility of the financial audit there are significant differences between perspectives and expectances between the three groups in Romania.

The Regulation proposed contains measures to improve the independence of auditors, to avoid conflict of interest, reinforce professional skepticism against fraud and error and proposes measures to extend the information provided by external users through the audit report. Countries members of the EU will be able to add to a national level those measures it deems necessary in accordance with the national specifics or realities of each country.

The financial audit has progressed and perfection itself at the same time to the economic development, as an answer to the society challenges, It has progressed from the historical point of view, being present in a certain form in all the periods, from the concept point of view and mostly from the objectives point of view. Therefore I believe that the auditors and the audit firms shouldn't pass over the social importance that is given today to the financial audit, the position obtained today in the society after hundreds of years of efforts and to enlarge the area of responsibilities, look for new methods or procedures compatible to the actual needs, which would come in the users support.

**Abstract:** *This paper presents Integrated informatics systems for public management and the implementation of the institutional architecture in public administration. Being implemented in Baia Mare City Hall, institutional architecture reunites the quality and environment management systems and the integrated informatics system into a uniquely assembled concept able to sustain the administration's activity in real time. For the strategic planning at the town level to be relevant, effective and efficient, the public administration authorities must take into account the importance of conducting certain analyses and of some strategic documents at neighbourhood level. The Urban Development Integrated Plan of the city of Baia Mare, is aimed at the public intervention on a well-defined area needing regeneration because of social, economic, territorial, functional and environmental discrepancies, as compared to other urban areas of the municipality. The perspective of the Urban Observer has as its basis on the permanent monitoring of urban indicators as well as the implication of all interested parties, including the citizens in view of defining the strategic directions of town development.*

**Keywords:** *informatics system, sustainable development, strategies, the institutional architecture, models*

**JEL classification:** *J11, R11, R23*

## 1. Introduction

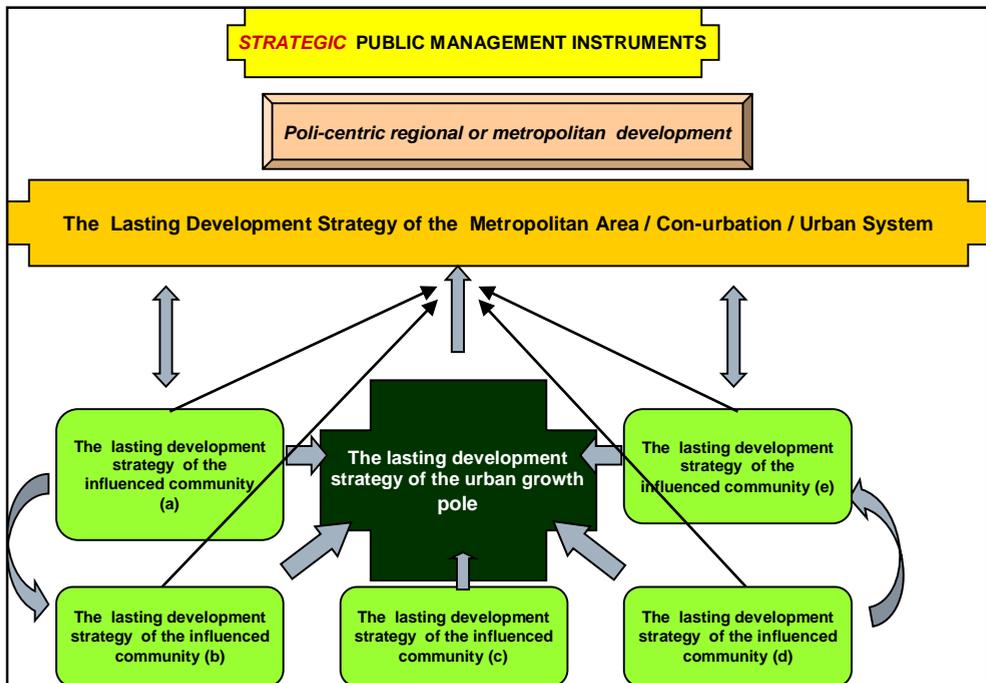

Integrated informational system is a dynamic tool that achieves a constant contact with the realities of the social environment it serves. As the operational tool of the public management, integrated informational system enables real-time monitoring of all activities and facilitates the development of an innovative management based on real time information allowing the processes and decision-making to be fully automated (Malhotra, 2005). Implementation of integrated informational systems in public administration is imposed by the lack of an objective analysis tool, quick and interdisciplinary support decisions that can substantiate strategies at regional level (Applen, 2002).

The concept of the Urban Observer has an extremely ample area of active structures at all territorial levels (national, regional, county level, town level, neighborhood level) in the field of urban development. Being experimented in the field of integrated and participative strategic planning in Romania, the Baia Mare municipality has created a model of Urban Observer in the local context specific to Romanian cities. In this context Baia Mare city has promoted a participative planning process, innovative for cities in Romania in which there has been conducted the analysis of needs and the

potential of the municipality neighborhoods. Another element of novelty which permits the rapid visualization of the main problems identified in each neighborhood is the utilization of thematic maps which accompany the quantitative description of data, such as (Anghel, 2006; Anghel, 2013):

- the map of population density in the neighborhoods
- the map of social risk in the neighborhoods
- the map estimating the unemployment rate in the neighborhoods
- the map of real estate value in the neighborhoods
- the map regarding levels of in the neighborhoods.

The development strategy of a local community represents the determining of long-term goals and objectives of collectivities, adopting local policies and allotting resources to complete those, taking into account the citizens' needs, expectancies and wishes and the components of the local political system (Rosenbloom, 2004). From the point of view of strategic management the instruments proposed within this paper envisage a three-dimensional approach of processes: the urban dimension, the zone of influence or the supra-urban dimension and the sub-urban dimension.

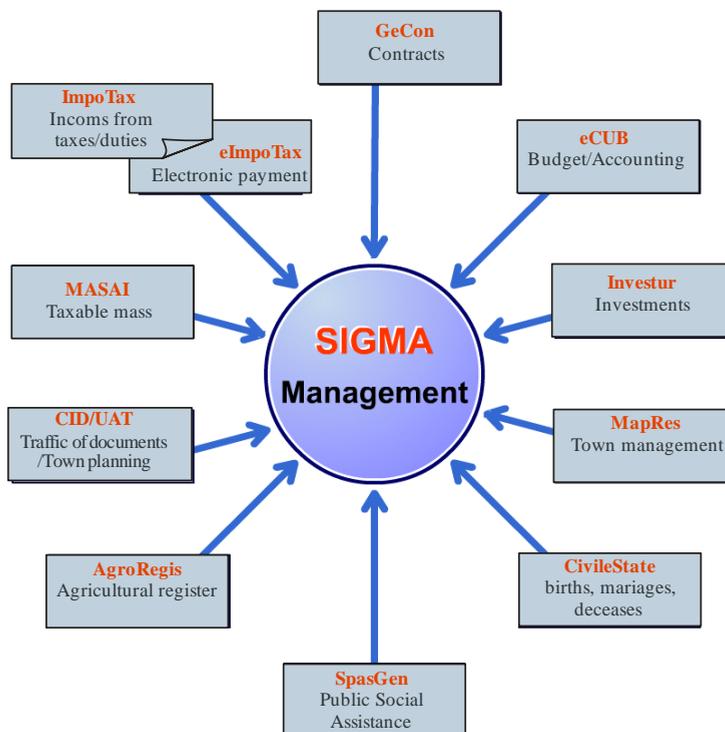

**Figure 1:** Analysis of supra-urban development in relation to a growth pole  
 Source: Anghel, 2013

## 2. Integrated informatics systems for public management, implementation of the institutional architecture in public administration

The system includes the assembly of data and information from local and central public administration documents, information circuits, fluxes and procedures as well as means of dealing with information (Radulescu, 2010; Alavi & Leidner, 2001).

Seen from the managerial point of view, the information system can be considered one of the main components of the real time governance of administrative institutions. It has the role to implement the concept of e-governance, according to the e-Administration National Action Plan (Aitken, 2003; Benston *et al.*, 2004).

GIS Urban – SIGMA, applied in Baia Mare City Hall is an integrated informatics system resulted from implementing a solution to interconnect specialized independent informatics components with the purpose of standardizing and jointly using the information found in different modules, and also for compiling the data obtained from various sources in order to obtain inter - department reports or statistics (Mullins, 2001; Matei, 2009).

**Figure 2:** Management of SIGMA processes

Source: Anghel, 2013

The development of inter – institutional cross-operation has been defined by the “e-Europe Action Plan 2005”, during the Seville Summit. Institutional architecture, the basic component of cross-operation, reunites all organizational architecture models according to institutional categories and activity areas.

- Building a “workshop”, permanently open to all interested parties in the field of developing urban, sector and territorial indicators.
- Building a monitoring system for urban development strategies and policies
- Setting the basis for making relevant statistic comparisons between urban indicators at county, regional, national, European and world level.

Through an efficient management of the Urban Observatory, a *Plan of Measures* can be developed at neighborhood level. This plan represents the development and life quality increase vision for this neighborhood.

Due to the fact that a plan of measures for a well defined space has to be acknowledged and implemented by all stakeholders (citizens, associations of owners, businesses, NGOs, public administration), the way of acknowledging and institutionalizing this Plan of Measures can be through a *Neighborhood Contract*.

This *Neighborhood Contract* is based on:

- Justifying and analyzing problems, developed in the Urban Observatory;
- Identifying adequate solutions for the Community through the CIVIC instrument;
- Planning action implementation, granting resources and establishing a corporate type responsibility;
- Acknowledging the granted responsibilities by all stakeholders.

The implementation of this Contract in Baia Mare City began in 2003, with the CIVIC project (Creativity, Initiative, Volunteering, Involvement, Consultation), and the year 2010 brought into discussion the implementation of Neighborhood Contracts.

Partnership technique has been used for the nominations. Thus, we have chosen a less sophisticated procedure and we have created the possibility for the educated in the field to promote those names, people and/or groups who have contributed to the sustainable development of the community through their activity.

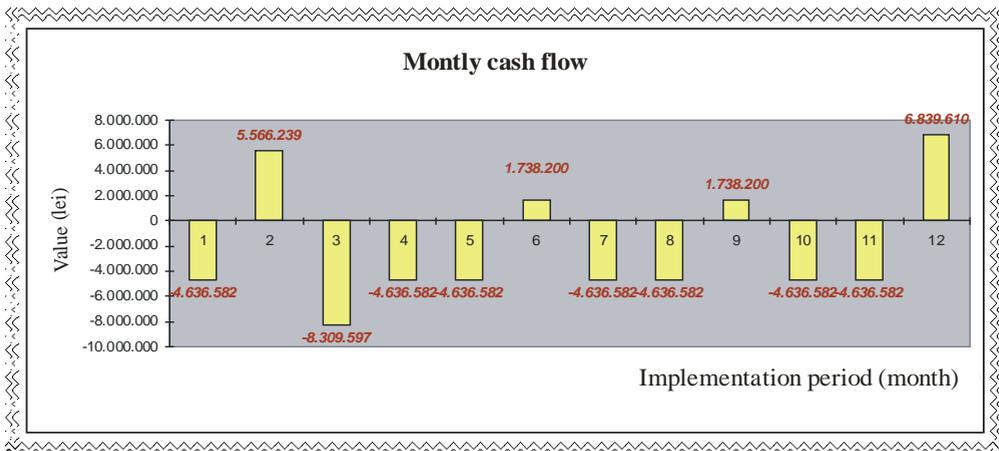

CiViC events that followed from 2003 to 2010, aimed at fields such as: School system, Architecture, Cults, Education, Art, completed by a meeting between CiViC and members of Parliament. In the years that followed up to now, the number of fields aimed for integration in the CiViC concept has grown, adding the following to the ones already mentioned: Sports, Mass-media, Businesses, NGO, Health, Economic, Urbanism, Strategy, Tourism, Youth.

Using key factors such as “performance recognition” and “continuous competition between values”, the CiViC concept has contributed to the development of communication between Local Public Administration and the Community, has promoted intellectual and industrial values, has integrated as much as possible the idea of transparency, has created strong structures in the sustainable development process.

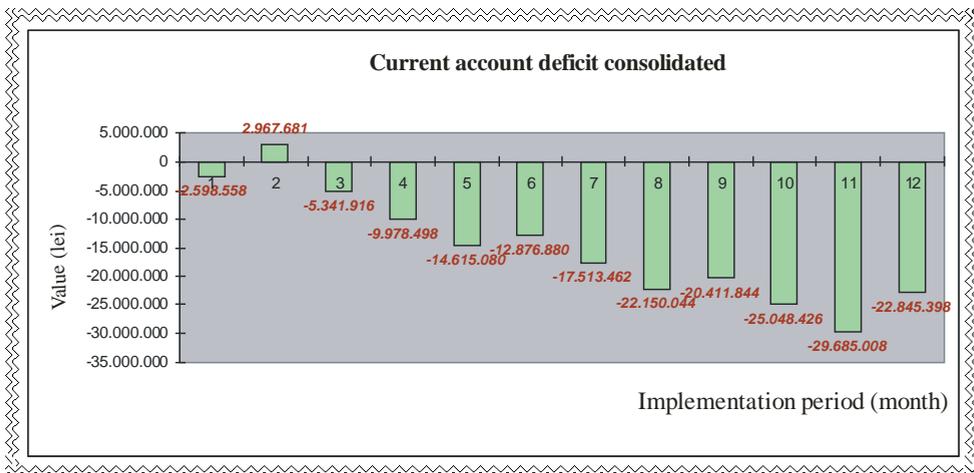

*The multi annual investment program* creates the premises of using resources in obtaining priority objectives by establishing the link between development strategy and annual budgets, as well as between financial programming and the execution of investment objectives.

Developed and implemented in Baia Mare city, the program ensures the link between local budgets and its expected allocations, action plan and city development strategy, offering predictability in development and socio-economic stability.

The graphical distribution of these total costs, analysed monthly during a year of implementation is presented below:

**Figure 4:** Monthly cash flow for year II of implementation  
Source: Anghel, 2013

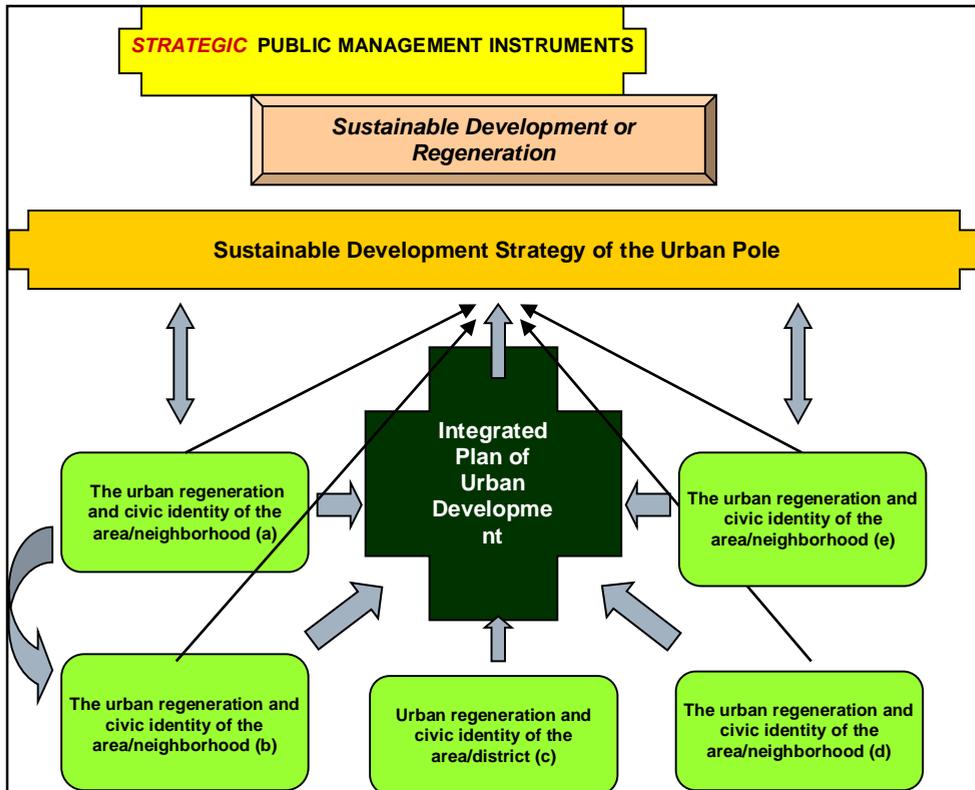

**Figure 5:** Current account deficit consolidated for year II of implementation  
Source: Anghel, 2013

Using these instruments of planning major investment, the predicted effort of public funds management can be controlled and optimally ensured.

#### 4. Integrated Plans of Urban Regeneration

To this purpose the *Integrated Plans of Urban Regeneration* were defined as a modern strategic management instrument, meant to ensure the diminishment of discrepancies regarding life quality and of the urban environment within the reference territorial units. The case study for this type of instrument consists of the Integrated Plan of Urban Regeneration “Phoenix”, a plan which envisages the largest “dormitory-type” neighborhood of Baia Mare, which, at the moment signals problems in the infrastructure field and public services, problems of cohesion and

social inclusion and the lack of an economic development specific to the intervention area. The disadvantages of such an approach are the concentration of public interventions in a well-defined urban area to the detriment of other urban areas that require interventions in an extended conceptual analysis (Choo & Bontis, 2002; O'Sullivan, 2007; Scott, 2002); a representation of the application or urban regeneration at the level of the entire community is represented as follows:

**Figure 6:** The analysis of the sub-urban development in relation to the entire local community  
 Source: Anghel, 2013

Within the urban ensemble of Baia Mare, the Vasile Alecsandri area and the area of the Old Town Centre are distinctly identified as integrated urban areas with mono-directed functions, positioned as an interface between the multi-functional urban space and the future residential areas of the mono-family type.

In this context, the functional approach of a Master Plan of urban regeneration for this area offers a series of competitive advantages on a long and medium-term, the most important being the following (Anghel, 2013):

- The integrated approach of some functional urban areas, in relation to the neighborhood creates the premises of a balanced, long-term sustainable development;

- The identification and the allotment of a social, cultural and administrative identity to an urban zone lead in perspective to social stability and an increase in the predictable competitiveness of any zone;
- The decentralization of administrative, economic and social functions at an urban level is the tendency of the third millennium, at all levels this optimal endeavor being correlated with the increase in the cooperation capacities and the social dialogue in a globalization world;
- The credibility of some long-term strategic projections not only renders more efficient the resources allotted for their completion, but also creates a favorable environment for an increase in the level of life quality due to the elimination of some development risks;
- The capacity to integrate distinct measures and actions having the same direct beneficiaries leads to the sustainability of long-term planning of certain objectives, the results and impact on a short- and medium term being synergic and comprehensive for these beneficiaries;

The instruments used were mainly those promoted by the public administration, these having the role to offer consistency to private and public policies. The decisive role of public management in the near future is to build the “frame” for the social and economic development of a well-defined space.

This space must address not only the local identity values (cultural, economic, social of natural and built frame), but also the major challenges linked to the phenomena of globalization or the degradation of the environment.

## 5. Conclusion

The adaptation of the Urban Observer in the processes of strategic planning starts from the analysis of disparities and specific needs existent at the neighborhood level in view to ensure a balanced development of the territory as well as a pertinent answer to the citizens' demands, most of the times complex and well-founded and which can be integrally included within the development plans of cities.

Considering the need for an integrated approach of the project portfolio for the Baia Mare Integrated Urban Development Plan, both from the perspective of integrated project and the functional relations between them, it is imperative that the assembled interventions prove synergy in their impact and results.

Thus, the implementation of the Baia Mare City Integrated Urban Development Plan, simultaneously implementing 8 large infrastructure projects, has been financially analysed taking into account the granting of pre-funding, reimbursement charts, work execution charts and the due costs for a planned implementation for a period of 4 years.

The Integrated Urban Regeneration Plan applied in Baia Mare city for a “contiguous” area is *structured* on objectives, development axis, major intervention fields, measures and distinct actions *responding in an integrated manner* to the social, economic, habitat or environment problems of the identified area.

The implementation of the Integrated Plan is a *long-term aim, integrated territory* approach converging with the sector approaches and directly contributing to the implementation of Baia Mare City Sustainable Development Strategy.

The role of “community facilitator” of the city, between the development potential of a metropolitan type and the suburban areas showing deficiencies in life quality, has successfully been demonstrated within the Baia Mare municipality. Both the Urban

System Baia Mare and the urban zone Vasile Alecsandri were conducted by the values and principles developed through the 21 Local Agenda. The distinct approach of these values led to the creation of a self-identity, both on urban and metropolitan levels, which should allow the realization of a common vision for implementing durability.

Through developing a set of integrated measures, applied at the level of a well-defined urban zone, a public intervention can be developed to answer all the long-term necessities of that community.

# EUROPEAN UNION ENLARGEMENT AS A CULTURAL SHOCK. THE ROLE OF INTERCULTURAL TEAMS' MANAGEMENT IN INCREASING EUROPEAN COHESION

**Bibu Nicolae, Lisetchi Mihai**

Management Department, Faculty of Economics and Business Administration,

**Abstract:** *The European Union is challenged nowadays by a dramatic multilevel process of integration. The Europe 2020 strategy promoting smart, sustainable and inclusive growth is defined by a set of ambitious objectives to be reached by 2020. On the other hand, the turbulent times of the economic crisis put even more pressure on the integration process. The success of this complex endeavor is heavily depending on the dimension of the cohesion specific to each of levels of the process. The cohesion of the European Union (EU) is stronger at macro (societal) level with regard to institutional, political, and economical dimensions. The cohesion of the European Union is less strong at micro level, the level of people, of the common individual, of the citizen. In other words, EU system has less cohesion at the level of individual and social fabric. An interesting hypothesis about EU enlargement is that every new "wave" of countries is a collective cultural shock for the European citizens. In conclusion, considering the history of the European Union, their citizens were subject to a constant flow of "cultural shocks", following each new EU enlargement though admission of new member states: the big lot of 10 new countries in 2004, Romania and Bulgaria in 2007. In this respect, immigrations waves from new member countries have preceded their country accession, and to various extents, have made a first impact on the host countries culture. This paper is discussing the issue of increasing European cohesion based on a management approach. It describes the positioning of Romania on the European map of cultures, in order to identify the convergence and divergence of its societal culture with various European cultural clusters. We are arguing that: a) European organizations have a major role to play in the process of increasing cohesion within the European Union (EU); b) Organizational Management and leadership are paramount to their success and to society welfare; c) Intercultural Knowledge Management is needed for achieving the high performance of the European organizations; d) Intercultural teams are one of the most effective ways to reduce the current cohesion-less of EU, both at individual and organizational level.*

## **1. European Union enlargement as a cultural shock**

The European Union is challenged nowadays by a dramatic multilevel process of integration. The Europe 2020 strategy promoting smart, sustainable and inclusive growth is defined by a set of ambitious objectives to be reached by 2020. On the other hand, the turbulent times of the economic crisis put even more pressure on the integration process. The success of this complex endeavor is heavily depending on the dimension of the cohesion specific to each of levels of the process.

Cohesion is the feature of a whole system which has all the component subsystems closely united (Larousse, 2011). It is mostly considered a result of an action, process. It is, also, an important characteristic of the structure of the system. Cohesion is defined, also, as "The act or process of holding together firmly as parts of the same mass, of adhering one to each other, and of becoming united in ideas or interests" (Longman Dictionary, 1995). Cohesion is multiple foundations-based, such as categories of links between component subsystems of society/organization: technological, social, managerial, economical, legal, political, cultural. The opposite of cohesion is cohesion-less, in which the links between subsystems are quite weak. However, the links should be strong enough to allow the system to exist and function as a whole. More cohesion means a stronger link between components of the system that is more bonding and increased stickiness.

The cohesion of the European Union (EU) is stronger at macro (societal) level with regard to institutional, political, and economical dimensions. The cohesion of the European Union is less strong at micro level, the level of people, of the common individual, of the citizen. In other words, EU system has less cohesion at the level of individual and social fabric. In this respect, there are many barriers to cohesion due to divergence on interests, to cultural differences, and to historical factors. Based on the nature of factors considered, there are several types of cohesion. The one that will be discussed here will be the cultural factor, which has been longtime considered to be a secondary factor by the politicians and administrators of the European Union.

There are strong arguments why the process of building the European Union, in the historical context of the 1950's in Europe and in the world, was very pragmatic, starting at macro-economic level. Hard systems such these are easier to build and reap positive outcomes as compared to soft systems, such as socio-cultural system. An interesting hypothesis about EU enlargement is that every new "wave" of countries is a collective cultural shock for the European citizens. Fink and Holden (2002) pointed out a similar process when Central and Eastern European countries experienced a collective cultural shock after the collapse of the communism in their respective countries. It took EU member states several years to understand such phenomenon and adopt the strategy of integration into EU in order to avoid the marginalization of these former communist countries.

In conclusion, considering the history of the European Union, their citizens were subject to a constant flow of "cultural shocks", following each new EU enlargement though admission of new member states: the big lot of 10 new countries in 2004, Romania and Bulgaria in 2007. In this respect, immigrations waves from new member countries have preceded their country accession, and to various extents, have made a first impact on the host countries culture.

On the other hand, we point out that economic cooperation, local government cooperation, nongovernmental organizations cooperation also have had a

significant impact on increasing cultural awareness of people from various European cultures. Whatever would be the type of institution they are acting in, individuals doing together very different activities, aiming at various outcomes, in various forms, represent a very important way of improving European cohesiveness at social and cultural level.

The GLOBE studies findings point out that there is not a single common European culture for Europe as a whole (House et al., 2004). Also, Hofstede (2001) reached the same conclusion. The first differentiation considers two big regions in Europe: the first one is North Western Europe from Great Britain to Austria, and the second one is South Eastern Europe from Spain to Georgia, through Central Europe (Koopman et al., 1999). The next level of differentiation indicates the existence of several European cultural clusters, grouping countries based on cultural proximity, such as: Anglo, Eastern Europe, German Europe, Latin Europe, Nordic Europe cluster. Diversity exists in Europe, and it will exist for some time in the future, as the societal values level indicates.

As demonstrated by Hofstede (2001), and GLOBE studies (House et al., 2004) there is a convergence between European clusters at values level (Annex 1). The Romanian GLOBE score (Bibu et al., 2007) for values is the result of the Romania GLOBE research executed by a large group of Academics under the coordination of GLOBE representatives in 2006. The European clusters common features are: reduced power distance actually very low, increased in group collectivism to a very high level, increased humane orientation to a high level, increased performance orientation to a very high level, (exception is Romania), increased Future orientation to a high level, increased gender egalitarianism to a medium to high level, increased Institutional collectivism, with exception of Nordic Europe. For the other two dimensions: Assertiveness level is decreasing remaining still in the medium range, exception is Eastern Europe and Romania, where it is highly increasing; Uncertainty Avoidance where Eastern Europe and to a slighter level, Latin Europe, desire more of it, while the rest of Europe want less of it.

## **2. Looking for solutions**

The preferred solution by European Union Commission is summed up in the axiom “Unity in diversity”. We consider that unity in diversity could become a major source and factor of progress, once and if it is acknowledged by more and more Europeans as desirable and positive.

Europe’s most spectacular achievements are tangible: the internal market, the Euro, the agricultural policy. These are means to achieve a more cohesive and integrated European Union, at the structural level. However, these things touch only the minds of EU citizens, not their hearts. As Jacques Delors, a former President of the European Commission, said: “You can’t fall in love with the single market. We need to bring Europe—its values, its debates and its policies—closer to the citizen.” The leaders of the European Union are realizing that winning the hearts of the European citizens, as much as their minds, is of main importance. They need to address the “soul” of the Europeans. The return to cultural and political values in Europe will avoid confusing means and ends.

The most important way to create European ownership is intercultural dialogue between Europeans. Recognizing Europe’s cultural diversity lies at the foundation of the European Union Commission’s idea of intercultural dialogue. The European

Union's increasing diversity is considered to represent an asset, not a threat or a problem. It is clearly stated that "the fundamental challenge of our process of [European Union] integration is in fact how to preserve distinct cultural identities while developing a multicultural society." (Figel, 2006).

Our main research question is the following: How to act to increase cohesion in Europe, at individual and organizational level?

Our main assumptions are based on a managerial approach, based on the following assumptions:

1. European organizations, including businesses, social economy organizations, public organizations and various hybrid forms, play a major role in the process of increasing European cohesion at group and individual level.

2. Intercultural teams are one of the most effective ways to reduce the current cohesion-less of EU at individual and organizational level. (Bibu, 2007).

2. Organizational Management and Leadership knowledge are paramount to their success and to society's welfare

3. Intercultural Knowledge Management is needed for achieving the high performance of the European organizations.

4. Teams are organized networks supporting the organization's mission, goals and strategy through creating, acquiring and transferring knowledge. There are new kinds of intercultural forms of teams such as intercultural project teams evolving towards becoming "project teams-based organizations". A relevant example is EMES, initially a project on the emergence of social enterprises in Europe, started in 1996 by an international group of scholars, which nowadays is formally established as a non-profit association.

There is also a shift from traditional model of building cross-cultural teams to improved models of building multicultural virtual teams for knowledge creation (like the committees organizing international academic conferences). Multicultural teams are diverse and hence their potential for creativity is higher than culturally homogenous teams. To maximize its use through synergistic effects, team members should be encouraged and supported to create common solutions in a collaborative manner to achieve their task effectively and efficiently.

Intercultural Knowledge management (IKM) is the collaborative knowledge creation, knowledge sharing and organizational learning that happen in an intercultural organizational setting, such as an international organization, international team or among international organizations (Holden, 2002). It involves individuals belonging to various cultures, national cultures mainly, working collectively, face to face or virtual, to achieve a common purpose.

Intercultural Knowledge Management principles in teams are the following:

1. Knowledge originates and resides in people's minds.

2. Teams are well suited to extract knowledge from the minds of members,

3. Maximizing explicit knowledge could be a measure of highly performing teams.

4. The creation, sharing and transfer of intercultural know-how through participative competence is the key to reach high performance in intercultural teams, in addition to all the other factors specific to homogenous teams.

5. Information Technology is well placed to support this process, if well designed and used.

6. Technology enables Intercultural Knowledge Management. When "technology" is associated with new forms of "organization" that fit to each other and both are fine

tuned to “people”, than that organization is in harmony and fit for performing at high level according to the anthropocentric model of organizations, “People-Organization-Technology”.

### **3. Research methodology**

The paper has explored the literature and formulated the main research questions, its assumptions from a managerial perspective, and future research directions in the field of the role of intercultural teams in increasing European identity.

A field research using a mixed research method, quantitative and qualitative, related to intercultural teams in European financed multicultural projects, involving actors from various European countries represents the next step.

### **4. Conclusions**

Our final conclusions are the following:

1. Intercultural teams using modern information technology, including IKM Portals are one of the modern forms of work organization for knowledge creation, sharing and using within an organization, and among different organizations
2. In order to increase their cohesion, and to contribute to the increase of European Union cohesion, European organizations should use extensively intercultural teams, and learn in the process to amplify the potential existing in diversity in order to increase European unity.
3. European organizations should use modern technology and modern forms of knowledge creation, sharing and using co-creatively, such as Knowledge Management Support Systems, mainly Intercultural Knowledge Management Portal (Brandas, 2003).

## APPENDIX 1

### Comparison between Romania and other clusters

Societal Variable	Romania	Eastern Europe	Latin Europe	German Europe	Nordic Europe	Anglo culture	World average
<b>As is (Practices)</b>							
1. Power Distance	5.63	5.25	5.21	4.95	4.54	4.97	5.17
2. Uncertainty Avoidance	3.66	3.57	4.18	5.12	5.19	4.42	4.16

**Abstract** *Various phenomena generated by the new context of globalization have focused our research interest towards studying in what ways management of Intercultural Work teams (IWT) could and should contribute to the increase of their performance at work. Despite the recognition of the fact that many MNCs fail in the management of IWTs, there is still a significant knowledge gap about their non-functionalities. Managerial literature „blames” national and organizational culture differences for the failure of this process. This is because each member brings his own style of work, with his own way of ensuring effective cooperation, making difficult to identify a clear recipe of a team organization and management in intercultural context. Teamwork, managing work teams made the subject of numerous researchers from many fields, denoting so difficult exercise in practice. However, we have identified high performance IWTs whose members are from different countries. Therefore, we assume that their management identified and used methods and instruments able to ensuring IWT performance. If we look at international research, intercultural teams management models have a reductionist and not holistic approach, namely stochastic in terms of selection of specific cultural dimensions cultural models specific to the interest of the researcher. In contrast, in Romania, intercultural management and intercultural management teams performance is less studied. The research presented below is set up to be a part of a pilot study, an exploratory research of how intercultural management assigned dimensions are directly related to the concept of EIA performance dimensions assigned. Our assumption for the empirical research is the following: work team performance (effective, efficient, with a high degree of satisfaction of its members) is the result of application performance management in the context of a particular style of interaction specific team. Because the dependent variables were nominal variables, and due to small size of the sample (10 managers and 33 employees), we applied „non-parametrical tests considered the only relevant tests” (Popa, 2008:214). The research is "degree of association", the independent and dependent variables of the same type. One more reason to choose this model of research is that we cannot claim a causal relationship, but the combination of variables that represent characteristics of a high performance team and not performance indicators. We will not venture to make judgments of causality based on done statistical tests.*

## 1.Literature review

We are defining intercultural team work (EIA) as a group of three or more individuals who belong to different national cultures, at least two, "with complementary skills, developing a distinct identity, working together in a coordinated and are committed to achieving a common goal whose achievement is considered equally responsible ". (Bibu, 2002)

We hereby mention the models which come to support [the team development process \(Yeh et al., 2006\)](#), *the implementation models* of the highly effective teams (Catska et al., 2001), testing studies for predictability models of the *effectiveness of the team homogenous from cultural point of view (Ross et al., 2008)*, models related to the performance of virtual teams (Courtney et al., 2007). Some authors debate the integral team (Cacioppe & Stace, 2009) and its effectiveness, reviews of decision models (Shetah, 2009) in order to increase the performance of teams, the intercultural competence (Ascalon et al., 2008).

All such researches have tried to explain which could be the causes for the failure of work teams, homogenous or not, from a cultural viewpoint, without offering however, clear theoretical and practical solutions.

An effective team is a team that achieves its tasks and reaches planned and assumed team goals "as is" and at the right moment, meaning as they were planned and in due time.

An effective team has 14 characteristics (Rampersaad, 2006), such as: clear team goals each member agrees to rally, coherence and good intentions, acceptance and considering cultural differences and mutual respect and trust, capability to solve internal problems and conflicts, capability to achieve collective learning, open communication, harmonious work climate and open and correct feedback, harmonious combination of personalities and abilities of team members, based on knowing and accepting by each team member of his own role and the roles of the others, assumed responsibilities and encouraging and stimulating individual and team creativity.

An effective Intercultural Work Team IWT is created and build and maintained in a deliberated manner. The decisive role in this process is played by the team manager. Our opinion (Bibu, 2007) is that in order to build an effective IWT the team manager has to execute at least the following eight activities: 1) to identify and build based on common team values; 2) to foster and achieve full agreement of the team members for the common goals and objectives of the team; 3) to show appreciation for each individual cultural uniqueness; 4) to reward excellent achievements in culturally acceptable ways for each one; 5) to recognize that cultural conflicts exists whenever they happen and to avoid considering each conflict as being culturally based; 6) to learn to become a better member of the team being more open to cultures of team members; 7) to encourage constantly the learning process about all others team members cultural based behaviours, attitude and values in order to make them accept and understand cultural differences in the team, and 8) to use alternative activities to strengthen the team cohesiveness and smothern its processes.

Highly performing work team is a team that is simultaneously effective (doing the right job) , highly efficient (doing right the job) and achieving the highest „quality of worklife”, that is job satisfaction of team members. We define „being efficient” as achieving the desired results with less resources (financial, material, human, time).

Performant management of teams is founded on performing managerial functions and roles in such a manner that the result of the managerial process is an effective, efficient, and high degree of satisfaction of team members. Consequently, the result is a performant team. Comparative study of bibliography related to several conceptual models of performant teams, allowed us to define performant teams as above, in the context of our research.

We consider that the role of performant management is to ensure, on one hand, achieving the desired long-term performance, and, on the other hand, to transform a common team into a highly performance team.

Our research is based first, on the fact that team work is a multidimensional construct, and second, managers have to develop simultaneously both each individual (team member) and the team as a whole.

Our conceptual model proposed by us is presented in Figure 1, on the next page.

Our first assumption for the empirical research is the following : IWT having a high level of performance (Effective, efficient, high degree of work satisfaction of its members) is the results of practicing performant management in the context of a certain interaction style specific to that team (Figure 1).

Our second fundamental assumption is that the performance level of IWT is positively influenced by the fact that the team manager is taking into account the consequences of intercultural characteristics of each member of the team.

## **2. Research methodology**

The respondent group was composed of 10 managers and 33 employees/team members, from countries, while the number of IWT researched was 10 belonging to 3 multinational companies, from 3 countries: Canada, United Kingdom and Germany. The members of IWT are individuals originating from Romania, Germany, England, Italy, Senegal, Guinea, Canada. We administrated one questionnaire to each respondent (so 43 validated questionnaires), and interviewed all the 10 team managers. We synthetised data and undertook the operationalisation of basic constructs, and next we analysed the preliminary analysis of variables, in order to check data validity. Because the dependent variables were nominal variables, and due to small size of the sample (10 managers and 33 employees), we applied „non-parametrical tests considered the only relevant tests”. (Popa, 2008:214) The research is "degree of association", the independent and dependent variables of the same type. One more reason to choose this model of research is that we cannot claim a causal relationship, but the combination of variables that represent characteristics of a high performance team and not performance indicators. We will not venture to make judgments of causality based on statistical tests done, this is conditional upon further research if this will be useful.

**Figure 1.** Performant management and the performant Intercultural Work Team  
Source: *own adaptation*

Since this is an artificial construction of the components of the conceptual model, we proceeded to identify the relationship of interdependence existing between input items assigned to each variable and each assigned element of the output variable. In other words, the aim of this stage of empirical research is to identify the existence of association, on one hand, between the variables we have assigned to constructs: intercultural management, performance management, contextual factors (personal characteristics, specific personal style as intercultural competence, leadership style and the style of interaction of the team manager) and on the other hand, of the variables defining the construct intercultural team work performance (effective, efficient, degree of satisfaction of team members).

This logical approach allows the identification of advanced constructs validity, too. Since this is a combination of nominal categorical variables, we chose to apply statistical test Chi-square and Fisher exact test. Because the sample of managers is made of only 10 respondents, we have chosen Chi-square test because it can be used also for a smaller volume of sample (but not less than 8), further increasing the

number of subjects having an impact on the critical value for rejecting null hypothesis. (Popa, 2008:219)

We performed data processing and analysis using statistical processing program SPSS (Statistical Package for the Social Sciences) version 16.0.

### 3.Results and discussion

In this paper we are discussing four of the thirteen sub-dimensions of the constructed concept of „effective intercultural work team” IWT (see Table 1, below, for a complete list of the variables of the construct „Effective team”). These four concepts are the following: consistency in achieving team’s goals, taking into consideration intercultural differences in IWT, combination of team’s member competencies, skills and abilities, and, the fourth, creativity development based on intercultural competence of team’s members.

We are discussing in detail these sub-dimensions because they are all fully accepted by managers of the researched IWTs.

**Table 1.** Operationalisation of variables construct *Effective team*

Nr.crt.	Item	Code
1	Consistency in achieving team goals	EFICACIT_1
2	Intercultural differences are considered	EFICACIT_2
3	The team learns from experiences	EFICACIT_3
4	Knowing the learning ability of colleagues	EFICACIT_4
5	Combination of skills in team	EFICACIT_5
6	Knowledge of team roles	EFICACIT_6
7	Development of creativity	EFICACIT_7
8	Harmonious working environment	EFICACIT_8
9	Mutual respect	EFICACIT_9
10	Mutual trust and obedience	EFICACIT_10
11	Mutual feedback	EFICACIT_11
12	Conflict resolution	EFICACIT_12
13	Timely communication of information	EFICACIT_13

*Source: own research*

Data from Table 2 (on the following page) shows that the association confirms the first identified association. From the sample of managers, 90% of them attributed this to the IWT they manage. The dimension “Formal education” of an effective team is associated, with perfect intensity (Cramer's V coefficient is equal to 1), first, with high formal education (10 managers all respondents at least 16 years of formal education manager of which 5 have a doctorate in management) and second, with the type of manager who explains (totally or partially) to the team the content of the management method he/she is using.

This attitude can be explained by focusing on the dimension “high uncertainty avoidance”, the role of explanations being to counteract the negative results due to misunderstanding by IWT members about what to do (Sinek, 2009; Potter et al. 2000)

We have identified a leadership attitude characteristic to the concept of "Golden Circle" (The Golden Circle). This concept is about the leader who inspires by: motivation by WHY, discipline by HOW and ensures consistency by WHAT. Good results can be achieved with people who are happy to come to work. People take risks only when they trust the organizational culture, which includes the management method applied, too. These results can fall into a cultural context characterized by low power distance, explained by high percentage of respondents managers (70%) coming from this type of culture. In support of this assertion we have identified that employees appreciate that the manager does not impose its own opinion (even if the percentage is 80% - individualism and masculinity among managers, which would make us believe that they apply a authoritarian management). Employees appreciate that professional development is taken into account which means that organizational culture values the performing employee. This is, in our opinion, explained by the high percentage of masculinity among the countries represented in the sample, masculine cultures are valuating performance. Analysis from the perspective of employees indicates that 73% have responded that there is consistency in achieving team objectives, variable positively associated with the fact that intercultural not affect their behavior (or only partially). Therefore, we appreciate that there is an association with the type of task-related conflict and not with the interpersonal conflict generated by cultural differences.

Source: our own research

They associated taking into consideration cultural differences with their ability to use emotions to promote intellectual growth, as a dimension of emotional intelligence, as a main feature of a transformational leader (there is a very high intensity of the association, Cramer's V coefficient being equal to 1). The associated cultural dimension to it is "Individualism-collectivism". Therefore, controlling tightly expression of emotions transforming them into a productive issue will be a difficult task for IWT manager.

Rewards are given based on individual performance (normal for individualism). 52.6% believe that individual motivation determines not necessarily follow personal interests, agreeing with it (individualism) and also, they agree with encouragement to award multiple roles (feminine culture). This variable is also associated with the fact that expression of emotions is not an impediment to communication (collectivist cultures, high uncertainty avoidance). Not respecting private time is not considered a problem (collectivist cultures).

Productive use of emotions as part of emotional intelligence and the ability not to judge (individual component of intercultural competence) are not found extensively in the respondents (11,1% of the respondents answered that they have the ability to not judge the other).

We have identified a typology of manager with an individualistic culture type, with low power distance, manager that uses management by objectives. From the perspective of other IWT members coming from other cultures (collectivism 61% and high power distance 64%), the manager must take into account the most valued element identified, such as various aspects of team communication, emotional expression side within IWT.

Only 40% of managers attributed the dimension *Intercultural differences are considered* (see Table 3) to the team they lead.

Source: own research

Managers have associated constructive interaction style in IWT to considering intercultural differences in characterized by a balanced approach between personal and team results, cooperation, creativity, free exchange of information and respect for others' opinions. This style allows satisfaction of individual achievement and team affiliation needs of IWT members. These are precisely the characteristics that theoretically define an IWT. We consider it to indicate that in such a situation the IWT is in the mature stage, closely to the ideal type of team.

Penalties in case of failure and rewards in case of success apply equally team members (collectivism), aspects that are reflected in strong associations with existing types of team conflict, both interpersonal and Task solving related conflicts. This is indicated by the fact that 61% are belonging to collectivistic cultures. The fact that 39% of the sample are people belonging to individualistic cultures, who are associating the above system of team reward and punishment to the fact that "cultural differences are not taken into account".

In terms of employees, the variable related to intercultural differences being considered (36% of them have responded that their team has this feature) is positively associated with first, granting rewards based on performance (individualism), second, encouraging collaborative solutions (low power distance), third, the manager does not impose his/her personal opinion (individualism), fourth, there is agreement for identical reward if successful.

64% of respondents associated compliance to group decisions with disregarding the intercultural differences (individualism), as well as 80% of employees responded that within their team exist more relationship-oriented roles (collectivist approach). In IWT where there is no taking into consideration of cultural differences, the manager is considered not to be cooperative and the team interaction style is passive.

We have identified in this model several relations between team effectiveness and team interaction style, in terms of managerial style, team roles, rewards and punishment system as part of human resource intercultural management.

The small percentage of respondents (40% of managers and 36% IWT members) who allocate this dimension to their team effectiveness indicates that cultural aspects are little taken into account, despite the fact that the team analyzed met the characteristic of an IWT. One possible explanation relates to the fact that these teams members were potentially acculturated from their home country culture, due to adopting the company's organizational culture in which he/she was working for more than two years. Another explanation is given by the conviction of IWT managers and members that the 'hard' part of the activities of team is enough to ensure effectiveness of the team, that is achieving its planned goals.

**Table 4.** Significant associations with dimension *Development of creativity* (own source)

Variable code	Variable name	Managers			Employees		
		Pearson Chi-Square Test	Cramer's V coefficient	Contingency Coefficient	Pearson Chi-Square test	Cramer's V coefficient	Contingency Coefficient

STILP_Intemot3	Intentional generation of emotions				4,95,026	,387,026	,361,026

Source: own research

According to data from Table 4, 50% of the respondent managers consider that the team they manage does not allow development of creativity, while considering that inter-cultural dimension of the team is influencing their behavior. The high coefficient Cramer's V (0.816), indicates a high degree of association between the two variables. The variable related to development of creativity (only 55% of employees answered that their team allows them to be creative) is positively associated with first, encouraging cooperation to find common solutions, second, with perfect knowledge of the language of communication in the team, and, third, with their predisposition to listening, as attributes of intercultural competence. We have also found a positive association between the ability to generate emotions intended to help solve problems and the fact that IWT that enables and develops creativity. However, it should be mentioned again that this should be moderated with the various cultural attitudes about showing or not openly your emotions.

## 5. Conclusions and recommendations

We consider that "Consistency in achieving goals" in an IWT is provided by the type of manager with high formal education, which explains to his/her team the content management method applied without imposing its own opinion. It is a context that takes into account the professional development and provides the opportunity to improve skills of the team members. Rewards are given based on individual performance; there is an agreement to encourage the allocation of multiple roles in IWT. Manifestation of emotions is not an impediment to communication within the team and failing to respect private time is not considered to be a problem. Managerial ability consists of finding satisfactory solutions related to communicating at work between people from cultures with low power distance, and emotionally neutral,

where emotions are controlled during communication, and people from affective cultures and individualistic, with desire for respect of private time. From the perspective of conflict, the challenge will be to manage the resolution of task related conflicts in such type of IWT.

The findings related to "Intercultural differences are considered" indicate that this goal is achieved when managers possess a high level of emotional intelligence so they have the ability to use emotions in order to promote intellectual growth. The manager does not impose his/her personal opinion and is encouraging collaborative solutions (low power distance). Another requirement for success is the existence of a constructive interaction style within IWT based on concern for a balance between personal and team results, cooperation, creativity, free exchange of information and respect for others' perspective. The constructive style leads to satisfaction of needs for personal achievement and affiliation to the team. Manager's ability will be tested in the application of the incentive system, giving reward and punishment, which should combine rewarding team performance according to the individual (individualism-collectivism) and take account of whether punishment is equally individualistically appreciated. A challenge for the team manager will be a preference for not conforming to group decisions (individualism) and relationship-oriented roles (collectivism preferred) that will generate task-related conflicts or relationship related conflicts in such teams.

Conclusions related to "Development of creativity" are that managers who are encouraging cooperation between team members to find common solutions, coupled with perfect knowledge of the language of communication in the team, with team members willing to listen the other team members, could expect better development of team creativity. Our findings indicate that managers have to develop their intercultural competence.

The analysis of data has confirmed that there are relations of interdependence, association between variables for "entry" items into the "system" named "Intercultural Team Work". This system is made of the following constructs: Contextual factors, Performant Management and Intercultural Management) and the characteristics of a performant IWT (i.e. effective and efficient team constructs Team). Our results consist in identifying a possible management "scenario", based on a given intercultural the intercultural aspect of a team determines, ultimately, a certain level of a result variable one of the characteristics attributed to effective and efficient EIA. A high or low level of this "indicator" IWT performance can be explained by the fact that it takes or not into account cultural differences between IWT members.

Due to the recognized limitations of our research: the small size of the sample and research model artificial construction, we cannot generalize the results. On another hand, we consider that results obtained confirmed that it is useful to undertake a broader research study.

# STUDY ON PACKAGING WASTE PREVENTION IN ROMANIA

**Scortar Lucia-Monica**

*Management Department, Faculty of Economics and Business Administration, Babeş-Bolyai University, Cluj-Napoca, Romania  
lucia.scortar@econ.ubbcluj.ro*

**Abstract** *This paper presents on the one hand, the packaging waste management in our country, and on the other hand the packaging waste – most of them disposable - prevention mechanisms. The study provides useful information regarding the quantities of the packaging waste, the capitalization methods and their impact on the environment and population.*

*Preventing waste means reducing the amount of waste generated, reducing the hazardous content of that waste and reducing its impact on the environment. The importance of waste prevention is nowadays fully recognized and generally considered as a priority within EU, as well as national and regional authorities' waste management strategies and plans, but many efforts still need to be made. In practice, local and regional authorities will have to prepare their own waste prevention plans. They will have to take into account that the waste hierarchy established by the Waste Framework Directive puts waste prevention as the top priority. Waste prevention plans shall in particular include a series of actions aimed at reducing the amount of waste to be managed and treated by public authorities.*

*The current national environmental policy is based on the concept known as "waste hierarchy". In an ideal situation, this means that the waste quantities should be prevented and the waste which cannot be prevented should be reused, recycled and recovered as much as possible, avoiding landfilling.*

*The uncontrolled landfilling is the most disadvantageous option for environment meaning resource losses with negative impact on the environment. The goal is to move forward to a society of recycling and recovery, meaning to climb the hierarchical scale, moving from landfill to recycling and recovery.*

*It is very important to mention that individuals and businesses can often save a significant amount of money through waste prevention: waste that never gets created doesn't have management costs (handling, transporting, treating and disposing of waste). The rule is simple: the best waste is that which is not produced.*

**Keywords:** *waste prevention, packaging waste, recycling, selective collection, environmental protection*

**JEL classification:** Q53

## 1. Introduction

Waste generation is a particularly important issue because, on the one hand, it affects the environment and the human health and on the other hand, it is a reflection of the inefficient use of natural resources by the society. At the beginning of XXI century, we believe that not us, but generally people do not have the required education to treat waste problem as something serious that can influence decisively our future existence.

Technical creativity in waste recovery did not have the same place as the creativity in developing new products and adopting and implementing the technologies for achieving them. We believe that, viewed as an actual and future businesses, waste recovery will find its required technical capacity.

The packaged goods are part of our world and in many ways the packages make our life easier. Unfortunately, the volume of the packaging waste has increased dramatically in recent years.

For the generated waste, it is essential to start the selective collection of the packaging waste among the population, which must be informed, and having its awareness raised through environmental education. Selective waste collection benefits include the selection of valuable fractions (paper/cardboard packaging, glass packaging, plastic packaging, metals packaging, textile packaging), avoid storing easily biodegradable waste in landfills, and increasing calorific value of waste remains.

## **2. The hierarchy of the waste management**

In the current waste management strategies, the trend is an integrated system based on prevention of waste, minimizing waste quantity, recycling and reusing of waste, treatment with a large number of technology, and ultimately, waste remains disposal, also taking care of population and environment health.

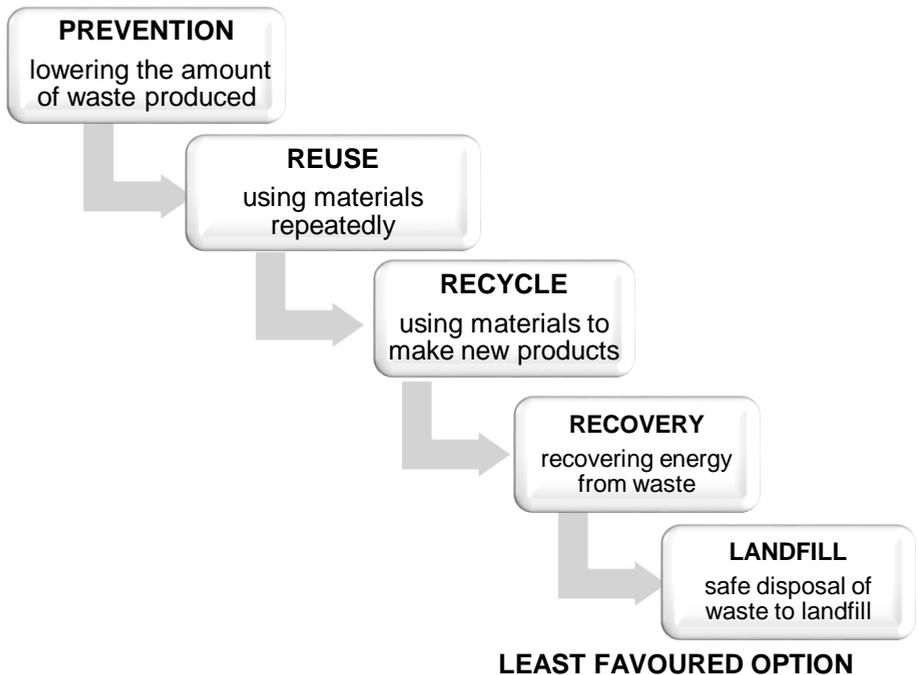

The sustainability of integrated waste management refers to an appropriate management system that fits best for society, economy and environment and that everyone, regardless of the degree of development of the country, is entitled to an appropriate sanitation service.

The European Directive lays down the five-step hierarchy of waste management options, with waste prevention as the preferred option, and then in descending order, reuse, recycling, recovery (including energy recovery) and safe disposal.

Packaging waste prevention is closely linked with improving manufacturing methods and influencing consumers to demand greener products and less packaging. Waste prevention includes measures to reduce the adverse impacts of the generated waste on the environment and human health. Waste prevention can be achieved by reducing the quantity of material used in the creation of products and increasing the efficiency with which products, once created, are used.

Preventing waste by limiting unnecessary consumption and by designing and consuming products that generate less waste are forms of strict avoidance of waste. Packaging waste prevention also encompasses actions that can be undertaken once a product reaches its end-of-life: rather than discarding the product, the final user should consider re-use or repair as options. Extending a product's lifetime or considering option like re-use is form of prevention. Re-use keeps products in the consumption sphere for a longer period and thus avoids the creation of waste. Re-use implies that a product is used again for the same purpose for which it was originally conceived.

## MOST FAVOURED OPTION

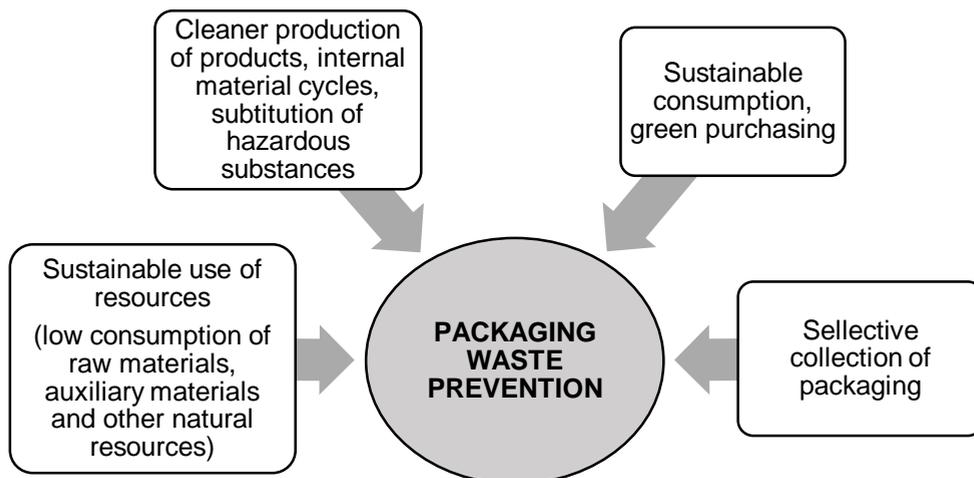

**Figure 1:** The hierarchy of the waste management

Source: [http://www.preventandsave.ie/Introduction\\_to\\_Packaging\\_Prevention.html%20](http://www.preventandsave.ie/Introduction_to_Packaging_Prevention.html%20) (Adapted)

Reducing the hazardous content of waste, rather than impacting the total volume of waste, is considered as qualitative waste prevention and contributes to reducing human and environmental exposure to hazardous materials.

A waste prevention scheme has its origin in the waste management sector, its scope, however, comprises the whole economy, all material flows and products used by a nation, from their respective cradles to their discarding. Thus, a comprehensive waste prevention scheme should not only concern the waste management sector but also the mining sector and productive industries, designers and service providers, the public and private consumers. Consequently, all economic sectors may be stakeholders in the waste prevention scheme and its preparation.

**Figure 2:** The main scope of the waste prevention

Source: EEA (2007): Chapter 6: Sustainable Consumption and Production and Waste Management

It is very difficult to measure the waste prevention, but certain statistics can be reliable in charting progress on defined objectives. The following statistics are helpful in assessing the current status of waste prevention:

- a. Quantities of collected packaging waste per person
- b. Quantities of hazardous waste generated by each person
- c. Public awareness of and declared actions for waste prevention
- d. Use of waste preventing services e.g. repair and reuse centers, home composting
- e. Consumption of ecolabelled products etc.

Eco labels, in particular the EU Flower, help consumers identify products that fulfil environmental criteria including material efficiency and limits on packaging and hazardous materials, thus providing waste prevention information directly to consumers at the time of purchase.

In addition to waste cycle data, information on national demographics, socio-economic characteristics, available infrastructure, reuse systems, trade and manufacturing activities should be collected.

Producer responsibility arrangements are in place throughout Europe, introducing measures relating to the prevention, reduction and elimination of pollution caused by waste and the management of packaging and packaging waste.

### **3. The importance of packaging for maintaining the product quality**

Packaging refers to all materials whose purpose is the containment, protection, shipping or presentation of goods, from their natural condition to saleable form, as handled by the producer or the consumer. Packaging is often divided into three broad categories: primary packaging, secondary packaging and tertiary packaging.

Primary packaging is the packaging which contains the product and is sometimes called sales packaging. Well-designed primary packaging protects the product from

damage and deterioration, it also provides essential information about the product including storage and storage date information and nutritional values. Primary packaging allows manufacturers and retailers to identify their products through brand marketing.

Secondary packaging is the term for the packaging used to contain a number of items of the same product during storage and handling. Cardboards are the most well-known items of secondary packaging but special trays and shrink-wrap plastic are also commonly used.

Tertiary packaging is used between product manufacturers, warehouses and sometimes the storage facilities at large stores. It consists of pallets, shrink-wrap plastic, large cardboard boxes and re-useable packing materials. It rarely becomes household waste and much of it is already recycled or reused.

Packaging waste is generated at all levels of the supply chain, but principally by consumers as the end user. Packaging waste policies may address tertiary packaging use with distinct measures as it is involved in a specific phase of the lifecycle and may implicate different stakeholders.

The packaging meet many functions, on their way from the supplier, to the distributor and finally, to the consumer, as follows:

- a. The packages preserve and protect the products;
- b. The packages facilitate handling, storage and transport of products;
- c. The packages promote the products and inform the consumer.

“In developing countries, the absence of the packaging or an inadequate packaging causes between 30 and 50 percent of the foodstuffs to decay before they even reach the consumers. In industrialized countries, product loss is only about two or three percent”, points out Professor Dr. Dr. Günter Grundke from the German Packaging Institute. Packages therefore protects and conserves the products. The first function refers to maintaining of the packaged product in the initial parameters. The product must be protected from the environmental influence. In this context, there are physical factors, chemical factors and biological factors.

The physical factors include the mechanical shocks, sand, dust, light, temperature, pressure and so on. The mechanical shocks influence both the product and package. They can compress or settle the product inside the package canceling the protection of the package. The light causes discoloration and degradation of goods (vitamins losses). The light-sensitive products must be packaged in opaque packages. The temperature is one of the factor that affects the quality of the product. A temperature over 40°C could determine deformation of products or change the taste and smell. The chemical factors include the water, water vapor, oxygen, carbon dioxide, etc. The packaging should be a barrier to the action of these factors in order to avoid losses of flavors, dehydration of products, loss of gas introduced into the package etc.

The biological factors refer to the microorganisms, insects, rodents. All these can affect the quality of the packages and the products. The package must ensure a very high degree of hygiene.

According to the second function, the packaging should have a shape, a volume and some accessories to facilitate proper grip and handling. In case of the storage, the package must be easily stacked and be resistant to the storage conditions (temperature, humidity, pressure).

Packaging must protect the product during transportation. If either the packaging or the product is damaged, this could lead to the whole pallet of goods having to be discarded as waste. The environmental impacts of overestimated packaging result only from the packaging itself. In the case of underestimated packaging, however, the environmental impact is significantly greater because the product also becomes waste.

According to the third function, the packaging is an important marketing tool. It makes products recognizable for the consumer. And it provides consumers with important product information (mostly required by law) on ingredients, additives, “best before” dates, producers, instructions for use, quality labels or recycling information. With the introduction of stricter requirements in respect of consumer protection and food safety, for instance, producers are increasingly being obliged to provide the necessary information and to ensure that their packaging has sufficient space to display it.

Packaging is an integral part of the product being offered to consumers. Packaging design must attract consumers in an increasingly competitive and quickly changing market while fulfilling the essential functions required for the extended supply chain.

#### 4. Analysis data and interpretation

The main materials used for manufacturing of the packages include the following categories: cellulosic materials (paper and cardboard), glass, plastic materials, metallic, materials, textile materials, wood materials, other (complex materials).

**Table 1:** The amount of generated packaging waste in Romania (tones)

<b>PACKAGING WASTE</b>	<b>2007</b>	<b>2008</b>	<b>2009</b>	<b>2010</b>

Source: EUROSTAT (2013)

During 2007 – 2010, a quantitative increase of the plastic packaging and paper/cardboard is noticed compared to the other materials, which shows the direction in the consumer behavior.

Currently, Romania registers the increasing tendency of the generated waste quantities (similar in most European countries).

A considerable effort is needed to stop this growth and then to guide this dynamic trend towards a reduction in the generated quantities.

Therefore the main objectives of Romania are the following:

- Stopping the increasing of the generated waste quantities by 2015;
- Subtracting the quantities of generated waste with a minimum 5% / year (previous year) since 2016.

Waste generation is the indicator which best illustrates the interaction between human activities and the environment. Waste generation usually follows the

consumption and production trends. For example, waste generation (quantity/inhabitant) increases together with the income level. The increase in economic production, but also the inefficient management of resources, lead to the generation of huge quantities of waste.

**Table 2:** The amount of recycled packaging waste in Romania (tones)

<b>PACKAGING WASTE</b>	<b>2007</b>	<b>2008</b>	<b>2009</b>	<b>2010</b>

Romania has a statutory producer responsibility regime for packaging. This places a legal obligation on businesses which make or use packaging (raw materials manufacturers, converters, packer/fillers and sellers) to ensure that a proportion of the packaging they place on the market is recovered and recycled.

**Table 3:** Total generated and recycled packaging waste in 2010 (Romania)

Source: Own processing using previously data

According to these data, Romania has fulfilled the recycling and recovery targets provided by the legislation in 2010, excepting the recycling rate for the glass packaging. This rate was under the value imposed by the EU.

Eco-Rom Ambalaje is the first organization in Romania which invests in the selective collection of packaging waste from the population in order to reduce the amount of the generated waste. Eco-Rom Ambalaje does not aim at making a profit from the package recycling activity, as its tariffs reflect the system operating tariffs. The operating profit is communicated in a transparent manner to all affiliated companies, and is fully reinvested in environmental protection: acquisition of selective collection infrastructure (containers) and development of educational programs (school handbook, campaigns etc.). Eco-Rom Ambalaje is the organization which holds the right to use the "Green Dot" mark on the Romanian territory. The presence of the

Green Dot mark on a packaging certifies that a financial contribution was paid for that type of package to a national packaging recovery organization, in accordance with the principles set out by European Directive 2004/12/ EC on packages and packaging waste. The Green Dot mark is a symbol of responsible companies, which have made a financial commitment that the packages of the products put on the national market should be collected selectively from the population, recycled and valorized in accordance with the objectives established by law.

Eco-Rom Ambalaje has fulfilled the recycling and recovery targets provided by the legislation in 2011.

**Table 4:** The recycling and recovery targets provided by the legislation in 2011

<b>Packaging waste</b>	<b>Packaging released on internal market (tones)</b>	<b>Packaging waste recycled (tones)</b>	<b>Targets 2011 (legal)</b>	<b>Targets met by Eco-Rom Ambalaje</b>
<b>Glass</b>	89,093	64,221	54%	72.08%
<b>Plastics</b>	196,757	93,653	22.5%	47.60%
<b>Paper/Cardboard</b>	174,956	136,226	60%	77.86%
<b>Metal</b>	33,466	24,309	50%	72.64%
<b>Wood</b>	118,905	36,586	15%	30.77%

Source: Annual Report Eco-Rom Ambalaje - 2011

For 2012, packaging recycling objectives for manufacturers was even higher than the previous year, reaching the maximum growth level, according to national and European legislation, as follows: the total recycling target grows from 50% to 55%; for targets per type of materials, increases are reported for PET packaging – from 42% to 55%, for glass – from 54% to 60% and for aluminum – from 17% to 21%. In 2011, achieving the recycling and recovery targets was possible due to the financial effort made by Eco-Rom Ambalaje, which last year invested about 8 million euros in packaging waste selective collection, about 17% more than the previous year. About 83% of this amount accounts for investment in services of collection, transport and selection of packaging waste from management companies – collectors and sanitation operators.

Selective waste collection is a solution easily available to everybody, and consists of the disposal of waste in specially arranged places, with a view to being recycled. Public institutions, associations, foundations and individuals have the obligation to collect selectively the packaging waste, in properly containers that are located in special places readily accessible to the population.

## **5. Conclusion**

Analyzing the registered date, the capitalization degree of packaging waste is quite low at national level. Primarily, the low capitalization is due to the technical reasons (the absence of the infrastructure for the separate collection and sorting in many areas of the country, and the absence of the recycling capacity for certain materials types). Secondly, the low capitalization is due to the economic reasons (the absence of the financial instruments to stimulate / to oblige the sanitation operators to deliver the collected waste for processing/capitalization and not for final disposal).

Waste prevention includes avoidance of waste generation, qualitative and quantitative reduction at source, and reuse of products. It doesn't include materials recycling and separate waste collection. Waste prevention is a global priority to avoid the uncontrolled accumulation of the packaging waste. The conception phase holds the widest possibilities for prevention. The waste quantities can be reduced at every step of a product's lifecycle. The packaging shall be designed so that performing its functions with minimal environmental impact.

The use or optimization of reusable distribution materials can lead to notable waste reduction and financial savings. For example, the plastic materials are much more durable than the wood materials. Increasing the longevity, reducing the volume and eliminating the single use packaging we can provide waste prevention opportunities in very large quantities.

At consumer level, informational strategies motivating consumers to buy products with minimized packaging content are appropriate, as well as efforts to normalize the purchase of bulk products.

The local authorities play an important role in stimulating public awareness and interest in packaging decreasing or avoidance and can support national efforts by demonstrating the demand for lower levels of packaging to manufacturers. Local authorities also play an essential role in informing local residents about reuse activities: how packaging are collected, where they can be deposited, how to contribute materials in good condition, and where to purchase reused products.

In conclusion, the packaging and the product must be seen as a single unit. The environmental impact of this single unit must be reduced by investigating and initiating waste prevention measures during development. A reduction of the environmental impact and economic efficiency often go hand in hand. Reducing packaging weight and using recycled materials conserves raw materials and reduces costs.

## 1. Introduction

Therefore, this paper aims to provide reasons on why some persons choose to become entrepreneurs by examining the motivational factors which differ among business market.

In this context, theoretical arguments and empirical findings are investigated in order to draw a picture of the factors that motivate women to start their own business, as well as factors that limit the growth and development of women entrepreneurship in transitional countries.

The 4R model provides a conceptual framework consisting of four comprehensive macro categories of leadership attitudes and behaviours and dynamics interaction of these categories.

The model provides a conceptual home for the critical variables in the transformational leadership process.

These variables are organized in four categories: relationship, reputation, research and recognition.

Similarly, the 4R's model details and organizes a vast amount of information of transformational management from theory to practice and presents it in a clear and accessible manner.

The model only approximates how transformational management works in economic organizational life.

Specifically, the 4R picture is:

1- **research** access to key information about markets, customers and competitors to improve marketing focus message;

2- **relationship** one to one or one to many relationships with individual customers that generate sale opportunities, the virtuous leader is depicted in specific organization context

3-**reputation** interest in company by target market based on company's and market understanding of it's capabilities and expertise;

4-**recognition** awareness of company and its value proposition by market position, results the attitudes and actions of the virtuous leader are depicted as linked to outcomes over time.

Each R category is discussed in light of the contemporary economical situation on Romanian and Albanian market.

The benefits of the 4R are explored and present the real situation on economical market and management production like a problem or a false fake?

## **2. Study case**

This research was designed to identify the motivational differences between production or services and trends in entrepreneurship.

The study investigates the reasons that motivate women to become and work as entrepreneurs along with the constraints they face when starting and developing their business activity.

In this context, theoretical arguments and empirical findings are investigated in order to draw a picture of the factors that motivate persons to start their own business, as well as factors that limit the growth and development of entrepreneurship in transitional countries like Albania and Romania.

This paper highlights the situation facing women entrepreneurs and describes the various forms, establish and develop their own business.

### **2.1. Methodology**

The sample was draw for people involved in business activity in Baia Mare and Durres city. A total of 500 respondents were contacted. Respondents were surveyed using a forth part structured questionnaire.

**Part 1-**measured demographic variables using single items such as age, educational background, type of business activity, type of organization.

**Part 2-** measured the factors which were classified into entrepreneurial core, work core, individual and social core relevant for leadership style of the respondent person.

**Part 3-** measure the profile of leadership, the attitude in different situation of the manager, and identify the type of leader.

**Part 4-** measure the perception for new development and new orientation into organization, identify some individual suggestions.

The internal consistency of the measure and the results indicate that the items in measuring the leadership dimensions are reliable.

Also the survey makes radiography upon the economic activity and gives an answer to the organization problems.

## 2.2. Results

Taking in consideration Harrison, R, (2008) article we used comparable data from two European countries.

Out of 250 respondents for each city, majority of them are aged educated that's the motive of involvement in his own business (26% baccalaureate and 57% academic studies).

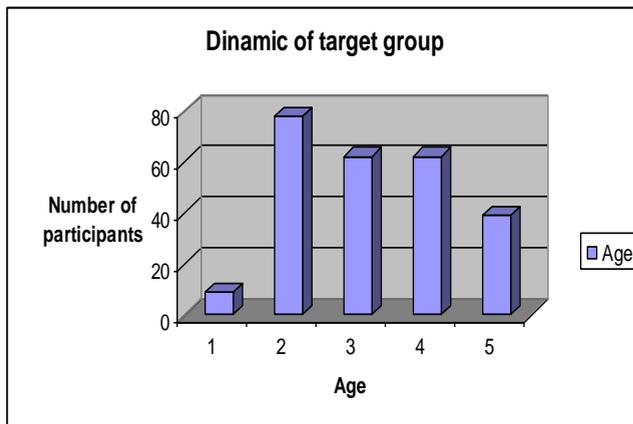

Women entrepreneurs were found to be more matured in terms of age and more educated, here fore, the educated generation is more interested in becoming entrepreneurs.

The importance of education for successful entrepreneurship has been well established.

A comparison of educational qualifications over a period of time (pre and post 2000) indicates a progressive trend of more MBAs, post graduates, professionals and individuals with work experience becoming entrepreneurs.

The respondents are also found to be very well equipped with work experience, to desire to have own preferred working style and change in working style may explain why they have decided to become entrepreneurs.

The demographic profile of entrepreneur show that women are basically below the age of forty, between 20-40 age old, (34%) Figure 1.

**Figure 1.** Evolution of age entrepreneur

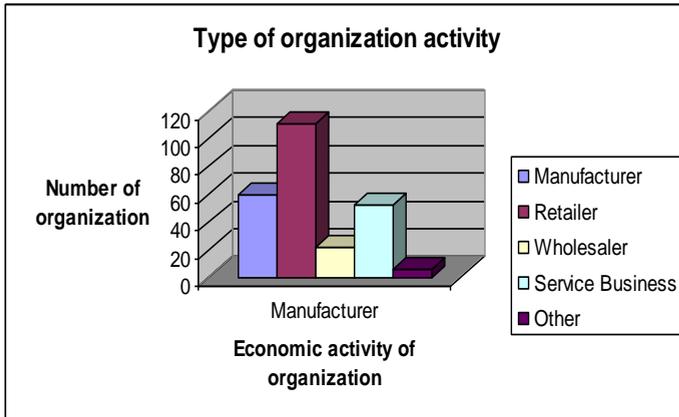

Archibugi (2001), Bogliacino and Pianta (2009, 2010) identify Pavitt's taxonomy groups (1984) that describe the level of technological opportunities in industry and the influence of innovation and new technology for future development and harmonization with market customers needs.

The ups and downs of aggregate demand have been shown to affect changes in production and demand for labor.

Taking in consideration the survey results, a classification can be easy done, the economical activities can be structure in the category of supplier dominated industries, here we include traditional sectors food, textiles, clothing, hand makes products, training and other activities.

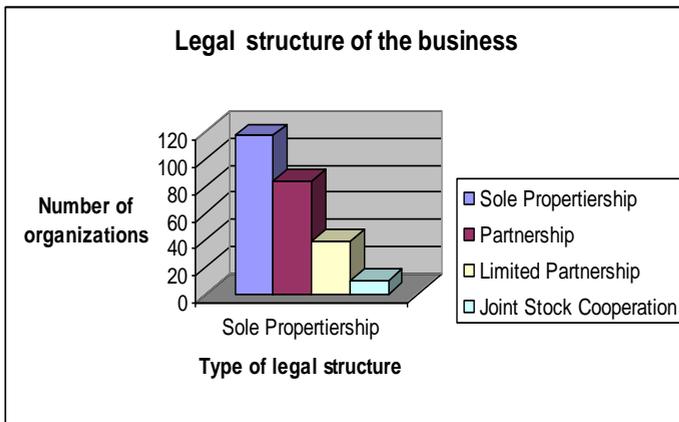

Evangelista and Savona (2003) present the importance of the relation between innovation and skills in services and the direct relation between the necessity of structural change and economic dynamics.

It is not surprising that the number of women entrepreneur gas increased and growing interests in privatisation, self employment and business oriented employment, all this facilitated by the growth in various sectors such as general commerce, personal and public services, training and consultancy and other (Figure 2).

**Figure 2.** Type of business activity

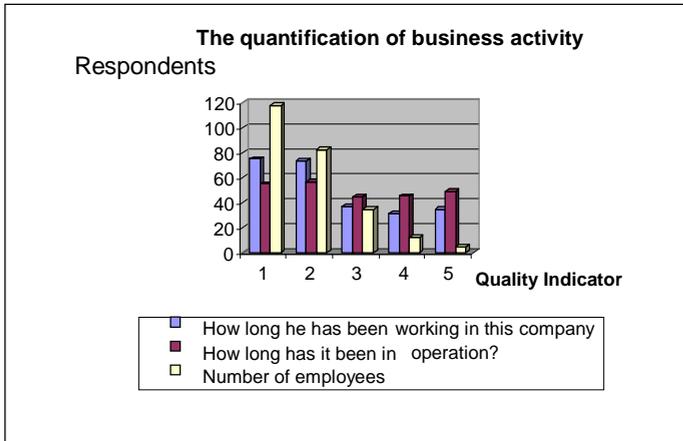

This is to ensure that entrepreneurs are not left out the process of national and economic development, particularly in important sectors of Small and Medium Enterprises (Figure 3).

**Figure 3.** Legal structure of the business

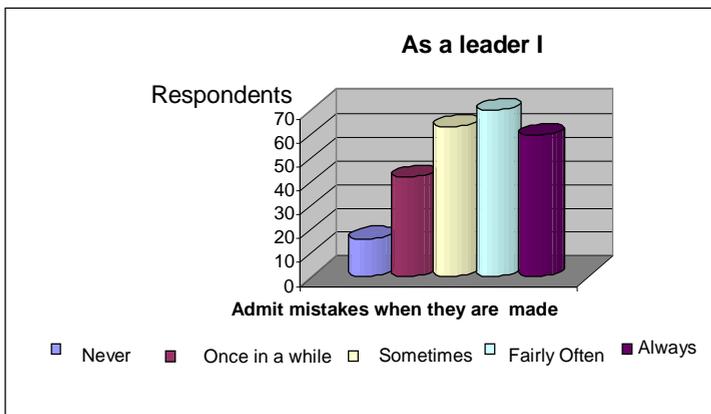

The diversity in the patterns of employment in the manufacturing sector is documented in this paper also where the dynamics of employment depends of economic cycle Boca G.D.(2011)

It is clear that government has been involved and concerned about unemployed person including women entrepreneur development in the last period. Desire for greater life flexibility, seeking challenges, fulfilling a long-felt desire or escaping from organizational glass ceiling is also among the motivation factors that women to start-up their own businesses (Figure 4).

**Figure 4.** Analyze of business characteristics

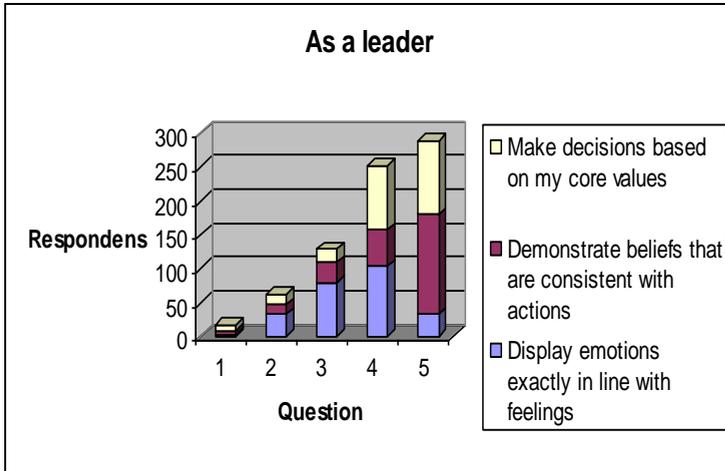

From the dates obtain we identify that major activity are non productive as a matter of fact the production it is not developed yet in our regions, we are under the discovering faze of the miracle products which can be produced (Figure 5).

**Figure 5.** Profile of leader

As the factors proposed are generic in leadership profile, they are also applicable to women entrepreneur and a practical change management in their own business. Leadership before, during and after change implementation is the golden key to getting success.

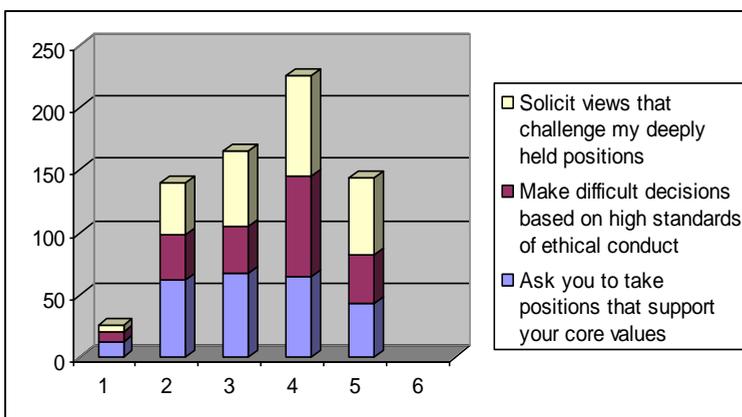

The Matrix factors for leadership profile examines the personal background, stage of career, early life experiences and growth environment, indirect benefits, opportunities in the carrier prospect and the impact of market conditions. From research work perspective various attempts were undertaken to identify factors that support the growth of women entrepreneurs as leadership and comprehensive list of factors are identified and put in evidence the object of this study (Figure 6).

**Figure 6.** Opinion of leadership

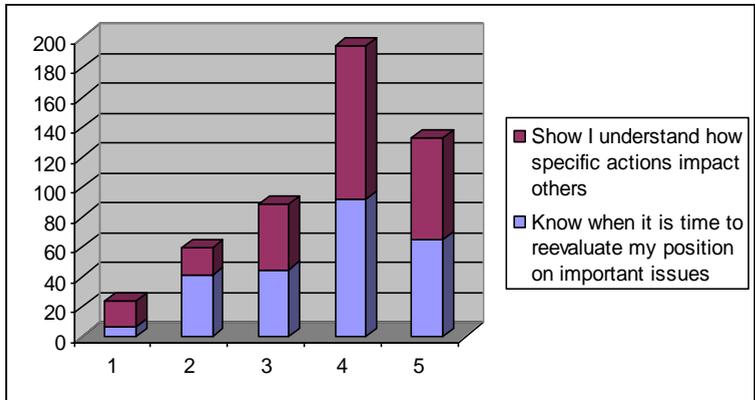

In this study comparing the motivational factors among males and females it was found that disagreements with the bosses, with the drive to control own destiny, were motivating factors for male entrepreneurs.

The women are involved in service activity because of their good communication and their spirit of creation always takes in consideration the benefits of the entire organization (Figure 7).

**Figure 7.** Leader style

Hence women were driven to entrepreneurship because the independence and sense of achievement which entrepreneurship offers. Management refers to the ways of the personnel in charge of directing the organization, which in this instance is an entrepreneurship (Figure.8).

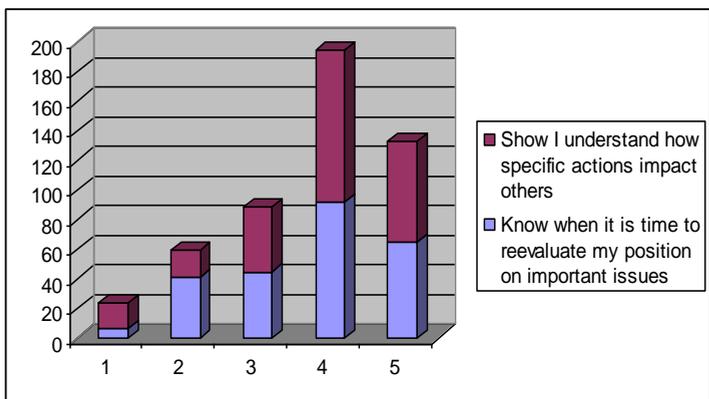

**Figure 8.** The flexibility of leader

Taking in consideration Barbuta-Misu, N.(2012) results regarding the possibility of modeling the Influence of Financial Variables on Enterprise, we should established also for entrepreneurs a model, to maintain an environment within the business to encourage efficiency among employees.

Part 4 of survey measure the perception for new development and new orientation into organization, identify some individual suggestions under the model of Pianta, M.,(2005).

Figure 9 plots the change of the manager mentality groups as the first evidence of the diversity in the relationship between innovation and employment during the economic cycle and their organization new orientation on market.

**Figure 9.** The flexibility of leader to innovation

An in depth understanding on the influence of these variables will be useful to understand the complex phenomenon of entrepreneurship.

Being in the management connotes power and influence for the person, it is not unusual for an entrepreneur to do all the management functions at the start of the business.

Poor leadership means an absence of hope, which, if allowed to go on for too long, results in an organization becoming completely nonfunctioning.

The organization must deal with the practical impact of unpleasant change, but more importantly, must labor under the weight of employees who have given up, have no faith in the system or in the ability of leaders to turn the organization around.

### 3. Conclusion

Based on the survey, we concluded that not in every organization management the manager leader, understand the managerial competency in the some connotation.

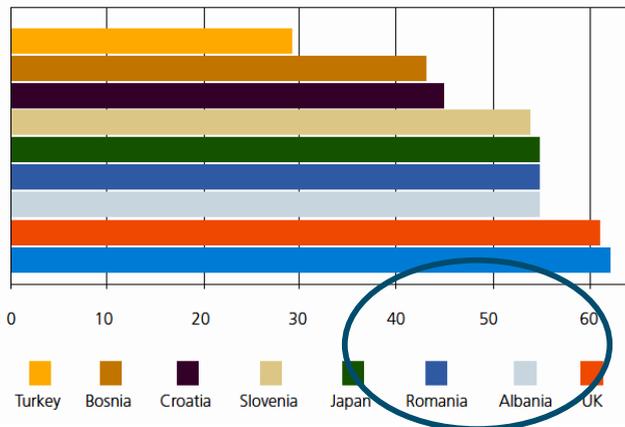

The system of independence of competencies with performance management, which has an impact on other areas of employee work like is not used in all companies in the survey.

Using competencies and skills assessment remains only on the formal level in most companies.

Since 48% entrepreneurs are focus on retailer activity and services, and only 24% it is involved in productivity activity, a new orientation it is necessary to encourage the economical growth of the city.

The individual and entrepreneurial core appears to be very important, it is important also to encourage the spirit of production as long we are in economical crises who need new alternatives and also new products.

The women voice was analyze in a global environment, so we can identify the labor women force and the impact on each country from this point of view ( Figure 10.).

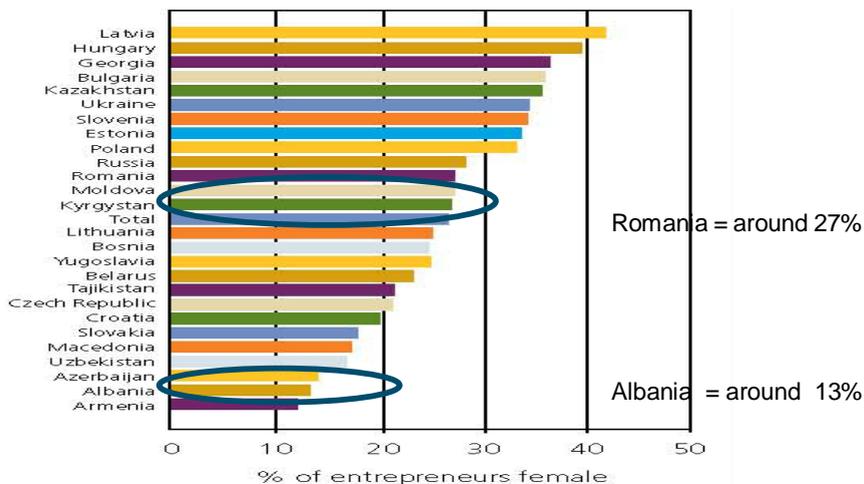

**Figure. 10.** Women Labor Force participation in Romania and Albania  
Source: IFC, Voices of Women Entrepreneurs in Bosnia and Herzegovina

## Main Obstacles for Entrepreneurs

- Licenses, taxation, cost of finance and labor issues are cited as the biggest obstacles to women owned businesses,
- Little coordination among each other,
- Unclear or varied business requirements of the different regions,
- Absence of strong women's business organizations,
- Much-needed training and networking,
- Female entrepreneurship has been recognized as an important source of economic growth.

## Global Trends in Female Entrepreneurship

Using the data base obtains by Sabarwal and Terrell (2008) (Figure 11.) we can observe some global trends between Romanians and Albanians Entrepreneurs.

**Figure 11.** Share of Female Entrepreneurship by countries

Source: IFC, Voices of Women Entrepreneurs in Bosnia and Herzegovina, Sabarwal and Terrell 2008

In conclusion the global trends in female entrepreneurship identify using the survey are similar with Sevi Simavi, (2009) remarks like:

- Regardless of gender, entrepreneurial activity is significantly higher in Romania = around 27% and in Albania = around 13%
- The level of female entrepreneurship in market typically is oriented especially in commerce- retailer.
- A systematic gender gap a business ownership,
- A big segment from adult population are working abroad in each country.
- Employment matters to entrepreneurial activity. Those women who are employed in a wage job are more likely to be involved in entrepreneurial activity than those who are not working, are retired, or are students.
- Training and involved adult population in projects, courses and specialization in learning how to provide their own business.

The future research will be focused on efficiency of methods used for competency development in companies and realised a diagnose in comparison with other countries.

#### **4. Acknowledgements**

This work has been realized as a research work between our universities to diagnose the regional potential of market from both countries and to identify the entrepreneurship pulse in a city where economic crises put his signature on industry and people life.

[www.carmenb@seap.usv.ro](mailto:www.carmenb@seap.usv.ro)

**Abstract:** *Apart from governance and risk management, internal control is a third major component of corporate governance. Proper corporate governance relies upon risk management in order to identify the problems faced by the organization and on internal control in order to achieve its objectives. Internal auditors, apart from supporting the organization and enabling it to identify and monitor the risks lying ahead, must also understand and monitor the functioning of the internal control system which is the key to implementing the corporate governance principles. Internal control is a process implemented by the management of the public organization and directed at providing reasonable assurance in terms of meeting the organizational goals, which are grouped in the following categories: operating effectiveness and efficiency; reliability of financial reporting; compliance with the laws and regulations.*

*The design of the control system is highly significant when the system is used, and the part it plays in the management of the business entity is fundamental. For instance, budget control is a measure of performance. A supervisor can use this variation with difficulty or with ease. Used differently, the same measuring system may convey different benefits.*

*The organization of the internal control system in a manner that is divergent with the principles of planned economy has led managers to believe that control activities are discretionary, and the subsequent lack of management responsibility has weakened the efficiency of internal control systems during the first years after 1989.*

**Keywords:** *internal management control, governance, risks.*

**JEL classification:** G28

## 1. Introduction

Professional literature in the field of internal corporate governance control often emphasizes some of the following aspects:

- Horngren and Foster's definition underlines the importance of adequate information: "a management control system is a means of gathering information that would assist and help coordinate the process of making and monitoring the decisions within the organization". (Horngren, C.T., G. Foster, 1991)

- Merchant describes control as “keeping things afloat” and “encouraging people to act as the organization would want them to”. He describes how behaviour is influenced by various control alternatives, such as focusing on results, actions or personnel and whether controls are the most appropriate.

- In his work, Decentralisation: managerial ambiguity by design, Vancil (1978) addresses some of the key control issues, such as: how to better structure an organization in order to manage the two “conflicting elements”, i.e. the need for efficiency (promoted by centralization) and the need for adjustment (promoted by decentralization). (Vancil, R. F., 1978)

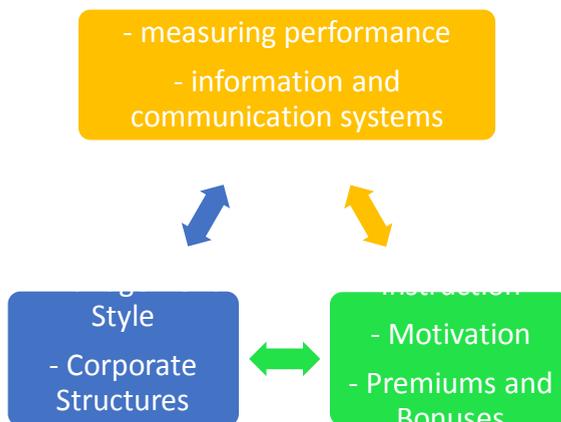

The design of a management control system that “ensures that the organization is doing what the management wishes”, is quite a difficult endeavour. In the opinion of certain professionals, an efficient system is made up of a number of interrelated elements, such as:

- performance measurement,
- motivation and
- organizational structure

These different approaches would suggest that certain manners of describing control systems are correct, while others are not or are less important. However, we believe that this perspective is less useful than the one that integrates various outlooks.

## 2. The correlation among the elements of the internal management control system

While each component of the diagram can be subject to analyses and conclusions, the key to understanding the control system is to comprehend the interdependence of its components. Interdependence affects all of these. None of them can be properly controlled without considering the impact on the other elements and the way they too need to be supported.

**Figure 1:** The components of the management control system

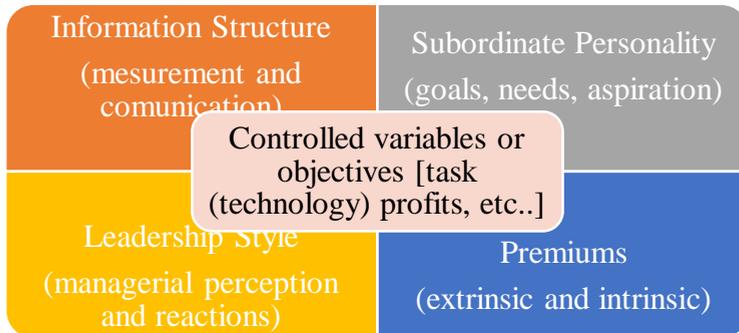

The relationship between performance assessment methods and direction has been analyzed from various angles. Euske (1984) mentions some of these approaches in his work *Management control: planning, control, measuring and evaluation*. (Euske, K.J. 1984). Euske presents a bi-dimensional framework to describe the characteristics of control in any specific organization. The horizontal axis displays three ways of classifying control sources into organizational, informal or individual groups. The classification can also be found in Dalton and Hopwood (1971), Dalton and Hopwood (1974), (Dalton, C.W., A. Hopwood, 1974). The vertical axis displays three types of controls: steering controls, yes-no controls and post-action controls (Newman, 1975; Amey, 1979). Euske's framework, shown in Table 1, uses nine cells and each of these contains a description of the control process that would correspond to the targeted source and to the type of control. Each cell reflects a definition of performance, whether or not the budget is met, and compliance with the group's code of conduct or the achievement of personal goals. Steering controls influence behaviour before it happens. Yes-no and post-action controls use the results of the last behaviour in order to influence future conduct. Knowing whether the control system is post-action, yes-no or steering or whether it is managed individually, socially or on an organizational level is not enough, as shown in Table 1. In order to understand the influence of a particular control system within an organization, one must identify the unique combination of the control characteristics and the statistical contingencies.

**Table 1:** Control possibilities within the organisation

	<b>Administrative or organizational</b>	<b>Informal social groups</b>	<b>Individual</b>
<i>Feed-forward or preliminary controls</i>	Using forecasts in order to identify budget fluctuations	Advising the new employees on the group's code of conduct	Setting personal short-term performance goals based on the position targeted 10 years ago
<i>Screening models</i>	Quarterly revision of the budget if a project must be continued	Not being invited to socialize with the group after work	Asking to be promoted after successfully negotiating an important contract
<i>Feedback or post-action controls</i>	A bonus offered to a manager for not exceeding the budget of the previous year	Joking about a colleague having lunch with the boss too often	Leaving the organization after not being promoted

By developing this matrix, Euske focuses on understanding the correlation between the characteristics of management control and situational contingencies. (Emmanuel et al., 1990) have made the following statements in their work, *Accounting for management control*: It is increasingly recognized that economic concepts represent only one part of the foundation upon which management

accounting rests. The internal functioning of the organization, the way in which people react to information and the design of the control systems to affect human behaviour are also fundamental to the operation of a complete accounting system. Ansari's integrated model (Ansari Consulting Group) includes four major components that focus on the objectives of the organisation (Figure 2). However, Ansari emphasizes the leadership style and places personality on a second place in terms of importance in designing an efficient management control system.

**Figure 2:** Components of the control system

If we analyze the components outlined in the model shown above, we can trace the correlations occurring among the different structures of the control system, while the necessary measure to be taken is to minimize the procedural differences between managers and subordinates.

### **3. The manner of conducting internal management control within organizations**

If the higher levels of management have manifested a risk-averse attitude in the organization and if certain other lower management levels or positions are risk-seekers, this may lead to confusion and even conflict within the organization. Certainly, the opposite scenario is equally alarming (Griffiths, 2005).

Risk-averse culture has the following characteristics:

- management tends to confine itself to what it knows for certain;
- stability, experience and knowledge are fundamental values and also the most sought after attributes;
- the organisation is very reactive, it tends to wait for something bad to happen and act afterwards;
- the hierarchical structure of the organisation has numerous levels and most decisions are made at the top levels;
- the management wastes a lot of time trying to determine how to develop activities in a more efficient manner, instead of focusing on the consumers' needs for services;
- strategies do not change very often within the organization and when they do, it is a rather momentous occasion;
- mistakes/errors are personalized, thus causing the employees' lack of initiative, as this is a typical "shame culture".

On the other hand, there is also a risk-seeking behaviour, called the “*can do*” culture, that is mostly characterized by:

- innovation and motivation are the most sought-after values;
- interest is manifested for capitalizing opportunities and engaging the employees;
- major decisions falls within the duties of the general management, while the entire organisation assumes the task of making routine decisions;
- the main orientation of the organisation is towards the external environment, focusing on the provision of services to customers;
- strategies and policies change frequently in order to emphasize the changing circumstances;
- mistakes are accepted – and even encouraged – but hiding the mistake is unacceptable.

Risk theorists argue that it is very important to understand *the culture or the sub-cultures of the organisation you work for*. If you are part of a risk seeking culture but one where there is a lot of opposition, this image will have to be compared with the findings of the internal audit.

At the same time, it is equally important to identify risk preference in organisations that are otherwise risk averse, as risk seekers can act like “*loose cannon*”, making the organisation vulnerable to unexpected threats.

In either of the two cases, the approach of the internal audit and their recommendations will have to provide a clear picture of such occurrences.

There are numerous benefits associated with the integration of the management control system in the corporate culture, among which:

- greater attention given to the issues that actually matter;
- reduced time spent by management in the settling of disputes;
- less surprises;
- more satisfied customers;
- safeguarded reputation;
- increased interest in doing the right things in the right way;
- increased probability of reaching the objectives set for the company;
- less complaints;
- increased probability of change initiatives and capitalization of the projected benefits;
- assuming risk and more informed decision-making;
- support for innovation;
- lower insurance costs.

According to the IIA (Institute of Internal Auditors), the main responsibilities of internal audit in terms of the implementation of the internal management control system are:

- provides assurance in terms of risk management processes;
- ensures that the risks are properly assessed;
- evaluates risk management processes;
- evaluates the reporting of significant risks;
- revises the management of significant risks;

**Table 2:** Statement on the relevancy of the internal audit activities performed in the organization

	YES	NO
Are there any internal audit procedures?	75 %	25%
Is there an audit plan based on risk assessment?	50%	50%
Is the information collected and processed?	66.7	33.3%
Is audit evidence collected?	50%	50%
Is the audit report prepared?	100%	-
Are recommendation considered for implementation?	100%	-

On the other hand, inadequate corporate governance impairs the efficient allocation of capital in the economy, hinders investment in administration and lowers the confidence of capital holders. James D. Wolfensohn, the former president of the World Bank once said: *corporate governance is more important for the world economy than the government of countries* (Cannon, D.M., Godwin, J.H., Goldberg, St. R., 2008).

**Table 3:** Correlation between the benefits and the disadvantages of implementing internal audit

Nr	Statements	Rating					
		1	2	3	4	5	6
<b>A</b>	<b>Internal audit conveys the following advantages/benefits to the organisation</b>						
1	It helps the business meet its objectives	5.3	8.8	17.5	43.9	10.5	14
2	It organizes and ensures the efficient functioning of the internal control system	5.4	3.6	19.6	41.1	16.1	14.3
3	It enables the proper running of external audit	3.8	1.9	15.1	39.6	17	22.6
4	It improves the efficiency and effectiveness of risk management	5.5	5.5	18.2	32.7	20	18.2
5	It helps diminish the costs of external audit	10	10	2	38	16	24
6	It issues recommendations that add value by improving the audited activity	5.6	5.6	18.5	31,5	22.2	16.7
7	Follow-up of the results after the management has implemented the recommendations of internal audit	5.8	3.8	7.7	40.4	25	17.3
8	Development of the quality assurance techniques	5.5	1.8	20	40	12.7	20

9	Constant bettering of professional competencies and experiences	7.1	3.6	10.7	39.3	23.2	16.1
<b>B. Internal audit generated the following disadvantages for the public organisation</b>							
1	High costs related to the internal audit function itself	10.7	21.4	21.4	12.5	10.7	23.2
2	Likelihood that IA may generate management tensions and discontent in the organisation	12.2	25.5	14.5	20	7,3	20
3	Likelihood that IA may generate employee tensions and discontent in the organisation	13	20.4	18.5	16.7	11,1	20.4
4	IA does not perform its risk prevention and control function	17.3	19.2	9.6	11.5	15,4	26.9
5	Failure to identify in due time any evidence of fraud or error in the organization	17	20.8	17	5.7	15,1	24.5

(1 = not at all; 2 =to a small extent; 3 = to an average extent; 4 =to a large extent; 5 = completely; 6 = don't know / don't want to answer)

Internal auditors provide assurance in terms of the feasibility and relevance of informing an organisation and its internal control. In a rapidly changing environment, with global competition, new types of organisational structures and up-to-date information technology, the measures the government takes in relation to present business organisations and the recent past are relatively less important, while the information and the steps to be taken in the near or distant future are much more decisive.

**Table 4:** Relevancy of the missions accomplished by the internal audit service

Nr	Statements	Rating					
		1	2	3	4	5	6
1	Audit of the human resources function	3.6	7.1	14.3	33.9	19.6	21.4
2	Audit of the legal function	7.8	7.8	17.6	25.5	17.6	23.5
3	Audit of IT systems	6	14	16	20	24	20
4	Audit of financial and accounting activities	3.6	5.4	5.4	25	41.1	19.6
5	Audit of the purchasing process	3.8	5.7	11.3	22.6	37.7	18.9

A closer look at the above table will reveal that the subjects answering the survey believe that the main priorities are the auditing of the financial and accounting activities (41,1%), the auditing of public procurement (37,7%), the auditing of the human resources of the organization (33,95%) and the audit plan of the public authority should not overlook the audit of the legal function and of the IT systems (with 25,5% and 24%, respectively).

Basically, the focus has shifted from the internal audit function to the threats undermining the strategies.

The objectives set by the organisation for the internal management control system guarantee that:

- risk management is a key part in the strategic management of the business;
- there is a positive approach to assuming risk;
- risks are considered when any decision is made;
- opportunities are capitalized by actively managing the risks and threats that may postpone success.

In order to meet these objectives, the organization will adopt the following approach:

- definite responsibilities, roles and reporting rules for risk management will be delineated and observed in all functions and departments;
- a program for training and learning opportunities will be introduced in order to supply managers with the acquisition and development of the skills and competencies needed for risk management;
- risk assessments will be incorporated and treated as part of decision-making, planning and revision of company operations;
- the measures taken for managing individual risks will take into account the potential occurrence and impact of these risks on the successful completion of the set objectives;
- an updated record that will be accessible to all who need it will identify all the strategic and operational risks, will supply estimates/identification/assessment and recording of the current measures directed at managing these risks;
- risk management activities will be measured in relation to the company goals and objectives;
- all the levels of the organization, partners and majority shareholders will try to understand risk and its management, alongside risk treatment options within the organization.

#### **4. Conclusions and suggestions**

The design of an internal management system is a spontaneous procedure; it resembles the design of a car, which leaves the user no clue as to how the car can be driven. It can be driven aggressively or carefully. It can receive constant care, or it can be automatically controlled and benefit from temporary maintenance. The whole picture entails both the design and the instructions manual on how the car actually runs.

An actual scale of the process encompasses a cycle that runs from planning, operation, revision and back to planning. The main requirements for setting up and implementing internal control (GO no.119/1999) in an organization are as follows:

*general requirements:*

- to ensure the completion of the general objectives by systematically assessing the risks related to structures, programs, projects or operations and keeping these risks within acceptable levels;
- to guarantee the considerate attitude of the managing and administrative staff, as they are required to promptly respond to the requests of the management and to effectively support internal control;
- to guarantee the integrity and the competency of the management and administrative staff, as well as ensure that they know and understand the importance and the role of internal control;

- to set the specific objectives of internal control and ensure that they are adequate, comprehensive, reasonable and aligned with the mission of the organization and with its overall objectives;
- managing staff should constantly monitor all the activities and should comply with the obligation to take corrective, prompt and responsible measures whenever the law or the regulations are breached during certain procedures or when certain activities are performed in an immoderate, ineffective, and inefficient manner;

*specific requirements:*

- to keep written records on the organization of internal control, on all the operations of the entity and on all significant events, as well as to record and file the documents appropriately, so that they can be promptly accessed for analysis by authorized parties;
- to record immediately and accurately all the significant operations and events;
- to ensure that the approval and performance of the procedures is exclusively in the hands of specifically authorized parties;
- to separate the responsibilities related to operations between parties, so that the approval, control and recording should be adequately assigned to different individuals;
- to ensure competent management on all levels;
- documents and resources should only be accessed by authorized parties that also bear the responsibility of properly using and keeping these resources.

Basically, indirect reference is made to the generally accepted models of organizing internal control, i.e. the COSO and CoCo control frameworks, to the internal audit standards and to the international best practice principles.

COSO defines internal control as a process conducted by the Board of Directors, by the management and by the entire staff of the organisation, directed at providing reasonable assurance on the completion of the objectives of the organisation, in terms of:

- the effectiveness and the efficiency of the operations;
- the accuracy of the financial statements;
- compliance with the current legal standards and regulations;

The control framework developed by CoCo is relevant for the boards of directors, for the general and the first line management, suppliers and auditors as well. This framework had a much broader theoretical approach than the familiar COSO framework and employs the term of “control” rather than internal control.

# COMMUNICATION STRATEGY ABOUT BUSINESS MODELS: STAKEHOLDERS PERSPECTIVE

**Bojoagă Alexandru, Petrișor Ioan**

*West University of Timișoara Faculty of Economics and Business Administration,  
Timișoara, Romania*

*alexbojoaga@gmail.com*

*ipetrisor53@yahoo.fr*

**Abstract:** *Organizations inform stakeholders about their current and future activities, processes, created value, strategic intentions, and other information that may influence the established relationships. Organizations choose to communicate with stakeholders by different means and in varied ways. The annual report represents a way of communicating between companies and their stakeholders, and it is offering comprehensive information about how companies operates and creates value. The business model is an emerging concept in management literature and practice. The concept describes the logic by which a organization creates, maintains and delivers value for its stakeholders. Through annual reports organisations can communicate to stakeholders information about their business models. We investigated how information about business models is explicitly communicated through annual reports, and how this information is referring to stakeholders. Our paper aims to reveal which stakeholders are more often mentioned when organizations are communicating about business models through annual reports. This approach shows the attention degree given by organizations to stakeholders. We perceived this from a strategic point of view, as a strategic signal. Thus, we considered if the stakeholder is mentioned more frequent in the communicated message it has a greater role in communication strategy about business model. We conducted an exploratory research and have realized a content analysis. The analysed data consist in over a thousand annual reports from 96 organizations. We analysed the informations transmitted by organizations through annual reports. The annual reports were for a time period of 12 years. Most of the selected companies are multi-business, and are operating in different industries. The results show the stakeholder's hierarchy based on how often they were mentioned in the communicated messages about business models through annual reports. Based on our results the communication strategy about business model is focused primarily on delivering messages about external stakeholders. The most attention is given to customers, followed by suppliers and partners.*

**Keywords:** business model, stakeholders, business model innovation

**JEL classification:** M19

## **1. Introduction**

The business model term is becoming increasingly used among academics and practitioners. It is an emerging concept in management and strategy literature, with accelerated growth after the year 1995 (Ghaziani and Ventresca, 2005; Zott et al. 2011).

The concept became popular in e-business research, and researchers used it to

explain how the new business, based on the internet created value (Timmers, 1998; Rappa, 2001). Nowadays, the concept is largely used to explain how value is created for every business. The idea that every business organisation has an business model is shared among many researchers (Chesbrough, 2007; Gambardella and McGahan, 2010).

Despite the fact that the business model concept is widespread in management and business vocabulary, there is no widespread shared definition among researchers (Lecocq et al., 2010; Zott et al. 2011), and some times the concept is used without a clear definition (Chesbrough, 2007).

The business model concept is defined in various ways by different authors, but the common idea, shared by many researchers is that the business model helps to explain how organizations creates, delivers and captures value (Amit and Zott, 2001, Johnson et al. 2008; Teece, 2010; Osterwalder and Pigneur, 2010).

According to Casadesus-Masanell and Ricart (2010) the business model concept is used by strategy scholars to describe the logic by which the organizations creates, distributes and captures value for stakeholders.

Every business model consist in more interconnected elements, that, taken together, creates, delivers and captures value. In the business model literature there are several opinions about which are the business model components.

There are some commonalities about business models components proposed by various authors (Rappa, 2001; Brousseau and Penard, 2006; Bonaccorsi et al., 2006; Johnson et al. 2008; Pigneur and Osterwalder, 2010): value proposition, revenue stream or incomes, cost structure, partners, clients, capabilities and processes.

Organisations communicate to stakeholders information about their business models. This information can refer to one or more business model components and it may be addressed to one or many stakeholders. Organizations choose to communicate with stakeholders by different means and in varied ways: presentations, press releases, meetings, annual reports, commercials etc. For example, organizations can express a new value proposition to its customers through a product and/or service presentation or advertise it through different marketing channels.

In our paper we studied how information about business models is explicitly communicated in annual reports. We have chosen the annual report because it offers comprehensive information about companies. The annual reports are primarily intended to give shareholders information about the company's activities and financial performance, but also include relevant informations about and for other stakeholders.

## **2. Methodology**

Our paper investigated how information about business models is explicitly communicated in annual reports, and how this information is referring to stakeholders. We have analysed the messages about business models and which had explicitly mentioned one or more stakeholders. The messages were interpreted as strategic signals and we highlight the assign attention given by organizations to each stakeholders when communicating messages about the business model. From the strategic point of view, as a strategic signal, we considered that if a stakeholder is mentioned more frequent in the communicated messages, than it has a bigger

role in the communication strategy about business model. Thus, our paper aims to reveal which stakeholders are more often mentioned when organizations are communicating about business models through annual reports.

The analysed data consist in 1124 annual reports from 96 organizations. The annual reports are for a time period of 12 years (between 2000 and 2011 inclusive). We chose the top 100 companies from Fortune 500 (of year 2011), and then selected only those for which we have obtained a number of over 8 annual reports. Most of the selected companies are multi-business, and are operating in different industries. We conducted an exploratory research and have realized a content analysis. We considered paragraphs as the context units and sentences as the recording units. First we have selected the annual reports in which the "business model" term was mentioned explicitly, and then, all the paragraphs that contained this term were chosen for analysis.

Then, we identified from those paragraphs the sentences containing explicitly the "business model" term, and also those that had a direct reference to a stakeholder. We have taken into consideration the following stakeholders: banks, clients, suppliers, partners, shareholders, employees and the government. Aiming to identify the references to stakeholders, we searched for the following terms (both singular and plural): "customers", "clients", "users", "shareholders", "banks", "suppliers", "government", "partners", "employees" and "stakeholders".

We calculated the frequency of those sentences that contained both the "business model" term and a direct reference to stakeholders. The frequencies were calculated for each stakeholder.

Also, we calculated the frequencies of all sentences (from paragraphs) in which were explicitly mentioned the stakeholders, regardless of the explicit message about business models. The frequencies were calculated for each stakeholder.

After, we searched to see if the messages from the analysed paragraphs and sentences were correlated.

### **3. Results and Discussions**

Organisations communicate to stakeholders information about their business models through annual reports. From the strategic point of view this information can represent a strategic signal. All stakeholders have a role in the business model, they help creating value and also capture a part of it. We assumed that if a stakeholder is mentioned more often in the explicit messages about business models, then the strategic signal is more powerful, and we had interpreted as a bigger role for that stakeholder in the communication strategy about business model. Thus, we wanted to hierarchize stakeholders based on how often they are mentioned in messages about business models.

We identified the sentences containing explicitly the "business model" term, and in the same time, a direct reference to a stakeholder.

The results (Table 1) highlight the attention given by organizations to each stakeholder when communicating messages about the business model.

**Table 1:** Stakeholders - frequency of occurrence in explicit messages (in phrases) about business models

<b>Stakeholders</b>	<b>Frequencies (intersection of business model term and stakeholders reference – in phrases)</b>	<b>Percent (%)</b>
Client/Customer/User	165	55.37
Supplier	32	10.74
Partener	32	10.74
Shareholders	22	7.38
Government	19	6.38
Bank	16	5.37
Employees	11	3.69
Stakeholders	1	0.34
<b>Total</b>	<b>298</b>	<b>100.00</b>

In our analysis we summed up the frequencies of the following terms: "clients", "customers" and "users". We are aware of the differences between the meaning of the terms, especially for e-businesses in which users are not similar with clients. However, we made only one dimension for clients/customers/users based on value proposition perspective. The value proposition is one of the key components of a business model. It is a bundle of products and/or services and it represents the benefits that a company offers to its customers. A user can be viewed as any entity who uses or consumes a good or service to obtain a benefit or to solve a problem and who may or may not be the purchaser of the item. So, because users benefit thanks to organization's value proposition, we included them among customers. In table 2 we present the frequencies for each term ("client", "customer", "user") that composed the client/customer/user dimension.

Our results show that most often the explicit messages about business models contain a direct reference to customers. Based on our results we consider, from strategic point of view, that customers have an important role in the business model.

**Table 2:** Clients/customers and users - frequency of occurrence in explicit messages (in phrases) about business models

Stakeholders	Frequencies (intersection of business model term and stakeholders reference – in phrases)	Percent (%)	Frequencies (stakeholders reference – all sentences in the paragraphs)	Percent (%)
Client	38	12.75	72	11.04
Customer	116	38.93	219	33.59
User	11	3.69	30	4.60
Total (Client/ Customer/User)	165	55.37	321	49.23

Also, according to Osterwalder and Pigneur (2010:20) “customers comprise the heart of any business model”, and also the business model can be designed around a well defined customer need.

The well known importance of the customers is that they have the ability to influence the firm's ability to generate incomes. From the business model perspective, the customer can be viewed more than just an actor that influence the organisations' revenue stream.

In the business model literature, customer is a frequently considered as one of the key components of business model. Beside that, many other business model components are close related and influenced by this important component.

For example, in great proportion, the value proposition is shaped after customer characteristics and needs. Based on the chosen value proposition, the companies are using various key resources, key processes. Also strategic relationships are shaped to serve the assumed objectives, and so on.

Beside the fact that the customer is viewed as an important component in business models because it is important for designing firm's value proposition, according to Plé et al. (2010), the customer is considered as a resource for the business model. The customers can participate at the innovation or production process of a firm. Based on the authors' research (Plé et al., 2010), the customers can contribute with the following inputs: relational, physical, mental, emotional, financial, temporal, and behavioral.

Our results show that second, after customers, the explicit messages about business models frequently contain a direct reference to supplier and partners. They also have an important role in the firms' business models. These stakeholders are treated in the business model literature as components of the business model.

Both suppliers and partners contribute at the creation and capture value. Companies create partnerships and nurture good relationships with supplier in order to reduce risks, optimize activities, and have access to resources.

Our analysis reveal that the other stakeholders: shareholders, banks, government and employees have relative small and close scores. We consider that the

communication strategy about business models is more focused on external stakeholders: customers, suppliers, partners, government, and banks. And from this external stakeholders, more attention is given on the ones that have a greater role in creating value.

The shareholders are the receivers of the messages. The annual report is primarily addressed to shareholders, and they are informed about relationships with other stakeholders. We believe that this could have a negative effect on frequencies relating to shareholders. Also, the employees are very important internal stakeholders, however, because the communication strategy about business models is more focused on external stakeholders these results are explicable.

The results also show that the explicit messages about business model are focused on each stakeholder, and are referred very rarely in the same time to all stakeholders. This means that organizations have clear messages related to each stakeholder in part.

We analysed the importance given by organizations to stakeholders in those phrases that explicitly contained the business model term and, also, in all phrases from selected paragraphs (the paragraphs that contain the "business model" expression). The purpose was to see if the analysed phrases contain the same strategic signal as selected paragraphs, from the perspective of communicated messages which mention stakeholders. We considered that if we obtained similar percentage frequencies, the messages are correlated, and a unitary signal was transmitted about stakeholders. The result (table 3) show the frequency of all phrases (referring to stakeholders) from the selected paragraphs. The result show that the stakeholders' hierarchy remain much the same from the point of view of strategic signal interpretation.

**Table 3:** Stakeholders - frequency of occurrence in paragraphs about business models

Stakeholders	Frequencies (stakeholders reference – all phrases in the paragraphs)	Percent (%)
Client/Customer/User	321	49.23
Supplier	78	11.96
Partener	76	11.66
Government	50	7.67
Shareholders	46	7.06
Employees	46	7.06
Bank	29	4.45
Stakeholders	6	0.92
Total	652	100.00

We consider that the strategic signals highlighted from both analysed phrases and paragraphs are much the same. Pearson's correlation test indicate a strong positive correlation ( $r = 0.996$ ,  $p = 0.000$ ).

The results (table 4) show that the difference (procentual) between frequencies obtained from the analysed phrases and paragraphs does vary a little, but not significant. The biggest frequency difference appears for customers about six percents. This can be interpreted that the messages are more targeted in phrases on customers than in the rest of the paragraphs. However, the difference does not change the hierarchy, and does not affect the meaning of the strategic signal.

**Table 4:** Stakeholders - frequency variation (procentual)

Stakeholders	Percent (intersection of business model term and stakeholders reference – in sentence)	Percent (stakeholders reference – all sentences in the paragraph)	Difference (Percent)
Client/Customer/User	55.37	49.23	6.14
Supplier	10.74	11.96	-1.22
Partener	10.74	11.66	-0.92
Shareholders	7.38	7.67	-0.29
Government	6.38	7.06	-0.68
Bank	5.37	7.06	-1.69
Employees	3.69	4.45	-0.76
Stakeholders	0.34	0.92	-0.58
Total	100.00	100.00	0.00

#### 4. Conclusions

We investigated how information about business models is explicitly communicated through annual reports, and how this information is referring to stakeholders. The paper reveals which stakeholders are more often mentioned in explicit messages about business models through annual reports. This information was investigated from a strategic point of view, and it was perceived as a strategic signal.

Thus, we assumed that if a stakeholder is mentioned more frequent in the communicated messages, it has a greater role in organization's communication strategy about business model. We do not exclude the importance of any stakeholder and their vital role for organizations. But, we consider that the importance given by organizations through communication is different.

The annual report is primarily addressed to shareholders, and they are informed about other stakeholders, we think that this could have a negative effect on frequencies relating to shareholders, and their role could be more important.

Organizations are using clear messages related to each stakeholder, and are referring very rarely, at the same time, to all stakeholders.

Our results show that the communication strategy about business model is focused primarily on delivering messages about external stakeholders. Utmost attention is given to customers, followed by suppliers and partners.

This paper represents a exploratory and preliminary study in explaining how stakeholders are viewed from the business models perspective. We have analysed

only explicit messages about business models (with reference to stakeholders) communicated through annual reports annual reports. For more insightful findings, other communication materials from other communication channels could be investigated in future research. Our results show the characteristics of a generic communication strategy, because we had analysed all messages express by all organizations, togheter like single unit. More research will be done in the near future to see if this characteristics differ throughout the years or from one industry to another.

## ETHICAL ASPECTS OF ENVIRONMENTAL MANAGEMENT

**Cîrstea Ștefan Dragos**

*Faculty of Economic Science and Business Administration, Babeș-Bolyai University, Cluj-Napoca, Romania*

[stefan.cirstea@yahoo.com](mailto:stefan.cirstea@yahoo.com)

**Abstract:** *The purpose of this article is to outline the main economical and social benefits that can be obtained by adopting an ethical attitude of the organisations which use a performant environmental management. From the idea that the human being is the master of nature, it was passed to the view according to which the human being must ensure a balance between consumption and the use of resources. In order to achieve our goal we identified the factors that lead to long term or even permanent destructive effects over the environment and we briefly present the reasons for which the organizations adopt and implement environmental management systems. Also, the difficulties encountered in implementing environmental strategies have been briefly enumerated and the competitive and economic advantages that can be achieved by adopting an efficient environmental management and the main reasons that grant to the environmental management a special significance were exposed. This theoretical paper emphasizes the importance of the adoption by organizations of a "green behavior" and reveals correlations between sustainability, economic growth and environmental performance in organizations. The analysis of the ethical aspects of environmental management shows the links that can be created between the development of an ethical culture of organizations and the achievement of the environmental excellence. The research provides an overview of the concept of environmental ethics and encloses it within the scope of environmental management. Someone needs to explain why an increasing number of organizations, both large and small, are setting up environmental management systems, making environmental investments and reducing risks over and beyond legal requirements, even when the benefits are not at all obvious, even in the long run. Also, this paper provides some practical examples of organizations environmental problems and points out how these organizations adapted their environmental strategies. The main conclusion of this conceptual paper is that organizations' competitiveness in any industry and environmental protection are two interconnected concepts and we believe that there can be no excellence in business without excellence in environmental protection or vice versa.*

**Keywords:** *environmental management; environmental ethics; business ethics; environmental performance.*

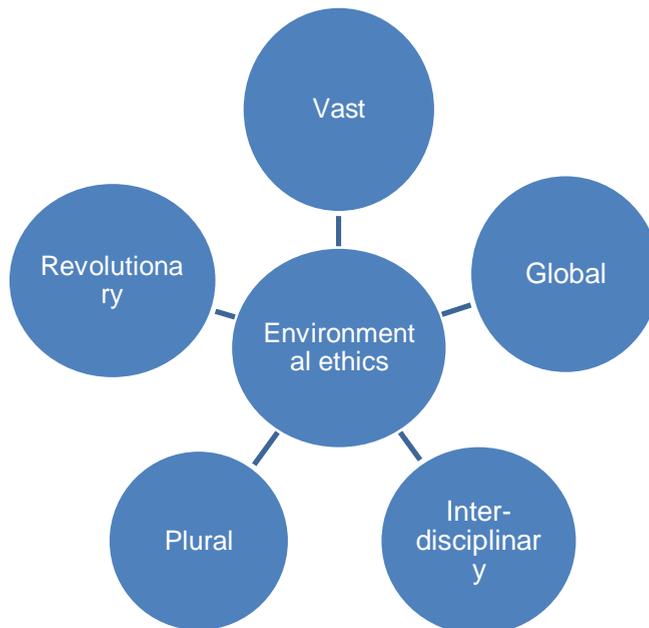

**JEL classification:** *M10, Q56*

### **1. Introduction**

Ethics, in its origins and in actual sense, is considered a branch of philosophy. We define ethics as a systematic study of morality and human behavior that attempts to extract from our moral codes and basic beliefs, concepts that morality is based on. By ethics we mainly refer to morality - imagining how we express our moral judgments, how they are justified if challenged, what weighs significantly in a

conversation, and how we know if we really reached a valid conclusion. One of the studied aspects of ethics is the environmental ethics or the way in which organizations try to face the challenges of the business environment, while demonstrating a high degree of morality and respect towards the environment. Undoubtedly, we can state that environmental ethics is a field that aims to provide a moral justification for the cause of global environmental protection. According to Yang (2006), the main features of environmental ethics (Figure 1) are:

- Environmental ethics is vast – including not only all people everywhere, but also animals and the whole nature.
- Environmental ethics is interdisciplinary - There are many overlapping concerns and areas of consensus among environmental ethics, environmental politics, environmental economics, environmental sciences and environmental literature
- Environmental ethics is plural - Anthropocentrism, animal rights theory, biocentrism and ecocentrism all provide unique and, in some sense, reasonable ethical justifications for environmental protection
- Environmental ethics is global - Ecological crisis is a global issue and environmental pollution does not respect national boundaries
- Environmental ethics is revolutionary – it criticizes the materialism, hedonism and consumerism that accompanies modern capitalism and instead, it calls for a 'green lifestyle' that is in harmony with nature.

**Figure 1 – The features of environmental ethics**

Source: Own projection

Throughout time, environmental ethics and business environment were considered as two opposing areas, sometimes even incompatible. Such a situation has often been translated in terms of environmental policy and management as a major contrast between supporters of economic performance and environmentalists. To strengthen the things mentioned above, we can take the example of a manager who, while facing financial problems, has to choose between saving the company and consolidating its position on the market or implementing environmentally beneficial actions. Choosing to consolidate the financial position of the organization, the same manager will have to argue why more and more companies, regardless of their size, analyse their environmental impact, implementing environmental management systems or adopting decisions to reduce environmental risks even beyond law.

The Industrial Revolution represented a period when environmental protection was not taken too much into account, excelling only the economic interests of organizations that aimed only at economic progress, economic development at any cost and intensive use of all categories of resources. The environment has been transformed into a "stage" of economic competition between the major industrialized nations.

A turning point, both for society and for business field and environmental protection, is the '90s. Environmental issues have become issues of business and play an increasingly more important role in the organizations' activity. One of the measures taken in this respect was the creation of tools to control and try to improve the environmental performance of an organization. An example of such tools of analysis and control is the environmental management systems and environmental audits.

## **2. Environmental Management – A Current Challenge**

Environmental management concept embodies the concept of sustainable development through various mechanisms that combine technological processes, sustainability and economic growth in the production processes of goods and services. We consider that an environmental management system implemented correctly in the management system of any organization contributes decisively at increasing its competitiveness with a significant reduction of environmental impact. Among the benefits that a competitive environmental management can bring to an organization we can mention: reducing the costs, improving the public and social image of the organization, conservation of non-renewable natural assets, attracting new customers, easier penetration in some markets, improving environmental performance improving the relations with central and local public authorities.

Among the main reasons which give great importance to environmental management, we can mention:

- Professional ethics;
- National and international legal rules;
- Economic profitability
- Macroeconomics
- Pragmatism.

Thus, many companies have realized the need to identify new production technologies and to implement actions that will result in improved environmental performance. Economic efficiency has led organizations to implement appropriate environmental management processes to meet economic and production intentions, having a proactive attitude towards improving their processes.

The main reason for which an organization should consider implementing an effective environmental management system is to protect, first, the health of the community to which it belongs and of all people and ecosystems that may be affected, and to increase their contribution to maintaining and improving environmental quality.

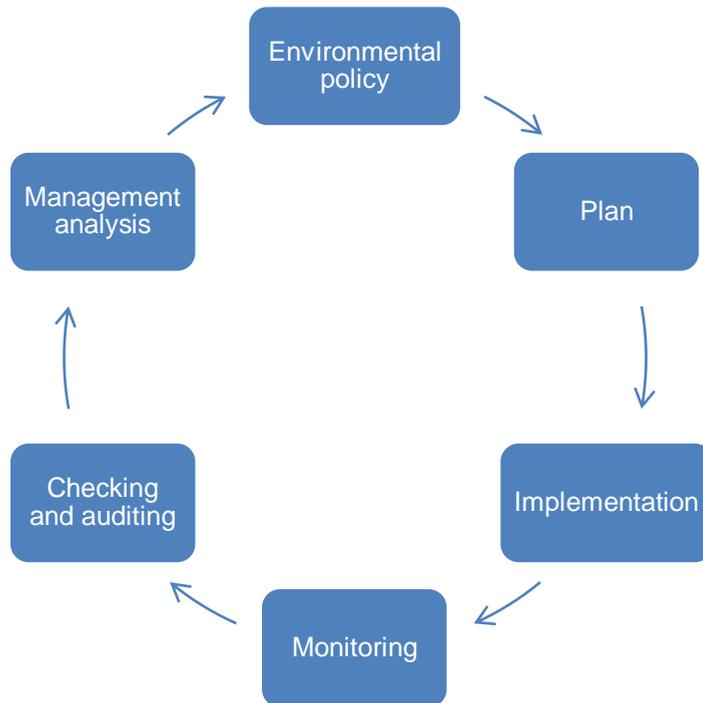

On the other hand, one shouldn't completely neglect economic and competitive advantages that can be achieved by adopting effective environmental management, among which we can mention:

- Improving control over expenditure;
- Improving the image and relations with the external environment;
- Facilitating the obtaining of certain approvals and authorizations;
- Increasing profitability of the organization
- Meeting the requirements of investors and other stakeholders.

At the same time, we can certainly say that the environmental management system is a systematic approach that aims to incorporate environmental goals and priorities in routine operations of an organization. Netherwood (1996) points out that every business is unique when developing their own environmental management systems. This is because each organization has its own management structure, products or services, processes, and financial and political priorities. The adopted systems should continually measure, plan, improve and revise the organization's strategies for achieving both business and environmental excellence.

Ledgerwood et al. (1997) noted that environment audits require a balance between the various actions and values, as opposed to financial audit which involves most of the time, the application of hard and fast action. Environmental audits can be designed to verify compliance with specific environmental regulations, to evaluate the effectiveness of environmental management systems or to assess the analyzed organization's environmental risks. The benefits of using these tools to check and control vary depending on the objectives and scope of environmental audits. Some common benefits of environmental audits can include: awareness of how to fulfill legislative requirements, demonstrating environmental responsibility, confirming compliance with the organization's environmental policy, awareness of how to improve environmental performance.

Just as James and Bennett (1994) noted, an environmental management system is a cyclical process (Figure 2) consisting in a number of methods that should be used in order to achieve an effective assessment of environmental performance. We agree with what Mosley (1996) said suggesting that such a cycle can be seen as a dialogue between the measures established by specialists and functionality required by managers.

**Figure 2 – The stages of an environmental management system**

Source: Own projection

In general, environmental management systems encourage companies to accept responsibility for protecting the environment, ensuring continuous improvement of the way in which they manage environmental requirements. When implementing an environmental management system, each organization must adopt environmental strategies correlated with its environmental performance by integrating all management functions. An efficient management without a proper analysis of environmental policy, can never be achieved. Contemporary organizations should aim to achieve excellence in business, including in their strategies a range of concepts without which such a target is difficult to achieve. In the specialized literature we can distinguish four major concepts:

- sustainability - the society should not use more natural resources than those that the natural environment can regenerate.
- qualitative growth (sustainable) - any organization should aim at sustainable growth according to the inhabitants; this growth can be achieved by a decreasing or constant use of natural resources and a decreasing or constant environmental expense.
- sustainable development - meeting the development needs of the present generation without compromising the ability of future generations to meet their own needs.

- sustainable society - a well-structured society that behaves so that it can exist for an indefinite number of generations.

### **3. Ethical Aspects of Environmental Management**

There are three major significance that the environment can have for humanity: (1) quality of life, (2) intrinsic value and (3) the means of production. An environmental problem occurs when an individual or organization believes that the relationship between him and the environment has suffered some unwanted changes. This happens when one of the three meanings is affected so much that a group of people considers it to be problematic. Consequently, environmental problems are not individual but are social problems.

The problems regarding environmental protection currently hold special significance, not only in terms of the technical aspect, but also morally. The idea that man is the owner of his nature turned into the perspective that man must ensure a balance between consumption and use of resources.

Currently, environmental issues evolve as fast as mankind develops and we get to face increasingly more destructive consequences of this development. Unfortunately, environmental issues are complex, specific and complicated because of their economic, social, cultural, technical size that we need to consider when trying to solve them. This complexity can be reduced only by changing human behavior towards the environment. Thus, it is necessary for humanity to adopt and harmonize ethical dimensions with scientific, economic, social and legislative aspects in order to control the environmental pollution and aiming at achieving an effective protection of the environment.

The environment is affected by a number of factors that generate destructive effects in the long-term or even permanently. Everything starts from the lack of minimum ethical principles and it continues with items that have a negative impact on the environment as directly as possible. Among the factors that most often bring damage to the environment we can mention:

- The lack of research responsibility - the desire to achieve profit regardless of the environment;
- The technology - a growing consumption of energy, having as main consequence the weakening of the environment;
- The religious orientation – it is considered that the only reason of nature's existence is to serve man;
- The lack of environmental education - too few educational institutions give due consideration to showing environmental protection principles among children and adolescents;
- The overdevelopment - its main effect in the long term is an economic downturn;
- The over consumption - the main factor generating destructive effects on the environment;
- The lack of social responsibility of most organizations - which had as main objective the achievement of profit by any means.

Unfortunately, the sense of voluntary responsibility and the desire to become sustainable were not the main motivations for most organizations when they undertook a series of environmental initiatives. The main reason that these actions took place was to comply with legal requirements and regulations. Thus corporate culture, aggregation of expectations, beliefs and values, must perceive greening in

the long term as a key business value, which should become an inherent activity, rather than a conscious problem.

We're pretty close to the end of current consumption habits and current lifestyle. Some problems occur suddenly and unexpectedly, so that the moment science will be caught up is inevitable. For example, we don't know when an ecological crisis might occur, in addition to the economic crisis of the last years or which will be the environmental impact of certain current technological breakthroughs such as the use of nanotechnology, the use of biofuel and the use of alternative energy. Therefore, it is imperative that every individual and every organization builds their own ethical framework to relate with nature through the assessment of the consequences of their own behavior on nature (Paslack, 2012).

Environmental ethics is a discipline in applied ethics which deals with the moral analysis of how companies, shareholders, employees, buyers act on the environment. Environmental ethics has emerged as a new discipline that joins ethical values of the natural world (Van de Veer and Pierce, 1994; Armstrong and Botzler, 1998). Environmental ethics tries to engross some principles and moral values on the environment, in the same way in which ethics, in general, has an impact on business, medicine, engineering or technology. Many organizations face problems incorporating some ecological principles such as sustainable development and environmental protection in their management practices.

One of the main reasons for the difficulties in implementing environmental strategies, is the difficulty to find a balance between economic and social factors. Aiming at effective participation in global environmental protection, environmental ethics specialists began to be actively involved, since the beginning of 1990, in implementing environmental ethics principles in establishing the organizations' policies. G. Winter (1995: 36-56) focuses on three main reasons for the introduction of good environmental practices:

- accepting responsibility for the conservation of natural resources;
- awareness of development opportunities through the establishment of measures to protect the environment and reduce costs, thereby increasing income;
- avoiding or reducing the risks, such as ignoring environmental problems or facing economic sanctions.

Therefore, we wanted to continue with identifying several instances where environmental ethics was both a central and important point in addressing some economic initiatives of organizations. A first example is that of Shell Company, that in 1995 wanted to drill in Brent Spar marine platform in the North Sea, and even if they had all the legal approvals of British government they became victim of Greenpeace campaigners and boycott consumers. As a result, the legal decision to install offshore was finally, not implemented, because the company did not take into account the demanding ethical expectations of the society.

Another example is that of Mc Donald's Company, which around 1970 was heavily criticized for its environmental policies. Since then, McDonald's has started a comprehensive program to reduce the quantities of packing they introduce on the market. Thus, if the average weight of the container for a menu was of 46 grams at the beginning of the 80's, today's average weight packaging is of 25 grams, resulting in a 46% reduction in the amount of packaging used.

According to Stainer and Stainer (1997) British Telecom, in their publication *Putting the Environment on the Agenda* (1996), point out that, in the pursuit of their mission to provide world class telecommunications and information products and services, they exploit technologies which are basically “friendly” to the environment. Furthermore, they aim to minimizing the impact of their operations through a programme of continuous environmental improvement.

#### **4. Conclusions**

In conclusion, we can say that the activities of environmental policy, audit or establishing an organization's strategy must be conducted in an ethical climate that basically aims at creating a corporate culture of high morality. However, both management and employees need guidance on how to deal with ethical issues. Therefore, several European organizations have established and implemented some codes of ethics that should address environmental concerns. They range from the simple phrase, such as Digital Equipment Corporation to the complete and explicit statements such as Shell code of ethics.

Environmental ethics is a field that aims to provide a moral justification of all decisions regarding the the worldwide environment. The fact that environmental ethics is vast, global, plural, revolutionary and interdisciplinary determine us to pay a growing attention to this area that can lead to the implementation of a competitive and sustainable environmental management.

One of the main motivations for companies to implement environmental management strategies is to comply with the law and we can observe that quite many organizations find it difficult to create balance between some economic reasons and the social factors. We believe that the benefits that add value to organizations by adopting an ethical environmental management are: sustainable development for a sustainable society, ensure a etichal balance between consumption and use of resources, cost reduction by creating a „green” image. As shown in the examples presented, mostly, the ethical reasons urged the companies to review certain decisions and strategies, despite the fact that they were in accordance with the laws.

We support the idea according to which organizations' competitiveness in any industry and environmental protection are two interconnected concepts and we believe that there can be no excellence in business without excellence in environmental protection or vice versa. The ethical conduct of each and everyone must evolve from meeting legislative requirements to what is moral.

# THE CONSEQUENCES OF ORGANIZATIONAL CHANGE ON THE HUMAN FACTOR IN THE TEXTILE INDUSTRY

**Chira Monica, Marian Liviu**

<sup>1</sup> Technical University of Cluj-Napoca, Romania

<sup>2</sup> Petru Maior University of Targu Mures, Romania

monichiradan@yahoo.com

Liviu.Marian@yahoo.com

**Abstract:** *The study of this paper emphasizes the aspects of change in organizations from the textile industry and the consequences of their implementation on human resources. The present paper falls within the non-experimental quantitative research, as well as having an explorative side due to the fact that it explores a reality in order to discover whether there are certain relationships between the chosen variables. The research is transversal because the data collection is achieved by applying a one-time, ad hoc questionnaire that was built specifically for the conduct of a research, partially presented in this paper. The research method or the procedure used is the survey, the technique employed is the one of the questionnaire applied through the process called "self administration" and the investigative tool is the questionnaire on paper.*

*Along with a change in design or implementation plan and organizational culture, human resources contribute significantly to the success of any kind of change. Compared to the current process of globalization in which the economies and the financial markets are closely linked, and given the highly dynamic industrial climate that is characterized by items such as restructuring, relocation and subcontracting, Romanian companies appear to be aware that the social and ethical role of firms attracts increased attention on the living standards of employees. The resources of an organization in solving the arising problems are many, varied, and it depends only on its willingness to discover and capitalize. Difficult moments generated by implementing changes or the onset of seizures are such problems, which can not only have technical, but also human aspects. In managing the latter the human capital owned by the firm is undoubtedly important, but this must be combined with the quality of good management. The literature is replete with conceptual models of effective organization that can improve or streamline the industrial process, but a strategic orientation towards effective personnel policy is not very expensive, it being very necessary to ensuring the sustainability of the firm. For the textile industry to be successful, we need a better communication between industry and the education system and training, so that the needs and the qualification skills be clearly indicated in order to have a properly trained human resource. So, we can say that for the successful implementation of changes in the textile enterprises the material components, the financial and the human ones, should be combined, organized and updated with the aim of improving human resources management by specializing and training the personnel.*

**Keywords:** Textile, human resources, organizational change, organizational culture.

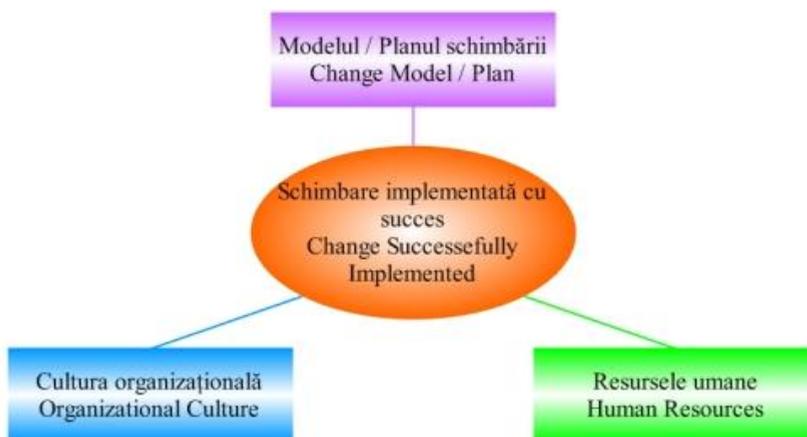

**JEL classification:** J24

## 1. Introduction

If the "structure" is the skeleton of the organization and the "process" is the nervous system or its infrastructure then the "employees" are the blood and the internal organs. Without understanding and mobilizing the energy of teams and individuals, no change, no matter how brilliantly conceived, will be viable. Understanding the employees, both as an inertia factor and as a lever for change, is a full understanding of what the company has and what are its needs in terms of complex skills, if the attitudes and leadership styles are suitable for the future trying to be created. (Kenney,1988).

To achieve a change strategy resources are required. These human resources can not be created overnight, because every "step" - training, restructuring through layoffs, retraining, recruitment, takes time. Changing culture raises the same issues. As for the success of a change in the company, the "corporate culture" is a double-edged sword. It is the mark of an organization that makes it unique, reflecting the history, ideas, values and behaviors of the organization. Without a good understanding of the traditions that underlie a particular organization changes that contradict them can be easily targeted and therefore will be rejected.

For the Romanian textile firms, the authors believe that successful implementation of change is determined by the following factors, shown in Figure 1: model and implementation plan for change, organizational culture and human resources that contribute decisively to the success of any kind of changes.

**Figure 1:** Factors contributing to the successful implementation of a change Source: (authors)

It can be said that the most valuable asset of a company is considered to be the human capital and its management lies at the boundary between science and art, therefore HR managers must possess equally relevant theoretical knowledge of business and personal skills in working with people(Armstrong,2001).

A strong culture can be considered the internal mark that gives to the organization's staff the same value as that given by the company's public relations department on foreign markets. Creating a suitable culture in a dynamic market is a challenge for

the current context: Culture is more important than the product. Increasingly often, companies have to sell culture and brand image, not just products, to defeat their competitors.

In the case of companies that have a strong culture, how to act is clearly systematized, it is communicated to the staff and even the newest employee knows and understands it. After all, in the case of the human resource management, forecasting plays a key role, if not a decisive role, in difficult times such as changes or crisis situations because the actions or the activities of a company are accomplished through people who have to be prepared for these moments, both professionally and individually, personally

## **2. Continuous training in the technological development**

The orientation towards a knowledge-based society requires investment in human resource development in order to encourage employees to acquire new skills and accept occupational mobility. At the same time, it is important to promote quality training offer and ensure its relevance in relation to skills, knowledge and individual needs. The acquisition of knowledge and skills can improved labor market position, while at the same time increasing productivity. Rapid changes in all areas cause a more dynamic spectrum of needs for new skills. „Human resources are seen as the crucial production factor, active and decisive, and the investment in training benefits both the person and the society” (Viăsceanu,2003).

The current situation shows that Romania has made progress in restructuring the system of continuous training. One of the courses of action to provide the necessary skilled labor / skills for companies is the lifelong learning policy correlated with labor market developments through wide consultation of social partners, businesses, other institutions / organizations involved in the system. (European Strategy for Employment).

### **2.1. The results of the research**

The Environment in which the research was done consists of textile profiled companies from Romania. For data collection a questionnaire was prepared for all human resource textile companies.

We chose in the sample to include the staff of several companies (SMEs and large companies), their structure reflecting the structure of human resources in this area. The choice of sampling strategy was made with judgment, thus companies in different cities namely (Arad, Timisoara, Baia Mare, Iasi and most of Satu Mare) having been selected in order to ensure a maximum possible representation, (Lewin ).

After a verbal participation agreement given by the management of each company, 1400 questionnaires were anonymously distributed, and of all the questionnaires we received a rate of 53%, that is 740 questionnaires. The period of practical research was 20.02.2012 -20.12.2012.

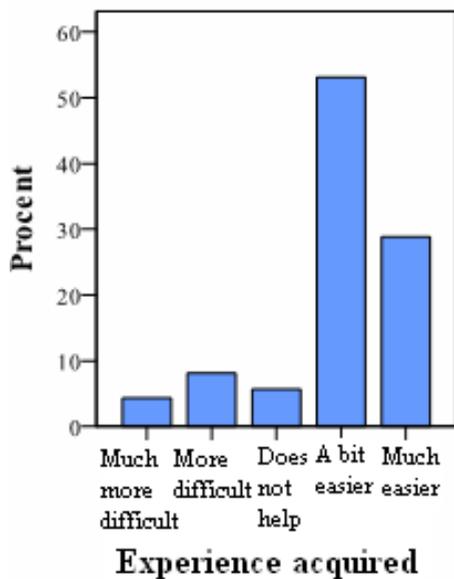

Following the questionnaire applied, we found: for employees to perform tasks properly, continuous training is required even if the utility is not always seen by the operators.

To "Question.1.3.": *The fact that a person goes through several organizational changes accumulating some experience helps him/her to overcome more easily the*

current changes?“ I had the following response: Much more difficult, more difficult, does not help, a bit easier, much easier.

**Table 1:** Usefulness of experience acquired throughout organizational changes

	Answers	Percent	Valid percent
Valid responses from 710 subjects	30	4.0	4.2
Much more difficult			
More difficult	57	7.7	8.1
Does not help	40	5.4	5.6
A bit easier	380	51.4	53.5
Much easier	203	27.4	28.6
Total answers	710	95.9	100.0
Missing answers: 30 subjects did not answer this question	30	4.1	
Total subjects	740	100.0	

**Figure 2:** Usefulness of experience acquired throughout organizational changes  
Source: (authors)

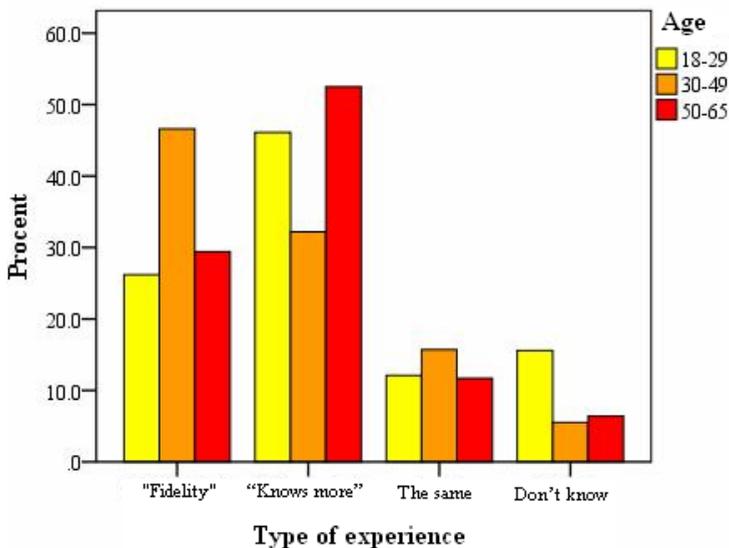

Responses were:

- 53.5% of respondents believe that any professional experience helps them to overcome a bit easier the present organizational changes;
- For only 28.6% of subjects work experience helps them move much easier through present changes ;

- The research results show that with age it is more likely to accept that professional experience may counteract any change;
  - There are differences between the answers given by the management of companies and the operators. The latter, in a small percentage believe that experience does not help, or helps quite little (much more difficult)
- To "Question. 2.5. *"In performing professional duties in terms of organizational change what experience helps more? The "fidelity" type (accumulated after many years of practicing one job) or that of "know more" (accumulated by practicing many professions)?*" I had the following response: "Fidelity", "knows more" Also, I do not know.

**Table 2:** Type of experience

	answers	Percent	Valid Percent
Valid responses from 732 subjects			
"Fidelity"	267	36.5	36.5
"Knows more"	309	41.9	42.2
The same	99	13.4	13.5
Don't know	57	7.7	7.8
Total responses	732	99.0	100.0
Missing answers: 8 subjects did not answer this question	8	1.0	
Total subjects	740	100.0	

**Figure3:** Type of experience and age  
Source: (authors)

The responses were:

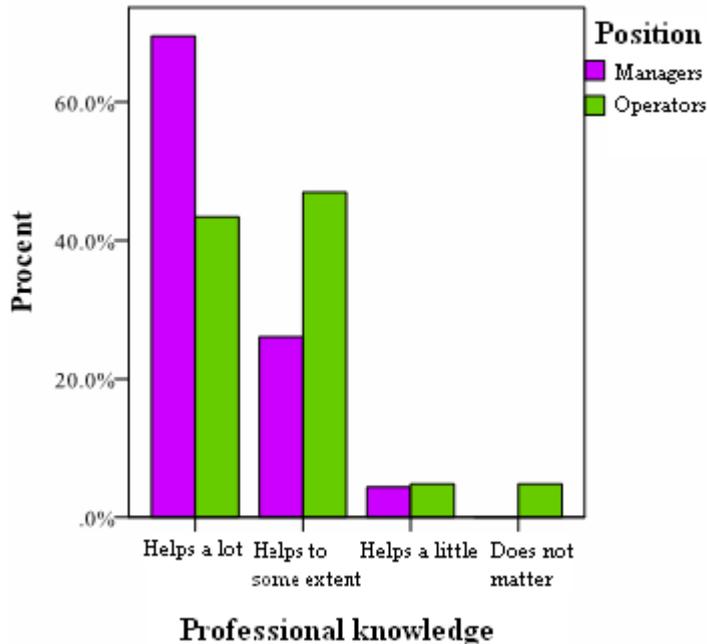

- 42.2% of respondents believe that for the achievement of professional duties in terms of organizational change, the "know more" type of experience accumulated by practicing more jobs, is more helpful while 36.5% believe that only the "fidelity" type of experience accumulated by practicing for several years one single job, can help in a time of change;
- subjects aged 30-49 consider that the "fidelity" type of experience accumulated by practicing for several years one single job, helps more. To be noticed however, that younger generations have felt the labor market as being very flexible and appreciate the experience of "knowing more" (accumulated by practicing many professions).
- The managers are those who want subordinates with experience, practicing several professions, while operators believe that for the achievement of professional duties in terms of organizational change, the "fidelity" type of experience accumulated by practicing more jobs, is more helpful.

To "Question. 2.7. *Before a change, or even during it, the organization can make available to its employees theoretical and practical knowledge through courses and trainings. How much would this knowledge help move more easily over change and get accustomed to the new circumstances?*" I had the following response: Helps a lot, helps to some extent, helps a little, does not matter.

**Table 3:** Professional knowledge

	Responses	Percent	valid percent
Valid responses from 724 subjects			
Helps a lot	324	43.8	44.8
Helps to some extent	331	44.7	45.7
Helps a little	32	4.3	4.4
Does not matter	37	5.0	5.1
Total responses	724	97.8	100.0
Missing answers: 16 subjects did not answer this question	16	2.2	
Total subjects	740	100.0	

Source: (authors)

**Figure 4:** Professional knowledge depending on the position in the company  
Source: (authors)

The responses were:

- approximately 90% of subjects considered that both the theoretical knowledge and the practical one help in a time of change;
- Managers argue that professional knowledge helps a lot, but most of the operators feel that it helps only to some extent;
- most respondents regardless of age, believe that by continuing professional qualifications they can adjust easier during organizational changes.

### 3.Conclusions

It can be said that the human factor is the key of the organizational changes if we take into account its qualifications and experience.

Garment textile and leather industry in Romania needs strong and relevant skills and abilities to successfully compete on this market. Of course they are different for each company. However, there are some common problems of competencies, skills, education and training that have an important role in increasing the competitiveness of many companies in the Garment Textile and Leather Industry.

It is needed now more than ever that manufacturers invest in training and in the specialization of labor, which is an important condition in the growth of the competitiveness on the textile and leather market. We must understand that the application of the law concerning the employer's obligation to periodically improve the workforce is also needed (NSTGLI).

In conclusion, the life of an organization, the change of any kind or the crisis situations are done through the people who have to be prepared for these times,

both professionally and individually-personally. Obviously, the human resources manager must act before these events take place, prediction playing an essential role.

# ENTREPRENEURSHIP CURRICULUM IN ROMANIAN UNIVERSITIES

**Cordea Claudia**

*West University of Timisoara, Timisoara, Romania*  
*claudia.cordea@feaa.uvt.ro*

## **Abstract:**

*The central focus of universities should be the improving the quality and quantity of entrepreneurs or students with an entrepreneurial attitude. We argue that the academic field of entrepreneurship is at a very low level in Romania on several axes and the University must determine the best fit for them given their students, their alumni, their stakeholders, the region and its economic base and the aspiration of institutions. Entrepreneurship should it be something that will have high and positive impact for students not just another course in the curriculum. Entrepreneurship is concerned with establishing new activities and about being able to perceive new opportunities. Entrepreneurship competence is relevant for all areas of working and business life, in both new and established activities and enterprises. The aim of this paper is to provide an analysis of the present situation and recent evolution of entrepreneurship education in Romanian universities and to discuss these courses and curricula match the demand for entrepreneurial competences. This paper presents a short summary of the status of entrepreneurship curriculum and different challenges. The information collected through the Internet refers to the academic year 2012-2013. The range of theoretical choices, objectives, publics, pedagogical methods and institutional context should be structured around a general framework.*

**Keywords:** *Entrepreneurship education; Romanian universities; Curricula; Learning process, Institutional context.*

## **1. Introduction**

Entrepreneurship has become an academic and teaching field (Davisson, 2003), considering the increasing number of programs and courses offering by universities. The promotion of entrepreneurship in education and training is an area that has been given broad priority in the EU. Due to emphasis in the Lisbon process on economic growth, entrepreneurship and innovation have been given increased attention within the education systems.

Despite the desperate financial disposition at universities today, entrepreneurship education continues to play a vital role at universities level. Increased competition from companies, international schools, the Internet, and a decrease in the number of foreigners applying to graduate schools has not stopped universities from building their entrepreneurship programs. This article will show that there is still a strong demand for entrepreneurship faculty.

The field of entrepreneurship education has been one of the hottest areas of study in higher education at colleges and universities throughout the world. Several researchers (see Finkle, 2001, Solomon et.al, 2002; Katz, 2005; Finkle, Kuratko, and Goldsby, 2006; Solomom, 2006) have done research on various aspects of entrepreneurship education.

Entrepreneurship education is able to address some of the deficiencies in the existing education system. Firstly, the development of entrepreneurial skills in the education system increases the supply of nature entrepreneurs in the country. A venture support system based on entrepreneurship education designed to stimulate and facilitate entrepreneurial activities, could result in a lower unemployment rate, increased establishment of new companies, and fewer failures of existing businesses. Entrepreneurship students do not simply learn small business information; they use it by writing business plans, launching and managing venture start-ups, and providing consulting services to prospective business owners (Kotts, 2011).

Nowadays, students have a need-to-know, short-term and goal-oriented world view that contrasts with the professor's values of life-long learning for learning 'sake (Lane, 2011). We must understand how curricular changes might affect student learning and how effective classroom teaching can accommodate changes in student learning styles and values.

There is a need to develop an education system that to a greater degree gives the students of today knowledge and skills adapted to the challenges of the future.

## **2. Data and methodology**

In order to elaborate a diagnosis regarding the current status of entrepreneurship education in Romanian higher education, we carried out a preliminary research. I selected seven universities from Romania. The most important criteria for selecting universities were: the most representative public university from each region from Romania which including also management and economics faculties.

The survey is based on data and information collected through the Internet. The information about the curricula offered by Romanian universities is available on the website. Once a course or curriculum was identified, it was easy to collect additional information about it. The Internet source is appropriate for the aim of this study as all Romanian universities supply information on their curricula and courses through this medium. All universities give basic information about the course on their web site, and most of them also supply detailed information about the content of the courses. The information was collected in 2013 from the website.

A common problem of survey about entrepreneurship courses is the separation of courses and curricula specifically devoted to entrepreneurship from those referring, more generally, to small business or innovation. In the analysis, we included all those courses and curricula that specifically referred to entrepreneurship. We also retained courses and curricula on small business and Management of innovation when they have a significant part dedicated to entrepreneurship issues.

As regard the cultural traditions prevailing in the Romanian university system, the one that has the greatest impact is the separation between theoretical and practical knowledge, the former being considering superior to the latter. Universities are the places where theoretical knowledge is developed and transmitted, with less attention paid to its practical use. This is reflected not only in the content of courses but also in the teaching methodology which is almost exclusively based on lectures with less consideration for the active role of students.

Information about courses related to entrepreneurship that have been identified in each university from our study is summarized in two tables. In Table 1 are summarized identified courses at undergraduate level and Table 2, courses at

master level as follow:

**Table 1: Entrepreneurship courses at first-degree level offering by Romanian universities (faculty of economics)**

University	Faculty	Course Title	Access Optional/ Compulsory	Credits (ECTS) No.
West University of Timisoara	Faculty of Economics and Business Administration	The Administration and Development of Tourism Enterprises; Entrepreneurial Simulation; European Business Environment and Competitive Strategies; Management & Leadership; Entrepreneurship & Leadership; Entrepreneurship Business Formation Start-up and Development; Entrepreneurial Marketing; E-business; Entrepreneurial Strategies and Business Internationalizations; Leadership and Entrepreneurship; Entrepreneurial Marketing; Entrepreneurship; New Product Development;	Compulsory and Optional	4-8
Babes-Bolyai University	Faculty of Economics and Business Management	Entrepreneurship; Internet usage in business; Marketing innovation and new products (optional); Business Communication;	Compulsory	4-6
Al. I. Cuza University	Faculty of Economics and Business Administration	Techniques and spirit of negotiation	Compulsory	6
Transilvania University	Faculty of Economics and Business Administration	Risk management; Business Communication; Entrepreneurship and Business Strategies.	Compulsory	5-6
Ovidius University of Constanta	Faculty of Economics	Entrepreneurial management;	Compulsory	4-6
University of Craiova	Faculty of Economics and Business Administration	Entrepreneurship, Entrepreneurship and business development (master program);	Compulsory	4-6

The Bucharest University of Economic Studies	Business negotiations; Social Entrepreneurship; Entrepreneurship and Business development (master program); On-line business administration; Business negotiation strategies and conflict management	Compulsory	4-6
--	--	------------	-----

University name	Faculty name	Course Title	Access Optional/ Compulsory	Credits (ECTS) No.
West University of Timisoara	Faculty of Economics and Business Administration	Innovation Management, E-business, SME management	Compulsory and Optional	6
Babes-Bolyai University	Faculty of Economics and Business Management	Investment management	Compulsory	4
Al. I. Cuza University	Faculty of Economics and Business Administration	Entrepreneurial finance; International business negotiations; Initiating and managing small business;	Compulsory	4
Transylvania University	Faculty of Economics and Business Administration	Leadership; Entrepreneurship and Business Strategy; E-business; Entrepreneurship; Risk management.	Compulsory	5-6
Ovidius University of Constanta	Faculty of Economics	Entrepreneurial management; Entrepreneurship.	Compulsory	4-6
University of Craiova	Faculty of Economics and Business Administration	Leadership;	Compulsory	5
The Bucharest University of Economic Studies		Entrepreneurial culture; Business negotiations; Social entrepreneurship;	Compulsory	4-6

### 3. Entrepreneurship education in Romanian universities

In some educational study programs, the Ministry of Education determines national curriculum regulations that specify the content of the programs at overarching level. Table 1 show the list of entrepreneurship courses offered in Romanian universities

in the academic year 2012-2013 at graduate and table 2 at postgraduate levels, respectively. Given the small number of courses, no statistical analyses have been carried out, but only a qualitative analysis of their content and their position within the curriculum was made.

Concerning the academic year 2012-2013, the university from our study offered entrepreneurship courses. Even if, we have in curriculum some entrepreneurial courses, there are still challenges, and work on entrepreneurship will continue to be in constant development.

Looking the content of the courses, most of them were dedicated to the various aspects of start-up: how to develop a business plan, what are the characteristics of an entrepreneur, what skills are needed and how to raise funds. However, even these courses devoted a significant amount of time to business planning.

Above all, three aspects characterized entrepreneurship courses in Romanian universities:

- They were present almost exclusively in economics and management faculties;
- Their main focus was on the start-up of new businesses;
- Their main aim was to transfer knowledge and competences to the development of the business plan.

There are some universities that offered a specific curriculum in entrepreneurship. Concerning the Master programmes, Table 2 shows that there was a significant increase in the supply of curricula in the last few years. This is because the master programs are more flexible than licence programs. For example, West University of Timisoara started a Master programme in “Entrepreneurial management”. Also, The Bucharest University of Economic Studies and University of Craiova have a master’s programme in “Entrepreneurship and Business development”.

Recognizing the importance of entrepreneurship education, several universities from Romanian started a number of extra-curricular initiatives dedicated to stimulating the start-up of new firms, soft skills development, especially among students and researchers. One of the most widespread activities in this area is the organization of business plan competitions. Within these competitions’ courses on business planning are normally offered. In all cases, these initiatives and courses continue to be outside the official university curricula. An extra-curricular program offered by universities is closely related to the financial potential. Regarding public university, the allocated budget is still very low, in other cases even missing.

Together with developing specific skills for business start-up, entrepreneurship education in higher education, especially those at first-degree level should pursue the following objectives:

- Enhance knowledge about the phenomenon of entrepreneurship and its role in the economic system and society as a whole;
- To promote entrepreneurship as a useful and respectable career prospect for graduates;
- Develop those competences, like relational and leadership competences that can contribute to the development of entrepreneurship.

Additionally, the portfolios of courses must answer very simple question: what in entrepreneurship? Is it for me? When is an idea a business opportunity? I have an idea, what should I do next? (Vyakarnam, 2012). The development of curriculum based around these kinds of questions has been positive, and suggestion is that

each university that is seeking to initiate entrepreneurship programmes finds the questions that are most relevant to its audiences and helps to answer them.

Compared with other disciplines, the entrepreneurship discipline is in its infancy, with no standard framework or agreed upon best practices (Solomon, 2007; Fiet, 2001). Our study indicates that entrepreneurship education exist mostly at the graduate and postgraduate level through business management courses. Although in many developed countries, the existing curricula encourage students to take initiative and responsibility, examples of more explicit entrepreneurship educations are few. Coherent initiatives or educational programs on entrepreneurship by state authorities are still rare in the field of school education.

Besides these general reasons, another important factor is the rigidity of the Romanian academic system. In Romanian, if you want to become a teacher within the university, you must have a PhD. Diploma. This requirement it is very difficult to accomplish by the practitioner because a PhD. Programme required a lot of time, and if you already run a business it is very difficult to have it.

If we consider that the entrepreneurship education is more effective if it is teach by entrepreneurs of practitioner, the system must allow them to teach without PhD.

To accelerate the closeness between academia and business, the system must allow an official partnership between teachers and practitioners. Therefore, the teachers can expose the theoretical aspects and the practitioners the practical part. They must collaborate in order to adapt the curriculum at the market demands. As a first step, it would be better if the university has an advisory Council formed by practitioners from each domain. This is necessarily because the besides the content of entrepreneurship courses, entrepreneurship education should address the present needs of the Romanian economic system. The best people to deliver education to students that will enable them to become entrepreneurs are practitioners whom themselves have the expertise and experience of entrepreneurship (Vyakarman, 2012).

The educational programme on entrepreneurship should aim at developing the following levels of learning: entrepreneurial attitudes, values and motivation; ability to develop networks and relational skills; skill-building courses in negotiations; new product development; creativity and innovation; creativeness and opportunity recognition; knowledge of institutional facts about entrepreneurship. Opportunity identification has also been identified as critical entrepreneurial skills that should be included in entrepreneurship curriculum (Shane & Venkataraman, 2000; Hindle, 2004). Educating students on entrepreneurship and how to become more entrepreneurial are also significant components of entrepreneurial education (Rae, 2000). Understanding the role of networks, and the stakeholders it is considered as important entrepreneurial concept (Taylor and Torpe, 2004).

In a more general perspective, entrepreneurship education should help students increase their “entrepreneurship awareness” and enlarge their perception and vision of social and institutional facts. At a more advanced level, (Master and postgraduate courses) students can acquire the technical abilities for an evaluation of new businesses opportunities and for new a venture creation (Iacobucci and Micozzi, 2012).

Gibb (2002) and Sogunro (2004) consider that traditional teaching methods such as lectures are less effective in teaching entrepreneurial principles. This is because the entrepreneurial skills can be developed with practical and dynamic methods.

Entrepreneurship courses and curriculum must be designed to encourage and stimulate business start-ups and in the same time to ensure the development of necessary skills: personal characteristics, interpersonal and networking skills, critical and creative thinking skills, practical skills, proactive empowerment, negotiation, leadership. The most used pedagogical approach is the writing of a business plan (primarily learning tool). At each level of education, it is reasonable to expect different outcomes as students mature and build on previous knowledge. But the overall purposes remain to develop expertise as an entrepreneur.

Curriculum development for entrepreneurship education should incorporate the principles of experiential and contextual education. Students can best develop the knowledge and skills necessary through the application of curriculum objectives in situations that replicate the business world. Simulations, role-plays, community based learning projects, student enterprises, and competitive events can all be powerful instructional activities when linked closely to the curriculum.

#### **4. Conclusion**

The role of universities in this context is to develop new knowledge and methodologies for teaching and carrying out research on entrepreneurship rather than simply starting a course. The limited presence of entrepreneurship courses and curricula in Romanian higher education system does not mean that the entrepreneurship as a strategic field is completely neglected in their activities. Issues such as accreditation, program funding, faculty goals and current programs clearly impact the importance of these criteria for anyone wanting to create a new, comprehensive programme in entrepreneurship (Heriot and Simpson, 2007).

Considering the actual supply of courses and curricula does not always respond to the demand for entrepreneurial competences. We believe that the actual supply of courses and curricula in Romanian universities, and their slow growth after the implementation of Bologna system started in 2005 does not always responds to the demand for entrepreneurial competences not only in quantitative but also in qualitative terms. The show pace with which Romanian universities are following the global trend in the development of entrepreneurship courses and curricula depends on two main factors related to the supply side: the presence of a cultural tradition that does not favor entrepreneurship education, and the rigidity of the Romanian university system when changing courses and curricula.

The main obstacles to increase courses in entrepreneurship offered by Romanian universities are: (1) centralization and organizational inertia of the higher education system; (2) diffidence about "practical knowledge" in higher education; (3) only few academics are committed to the subject; (4) lack of cooperation with international universities; (5) low wages.

Entrepreneurship education must cover all education stages. The overall goal must ensure that young people can progress coherently in acquiring entrepreneurial competences across all stages of the education system.

Formal education must encourage the entrepreneurship. Entrepreneurial education therefore needs to focus on knowledge of small business ownership and self-employment, as well as entrepreneurial skills and attributes which cannot be fostered through traditional teaching methods. Action learning, learning by doing, learning by experience, learning by mistakes represent the paradigm to build up a teaching method that improves entrepreneurial attitude, problem solving, entrepreneurial

skills, opportunity recognition (Iacobucci and Micozzi, 2012). In addition to that needs, we must consider the student journey from wanting to raise awareness through to seeking help and support in creating ventures.

There is a clear cut role for the faculty to develop appropriate curricula and to create a learning atmosphere but without the active engagement of practitioners such as entrepreneurs who have been invited and carefully briefed then it is very difficult for students to “feel” that they are gaining real practical knowledge that will enable them to actually go out and create a new venture or become more employable.

As a recommendation, in order to improve the entrepreneurship curriculum it is necessary to have some standards and performance indicators framework. Using a coherent framework, we can build for students: progressively more challenging educational activities; experiences that will enable them to develop the insight needed to discover and create entrepreneurial opportunities; and expertise to successfully start and manage their own businesses to take advantage of these opportunities.

# A STUDY ON THE CULTURAL DIFFERENCES BETWEEN PUBLIC AND PRIVATE HOSPITALS FROM BUCHAREST

**Dobre Ovidiu-Iliuta**

*The Bucharest University of Economic Studies (Institute of Doctoral Studies, Business Administration), Bucharest, Romania  
ovidudobre87@gmail.com*

**Abstract:** *Turnover rates for hospital personnel (nurses, doctors and auxiliary staff) have been increasing in recent years, especially in the public sector, being the result of a couple of factors. I believe that one of the main causes is related to organizational culture aspects. This research analyses if dated facilities, unpleasant work environment and lack of personnel contribute to a low job satisfaction and involvement. The study also compares the results obtained from persons working in the public sectors with the results given by respondents from private clinics. An organization's culture could be strong or weak, being dependent to cohesiveness, value consensus and individual commitment to collective goals. Effective cultures help organizations anticipate and adapt to environment changes, thus proactive cultures should enhance and support profitability on the long-run. This research also investigates strength of the occupational culture by comparing the results obtained in the public sector with results from private sector. My study is developed on 63 professionals working in the medical system and it is based mainly on quantitative methods. The instrument of the research is the structured questionnaire. The main goal of the study is to highlight the significant cultural differences between the state-owned and public-owned hospitals and to assess if they have a greater influence to the institutions, as compared to common occupational values and norms. The implications of my research for the field of organizational behavior refers to the fact that I have identified the organizational elements that are common to both public and private hospitals, influenced by a strong occupational culture, and those that differ significantly, being the result of underfunding and poor management. As a conclusion, I consider that this is a great starting point for further research in the field and I plan to enlarge the investigation on a greater number of respondents and to come up with solutions for the identified issues.*

## 1. Introduction

Culture can be broadly defined as “a set of basic tacit assumptions about how the world is and ought to be that a group of people share and that determines their perceptions, thoughts, feelings, and to some degree, their overt behavior (Schein, 1996). Moreover, according to Hofstede (1991) there are three main factors that influence the behavior of a person in the workplace: national culture, occupational culture and organization culture.

National culture is mainly based on differences in values that are learned in early childhood from the family. These values have a significant impact on a person's beliefs and are very unlikely to change over time. Occupational culture is acquired

through schooling and training between childhood and adulthood. Moreover it consists of values and shared practices (learned perceptions about how things should be done in the context of an occupation). Lastly, occupational culture is based on the norms and shared practices which are learned in the workplace. The influence that occupational and organizational cultures exert on people's behavior varies significantly over organizations (Trice and Beyer, 1993). Some professional groups have the exclusive right to perform certain kinds of work, to control the training requirements for performing that work and to control how the work is performed. Because of these constraints and due to the fact that the behavior of these professionals is mainly influenced by their occupational culture, the organizational cultures associated with them are only slightly influenced by administrative practices. On the other hand, the behavior of professionals from occupations that are less regulated can be influenced to a greater extent by the organizational culture. National culture can also be a barrier to organizational culture implementation, such as when transferring technology across nations or creating culturally diverse work teams.
